After parallel query is turned on, two steps in this query plan can use the parallel query optimization, as shown under the Extra column in the EXPLAIN output. The I/O-intensive and CPU-intensive processing for those steps is pushed down to the storage layer.
For information about how to interpret EXPLAIN output for a parallel query and the parts of SQL statements that parallel query can apply to, see How parallel query works with SQL constructs (p. 965). The following example output shows the results of running the preceding query on a db.r4.2xlarge instance with a cold buffer pool. The query runs substantially faster when using parallel query.

**Note**
Because timings depend on many environmental factors, your results might be different. Always conduct your own performance tests to confirm the findings with your own environment, workload, and so on.

```

Experiment with your workload to get a sense of whether individual SQL statements can take advantage of parallel query. Then use the following monitoring techniques to help verify how often parallel query is used in real workloads over time. For real workloads, extra factors such as concurrency limits apply.
Monitoring parallel query

If your Aurora MySQL cluster uses parallel query, you might see an increase in VolumeReadIOPS values. Parallel queries don't use the buffer pool. Thus, although the queries are fast, this optimized processing can result in an increase in read operations and associated charges.

In addition to the Amazon CloudWatch metrics described in Viewing metrics in the Amazon RDS console (p. 535), Aurora provides other global status variables. You can use these global status variables to help monitor parallel query execution. They can give you insights into why the optimizer might use or not use parallel query in a given situation. To access these variables, you can use the SHOW GLOBAL STATUS command. You can also find these variables listed following.

A parallel query session isn't necessarily a one-to-one mapping with the queries performed by the database. For example, suppose that your query plan has two steps that use parallel query. In that case, the query involves two parallel sessions and the counters for requests attempted and requests successful are incremented by two.

When you experiment with parallel query by issuing EXPLAIN statements, expect to see increases in the counters designated as "not chosen" even though the queries aren't actually running. When you work with parallel query in production, you can check if the "not chosen" counters are increasing faster than you expect. At this point, you can adjust so that parallel query runs for the queries that you expect. To do so, you can change your cluster settings, query mix, DB instances where parallel query is turned on, and so on.

These counters are tracked at the DB instance level. When you connect to a different endpoint, you might see different metrics because each DB instance runs its own set of parallel queries. You might also see different metrics when the reader endpoint connects to a different DB instance for each session.

<table>

</tbody>
</table>

### How parallel query works with SQL constructs

In the following section, you can find more detail about why particular SQL statements use or don't use parallel query. This section also details how Aurora MySQL features interact with parallel query. This information can help you diagnose performance issues for a cluster that uses parallel query or understand how parallel query applies for your particular workload.

The decision to use parallel query relies on many factors that occur at the moment that the statement runs. Thus, parallel query might be used for certain queries always, never, or only under certain conditions.

**Tip**  
When you view these examples in HTML, you can use the Copy widget in the upper-right corner of each code listing to copy the SQL code to try yourself. Using the Copy widget avoids copying the extra characters around the mysql> prompt and - > continuation lines.

**Topics**
- EXPLAIN statement (p. 966)
- WHERE clause (p. 967)
As shown in examples throughout this section, the EXPLAIN statement indicates whether each stage of a query is currently eligible for parallel query. It also indicates which aspects of a query can be pushed down to the storage layer. The most important items in the query plan are the following:

- A value other than NULL for the key column suggests that the query can be performed efficiently using index lookups, and parallel query is unlikely.
- A small value for the rows column (a value not in the millions) suggests that the query isn't accessing enough data to make parallel query worthwhile. This means that parallel query is unlikely.
- The Extra column shows you if parallel query is expected to be used. This output looks like the following example.

```
Using parallel query (A columns, B filters, C exprs; D extra)
```

The columns number represents how many columns are referred to in the query block.

The filters number represents the number of WHERE predicates representing a simple comparison of a column value to a constant. The comparison can be for equality, inequality, or a range. Aurora can parallelize these kinds of predicates most effectively.

The exprs number represents the number of expressions such as function calls, operators, or other expressions that can also be parallelized, though not as effectively as a filter condition.

The extra number represents how many expressions can't be pushed down and are performed by the head node.

For example, consider the following EXPLAIN output.

```
mysql> explain select p_name, p_mfgr from part
```

```
Using parallel query (6 columns, 1 filters, 0 exprs; 0 extra)
```

```
+----+----------+--------+-----------------+-------+--------+---------+----------------+--------+--------+--------+-----------------+---------+-----------------+--------+--------+--------+-----------------+-------+

|    |          |        |                 |       |        |          |     |          |     |       |        |              |         | Other_info              |       |       |       | Other_info              |       |
|    |          |        |                 |       |        |          |     |          |     |       |        |              |         | Other_info              |       |       |       | Other_info              |       |
|    |          |        |                 |       |        |          |     |          |     |       |        |              |         | Other_info              |       |       |       | Other_info              |       |
|    |          |        |                 |       |        |          |     |          |     |       |        |              |         | Other_info              |       |       |       | Other_info              |       |
```
-> where p_brand is not null
-> and upper(p_type) is not null
-> and round(p_retailprice) is not null;
+--------------------------+
| id  | select_type | table |...| rows     | Extra               |
|-----|-------------+-------|...|----------|--------------------|
+--------------------------+
Using where; Using parallel query (5 columns, 1 filters, 2 exprs; 0 extra) |
+--------------------------+

The information from the Extra column shows that five columns are extracted from each row to evaluate the query conditions and construct the result set. One WHERE predicate involves a filter, that is, a column that is directly tested in the WHERE clause. Two WHERE clauses require evaluating more complicated expressions, in this case involving function calls. The 0 extra field confirms that all the operations in the WHERE clause are pushed down to the storage layer as part of parallel query processing.

In cases where parallel query isn't chosen, you can typically deduce the reason from the other columns of the EXPLAIN output. For example, the rows value might be too small, or the possible_keys column might indicate that the query can use an index lookup instead of a data-intensive scan. The following example shows a query where the optimizer can estimate that the query will scan only a small number of rows. It does so based on the characteristics of the primary key. In this case, parallel query isn't required.

mysql> explain select count(*) from part where p_partkey between 1 and 100;
+--------------------------+
| id  | select_type | table | type  | possible_keys | key     | key_len | ref  | rows |
|-----|-------------+-------|-------|---------------+---------+---------+------|------|
| 1   | SIMPLE      | part  | range | PRIMARY       | PRIMARY | 4       | NULL | 99   |
Extra               |
+--------------------------+
Using where; Using index |
+--------------------------+

The output showing whether parallel query will be used takes into account all available factors at the moment that the EXPLAIN statement is run. The optimizer might make a different choice when the query is actually run, if the situation changed in the meantime. For example, EXPLAIN might report that a statement will use parallel query. But when the query is actually run later, it might not use parallel query based on the conditions then. Such conditions can include several other parallel queries running concurrently. They can also include rows being deleted from the table, a new index being created, too much time passing within an open transaction, and so on.

WHERE clause

For a query to use the parallel query optimization, it must include a WHERE clause.

The parallel query optimization speeds up many kinds of expressions used in the WHERE clause:

- Simple comparisons of a column value to a constant, known as filters. These comparisons benefit the most from being pushed down to the storage layer. The number of filter expressions in a query is reported in the EXPLAIN output.
- Other kinds of expressions in the WHERE clause are also pushed down to the storage layer where possible. The number of such expressions in a query is reported in the EXPLAIN output. These expressions can be function calls, LIKE operators, CASE expressions, and so on.
• Certain functions and operators aren’t currently pushed down by parallel query. The number of such expressions in a query is reported as the extra counter in the EXPLAIN output. The rest of the query can still use parallel query.

• While expressions in the select list aren’t pushed down, queries containing such functions can still benefit from reduced network traffic for the intermediate results of parallel queries. For example, queries that call aggregation functions in the select list can benefit from parallel query, even though the aggregation functions aren’t pushed down.

For example, the following query does a full-table scan and processes all the values for the P.Brand column. However, it doesn’t use parallel query because the query doesn’t include any WHERE clause.

```
mysql> explain select count(*), p_brand from part group by p_brand;
```

```
+----+-------------+-------+------+---------------+------+---------+------+----------+
<table>
<thead>
<tr>
<th>id</th>
<th>select_type</th>
<th>table</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>
<th>rows</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SIMPLE</td>
<td>part</td>
<td>ALL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>20427936</td>
<td>Using temporary; Using filesort</td>
</tr>
</tbody>
</table>
+----+-------------+-------+------|---------------|------|---------|------|----------|--------------------------------------------------------------------------------|
```

In contrast, the following query includes WHERE predicates that filter the results, so parallel query can be applied:

```
mysql> explain select count(*), p_brand from part where p_name is not null
    -> and p_mfgr in ('Manufacturer#1', 'Manufacturer#3') and p_retailprice > 1000
    -> group by p_brand;
```

```
+----+...+----------+-------------------------------------------------------------------------------------------------------------+
| id |...| rows     | Extra                                                                                                        |
|----|...|----------|-------------------------------------------------------------------------------------------------------------|
|  1 |...| 20427936 | Using where; Using temporary; Using filesort; Using parallel query (5 columns, 1 filters, 2 exprs; 0 extra) |
+----+...+----------+-------------------------------------------------------------------------------------------------------------+
```

If the optimizer estimates that the number of returned rows for a query block is small, parallel query isn’t used for that query block. The following example shows a case where a greater-than operator on the primary key column applies to millions of rows, which causes parallel query to be used. The converse less-than test is estimated to apply to only a few rows and doesn’t use parallel query.

```
mysql> explain select count(*) from part where p_partkey > 10;
```

```
+----+-----------------------------------------------------------+----------+----------------+--------------------------------------------------------------------|
| id |...| rows     | Extra                                                                                                        |
|----|...|----------|--------------------------------------------------------------------|
|  1 |...| 20427936 | Using where; Using parallel query (1 columns, 1 filters, 0 exprs; 0 extra)                                 |
+----+-----------------------------------------------------------+----------+----------------+--------------------------------------------------------------------+
```
mysql> explain select count(*) from part where p_partkey < 10;
+----+...+------+--------------------------+
| id |...| rows | Extra                    |
+----+...+------+--------------------------+
|  1 |...|    9 | Using where; Using index |
+----+...+------+--------------------------+

Data definition language (DDL)

In Aurora MySQL version 2, parallel query is only available for tables for which no fast data definition language (DDL) operations are pending. In Aurora MySQL version 3, you can use parallel query on a table at the same time as an instant DDL operation.

Instant DDL in Aurora MySQL version 3 replaces the fast DDL feature in Aurora MySQL version 2. For information about instant DDL, see [Instant DDL (Aurora MySQL version 3) (p. 897)].

Column data types

In Aurora MySQL version 3, parallel query can work with tables containing columns with data types TEXT, BLOB, JSON, and GEOMETRY. It can also work with VARCHAR and CHAR columns with a maximum declared length longer than 768 bytes. If your query refers to any columns containing such large object types, the additional work to retrieve them does add some overhead to query processing. In that case, check if the query can omit the references to those columns. If not, run benchmarks to confirm if such queries are faster with parallel query turned on or turned off.

In Aurora MySQL version 2, parallel query has these limitations for large object types:

- TEXT, BLOB, JSON, and GEOMETRY data types aren't supported with parallel query. A query that refers to any columns of these types can't use parallel query.
- Variable-length columns (VARCHAR and CHAR data types) are compatible with parallel query up to a maximum declared length of 768 bytes. A query that refers to any columns of the types declared with a longer maximum length can't use parallel query. For columns that use multibyte character sets, the byte limit takes into account the maximum number of bytes in the character set. For example, for the character set utf8mb4 (which has a maximum character length of 4 bytes), a VARCHAR(192) column is compatible with parallel query but a VARCHAR(193) column isn't.

Partitioned tables

You can use partitioned tables with parallel query in Aurora MySQL version 3. Because partitioned tables are represented internally as multiple smaller tables, a query that uses parallel query on a nonpartitioned table might not use parallel query on an identical partitioned table. Aurora MySQL considers whether each partition is large enough to qualify for the parallel query optimization, instead of evaluating the size of the entire table. Check whether the Aurora_pq_request_not_chosen_small_table status variable is incremented if a query on a partitioned table doesn't use parallel query when you expect it to.

For example, consider one table partitioned with PARTITION BY HASH (column) PARTITIONS 2 and another table partitioned with PARTITION BY HASH (column) PARTITIONS 10. In the table with two partitions, the partitions are five times as large as the table with ten partitions. Thus, parallel query is more likely to be used for queries against the table with fewer partitions. In the following example, the table PART_BIG_PARTITIONS has two partitions and PART_SMALL_PARTITIONS has ten partitions. With identical data, parallel query is more likely to be used for the table with fewer big partitions.

mysql> explain select count(*), p_brand from part_big_partitions where p_name is not null
-> and p_mfgr in ('Manufacturer#1', 'Manufacturer#3') and p_retailprice > 1000 group
by p_brand;
+-----+---------------------+-------------+------------+
| id  | select_type | table               | partitions | Extra      |
+-----+-------------+---------------------+------------+
| 1   | SIMPLE      | part_big_partitions | p0,p1      | Using where; Using temporary; Using parallel query (4 columns, 1 filters, 1 exprs; 0 extra; 1 group-bys, 1 aggrs) |
+-----+-------------+---------------------+------------+

mysql> explain select count(*), p_brand from part_small_partitions where p_name is not null
-> and p_mfgr in ('Manufacturer#1', 'Manufacturer#3') and p_retailprice > 1000 group
by p_brand;
+----+-------------+-----------------------+-------------------------------+
| id | select_type | table                 | partitions                    | Extra |
+----+-------------+-----------------------+-------------------------------+
| 1  | SIMPLE      | part_small_partitions | p0,p1,p2,p3,p4,p5,p6,p7,p8,p9 | Using where; Using temporary |
+----+-------------+-----------------------+-------------------------------+

Aggregate functions, GROUP BY clauses, and HAVING clauses

Queries involving aggregate functions are often good candidates for parallel query, because they involve
scanning large numbers of rows within large tables.

In Aurora MySQL 3, parallel query can optimize aggregate function calls in the select list and the HAVING
clause.

Before Aurora MySQL 3, aggregate function calls in the select list or the HAVING clause aren't pushed
down to the storage layer. However, parallel query can still improve the performance of such queries
with aggregate functions. It does so by first extracting column values from the raw data pages in parallel
at the storage layer. It then transmits those values back to the head node in a compact tuple format
instead of as entire data pages. As always, the query requires at least one WHERE predicate for parallel
query to be activated.

The following simple examples illustrate the kinds of aggregate queries that can benefit from parallel
query. They do so by returning intermediate results in compact form to the head node, filtering
nonmatching rows from the intermediate results, or both.

mysql> explain select count(*), p_brand from part_small_partitions where p_name is not null
-> and p_mfgr in ('Manufacturer#1', 'Manufacturer#3') and p_retailprice > 1000 group
by p_brand;
+----+-------------+-----------------------+-------------------------------+
| id | select_type | table                 | partitions                    | Extra |
+----+-------------+-----------------------+-------------------------------+
| 1  | SIMPLE      | part_small_partitions | p0,p1,p2,p3,p4,p5,p6,p7,p8,p9 | Using where; Using temporary |
+----+-------------+-----------------------+-------------------------------+
Function calls in WHERE clause

Aurora can apply the parallel query optimization to calls to most built-in functions in the WHERE clause. Parallelizing these function calls offloads some CPU work from the head node. Evaluating the predicate functions in parallel during the earliest query stage helps Aurora minimize the amount of data transmitted and processed during later stages.

Currently, the parallelization doesn't apply to function calls in the select list. Those functions are evaluated by the head node, even if identical function calls appear in the WHERE clause. The original values from relevant columns are included in the tuples transmitted from the storage nodes back to the head node. The head node performs any transformations such as UPPER, CONCATENATE, and so on to produce the final values for the result set.

In the following example, parallel query parallelizes the call to LOWER because it appears in the WHERE clause. Parallel query doesn't affect the calls to SUBSTR and UPPER because they appear in the select list.

```sql
mysql> explain select sql_no_cache distinct substr(upper(p_name),1,5) from part
        -> where lower(p_name) like '%cornflower%' or lower(p_name) like '%goldenrod%';
+----+...| Extra
|  1 |...| Using where; Using temporary; Using parallel query (2 columns, 0 filters, 1 exprs; 0 extra) |
+----+...|
```

The same considerations apply to other expressions, such as CASE expressions or LIKE operators. For example, the following example shows that parallel query evaluates the CASE expression and LIKE operators in the WHERE clause.

```sql
mysql> explain select p_mfgr, p_retailprice from part
        -> where p_retailprice > case p_mfgr
        ->   when 'Manufacturer#1' then 1000
        ->   when 'Manufacturer#2' then 1200
        ->   else 950
        -> end
        -> and p_name like '%vanilla%'
        -> group by p_retailprice;
+----+...| Extra
|  1 |...| Using where; Using temporary; Using parallel query (3 columns, 0 filters, 1 exprs; 0 extra) |
+----+...|
```

971
LIMIT clause

Currently, parallel query isn't used for any query block that includes a LIMIT clause. Parallel query might still be used for earlier query phases with GROUP by, ORDER BY, or joins.

Comparison operators

The optimizer estimates how many rows to scan to evaluate comparison operators, and determines whether to use parallel query based on that estimate.

The first example following shows that an equality comparison against the primary key column can be performed efficiently without parallel query. The second example following shows that a similar comparison against an unindexed column requires scanning millions of rows and therefore can benefit from parallel query.

```sql
mysql> explain select * from part where p_partkey = 10;
+----+----+------+-------+
| id | ...| rows | Extra |
+----+----+------+-------+
|  1 | ...|    1 | NULL  |
+----+----+------+-------+

mysql> explain select * from part where p_type = 'LARGE BRUSHED BRASS';
+----+--------------------------+
| id | rows | Extra |
+----+--------------------------+
|  1 | 20427936 | Using where; Using parallel query (9 columns, 1 filters, 0 exprs; 0 extra) |
+----+--------------------------+
```

The same considerations apply for not-equals tests and for range comparisons such as less than, greater than or equal to, or BETWEEN. The optimizer estimates the number of rows to scan, and determines whether parallel query is worthwhile based on the overall volume of I/O.

Joins

Join queries with large tables typically involve data-intensive operations that benefit from the parallel query optimization. The comparisons of column values between multiple tables (that is, the join predicates themselves) currently aren't parallelized. However, parallel query can push down some of the internal processing for other join phases, such as constructing the Bloom filter during a hash join. Parallel query can apply to join queries even without a WHERE clause. Therefore, a join query is an exception to the rule that a WHERE clause is required to use parallel query.

Each phase of join processing is evaluated to check if it is eligible for parallel query. If more than one phase can use parallel query, these phases are performed in sequence. Thus, each join query counts as a single parallel query session in terms of concurrency limits.
For example, when a join query includes WHERE predicates to filter the rows from one of the joined tables, that filtering option can use parallel query. As another example, suppose that a join query uses the hash join mechanism, for example to join a big table with a small table. In this case, the table scan to produce the Bloom filter data structure might be able to use parallel query.

**Note**
Parallel query is typically used for the kinds of resource-intensive queries that benefit from the hash join optimization. The method for turning on the hash join optimization depends on the Aurora MySQL version. For details for each version, see *Turning on hash join for parallel query clusters* (p. 956). For information about how to use hash joins effectively, see *Optimizing large Aurora MySQL join queries with hash joins* (p. 1106).

```sql
mysql> explain select count(*) from orders join customer where o_custkey = c_custkey;
+----+...+----------+-------+---------------+-------------+...+-----------
| id |...| table    | type  | possible_keys | key         |...| rows      | Extra
|  1 |...| customer | index | PRIMARY       | c_nationkey |...| 15051972 | Using index
|  1 |...| orders   | ALL   | o_custkey     | NULL        |...| 154545408 | Using join buffer (Hash Join Outer table orders); Using parallel query (1 columns, 0 filters, 1 exprs; 0 extra)
```

For a join query that uses the nested loop mechanism, the outermost nested loop block might use parallel query. The use of parallel query depends on the same factors as usual, such as the presence of additional filter conditions in the WHERE clause.

```sql
mysql> -- Nested loop join with extra filter conditions can use parallel query.
mysql> explain select count(*) from part, partsupp where p_partkey != ps_partkey and p_name is not null and ps_availqty > 0;
+----+-------------+----------+...+----------
| id | select_type | table    |...| rows     | Extra
|  1 | SIMPLE      | part     |...| 20427936 | Using where; Using parallel query (2 columns, 1 filters, 0 exprs; 0 extra)
|  1 | SIMPLE      | partsupp |...| 78164450 | Using where; Using join buffer (Block Nested Loop)
```

**Subqueries**

The outer query block and inner subquery block might each use parallel query, or not. Whether they do is based on the usual characteristics of the table, WHERE clause, and so on, for each block. For example, the following query uses parallel query for the subquery block but not the outer block.

```sql
mysql> explain select count(*) from part where
        -- p_partkey < (select max(p_partkey) from part where p_name like '%vanilla%');
```
Currently, correlated subqueries can't use the parallel query optimization.

**UNION**

Each query block in a **UNION** query can use parallel query, or not, based on the usual characteristics of the table, **WHERE** clause, and so on, for each part of the **UNION**.

Note

Each **UNION** clause within the query is run sequentially. Even if the query includes multiple stages that all use parallel query, it only runs a single parallel query at any one time. Therefore, even a complex multistage query only counts as 1 toward the limit of concurrent parallel queries.

**Views**

The optimizer rewrites any query using a view as a longer query using the underlying tables. Thus, parallel query works the same whether table references are views or real tables. All the same considerations about whether to use parallel query for a query, and which parts are pushed down, apply to the final rewritten query.

For example, the following query plan shows a view definition that usually doesn't use parallel query. When the view is queried with additional **WHERE** clauses, Aurora MySQL uses parallel query.
Data manipulation language (DML) statements

The INSERT statement can use parallel query for the SELECT phase of processing, if the SELECT part meets the other conditions for parallel query.

```sql
mysql> create table part_subset like part;
mysql> explain insert into part_subset select * from part where p_mfgr = 'Manufacturer#1';
```

<table>
<thead>
<tr>
<th>id</th>
<th>...</th>
<th>rows</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>...</td>
<td>20427936</td>
<td>Using where; Using parallel query (9 columns, 1 filters, 0 exprs; 0 extra)</td>
</tr>
</tbody>
</table>

**Note**

Typically, after an INSERT statement, the data for the newly inserted rows is in the buffer pool. Therefore, a table might not be eligible for parallel query immediately after inserting a large number of rows. Later, after the data is evicted from the buffer pool during normal operation, queries against the table might begin using parallel query again.

The CREATE TABLE AS SELECT statement doesn't use parallel query, even if the SELECT portion of the statement would otherwise be eligible for parallel query. The DDL aspect of this statement makes it incompatible with parallel query processing. In contrast, in the INSERT ... SELECT statement, the SELECT portion can use parallel query.

Parallel query is never used for DELETE or UPDATE statements, regardless of the size of the table and predicates in the WHERE clause.

```sql
mysql> explain delete from part where p_name is not null;
```

<table>
<thead>
<tr>
<th>id</th>
<th>select_type</th>
<th>...</th>
<th>rows</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SIMPLE</td>
<td>...</td>
<td>20427936</td>
<td>Using where</td>
</tr>
</tbody>
</table>

Transactions and locking

You can use all the isolation levels on the Aurora primary instance.

On Aurora reader DB instances, parallel query applies to statements performed under the REPEATABLE READ isolation level. Aurora MySQL version 2.09 or higher can also use the READ COMMITTED isolation level on reader DB instances. REPEATABLE READ is the default isolation level for Aurora reader DB instances. To use READ COMMITTED isolation level on reader DB instances requires setting the `aurora_read_replica_read_committed` configuration option at the session level. The READ COMMITTED isolation level for reader instances complies with SQL standard behavior. However, the isolation is less strict on reader instances than when queries use READ COMMITTED isolation level on the writer instance.
For more information about Aurora isolation levels, especially the differences in READ COMMITTED between writer and reader instances, see Aurora MySQL isolation levels (p. 1158).

After a big transaction is finished, the table statistics might be stale. Such stale statistics might require an ANALYZE TABLE statement before Aurora can accurately estimate the number of rows. A large-scale DML statement might also bring a substantial portion of the table data into the buffer pool. Having this data in the buffer pool can lead to parallel query being chosen less frequently for that table until the data is evicted from the pool.

When your session is inside a long-running transaction (by default, 10 minutes), further queries inside that session don’t use parallel query. A timeout can also occur during a single long-running query. This type of timeout might happen if the query runs for longer than the maximum interval (currently 10 minutes) before the parallel query processing starts.

You can reduce the chance of starting long-running transactions accidentally by setting autocommit=1 in mysql sessions where you perform ad hoc (one-time) queries. Even a SELECT statement against a table begins a transaction by creating a read view. A read view is a consistent set of data for subsequent queries that remains until the transaction is committed. Be aware of this restriction also when using JDBC or ODBC applications with Aurora, because such applications might run with the autocommit setting turned off.

The following example shows how, with the autocommit setting turned off, running a query against a table creates a read view that implicitly begins a transaction. Queries that are run shortly afterward can still use parallel query. However, after a pause of several minutes, queries are no longer eligible for parallel query. Ending the transaction with COMMIT or ROLLBACK restores parallel query eligibility.

```
mysql> set autocommit=0;

mysql> explain select sql_no_cache count(*) from part where p_retailprice > 10.0;
+----+...+---------+-------------+
| id |...| rows    | Extra       |
+----+...+---------+-------------+
|  1 |...| 2976129 | Using where; Using parallel query (1 columns, 1 filters, 0 exprs; 0 extra) |
+----+...+---------+-------------+

mysql> select sleep(720); explain select sql_no_cache count(*) from part where p_retailprice > 10.0;
+------------+
| sleep(720) |
+------------+
|          0 |
+------------+
1 row in set (12 min 0.00 sec)

mysql> commit;

mysql> explain select sql_no_cache count(*) from part where p_retailprice > 10.0;
+----+...+---------+-------------+
| id |...| rows    | Extra       |
+----+...+---------+-------------+
```
To see how many times queries weren't eligible for parallel query because they were inside long-running transactions, check the status variable `Aurora_pq_request_not_chosen_long_trx`.

```
mysql> show global status like '%pq%trx%';
+---------------------------------------+-------+
| Variable_name                         | Value |
+---------------------------------------+-------+
| Aurora_pq_request_not_chosen_long_trx | 4     |
+-------------------------------+-------+
```

Any SELECT statement that acquires locks, such as the SELECT FOR UPDATE or SELECT LOCK IN SHARE MODE syntax, can't use parallel query.

Parallel query can work for a table that is locked by a LOCK TABLES statement.

```
mysql> explain select o_orderpriority, o_shippriority from orders where o_clerk = 'Clerk#000095055';
+----+...+-----------+-------------+
| id |...| rows      | Extra       |
+----+...+-----------+-------------+
|  1 |...| 154545408 | Using where |
+----+...+-----------+-------------+

mysql> explain select o_orderpriority, o_shippriority from orders where o_clerk = 'Clerk#000095055' for update;
+----+...+-----------+-------------+
| id |...| rows      | Extra       |
+----+...+-----------+-------------+
|  1 |...| 154545408 | Using where |
+----+...+-----------+-------------+
```

### B-tree indexes

The statistics gathered by the ANALYZE TABLE statement help the optimizer to decide when to use parallel query or index lookups, based on the characteristics of the data for each column. Keep statistics current by running ANALYZE TABLE after DML operations that make substantial changes to the data within a table.

If index lookups can perform a query efficiently without a data-intensive scan, Aurora might use index lookups. Doing so avoids the overhead of parallel query processing. There are also concurrency limits on the number of parallel queries that can run simultaneously on any Aurora DB cluster. Make sure to use best practices for indexing your tables, so that your most frequent and most highly concurrent queries use index lookups.

### Full-text search (FTS) indexes

Currently, parallel query isn't used for tables that contain a full-text search index, regardless of whether the query refers to such indexed columns or uses the MATCH operator.
Virtual columns

Currently, parallel query isn't used for tables that contain a virtual column, regardless of whether the query refers to any virtual columns.

Built-in caching mechanisms

Aurora includes built-in caching mechanisms, namely the buffer pool and the query cache. The Aurora optimizer chooses between these caching mechanisms and parallel query depending on which one is most effective for a particular query.

When a parallel query filters rows and transforms and extracts column values, data is transmitted back to the head node as tuples rather than as data pages. Therefore, running a parallel query doesn't add any pages to the buffer pool, or evict pages that are already in the buffer pool.

Aurora checks the number of pages of table data that are present in the buffer pool, and what proportion of the table data that number represents. Aurora uses that information to determine whether it is more efficient to use parallel query (and bypass the data in the buffer pool). Alternatively, Aurora might use the nonparallel query processing path, which uses data cached in the buffer pool. Which pages are cached and how data-intensive queries affect caching and eviction depends on configuration settings related to the buffer pool. Therefore, it can be hard to predict whether any particular query uses parallel query, because the choice depends on the ever-changing data within the buffer pool.

Also, Aurora imposes concurrency limits on parallel queries. Because not every query uses parallel query, tables that are accessed by multiple queries simultaneously typically have a substantial portion of their data in the buffer pool. Therefore, Aurora often doesn't choose these tables for parallel queries.

When you run a sequence of nonparallel queries on the same table, the first query might be slow due to the data not being in the buffer pool. Then the second and subsequent queries are much faster because the buffer pool is now “warmed up”. Parallel queries typically show consistent performance from the very first query against the table. When conducting performance tests, benchmark the nonparallel queries with both a cold and a warm buffer pool. In these cases, the results with a warm buffer pool can compare well to parallel query times. In these cases, consider factors such as the frequency of queries against that table. Also consider whether it is worthwhile to keep the data for that table in the buffer pool.

The query cache avoids rerunning a query when an identical query is submitted and the underlying table data hasn't changed. Queries optimized by parallel query feature can go into the query cache, effectively making them instantaneous when run again.

Note

When conducting performance comparisons, the query cache can produce artificially low timing numbers. Therefore, in benchmark-like situations, you can use the sql_no_cache hint. This hint prevents the result from being served from the query cache, even if the same query had been run previously. The hint comes immediately after the SELECT statement in a query. Many parallel query examples in this topic include this hint, to make query times comparable between versions of the query for which parallel query is turned on and turned off.

Make sure that you remove this hint from your source when you move to production use of parallel query.

Optimizer hints

Another way to control the optimizer is by using optimizer hints, which can be specified within individual statements. For example, you can turn on an optimization for one table in a statement, and then turn off the optimization for a different table. For more information about these hints, see Optimizer Hints in the MySQL Reference Manual.

You can use SQL hints with Aurora MySQL queries to fine-tune performance. You can also use hints to prevent execution plans for important queries from changing because of unpredictable conditions.
We have extended the SQL hints feature to help you control optimizer choices for your query plans. These hints apply to queries that use parallel query optimization. For more information, see *Aurora MySQL hints* (p. 1162).

**MyISAM temporary tables**

The parallel query optimization only applies to InnoDB tables. Because Aurora MySQL uses MyISAM behind the scenes for temporary tables, internal query phases involving temporary tables never use parallel query. These query phases are indicated by *Using temporary* in the EXPLAIN output.
Using Advanced Auditing with an Amazon Aurora MySQL DB cluster

You can use the high-performance Advanced Auditing feature in Amazon Aurora MySQL to audit database activity. To do so, you enable the collection of audit logs by setting several DB cluster parameters. When Advanced Auditing is enabled, you can use it to log any combination of supported events.

You can view or download the audit logs to review the audit information for one DB instance at a time. To do so, you can use the procedures in Monitoring Amazon Aurora log files (p. 722).

Tip
For an Aurora DB cluster containing multiple DB instances, you might find it more convenient to examine the audit logs for all instances in the cluster. To do so, you can use CloudWatch Logs. You can turn on a setting at the cluster level to publish the Aurora MySQL audit log data to a log group in CloudWatch. Then you can view, filter, and search the audit logs through the CloudWatch interface. For more information, see Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs (p. 1083).

Enabling Advanced Auditing

Use the parameters described in this section to enable and configure Advanced Auditing for your DB cluster.

Use the server_audit_logging parameter to enable or disable Advanced Auditing.

Use the server_audit_events parameter to specify what events to log.

Use the server_audit_incl_users and server_audit_excl_users parameters to specify who gets audited. By default, all users are audited. For details about how these parameters work when one or both are left empty, or the same user names are specified in both, see server_audit_incl_users (p. 981) and server_audit_excl_users (p. 982).

Configure Advanced Auditing by setting these parameters in the parameter group used by your DB cluster. You can use the procedure shown in Modifying parameters in a DB parameter group (p. 229) to modify DB cluster parameters using the AWS Management Console. You can use the modify-db-cluster-parameter-group AWS CLI command or the ModifyDBClusterParameterGroup Amazon RDS API operation to modify DB cluster parameters programmatically.

Modifying these parameters doesn't require a DB cluster restart when the parameter group is already associated with your cluster. When you associate the parameter group with the cluster for the first time, a cluster restart is required.

Topics
- server_audit_logging (p. 980)
- server_audit_events (p. 981)
- server_audit_incl_users (p. 981)
- server_audit_excl_users (p. 982)

server_audit_logging

Enables or disables Advanced Auditing. This parameter defaults to OFF; set it to ON to enable Advanced Auditing.
No audit data appears in the logs unless you also define one or more types of events to audit using the `server_audit_events` parameter.

To confirm that audit data is logged for a DB instance, check that some log files for that instance have names of the form `audit/audit.log.` To see the names of the log files, follow the procedure in `Viewing and listing database log files` (p. 722).

**server_audit_events**

Contains the comma-delimited list of events to log. Events must be specified in all caps, and there should be no white space between the list elements, for example: `CONNECT, QUERY_DDL`. This parameter defaults to an empty string.

You can log any combination of the following events:

- **CONNECT** – Logs both successful and failed connections and also disconnections. This event includes user information.
- **QUERY** – Logs all queries in plain text, including queries that fail due to syntax or permission errors.
  
  **Tip**
  
  With this event type turned on, the audit data includes information about the continuous monitoring and health-checking information that Aurora does automatically. If you are only interested in particular kinds of operations, you can use the more specific kinds of events.
  
  You can also use the CloudWatch interface to search in the logs for events related to specific databases, tables, or users.

- **QUERY_DCL** – Similar to the QUERY event, but returns only data control language (DCL) queries (GRANT, REVOKE, and so on).
- **QUERY_DDL** – Similar to the QUERY event, but returns only data definition language (DDL) queries (CREATE, ALTER, and so on).
- **QUERY_DML** – Similar to the QUERY event, but returns only data manipulation language (DML) queries (INSERT, UPDATE, and so on, and also SELECT).
- **TABLE** – Logs the tables that were affected by query execution.

**server_audit_incl_users**

Contains the comma-delimited list of user names for users whose activity is logged. There should be no white space between the list elements, for example: `user_3, user_4`. This parameter defaults to an empty string. The maximum length is 1024 characters. Specified user names must match corresponding values in the `User` column of the `mysql.user` table. For more information about user names, see `Account User Names and Passwords` in the MySQL documentation.

If `server_audit_incl_users` and `server_audit_excl_users` are both empty (the default), all users are audited.

If you add users to `server_audit_incl_users` and leave `server_audit_excl_users` empty, then only those users are audited.

If you add users to `serveraudit_excl_users` and leave `server_audit_incl_users` empty, then all users are audited, except for those listed in `server_audit_excl_users`.

If you add the same users to both `server_audit_excl_users` and `server_audit_incl_users`, then those users are audited. When the same user is listed in both settings, `server_audit_incl_users` is given higher priority.

Connect and disconnect events aren't affected by this variable; they are always logged if specified. A user is logged even if that user is also specified in the `server_audit_excl_users` parameter, because `server_audit_incl_users` has higher priority.
server_audit_excl_users

Contains the comma-delimited list of user names for users whose activity isn't logged. There should be no white space between the list elements, for example: rdsadmin, user_1, user_2. This parameter defaults to an empty string. The maximum length is 1024 characters. Specified user names must match corresponding values in the User column of the mysql.user table. For more information about user names, see Account User Names and Passwords in the MySQL documentation.

If server_audit_incl_users and server_audit_excl_users are both empty (the default), all users are audited.

If you add users to server_audit_excl_users and leave server_audit_incl_users empty, then only those users that you list in server_audit_excl_users are not audited, and all other users are.

If you add the same users to both server_audit_excl_users and server_audit_incl_users, then those users are audited. When the same user is listed in both settings, server_audit_incl_users is given higher priority.

Connect and disconnect events aren't affected by this variable; they are always logged if specified. A user is logged if that user is also specified in the server_audit_incl_users parameter, because that setting has higher priority than server_audit_excl_users.

Viewing audit logs

You can view and download the audit logs by using the console. On the Databases page, choose the DB instance to show its details, then scroll to the Logs section. The audit logs produced by the Advanced Auditing feature have names of the form audit/audit.log.<other_identifying_information>.

To download a log file, choose that file in the Logs section and then choose Download.

You can also get a list of the log files by using the describe-db-log-files AWS CLI command. You can download the contents of a log file by using the download-db-log-file-portion AWS CLI command. For more information, see Viewing and listing database log files (p. 722) and Downloading a database log file (p. 723).

Audit log details

Log files are represented as comma-separated variable (CSV) files in UTF-8 format. Queries are also wrapped in single quotes (').

The audit log is stored separately on the local (ephemeral) storage of each instance. Each Aurora instance distributes writes across four log files at a time. The maximum size of the logs is 100 MB in aggregate. When this non-configurable limit is reached, Aurora rotates the files and generates four new files.

Tip
Log file entries are not in sequential order. To order the entries, use the timestamp value. To see the latest events, you might have to review all log files. For more flexibility in sorting and searching the log data, turn on the setting to upload the audit logs to CloudWatch and view them using the CloudWatch interface.

To view audit data with more types of fields and with output in JSON format, you can also use the Database Activity Streams feature. For more information, see Monitoring Amazon Aurora with Database Activity Streams (p. 746).

The audit log files include the following comma-delimited information in rows, in the specified order:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timestamp</td>
<td>The Unix time stamp for the logged event with microsecond precision.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>serverhost</td>
<td>The name of the instance that the event is logged for.</td>
</tr>
<tr>
<td>username</td>
<td>The connected user name of the user.</td>
</tr>
<tr>
<td>host</td>
<td>The host that the user connected from.</td>
</tr>
<tr>
<td>connectionid</td>
<td>The connection ID number for the logged operation.</td>
</tr>
<tr>
<td>queryid</td>
<td>The query ID number, which can be used for finding the relational table events and related queries. For TABLE events, multiple lines are added.</td>
</tr>
<tr>
<td>operation</td>
<td>The recorded action type. Possible values are: CONNECT, QUERY, READ, WRITE, CREATE, ALTER, RENAME, and DROP.</td>
</tr>
<tr>
<td>database</td>
<td>The active database, as set by the USE command.</td>
</tr>
<tr>
<td>object</td>
<td>For QUERY events, this value indicates the query that the database performed. For TABLE events, it indicates the table name.</td>
</tr>
<tr>
<td>retcode</td>
<td>The return code of the logged operation.</td>
</tr>
</tbody>
</table>
Replication with Amazon Aurora MySQL

The Aurora MySQL replication features are key to the high availability and performance of your cluster. Aurora makes it easy to create or resize clusters with up to 15 Aurora Replicas.

All the replicas work from the same underlying data. If some database instances go offline, others remain available to continue processing queries or to take over as the writer if needed. Aurora automatically spreads your read-only connections across multiple database instances, helping an Aurora cluster to support query-intensive workloads.

In the following topics, you can find information about how Aurora MySQL replication works and how to fine-tune replication settings for best availability and performance.

Topics
- Using Aurora Replicas (p. 984)
- Replication options for Amazon Aurora MySQL (p. 985)
- Performance considerations for Amazon Aurora MySQL replication (p. 985)
- Zero-downtime restart (ZDR) for Amazon Aurora MySQL (p. 986)
- Configuring replication filters with Aurora MySQL (p. 987)
- Monitoring Amazon Aurora MySQL replication (p. 992)
- Using local write forwarding in an Amazon Aurora MySQL DB cluster (p. 993)
- Replicating Amazon Aurora MySQL DB clusters across AWS Regions (p. 1005)
- Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication) (p. 1015)
- Using GTID-based replication for Amazon Aurora MySQL (p. 1043)

Using Aurora Replicas

Aurora Replicas are independent endpoints in an Aurora DB cluster, best used for scaling read operations and increasing availability. Up to 15 Aurora Replicas can be distributed across the Availability Zones that a DB cluster spans within an AWS Region. Although the DB cluster volume is made up of multiple copies of the data for the DB cluster, the data in the cluster volume is represented as a single, logical volume to the primary instance and to Aurora Replicas in the DB cluster. For more information about Aurora Replicas, see Aurora Replicas (p. 104).

Aurora Replicas work well for read scaling because they are fully dedicated to read operations on your cluster volume. Write operations are managed by the primary instance. Because the cluster volume is shared among all instances in your Aurora MySQL DB cluster, no additional work is required to replicate a copy of the data for each Aurora Replica. In contrast, MySQL read replicas must replay, on a single thread, all write operations from the source DB instance to their local data store. This limitation can affect the ability of MySQL read replicas to support large volumes of read traffic.

With Aurora MySQL, when an Aurora Replica is deleted, its instance endpoint is removed immediately, and the Aurora Replica is removed from the reader endpoint. If there are statements running on the Aurora Replica that is being deleted, there is a three minute grace period. Existing statements can finish gracefully during the grace period. When the grace period ends, the Aurora Replica is shut down and deleted.

Important
Aurora Replicas for Aurora MySQL always use the REPEATABLE.READ default transaction isolation level for operations on InnoDB tables. You can use the SET TRANSACTION ISOLATION LEVEL command to change the transaction level only for the primary instance of an Aurora MySQL DB cluster. This restriction avoids user-level locks on Aurora Replicas.
and allows Aurora Replicas to scale to support thousands of active user connections while still keeping replica lag to a minimum.

**Note**
DDL statements that run on the primary instance might interrupt database connections on the associated Aurora Replicas. If an Aurora Replica connection is actively using a database object, such as a table, and that object is modified on the primary instance using a DDL statement, the Aurora Replica connection is interrupted.

**Note**
The China (Ningxia) Region does not support cross-Region read replicas.

### Replication options for Amazon Aurora MySQL

You can set up replication between any of the following options:

- Two Aurora MySQL DB clusters in different AWS Regions, by creating a cross-Region read replica of an Aurora MySQL DB cluster.
  
  For more information, see [Replicating Amazon Aurora MySQL DB clusters across AWS Regions (p. 1005)](#).

- Two Aurora MySQL DB clusters in the same AWS Region, by using MySQL binary log (binlog) replication.
  
  For more information, see [Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication) (p. 1015)](#).

- An RDS for MySQL DB instance as the source and an Aurora MySQL DB cluster, by creating an Aurora read replica of an RDS for MySQL DB instance.

  You can use this approach to bring existing and ongoing data changes into Aurora MySQL during migration to Aurora. For more information, see [Migrating data from an RDS for MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica (p. 865)](#).

  You can also use this approach to increase the scalability of read queries for your data. You do so by querying the data using one or more DB instances within a read-only Aurora MySQL cluster. For more information, see [Using Amazon Aurora to scale reads for your MySQL database (p. 1029)](#).

- An Aurora MySQL DB cluster in one AWS Region and up to five Aurora read-only Aurora MySQL DB clusters in different Regions, by creating an Aurora global database.

  You can use an Aurora global database to support applications with a world-wide footprint. The primary Aurora MySQL DB cluster has a Writer instance and up to 15 Aurora Replicas. The read-only secondary Aurora MySQL DB clusters can each be made up of as many as 16 Aurora Replicas. For more information, see [Using Amazon Aurora global databases (p. 1800)](#).

  **Note**
  Rebooting the primary instance of an Amazon Aurora DB cluster also automatically reboots the Aurora Replicas for that DB cluster, to re-establish an entry point that guarantees read/write consistency across the DB cluster.

### Performance considerations for Amazon Aurora MySQL replication

The following features help you to fine-tune the performance of Aurora MySQL replication.

The replica log compression feature automatically reduces network bandwidth for replication messages. Because each message is transmitted to all Aurora Replicas, the benefits are greater for larger clusters.
This feature involves some CPU overhead on the writer node to perform the compression. It's always enabled in Aurora MySQL version 2 and version 3.

The binlog filtering feature automatically reduces network bandwidth for replication messages. Because the Aurora Replicas don't use the binlog information that is included in the replication messages, that data is omitted from the messages sent to those nodes.

In Aurora MySQL version 2, you can control this feature by changing the `aurora_enable_repl_bin_log_filtering` parameter. This parameter is on by default. Because this optimization is intended to be transparent, you might turn off this setting only during diagnosis or troubleshooting for issues related to replication. For example, you can do so to match the behavior of an older Aurora MySQL cluster where this feature was not available.

Binlog filtering is always enabled in Aurora MySQL version 3.

### Zero-downtime restart (ZDR) for Amazon Aurora MySQL

The zero-downtime restart (ZDR) feature can preserve some or all of the active connections to DB instances during certain kinds of restarts. ZDR applies to restarts that Aurora performs automatically to resolve error conditions, for example when a replica begins to lag too far behind the source.

**Important**

The ZDR mechanism operates on a best-effort basis. The Aurora MySQL versions, instance classes, error conditions, compatible SQL operations, and other factors that determine where ZDR applies are subject to change at any time.

In Aurora MySQL 1.* versions where ZDR is available, you turn on this feature by turning on the `aurora_enable_zdr` parameter in the cluster parameter group. ZDR for Aurora MySQL 2.* requires version 2.10 and higher. ZDR is available in all minor versions of Aurora MySQL 3.*. In Aurora MySQL version 2 and 3, the ZDR mechanism is turned on by default and Aurora doesn't use the `aurora_enable_zdr` parameter.

Aurora reports on the **Events** page activities related to zero-downtime restart. Aurora records an event when it attempts a restart using the ZDR mechanism. This event states why Aurora performs the restart. Then Aurora records another event when the restart finishes. This final event reports how long the process took, and how many connections were preserved or dropped during the restart. You can consult the database error log to see more details about what happened during the restart.

Although connections remain intact following a successful ZDR operation, some variables and features are reinitialized. The following kinds of information aren't preserved through a restart caused by zero-downtime restart:

- Global variables. Aurora restores session variables, but it doesn't restore global variables after the restart.
- Status variables. In particular, the uptime value reported by the engine status is reset.
- `LAST_INSERT_ID`.
- Diagnostic information from INFORMATION_SCHEMA and PERFORMANCE_SCHEMA tables. This diagnostic information also appears in the output of commands such as `SHOW PROFILE` and `SHOW PROFILES`.

The following table shows the versions, instance roles, instance classes, and other circumstances that determine whether Aurora can use the ZDR mechanism when restarting DB instances in your cluster.
Configuring replication filters with Aurora MySQL

You can use replication filters to specify which databases and tables are replicated with a read replica. Replication filters can include databases and tables in replication or exclude them from replication.

The following are some use cases for replication filters:

- To reduce the size of a read replica. With replication filtering, you can exclude the databases and tables that aren't needed on the read replica.
- To exclude databases and tables from read replicas for security reasons.
- To replicate different databases and tables for specific use cases at different read replicas. For example, you might use specific read replicas for analytics or sharding.
- For a DB cluster that has read replicas in different AWS Regions, to replicate different databases or tables in different AWS Regions.
- To specify which databases and tables are replicated with an Aurora MySQL DB cluster that is configured as a replica in an inbound replication topology. For more information about this configuration, see Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication) (p. 1015).

Topics

- Setting replication filtering parameters for Aurora MySQL (p. 988)
- Replication filtering limitations for Aurora MySQL (p. 989)
- Replication filtering examples for Aurora MySQL (p. 989)
- Viewing the replication filters for a read replica (p. 991)
Setting replication filtering parameters for Aurora MySQL

To configure replication filters, set the following replication filtering parameters on the Aurora read replica:

- **binlog-do-db** – Replicate changes to the specified binary logs. When you set this parameter for a read replica, only the binary logs specified in the parameter are replicated.
- **binlog-ignore-db** – Don't replicate changes to the specified binary logs. When the binlog-do-db parameter is set for a read replica, this parameter isn't evaluated.
- **replicate-do-db** – Replicate changes to the specified databases. When you set this parameter for a read replica, only the databases specified in the parameter are replicated.
- **replicate-ignore-db** – Don't replicate changes to the specified databases. When the replicate-do-db parameter is set for a read replica, this parameter isn't evaluated.
- **replicate-do-table** – Replicate changes to the specified tables. When you set this parameter for a read replica, only the tables specified in the parameter are replicated. Also, when the replicate-do-db or replicate-ignore-db parameter is set, make sure to include the database that includes the specified tables in replication with the read replica.
- **replicate-ignore-table** – Don't replicate changes to the specified tables. When the replicate-do-table parameter is set for a read replica, this parameter isn't evaluated.
- **replicate-wild-do-table** – Replicate tables based on the specified database and table name patterns. The % and _ wildcard characters are supported. When the replicate-do-db or replicate-ignore-db parameter is set, make sure to include the database that includes the specified tables in replication with the read replica.
- **replicate-wild-ignore-table** – Don't replicate tables based on the specified database and table name patterns. The % and _ wildcard characters are supported. When the replicate-do-table or replicate-wild-do-table parameter is set for a read replica, this parameter isn't evaluated.

The parameters are evaluated in the order that they are listed. For more information about how these parameters work, see the MySQL documentation:

- For general information, see [Replica Server Options and Variables](#).
- For information about how database replication filtering parameters are evaluated, see [Evaluation of Database-Level Replication and Binary Logging Options](#).
- For information about how table replication filtering parameters are evaluated, see [Evaluation of Table-Level Replication Options](#).

By default, each of these parameters has an empty value. On each read replica, you can use these parameters to set, change, and delete replication filters. When you set one of these parameters, separate each filter from others with a comma.

You can use the % and _ wildcard characters in the replicate-wild-do-table and replicate-wild-ignore-table parameters. The % wildcard matches any number of characters, and the _ wildcard matches only one character.

The binary logging format of the source DB instance is important for replication because it determines the record of data changes. The setting of the binlog_format parameter determines whether the replication is row-based or statement-based. For more information, see [Configuring Aurora MySQL binary logging (p. 732)](#).

**Note**

All data definition language (DDL) statements are replicated as statements, regardless of the binlog_format setting on the source DB instance.
Replication filtering limitations for Aurora MySQL

The following limitations apply to replication filtering for Aurora MySQL:

- Replication filters are supported only for Aurora MySQL version 3.
- Each replication filtering parameter has a 2,000-character limit.
- Commas aren't supported in replication filters.
- Replication filtering doesn't support XA transactions.

For more information, see Restrictions on XA Transactions in the MySQL documentation.

Replication filtering examples for Aurora MySQL

To configure replication filtering for a read replica, modify the replication filtering parameters in the DB cluster parameter group associated with the read replica.

Note
You can't modify a default DB cluster parameter group. If the read replica is using a default parameter group, create a new parameter group and associate it with the read replica. For more information on DB cluster parameter groups, see Working with parameter groups (p. 212).

You can set parameters in a DB cluster parameter group using the AWS Management Console, AWS CLI, or RDS API. For information about setting parameters, see Modifying parameters in a DB parameter group (p. 229). When you set parameters in a DB cluster parameter group, all of the DB clusters associated with the parameter group use the parameter settings. If you set the replication filtering parameters in a DB cluster parameter group, make sure that the parameter group is associated only with read replica clusters. Leave the replication filtering parameters empty for source DB instances.

The following examples set the parameters using the AWS CLI. These examples set ApplyMethod to immediate so that the parameter changes occur immediately after the CLI command completes. If you want a pending change to be applied after the read replica is rebooted, set ApplyMethod to pending-reboot.

The following examples set replication filters:

- Including databases in replication
- Including tables in replication
- Including tables in replication with wildcard characters
- Excluding databases from replication
- Excluding tables from replication
- Excluding tables from replication using wildcard characters

Example Including databases in replication

The following example includes the mydb1 and mydb2 databases in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group \
  --db-cluster-parameter-group-name myparametergroup \
  --parameters "ParameterName=replicate-do-db,ParameterValue='mydb1,mydb2',ApplyMethod=immediate"
```

For Windows:
**Configuring replication filters**

```
aws rds modify-db-cluster-parameter-group
   --db-cluster-parameter-group-name myparametergroup
   --parameters "ParameterName=replicate-do-db,ParameterValue='mydb1,mydb2',ApplyMethod=immediate"
```

**Example Including tables in replication**

The following example includes the `table1` and `table2` tables in database `mydb1` in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group
   --db-cluster-parameter-group-name myparametergroup
   --parameters "ParameterName=replicate-do-table,ParameterValue='mydb1.table1,mydb1.table2',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-cluster-parameter-group
   --db-cluster-parameter-group-name myparametergroup
   --parameters "ParameterName=replicate-do-table,ParameterValue='mydb1.table1,mydb1.table2',ApplyMethod=immediate"
```

**Example Including tables in replication using wildcard characters**

The following example includes tables with names that begin with `order` and `return` in database `mydb` in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group
   --db-cluster-parameter-group-name myparametergroup
   --parameters "ParameterName=replicate-wild-do-table,ParameterValue='mydb.order %,mydb.return %',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-cluster-parameter-group
   --db-cluster-parameter-group-name myparametergroup
   --parameters "ParameterName=replicate-wild-do-table,ParameterValue='mydb.order %,mydb.return %',ApplyMethod=immediate"
```

**Example Excluding databases from replication**

The following example excludes the `mydb5` and `mydb6` databases from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group
   --db-cluster-parameter-group-name myparametergroup
   --parameters "ParameterName=replicate-ignore-db,ParameterValue='mydb5,mydb6',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-cluster-parameter-group
   --db-cluster-parameter-group-name myparametergroup
   --parameters "ParameterName=replicate-ignore-db,ParameterValue='mydb5,mydb6',ApplyMethod=immediate"
```
Configuring replication filters

Example Excluding tables from replication

The following example excludes tables `table1` in database `mydb5` and `table2` in database `mydb6` from replication.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster-parameter-group
--db-cluster-parameter-group-name myparametergroup
--parameters "ParameterName=replicate-ignore-table,ParameterValue='mydb5.table1,mydb6.table2',ApplyMethod=immediate"
```

For Windows:

```bash
aws rds modify-db-cluster-parameter-group
--db-cluster-parameter-group-name myparametergroup
--parameters "ParameterName=replicate-ignore-table,ParameterValue='mydb5.table1,mydb6.table2',ApplyMethod=immediate"
```

Example Excluding tables from replication using wildcard characters

The following example excludes tables with names that begin with `order` and `return` in database `mydb7` from replication.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster-parameter-group
--db-cluster-parameter-group-name myparametergroup
--parameters "ParameterName=replicate-wild-ignore-table,ParameterValue='mydb7.order%,mydb7.return%',ApplyMethod=immediate"
```

For Windows:

```bash
aws rds modify-db-cluster-parameter-group
--db-cluster-parameter-group-name myparametergroup
--parameters "ParameterName=replicate-wild-ignore-table,ParameterValue='mydb7.order%,mydb7.return%',ApplyMethod=immediate"
```

Viewing the replication filters for a read replica

You can view the replication filters for a read replica in the following ways:

- Check the settings of the replication filtering parameters in the parameter group associated with the read replica.
  
  For instructions, see Viewing parameter values for a DB parameter group (p. 235).
- In a MySQL client, connect to the read replica and run the `SHOW REPLICA STATUS` statement.

In the output, the following fields show the replication filters for the read replica:
Monitoring Amazon Aurora MySQL replication

Read scaling and high availability depend on minimal lag time. You can monitor how far an Aurora Replica is lagging behind the primary instance of your Aurora MySQL DB cluster by monitoring the Amazon CloudWatch `AuroraReplicaLag` metric. The `AuroraReplicaLag` metric is recorded in each Aurora Replica.

The primary DB instance also records the `AuroraReplicaLagMaximum` and `AuroraReplicaLagMinimum` Amazon CloudWatch metrics. The `AuroraReplicaLagMaximum` metric records the maximum amount of lag between the primary DB instance and each Aurora Replica in the DB cluster. The `AuroraReplicaLagMinimum` metric records the minimum amount of lag between the primary DB instance and each Aurora Replica in the DB cluster.

If you need the most current value for Aurora Replica lag, you can check the `AuroraReplicaLag` metric in Amazon CloudWatch. The Aurora Replica lag is also recorded on each Aurora Replica of your Aurora MySQL DB cluster in the `information_schema.replica_host_status` table. For more information on this table, see `information_schema.replica_host_status (p. 1197)`.

For more information on monitoring RDS instances and CloudWatch metrics, see `Monitoring metrics in an Amazon Aurora cluster (p. 509)`.

- `Binlog_Do_DB`
- `Binlog_Ignore_DB`
- `Replicate_Do_DB`
- `Replicate_Ignore_DB`
- `Replicate_Do_Table`
- `Replicate_Ignore_Table`
- `Replicate_Wild_Do_Table`
- `Replicate_Wild_Ignore_Table`

For more information about these fields, see `Checking Replication Status` in the MySQL documentation.
Using local write forwarding in an Amazon Aurora MySQL DB cluster

Local (in-cluster) write forwarding allows your applications to issue read/write transactions directly on an Aurora Replica. These transactions are then forwarded to the writer DB instance to be committed. You can use local write forwarding when your applications require read-after-write consistency, which is the ability to read the latest write in a transaction.

Read replicas receive updates asynchronously from the writer. Without write forwarding, you have to transact any reads that require read-after-write consistency on the writer DB instance. Or you have to develop complex custom application logic to take advantage of multiple read replicas for scalability. Your applications must fully split all read and write traffic, maintaining two sets of database connections to send the traffic to the correct endpoint. This development overhead complicates application design when the queries are part of a single logical session, or transaction, within the application. Moreover, because replication lag can differ among read replicas, it's difficult to achieve global read consistency across all instances in the database.

Write forwarding avoids the need to split those transactions or send them exclusively to the writer, which simplifies application development. This new capability makes it easy to achieve read scale for workloads that need to read the latest write in a transaction and aren't sensitive to write latency.

Local write forwarding is different from global write forwarding, which forwards writes from a secondary DB cluster to the primary DB cluster in an Aurora global database. You can use local write forwarding in a DB cluster that is part of an Aurora global database. For more information, see Using write forwarding in an Amazon Aurora global database (p. 1831).

Local write forwarding requires Aurora MySQL version 3.04 or higher.

Topics
- Enabling local write forwarding (p. 993)
- Checking if a DB cluster has write forwarding enabled (p. 994)
- Application and SQL compatibility with write forwarding (p. 995)
- Isolation levels for write forwarding (p. 997)
- Read consistency for write forwarding (p. 997)
- Running multipart statements with write forwarding (p. 999)
- Transactions with write forwarding (p. 999)
- Configuration parameters for write forwarding (p. 1000)
- Amazon CloudWatch metrics and Aurora MySQL status variables for write forwarding (p. 1001)
- Identifying forwarded transactions and queries (p. 1003)

Enabling local write forwarding

By default, local write forwarding isn't enabled for Aurora MySQL DB clusters. You enable local write forwarding at the cluster level, not at the instance level.

Important
You can also enable local write forwarding for cross-Region read replicas that use binary logging, but write operations aren't forwarded to the source AWS Region. They're forwarded to the writer DB instance of the binlog read replica cluster. Use this method only if you have a use case for writing to the binlog read replica in the secondary AWS Region. Otherwise, you might end up with a "split-brain" scenario where replicated datasets are inconsistent with each other.
We recommend that you use global write forwarding with global databases, rather than local write forwarding on cross-Region read replicas, unless absolutely necessary. For more information, see Using write forwarding in an Amazon Aurora global database (p. 1831).

**Console**

Using the AWS Management Console, select the Turn on local write forwarding check box under Read replica write forwarding when you create or modify a DB cluster.

**AWS CLI**

To enable write forwarding with the AWS CLI, use the --enable-local-write-forwarding option. This option works when you create a new DB cluster using the create-db-cluster command. It also works when you modify an existing DB cluster using the modify-db-cluster command. You can disable write forwarding by using the --no-enable-local-write-forwarding option with these same CLI commands.

The following example creates an Aurora MySQL DB cluster with write forwarding enabled.

```bash
aws rds create-db-cluster
   --db-cluster-identifier write-forwarding-test-cluster
   --enable-local-write-forwarding
   --engine aurora-mysql
   --engine-version 8.0.mysql_aurora.3.04.0
   --master-username myuser
   --master-user-password mypassword
   --backup-retention 1
```

You then create writer and reader DB instances so that you can use write forwarding. For more information, see Creating an Amazon Aurora DB cluster (p. 179).

**RDS API**

To enable write forwarding using the Amazon RDS API, set the EnableLocalWriteForwarding parameter to true. This parameter works when you create a new DB cluster using the CreateDBCluster operation. It also works when you modify an existing DB cluster using the ModifyDBCluster operation. You can disable write forwarding by setting the EnableLocalWriteForwarding parameter to false.

**Enabling write forwarding for database sessions**

The aurora_replica_read_consistency parameter is a DB parameter and DB cluster parameter that enables write forwarding. You can specify EVENTUAL, SESSION, or GLOBAL for the read consistency level. To learn more about consistency levels, see Read consistency for write forwarding (p. 997).

The following rules apply to this parameter:

- The default value is " (null).
- Write forwarding is available only if you set aurora_replica_read_consistency to EVENTUAL, SESSION, or GLOBAL. This parameter is relevant only in reader instances of DB clusters that have write forwarding enabled.
- You can't set this parameter (when empty) or unset it (when already set) inside a multistatement transaction. You can change it from one valid value to another valid value during such a transaction, but we don't recommend this action.

**Checking if a DB cluster has write forwarding enabled**

To determine that you can use write forwarding in a DB cluster, confirm that the cluster has the attribute LocalWriteForwardingStatus set to enabled.
In the AWS Management Console, on the **Configuration** tab of the details page for the cluster, you see the status **Enabled** for **Local read replica write forwarding**.

To see the status of the write forwarding setting for all of your clusters, run the following AWS CLI command.

**Example**

```
aws rds describe-db-clusters \
--query '.[0].{DBClusterIdentifier:DBClusterIdentifier,LocalWriteForwardingStatus:LocalWriteForwardingStatus}]

[  
  {  
    "LocalWriteForwardingStatus": "enabled",  
    "DBClusterIdentifier": "write-forwarding-test-cluster-1"  
  },  
  {  
    "LocalWriteForwardingStatus": "disabled",  
    "DBClusterIdentifier": "write-forwarding-test-cluster-2"  
  },  
  {  
    "LocalWriteForwardingStatus": "requested",  
    "DBClusterIdentifier": "test-global-cluster-2"  
  },  
  {  
    "LocalWriteForwardingStatus": "null",  
    "DBClusterIdentifier": "aurora-mysql-v2-cluster"  
  }
]
```

A DB cluster can have the following values for **LocalWriteForwardingStatus**:

- **disabled** – Write forwarding is disabled.
- **disabling** – Write forwarding is in the process of being disabled.
- **enabled** – Write forwarding is enabled.
- **enabling** – Write forwarding is in the process of being enabled.
- **null** – Write forwarding isn't available for this DB cluster.
- **requested** – Write forwarding has been requested, but is not yet active.

**Application and SQL compatibility with write forwarding**

You can use the following kinds of SQL statements with write forwarding:

- Data manipulation language (DML) statements, such as INSERT, DELETE, and UPDATE. There are some restrictions on the properties of these statements that you can use with write forwarding, as described following.
- SELECT ... LOCK IN SHARE MODE and SELECT FOR UPDATE statements.
- PREPARE and EXECUTE statements.

Certain statements aren't allowed or can produce stale results when you use them in a DB cluster with write forwarding. Thus, the EnableLocalWriteForwarding setting is disabled by default for DB clusters. Before enabling it, check to make sure that your application code isn't affected by any of these restrictions.

The following restrictions apply to the SQL statements you use with write forwarding. In some cases, you can use the statements on DB clusters with write forwarding enabled. This approach works if
write forwarding isn't enabled within the session by the `aurora_replica_read_consistency` configuration parameter. If you try to use a statement when it's not allowed because of write forwarding, then you will see an error message similar to the following:

```
ERROR 1235 (42000): This version of MySQL doesn't yet support 'operation with write forwarding'.
```

**Data definition language (DDL)**

Connect to the writer DB instance to run DDL statements. You can't run them from reader DB instances.

**Updating a permanent table using data from a temporary table**

You can use temporary tables on DB clusters with write forwarding enabled. However, you can't use a DML statement to modify a permanent table if the statement refers to a temporary table. For example, you can't use an `INSERT ... SELECT` statement that takes the data from a temporary table.

**XA transactions**

You can't use the following statements on a DB cluster when write forwarding is enabled within the session. You can use these statements on DB clusters that don't have write forwarding enabled, or within sessions where the `aurora_replica_read_consistency` setting is empty. Before enabling write forwarding within a session, check if your code uses these statements.

```
XA {START|BEGIN} xid [JOIN|RESUME]
XA END xid [SUSPEND [FOR MIGRATE]]
XA PREPARE xid
XA COMMIT xid [ONE PHASE]
XA ROLLBACK xid
XA RECOVER [CONVERT XID]
```

**LOAD statements for permanent tables**

You can't use the following statements on a DB cluster with write forwarding enabled.

```
LOAD DATA INFILE 'data.txt' INTO TABLE t1;
LOAD XML LOCAL INFILE 'test.xml' INTO TABLE t1;
```

**Plugin statements**

You can't use the following statements on a DB cluster with write forwarding enabled.

```
INSTALL PLUGIN example SONAME 'ha_example.so';
UNINSTALL PLUGIN example;
```

**SAVEPOINT statements**

You can't use the following statements on a DB cluster when write forwarding is enabled within the session. You can use these statements on DB clusters that don't have write forwarding enabled, or within sessions where the `aurora_replica_read_consistency` setting is blank. Check if your code uses these statements before enabling write forwarding within a session.

```
SAVEPOINT t1_save;
ROLLBACK TO SAVEPOINT t1_save;
RELEASE SAVEPOINT t1_save;
```
Isolation levels for write forwarding

In sessions that use write forwarding, you can only use the REPEATABLE READ isolation level. Although you can also use the READ COMMITTED isolation level with Aurora Replicas, that isolation level doesn't work with write forwarding. For information about the REPEATABLE READ and READ COMMITTED isolation levels, see Aurora MySQL isolation levels (p. 1158).

Read consistency for write forwarding

You can control the degree of read consistency on a DB cluster. The read consistency level determines how long the DB cluster waits before each read operation to ensure that some or all changes are replicated from the writer. You can adjust the read consistency level to make sure that all forwarded write operations from your session are visible in the DB cluster before any subsequent queries. You can also use this setting to make sure that queries on the DB cluster always see the most current updates from the writer. This setting also applies to queries submitted by other sessions or other clusters. To specify this type of behavior for your application, choose a value for the aurora_replica_read_consistency DB parameter or DB cluster parameter.

Important

Always set the aurora_replica_read_consistency DB parameter or DB cluster parameter when you want to forward writes. If you don't, then Aurora doesn't forward writes. This parameter has an empty value by default, so choose a specific value when you use this parameter. The aurora_replica_read_consistency parameter only affects DB clusters or instances that have write forwarding enabled.

As you increase the consistency level, your application spends more time waiting for changes to be propagated between DB instances. You can choose the balance between fast response time and making sure that changes made in other DB instances are fully available before your queries run.

You can specify the following values for the aurora_replica_read_consistency parameter:

- EVENTUAL – Results of write operations in the same session aren't visible until the write operation is performed on the writer DB instance. The query doesn't wait for the updated results to be available. Thus it might retrieve the older data or the updated data, depending on the timing of the statements and the amount of replication lag. This is the same consistency as for Aurora MySQL DB clusters that don't use write forwarding.
- SESSION – All queries that use write forwarding see the results of all changes made in that session. The changes are visible regardless of whether the transaction is committed. If necessary, the query waits for the results of forwarded write operations to be replicated.
- GLOBAL – A session sees all committed changes across all sessions and instances in the DB cluster. Each query might wait for a period that varies depending on the amount of session lag. The query proceeds when the DB cluster is up-to-date with all committed data from the writer, as of the time that the query began.

For information about the configuration parameters involved in write forwarding, see Configuration parameters for write forwarding (p. 1000).

Note

You can also use aurora_replica_read_consistency as a session variable, for example:

```sql
mysql> set aurora_replica_read_consistency = 'session';
```

Examples of using write forwarding

The following examples show the effects of the aurora_replica_read_consistency parameter on running INSERT statements followed by SELECT statements. The results can differ, depending on the value of aurora_replica_read_consistency and the timing of the statements.
To achieve higher consistency, you might wait briefly before issuing the SELECT statement. Or Aurora can automatically wait until the results finish replicating before proceeding with SELECT.

For information on setting DB parameters, see Working with parameter groups (p. 212).

**Example with aurora_replica_read_consistency set to EVENTUAL**

Running an INSERT statement, immediately followed by a SELECT statement, returns a value for COUNT(*) with the number of rows before the new row is inserted. Running the SELECT again a short time later returns the updated row count. The SELECT statements don’t wait.

```sql
mysql> select count(*) from t1;
+----------+
| count(*) |
+----------+
|     5    |
+----------+
1 row in set (0.00 sec)

mysql> insert into t1 values (6); select count(*) from t1;
+----------+
| count(*) |
+----------+
|     5    |
+----------+
1 row in set (0.00 sec)

mysql> select count(*) from t1;
+----------+
| count(*) |
+----------+
|     6    |
+----------+
1 row in set (0.00 sec)
```

**Example with aurora_replica_read_consistency set to SESSION**

A SELECT statement immediately after an INSERT waits until the changes from the INSERT statement are visible. Subsequent SELECT statements don’t wait.

```sql
mysql> select count(*) from t1;
+----------+
| count(*) |
+----------+
|     6    |
+----------+
1 row in set (0.01 sec)

mysql> insert into t1 values (6); select count(*) from t1; select count(*) from t1;
Query OK, 1 row affected (0.08 sec)
+----------+
| count(*) |
+----------+
|     7    |
+----------+
1 row in set (0.37 sec)

mysql> select count(*) from t1;
+----------+
| count(*) |
+----------+
|     7    |
+----------+
1 row in set (0.00 sec)
```
With the read consistency setting still set to SESSION, introducing a brief wait after performing an INSERT statement makes the updated row count available by the time the next SELECT statement runs.

```sql
mysql> insert into t1 values (6); select sleep(2); select count(*) from t1;
Query OK, 1 row affected (0.07 sec)
+---------+
| sleep(2) |
+---------+
|        0 |
+---------+
1 row in set (2.01 sec)
+---------+
| count(*) |
+---------+
|        8 |
+---------+
1 row in set (0.00 sec)
```

**Example with aurora_replica_read_consistency set to GLOBAL**

Each SELECT statement waits for all data changes, as of the start time of the statement, to be visible before performing the query. The wait time for each SELECT statement varies, depending on the amount of replication lag.

```sql
mysql> select count(*) from t1;
+---------+
| count(*) |
+---------+
|        8 |
+---------+
1 row in set (0.75 sec)
mysql> select count(*) from t1;
+---------+
| count(*) |
+---------+
|        8 |
+---------+
1 row in set (0.37 sec)
mysql> select count(*) from t1;
+---------+
| count(*) |
+---------+
|        8 |
+---------+
1 row in set (0.66 sec)
```

**Running multipart statements with write forwarding**

A DML statement might consist of multiple parts, such as an INSERT ... SELECT statement or a DELETE ... WHERE statement. In this case, the entire statement is forwarded to the writer DB instance and run there.

**Transactions with write forwarding**

If the transaction access mode is set to read only, write forwarding isn't used. You can specify the access mode for the transaction by using the SET TRANSACTION statement or the START TRANSACTION statement. You can also specify the transaction access mode by changing the value of the
transaction_read_only session variable. You can change this session value only while you're connected to a DB cluster that has write forwarding enabled.

If a long-running transaction doesn't issue any statement for a substantial period of time, it might exceed the idle timeout period. This period has a default of one minute. You can set the aurora_fwd_writer_idle_timeout parameter to increase it up to one day. A transaction that exceeds the idle timeout is canceled by the writer instance. The next subsequent statement you submit receives a timeout error. Then Aurora rolls back the transaction.

This type of error can occur in other cases when write forwarding becomes unavailable. For example, Aurora cancels any transactions that use write forwarding if you restart the DB cluster or if you disable write forwarding.

When a writer instance in a cluster using local write forwarding is restarted, any active, forwarded transactions and queries on reader instances using local write forwarding are automatically closed. After the writer instance is available again, you can retry these transactions.

Configuration parameters for write forwarding

The Aurora DB parameter groups include settings for the write forwarding feature. Details about these parameters are summarized in the following table, with usage notes after the table.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Scope</th>
<th>Type</th>
<th>Default value</th>
<th>Valid values</th>
</tr>
</thead>
<tbody>
<tr>
<td>aurora_fwd_writer_idle_timeout</td>
<td>Cluster</td>
<td>Unsigned integer</td>
<td>60</td>
<td>1–86,400</td>
</tr>
<tr>
<td>aurora_fwd_writer_max_connections_pct</td>
<td>Cluster</td>
<td>Unsigned long integer</td>
<td>10</td>
<td>0–90</td>
</tr>
<tr>
<td>aurora_replica_read_consistency</td>
<td>Cluster or instance</td>
<td>Enum</td>
<td>&quot; (null)</td>
<td>EVENTUAL, SESSION, GLOBAL</td>
</tr>
</tbody>
</table>

To control incoming write requests, use these settings:

- aurora_fwd_writer_idle_timeout – The number of seconds the writer DB instance waits for activity on a connection that's forwarded from a reader instance before closing it. If the session remains idle beyond this period, Aurora cancels the session.
- aurora_fwd_writer_max_connections_pct – The upper limit on database connections that can be used on a writer DB instance to handle queries forwarded from reader instances. It's expressed as a percentage of the max_connections setting for the writer. For example, if max_connections is 800 and aurora_fwd_master_max_connections_pct or aurora_fwd_writer_max_connections_pct is 10, then the writer allows a maximum of 80 simultaneous forwarded sessions. These connections come from the same connection pool managed by the max_connections setting.

This setting applies only on the writer when it has write forwarding enabled. If you decrease the value, existing connections aren't affected. Aurora takes the new value of the setting into account when attempting to create a new connection from a DB cluster. The default value is 10, representing 10% of the max_connections value.

Note
Because aurora_fwd_writer_idle_timeout and aurora_fwd_writer_max_connections_pct are DB cluster parameters, all DB instances in each cluster have the same values for these parameters.
For more information about aurora_replica_read_consistency, see *Read consistency for write forwarding* (p. 997).

For more information on DB parameter groups, see *Working with parameter groups* (p. 212).

## Amazon CloudWatch metrics and Aurora MySQL status variables for write forwarding

The following Amazon CloudWatch metrics and Aurora MySQL status variables apply when you use write forwarding on one or more DB clusters. These metrics and status variables are all measured on the writer DB instance.

<table>
<thead>
<tr>
<th>CloudWatch metric</th>
<th>Aurora MySQL status variable</th>
<th>Unit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ForwardingWriterDMLLatency</td>
<td></td>
<td>Milliseconds</td>
<td>Average time to process each forwarded DML statement on the writer DB instance. It doesn't include the time for the DB cluster to forward the write request, or the time to replicate changes back to the writer.</td>
</tr>
<tr>
<td>ForwardingWriterDMLThroughput</td>
<td></td>
<td>Count per second</td>
<td>Number of forwarded DML statements processed each second by this writer DB instance.</td>
</tr>
<tr>
<td>ForwardingWriterOpenSessions</td>
<td>Aurora_fwd_writer_open_sessions</td>
<td>Count</td>
<td>Number of forwarded sessions on the writer DB instance.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Total number of DML statements forwarded to this writer DB instance.</td>
</tr>
<tr>
<td></td>
<td>Aurora_fwd_writer_dml_count</td>
<td></td>
<td>Total duration of DML statements forwarded to this writer DB instance.</td>
</tr>
<tr>
<td></td>
<td>Aurora_fwd_writer_dml_micoseconds</td>
<td></td>
<td>Total number of SELECT statements forwarded to this writer DB instance.</td>
</tr>
<tr>
<td></td>
<td>Aurora_fwd_writer_select_count</td>
<td></td>
<td>Total duration of SELECT statements forwarded to this writer DB instance.</td>
</tr>
<tr>
<td></td>
<td>Aurora_fwd_writer_select_micoseconds</td>
<td></td>
<td>Total number of SELECT statements forwarded to this writer DB instance.</td>
</tr>
</tbody>
</table>

The following CloudWatch metrics and Aurora MySQL status variables are measured on each reader DB instance in a DB cluster with write forwarding enabled.
<table>
<thead>
<tr>
<th>CloudWatch metric</th>
<th>Aurora MySQL status variable</th>
<th>Unit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ForwardingReplicaDMLLatency</td>
<td></td>
<td>Milliseconds</td>
<td>Average response time of forwarded DMLs on replica.</td>
</tr>
<tr>
<td>ForwardingReplicaDMLThroughput</td>
<td></td>
<td>Count per second</td>
<td>Number of forwarded DML statements processed each second.</td>
</tr>
<tr>
<td>ForwardingReplicaOpenSessions</td>
<td></td>
<td>Count</td>
<td>Number of sessions that are using write forwarding on a reader DB instance.</td>
</tr>
<tr>
<td>ForwardingReplicaReadWaitLatency</td>
<td></td>
<td>Milliseconds</td>
<td>Average wait time that a SELECT statement on a reader DB instance waits to catch up to the writer.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>The degree to which the reader DB instance waits before processing a query depends on the aurora_replica_read_consistency setting.</td>
</tr>
<tr>
<td>ForwardingReplicaReadWaitThroughput</td>
<td></td>
<td>Count per second</td>
<td>Total number of SELECT statements processed each second in all sessions that are forwarding writes.</td>
</tr>
<tr>
<td>ForwardingReplicaSelectLatency</td>
<td></td>
<td>Milliseconds</td>
<td>Forwarded SELECT latency, averaged over all forwarded SELECT statements within the monitoring period.</td>
</tr>
<tr>
<td>ForwardingReplicaSelectThroughput</td>
<td></td>
<td>Count per second</td>
<td>Forwarded SELECT throughput per second average within the monitoring period.</td>
</tr>
<tr>
<td>-</td>
<td>Aurora_fwd_replica_dml_count</td>
<td>Count</td>
<td>Total number of DML statements forwarded from this reader DB instance.</td>
</tr>
<tr>
<td>-</td>
<td>Aurora_fwd_replica_dml_duration</td>
<td>Microseconds</td>
<td>Total duration of all DML statements forwarded from this reader DB instance.</td>
</tr>
<tr>
<td>-</td>
<td>Aurora_fwd_replica_err_session_limit</td>
<td>Count</td>
<td>Number of sessions rejected by the primary cluster due to one of the following error conditions:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• writer full</td>
</tr>
</tbody>
</table>
### Identifying forwarded transactions and queries

You can use the `information_schema.aurora_forwarding_processlist` table to identify forwarded transactions and queries. For more information on this table, see `information_schema.aurora_forwarding_processlist (p. 1198)`.

The following example shows all forwarded connections on a writer DB instance.

```sql
mysql> select * from information_schema.AURORA_FORWARDING_PROCESSLIST where IS_FORWARDED=1 order by REPLICA_SESSION_ID;
```

<table>
<thead>
<tr>
<th>ID</th>
<th>USER</th>
<th>HOST</th>
<th>DB</th>
<th>COMMAND</th>
<th>TIME</th>
<th>STATE</th>
<th>REPLICA_INSTANCE_IDENTIFIER</th>
<th>REPLICA_CLUSTER_NAME</th>
<th>REPLICA_REGION</th>
</tr>
</thead>
<tbody>
<tr>
<td>648</td>
<td>myuser</td>
<td>IP_address:port1</td>
<td>sysbench</td>
<td>Query</td>
<td>0</td>
<td>async commit</td>
<td>my-db-cluster-instance-2</td>
<td>my-db-cluster</td>
<td>us-west-2</td>
</tr>
<tr>
<td>650</td>
<td>myuser</td>
<td>IP_address:port2</td>
<td>sysbench</td>
<td>Query</td>
<td>0</td>
<td>async commit</td>
<td>my-db-cluster-instance-2</td>
<td>my-db-cluster</td>
<td>us-west-2</td>
</tr>
</tbody>
</table>

On the forwarding reader DB instance, you can see the threads associated with these writer DB connections by running `SHOW PROCESSLIST`. The REPLICA_SESSION_ID values on the writer, 637 and 639, are the same as the `Id` values on the reader.
mysql> select @@aurora_server_id;
+-------------------+
| @@aurora_server_id |
+-------------------+
| my-db-cluster-instance-2 |
+-------------------+
1 row in set (0.00 sec)

mysql> show processlist;
+-----+----------+--------------------+----------+---------+------+--------------+
|    | 637 | myuser | IP_address:port1 | sysbench | Query   | 0 | async commit | UPDATE
|    | 639 | myuser | IP_address:port2 | sysbench | Query   | 0 | async commit | UPDATE
+-----+----------+--------------------+----------+---------+------+--------------+
12 rows in set (0.00 sec)
Replicating Amazon Aurora MySQL DB clusters across AWS Regions

You can create an Amazon Aurora MySQL DB cluster as a read replica in a different AWS Region than the source DB cluster. Taking this approach can improve your disaster recovery capabilities, let you scale read operations into an AWS Region that is closer to your users, and make it easier to migrate from one AWS Region to another.

You can create read replicas of both encrypted and unencrypted DB clusters. The read replica must be encrypted if the source DB cluster is encrypted.

For each source DB cluster, you can have up to five cross-Region DB clusters that are read replicas.

**Note**
As an alternative to cross-Region read replicas, you can scale read operations with minimal lag time by using an Aurora global database. An Aurora global database has a primary Aurora DB cluster in one AWS Region and up to five secondary read-only DB clusters in different Regions. Each secondary DB cluster can include up to 16 (rather than 15) Aurora Replicas. Replication from the primary DB cluster to all secondaries is handled by the Aurora storage layer rather than by the database engine, so lag time for replicating changes is minimal—typically, less than 1 second. Keeping the database engine out of the replication process means that the database engine is dedicated to processing workloads. It also means that you don't need to configure or manage the Aurora MySQL binlog (binary logging) replication. To learn more, see Using Amazon Aurora global databases (p. 1800).

When you create an Aurora MySQL DB cluster read replica in another AWS Region, you should be aware of the following:

- Both your source DB cluster and your cross-Region read replica DB cluster can have up to 15 Aurora Replicas, along with the primary instance for the DB cluster. By using this functionality, you can scale read operations for both your source AWS Region and your replication target AWS Region.
- In a cross-Region scenario, there is more lag time between the source DB cluster and the read replica due to the longer network channels between AWS Regions.
- Data transferred for cross-Region replication incurs Amazon RDS data transfer charges. The following cross-Region replication actions generate charges for the data transferred out of the source AWS Region:
  - When you create the read replica, Amazon RDS takes a snapshot of the source cluster and transfers the snapshot to the AWS Region that holds the read replica.
  - For each data modification made in the source databases, Amazon RDS transfers data from the source region to the AWS Region that holds the read replica.

For more information about Amazon RDS data transfer pricing, see Amazon Aurora pricing.

- You can run multiple concurrent create or delete actions for read replicas that reference the same source DB cluster. However, you must stay within the limit of five read replicas for each source DB cluster.
- For replication to operate effectively, each read replica should have the same amount of compute and storage resources as the source DB cluster. If you scale the source DB cluster, you should also scale the read replicas.

Topics
- Before you begin (p. 1006)
- Creating an Amazon Aurora MySQL DB cluster that is a cross-Region read replica (p. 1006)
- Viewing Amazon Aurora MySQL cross-Region replicas (p. 1012)
- Promoting a read replica to be a DB cluster (p. 1013)
Before you begin

Before you can create an Aurora MySQL DB cluster that is a cross-Region read replica, you must turn on binary logging on your source Aurora MySQL DB cluster. Cross-region replication for Aurora MySQL uses MySQL binary replication to replay changes on the cross-Region read replica DB cluster.

To turn on binary logging on an Aurora MySQL DB cluster, update the \texttt{binlog\_format} parameter for your source DB cluster. The \texttt{binlog\_format} parameter is a cluster-level parameter that is in the default cluster parameter group. If your DB cluster uses the default DB cluster parameter group, create a new DB cluster parameter group to modify \texttt{binlog\_format} settings. We recommend that you set the \texttt{binlog\_format} to \texttt{MIXED}. However, you can also set \texttt{binlog\_format} to \texttt{ROW} or \texttt{STATEMENT} if you need a specific binlog format. Reboot your Aurora DB cluster for the change to take effect.

For more information about using binary logging with Aurora MySQL, see Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication) (p. 1015). For more information about modifying Aurora MySQL configuration parameters, see Amazon Aurora DB cluster and DB instance parameters (p. 215) and Working with parameter groups (p. 212).

Creating an Amazon Aurora MySQL DB cluster that is a cross-Region read replica

You can create an Aurora DB cluster that is a cross-Region read replica by using the AWS Management Console, the AWS Command Line Interface (AWS CLI), or the Amazon RDS API. You can create cross-Region read replicas from both encrypted and unencrypted DB clusters.

When you create a cross-Region read replica for Aurora MySQL by using the AWS Management Console, Amazon RDS creates a DB cluster in the target AWS Region, and then automatically creates a DB instance that is the primary instance for that DB cluster.

When you create a cross-Region read replica using the AWS CLI or RDS API, you first create the DB cluster in the target AWS Region and wait for it to become active. Once it is active, you then create a DB instance that is the primary instance for that DB cluster.

Replication begins when the primary instance of the read replica DB cluster becomes available.

Use the following procedures to create a cross-Region read replica from an Aurora MySQL DB cluster. These procedures work for creating read replicas from either encrypted or unencrypted DB clusters.

**Console**

**To create an Aurora MySQL DB cluster that is a cross-Region read replica with the AWS Management Console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the top-right corner of the AWS Management Console, select the AWS Region that hosts your source DB cluster.
3. In the navigation pane, choose Databases.
4. Choose the DB cluster for which you want to create a cross-Region read replica.
5. For Actions, choose Create cross-Region read replica.
6. On the Create cross region read replica page, choose the option settings for your cross-Region read replica DB cluster, as described in the following table.
### Cross-Region replication

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Destination region</strong></td>
<td>Choose the AWS Region to host the new cross-Region read replica DB cluster.</td>
</tr>
<tr>
<td><strong>Destination DB subnet group</strong></td>
<td>Choose the DB subnet group to use for the cross-Region read replica DB cluster.</td>
</tr>
<tr>
<td><strong>Publicly accessible</strong></td>
<td>Choose Yes to give the cross-Region read replica DB cluster a public IP address; otherwise, select No.</td>
</tr>
<tr>
<td><strong>Encryption</strong></td>
<td>Select Enable Encryption to turn on encryption at rest for this DB cluster. For more information, see Encrypting Amazon Aurora resources (p. 2381).</td>
</tr>
<tr>
<td><strong>AWS KMS key</strong></td>
<td>Only available if Encryption is set to Enable Encryption. Select the AWS KMS key to use for encrypting this DB cluster. For more information, see Encrypting Amazon Aurora resources (p. 2381).</td>
</tr>
<tr>
<td><strong>DB instance class</strong></td>
<td>Choose a DB instance class that defines the processing and memory requirements for the primary instance in the DB cluster. For more information about DB instance class options, see Aurora DB instance classes (p. 84).</td>
</tr>
<tr>
<td><strong>Multi-AZ deployment</strong></td>
<td>Choose Yes to create a read replica of the new DB cluster in another Availability Zone in the target AWS Region for failover support. For more information about multiple Availability Zones, see Regions and Availability Zones (p. 16).</td>
</tr>
<tr>
<td><strong>Read replica source</strong></td>
<td>Choose the source DB cluster to create a cross-Region read replica for.</td>
</tr>
</tbody>
</table>
| **DB instance identifier**  | Type a name for the primary instance in your cross-Region read replica DB cluster. This identifier is used in the endpoint address for the primary instance of the new DB cluster.  

The DB instance identifier has the following constraints:  
- It must contain from 1 to 63 alphanumeric characters or hyphens.  
- Its first character must be a letter.  
- It cannot end with a hyphen or contain two consecutive hyphens.  
- It must be unique for all DB instances for each AWS account, for each AWS Region.  

Because the cross-Region read replica DB cluster is created from a snapshot of the source DB cluster, the master user name and master password for the read replica are the same as the master user name and master password for the source DB cluster. |
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| DB cluster identifier      | Type a name for your cross-Region read replica DB cluster that is unique for your account in the target AWS Region for your replica. This identifier is used in the cluster endpoint address for your DB cluster. For information on the cluster endpoint, see Amazon Aurora connection management (p. 62). The DB cluster identifier has the following constraints:  
  • It must contain from 1 to 63 alphanumeric characters or hyphens.  
  • Its first character must be a letter.  
  • It cannot end with a hyphen or contain two consecutive hyphens.  
  • It must be unique for all DB clusters for each AWS account, for each AWS Region. |
| Priority                    | Choose a failover priority for the primary instance of the new DB cluster. This priority determines the order in which Aurora Replicas are promoted when recovering from a primary instance failure. If you don't select a value, the default is tier-1. For more information, see Fault tolerance for an Aurora DB cluster (p. 103). |
| Database port               | Specify the port for applications and utilities to use to access the database. Aurora DB clusters default to the default MySQL port, 3306. Firewalls at some companies block connections to this port. If your company firewall blocks the default port, choose another port for the new DB cluster. |
| Enhanced monitoring         | Choose Enable enhanced monitoring to turn on gathering metrics in real time for the operating system that your DB cluster runs on. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 631). |
| Monitoring Role             | Only available if Enhanced Monitoring is set to Enable enhanced monitoring. Choose the IAM role that you created to permit Amazon RDS to communicate with Amazon CloudWatch Logs for you, or choose Default to have RDS create a role for you named rds-monitoring-role. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 631). |
| Granularity                 | Only available if Enhanced Monitoring is set to Enable enhanced monitoring. Set the interval, in seconds, between when metrics are collected for your DB cluster. |
| Auto minor version upgrade  | This setting doesn't apply to Aurora MySQL DB clusters. For more information about engine updates for Aurora MySQL, see Database engine updates for Amazon Aurora MySQL (p. 1200). |

7. Choose Create to create your cross-Region read replica for Aurora.
AWS CLI

To create an Aurora MySQL DB cluster that is a cross-Region read replica with the CLI

1. Call the AWS CLI `create-db-cluster` command in the AWS Region where you want to create the read replica DB cluster. Include the `--replication-source-identifier` option and specify the Amazon Resource Name (ARN) of the source DB cluster to create a read replica for.

   For cross-Region replication where the DB cluster identified by `--replication-source-identifier` is encrypted, specify the `--kms-key-id` option and the `--storage-encrypted` option.

   **Note**
   
   You can set up cross-Region replication from an unencrypted DB cluster to an encrypted read replica by specifying `--storage-encrypted` and providing a value for `--kms-key-id`.

   You can’t specify the `--master-username` and `--master-user-password` parameters. Those values are taken from the source DB cluster.

   The following code example creates a read replica in the us-east-1 Region from an unencrypted DB cluster snapshot in the us-west-2 Region. The command is called in the us-east-1 Region. This example specifies the `--manage-master-user-password` option to generate the master user password and manage it in Secrets Manager. For more information, see Password management with Amazon Aurora and AWS Secrets Manager (p. 2371). Alternatively, you can use the `--master-password` option to specify and manage the password yourself.

   For Linux, macOS, or Unix:

   ```
   aws rds create-db-cluster \
   --db-cluster-identifier sample-replica-cluster \
   --engine aurora \
   ```

   For Windows:

   ```
   aws rds create-db-cluster ^
   --db-cluster-identifier sample-replica-cluster ^
   --engine aurora ^
   ```

   The following code example creates a read replica in the us-east-1 Region from an encrypted DB cluster snapshot in the us-west-2 Region. The command is called in the us-east-1 Region.

   For Linux, macOS, or Unix:

   ```
   aws rds create-db-cluster \
   --db-cluster-identifier sample-replica-cluster \
   --engine aurora \
   --kms-key-id my-us-east-1-key \
   --storage-encrypted
   ```

   For Windows:

   ```
   aws rds create-db-cluster ^
   --db-cluster-identifier sample-replica-cluster ^
   --engine aurora ^
   --kms-key-id my-us-east-1-key ^
   --storage-encrypted
   ```
aws rds create-db-cluster ^
   --db-cluster-identifier sample-replica-cluster ^
   --engine aurora ^
   --kms-key-id my-us-east-1-key ^
   --storage-encrypted

The `--source-region` option is required for cross-Region replication between the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions, where the DB cluster identified by `--replication-source-identifier` is encrypted. For `--source-region`, specify the AWS Region of the source DB cluster.

If `--source-region` isn't specified, specify a `--pre-signed-url` value. A presigned URL is a URL that contains a Signature Version 4 signed request for the `create-db-cluster` command that is called in the source AWS Region. To learn more about the `pre-signed-url` option, see `create-db-cluster` in the AWS CLI Command Reference.

2. Check that the DB cluster has become available to use by using the AWS CLI `describe-db-clusters` command, as shown in the following example.

```bash
aws rds describe-db-clusters --db-cluster-identifier sample-replica-cluster
```

When the `describe-db-clusters` results show a status of available, create the primary instance for the DB cluster so that replication can begin. To do so, use the AWS CLI `create-db-instance` command as shown in the following example.

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance \
   --db-cluster-identifier sample-replica-cluster \
   --db-instance-class db.r3.large \
   --db-instance-identifier sample-replica-instance \
   --engine aurora
```

For Windows:

```bash
aws rds create-db-instance ^
   --db-cluster-identifier sample-replica-cluster ^
   --db-instance-class db.r3.large ^
   --db-instance-identifier sample-replica-instance ^
   --engine aurora
```

When the DB instance is created and available, replication begins. You can determine if the DB instance is available by calling the AWS CLI `describe-db-instances` command.

RDS API

To create an Aurora MySQL DB cluster that is a cross-Region read replica with the API

1. Call the RDS API `CreateDBCluster` operation in the AWS Region where you want to create the read replica DB cluster. Include the `ReplicationSourceIdentifier` parameter and specify the Amazon Resource Name (ARN) of the source DB cluster to create a read replica for.

   For cross-Region replication where the DB cluster identified by `ReplicationSourceIdentifier` is encrypted, specify the `KmsKeyId` parameter and set the `StorageEncrypted` parameter to true.
Note
You can set up cross-region replication from an unencrypted DB cluster to an encrypted read replica by specifying `StorageEncrypted` as `true` and providing a value for `KmsKeyId`. In this case, you don't need to specify `PreSignedUrl`.

You don't need to include the `MasterUsername` and `MasterUserPassword` parameters, because those values are taken from the source DB cluster.

The following code example creates a read replica in the us-east-1 Region from an unencrypted DB cluster snapshot in the us-west-2 Region. The action is called in the us-east-1 Region.

```python
https://rds.us-east-1.amazonaws.com/
?Action=CreateDBCluster
&DBClusterIdentifier=sample-replica-cluster
&Engine=aurora
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Version=2014-10-31
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20161117/us-east-1/rds/aws4_request
&X-Amz-Date=20160201T001547Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=a04c831a0b54b5e4cd236a90dbcb9f5fab7185eb372b5bebe9a7a4e95798c8b7
```

The following code example creates a read replica in the us-east-1 Region from an encrypted DB cluster snapshot in the us-west-2 Region. The action is called in the us-east-1 Region.

```python
https://rds.us-east-1.amazonaws.com/
?Action=CreateDBCluster
&KmsKeyId=my-us-east-1-key
&StorageEncrypted=true
&PreSignedUrl=https%253A%252F%252Frds.us-west-2.amazonaws.com%252F%253FAction%253DCreateDBCluster%2526DestinationRegion%253Dus-east-1%2526ReplicationSourceIdentifier%253Darn%25253Aaws%25253Ards%25253Aus-west-2%25253A123456789012%25253Acluster%25253Asample-master-cluster%252526SignatureMethod%252526SignatureVersion%252526Version%252526X-Amz-Algorithm%252526X-Amz-Credential%252526X-Amz-Date%252526X-Amz-SignedHeaders%252526X-Amz-Signature
```

1011
For cross-Region replication between the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions, where the DB cluster identified by ReplicationSourceIdentifier is encrypted, also specify the PreSignedUrl parameter. The presigned URL must be a valid request for the CreateDBCluster API operation that can be performed in the source AWS Region that contains the encrypted DB cluster to be replicated. The KMS key identifier is used to encrypt the read replica, and must be a KMS key valid for the destination AWS Region. To automatically rather than manually generate a presigned URL, use the AWS CLI create-db-cluster command with the --source-region option instead.

2. Check that the DB cluster has become available to use by using the RDS API DescribeDBClusters operation, as shown in the following example.

https://rds.us-east-1.amazonaws.com/?Action=DescribeDBClusters
&DBClusterIdentifier=sample-replica-cluster
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Version=2014-10-31
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20161117/us-east-1/rds/aws4_request
&X-Amz-Date=20160201T002223Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=84c2e4f8fba7c577ac5d820711e34c645ffcd35be8a6b7c50f329a74f35f426

When DescribeDBClusters results show a status of available, create the primary instance for the DB cluster so that replication can begin. To do so, use the RDS API CreateDBInstance action as shown in the following example.

https://rds.us-east-1.amazonaws.com/?Action=CreateDBInstance
&DBClusterIdentifier=sample-replica-cluster
&DBInstanceClass=db.r3.large
&DBInstanceIdentifier=sample-replica-instance
&Engine=aurora
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Version=2014-10-31
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20161117/us-east-1/rds/aws4_request
&X-Amz-Date=20160201T003808Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=125fe575959f5bbcebd53f2365f907179757a08b5d7a16a378dfa59387f58cdb

When the DB instance is created and available, replication begins. You can determine if the DB instance is available by calling the AWS CLI DescribeDBInstances command.

**Viewing Amazon Aurora MySQL cross-Region replicas**

You can view the cross-Region replication relationships for your Amazon Aurora MySQL DB clusters by calling the describe-db-clusters AWS CLI command or the DescribeDBClusters RDS API operation. In the response, refer to the ReadReplicaIdentifiers field for the DB cluster identifiers of any cross-Region read replica DB clusters. Refer to the ReplicationSourceIdentifier element for the ARN of the source DB cluster that is the replication source.
Promoting a read replica to be a DB cluster

You can promote an Aurora MySQL read replica to a standalone DB cluster. When you promote an Aurora MySQL read replica, its DB instances are rebooted before they become available.

Typically, you promote an Aurora MySQL read replica to a standalone DB cluster as a data recovery scheme if the source DB cluster fails.

To do this, first create a read replica and then monitor the source DB cluster for failures. In the event of a failure, do the following:

1. Promote the read replica.
2. Direct database traffic to the promoted DB cluster.
3. Create a replacement read replica with the promoted DB cluster as its source.

When you promote a read replica, the read replica becomes a standalone Aurora DB cluster. The promotion process can take several minutes or longer to complete, depending on the size of the read replica. After you promote the read replica to a new DB cluster, it's just like any other DB cluster. For example, you can create read replicas from it and perform point-in-time restore operations. You can also create Aurora Replicas for the DB cluster.

Because the promoted DB cluster is no longer a read replica, you can't use it as a replication target.

The following steps show the general process for promoting a read replica to a DB cluster:

1. Stop any transactions from being written to the read replica source DB cluster, and then wait for all updates to be made to the read replica. Database updates occur on the read replica after they have occurred on the source DB cluster, and this replication lag can vary significantly. Use the ReplicaLag metric to determine when all updates have been made to the read replica. The ReplicaLag metric records the amount of time a read replica DB instance lags behind the source DB instance. When the ReplicaLag metric reaches 0, the read replica has caught up to the source DB instance.
2. Promote the read replica by using the Promote option on the Amazon RDS console, the AWS CLI command promote-read-replica-db-cluster, or the PromoteReadReplicaDBCluster Amazon RDS API operation.

You choose an Aurora MySQL DB instance to promote the read replica. After the read replica is promoted, the Aurora MySQL DB cluster is promoted to a standalone DB cluster. The DB instance with the highest failover priority is promoted to the primary DB instance for the DB cluster. The other DB instances become Aurora Replicas.

Note
The promotion process takes a few minutes to complete. When you promote a read replica, replication is stopped and the DB instances are rebooted. When the reboot is complete, the read replica is available as a new DB cluster.

Console

To promote an Aurora MySQL read replica to a DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. On the console, choose Instances.
   
   The Instance pane appears.
3. In the Instances pane, choose the read replica that you want to promote.
The read replicas appear as Aurora MySQL DB instances.

4. For Actions, choose Promote read replica.
5. On the acknowledgment page, choose Promote read replica.

**AWS CLI**

To promote a read replica to a DB cluster, use the AWS CLI `promote-read-replica-db-cluster` command.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds promote-read-replica-db-cluster \
  --db-cluster-identifier mydbcluster
```

For Windows:

```bash
aws rds promote-read-replica-db-cluster ^
  --db-cluster-identifier mydbcluster
```

**RDS API**

To promote a read replica to a DB cluster, call `PromoteReadReplicaDBCluster`.

**Troubleshooting Amazon Aurora MySQL cross Region replicas**

Following you can find a list of common error messages that you might encounter when creating an Amazon Aurora cross-Region read replica, and how to resolve the specified errors.

**Source cluster [DB cluster ARN] doesn't have binlogs enabled**

To resolve this issue, turn on binary logging on the source DB cluster. For more information, see  Before you begin (p. 1006).

**Source cluster [DB cluster ARN] doesn't have cluster parameter group in sync on writer**

You receive this error if you have updated the `binlog_format` DB cluster parameter, but have not rebooted the primary instance for the DB cluster. Reboot the primary instance (that is, the writer) for the DB cluster and try again.

**Source cluster [DB cluster ARN] already has a read replica in this region**

You can have up to five cross-Region DB clusters that are read replicas for each source DB cluster in any AWS Region. If you already have the maximum number of read replicas for a DB cluster in a particular AWS Region, you must delete an existing one before you can create a new cross-Region DB cluster in that Region.

**DB cluster [DB cluster ARN] requires a database engine upgrade for cross-Region replication support**

To resolve this issue, upgrade the database engine version for all of the instances in the source DB cluster to the most recent database engine version, and then try creating a cross-Region read replica DB again.
Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication)

Because Amazon Aurora MySQL is compatible with MySQL, you can set up replication between a MySQL database and an Amazon Aurora MySQL DB cluster. This type of replication uses the MySQL binary log replication, also referred to as binlog replication. If you use binary log replication with Aurora, we recommend that your MySQL database run MySQL version 5.5 or later. You can set up replication where your Aurora MySQL DB cluster is the replication source or the replica. You can replicate with an Amazon RDS MySQL DB instance, a MySQL database external to Amazon RDS, or another Aurora MySQL DB cluster.

Note
You can't use binlog replication to or from certain types of Aurora DB clusters. In particular, binlog replication isn't available for Aurora Serverless v1 clusters. If the SHOW MASTER STATUS and SHOW SLAVE STATUS (Aurora MySQL version 2) or SHOW REPLICA STATUS (Aurora MySQL version 3) statement returns no output, check that the cluster you're using supports binlog replication.

In Aurora MySQL version 3, binary log replication doesn't replicate to the mysql system database. Passwords and accounts aren't replicated by binlog replication in Aurora MySQL version 3. Therefore, Data Control Language (DCL) statements such as CREATE USER, GRANT, and REVOKE aren't replicated.

You can also replicate with an RDS for MySQL DB instance or Aurora MySQL DB cluster in another AWS Region. When you're performing replication across AWS Regions, make sure that your DB clusters and DB instances are publicly accessible. If the Aurora MySQL DB clusters are in private subnets in your VPC, use VPC peering between the AWS Regions. For more information, see A DB cluster in a VPC accessed by an EC2 instance in a different VPC (p. 2491).

If you want to configure replication between an Aurora MySQL DB cluster and an Aurora MySQL DB cluster in another AWS Region from the source DB cluster. For more information, see Replicating Amazon Aurora MySQL DB clusters across AWS Regions (p. 1005).

With Aurora MySQL version 2 and 3, you can replicate between Aurora MySQL and an external source or target that uses global transaction identifiers (GTIDs) for replication. Ensure that the GTID-related parameters in the Aurora MySQL DB cluster have settings that are compatible with the GTID status of the external database. To learn how to do this, see Using GTID-based replication for Amazon Aurora MySQL (p. 1043). In Aurora MySQL version 3.01 and higher, you can choose how to assign GTIDs to transactions that are replicated from a source that doesn't use GTIDs. For information about the stored procedure that controls that setting, see mysql.rds_assign_gtids_to_anonymous_transactions (Aurora MySQL version 3) (p. 1173).

Warning
When you replicate between Aurora MySQL and MySQL, make sure that you use only InnoDB tables. If you have MyISAM tables that you want to replicate, you can convert them to InnoDB before setting up replication with the following command.

```sql
alter table <schema>.<table_name> engine=innodb, algorithm=copy;
```

Setting up replication with MySQL or another Aurora DB cluster

Setting up MySQL replication with Aurora MySQL involves the following steps, which are discussed in detail:

1. Turn on binary logging on the replication source (p. 1016)
2. Retain binary logs on the replication source until no longer needed (p. 1019)

3. Create a snapshot or dump of your replication source (p. 1020)

4. Load the snapshot or dump into your replica target (p. 1022)

5. Create a replication user on your replication source (p. 1024)

6. Turn on replication on your replica target (p. 1024)

7. Monitor your replica (p. 1027)

1. Turn on binary logging on the replication source

Find instructions on how to turn on binary logging on the replication source for your database engine following.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL</td>
<td>To turn on binary logging on an Aurora MySQL DB cluster</td>
</tr>
<tr>
<td></td>
<td>Set the binlog_format DB cluster parameter to ROW, STATEMENT, or MIXED. MIXED is recommended unless you have a need for a specific binlog format. (The default value is OFF.)</td>
</tr>
<tr>
<td></td>
<td>To change the binlog_format parameter, create a custom DB cluster parameter group and associate that custom parameter group with your DB cluster. You can't change parameters in the default DB cluster parameter group.</td>
</tr>
<tr>
<td></td>
<td>If you're changing the binlog_format parameter from OFF to another value, reboot your Aurora DB cluster for the change to take effect.</td>
</tr>
<tr>
<td></td>
<td>For more information, see Amazon Aurora DB cluster and DB instance parameters (p. 215) and Working with parameter groups (p. 212).</td>
</tr>
<tr>
<td>RDS for MySQL</td>
<td>To turn on binary logging on an Amazon RDS DB instance</td>
</tr>
<tr>
<td></td>
<td>You can't turn on binary logging directly for an Amazon RDS DB instance, but you can turn it on by doing one of the following:</td>
</tr>
<tr>
<td></td>
<td>• Turn on automated backups for the DB instance. You can turn on automated backups when you create a DB instance, or you can turn on backups by modifying an existing DB instance. For more information, see Creating a DB instance in the Amazon RDS User Guide.</td>
</tr>
<tr>
<td></td>
<td>• Create a read replica for the DB instance. For more information, see Working with read replicas in the Amazon RDS User Guide.</td>
</tr>
<tr>
<td>MySQL (external)</td>
<td>To set up encrypted replication</td>
</tr>
<tr>
<td></td>
<td>To replicate data securely with Aurora MySQL version 2, you can use encrypted replication.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong></td>
</tr>
<tr>
<td></td>
<td>If you don't need to use encrypted replication, you can skip these steps.</td>
</tr>
<tr>
<td></td>
<td>The following are prerequisites for using encrypted replication:</td>
</tr>
<tr>
<td></td>
<td>• Secure Sockets Layer (SSL) must be enabled on the external MySQL source database.</td>
</tr>
<tr>
<td></td>
<td>• A client key and client certificate must be prepared for the Aurora MySQL DB cluster.</td>
</tr>
</tbody>
</table>
During encrypted replication, the Aurora MySQL DB cluster acts a client to the MySQL database server. The certificates and keys for the Aurora MySQL client are in files in .pem format.

1. Ensure that you are prepared for encrypted replication:
   
   - If you don't have SSL enabled on the external MySQL source database and don't have a client key and client certificate prepared, turn on SSL on the MySQL database server and generate the required client key and client certificate.
   
   - If SSL is enabled on the external source, supply a client key and certificate for the Aurora MySQL DB cluster. If you don't have these, generate a new key and certificate for the Aurora MySQL DB cluster. To sign the client certificate, you must have the certificate authority key that you used to configure SSL on the external MySQL source database.

   For more information, see [Creating SSL certificates and keys using openssl](https://dev.mysql.com/doc/refman/8.0/en/creating-ssl-certificates.html) in the MySQL documentation.

   You need the certificate authority certificate, the client key, and the client certificate.

2. Connect to the Aurora MySQL DB cluster as the master user using SSL.

   For information about connecting to an Aurora MySQL DB cluster with SSL, see [Using TLS with Aurora MySQL DB clusters](https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUserGuide/using-binary-log-tls.html).

3. Run the `mysql.rds_import_binlog_ssl_material` stored procedure to import the SSL information into the Aurora MySQL DB cluster.

   For the `ssl_material_value` parameter, insert the information from the .pem format files for the Aurora MySQL DB cluster in the correct JSON payload.

   The following example imports SSL information into an Aurora MySQL DB cluster.

   In .pem format files, the body code typically is longer than the body code shown in the example.

```sql
CALL mysql.rds_import_binlog_ssl_material(
    '{"ssl_ca":"-----BEGIN CERTIFICATE-----
    AAAAB3NzaC1yc2EAAAADAQABAAABAQClKsfkNkuSevGj3eYhCe53pcjqP3maAhDFcvBS706V

### Using binary log (binlog) replication

#### Instructions

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>lsLnB1ntntckiJ7FbtxJMXLvwwJryDUi1bMTjYtwB+QhYXUM0zce5Pjz5/i8SeJtjnV3iAoG/cQk+OFzZqaJAAhco+CY/SWhUBkzhmJfr6HCXkv3dWpkYQSxqcC0+FmuUzofz22ICBt5IMucxXPkX4zWi+z7wB3RbBQqzd9vye70zIPnw0yn80qFU8A246RAQFY1CNYwI3f0Sp6KLxEXAMPLE-----END RSA PRIVATE KEY-----</td>
</tr>
</tbody>
</table>

For more information, see [mysql.rds_import_binlog_ssl_material](p. 1176) and Using TLS with Aurora MySQL DB clusters (p. 814).

**Note**

After running the procedure, the secrets are stored in files. To erase the files later, you can run the [mysql.rds_remove_binlog_ssl_material](p. 1181) stored procedure.

**To turn on binary logging on an external MySQL database**

1. From a command shell, stop the mysql service.

   ```bash
   sudo service mysqld stop
   ```

2. Edit the my.cnf file (this file is usually under /etc).

   ```bash
   sudo vi /etc/my.cnf
   ```

   Add the `log_bin` and `server_id` options to the `[mysqld]` section. The `log_bin` option provides a file name identifier for binary log files. The `server_id` option provides a unique identifier for the server in source-replica relationships.

   If encrypted replication isn't required, ensure that the external MySQL database is started with binlogs enabled and SSL is turned off.

   The following are the relevant entries in the `/etc/my.cnf` file for unencrypted data.

   ```cnf
   log-bin=mysql-bin
   server-id=2133421
   innodb_flush_log_at_trx_commit=1
   sync_binlog=1
   ```

   If encrypted replication is required, ensure that the external MySQL database is started with SSL and binlogs enabled.

   The entries in the `/etc/my.cnf` file include the .pem file locations for the MySQL database server.

   ```cnf
   log-bin=mysql-bin
   server-id=2133421
   innodb_flush_log_at_trx_commit=1
   sync_binlog=1

   # Setup SSL.
   ssl-ca=/home/sslcerts/ca.pem
   ssl-cert=/home/sslcerts/server-cert.pem
   ssl-key=/home/sslcerts/server-key.pem
   ```
2. **Retain binary logs on the replication source until no longer needed**

When you use MySQL binary log replication, Amazon RDS doesn't manage the replication process. As a result, you need to ensure that the binlog files on your replication source are retained until after the changes have been applied to the replica. This maintenance helps you to restore your source database in the event of a failure.

Use the following instructions to retain binary logs for your database engine.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL</td>
<td><strong>To retain binary logs on an Aurora MySQL DB cluster</strong></td>
</tr>
<tr>
<td></td>
<td>You don't have access to the binlog files for an Aurora MySQL DB cluster. As a result, you must choose a time frame to retain the binlog files on your replication source long enough to ensure that the changes have been applied to your replica before the binlog file is deleted by Amazon RDS. You can retain binlog files on an Aurora MySQL DB cluster for up to 90 days.</td>
</tr>
<tr>
<td></td>
<td>If you're setting up replication with a MySQL database or RDS for MySQL DB instance as the replica, and the database that you are creating a replica for is very large, choose a large time frame to retain binlog files until the initial copy of the database to the replica is complete and the replica lag has reached 0.</td>
</tr>
</tbody>
</table>
### Database engine | Instructions
---|---
Amazon Aurora | To set the binary log retention time frame, use the `mysql.rds_set_configuration` procedure and specify a configuration parameter of 'binlog retention hours' along with the number of hours to retain binlog files on the DB cluster. The maximum value for Aurora MySQL version 2.11.0 and higher and version 3 is 2160 (90 days).

The following example sets the retention period for binlog files to 6 days:

```sql
CALL mysql.rds_set_configuration('binlog retention hours', 144);
```

After replication has been started, you can verify that changes have been applied to your replica by running the `SHOW SLAVE STATUS` (Aurora MySQL version 2) or `SHOW REPLICA STATUS` (Aurora MySQL version 3) command on your replica and checking the `Seconds behind master` field. If the `Seconds behind master` field is 0, then there is no replica lag. When there is no replica lag, reduce the length of time that binlog files are retained by setting the `binlog retention hours` configuration parameter to a smaller time frame.

If this setting isn't specified, the default for Aurora MySQL is 24 (1 day).

If you specify a value for 'binlog retention hours' that is higher than the maximum value, then Aurora MySQL uses the maximum.

Amazon RDS for MySQL | To retain binary logs on an Amazon RDS DB instance
---|---

You can retain binary log files on an Amazon RDS DB instance by setting the binlog retention hours just as with an Aurora MySQL DB cluster, described in the previous row.

You can also retain binlog files on an Amazon RDS DB instance by creating a read replica for the DB instance. This read replica is temporary and solely for the purpose of retaining binlog files. After the read replica has been created, call the `mysql.rds_stop_replication` procedure on the read replica. While replication is stopped, Amazon RDS doesn't delete any of the binlog files on the replication source. After you have set up replication with your permanent replica, you can delete the read replica when the replica lag (Seconds behind master field) between your replication source and your permanent replica reaches 0.

MySQL (external) | To retain binary logs on an external MySQL database
---|---

Because binlog files on an external MySQL database are not managed by Amazon RDS, they are retained until you delete them.

After replication has been started, you can verify that changes have been applied to your replica by running the `SHOW SLAVE STATUS` (Aurora MySQL version 2) or `SHOW REPLICA STATUS` (Aurora MySQL version 3) command on your replica and checking the `Seconds behind master` field. If the `Seconds behind master` field is 0, then there is no replica lag. When there is no replica lag, you can delete old binlog files.

### 3. Create a snapshot or dump of your replication source

You use a snapshot or dump of your replication source to load a baseline copy of your data onto your replica and then start replicating from that point on.

Use the following instructions to create a snapshot or dump of the replication source for your database engine.
<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL</td>
<td><strong>To create a snapshot of an Aurora MySQL DB cluster</strong></td>
</tr>
<tr>
<td></td>
<td>1. Create a DB cluster snapshot of your Amazon Aurora DB cluster. For more information, see [Creating a DB cluster snapshot](p. 437).</td>
</tr>
<tr>
<td></td>
<td>2. Create a new Aurora DB cluster by restoring from the DB cluster snapshot that you just created. Be sure to retain the same DB parameter group for your restored DB cluster as your original DB cluster. Doing this ensures that the copy of your DB cluster has binary logging enabled. For more information, see [Restoring from a DB cluster snapshot](p. 439).</td>
</tr>
<tr>
<td></td>
<td>3. In the console, choose <strong>Databases</strong> and choose the primary instance (writer) for your restored Aurora DB cluster to show its details. Scroll to <strong>Recent Events</strong>. An event message shows that includes the binlog file name and position. The event message is in the following format.</td>
</tr>
<tr>
<td></td>
<td><strong>Binlog position from crash recovery is</strong> <code>binlog-file-name binlog-position</code></td>
</tr>
<tr>
<td></td>
<td>Save the binlog file name and position values for when you start replication.</td>
</tr>
<tr>
<td></td>
<td>You can also get the binlog file name and position by calling the <strong>describe-events</strong> command from the AWS CLI. The following shows an example <strong>describe-events</strong> command with example output.</td>
</tr>
<tr>
<td></td>
<td><strong>PROMPT&gt; aws rds describe-events</strong></td>
</tr>
</tbody>
</table>
|                 | ```
<p>|                 | { |
|                 |   &quot;Events&quot;: [ |
|                 |     |
|                 |       |
|                 |         |
|                 |     |
|                 |     |
|                 |       |
|                 |         |
|                 |     |
|                 |     |
|                 |       |
|                 |         |
|                 |     |
|                 |     |
|                 |       |
|                 |         |
|                 |     |
|                 |     |
|                 |       |
|                 |         |
|                 |     |
|                 |     |
|                 |       |
|                 |         |
|                 |     |
|                 |     |
|                 |       |
|                 |         |
|                 |     |
|                 |     |
|                 |       |
|                 |         |
|                 |   ``` |
|                 | You can also get the binlog file name and position by checking the MySQL error log for the last MySQL binlog file position. |
|                 | 4. If your replica target is an Aurora DB cluster owned by another AWS account, an external MySQL database, or an RDS for MySQL DB instance, then you can't load the data from an Amazon Aurora DB cluster snapshot. Instead, create a dump of your Aurora DB cluster by connecting to your DB cluster using a MySQL client and issuing the <code>mysqldump</code> command. Be sure to run the <code>mysqldump</code> command against the copy of your Aurora DB cluster that you created. The following is an example. |
|                 | <strong>PROMPT&gt; mysqldump --databases &lt;database_name&gt; --single-transaction --order-by-primary -r backup.sql -u &lt;local_user&gt; -p</strong> |</p>
<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>RDS for MySQL</td>
<td>5. When you have finished creating the dump of your data from the newly created Aurora DB cluster, delete that DB cluster as it is no longer needed.</td>
</tr>
</tbody>
</table>

**To create a snapshot of an Amazon RDS DB instance**

Create a read replica of your Amazon RDS DB instance. For more information, see [Creating a read replica](#) in the *Amazon Relational Database Service User Guide*.

1. Connect to your read replica and stop replication by running the `mysql.rds_stop_replication` ([p. 1195](#)) procedure.
2. While the read replica is Stopped, Connect to the read replica and run the `SHOW SLAVE STATUS` (Aurora MySQL version 2) or `SHOW REPLICA STATUS` (Aurora MySQL version 3) command. Retrieve the current binary log file name from the `Relay_Master_Log_File` field and the log file position from the `Exec_Master_Log_Pos` field. Save these values for when you start replication.
3. While the read replica remains Stopped, create a DB snapshot of the read replica. For more information, see [Creating a DB snapshot](#) in the *Amazon Relational Database Service User Guide*.
4. Delete the read replica.

**To create a dump of an external MySQL database**

1. Before you create a dump, you need to ensure that the binlog location for the dump is current with the data in your source instance. To do this, you must first stop any write operations to the instance with the following command:

   ```mysql>
   FLUSH TABLES WITH READ LOCK;
   ```

2. Create a dump of your MySQL database using the `mysqldump` command as shown following:

   ```prompt>
   sudo mysqldump --databases <database_name> --master-data=2 --single-transaction --order-by-primary -r backup.sql -u <local_user> -p
   ```

3. After you have created the dump, unlock the tables in your MySQL database with the following command:

   ```mysql>
   UNLOCK TABLES;
   ```

4. **Load the snapshot or dump into your replica target**

   If you plan to load data from a dump of a MySQL database that is external to Amazon RDS, then you might want to create an EC2 instance to copy the dump files to, and then load the data into your DB cluster or DB instance from that EC2 instance. Using this approach, you can compress the dump file(s) before copying them to the EC2 instance in order to reduce the network costs associated with copying data to Amazon RDS. You can also encrypt the dump file or files to secure the data as it is being transferred across the network.

   Use the following instructions to load the snapshot or dump of your replication source into your replica target for your database engine.
**Database engine** | **Instructions**
--- | ---
Aurora MySQL | **To load a snapshot or dump into an Aurora MySQL DB cluster**
  - If the snapshot of your replication source is a DB cluster snapshot, then you can restore from the DB cluster snapshot to create a new Aurora MySQL DB cluster as your replica target. For more information, see [Restoring from a DB cluster snapshot](#).  
  - If the snapshot of your replication source is a DB snapshot, then you can migrate the data from your DB snapshot into a new Aurora MySQL DB cluster. For more information, see [Migrating data to an Amazon Aurora MySQL DB cluster](#).  
  - If the data from your replication source is the output from the `mysqldump` command, then follow these steps:
    1. Copy the output of the `mysqldump` command from your replication source to a location that can also connect to your Aurora MySQL DB cluster.  
    2. Connect to your Aurora MySQL DB cluster using the `mysql` command. The following is an example.
       ```
PROMPT> mysql -h <host_name> -port=3306 -u <db_master_user> -p
```
    3. At the `mysql` prompt, run the `source` command and pass it the name of your database dump file to load the data into the Aurora MySQL DB cluster, for example:
       ```
   mysql> source backup.sql;
   ```

RDS for MySQL | **To load a dump into an Amazon RDS DB instance**
  1. Copy the output of the `mysqldump` command from your replication source to a location that can also connect to your MySQL DB instance.  
  2. Connect to your MySQL DB instance using the `mysql` command. The following is an example.
       ```
PROMPT> mysql -h <host_name> -port=3306 -u <db_master_user> -p
```
  3. At the `mysql` prompt, run the `source` command and pass it the name of your database dump file to load the data into the MySQL DB instance, for example:
       ```
   mysql> source backup.sql;
   ```

MySQL (external) | **To load a dump into an external MySQL database**
You can't load a DB snapshot or a DB cluster snapshot into an external MySQL database. Instead, you must use the output from the `mysqldump` command.  
  1. Copy the output of the `mysqldump` command from your replication source to a location that can also connect to your MySQL database.  
  2. Connect to your MySQL database using the `mysql` command. The following is an example.
       ```
PROMPT> mysql -h <host_name> -port=3306 -u <db_master_user> -p
```
  3. At the `mysql` prompt, run the `source` command and pass it the name of your database dump file to load the data into your MySQL database. The following is an example.
5. Create a replication user on your replication source

Create a user ID on the source that is used solely for replication. The following is an example.

```sql
mysql> CREATE USER 'repl_user' '@<domain_name>' IDENTIFIED BY '<password>';  
```

The user requires the REPLICATION CLIENT and REPLICATION SLAVE privileges. Grant these
privileges to the user.

If you need to use encrypted replication, require SSL connections for the replication user. For example,
you can use one of the following statement to require SSL connections on the user account repl_user.

```sql
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user' '@<domain_name>';  
GRANT USAGE ON *.* TO 'repl_user' '@<domain_name>' REQUIRE SSL;  
```

Note
---
If REQUIRE SSL isn't included, the replication connection might silently fall back to an
unencrypted connection.

6. Turn on replication on your replica target

Before you turn on replication, we recommend that you take a manual snapshot of the Aurora MySQL
DB cluster or RDS for MySQL DB instance replica target. If a problem arises and you need to re-establish
replication with the DB cluster or DB instance replica target, you can restore the DB cluster or DB
instance from this snapshot instead of having to import the data into your replica target again.

Use the following instructions to turn on replication for your database engine.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL</td>
<td><strong>To turn on replication from an Aurora MySQL DB cluster</strong></td>
</tr>
<tr>
<td></td>
<td>1. Find the starting place for replication. You need the binlog file name and binlog position.</td>
</tr>
<tr>
<td></td>
<td>If your DB cluster replica target was created from the following:</td>
</tr>
<tr>
<td></td>
<td>• DB cluster snapshot – Retrieve the binlog file name and position from the recent events for your restored DB cluster, as shown in 3. Create a snapshot or dump of your replication source (p. 1020).</td>
</tr>
<tr>
<td></td>
<td>• DB snapshot – You retrieved the binlog file name and position from the SHOW SLAVE STATUS (Aurora MySQL version 2) or SHOW REPLICA STATUS (Aurora MySQL version 3) command when you created the snapshot of your replication source.</td>
</tr>
<tr>
<td></td>
<td>2. Connect to the DB cluster and call the following procedures to start replication with your replication source using the binary log file name and location from the previous step:</td>
</tr>
</tbody>
</table>
Using binary log (binlog) replication

### Database engine

<table>
<thead>
<tr>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>• <code>mysql.rds_set_external_source (Aurora MySQL version 3)</code> (p. 1186)</td>
</tr>
<tr>
<td>• <code>mysql.rds_set_external_master (Aurora MySQL version 2)</code> (p. 1182)</td>
</tr>
<tr>
<td>• <code>mysql.rds_start_replication (p. 1193)</code> (all versions)</td>
</tr>
</tbody>
</table>

The following example is for Aurora MySQL version 3.

```sql
CALL mysql.rds_set_external_source ('mydbinstance.123456789012.us-east-1.rds.amazonaws.com', 3306, 'repl_user', '<password>', 'mysql-bin-changelog.000031', 107, 0);
CALL mysql.rds_start_replication;
```

To use SSL encryption, set the final value to 1 instead of 0.

### RDS for MySQL

**To turn on replication from an Amazon RDS DB instance**

1. If your DB instance replica target was created from a DB snapshot, then you need the binlog file and binlog position that are the starting place for replication. You retrieved these values from the `SHOW SLAVE STATUS` (Aurora MySQL version 2) or `SHOW REPLICA STATUS` (Aurora MySQL version 3) command when you created the snapshot of your replication source.

2. Connect to the DB instance and call the `mysql.rds_set_external_master (Aurora MySQL version 2)` (p. 1182) or `mysql.rds_set_external_source (Aurora MySQL version 3)` (p. 1186) and `mysql.rds_start_replication (p. 1193)` procedures to start replication with your replication source. Use the binary log file name and location from the previous step. The following is an example.

```sql
CALL mysql.rds_set_external_master ('mydbcluster.cluster-123456789012.us-east-1.rds.amazonaws.com', 3306, 'repl_user', '<password>', 'mysql-bin-changelog.000031', 107, 0);
CALL mysql.rds_start_replication;
```

To use SSL encryption, set the final value to 1 instead of 0.
To turn on replication from an external MySQL database

1. Retrieve the binlog file and binlog position that are the starting place for replication. You retrieved these values from the `SHOW SLAVE STATUS` (Aurora MySQL version 2) or `SHOW REPLICA STATUS` (Aurora MySQL version 3) command when you created the snapshot of your replication source. If your external MySQL replica target was populated from the output of the `mysqldump` command with the `--master-data=2` option, then the binlog file and binlog position are included in the output. The following is an example.

```
-- Position to start replication or point-in-time recovery from
--
-- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031',
MASTER_LOG_POS=107;
```

2. Connect to the external MySQL replica target, and issue `CHANGE MASTER TO` and `START SLAVE` (Aurora MySQL version 2) or `START REPLICA` (Aurora MySQL version 3) to start replication with your replication source using the binary log file name and location from the previous step, for example:

```
CHANGE MASTER TO
    MASTER_HOST = 'mydbcluster.cluster-123456789012.us-east-1.rds.amazonaws.com',
    MASTER_PORT = 3306,
    MASTER_USER = 'repl_user',
    MASTER_PASSWORD = '<password>',
    MASTER_LOG_FILE = 'mysql-bin-changelog.000031',
    MASTER_LOG_POS = 107;
-- And one of these statements depending on your engine version:
START SLAVE; -- Aurora MySQL version 2
START REPLICA; -- Aurora MySQL version 3
```

If replication fails, it can result in a large increase in unintentional I/O on the replica, which can degrade performance. If replication fails or is no longer needed, you can run the `mysql.rds_reset_external_master` (Aurora MySQL version 2) (p. 1181) or `mysql.rds_reset_external_source` (Aurora MySQL version 3) (p. 1182) stored procedure to remove the replication configuration.

Setting a location to stop replication to a read replica

In Aurora MySQL version 3.04 and higher, you can start replication and then stop it at a specified binary log file location using the `mysql.rds_start_replication_until` (Aurora MySQL version 3) (p. 1193) stored procedure.

To start replication to a read replica and stop replication at a specific location

1. Using a MySQL client, connect to the source Aurora MySQL DB cluster as the master user.
2. Run the `mysql.rds_start_replication_until` (Aurora MySQL version 3) (p. 1193) stored procedure.

The following example initiates replication and replicates changes until it reaches location 120 in the `mysql-bin-changelog.000777` binary log file. In a disaster recovery scenario, assume that location 120 is just before the disaster.

```
call mysql.rds_start_replication_until(
```
Replication stops automatically when the stop point is reached. The following RDS event is generated:

```
Replication has been stopped since the replica reached the stop point specified by the rds_start_replication_until stored procedure.
```

If you use GTID-based replication, use the `mysql.rds_start_replication_until_gtid` (Aurora MySQL version 3) stored procedure instead of the `mysql.rds_start_replication_until` (Aurora MySQL version 3) stored procedure. For more information about GTID-based replication, see Using GTID-based replication for Amazon Aurora MySQL (p. 1043).

### 7. Monitor your replica

When you set up MySQL replication with an Aurora MySQL DB cluster, you must monitor failover events for the Aurora MySQL DB cluster when it is the replica target. If a failover occurs, then the DB cluster that is your replica target might be recreated on a new host with a different network address. For information on how to monitor failover events, see Working with Amazon RDS event notification (p. 690).

You can also monitor how far the replica target is behind the replication source by connecting to the replica target and running the `SHOW SLAVE STATUS` (Aurora MySQL version 2) or `SHOW REPLICA STATUS` (Aurora MySQL version 3) command. In the command output, the `Seconds Behind Master` field tells you how far the replica target is behind the source.

### Synchronizing passwords between replication source and target

When you change user accounts and passwords on the replication source using SQL statements, those changes are replicated to the replication target automatically.

If you use the AWS Management Console, the AWS CLI, or the RDS API to change the master password on the replication source, those changes are not automatically replicated to the replication target. If you want to synchronize the master user and master password between the source and target systems, you must make the same change on the replication target yourself.

### Stopping replication between Aurora and MySQL or between Aurora and another Aurora DB cluster

To stop binary log replication with a MySQL DB instance, external MySQL database, or another Aurora DB cluster, follow these steps, discussed in detail following in this topic.

1. **Stop binary log replication on the replica target** (p. 1027)
2. **Turn off binary logging on the replication source** (p. 1028)

#### 1. Stop binary log replication on the replica target

Use the following instructions to stop binary log replication for your database engine.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL</td>
<td>To stop binary log replication on an Aurora MySQL DB cluster replica target. Connect to the Aurora DB cluster that is the replica target, and call the <code>mysql.rds_stop_replication</code> procedure.</td>
</tr>
<tr>
<td>RDS for MySQL</td>
<td>To stop binary log replication on an Amazon RDS DB instance</td>
</tr>
</tbody>
</table>
### Database engine

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instructions</th>
</tr>
</thead>
</table>
| Aurora MySQL    | To turn off binary logging on an Amazon Aurora DB cluster  
1. Connect to the Aurora DB cluster that is the replication source.  
2. Use the `mysql.rds_set_configuration` procedure and specify the configuration parameter `binlog_retention_hours`, with the value `NULL`, as shown in the following example.  
```sql  
CALL mysql.rds_set_configuration('binlog_retention_hours', NULL);  
```
3. Set the `binlog_format` parameter to `OFF` on the replication source. The `binlog_format` parameter is in the custom DB cluster parameter group associated with your DB cluster.  
After you've changed the `binlog_format` parameter value, reboot your DB cluster for the change to take effect.  
For more information, see Amazon Aurora DB cluster and DB instance parameters (p. 215) and Modifying parameters in a DB parameter group (p. 229). |
| RDS for MySQL   | To turn off binary logging on an Amazon RDS DB instance  
You can't turn off binary logging directly for an Amazon RDS DB instance, but you can turn it off by doing the following:  
1. Turn off automated backups for the DB instance. You can turn off automated backups by modifying an existing DB instance and setting the `Backup Retention Period` to 0.  
For more information, see Modifying an Amazon RDS DB instance and Working with backups in the Amazon Relational Database Service User Guide.  
2. Delete all read replicas for the DB instance. For more information, see Working with read replicas of MariaDB, MySQL, and PostgreSQL DB instances in the Amazon Relational Database Service User Guide. |
| MySQL (external)| To turn off binary logging on an external MySQL database  
Connect to the MySQL database and call the `STOP REPLICA` command. |

### 2. Turn off binary logging on the replication source

Use the instructions in the following table to turn off binary logging on the replication source for your database engine.
<table>
<thead>
<tr>
<th><strong>Database engine</strong></th>
<th><strong>Instructions</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1. From a command shell, stop the <code>mysqld</code> service,</td>
</tr>
<tr>
<td></td>
<td><code>sudo service mysqld stop</code></td>
</tr>
<tr>
<td></td>
<td>2. Edit the <code>my.cnf</code> file (this file is usually under <code>/etc</code>).</td>
</tr>
<tr>
<td></td>
<td><code>sudo vi /etc/my.cnf</code></td>
</tr>
<tr>
<td></td>
<td>Delete the <code>log_bin</code> and <code>server_id</code> options from the <code>[mysqld]</code> section.</td>
</tr>
<tr>
<td></td>
<td>For more information, see <a href="https://dev.mysql.com/doc/refman/8.0/en/replication-configuration-source.html">Setting the replication source configuration</a> in the MySQL documentation.</td>
</tr>
<tr>
<td></td>
<td>3. Start the <code>mysql</code> service.</td>
</tr>
<tr>
<td></td>
<td><code>sudo service mysqld start</code></td>
</tr>
</tbody>
</table>

### Using Amazon Aurora to scale reads for your MySQL database

You can use Amazon Aurora with your MySQL DB instance to take advantage of the read scaling capabilities of Amazon Aurora and expand the read workload for your MySQL DB instance. To use Aurora to scale reads for your MySQL DB instance, create an Amazon Aurora MySQL DB cluster and make it a read replica of your MySQL DB instance. This applies to an RDS for MySQL DB instance, or a MySQL database running external to Amazon RDS.

For information on creating an Amazon Aurora DB cluster, see [Creating an Amazon Aurora DB cluster](https://docs.aws.amazon.com/AmazonAurora/latest/ alarmtutorial/aurora-create-cluster.html) (p. 179).

When you set up replication between your MySQL DB instance and your Amazon Aurora DB cluster, be sure to follow these guidelines:

- Use the Amazon Aurora DB cluster endpoint address when you reference your Amazon Aurora MySQL DB cluster. If a failover occurs, then the Aurora Replica that is promoted to the primary instance for the Aurora MySQL DB cluster continues to use the DB cluster endpoint address.

- Maintain the binlogs on your writer instance until you have verified that they have been applied to the Aurora Replica. This maintenance ensures that you can restore your writer instance in the event of a failure.

**Important**

When using self-managed replication, you're responsible for monitoring and resolving any replication issues that may occur. For more information, see [Diagnosing and resolving lag between read replicas](https://docs.aws.amazon.com/AmazonAurora/latest/ alarmtutorial/aurora-diagnose-lag.html) (p. 2516).

**Note**

The permissions required to start replication on an Aurora MySQL DB cluster are restricted and not available to your Amazon RDS master user. Therefore, you must use the `mysql.rds_set_external_master` (Aurora MySQL version 2) (p. 1182) or `mysql.rds_set_external_source` (Aurora MySQL version 3) (p. 1186) and `mysql.rds_start_replication` (p. 1193) procedures to set up replication between your Aurora MySQL DB cluster and your MySQL DB instance.
Start replication between an external source instance and an Aurora MySQL DB cluster

1. Make the source MySQL DB instance read-only:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

2. Run the `SHOW MASTER STATUS` command on the source MySQL DB instance to determine the binlog location. You receive output similar to the following example:

```
<table>
<thead>
<tr>
<th>File</th>
<th>Position</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql-bin-changelog.000031</td>
<td>107</td>
</tr>
</tbody>
</table>
```

3. Copy the database from the external MySQL DB instance to the Amazon Aurora MySQL DB cluster using `mysqldump`. For very large databases, you might want to use the procedure in [Importing data to a MySQL or MariaDB DB instance with reduced downtime](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/Import.MariaDB.AuroraMySQL.html) in the *Amazon Relational Database Service User Guide*.

For Linux, macOS, or Unix:

```
mysqldump \
--databases <database_name> \ 
--single-transaction \ 
--compress \ 
--order-by-primary \ 
-u <local_user> \ 
-p <local_password> | mysql \
  --host aurora_cluster_endpoint_address \
  --port 3306 \
  -u <RDS_user_name> \ 
  -p <RDS_password>
```

For Windows:

```
mypqldump ^ \
--databases <database_name> ^ \
--single-transaction ^ \
--compress ^ \
--order-by-primary ^ \
-u <local_user> ^ 
-p <local_password> | mysql ^ \
  --host aurora_cluster_endpoint_address ^ \
  --port 3306 ^ \
  -u <RDS_user_name> ^ 
  -p <RDS_password>
```

**Note**
Make sure that there is not a space between the `-p` option and the entered password.

Use the `--host`, `--user (-u)`, `--port` and `-p` options in the `mysql` command to specify the hostname, user name, port, and password to connect to your Aurora DB cluster. The host name is the DNS name from the Amazon Aurora DB cluster endpoint, for example, `mydbcluster.cluster-123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the cluster details in the Amazon RDS Management Console.

4. Make the source MySQL DB instance writeable again:
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;

For more information on making backups for use with replication, see **Backing up a source or replica by making it read only** in the MySQL documentation.

5. In the Amazon RDS Management Console, add the IP address of the server that hosts the source MySQL database to the VPC security group for the Amazon Aurora DB cluster. For more information on modifying a VPC security group, see **Security groups for your VPC** in the Amazon Virtual Private Cloud User Guide.

You might also need to configure your local network to permit connections from the IP address of your Amazon Aurora DB cluster, so that it can communicate with your source MySQL instance. To find the IP address of the Amazon Aurora DB cluster, use the `host` command.

```
host <aurora_endpoint_address>
```

The host name is the DNS name from the Amazon Aurora DB cluster endpoint.

6. Using the client of your choice, connect to the external MySQL instance and create a MySQL user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY '<password>';
```

7. For the external MySQL instance, grant **REPLICATION CLIENT** and **REPLICATION SLAVE** privileges to your replication user. For example, to grant the **REPLICATION CLIENT** and **REPLICATION SLAVE** privileges on all databases for the 'repl_user' user for your domain, issue the following command.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
    IDENTIFIED BY '<password>';
```

8. Take a manual snapshot of the Aurora MySQL DB cluster to be the read replica before setting up replication. If you need to reestablish replication with the DB cluster as a read replica, you can restore the Aurora MySQL DB cluster from this snapshot instead of having to import the data from your MySQL DB instance into a new Aurora MySQL DB cluster.

9. Make the Amazon Aurora DB cluster the replica. Connect to the Amazon Aurora DB cluster as the master user and identify the source MySQL database as the replication master by using the `mysql.rds_set_external_master` ([Aurora MySQL version 2](p. 1182)) or `mysql.rds_set_external_source` ([Aurora MySQL version 3](p. 1186)) and `mysql.rds_start_replication` ([p. 1193]) procedures.

Use the master log file name and master log position that you determined in Step 2. The following is an example.

```
For Aurora MySQL version 2:
CALL mysql.rds_set_external_master ('mymasterserver.mydomain.com', 3306,
    'repl_user', '<password>', 'mysql-bin-changelog.000031', 107, 0);

For Aurora MySQL version 3:
CALL mysql.rds_set_external_source ('mymasterserver.mydomain.com', 3306,
    'repl_user', '<password>', 'mysql-bin-changelog.000031', 107, 0);
```

10. On the Amazon Aurora DB cluster, call the `mysql.rds_start_replication` ([p. 1193]) procedure to start replication.

```
CALL mysql.rds_start_replication;
```
After you have established replication between your source MySQL DB instance and your Amazon Aurora DB cluster, you can add Aurora Replicas to your Amazon Aurora DB cluster. You can then connect to the Aurora Replicas to read scale your data. For information on creating an Aurora Replica, see Adding Aurora Replicas to a DB cluster (p. 293).

Optimizing binary log replication

Following, you can learn how to optimize binary log replication performance and troubleshoot related issues in Aurora MySQL.

Tip
This discussion presumes that you are familiar with the MySQL binary log replication mechanism and how it works. For background information, see Replication Implementation in the MySQL documentation.

Multithreaded binary log replication (Aurora MySQL version 3 and higher)

With multithreaded binary log replication, a SQL thread reads events from the relay log and queues them up for SQL worker threads to apply. The SQL worker threads are managed by a coordinator thread. The binary log events are applied in parallel when possible.

When an Aurora MySQL instance is configured to use binary log replication, by default the replica instance uses single-threaded replication. To enable multithreaded replication, you update the replica_parallel_workers parameter to a value greater than zero in your custom parameter group.

The following configuration options help you to fine-tune multithreaded replication. For usage information, see Replication and Binary Logging Options and Variables in the MySQL Reference Manual.

Optimal configuration depends on several factors. For example, performance for binary log replication is influenced by your database workload characteristics and the DB instance class the replica is running on. Thus, we recommend that you thoroughly test all changes to these configuration parameters before applying new parameter settings to a production instance.

• replica_parallel_workers
• replica_parallel_type
• replica_preserve_commit_order
• binlog_transaction_dependency_tracking
• binlog_transaction_dependency_history_size
• binlog_group_commit_sync_delay
• binlog_group_commit_sync_no_delay_count

Optimizing binlog replication (Aurora MySQL 2.10 and higher)

In Aurora MySQL 2.10 and higher, Aurora automatically applies an optimization known as the binlog I/O cache to binary log replication. By caching the most recently committed binlog events, this optimization is designed to improve binlog dump thread performance while limiting the impact to foreground transactions on the binlog source instance.

Note
This memory used for this feature is independent of the MySQL binlog_cache setting. This feature doesn't apply to Aurora DB instances that use the db.t2 and db.t3 instance classes.

You don't need to adjust any configuration parameters to turn on this optimization. In particular, if you adjust the configuration parameter aurora_binlog_replication_max_yield_seconds to a nonzero value in earlier Aurora MySQL versions, set it back to zero for Aurora MySQL 2.10 and higher.
The status variables `aurora_binlog_io_cache_reads` and `aurora_binlog_io_cache_read_requests` are available in Aurora MySQL 2.10 and higher. These status variables help you to monitor how often the data is read from the binlog I/O cache.

- `aurora_binlog_io_cache_read_requests` shows the number of binlog I/O read requests from the cache.
- `aurora_binlog_io_cache_reads` shows the number of binlog I/O reads that retrieve information from the cache.

The following SQL query computes the percentage of binlog read requests that take advantage of the cached information. In this case, the closer the ratio is to 100, the better it is.

```sql
mysql> SELECT
    (SELECT VARIABLE_VALUE FROM INFORMATION_SCHEMA.GLOBAL_STATUS
    WHERE VARIABLE_NAME='aurora_binlog_io_cache_reads')
  / (SELECT VARIABLE_VALUE FROM INFORMATION_SCHEMA.GLOBAL_STATUS
    WHERE VARIABLE_NAME='aurora_binlog_io_cache_read_requests')
* 100
  as binlog_io_cache_hit_ratio;
```

<table>
<thead>
<tr>
<th>binlog_io_cache_hit_ratio</th>
</tr>
</thead>
<tbody>
<tr>
<td>99.99847949080622</td>
</tr>
</tbody>
</table>

The binlog I/O cache feature also includes new metrics related to the binlog dump threads. *Dump threads* are the threads that are created when new binlog replicas are connected to the binlog source instance.

The dump thread metrics are printed to the database log every 60 seconds with the prefix `[Dump thread metrics]`. The metrics include information for each binlog replica such as `Secondary_id`, `Secondary_uuid`, binlog file name, and the position that each replica is reading. The metrics also include `Bytes_behind_primary` representing the distance in bytes between replication source and replica. This metric measures the lag of the replica I/O thread. That figure is different from the lag of the replica SQL applier thread, which is represented by the `seconds_behind_master` metric on the binlog replica. You can determine whether binlog replicas are catching up to the source or falling behind by checking whether the distance decreases or increases.

**Optimizing binlog replication (Aurora MySQL version 2 through 2.09)**

To optimize binary log replication for Aurora MySQL, you adjust the following cluster-level optimization parameters. These parameters help you to specify the right balance between latency on the binlog source instance and replication lag.

- `aurora_binlog_use_large_read_buffer`
- `aurora_binlog_read_buffer_size`
- `aurora_binlog_replication_max_yield_seconds`

**Note**

For MySQL 5.7-compatible clusters, you can use these parameters in Aurora MySQL version 2 through 2.09. In Aurora MySQL 2.10.0 and higher, these parameters are superseded by the binlog I/O cache optimization and you don't need to use them.

**Topics**

- [Overview of the large read buffer and max-yield optimizations](p. 1034)
- [Related parameters](p. 1035)
Overview of the large read buffer and max-yield optimizations

You might experience reduced binary log replication performance when the binary log dump thread accesses the Aurora cluster volume while the cluster processes a high number of transactions. You can use the parameters `aurora_binlog_use_large_read_buffer`, `aurora_binlog_replication_max_yield_seconds`, and `aurora_binlog_read_buffer_size` to help minimize this type of contention.

Suppose that you have a situation where `aurora_binlog_replication_max_yield_seconds` is set to greater than 0 and the current binlog file of the dump thread is active. In this case, the binary log dump thread waits up to a specified number of seconds for the current binlog file to be filled by transactions. This wait period avoids contention that can arise from replicating each binlog event individually. However, doing so increases the replica lag for binary log replicas. Those replicas can fall behind the source by the same number of seconds as the `aurora_binlog_replication_max_yield_seconds` setting.

The current binlog file means the binlog file that the dump thread is currently reading to perform replication. We consider that a binlog file is active when the binlog file is updating or open to be updated by incoming transactions. After Aurora MySQL fills up the active binlog file, MySQL creates and switches to a new binlog file. The old binlog file becomes inactive. It isn't updated by incoming transactions any longer.

**Note**

Before adjusting these parameters, measure your transaction latency and throughput over time. You might find that binary log replication performance is stable and has low latency even if there is occasional contention.

`aurora_binlog_use_large_read_buffer`

If this parameter is set to 1, Aurora MySQL optimizes binary log replication based on the settings of the parameters `aurora_binlog_read_buffer_size` and `aurora_binlog_replication_max_yield_seconds`. If `aurora_binlog_use_large_read_buffer` is 0, Aurora MySQL ignores the values of the `aurora_binlog_read_buffer_size` and `aurora_binlog_replication_max_yield_seconds` parameters.

`aurora_binlog_read_buffer_size`

Binary log dump threads with larger read buffer minimize the number of read I/O operations by reading more events for each I/O. The parameter `aurora_binlog_read_buffer_size` sets the read buffer size. The large read buffer can reduce binary log contention for workloads that generate a large amount of binlog data.

**Note**

This parameter only has an effect when the cluster also has the setting `aurora_binlog_use_large_read_buffer=1`. Increasing the size of the read buffer doesn't affect the performance of binary log replication. Binary log dump threads don't wait for updating transactions to fill up the read buffer.

`aurora_binlog_replication_max_yield_seconds`

If your workload requires low transaction latency, and you can tolerate some replication lag, you can increase the `aurora_binlog_replication_max_yield_seconds` parameter. This parameter controls the maximum yield property of binary log replication in your cluster.
Note
This parameter only has an effect when the cluster also has the setting `aurora_binlog_use_large_read_buffer=1`.

Aurora MySQL recognizes any change to the `aurora_binlog_replication_max_yield_seconds` parameter value immediately. You don't need to restart the DB instance. However, when you turn on this setting, the dump thread only starts to yield when the current binlog file reaches its maximum size of 128 MB and is rotated to a new file.

Related parameters

Use the following DB cluster parameters to turn on binlog optimization.

<table>
<thead>
<tr>

<td></td>
<td>For version 2, this parameter works only when the parameter <code>aurora_binlog_use_large_read_buffer</code> is set to 1.</td>
</tr>
</tbody>
</table>

Enabling the max-yield mechanism for binary log replication

You can turn on the binary log replication max-yield optimization as follows. Doing so minimizes latency for transactions on the binlog source instance. However, you might experience higher replication lag.
To turn on the max-yield binlog optimization for an Aurora MySQL cluster

1. Create or edit a DB cluster parameter group using the following parameter settings:
   - `aurora_binlog_use_large_read_buffer`: turn on with a value of ON or 1.
   - `aurora_binlog_replication_max_yield_seconds`: specify a value greater than 0.
2. Associate the DB cluster parameter group with the Aurora MySQL cluster that works as the binlog source. To do so, follow the procedures in Working with parameter groups (p. 212).
3. Confirm that the parameter change takes effect. To do so, run the following query on the binlog source instance.

   ```sql
   SELECT @@aurora_binlog_use_large_read_buffer,
           @@aurora_binlog_replication_max_yield_seconds;
   ```

   Your output should be similar to the following.

   ```sql
   +---------------------------------------|
   | @@aurora_binlog_use_large_read_buffer | @@aurora_binlog_replication_max_yield_seconds |
   +---------------------------------------|
   |                                     1 |                                            45 |
   +---------------------------------------|
   ```

Turning off the binary log replication max-yield optimization

You can turn off the binary log replication max-yield optimization as follows. Doing so minimizes replication lag. However, you might experience higher latency for transactions on the binlog source instance.

To turn off the max-yield optimization for an Aurora MySQL cluster

1. Make sure that the DB cluster parameter group associated with the Aurora MySQL cluster has `aurora_binlog_replication_max_yield_seconds` set to 0. For more information about setting configuration parameters using parameter groups, see Working with parameter groups (p. 212).
2. Confirm that the parameter change takes effect. To do so, run the following query on the binlog source instance.

   ```sql
   SELECT @@aurora_binlog_replication_max_yield_seconds;
   ```

   Your output should be similar to the following.

   ```sql
   +-----------------------------------------------|
   | @@aurora_binlog_replication_max_yield_seconds |
   +-----------------------------------------------|
   |                                             0 |
   +-----------------------------------------------|
   ```

Turning off the large read buffer

You can turn off the entire large read buffer feature as follows.
To turn off the large binary log read buffer for an Aurora MySQL cluster

1. Reset the `aurora_binlog_use_large_read_buffer` to OFF or 0.

   Make sure that the DB cluster parameter group associated with the Aurora MySQL cluster has `aurora_binlog_use_large_read_buffer` set to 0. For more information about setting configuration parameters using parameter groups, see Working with parameter groups (p. 212).

2. On the binlog source instance, run the following query.

   ```sql
   SELECT @@ aurora_binlog_use_large_read_buffer;
   ```

   Your output should be similar to the following.

   ```
   +---------------------------------------+
   | @@aurora_binlog_use_large_read_buffer | 0
   +---------------------------------------+
   ```

Setting up enhanced binlog

Enhanced binlog reduces the compute performance overhead caused by turning on binlog, which can reach up to 50% in certain cases. With enhanced binlog, this overhead can be reduced to about 13%. To reduce overhead, enhanced binlog writes the binary and transactions logs to storage in parallel, which minimizes the data written at the transaction commit time.

Using enhanced binlog also improves database recovery time after restarts and failovers by up to 99% compared to community MySQL binlog. The enhanced binlog is compatible with existing binlog-based workloads, and you interact with it the same way you interact with the community MySQL binlog.

Enhanced binlog is available on Aurora MySQL version 3.03.1 and higher.

Configuring enhanced binlog parameters

You can switch between community MySQL binlog and enhanced binlog by turning on/off the enhanced binlog parameters. The existing binlog consumers can continue to read and consume the binlog files without any gaps in the binlog file sequence.

To turn on enhanced binlog

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
</table>
## Using binary log (binlog) replication

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>you change the value of this parameter, you must reboot the writer instance when the DBClusterParameterGroupStatus value is shown as pending-reboot.</td>
</tr>
<tr>
<td>binlog_backup</td>
<td>1</td>
<td>Turn off this parameter to turn on enhanced binlog. To do so, set the value of this parameter to 0.</td>
</tr>
<tr>
<td>binlog_replication_globaldb</td>
<td></td>
<td>Turn off this parameter to turn on enhanced binlog. To do so, set the value of this parameter to 0.</td>
</tr>
</tbody>
</table>

**Important**
You can turn off the `binlog_backup` and `binlog_replication_globaldb` parameters only when you use enhanced binlog.

### To turn off the enhanced binlog

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aurora_enhanced_binlog</td>
<td>Set the value of this parameter to 0 in the DB cluster parameter group associated with the Aurora MySQL cluster. Whenever you change the value of this parameter, you must reboot the writer instance when the DBClusterParameterGroupStatus value is shown as pending-reboot.</td>
</tr>
<tr>
<td>binlog_backup</td>
<td>Turn on this parameter when you turn off enhanced binlog. To do so, set the value of this parameter to 1.</td>
</tr>
<tr>
<td>binlog_replication_globaldb</td>
<td>Turn on this parameter when you turn off enhanced binlog. To do so, set the value of this parameter to 1.</td>
</tr>
</tbody>
</table>

To check whether enhanced binlog is turned on, use the following command in the MySQL client:

```sql
mysql> show status like 'aurora_enhanced_binlog';
+------------------------+--------+
| Variable_name          | Value  |
+------------------------+--------+
| aurora_enhanced_binlog | ACTIVE |
+------------------------+--------+
1 row in set (0.00 sec)
```

When enhanced binlog is turned on, the output shows ACTIVE for `aurora_enhanced_binlog`.  

1038
Other related parameters

When you turn on the enhanced binlog, the following parameters are affected:

- The `max_binlog_size` parameter is visible but not modifiable. It's default value 134217728 is automatically adjusted to 268435456 when enhanced binlog is turned on.
- Unlike in community MySQL binlog, the `binlog_checksum` doesn't act as a dynamic parameter when the enhanced binlog is turned on. For the change to this parameter to take effect, you must manually reboot the DB cluster even when the ApplyMethod is immediate.
- The value you set on the `binlog_order_commits` parameter has no effect on the order of the commits when enhanced binlog is turned on. The commits are always ordered without any further performance implications.

Differences between enhanced binlog and community MySQL binlog

Enhanced binlog interacts differently with clones, backups, and Aurora global database when compared to community MySQL binlog. We recommend that you understand the following differences before using enhanced binlog.

- Enhanced binlog files from the source DB cluster aren't available on a cloned DB cluster.
- Enhanced binlog files aren't included in Aurora backups. Therefore, enhanced binlog files from the source DB cluster aren't available after restoring a DB cluster despite any retention period set on it.
- When used with an Aurora global database, the enhanced binlog files of the primary DB cluster aren't replicated to the DB cluster in the secondary regions.

Examples

The following examples illustrate the differences between enhanced binlog and community MySQL binlog.

On a restored or cloned DB cluster

When enhanced binlog is turned on, the historical binlog files aren't available in the restored or cloned DB cluster. After a restore or clone operation, if binlog is turned on, the new DB cluster starts writing its own sequence of binlog files, starting from 1 (mysql-bin-changelog.000001).

To turn on enhanced binlog after a restore or clone operation, set the required DB cluster parameters on the restored or cloned DB cluster. For more information, see Configuring enhanced binlog parameters (p. 1037).

Example Clone or restore operation performed when enhanced binlog is turned on

Source DB Cluster:

```
mysql> show binary logs;
```

```
+----------------------------+-----------+-----------+
| Log_name                   | File_size | Encrypted |
+----------------------------+-----------+-----------+
| mysql-bin-changelog.000001 | 156       | No        | --> Enhanced Binlog turned on
| mysql-bin-changelog.000002 | 156       | No        | --> Enhanced Binlog turned on
| mysql-bin-changelog.000003 | 156       | No        | --> Enhanced Binlog turned on
| mysql-bin-changelog.000004 | 156       | No        |
| mysql-bin-changelog.000005 | 156       | No        | --> Enhanced Binlog turned on
| mysql-bin-changelog.000006 | 156       | No        | --> Enhanced Binlog turned on
```
On a restored or cloned DB cluster, binlog files aren't backed up when enhanced binlog is turned on. To avoid discontinuity in the binlog data, the binlog files written before turning on the enhanced binlog are also not available.

```
show binary logs;
```

<table>
<thead>
<tr>
<th>Log_name</th>
<th>File_size</th>
<th>Encrypted</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql-bin-changelog.000001</td>
<td>156</td>
<td>No</td>
<td>New sequence of Binlog files</td>
</tr>
</tbody>
</table>

1 row in set (0.00 sec)

**Example Clone or restore operation performed when enhanced binlog is turned off**

Source DB cluster:

```
show binary logs;
```

<table>
<thead>
<tr>
<th>Log_name</th>
<th>File_size</th>
<th>Encrypted</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql-bin-changelog.000001</td>
<td>156</td>
<td>No</td>
<td></td>
</tr>
<tr>
<td>mysql-bin-changelog.000002</td>
<td>156</td>
<td>No</td>
<td>Enhanced Binlog enabled</td>
</tr>
<tr>
<td>mysql-bin-changelog.000003</td>
<td>156</td>
<td>No</td>
<td>Enhanced Binlog enabled</td>
</tr>
<tr>
<td>mysql-bin-changelog.000004</td>
<td>156</td>
<td>No</td>
<td></td>
</tr>
<tr>
<td>mysql-bin-changelog.000005</td>
<td>156</td>
<td>No</td>
<td></td>
</tr>
<tr>
<td>mysql-bin-changelog.000006</td>
<td>156</td>
<td>No</td>
<td></td>
</tr>
</tbody>
</table>

6 rows in set (0.00 sec)

On a restored or cloned DB cluster, binlog files written after turning off the enhanced binlog are available.

```
show binary logs;
```

<table>
<thead>
<tr>
<th>Log_name</th>
<th>File_size</th>
<th>Encrypted</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql-bin-changelog.000004</td>
<td>156</td>
<td>No</td>
<td></td>
</tr>
<tr>
<td>mysql-bin-changelog.000005</td>
<td>156</td>
<td>No</td>
<td></td>

<tr>
<td>mysql-bin-changelog.000006</td>
<td>156</td>
<td>No</td>
<td></td>
</tr>
</tbody>
</table>

1 row in set (0.00 sec)

**On an Amazon Aurora global database**

On an Amazon Aurora global database, the binlog data of the primary DB cluster isn't replicated to the secondary DB clusters. After a cross-Region failover process, the binlog data isn't available in the
newly promoted primary DB cluster. If binlog is turned on, the newly promoted DB cluster starts its own sequence of binlog files, starting from 1 (mysql-bin-changelog.000001).

To turn on enhanced binlog after failover, you must set the required DB cluster parameters on the secondary DB cluster. For more information, see Configuring enhanced binlog parameters (p. 1037).

**Example Global database failover operation is performed when enhanced binlog is turned on**

**Old primary DB Cluster (before failover):**

mysql> show binary logs;
+----------------------------+-----------+-----------+
| Log_name                   | File_size | Encrypted |
+----------------------------+-----------+-----------+
| mysql-bin-changelog.000001 |       156 | No        |
| mysql-bin-changelog.000002 |       156 | No        |
| mysql-bin-changelog.000003 |       156 | No        |
| mysql-bin-changelog.000004 |       156 | No        | --> Enhanced Binlog enabled
| mysql-bin-changelog.000005 |       156 | No        | --> Enhanced Binlog enabled
| mysql-bin-changelog.000006 |       156 | No        | --> Enhanced Binlog enabled
+----------------------------+-----------+-----------+
6 rows in set (0.00 sec)

**New primary DB cluster (after failover):**

Binlog files aren't replicated to secondary regions when enhanced binlog is turned on. To avoid discontinuity in the binlog data, the binlog files written before turning on the enhanced binlog aren't available.

mysql> show binary logs;
+----------------------------+-----------+-----------+
| Log_name                   | File_size | Encrypted |
+----------------------------+-----------+-----------+
| mysql-bin-changelog.000001 |       156 | No        | --> Fresh sequence of Binlog files
+----------------------------+-----------+-----------+
1 row in set (0.00 sec)

**Example Global database failover operation is performed when enhanced binlog is turned off**

**Source DB Cluster:**

mysql> show binary logs;
+----------------------------+-----------+-----------+
| Log_name                   | File_size | Encrypted |
+----------------------------+-----------+-----------+
| mysql-bin-changelog.000001 |       156 | No        | --> Enhanced Binlog enabled
| mysql-bin-changelog.000002 |       156 | No        | --> Enhanced Binlog enabled
| mysql-bin-changelog.000003 |       156 | No        | --> Enhanced Binlog enabled
| mysql-bin-changelog.000004 |       156 | No        |
| mysql-bin-changelog.000005 |       156 | No        |
| mysql-bin-changelog.000006 |       156 | No        |
+----------------------------+-----------+-----------+

Amazon CloudWatch metrics for enhanced binlog

The following Amazon CloudWatch metrics are published only when enhanced binlog is turned on.

<table>
<thead>
<tr>
<th>CloudWatch metric</th>
<th>Description</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>ChangeLogBytesUsed</td>
<td>The amount of storage used by the enhanced binlog.</td>
<td>Bytes</td>
</tr>
<tr>
<td>ChangeLogReadIOPs</td>
<td>The number of read I/O operations performed in the enhanced binlog within a 5-minute interval.</td>
<td>Count per 5 minutes</td>
</tr>
<tr>
<td>ChangeLogWriteIOPs</td>
<td>The number of write disk I/O operations performed in the enhanced binlog within a 5-minute interval.</td>
<td>Count per 5 minutes</td>
</tr>
</tbody>
</table>

Enhanced binlog limitations

The following limitations apply to Amazon Aurora DB clusters when enhanced binlog is turned on.

- Enhanced binlog is only supported on Aurora MySQL version 3.03.1 and higher.
- The enhanced binlog files written on the primary DB cluster aren't copied to the cloned or restored DB clusters.
- When used with Amazon Aurora global database, the enhanced binlog files of the primary DB cluster aren't replicated to the secondary DB clusters. Therefore, after the failover process, the historical binlog data isn't available in the new primary DB cluster.
- The following binlog configuration parameters are ignored:
  - `binlog_group_commit_sync_delay`
  - `binlog_group_commit_sync_no_delay_count`
  - `binlog_max_flush_queue_time`
- You can't drop or rename a corrupted table in a database. To drop these tables, you can contact AWS Support.
• The binlog I/O cache is disabled when enhanced binlog is turned on. For more information, see Optimizing binary log replication (p. 1032).

  **Note**
  Enhanced binlog provides similar read performance improvements as binlog I/O cache and better write performance improvements.

• The backtrack feature is not supported. Enhanced binlog can't be turned on in a DB cluster under the following conditions:
  • DB cluster with the backtrack feature currently enabled.
  • DB cluster with the backtrack feature previously enabled but not disabled.
  • DB cluster restored from a source DB cluster or a snapshot with the backtrack feature enabled.

**Using GTID-based replication for Amazon Aurora MySQL**

Following, you can learn how to use global transaction identifiers (GTIDs) with binary log (binlog) replication between an Aurora MySQL cluster and an external source.

  **Note**
  For Aurora, you can use this feature only with Aurora MySQL clusters that use binlog replication to or from an external MySQL database. The other database might be an Amazon RDS MySQL instance, an on-premises MySQL database, or an Aurora DB cluster in a different AWS Region. To learn how to configure that kind of replication, see Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication) (p. 1015).

If you use binlog replication and aren't familiar with GTID-based replication with MySQL, see Replication with global transaction identifiers in the MySQL documentation for background.

GTID-based replication is supported for Aurora MySQL version 2 and 3.

**Topics**

- Overview of global transaction identifiers (GTIDs) (p. 1043)
- Parameters for GTID-based replication (p. 1044)
- Configuring GTID-based replication for an Aurora MySQL cluster (p. 1045)
- Disabling GTID-based replication for an Aurora MySQL DB cluster (p. 1045)

**Overview of global transaction identifiers (GTIDs)**

*Global transaction identifiers (GTIDs)* are unique identifiers generated for committed MySQL transactions. You can use GTIDs to make binlog replication simpler and easier to troubleshoot.

  **Note**
  When Aurora synchronizes data among the DB instances in a cluster, that replication mechanism doesn't involve the binary log (binlog). For Aurora MySQL, GTID-based replication only applies when you also use binlog replication to replicate into or out of an Aurora MySQL DB cluster from an external MySQL-compatible database.

MySQL uses two different types of transactions for binlog replication:

• **GTID transactions** – Transactions that are identified by a GTID.
• **Anonymous transactions** – Transactions that don't have a GTID assigned.

In a replication configuration, GTIDs are unique across all DB instances. GTIDs simplify replication configuration because when you use them, you don't have to refer to log file positions. GTIDs also make
it easier to track replicated transactions and determine whether the source instance and replicas are consistent.

You typically use GTID-based replication with Aurora when replicating from an external MySQL-compatible database into an Aurora cluster. You can set up this replication configuration as part of a migration from an on-premises or Amazon RDS database into Aurora MySQL. If the external database already uses GTIDs, enabling GTID-based replication for the Aurora cluster simplifies the replication process.

You configure GTID-based replication for an Aurora MySQL cluster by first setting the relevant configuration parameters in a DB cluster parameter group. You then associate that parameter group with the cluster.

### Parameters for GTID-based replication

Use the following parameters to configure GTID-based replication.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gtid_mode</td>
<td>OFF, OFF_PERMISSIVE, ON_PERMISSIVE, ON</td>
<td>OFF specifies that new transactions are anonymous transactions (that is, don't have GTIDs), and a transaction must be anonymous to be replicated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>OFF_PERMISSIVE specifies that new transactions are anonymous transactions, but all transactions can be replicated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ON_PERMISSIVE specifies that new transactions are GTID transactions, but all transactions can be replicated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ON specifies that new transactions are GTID transactions, and a transaction must be a GTID transaction to be replicated.</td>
</tr>
<tr>
<td>enforce_gtid_consistency</td>
<td>OFF, ON, WARN</td>
<td>OFF allows transactions to violate GTID consistency.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ON prevents transactions from violating GTID consistency.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>WARN allows transactions to violate GTID consistency but generates a warning when a violation occurs.</td>
</tr>
</tbody>
</table>

**Note**

In the AWS Management Console, the `gtid_mode` parameter appears as `gtid-mode`.

For GTID-based replication, use these settings for the DB cluster parameter group for your Aurora MySQL DB cluster:

- **ON** and **ON_PERMISSIVE** apply only to outgoing replication from an Aurora MySQL cluster. Both of these values cause your Aurora DB cluster to use GTIDs for transactions that are replicated to an external database. **ON** requires that the external database also use GTID-based replication. **ON_PERMISSIVE** makes GTID-based replication optional on the external database.
- **OFF_PERMISSIVE**, if set, means that your Aurora DB cluster can accept incoming replication from an external database. It can do this whether the external database uses GTID-based replication or not.
• OFF, if set, means that your Aurora DB cluster only accepts incoming replication from external databases that don't use GTID-based replication.

**Tip**
Incoming replication is the most common binlog replication scenario for Aurora MySQL clusters. For incoming replication, we recommend that you set the GTID mode to OFF_PERMISSIVE. That setting allows incoming replication from external databases regardless of the GTID settings at the replication source.

For more information about parameter groups, see [Working with parameter groups](p. 212).

### Configuring GTID-based replication for an Aurora MySQL cluster

When GTID-based replication is enabled for an Aurora MySQL DB cluster, the GTID settings apply to both inbound and outbound binlog replication.

**To enable GTID-based replication for an Aurora MySQL cluster**

1. Create or edit a DB cluster parameter group using the following parameter settings:
   - `gtid_mode` – ON or ON_PERMISSIVE
   - `enforce_gtid_consistency` – ON
2. Associate the DB cluster parameter group with the Aurora MySQL cluster. To do so, follow the procedures in [Working with parameter groups](p. 212).
3. (Optional) Specify how to assign GTIDs to transactions that don't include them. To do so, call the stored procedure in `mysql.rds_assign_gtids_to_anonymous_transactions (Aurora MySQL version 3)` (p. 1173).

### Disabling GTID-based replication for an Aurora MySQL DB cluster

You can disable GTID-based replication for an Aurora MySQL DB cluster. Doing so means that the Aurora cluster can't perform inbound or outbound binlog replication with external databases that use GTID-based replication.

**Note**
In the following procedure, *read replica* means the replication target in an Aurora configuration with binlog replication to or from an external database. It doesn't mean the read-only Aurora Replica DB instances. For example, when an Aurora cluster accepts incoming replication from an external source, the Aurora primary instance acts as the read replica for binlog replication.

For more details about the stored procedures mentioned in this section, see [Aurora MySQL stored procedures](p. 1164).

**To disable GTID-based replication for an Aurora MySQL DB cluster**

1. On the Aurora primary instance, run the following procedure.

   ```sql
   CALL mysql.rds_set_master_auto_position(0); (Aurora MySQL version 2)
   CALL mysql.rds_set_source_auto_position(0); (Aurora MySQL version 3)
   ```

2. Reset the `gtid_mode` to ON_PERMISSIVE.
   a. Make sure that the DB cluster parameter group associated with the Aurora MySQL cluster has `gtid_mode` set to ON_PERMISSIVE.
For more information about setting configuration parameters using parameter groups, see Working with parameter groups (p. 212).

b. Restart the Aurora MySQL DB cluster.

3. Reset the gtid_mode to OFF_PERMISSIVE:
   a. Make sure that the DB cluster parameter group associated with the Aurora MySQL cluster has gtid_mode set to OFF_PERMISSIVE.
   b. Restart the Aurora MySQL DB cluster.
4. a. On the Aurora primary instance, run the SHOW MASTER STATUS command.

   Your output should be similar to the following.

<table>
<thead>
<tr>
<th>File</th>
<th>Position</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql-bin-changelog.000031</td>
<td>107</td>
</tr>
</tbody>
</table>

   Note the file and position in your output.
   b. On each read replica, use the file and position information from its source instance in the previous step to run the following query.

   ```sql
   SELECT MASTER_POS_WAIT('file', position);
   ```

   For example, if the file name is `mysql-bin-changelog.000031` and the position is 107, run the following statement.

   ```sql
   SELECT MASTER_POS_WAIT('mysql-bin-changelog.000031', 107);
   ```

   If the read replica is past the specified position, the query returns immediately. Otherwise, the function waits. When the query returns for all read replicas, go to the next step.

5. Reset the GTID parameters to disable GTID-based replication:
   a. Make sure that the DB cluster parameter group associated with the Aurora MySQL cluster has the following parameter settings:
      - gtid_mode – OFF
      - enforce_gtid_consistency – OFF
   b. Restart the Aurora MySQL DB cluster.
Integrating Amazon Aurora MySQL with other AWS services

Amazon Aurora MySQL integrates with other AWS services so that you can extend your Aurora MySQL DB cluster to use additional capabilities in the AWS Cloud. Your Aurora MySQL DB cluster can use AWS services to do the following:

- Synchronously or asynchronously invoke an AWS Lambda function using the native functions `lambda_sync` or `lambda_async`. For more information, see Invoking a Lambda function from an Amazon Aurora MySQL DB cluster (p. 1075).
- Load data from text or XML files stored in an Amazon Simple Storage Service (Amazon S3) bucket into your DB cluster using the LOAD DATA FROM S3 or LOAD XML FROM S3 command. For more information, see Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket (p. 1059).
- Save data to text files stored in an Amazon S3 bucket from your DB cluster using the `SELECT INTO OUTFILE S3` command. For more information, see Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket (p. 1068).
- Automatically add or remove Aurora Replicas with Application Auto Scaling. For more information, see Using Amazon Aurora Auto Scaling with Aurora Replicas (p. 328).
- Perform sentiment analysis with Amazon Comprehend, or a wide variety of machine learning algorithms with SageMaker. For more information, see Using machine learning capabilities with Amazon Aurora (p. 343).

Aurora secures the ability to access other AWS services by using AWS Identity and Access Management (IAM). You grant permission to access other AWS services by creating an IAM role with the necessary permissions, and then associating the role with your DB cluster. For details and instructions on how to permit your Aurora MySQL DB cluster to access other AWS services on your behalf, see Authorizing Amazon Aurora MySQL to access other AWS services on your behalf (p. 1047).

Authorizing Amazon Aurora MySQL to access other AWS services on your behalf

For your Aurora MySQL DB cluster to access other services on your behalf, create and configure an AWS Identity and Access Management (IAM) role. This role authorizes database users in your DB cluster to access other AWS services. For more information, see Setting up IAM roles to access AWS services (p. 1048).

You must also configure your Aurora DB cluster to allow outbound connections to the target AWS service. For more information, see Enabling network communication from Amazon Aurora MySQL to other AWS services (p. 1058).

If you do so, your database users can perform these actions using other AWS services:

- Synchronously or asynchronously invoke an AWS Lambda function using the native functions `lambda_sync` or `lambda_async`. Or, asynchronously invoke an AWS Lambda function using the `mysql.lambda_async` procedure. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 1076).
- Load data from text or XML files stored in an Amazon S3 bucket into your DB cluster by using the LOAD DATA FROM S3 or LOAD XML FROM S3 statement. For more information, see Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket (p. 1059).
• Save data from your DB cluster into text files stored in an Amazon S3 bucket by using the `SELECT INTO OUTFILE S3` statement. For more information, see Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket (p. 1068).

• Export log data to Amazon CloudWatch Logs MySQL. For more information, see Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs (p. 1083).

• Automatically add or remove Aurora Replicas with Application Auto Scaling. For more information, see Using Amazon Aurora Auto Scaling with Aurora Replicas (p. 328).

### Setting up IAM roles to access AWS services

To permit your Aurora DB cluster to access another AWS service, do the following:

1. Create an IAM policy that grants permission to the AWS service. For more information, see:
   - Creating an IAM policy to access Amazon S3 resources (p. 1048)
   - Creating an IAM policy to access AWS Lambda resources (p. 1050)
   - Creating an IAM policy to access CloudWatch Logs resources (p. 1051)
   - Creating an IAM policy to access AWS KMS resources (p. 1053)

2. Create an IAM role and attach the policy that you created. For more information, see Creating an IAM role to allow Amazon Aurora to access AWS services (p. 1053).

3. Associate that IAM role with your Aurora DB cluster. For more information, see Associating an IAM role with an Amazon Aurora MySQL DB cluster (p. 1054).

### Creating an IAM policy to access Amazon S3 resources

Aurora can access Amazon S3 resources to either load data to or save data from an Aurora DB cluster. However, you must first create an IAM policy that provides the bucket and object permissions that allow Aurora to access Amazon S3.

The following table lists the Aurora features that can access an Amazon S3 bucket on your behalf, and the minimum required bucket and object permissions required by each feature.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Bucket permissions</th>
<th>Object permissions</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOAD DATA FROM S3</td>
<td>ListBucket</td>
<td>GetObject</td>
</tr>
<tr>
<td></td>
<td></td>
<td>GetObjectVersion</td>
</tr>
<tr>
<td>LOAD XML FROM S3</td>
<td>ListBucket</td>
<td>GetObject</td>
</tr>
<tr>
<td></td>
<td></td>
<td>GetObjectVersion</td>
</tr>
<tr>
<td>SELECT INTO OUTFILE S3</td>
<td>ListBucket</td>
<td>AbortMultipartUpload</td>
</tr>
<tr>
<td></td>
<td></td>
<td>DeleteObject</td>
</tr>
<tr>
<td></td>
<td></td>
<td>GetObject</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ListMultipartUploadParts</td>
</tr>
<tr>
<td></td>
<td></td>
<td>PutObject</td>
</tr>
</tbody>
</table>

The following policy adds the permissions that might be required by Aurora to access an Amazon S3 bucket on your behalf.
Note
Make sure to include both entries for the Resource value. Aurora needs the permissions on both the bucket itself and all the objects inside the bucket.
Based on your use case, you might not need to add all of the permissions in the sample policy.
Also, other permissions might be required. For example, if your Amazon S3 bucket is encrypted, you need to add kms:Decrypt permissions.

You can use the following steps to create an IAM policy that provides the minimum required permissions for Aurora to access an Amazon S3 bucket on your behalf. To allow Aurora to access all of your Amazon S3 buckets, you can skip these steps and use either the AmazonS3ReadOnlyAccess or AmazonS3FullAccess predefined IAM policy instead of creating your own.

To create an IAM policy to grant access to your Amazon S3 resources
1. Open the IAM Management Console.
2. In the navigation pane, choose Policies.
3. Choose Create policy.
4. On the Visual editor tab, choose Choose a service, and then choose S3.
5. For Actions, choose Expand all, and then choose the bucket permissions and object permissions needed for the IAM policy.

Object permissions are permissions for object operations in Amazon S3, and need to be granted for objects in a bucket, not the bucket itself. For more information about permissions for object operations in Amazon S3, see Permissions for object operations.
6. Choose Resources, and choose Add ARN for bucket.
7. In the Add ARN(s) dialog box, provide the details about your resource, and choose Add.

Specify the Amazon S3 bucket to allow access to. For instance, if you want to allow Aurora to access the Amazon S3 bucket named example-bucket, then set the Amazon Resource Name (ARN) value to arn:aws:s3:::example-bucket.
8. If the object resource is listed, choose Add ARN for object.
9. In the Add ARN(s) dialog box, provide the details about your resource.

For the Amazon S3 bucket, specify the Amazon S3 bucket to allow access to. For the object, you can choose Any to grant permissions to any object in the bucket.
Note
You can set Amazon Resource Name (ARN) to a more specific ARN value in order to allow Aurora to access only specific files or folders in an Amazon S3 bucket. For more information about how to define an access policy for Amazon S3, see Managing access permissions to your Amazon S3 resources.

10. (Optional) Choose Add ARN for bucket to add another Amazon S3 bucket to the policy, and repeat the previous steps for the bucket.

Note
You can repeat this to add corresponding bucket permission statements to your policy for each Amazon S3 bucket that you want Aurora to access. Optionally, you can also grant access to all buckets and objects in Amazon S3.

12. For Name, enter a name for your IAM policy, for example AllowAuroraToExampleBucket. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional Description value.

13. Choose Create policy.

14. Complete the steps in Creating an IAM role to allow Amazon Aurora to access AWS services (p. 1053).

Creating an IAM policy to access AWS Lambda resources

You can create an IAM policy that provides the minimum required permissions for Aurora to invoke an AWS Lambda function on your behalf.

The following policy adds the permissions required by Aurora to invoke an AWS Lambda function on your behalf.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAuroraToExampleFunction",
      "Effect": "Allow",
      "Action": "lambda:InvokeFunction",
      "Resource": "arn:aws:lambda:<region>:<123456789012>:function:<example_function>"
    }
  ]
}
```

You can use the following steps to create an IAM policy that provides the minimum required permissions for Aurora to invoke an AWS Lambda function on your behalf. To allow Aurora to invoke all of your AWS Lambda functions, you can skip these steps and use the predefined AWSLambdaRole policy instead of creating your own.

To create an IAM policy to grant invoke to your AWS Lambda functions

1. Open the IAM console.
2. In the navigation pane, choose Policies.
3. Choose Create policy.
4. On the Visual editor tab, choose Choose a service, and then choose Lambda.
5. For Actions, choose Expand all, and then choose the AWS Lambda permissions needed for the IAM policy.
Ensure that InvokeFunction is selected. It is the minimum required permission to enable Amazon Aurora to invoke an AWS Lambda function.

6. Choose Resources and choose Add ARN for function.

7. In the Add ARN(s) dialog box, provide the details about your resource.

Specify the Lambda function to allow access to. For instance, if you want to allow Aurora to access a Lambda function named example_function, then set the ARN value to arn:aws:lambda:::function:example_function.

For more information on how to define an access policy for AWS Lambda, see Authentication and access control for AWS Lambda.

8. Optionally, choose Add additional permissions to add another AWS Lambda function to the policy, and repeat the previous steps for the function.

Note
You can repeat this to add corresponding function permission statements to your policy for each AWS Lambda function that you want Aurora to access.

10. Set Name to a name for your IAM policy, for example AllowAuroraToExampleFunction. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional Description value.

11. Choose Create policy.

12. Complete the steps in Creating an IAM role to allow Amazon Aurora to access AWS services (p. 1053).

Creating an IAM policy to access CloudWatch Logs resources

Aurora can access CloudWatch Logs to export audit log data from an Aurora DB cluster. However, you must first create an IAM policy that provides the log group and log stream permissions that allow Aurora to access CloudWatch Logs.

The following policy adds the permissions required by Aurora to access Amazon CloudWatch Logs on your behalf, and the minimum required permissions to create log groups and export data.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "EnableCreationAndManagementOfRDSCloudwatchLogEvents",
         "Effect": "Allow",
         "Action": [
            "logs:GetLogEvents",
            "logs:PutLogEvents"
         ],
         "Resource": "arn:aws:logs:*:*:log-group:/aws/rds/*:log-stream:*"
      },
      {
         "Sid": "EnableCreationAndManagementOfRDSCloudwatchLogGroupsAndStreams",
         "Effect": "Allow",
         "Action": [
            "logs:CreateLogStream",
            "logs:DescribeLogStreams",
            "logs:PutRetentionPolicy",
            "logs:CreateLogGroup"
         ],
         "Resource": "arn:aws:logs:*:*:log-group:/aws/rds/*"
      }
   ]
}
```
You can modify the ARNs in the policy to restrict access to a specific AWS Region and account.

You can use the following steps to create an IAM policy that provides the minimum required permissions for Aurora to access CloudWatch Logs on your behalf. To allow Aurora full access to CloudWatch Logs, you can skip these steps and use the CloudWatchLogsFullAccess predefined IAM policy instead of creating your own. For more information, see Using identity-based policies (IAM policies) for CloudWatch Logs in the Amazon CloudWatch User Guide.

To create an IAM policy to grant access to your CloudWatch Logs resources

1. Open the IAM console.
2. In the navigation pane, choose Policies.
3. Choose Create policy.
4. On the Visual editor tab, choose Choose a service, and then choose CloudWatch Logs.
5. For Actions, choose Expand all (on the right), and then choose the Amazon CloudWatch Logs permissions needed for the IAM policy.

   Ensure that the following permissions are selected:
   
   • CreateLogGroup
   • CreateLogStream
   • DescribeLogStreams
   • GetLogEvents
   • PutLogEvents
   • PutRetentionPolicy
6. Choose Resources and choose Add ARN for log-group.
7. In the Add ARN(s) dialog box, enter the following values:
   
   • Region – An AWS Region or *
   • Account – An account number or *
   • Log Group Name – /aws/rds/*
8. In the Add ARN(s) dialog box, choose Add.
10. In the Add ARN(s) dialog box, enter the following values:
    
    • Region – An AWS Region or *
    • Account – An account number or *
    • Log Group Name – /aws/rds/*
    • Log Stream Name – *
11. In the Add ARN(s) dialog box, choose Add.
13. Set Name to a name for your IAM policy, for example AmazonRDSCloudWatchLogs. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional Description value.
14. Choose Create policy.
15. Complete the steps in Creating an IAM role to allow Amazon Aurora to access AWS services (p. 1053).
Creating an IAM policy to access AWS KMS resources

Aurora can access the AWS KMS keys used for encrypting their database backups. However, you must first create an IAM policy that provides the permissions that allow Aurora to access KMS keys.

The following policy adds the permissions required by Aurora to access KMS keys on your behalf.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "kms:Decrypt"
            ],
            "Resource": "arn:aws:kms:<region>:<123456789012>:key/<key-ID>"
        }
    ]
}
```

You can use the following steps to create an IAM policy that provides the minimum required permissions for Aurora to access KMS keys on your behalf.

**To create an IAM policy to grant access to your KMS keys**

1. Open the IAM console.
2. In the navigation pane, choose Policies.
3. Choose Create policy.
4. On the Visual editor tab, choose Choose a service, and then choose KMS.
5. For Actions, choose Write, and then choose Decrypt.
6. Choose Resources, and choose Add ARN.
7. In the Add ARN(s) dialog box, enter the following values:
   - Region – Type the AWS Region, such as us-west-2.
   - Account – Type the user account number.
   - Log Stream Name – Type the KMS key identifier.
8. In the Add ARN(s) dialog box, choose Add.
10. Set Name to a name for your IAM policy, for example AmazonRDSKMSKey. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional Description value.
11. Choose Create policy.
12. Complete the steps in Creating an IAM role to allow Amazon Aurora to access AWS services (p. 1053).

Creating an IAM role to allow Amazon Aurora to access AWS services

After creating an IAM policy to allow Aurora to access AWS resources, you must create an IAM role and attach the IAM policy to the new IAM role.

To create an IAM role to permit your Amazon RDS cluster to communicate with other AWS services on your behalf, take the following steps.

**To create an IAM role to allow Amazon RDS to access AWS services**

1. Open the IAM console.
2. In the navigation pane, choose Roles.
3. Choose Create role.
4. Under AWS service, choose RDS.
5. Under Select your use case, choose RDS – Add Role to Database.
6. Choose Next.
7. On the Permissions policies page, enter the name of your policy in the Search field.
8. When it appears in the list, select the policy that you defined earlier using the instructions in one of the following sections:
   • Creating an IAM policy to access Amazon S3 resources (p. 1048)
   • Creating an IAM policy to access AWS Lambda resources (p. 1050)
   • Creating an IAM policy to access CloudWatch Logs resources (p. 1051)
   • Creating an IAM policy to access AWS KMS resources (p. 1053)
9. Choose Next.
10. In Role name, enter a name for your IAM role, for example RDSLoadFromS3. You can also add an optional Description value.
11. Choose Create Role.
12. Complete the steps in Associating an IAM role with an Amazon Aurora MySQL DB cluster (p. 1054).

**Associating an IAM role with an Amazon Aurora MySQL DB cluster**

To permit database users in an Amazon Aurora DB cluster to access other AWS services, you associate the IAM role that you created in Creating an IAM role to allow Amazon Aurora to access AWS services (p. 1053) with that DB cluster. You can also have AWS create a new IAM role by associating the service directly.

**Note**
You can't associate an IAM role with an Aurora Serverless v1 DB cluster. For more information, see Using Amazon Aurora Serverless v1 (p. 2023). You can associate an IAM role with an Aurora Serverless v2 DB cluster.

To associate an IAM role with a DB cluster you do two things:

1. Add the role to the list of associated roles for a DB cluster by using the RDS console, the add-role-to-db-cluster AWS CLI command, or the AddRoleToDBCluster RDS API operation.
   
   You can add a maximum of five IAM roles for each Aurora DB cluster.

2. Set the cluster-level parameter for the related AWS service to the ARN for the associated IAM role.

The following table describes the cluster-level parameter names for the IAM roles used to access other AWS services.

<table>
<thead>
<tr>
<th>Cluster-level parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aws_default_lambda_role</td>
<td>Used when invoking a Lambda function from your DB cluster.</td>
</tr>
<tr>
<td>aws_default_logs_role</td>
<td>This parameter is no longer required for exporting log data from your DB cluster to Amazon CloudWatch Logs. Aurora MySQL now uses a service-linked role for the required permissions. For more information about</td>
</tr>
</tbody>
</table>
Authorizing Aurora MySQL to access AWS services

<table>
<thead>
<tr>
<th>Cluster-level parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>service-linked roles, see Using service-linked roles for Amazon Aurora (p. 2475).</td>
</tr>
<tr>
<td>aws_default_s3_role</td>
<td>Used when invoking the LOAD DATA FROM S3, LOAD XML FROM S3, or SELECT INTO OUTFILE S3 statement from your DB cluster. In Aurora MySQL version 2, the IAM role specified in this parameter is used if an IAM role isn't specified for aurora_load_from_s3_role or aurora_select_into_s3_role for the appropriate statement. In Aurora MySQL version 3, the IAM role specified for this parameter is always used.</td>
</tr>
<tr>
<td>aurora_load_from_s3_role</td>
<td>Used when invoking the LOAD DATA FROM S3 or LOAD XML FROM S3 statement from your DB cluster. If an IAM role is not specified for this parameter, the IAM role specified in aws_default_s3_role is used. In Aurora MySQL version 3, this parameter isn't available.</td>
</tr>
<tr>
<td>aurora_select_into_s3_role</td>
<td>Used when invoking the SELECT INTO OUTFILE S3 statement from your DB cluster. If an IAM role is not specified for this parameter, the IAM role specified in aws_default_s3_role is used. In Aurora MySQL version 3, this parameter isn't available.</td>
</tr>
</tbody>
</table>

To associate an IAM role to permit your Amazon RDS cluster to communicate with other AWS services on your behalf, take the following steps.

**Console**

**To associate an IAM role with an Aurora DB cluster using the console**

2. Choose Databases.
3. Choose the name of the Aurora DB cluster that you want to associate an IAM role with to show its details.
4. On the Connectivity & security tab, in the Manage IAM roles section, do one of the following:
   - Select IAM roles to add to this cluster (default)
   - Select a service to connect to this cluster
To use an existing IAM role, choose it from the menu, then choose Add role.

If adding the role is successful, its status shows as Pending, then Available.

To connect a service directly:

a. Choose Select a service to connect to this cluster.

b. Choose the service from the menu, then choose Connect service.

c. For Connect cluster to Service Name, enter the Amazon Resource Name (ARN) to use to connect to the service, then choose Connect service.

AWS creates a new IAM role for connecting to the service. Its status shows as Pending, then Available.

(Optional) To stop associating an IAM role with a DB cluster and remove the related permission, choose the role and then choose Delete.

To set the cluster-level parameter for the associated IAM role

1. In the RDS console, choose Parameter groups in the navigation pane.

2. If you are already using a custom DB parameter group, you can select that group to use instead of creating a new DB cluster parameter group. If you are using the default DB cluster parameter group, create a new DB cluster parameter group, as described in the following steps:

a. Choose Create parameter group.

b. For Parameter group family, choose aurora-mysql8.0 for an Aurora MySQL 8.0-compatible DB cluster, or aurora-mysql5.7 for an Aurora MySQL 5.7-compatible DB cluster.

c. For Type, choose DB Cluster Parameter Group.

d. For Group name, type the name of your new DB cluster parameter group.

e. For Description, type a description for your new DB cluster parameter group.
f. Choose Create.

3. On the Parameter groups page, select your DB cluster parameter group and choose Edit for Parameter group actions.

4. Set the appropriate cluster-level parameters (p. 1054) to the related IAM role ARN values.

   For example, you can set just the aws_default_s3_role parameter to arn:aws:iam::123456789012:role/AllowS3Access.

5. Choose Save changes.

6. To change the DB cluster parameter group for your DB cluster, complete the following steps:
   a. Choose Databases, and then choose your Aurora DB cluster.
   b. Choose Modify.
   c. Scroll to Database options and set DB cluster parameter group to the DB cluster parameter group.
   d. Choose Continue.
   e. Verify your changes and then choose Apply immediately.
   f. Choose Modify cluster.
   g. Choose Databases, and then choose the primary instance for your DB cluster.
   h. For Actions, choose Reboot.

   When the instance has rebooted, your IAM role is associated with your DB cluster.

   For more information about cluster parameter groups, see Aurora MySQL configuration parameters (p. 1115).

CLI

To associate an IAM role with a DB cluster by using the AWS CLI

1. Call the add-role-to-db-cluster command from the AWS CLI to add the ARNs for your IAM roles to the DB cluster, as shown following.

   PROMPT> aws rds add-role-to-db-cluster --db-cluster-identifier my-cluster --role-arn arn:aws:iam::123456789012:role/AllowAuroraS3Role
2. If you are using the default DB cluster parameter group, create a new DB cluster parameter group. If you are already using a custom DB parameter group, you can use that group instead of creating a new DB cluster parameter group.

To create a new DB cluster parameter group, call the create-db-cluster-parameter-group command from the AWS CLI, as shown following.

```bash
aws rds create-db-cluster-parameter-group --db-cluster-parameter-group-name AllowAWSAccess --db-parameter-group-family aurora5.7 --description "Allow access to Amazon S3 and AWS Lambda"
```

For an Aurora MySQL 5.7-compatible DB cluster, specify `aurora-mysql5.7` for `--db-parameter-group-family`. For an Aurora MySQL 8.0-compatible DB cluster, specify `aurora-mysql8.0` for `--db-parameter-group-family`.

3. Set the appropriate cluster-level parameter or parameters and the related IAM role ARN values in your DB cluster parameter group, as shown following.

```bash
aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name AllowAWSAccess --parameters "ParameterName=aws_default_s3_role,ParameterValue=arn:aws:iam::123456789012:role/AllowAuroraS3Role,method=pending-reboot" --parameters "ParameterName=aws_default_lambda_role,ParameterValue=arn:aws:iam::123456789012:role/AllowAuroraLambdaRole,method=pending-reboot"
```

4. Modify the DB cluster to use the new DB cluster parameter group and then reboot the cluster, as shown following.

```bash
aws rds modify-db-cluster --db-cluster-identifier my-cluster --db-cluster-parameter-group-name AllowAWSAccess
aws rds reboot-db-instance --db-instance-identifier my-cluster-primary
```

When the instance has rebooted, your IAM roles are associated with your DB cluster.

For more information about cluster parameter groups, see Aurora MySQL configuration parameters (p. 1115).

### Enabling network communication from Amazon Aurora MySQL to other AWS services

To use certain other AWS services with Amazon Aurora, the network configuration of your Aurora DB cluster must allow outbound connections to endpoints for those services. The following operations require this network configuration.

- **Invoking AWS Lambda functions.** To learn about this feature, see Invoking a Lambda function with an Aurora MySQL native function (p. 1076).
- **Accessing files from Amazon S3.** To learn about this feature, see Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket (p. 1059) and Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket (p. 1068).
Loading data from text files in Amazon S3

- Accessing AWS KMS endpoints. AWS KMS access is required to use database activity streams with Aurora MySQL. To learn about this feature, see Monitoring Amazon Aurora with Database Activity Streams (p. 746).
- Accessing SageMaker endpoints. SageMaker access is required to use SageMaker machine learning with Aurora MySQL. To learn about this feature, see Using Amazon Aurora machine learning with Aurora MySQL (p. 1086).

Aurora returns the following error messages if it can't connect to a service endpoint.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR 1871</td>
<td>S3 API returned error: Network Connection</td>
</tr>
<tr>
<td>ERROR 1873</td>
<td>Lambda API returned error: Network Connection. Unable to connect to endpoint</td>
</tr>
<tr>
<td>ERROR 1815</td>
<td>Internal error: Unable to initialize S3Stream</td>
</tr>
</tbody>
</table>

For database activity streams using Aurora MySQL, the activity stream stops functioning if the DB cluster can't access the AWS KMS endpoint. Aurora notifies you about this issue using RDS Events.

If you encounter these messages while using the corresponding AWS services, check if your Aurora DB cluster is public or private. If your Aurora DB cluster is private, you must configure it to enable connections.

For an Aurora DB cluster to be public, it must be marked as publicly accessible. If you look at the details for the DB cluster in the AWS Management Console, Publicly Accessible is Yes if this is the case. The DB cluster must also be in an Amazon VPC public subnet. For more information about publicly accessible DB instances, see Working with a DB cluster in a VPC (p. 2478). For more information about public Amazon VPC subnets, see Your VPC and subnets.

If your Aurora DB cluster isn't publicly accessible and in a VPC public subnet, it is private. You might have a DB cluster that is private and want to use one of the features that requires this network configuration. If so, configure the cluster so that it can connect to Internet addresses through Network Address Translation (NAT). As an alternative for Amazon S3, Amazon SageMaker, and AWS Lambda, you can instead configure the VPC to have a VPC endpoint for the other service associated with the DB cluster's route table, see Working with a DB cluster in a VPC (p. 2478). For more information about configuring NAT in your VPC, see NAT gateways. For more information about configuring VPC endpoints, see VPC endpoints. You can also create an S3 gateway endpoint to access your S3 bucket. For more information, see Gateway endpoints for Amazon S3.

You might also have to open the ephemeral ports for your network access control lists (ACLs) in the outbound rules for your VPC security group. For more information on ephemeral ports for network ACLs, see Ephemeral ports in the Amazon Virtual Private Cloud User Guide.

Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket

You can use the LOAD DATA FROM S3 or LOAD XML FROM S3 statement to load data from files stored in an Amazon S3 bucket.
Note
Loading data into a table from text files isn't supported for Aurora Serverless v1. It is supported for Aurora Serverless v2.

Giving Aurora access to Amazon S3

Before you can load data from an Amazon S3 bucket, you must first give your Aurora MySQL DB cluster permission to access Amazon S3.

To give Aurora MySQL access to Amazon S3

1. Create an AWS Identity and Access Management (IAM) policy that provides the bucket and object permissions that allow your Aurora MySQL DB cluster to access Amazon S3. For instructions, see Creating an IAM policy to access Amazon S3 resources (p. 1048).

   Note
   In Aurora MySQL version 3.05 and higher, you can load objects that are encrypted using customer-managed AWS KMS keys. To do so, include the kms:Decrypt permission in your IAM policy. For more information, see Creating an IAM policy to access AWS KMS resources (p. 1053).
   You don't need this permission to load objects that are encrypted using AWS managed keys or Amazon S3 managed keys (SSE-S3).

2. Create an IAM role, and attach the IAM policy you created in Creating an IAM policy to access Amazon S3 resources (p. 1048) to the new IAM role. For instructions, see Creating an IAM role to allow Amazon Aurora to access AWS services (p. 1053).

3. Make sure the DB cluster is using a custom DB cluster parameter group.

   For more information about creating a custom DB cluster parameter group, see Creating a DB cluster parameter group (p. 216).

4. For Aurora MySQL version 2, set either the aurora_load_from_s3_role or aws_default_s3_role DB cluster parameter to the Amazon Resource Name (ARN) of the new IAM role. If an IAM role isn't specified for aurora_load_from_s3_role, Aurora uses the IAM role specified in aws_default_s3_role.

   For Aurora MySQL version 3, use aws_default_s3_role.

   If the cluster is part of an Aurora global database, set this parameter for each Aurora cluster in the global database. Although only the primary cluster in an Aurora global database can load data, another cluster might be promoted by the failover mechanism and become the primary cluster.

   For more information about DB cluster parameters, see Amazon Aurora DB cluster and DB instance parameters (p. 215).

5. To permit database users in an Aurora MySQL DB cluster to access Amazon S3, associate the role that you created in Creating an IAM role to allow Amazon Aurora to access AWS services (p. 1053) with the DB cluster. For an Aurora global database, associate the role with each Aurora cluster in the global database. For information about associating an IAM role with a DB cluster, see Associating an IAM role with an Amazon Aurora MySQL DB cluster (p. 1054).

6. Configure your Aurora MySQL DB cluster to allow outbound connections to Amazon S3. For instructions, see Enabling network communication from Amazon Aurora MySQL to other AWS services (p. 1058).

   If your DB cluster isn't publicly accessible and in a VPC public subnet, it is private. You can create an S3 gateway endpoint to access your S3 bucket. For more information, see Gateway endpoints for Amazon S3.

   For an Aurora global database, enable outbound connections for each Aurora cluster in the global database.
Granting privileges to load data in Amazon Aurora MySQL

The database user that issues the LOAD DATA FROM S3 or LOAD XML FROM S3 statement must have a specific role or privilege to issue either statement. In Aurora MySQL version 3, you grant the AWS_LOAD_S3_ACCESS role. In Aurora MySQL version 2, you grant the LOAD FROM S3 privilege. The administrative user for a DB cluster is granted the appropriate role or privilege by default. You can grant the privilege to another user by using one of the following statements.

Use the following statement for Aurora MySQL version 3:

```sql
GRANT AWS_LOAD_S3_ACCESS TO 'user'@'domain-or-ip-address'
```

**Tip**
When you use the role technique in Aurora MySQL version 3, you can also activate the role by using the SET ROLE role_name or SET ROLE ALL statement. If you aren't familiar with the MySQL 8.0 role system, you can learn more in Role-based privilege model (p. 797). And for more details, see Using roles in the MySQL Reference Manual.

This only applies to the current active session. When you reconnect, you have to run the SET ROLE statement again to grant privileges. For more information, see SET ROLE statement in the MySQL Reference Manual.

You can use the activate_all_roles_on_login DB cluster parameter to automatically activate all roles when a user connects to a DB instance. When this parameter is set, you don't have to call the SET ROLE statement explicitly to activate a role. For more information, see activate_all_roles_on_login in the MySQL Reference Manual.

Use the following statement for Aurora MySQL version 2:

```sql
GRANT LOAD FROM S3 ON *.* TO 'user'@'domain-or-ip-address'
```

The AWS_LOAD_S3_ACCESS role and LOAD FROM S3 privilege are specific to Amazon Aurora and are not available for external MySQL databases or RDS for MySQL DB instances. If you have set up replication between an Aurora DB cluster as the replication master and a MySQL database as the replication client, then the GRANT statement for the role or privilege causes replication to stop with an error. You can safely skip the error to resume replication. To skip the error on an RDS for MySQL instance, use the mysql_rds_skip_repl_error procedure. To skip the error on an external MySQL database, use the slave_skip_errors system variable (Aurora MySQL version 2) or replica_skip_errors system variable (Aurora MySQL version 3).

Specifying the path (URI) to an Amazon S3 bucket

The syntax for specifying the path (URI) to files stored on an Amazon S3 bucket is as follows.

```sql
s3-region://bucket-name/file-name-or-prefix
```

The path includes the following values:

- **region** (optional) – The AWS Region that contains the Amazon S3 bucket to load from. This value is optional. If you don't specify a region value, then Aurora loads your file from Amazon S3 in the same region as your DB cluster.
- **bucket-name** – The name of the Amazon S3 bucket that contains the data to load. Object prefixes that identify a virtual folder path are supported.
- **file-name-or-prefix** – The name of the Amazon S3 text file or XML file, or a prefix that identifies one or more text or XML files to load. You can also specify a manifest file that identifies one or more text files to load. For more information about using a manifest file to load text files from Amazon S3, see Using a manifest to specify data files to load (p. 1064).
To copy the URI for files in an S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the navigation pane, choose Buckets, and then choose the bucket whose URI you want to copy.
3. Select the prefix or file that you want to load from S3.
4. Choose Copy S3 URI.

LOAD DATA FROM S3

You can use the LOAD DATA FROM S3 statement to load data from any text file format that is supported by the MySQL LOAD DATA INFILE statement, such as text data that is comma-delimited. Compressed files are not supported.

Note
Make sure that your Aurora MySQL DB cluster allows outbound connections to S3. For more information, see Enabling network communication from Amazon Aurora MySQL to other AWS services (p. 1058).

Syntax

```
LOAD DATA [FROM] S3 [FILE | PREFIX | MANIFEST] 'S3-URI'
[REPLACE | IGNORE]
INTO TABLE tbl_name
[PARTITION (partition_name,...)]
[CHARACTER SET charset_name]
[(FIELDS | COLUMNS]
  [[TERMINATED BY 'string']
   [OPTIONALLY] ENCLOSED BY 'char']
   [ESCAPED BY 'char']
]
[LINES
  [STARTING BY 'string']
  [TERMINATED BY 'string']
]
[IGNORE number {LINES | ROWS}]
[({col_name_or_user_var,...})]
[SET col_name = expr,...]
```

Note
In Aurora MySQL version 3.05 and higher, the keyword FROM is optional.

Parameters

The LOAD DATA FROM S3 statement uses the following required and optional parameters. You can find more details about some of these parameters in LOAD DATA Statement in the MySQL documentation.

FILE | PREFIX | MANIFEST
Identifies whether to load the data from a single file, from all files that match a given prefix, or from all files in a specified manifest. FILE is the default.

S3-URI
Specifies the URI for a text or manifest file to load, or an Amazon S3 prefix to use. Specify the URI using the syntax described in Specifying the path (URI) to an Amazon S3 bucket (p. 1061).

REPLACE | IGNORE
Determines what action to take if an input row has the same unique key values as an existing row in the database table.
- Specify REPLACE if you want the input row to replace the existing row in the table.
- Specify IGNORE if you want to discard the input row.

**INTO TABLE**

Identifies the name of the database table to load the input rows into.

**PARTITION**

Requires that all input rows be inserted into the partitions identified by the specified list of comma-separated partition names. If an input row cannot be inserted into one of the specified partitions, then the statement fails and an error is returned.

**CHARACTER SET**

Identifies the character set of the data in the input file.

**FIELDS | COLUMNS**

Identifies how the fields or columns in the input file are delimited. Fields are tab-delimited by default.

**LINES**

Identifies how the lines in the input file are delimited. Lines are delimited by a newline character (\n) by default.

**IGNORE number LINES | ROWS**

Specifies to ignore a certain number of lines or rows at the start of the input file. For example, you can use IGNORE 1 LINES to skip over an initial header line containing column names, or IGNORE 2 ROWS to skip over the first two rows of data in the input file. If you also use PREFIX, IGNORE skips a certain number of lines or rows at the start of the first input file.

**col_name_or_user_var, ...**

Specifies a comma-separated list of one or more column names or user variables that identify which columns to load by name. The name of a user variable used for this purpose must match the name of an element from the text file, prefixed with @. You can employ user variables to store the corresponding field values for subsequent reuse.

For example, the following statement loads the first column from the input file into the first column of table1, and sets the value of the table_column2 column in table1 to the input value of the second column divided by 100.

```
LOAD DATA FROM S3 's3://mybucket/data.txt'
  INTO TABLE table1
  (column1, @var1)
  SET table_column2 = @var1/100;
```

**SET**

Specifies a comma-separated list of assignment operations that set the values of columns in the table to values not included in the input file.

For example, the following statement sets the first two columns of table1 to the values in the first two columns from the input file, and then sets the value of the column3 in table1 to the current time stamp.

```
LOAD DATA FROM S3 's3://mybucket/data.txt'
  INTO TABLE table1
  (column1, column2)
  SET column3 = CURRENT_TIMESTAMP;
```
You can use subqueries in the right side of SET assignments. For a subquery that returns a value to be assigned to a column, you can use only a scalar subquery. Also, you cannot use a subquery to select from the table that is being loaded.

You can't use the LOCAL keyword of the LOAD DATA FROM S3 statement if you're loading data from an Amazon S3 bucket.

**Using a manifest to specify data files to load**

You can use the LOAD DATA FROM S3 statement with the MANIFEST keyword to specify a manifest file in JSON format that lists the text files to be loaded into a table in your DB cluster.

The following JSON schema describes the format and content of a manifest file.

```json
{
   "$schema": "http://json-schema.org/draft-04/schema#",
   "additionalProperties": false,
   "definitions": {},
   "id": "Aurora_LoadFromS3_Manifest",
   "properties": {
      "entries": {
         "additionalItems": false,
         "id": "/properties/entries",
         "items": {
            "additionalProperties": false,
            "id": "/properties/entries/items",
            "properties": {
               "mandatory": {
                  "default": "false",
                  "id": "/properties/entries/items/properties/mandatory",
                  "type": "boolean"
               },
               "url": {
                  "id": "/properties/entries/items/properties/url",
                  "maxLength": 1024,
                  "minLength": 1,
                  "type": "string"
               }
            },
            "required": [
               "url"
            ],
            "type": "object"
         },
         "type": "array",
         "uniqueItems": true
      }
   },
   "required": [
      "entries"
   ],
   "type": "object"
}
```

Each `url` in the manifest must specify a URL with the bucket name and full object path for the file, not just a prefix. You can use a manifest to load files from different buckets, different regions, or files that do not share the same prefix. If a region is not specified in the URL, the region of the target Aurora DB cluster is used. The following example shows a manifest file that loads four files from different buckets.

```json
{
   "entries": [
      {
```

1064
The optional mandatory flag specifies whether LOAD DATA FROM S3 should return an error if the file is not found. The mandatory flag defaults to false. Regardless of how mandatory is set, LOAD DATA FROM S3 terminates if no files are found.

Manifest files can have any extension. The following example runs the LOAD DATA FROM S3 statement with the manifest in the previous example, which is named `customer.manifest`.

```
LOAD DATA FROM S3 MANIFEST 's3-us-west-2://aurora-bucket/customer.manifest'
  INTO TABLE CUSTOMER
  FIELDS TERMINATED BY ','
  LINES TERMINATED BY '
'
  (ID, FIRSTNAME, LASTNAME, EMAIL);
```

After the statement completes, an entry for each successfully loaded file is written to the `aurora_s3_load_history` table.

### Verifying loaded files using the aurora_s3_load_history table

Every successful LOAD DATA FROM S3 statement updates the `aurora_s3_load_history` table in the `mysql` schema with an entry for each file that was loaded.

After you run the LOAD DATA FROM S3 statement, you can verify which files were loaded by querying the `aurora_s3_load_history` table. To see the files that were loaded from one iteration of the statement, use the WHERE clause to filter the records on the Amazon S3 URI for the manifest file used in the statement. If you have used the same manifest file before, filter the results using the timestamp field.

```
select * from mysql.aurora_s3_load_history where load_prefix = 'S3_URI';
```

The following table describes the fields in the `aurora_s3_load_history` table.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>load_prefix</td>
<td>The URI that was specified in the load statement. This URI can map to any of the following:</td>
</tr>
<tr>
<td></td>
<td>• A single data file for a LOAD DATA FROM S3 FILE statement</td>
</tr>
<tr>
<td></td>
<td>• An Amazon S3 prefix that maps to multiple data files for a LOAD DATA FROM S3 PREFIX statement</td>
</tr>
<tr>
<td></td>
<td>• A single manifest file that contains the names of files to be loaded for a LOAD DATA FROM S3 MANIFEST statement</td>
</tr>
</tbody>
</table>
Field | Description
---|---
file_name | The name of a file that was loaded into Aurora from Amazon S3 using the URI identified in the load_prefix field.
version_number | The version number of the file identified by the file_name field that was loaded, if the Amazon S3 bucket has a version number.
bytes_loaded | The size of the file loaded, in bytes.
load_timestamp | The timestamp when the LOAD DATA FROM S3 statement completed.

**Examples**

The following statement loads data from an Amazon S3 bucket that is in the same region as the Aurora DB cluster. The statement reads the comma-delimited data in the file `customerdata.txt` that is in the `dbbucket` Amazon S3 bucket, and then loads the data into the table `store-schema.customer-table`.

```
LOAD DATA FROM S3 's3://dbbucket/customerdata.csv'
  INTO TABLE store-schema.customer-table
  FIELDS TERMINATED BY ','
  LINES TERMINATED BY '\n'
  (ID, FIRSTNAME, LASTNAME, ADDRESS, EMAIL, PHONE);
```

The following statement loads data from an Amazon S3 bucket that is in a different region from the Aurora DB cluster. The statement reads the comma-delimited data from all files that match the `employee-data` object prefix in the `my-data` Amazon S3 bucket in the `us-west-2` region, and then loads the data into the `employees` table.

```
LOAD DATA FROM S3 PREFIX 's3-us-west-2://my-data/employee_data'
  INTO TABLE employees
  FIELDS TERMINATED BY ','
  LINES TERMINATED BY '\n'
  (ID, FIRSTNAME, LASTNAME, EMAIL, SALARY);
```

The following statement loads data from the files specified in a JSON manifest file named `q1_sales.json` into the `sales` table.

```
LOAD DATA FROM S3 MANIFEST 's3-us-west-2://aurora-bucket/q1_sales.json'
  INTO TABLE sales
  FIELDS TERMINATED BY ','
  LINES TERMINATED BY '\n'
  (MONTH, STORE, GROSS, NET);
```

**LOAD XML FROM S3**

You can use the LOAD XML FROM S3 statement to load data from XML files stored on an Amazon S3 bucket in one of three different XML formats:

- Column names as attributes of a `<row>` element. The attribute value identifies the contents of the table field.

  `<row column1="value1" column2="value2" .../>`
• Column names as child elements of a `<row>` element. The value of the child element identifies the contents of the table field.

```
<row>
  <column1>value1</column1>
  <column2>value2</column2>
</row>
```

• Column names in the name attribute of `<field>` elements in a `<row>` element. The value of the `<field>` element identifies the contents of the table field.

```
<row>
  <field name='column1'>value1</field>
  <field name='column2'>value2</field>
</row>
```

## Syntax

```
LOAD XML FROM S3 'S3-URI'
  [REPLACE | IGNORE]
  INTO TABLE tbl_name
  [PARTITION (partition_name,...)]
  [CHARACTER SET charset_name]
  [ROWS IDENTIFIED BY '<element-name>']
  [IGNORE number {LINES | ROWS}]
  [(field_name_or_user_var,...)]
  [SET col_name = expr,...]
```

## Parameters

The `LOAD XML FROM S3` statement uses the following required and optional parameters. You can find more details about some of these parameters in [LOAD XML Statement](https://dev.mysql.com/doc/refman/8.0/en/load-xml.html) in the MySQL documentation.

**FILE | PREFIX**

Identifies whether to load the data from a single file, or from all files that match a given prefix. FILE is the default.

**REPLACE | IGNORE**

Determines what action to take if an input row has the same unique key values as an existing row in the database table.
- Specify REPLACE if you want the input row to replace the existing row in the table.
- Specify IGNORE if you want to discard the input row. IGNORE is the default.

**INTO TABLE**

Identifies the name of the database table to load the input rows into.

**PARTITION**

Requires that all input rows be inserted into the partitions identified by the specified list of comma-separated partition names. If an input row cannot be inserted into one of the specified partitions, then the statement fails and an error is returned.

**CHARACTER SET**

Identifies the character set of the data in the input file.

**ROWS IDENTIFIED BY**

Identifies the element name that identifies a row in the input file. The default is `<row>`.
IGNORE number LINES | ROWS

Specifies to ignore a certain number of lines or rows at the start of the input file. For example, you can use IGNORE 1 LINES to skip over the first line in the text file, or IGNORE 2 ROWS to skip over the first two rows of data in the input XML.

field_name_or_user_var, ...

Specifies a comma-separated list of one or more XML element names or user variables that identify which elements to load by name. The name of a user variable used for this purpose must match the name of an element from the XML file, prefixed with @. You can employ user variables to store the corresponding field values for subsequent reuse.

For example, the following statement loads the first column from the input file into the first column of table1, and sets the value of the table_column2 column in table1 to the input value of the second column divided by 100.

```sql
LOAD XML FROM S3 's3://mybucket/data.xml'
INTO TABLE table1
(column1, @var1)
SET table_column2 = @var1/100;
```

SET

Specifies a comma-separated list of assignment operations that set the values of columns in the table to values not included in the input file.

For example, the following statement sets the first two columns of table1 to the values in the first two columns from the input file, and then sets the value of the column3 column in table1 to the current time stamp.

```sql
LOAD XML FROM S3 's3://mybucket/data.xml'
INTO TABLE table1
(column1, column2)
SET column3 = CURRENT_TIMESTAMP;
```

You can use subqueries in the right side of SET assignments. For a subquery that returns a value to be assigned to a column, you can use only a scalar subquery. Also, you can't use a subquery to select from the table that's being loaded.

Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket

You can use the SELECT INTO OUTFILE S3 statement to query data from an Amazon Aurora MySQL DB cluster and save it directly into text files stored in an Amazon S3 bucket. You can use this functionality to skip bringing the data down to the client first, and then copying it from the client to Amazon S3. The LOAD DATA FROM S3 statement can use the files created by this statement to load data into an Aurora DB cluster. For more information, see Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket (p. 1059).

You can encrypt the Amazon S3 bucket using an Amazon S3 managed key (SSE-S3) or AWS KMS key (SSE-KMS: AWS managed key or customer managed key).

This feature isn't supported for Aurora Serverless v1 DB clusters. It is supported for Aurora Serverless v2 DB clusters.
Note
You can save DB cluster snapshot data to Amazon S3 using the AWS Management Console, AWS CLI, or Amazon RDS API. For more information, see Exporting DB cluster snapshot data to Amazon S3 (p. 471).

Giving Aurora MySQL access to Amazon S3

Before you can save data into an Amazon S3 bucket, you must first give your Aurora MySQL DB cluster permission to access Amazon S3.

To give Aurora MySQL access to Amazon S3

1. Create an AWS Identity and Access Management (IAM) policy that provides the bucket and object permissions that allow your Aurora MySQL DB cluster to access Amazon S3. For instructions, see Creating an IAM policy to access Amazon S3 resources (p. 1048).

   Note
   In Aurora MySQL version 3.05 and higher, you can encrypt objects using AWS KMS customer managed keys. To do so, include the kms:GenerateDataKey permission in your IAM policy. For more information, see Creating an IAM policy to access AWS KMS resources (p. 1053).
   You don't need this permission to encrypt objects using AWS managed keys or Amazon S3 managed keys (SSE-S3).

2. Create an IAM role, and attach the IAM policy you created in Creating an IAM policy to access Amazon S3 resources (p. 1048) to the new IAM role. For instructions, see Creating an IAM role to allow Amazon Aurora to access AWS services (p. 1053).

3. For Aurora MySQL version 2, set either the aurora_select_into_s3_role or aws_default_s3_role DB cluster parameter to the Amazon Resource Name (ARN) of the new IAM role. If an IAM role isn't specified for aurora_select_into_s3_role, Aurora uses the IAM role specified in aws_default_s3_role.

   For Aurora MySQL version 3, use aws_default_s3_role.

   If the cluster is part of an Aurora global database, set this parameter for each Aurora cluster in the global database.

   For more information about DB cluster parameters, see Amazon Aurora DB cluster and DB instance parameters (p. 215).

4. To permit database users in an Aurora MySQL DB cluster to access Amazon S3, associate the role that you created in Creating an IAM role to allow Amazon Aurora to access AWS services (p. 1053) with the DB cluster.

   For an Aurora global database, associate the role with each Aurora cluster in the global database.

   For information about associating an IAM role with a DB cluster, see Associating an IAM role with an Amazon Aurora MySQL DB cluster (p. 1054).

5. Configure your Aurora MySQL DB cluster to allow outbound connections to Amazon S3. For instructions, see Enabling network communication from Amazon Aurora MySQL to other AWS services (p. 1058).

   For an Aurora global database, enable outbound connections for each Aurora cluster in the global database.

Granting privileges to save data in Aurora MySQL

The database user that issues the SELECT INTO OUTFILE S3 statement must have a specific role or privilege. In Aurora MySQL version 3, you grant the AWS_SELECT_S3_ACCESS role. In Aurora MySQL
version 2, you grant the SELECT INTO S3 privilege. The administrative user for a DB cluster is granted the appropriate role or privilege by default. You can grant the privilege to another user by using one of the following statements.

Use the following statement for Aurora MySQL version 3:

```sql
GRANT AWS_SELECT_S3_ACCESS TO 'user'@'domain-or-ip-address'
```

**Tip**

When you use the role technique in Aurora MySQL version 3, you can also activate the role by using the SET ROLE role_name or SET ROLE ALL statement. If you aren't familiar with the MySQL 8.0 role system, you can learn more in Role-based privilege model (p. 797). And for more details, see Using roles in the MySQL Reference Manual.

This only applies to the current active session. When you reconnect, you have to run the SET ROLE statement again to grant privileges. For more information, see SET ROLE statement in the MySQL Reference Manual.

You can use the activate_all_roles_on_login DB cluster parameter to automatically activate all roles when a user connects to a DB instance. When this parameter is set, you don’t have to call the SET ROLE statement explicitly to activate a role. For more information, see activate_all_roles_on_login in the MySQL Reference Manual.

Use the following statement for Aurora MySQL version 2:

```sql
GRANT SELECT INTO S3 ON *.* TO 'user'@'domain-or-ip-address'
```

The AWS_SELECT_S3_ACCESS role and SELECT INTO S3 privilege are specific to Amazon Aurora MySQL and are not available for MySQL databases or RDS for MySQL DB instances. If you have set up replication between an Aurora MySQL DB cluster as the replication master and a MySQL database as the replication client, then the GRANT statement for the role or privilege causes replication to stop with an error. You can safely skip the error to resume replication. To skip the error on an RDS for MySQL DB instance, use the mysql_rds_skip_repl_error procedure. To skip the error on an external MySQL database, use the slave_skip_errors system variable (Aurora MySQL version 2) or replica_skip_errors system variable (Aurora MySQL version 3).

**Specifying a path to an Amazon S3 bucket**

The syntax for specifying a path to store the data and manifest files on an Amazon S3 bucket is similar to that used in the LOAD DATA FROM S3 PREFIX statement, as shown following.

```sql
s3-region://bucket-name/file-prefix
```

The path includes the following values:

- **region** (optional) – The AWS Region that contains the Amazon S3 bucket to save the data into. This value is optional. If you don't specify a region value, then Aurora saves your files into Amazon S3 in the same region as your DB cluster.
- **bucket-name** – The name of the Amazon S3 bucket to save the data into. Object prefixes that identify a virtual folder path are supported.
- **file-prefix** – The Amazon S3 object prefix that identifies the files to be saved in Amazon S3.

The data files created by the SELECT INTO OUTFILE S3 statement use the following path, in which 00000 represents a 5-digit, zero-based integer number.

```sql
s3-region://bucket-name/file-prefix.part_00000
```
For example, suppose that a `SELECT INTO OUTFILE S3` statement specifies `s3-us-west-2://bucket/prefix` as the path in which to store data files and creates three data files. The specified Amazon S3 bucket contains the following data files.

- `s3-us-west-2://bucket/prefix.part_00000`
- `s3-us-west-2://bucket/prefix.part_00001`
- `s3-us-west-2://bucket/prefix.part_00002`

### Creating a manifest to list data files

You can use the `SELECT INTO OUTFILE S3` statement with the `MANIFEST ON` option to create a manifest file in JSON format that lists the text files created by the statement. The `LOAD DATA FROM S3` statement can use the manifest file to load the data files back into an Aurora MySQL DB cluster. For more information about using a manifest to load data files from Amazon S3 into an Aurora MySQL DB cluster, see [Using a manifest to specify data files to load](p. 1064).

The data files included in the manifest created by the `SELECT INTO OUTFILE S3` statement are listed in the order that they're created by the statement. For example, suppose that a `SELECT INTO OUTFILE S3` statement specified `s3-us-west-2://bucket/prefix` as the path in which to store data files and creates three data files and a manifest file. The specified Amazon S3 bucket contains a manifest file named `s3-us-west-2://bucket/prefix.manifest`, that contains the following information.

```json
{
  "entries": [
    {
      "url": "s3-us-west-2://bucket/prefix.part_00000"
    },
    {
      "url": "s3-us-west-2://bucket/prefix.part_00001"
    },
    {
      "url": "s3-us-west-2://bucket/prefix.part_00002"
    }
  ]
}
```

### SELECT INTO OUTFILE S3

You can use the `SELECT INTO OUTFILE S3` statement to query data from a DB cluster and save it directly into delimited text files stored in an Amazon S3 bucket.

Compressed files aren't supported. Encrypted files are supported starting in Aurora MySQL version 2.09.0.

#### Syntax

```sql
SELECT
  [ALL | DISTINCT | DISTINCTROW ]
  [HIGH_PRIORITY]
  [STRAIGHT_JOIN]
  [SQL_SMALL_RESULT] [SQL_BIG_RESULT] [SQL_BUFFER.getResult]
  [SQL_CACHE | SQL_NO_CACHE] [SQL_CALC_FOUND_ROWS]
  select_expr [, select_expr ...]
FROM table_references
[PARTITION partition_list]
[WHERE where_condition]
[GROUP BY {col_name | expr | position}
  [ASC | DESC], ... [WITH ROLLUP]]
```
[HAVING where_condition]
[ORDER BY {col_name | expr | position}
   [ASC | DESC], ...]
[LIMIT {{offset,] row_count | row_count OFFSET offset}]
INTO OUTFILE S3 's3_uri'
[CHARACTER SET charset_name]
[export_options]
[MANIFEST {ON | OFF}]
[OVERWRITE {ON | OFF}]
[ENCRYPTION {ON | OFF | SSE_S3 | SSE_KMS ['cmk_id']}]]

export_options:
[FORMAT {CSV|TEXT} [HEADER]]
{{FIELDS | COLUMNS}
   [TERMINATED BY 'string']
   [[OPTIONALLY] ENCLOSED BY 'char']
   [ESCAPED BY 'char']
   ]
[LINES
   [STARTING BY 'string']
   [TERMINATED BY 'string']
   ]

Parameters

The SELECT INTO OUTFILE S3 statement uses the following required and optional parameters that are specific to Aurora.

s3-uri

Specifies the URI for an Amazon S3 prefix to use. Use the syntax described in Specifying a path to an Amazon S3 bucket (p. 1070).

FORMAT (CSV|TEXT) [HEADER]

Optionally saves the data in CSV format.

The TEXT option is the default and produces the existing MySQL export format.

The CSV option produces comma-separated data values. The CSV format follows the specification in RFC-4180. If you specify the optional keyword HEADER, the output file contains one header line. The labels in the header line correspond to the column names from the SELECT statement. You can use the CSV files for training data models for use with AWS ML services. For more information about using exported Aurora data with AWS ML services, see Exporting data to Amazon S3 for SageMaker model training (Advanced) (p. 1098).

MANIFEST (ON | OFF)

Indicates whether a manifest file is created in Amazon S3. The manifest file is a JavaScript Object Notation (JSON) file that can be used to load data into an Aurora DB cluster with the LOAD DATA FROM S3 MANIFEST statement. For more information about LOAD DATA FROM S3 MANIFEST, see Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket (p. 1059).

If MANIFEST ON is specified in the query, the manifest file is created in Amazon S3 after all data files have been created and uploaded. The manifest file is created using the following path:

s3-region://bucket-name/file-prefix.manifest

For more information about the format of the manifest file's contents, see Creating a manifest to list data files (p. 1071).
OVERWRITE {ON | OFF}

Indicates whether existing files in the specified Amazon S3 bucket are overwritten. If OVERWRITE ON is specified, existing files that match the file prefix in the URI specified in s3-uri are overwriten. Otherwise, an error occurs.

ENCRYPTION {ON | OFF | SSE_S3 | SSE_KMS ['cmk_id']}

Indicates whether to use server-side encryption with Amazon S3 managed keys (SSE-S3) or AWS KMS keys (SSE-KMS, including AWS managed keys and customer managed keys). The SSE_S3 and SSE_KMS settings are available in Aurora MySQL version 3.05 and higher.

You can also use the aurora_select_into_s3_encryption_default session variable instead of the ENCRYPTION clause, as shown in the following example. Use either the SQL clause or the session variable, but not both.

```
set session aurora_select_into_s3_encryption_default={ON | OFF | SSE_S3 | SSE_KMS};
```

The SSE_S3 and SSE_KMS settings are available in Aurora MySQL version 3.05 and higher.

When you set aurora_select_into_s3_encryption_default to the following value:

- OFF – The default encryption policy of the S3 bucket is followed. The default value of aurora_select_into_s3_encryption_default is OFF.
- ON or SSE_S3 – The S3 object is encrypted using Amazon S3 managed keys (SSE-S3).
- SSE_KMS – The S3 object is encrypted using an AWS KMS key.

In this case, you also include the session variable aurora_s3_default_cmk_id, for example:

```
set session aurora_select_into_s3_encryption_default={SSE_KMS};
set session aurora_s3_default_cmk_id={NULL | 'cmk_id'};
```

- When aurora_s3_default_cmk_id is NULL, the S3 object is encrypted using an AWS managed key.
- When aurora_s3_default_cmk_id is a nonempty string cmk_id, the S3 object is encrypted using a customer managed key.

The value of cmk_id can't be an empty string.

When you use the SELECT INTO OUTFILE S3 command, Aurora determines the encryption as follows:

- If the ENCRYPTION clause is present in the SQL command, Aurora relies only on the value of ENCRYPTION, and doesn't use a session variable.
- If the ENCRYPTION clause isn't present, Aurora relies on the value of the session variable.

For more information, see Using server-side encryption with Amazon S3 managed keys (SSE-S3) and Using server-side encryption with AWS KMS keys (SSE-KMS) in the Amazon Simple Storage Service User Guide.

You can find more details about other parameters in SELECT statement and LOAD DATA statement, in the MySQL documentation.

**Considerations**

The number of files written to the Amazon S3 bucket depends on the amount of data selected by the SELECT INTO OUTFILE S3 statement and the file size threshold for Aurora MySQL. The default
file size threshold is 6 gigabytes (GB). If the data selected by the statement is less than the file size threshold, a single file is created; otherwise, multiple files are created. Other considerations for files created by this statement include the following:

- Aurora MySQL guarantees that rows in data files are not split across file boundaries. For multiple files, the size of every data file except the last is typically close to the file size threshold. However, occasionally staying under the size threshold results in a row being split across two data files. In this case, Aurora MySQL creates a data file that keeps the row intact, but might be larger than the file size threshold.

- Because each SELECT statement in Aurora MySQL runs as an atomic transaction, a SELECT INTO OUTFILE S3 statement that selects a large data set might run for some time. If the statement fails for any reason, you might need to start over and issue the statement again. If the statement fails, however, files already uploaded to Amazon S3 remain in the specified Amazon S3 bucket. You can use another statement to upload the remaining data instead of starting over again.

- If the amount of data to be selected is large (more than 25 GB), we recommend that you use multiple SELECT INTO OUTFILE S3 statements to save the data to Amazon S3. Each statement should select a different portion of the data to be saved, and also specify a different file_prefix in the s3-uri parameter to use when saving the data files. Partitioning the data to be selected with multiple statements makes it easier to recover from an error in one statement. If an error occurs for one statement, only a portion of data needs to be re-selected and uploaded to Amazon S3. Using multiple statements also helps to avoid a single long-running transaction, which can improve performance.

- If multiple SELECT INTO OUTFILE S3 statements that use the same file_prefix in the s3-uri parameter run in parallel to select data into Amazon S3, the behavior is undefined.

- Metadata, such as table schema or file metadata, is not uploaded by Aurora MySQL to Amazon S3.

- In some cases, you might re-run a SELECT INTO OUTFILE S3 query, such as to recover from a failure. In these cases, you must either remove any existing data files in the Amazon S3 bucket with the same file prefix specified in s3-uri, or include OVERWRITE ON in the SELECT INTO OUTFILE S3 query.

The SELECT INTO OUTFILE S3 statement returns a typical MySQL error number and response on success or failure. If you don’t have access to the MySQL error number and response, the easiest way to determine when it’s done is by specifying MANIFEST ON in the statement. The manifest file is the last file written by the statement. In other words, if you have a manifest file, the statement has completed.

Currently, there’s no way to directly monitor the progress of the SELECT INTO OUTFILE S3 statement while it runs. However, suppose that you’re writing a large amount of data from Aurora MySQL to Amazon S3 using this statement, and you know the size of the data selected by the statement. In this case, you can estimate progress by monitoring the creation of data files in Amazon S3.

To do so, you can use the fact that a data file is created in the specified Amazon S3 bucket for about every 6 GB of data selected by the statement. Divide the size of the data selected by 6 GB to get the estimated number of data files to create. You can then estimate the progress of the statement by monitoring the number of files uploaded to Amazon S3 while the statement runs.

**Examples**

The following statement selects all of the data in the employees table and saves the data into an Amazon S3 bucket that is in a different region from the Aurora MySQL DB cluster. The statement creates data files in which each field is terminated by a comma (,) character and each row is terminated by a newline (\n) character. The statement returns an error if files that match the sample_employee_data file prefix exist in the specified Amazon S3 bucket.

```
SELECT * FROM employees INTO OUTFILE S3 's3-us-west-2://aurora-select-into-s3-pdx/sample_employee_data'
    FIELDS TERMINATED BY ',',
```
**Invoking a Lambda function from an Amazon Aurora MySQL DB cluster**

You can invoke an AWS Lambda function from an Amazon Aurora MySQL-Compatible Edition DB cluster with the native function `lambda_sync` or `lambda_async`. Before invoking a Lambda function from an Aurora MySQL, the Aurora DB cluster must have access to Lambda. For details about granting access to Aurora MySQL, see [Giving Aurora access to Lambda](p. 1076). For information about the `lambda_sync` and `lambda_async` stored functions, see [Invoking a Lambda function with an Aurora MySQL native function](p. 1076).

You can also call an AWS Lambda function by using a stored procedure. However, using a stored procedure is deprecated. We strongly recommend using an Aurora MySQL native function if you are using one of the following Aurora MySQL versions:

- Aurora MySQL version 2, for MySQL 5.7-compatible clusters.
• Aurora MySQL version 3.01 and higher, for MySQL 8.0-compatible clusters. The stored procedure isn't available in Aurora MySQL version 3.

Topics

• Giving Aurora access to Lambda (p. 1076)
• Invoking a Lambda function with an Aurora MySQL native function (p. 1076)
• Invoking a Lambda function with an Aurora MySQL stored procedure (deprecated) (p. 1079)

Giving Aurora access to Lambda

Before you can invoke Lambda functions from an Aurora MySQL DB cluster, make sure to first give your cluster permission to access Lambda.

To give Aurora MySQL access to Lambda

1. Create an AWS Identity and Access Management (IAM) policy that provides the permissions that allow your Aurora MySQL DB cluster to invoke Lambda functions. For instructions, see Creating an IAM policy to access AWS Lambda resources (p. 1050).

2. Create an IAM role, and attach the IAM policy you created in Creating an IAM policy to access AWS Lambda resources (p. 1050) to the new IAM role. For instructions, see Creating an IAM role to allow Amazon Aurora to access AWS services (p. 1053).

3. Set the aws_default_lambda_role DB cluster parameter to the Amazon Resource Name (ARN) of the new IAM role.

   If the cluster is part of an Aurora global database, apply the same setting for each Aurora cluster in the global database.

   For more information about DB cluster parameters, see Amazon Aurora DB cluster and DB instance parameters (p. 215).

4. To permit database users in an Aurora MySQL DB cluster to invoke Lambda functions, associate the role that you created in Creating an IAM role to allow Amazon Aurora to access AWS services (p. 1053) with the DB cluster. For information about associating an IAM role with a DB cluster, see Associating an IAM role with an Amazon Aurora MySQL DB cluster (p. 1054).

   If the cluster is part of an Aurora global database, associate the role with each Aurora cluster in the global database.

5. Configure your Aurora MySQL DB cluster to allow outbound connections to Lambda. For instructions, see Enabling network communication from Amazon Aurora MySQL to other AWS services (p. 1058).

   If the cluster is part of an Aurora global database, enable outbound connections for each Aurora cluster in the global database.

Invoking a Lambda function with an Aurora MySQL native function

Note

You can call the native functions lambda_sync and lambda_async when you use Aurora MySQL version 2, or Aurora MySQL version 3.01 and higher. For more information about Aurora MySQL versions, see Database engine updates for Amazon Aurora MySQL (p. 1200).

You can invoke an AWS Lambda function from an Aurora MySQL DB cluster by calling the native functions lambda_sync and lambda_async. This approach can be useful when you want to integrate your database running on Aurora MySQL with other AWS services. For example, you might want to send
a notification using Amazon Simple Notification Service (Amazon SNS) whenever a row is inserted into a specific table in your database.

  - Example for the lambda_async function (p. 1079)
  - Invoking a Lambda function within a trigger (p. 1079)

Working with native functions to invoke a Lambda function

The `lambda_sync` and `lambda_async` functions are built-in, native functions that invoke a Lambda function synchronously or asynchronously. When you must know the result of the Lambda function before moving on to another action, use the synchronous function `lambda_sync`. When you don't need to know the result of the Lambda function before moving on to another action, use the asynchronous function `lambda_async`.

Granting the role in Aurora MySQL version 3

In Aurora MySQL version 3, the user invoking a native function must be granted the `AWS_LAMBDA_ACCESS` role. To grant this role to a user, connect to the DB instance as the administrative user, and run the following statement.

```
GRANT AWS_LAMBDA_ACCESS TO user@domain-or-ip-address
```

You can revoke this role by running the following statement.

```
REVOKE AWS_LAMBDA_ACCESS FROM user@domain-or-ip-address
```

Tip

When you use the role technique in Aurora MySQL version 3, you can also activate the role by using the `SET ROLE role_name` or `SET ROLE ALL` statement. If you aren't familiar with the MySQL 8.0 role system, you can learn more in Role-based privilege model (p. 797). And for more details, see Using roles in the MySQL Reference Manual.

This only applies to the current active session. When you reconnect, you have to run the `SET ROLE` statement again to grant privileges. For more information, see SET ROLE statement in the MySQL Reference Manual.

You can use the `activate_all_roles_on_login` DB cluster parameter to automatically activate all roles when a user connects to a DB instance. When this parameter is set, you don't have to call the `SET ROLE` statement explicitly to activate a role. For more information, see activate_all_roles_on_login in the MySQL Reference Manual.

If you get an error such as the following when you try to invoke a Lambda function, then run a `SET ROLE` statement.

```
SQL Error [1227] [42000]: Access denied; you need (at least one of) the Invoke Lambda privilege(s) for this operation
```
Granting the privilege in Aurora MySQL version 2

In Aurora MySQL version 2, the user invoking a native function must be granted the INVOKE LAMBDA privilege. To grant this privilege to a user, connect to the DB instance as the administrative user, and run the following statement.

```
GRANT INVOKE LAMBDA ON *.* TO user@domain-or-ip-address
```

You can revoke this privilege by running the following statement.

```
REVOKE INVOKE LAMBDA ON *.* FROM user@domain-or-ip-address
```

Syntax for the `lambda_sync` function

You invoke the `lambda_sync` function synchronously with the RequestResponse invocation type. The function returns the result of the Lambda invocation in a JSON payload. The function has the following syntax.

```
lambda_sync (lambda_function_ARN, JSON_payload)
```

Parameters for the `lambda_sync` function

The `lambda_sync` function has the following parameters.

- `lambda_function_ARN`:
  The Amazon Resource Name (ARN) of the Lambda function to invoke.

- `JSON_payload`:
  The payload for the invoked Lambda function, in JSON format.

*Note*

Aurora MySQL version 3 supports the JSON parsing functions from MySQL 8.0. However, Aurora MySQL version 2 doesn't include those functions. JSON parsing isn't required when a Lambda function returns an atomic value, such as a number or a string.

Example for the `lambda_sync` function

The following query based on `lambda_sync` invokes the Lambda function `BasicTestLambda` synchronously using the function ARN. The payload for the function is `{"operation": "ping"}`.

```
SELECT lambda_sync(
    'arn:aws:lambda:us-east-1:123456789012:function:BasicTestLambda',
    '{"operation": "ping"}');
```

Syntax for the `lambda_async` function

You invoke the `lambda_async` function asynchronously with the Event invocation type. The function returns the result of the Lambda invocation in a JSON payload. The function has the following syntax.

```
lambda_async (lambda_function_ARN, JSON_payload)
```
Parameters for the `lambda_async` function

The `lambda_async` function has the following parameters.

* **lambda_function_ARN**
  
  The Amazon Resource Name (ARN) of the Lambda function to invoke.

* **JSON_payload**
  
  The payload for the invoked Lambda function, in JSON format.

**Note**

Aurora MySQL version 3 supports the JSON parsing functions from MySQL 8.0. However, Aurora MySQL version 2 doesn't include those functions. JSON parsing isn't required when a Lambda function returns an atomic value, such as a number or a string.

Example for the `lambda_async` function

The following query based on `lambda_async` invokes the Lambda function `BasicTestLambda` asynchronously using the function ARN. The payload for the function is `"operation": "ping"`.

```sql
SELECT lambda_async(  
  'arn:aws:lambda:us-east-1:123456789012:function:BasicTestLambda',  
  '{"operation": "ping"}');
```

Invoking a Lambda function within a trigger

You can use triggers to call Lambda on data-modifying statements. The following example uses the `lambda_async` native function and stores the result in a variable.

```sql
mysql> SET @result=0;
mysql> DELIMITER //
mysql> CREATE TRIGGER myFirstTrigger  
  AFTER INSERT  
  ON Test_trigger FOR EACH ROW  
  BEGIN  
  SELECT lambda_async(  
    'arn:aws:lambda:us-east-1:123456789012:function:BasicTestLambda',  
    '{"operation": "ping"}')  
  INTO @result;  
  END; //
mysql> DELIMITER ;
```

**Note**

Triggers aren't run once per SQL statement, but once per row modified, one row at a time. When a trigger runs, the process is synchronous. The data-modifying statement only returns when the trigger completes.

Be careful when invoking an AWS Lambda function from triggers on tables that experience high write traffic. INSERT, UPDATE, and DELETE triggers are activated per row. A write-heavy workload on a table with INSERT, UPDATE, or DELETE triggers results in a large number of calls to your AWS Lambda function.

Invoking a Lambda function with an Aurora MySQL stored procedure (deprecated)

You can invoke an AWS Lambda function from an Aurora MySQL DB cluster by calling the `mysql.lambda_async` procedure. This approach can be useful when you want to integrate your
database running on Aurora MySQL with other AWS services. For example, you might want to send a notification using Amazon Simple Notification Service (Amazon SNS) whenever a row is inserted into a specific table in your database.

Contents

- Aurora MySQL version considerations (p. 1080)
- Working with the mysql.lambda_async procedure to invoke a Lambda function (deprecated) (p. 1080)
  - Syntax (p. 1080)
  - Parameters (p. 1080)
  - Examples (p. 1080)

Aurora MySQL version considerations

Starting in Aurora MySQL version 2, you can use the native function method instead of these stored procedures to invoke a Lambda function. For more information about the native functions, see Working with native functions to invoke a Lambda function (p. 1077).

In Aurora MySQL version 2, the stored procedure `mysql.lambda_async` is no longer supported. We strongly recommend that you work with native Lambda functions instead.

In Aurora MySQL version 3, the stored procedure isn't available.

Working with the mysql.lambda_async procedure to invoke a Lambda function (deprecated)

The `mysql.lambda_async` procedure is a built-in stored procedure that invokes a Lambda function asynchronously. To use this procedure, your database user must have `EXECUTE` privilege on the `mysql.lambda_async` stored procedure.

Syntax

The `mysql.lambda_async` procedure has the following syntax.

```
CALL mysql.lambda_async (lambda_function_ARN, lambda_function_input)
```

Parameters

The `mysql.lambda_async` procedure has the following parameters.

`lambda_function_ARN`

The Amazon Resource Name (ARN) of the Lambda function to invoke.

`lambda_function_input`

The input string, in JSON format, for the invoked Lambda function.

Examples

As a best practice, we recommend that you wrap calls to the `mysql.lambda_async` procedure in a stored procedure that can be called from different sources such as triggers or client code. This approach can help to avoid impedance mismatch issues and make it easier to invoke Lambda functions.
Note
Be careful when invoking an AWS Lambda function from triggers on tables that experience high write traffic. INSERT, UPDATE, and DELETE triggers are activated per row. A write-heavy workload on a table with INSERT, UPDATE, or DELETE triggers results in a large number of calls to your AWS Lambda function. Although calls to the mysql.lambda_async procedure are asynchronous, triggers are synchronous. A statement that results in a large number of trigger activations doesn’t wait for the call to the AWS Lambda function to complete, but it does wait for the triggers to complete before returning control to the client.

Example: Invoke an AWS Lambda function to send email

The following example creates a stored procedure that you can call in your database code to send an email using a Lambda function.

AWS Lambda Function

```python
import boto3
ses = boto3.client('ses')
def SES_send_email(event, context):
    return ses.send_email(
        Source=event['email_from'],
        Destination={
            'ToAddresses': [event['email_to'],
        ],
        },
        Message={
            'Subject': {
                'Data': event['email_subject']
            },
            'Body': {
                'Text': {
                    'Data': event['email_body']
                }
            }
        })
```

Stored Procedure

```sql
DROP PROCEDURE IF EXISTS SES_send_email;
DELIMITER ;;
CREATE PROCEDURE SES_send_email(IN email_from VARCHAR(255),
                                IN email_to VARCHAR(255),
                                IN subject VARCHAR(255),
                                IN body TEXT) LANGUAGE SQL
BEGIN
    CALL mysql.lambda_async(
        CONCAT({"email_to" : ", email_to,
        "email_from" : ", email_from,
        "email_subject" : ", subject,
        "email_body" : ", body, '")
    );
END ;;
DELIMITER ;
```
Amazon Aurora User Guide for Aurora
Invoking a Lambda function from Aurora MySQL

Call the Stored Procedure to Invoke the AWS Lambda Function
mysql> call SES_send_email('example_from@amazon.com', 'example_to@amazon.com', 'Email
subject', 'Email content');

Example Example: Invoke an AWS Lambda function to publish an event from a trigger
The following example creates a stored procedure that publishes an event by using Amazon SNS. The
code calls the procedure from a trigger when a row is added to a table.
AWS Lambda Function
import boto3
sns = boto3.client('sns')
def SNS_publish_message(event, context):
return sns.publish(
Message=event['message'],
Subject=event['subject'],
MessageStructure='string'
)

Stored Procedure
DROP PROCEDURE IF EXISTS SNS_Publish_Message;
DELIMITER ;;
CREATE PROCEDURE SNS_Publish_Message (IN subject VARCHAR(255),
IN message TEXT) LANGUAGE SQL
BEGIN
CONCAT('{ "subject" : "', subject,
'", "message" : "', message, '" }')
);
END
;;
DELIMITER ;

Table
CREATE TABLE 'Customer_Feedback' (
'id' int(11) NOT NULL AUTO_INCREMENT,
'customer_name' varchar(255) NOT NULL,
'customer_feedback' varchar(1024) NOT NULL,
PRIMARY KEY ('id')
) ENGINE=InnoDB DEFAULT CHARSET=utf8;

Trigger
DELIMITER ;;
CREATE TRIGGER TR_Customer_Feedback_AI
AFTER INSERT ON Customer_Feedback
FOR EACH ROW
BEGIN
SELECT CONCAT('New customer feedback from ', NEW.customer_name), NEW.customer_feedback
INTO @subject, @feedback;

1082


Insert a Row into the Table to Trigger the Notification

```sql
mysql> insert into Customer_Feedback (customer_name, customer_feedback) VALUES ('Sample Customer', 'Good job guys!');
```

Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs

You can configure your Aurora MySQL DB cluster to publish general, slow, audit, and error log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage.

To publish logs to CloudWatch Logs, the respective logs must be enabled. Error logs are enabled by default, but you must enable the other types of logs explicitly. For information about enabling logs in MySQL, see Selecting general query and slow query log output destinations in the MySQL documentation. For more information about enabling Aurora MySQL audit logs, see Enabling Advanced Auditing (p. 980).

**Note**

Be aware of the following:

- You can't publish logs to CloudWatch Logs for the China (Ningxia) region.
- If exporting log data is disabled, Aurora doesn't delete existing log groups or log streams. If exporting log data is disabled, existing log data remains available in CloudWatch Logs, depending on log retention, and you still incur charges for stored audit log data. You can delete log streams and log groups using the CloudWatch Logs console, the AWS CLI, or the CloudWatch Logs API.
- An alternative way to publish audit logs to CloudWatch Logs is by enabling Advanced Auditing, then creating a custom DB cluster parameter group and setting the `server_audit_logs_upload` parameter to 1. The default for the `server_audit_logs_upload` DB cluster parameter is 0. For information on enabling Advanced Auditing, see Using Advanced Auditing with an Amazon Aurora MySQL DB cluster (p. 980).

If you use this alternative method, you must have an IAM role to access CloudWatch Logs and set the `aws_default_logs_role` cluster-level parameter to the ARN for this role. For information about creating the role, see Setting up IAM roles to access AWS services (p. 1048). However, if you have the `AWSServiceRoleForRDS` service-linked role, it provides access to CloudWatch Logs and overrides any custom-defined roles. For information about service-linked roles for Amazon RDS, see Using service-linked roles for Amazon Aurora (p. 2475).

- If you don't want to export audit logs to CloudWatch Logs, make sure that all methods of exporting audit logs are disabled. These methods are the AWS Management Console, the AWS CLI, the RDS API, and the `server_audit_logs_upload` parameter.
- The procedure is slightly different for Aurora Serverless v1 clusters than for clusters with provisioned or Aurora Serverless v2 instances. Aurora Serverless v1 clusters automatically upload all the kinds of logs that you enable through the configuration parameters. Therefore, you turn on or turn off log upload for Serverless clusters by turning different log types on and off in the DB cluster parameter group. You don't modify the settings of the cluster itself.
Publishing Aurora MySQL logs to CloudWatch Logs

through the AWS Management Console, AWS CLI, or RDS API. For information about turning on and off MySQL logs for Aurora Serverless v1 clusters, see Parameter groups for Aurora Serverless v1 (p. 2034).

**Console**

You can publish Aurora MySQL logs for provisioned clusters to CloudWatch Logs with the console.

**To publish Aurora MySQL logs from the console**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Databases.
3. Choose the Aurora MySQL DB cluster that you want to publish the log data for.
4. Choose Modify.
5. In the Log exports section, choose the logs that you want to start publishing to CloudWatch Logs.
6. Choose Continue, and then choose Modify DB Cluster on the summary page.

**AWS CLI**

You can publish Aurora MySQL logs for provisioned clusters with the AWS CLI. To do so, you run the `modify-db-cluster` AWS CLI command with the following options:

- `--db-cluster-identifier`—The DB cluster identifier.
- `--cloudwatch-logs-export-configuration`—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

You can also publish Aurora MySQL logs by running one of the following AWS CLI commands:

- `create-db-cluster`
- `restore-db-cluster-from-s3`
- `restore-db-cluster-from-snapshot`
- `restore-db-cluster-to-point-in-time`

Run one of these AWS CLI commands with the following options:

- `--db-cluster-identifier`—The DB cluster identifier.
- `--engine`—The database engine.
- `--enable-cloudwatch-logs-exports`—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

Other options might be required depending on the AWS CLI command that you run.

**Example**

The following command modifies an existing Aurora MySQL DB cluster to publish log files to CloudWatch Logs.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster
   --db-cluster-identifier mydbcluster
```
Publishing Aurora MySQL logs to CloudWatch Logs

Example

The following command creates an Aurora MySQL DB cluster to publish log files to CloudWatch Logs.

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster
--db-cluster-identifier mydbcluster
--engine aurora
--enable-cloudwatch-logs-exports
["error", "general", "slowquery", "audit"]
```

For Windows:

```bash
aws rds create-db-cluster
--db-cluster-identifier mydbcluster
--engine aurora
--enable-cloudwatch-logs-exports
["error", "general", "slowquery", "audit"]
```

RDS API

You can publish Aurora MySQL logs for provisioned clusters with the RDS API. To do so, you run the `ModifyDBCluster` operation with the following options:

- **DBClusterIdentifier**—The DB cluster identifier.
- **CloudwatchLogsExportConfiguration**—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

You can also publish Aurora MySQL logs with the RDS API by running one of the following RDS API operations:

- `CreateDBCluster`
- `RestoreDBClusterFromS3`
- `RestoreDBClusterFromSnapshot`
- `RestoreDBClusterToPointInTime`

Run the RDS API operation with the following parameters:

- **DBClusterIdentifier**—The DB cluster identifier.
- **Engine**—The database engine.
- **EnableCloudwatchLogsExports**—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.
Monitoring log events in Amazon CloudWatch

After enabling Aurora MySQL log events, you can monitor the events in Amazon CloudWatch Logs. A new log group is automatically created for the Aurora DB cluster under the following prefix, in which `cluster-name` represents the DB cluster name, and `log_type` represents the log type.

```
/aws/rds/cluster/cluster-name/log_type
```

For example, if you configure the export function to include the slow query log for a DB cluster named `mydbcluster`, slow query data is stored in the `/aws/rds/cluster/mydbcluster/slowquery` log group.

The events from all instances in your cluster are pushed to a log group using different log streams. The behavior depends on which of the following conditions is true:

- A log group with the specified name exists.
  - Aurora uses the existing log group to export log data for the cluster. To create log groups with predefined log retention periods, metric filters, and customer access, you can use automated configuration, such as AWS CloudFormation.
- A log group with the specified name doesn't exist.
  - When a matching log entry is detected in the log file for the instance, Aurora MySQL creates a new log group in CloudWatch Logs automatically. The log group uses the default log retention period of **Never Expire**.

  To change the log retention period, use the CloudWatch Logs console, the AWS CLI, or the CloudWatch Logs API. For more information about changing log retention periods in CloudWatch Logs, see [Change log data retention in CloudWatch Logs](#).

To search for information within the log events for a DB cluster, use the CloudWatch Logs console, the AWS CLI, or the CloudWatch Logs API. For more information about searching and filtering log data, see [Searching and filtering log data](#).

Using Amazon Aurora machine learning with Aurora MySQL

By using Amazon Aurora machine learning with your Aurora MySQL DB cluster, you can use Amazon Comprehend or Amazon SageMaker or both, depending on your needs. Amazon Comprehend and SageMaker each support different machine learning use cases, as follows.

**Amazon Comprehend**

Amazon Comprehend is a managed natural language processing (NLP) service that's used to extract insights from documents. With Amazon Comprehend, you can deduce sentiment based on the content of documents, by analyzing entities, key phrases, language, and other features. To learn more, see [What is Amazon Comprehend?](#) in the [Amazon Comprehend Developer Guide](#).

**SageMaker**

Amazon SageMaker is a fully managed machine learning service. Data scientists and developers use Amazon SageMaker to build, train, and test machine learning models for a variety of inference tasks, such as fraud detection and product recommendation. When a machine learning model is ready
for use in production, it can be deployed to the Amazon SageMaker hosted environment. For more information, see What Is Amazon SageMaker? in the Amazon SageMaker Developer Guide.

Using Amazon Comprehend with your Aurora DB cluster has less preliminary setup than using SageMaker. If you're new to both AWS machine learning and to Aurora machine learning, we recommend that you start by exploring Amazon Comprehend.

Aurora machine learning is supported in certain AWS Regions and for specific versions of Aurora MySQL only. Before trying to set up Aurora machine learning, check availability for your Aurora MySQL version and your Region. For details, see Aurora machine learning with Aurora MySQL (p. 40).

Topics
- Requirements for using Aurora machine learning with Aurora MySQL (p. 1087)
- Prerequisites for Aurora machine learning (p. 1087)
- Region and version availability (p. 1087)
- Enabling Aurora machine learning (p. 1087)
- Supported features and limitations of Aurora machine learning with Aurora MySQL (p. 1088)
- Setting up your Aurora MySQL DB cluster to use Aurora machine learning (p. 1089)
- Using Amazon Comprehend with your Aurora MySQL DB cluster (p. 1094)
- Using SageMaker with your Aurora MySQL DB cluster (p. 1096)
- Performance considerations for using Aurora machine learning with Aurora MySQL (p. 1098)
- Monitoring Aurora machine learning (p. 1100)

Requirements for using Aurora machine learning with Aurora MySQL

AWS machine learning services are managed services that are set up and run in their own production environments. Aurora machine learning supports integration with Amazon Comprehend and SageMaker. Before trying to set up your Aurora MySQL DB cluster to use Aurora machine learning, be sure you understand the following requirements and prerequisites.

Prerequisites for Aurora machine learning

You can upgrade an Aurora cluster that's running a lower version of Aurora MySQL to a supported higher version if you want to use Aurora machine learning with that cluster. For more information, see Database engine updates for Amazon Aurora MySQL (p. 1200).

Region and version availability

Feature availability and support varies across specific versions of each Aurora database engine, and across AWS Regions. For more information on version and Region availability with Aurora MySQL and Aurora machine learning, see Aurora machine learning with Aurora MySQL (p. 40).

Enabling Aurora machine learning

Enabling the ML capabilities involves the following steps:

- The Amazon Comprehend and SageMaker services must be running in the same AWS Region as your Aurora MySQL DB cluster. You can't use Amazon Comprehend or SageMaker services from an Aurora MySQL DB cluster in a different Region.
• If your Aurora MySQL DB cluster is in a different virtual public cloud (VPC) based on the Amazon VPC service than your Amazon Comprehend and SageMaker services, the VPC’s Security group needs to allow outbound connections to the target Aurora machine learning service. For more information, see Enabling network communication from Amazon Aurora MySQL to other AWS services (p. 1058).

• Your Aurora MySQL DB cluster needs to use a custom DB cluster parameter group. At the end of the setup process for each Aurora machine learning service that you want to use, you add the Amazon Resource Name (ARN) of the associated IAM role that was created for the service. We recommend that you create a custom DB cluster parameter group for your Aurora MySQL in advance and configure your Aurora MySQL DB cluster to use it so that it’s ready for you to modify at the end of the setup process.

• For SageMaker, the machine learning components that you want to use for inferences must be setup and ready to use. During the configuration process for your Aurora MySQL DB cluster, you need to have the Amazon Resource Name (ARN) of the SageMaker endpoint available. The data scientists on your team are likely best able to handle working with SageMaker to prepare the models and handle the other such tasks. To get started with Amazon SageMaker, see Get Started with Amazon SageMaker. For more information about inferences and endpoints, see Real-time inference.

• To use SageMaker with your own training data, you need to set up an Amazon Simple Storage Service (Amazon S3) bucket as part of your Aurora MySQL configuration for Aurora machine learning. To do so, you follow the same general process as for setting up the SageMaker integration. For a summary of this optional setup process, see Setting up your Aurora MySQL DB cluster to use Amazon S3 for SageMaker (Optional) (p. 1092).

• For Aurora global databases, you set up the Aurora machine learning services that you want to use in all AWS Regions that make up your Aurora global database. For example, if you want to use Aurora machine learning with SageMaker for your Aurora global database, you do as follows for every Aurora MySQL DB cluster in every AWS Region.

  • Set up the Amazon SageMaker services with the same SageMaker training models and endpoints. These must also use the same names.
  • Create the IAM roles as detailed in Setting up your Aurora MySQL DB cluster to use Aurora machine learning (p. 1089).
  • Add the ARN of the IAM role to the custom DB cluster parameter group for each Aurora MySQL DB cluster in every AWS Region.

These tasks require that Aurora machine learning is available for your version of Aurora MySQL in all AWS Regions that make up your Aurora global database.

Supported features and limitations of Aurora machine learning with Aurora MySQL

When using Aurora MySQL with Aurora machine learning, the following limitations apply.

• **Supported SageMaker algorithm formats** – Aurora MySQL supports any SageMaker endpoint that read and write comma-separated value (CSV) format, through a ContentType of text/csv. Currently, this format is accepted by the following built-in SageMaker algorithms.
  • Linear Learner
  • Random Cut Forest
  • XGBoost

To learn more about these algorithms, see Choose an Algorithm in the Amazon SageMaker Developer Guide.

• **Aurora MySQL stored function limitations** – Aurora machine learning functions aren't compatible with the binary log (binlog) format. This affects your Aurora machine learning integration as follows.

  • Stored functions that call tables with generated-always columns aren’t supported. This applies to any Aurora MySQL stored function. To learn more about this column type, see CREATE TABLE and Generated Columns in the MySQL documentation.
• The setting --binlog-format=STATEMENT throws an exception for calls to Aurora machine learning functions. Aurora machine learning functions are nondeterministic, and nondeterministic stored functions aren't compatible with the binlog format.

For more information about the binlog format, see Binary Logging Formats in the MySQL documentation.

Setting up your Aurora MySQL DB cluster to use Aurora machine learning

As mentioned in Using Amazon Aurora machine learning with Aurora MySQL (p. 1086), Amazon Comprehend and SageMaker support different machine learning use cases. In the following topics, you can find separate setup procedures for each of these Aurora machine learning services.

Topics
• Setting up your Aurora MySQL DB cluster to use Amazon Comprehend (p. 1089)
• Setting up your Aurora MySQL DB cluster to use SageMaker (p. 1090)
  • Setting up your Aurora MySQL DB cluster to use Amazon S3 for SageMaker (Optional) (p. 1092)
• Granting database users access to Aurora machine learning (p. 1093)
  • Granting access to Amazon Comprehend functions (p. 1094)
  • Granting access to SageMaker functions (p. 1094)

Setting up your Aurora MySQL DB cluster to use Amazon Comprehend

Aurora machine learning relies on AWS Identity and Access Management roles and policies to allow your Aurora MySQL DB cluster to access and use the Amazon Comprehend services. The following procedure automatically creates an IAM role and policy for your cluster so that it can use Amazon Comprehend.

To set up your Aurora MySQL DB cluster to use Amazon Comprehend

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Databases from the Amazon RDS navigation menu and then choose the Aurora MySQL DB cluster that you want to connect to Amazon Comprehend services.
3. Choose the Connectivity & security tab.
4. Scroll to the Manage IAM roles section, and then choose Select a service to connect to this cluster. Choose Amazon Comprehend from the selector, and then choose Connect service.

5. The Connect cluster to Amazon Comprehend dialog doesn't require any additional information. However, you might see a message notifying you that the integration between Aurora and Amazon

1089
Comprehend is currently in preview. Be sure to read the message before you continue. You can choose Cancel if you prefer not to proceed.

6. Choose Connect service to complete the integration process.

Aurora creates the IAM role. It also creates the policy that allows the Aurora MySQL to use Amazon Comprehend services and attaches the policy to the role. When the process completes, you can find the role in the Current IAM roles for this cluster list as shown in the following image.

![Current IAM roles for this cluster](image)

You need to add the ARN of this IAM role to the aws_default_comprehend_role parameter of your Aurora MySQL DB cluster. If your Aurora MySQL DB cluster doesn't use a custom DB cluster parameter group, you need to create one to use with your Aurora MySQL DB cluster to complete the integration. For more information, see Working with DB cluster parameter groups (p. 214).

After creating your custom DB cluster parameter group and associating it with your Aurora MySQL DB cluster, you can continue following these steps.

If your cluster uses a custom DB cluster parameter group, do as follows.

a. In the Amazon RDS Console, open the Configuration tab of your Aurora MySQL DB cluster.

b. Locate the DB cluster parameter group configured for your cluster, and choose the link to open your custom DB cluster parameter group. Choose Edit parameters.

c. Find the aws_default_comprehend_role parameter in your custom DB cluster parameter group.

d. In the Value field, enter the ARN of the IAM role.

e. Choose Save changes to save the setting. In the following image, you can find an example.

![Example of adding IAM role ARN](image)

Reboot the primary instance of your Aurora MySQL DB cluster so that this parameter setting takes effect.

The IAM integration for Amazon Comprehend is complete. Continue setting up your Aurora MySQL DB cluster to work with Amazon Comprehend by granting access to the appropriate database users.

Setting up your Aurora MySQL DB cluster to use SageMaker

The following procedure automatically creates the IAM role and policy for your Aurora MySQL DB cluster so that it can use SageMaker. Before trying to follow this procedure, be sure that you have the
SageMaker endpoint available so that you can enter it when needed. Typically, data scientists on your team would do the work to produce an endpoint that you can use from your Aurora MySQL DB cluster. You can find such endpoints in the SageMaker console. In the navigation pane, open the Inference menu and choose Endpoints. In the following image, you can find an example.

To set up your Aurora MySQL DB cluster to use SageMaker

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Databases from the Amazon RDS navigation menu and then choose the Aurora MySQL DB cluster that you want to connect to SageMaker services.
3. Choose the Connectivity & security tab
4. Scroll to the Manage IAM roles section, and then choose Select a service to connect to this cluster. Choose SageMaker from the selector.
5. Choose Connect service.
6. In the Connect cluster to SageMaker dialog, enter the Amazon Resource Name (ARN) of the SageMaker endpoint.

An Amazon Resource Name (ARN) of an Amazon SageMaker endpoint is required to connect to the service.
7. Aurora creates the IAM role. It also creates the policy that allows the Aurora MySQL to use SageMaker services and attaches the policy to the role. When the process completes, you can find the role in the **Current IAM roles for this cluster** list.

9. Choose **Roles** from the Access management section of the AWS Identity and Access Management navigation menu.

10. Find the role from among those listed. Its name uses the following pattern:

    ```markdown
    rds-sagemaker-<your-cluster-name>-role-auto-generated-digits
    ```

11. Open the role's Summary page and locate the ARN. Note the ARN or copy it using the copy widget.

13. Choose your Aurora MySQL DB cluster, and then choose its **Configuration** tab.

14. Locate the DB cluster parameter group, and choose the link to open your custom DB cluster parameter group. Find the `aws_default_sagemaker_role` parameter and enter the ARN of the IAM role in the Value field and Save the setting.

15. Reboot the primary instance of your Aurora MySQL DB cluster so that this parameter setting takes effect.

The IAM setup is now complete. Continue setting up your Aurora MySQL DB cluster to work with SageMaker by granting access to the appropriate database users.

If you want to use your SageMaker models for training rather than using pre-built SageMaker components, you also need to add the Amazon S3 bucket to your Aurora MySQL DB cluster, as outlined in the Setting up your Aurora MySQL DB cluster to use Amazon S3 for SageMaker (Optional) (p. 1092) that follows.

### Setting up your Aurora MySQL DB cluster to use Amazon S3 for SageMaker (Optional)

To use SageMaker with your own models rather than using the pre-built components provided by SageMaker, you need to set up an Amazon Simple Storage Service (Amazon S3) bucket for Aurora MySQL DB cluster to use. For more information about creating an Amazon S3 bucket, see [Creating a bucket](https://docs.aws.amazon.com/AmazonS3/latest/userguide/) in the Amazon Simple Storage Service User Guide.

**To set up your Aurora MySQL DB cluster to use an Amazon S3 bucket for SageMaker**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).

2. Choose **Databases** from the Amazon RDS navigation menu and then choose the Aurora MySQL DB cluster that you want to connect to SageMaker services.

3. Choose the **Connectivity & security** tab.

4. Scroll to the **Manage IAM roles** section, and then choose **Select a service to connect to this cluster**. Choose **Amazon S3** from the selector.
5. Choose **Connect service**.

6. In the **Connect cluster to Amazon S3** dialog, enter the Amazon Resource Name (ARN) of the Amazon S3 bucket, as shown in the following image.

![Connect cluster to Amazon S3](image)

7. Choose **Connect service** to complete this process.

For more information about using Amazon S3 buckets with SageMaker, see [Specify an Amazon S3 Bucket to Upload Training Datasets and Store Output Data](amazon_sagemaker_documentation) in the *Amazon SageMaker Developer Guide*. To learn more about working with SageMaker, see [Get Started with Amazon SageMaker Notebook Instances](amazon_sagemaker_documentation) in the *Amazon SageMaker Developer Guide*.

### Granting database users access to Aurora machine learning

Aurora machine learning includes built-in functions for working with Amazon Comprehend and SageMaker. Database users must be granted permission to invoke these built-in functions. How you grant permission depends on the version of MySQL that you use for your Aurora MySQL DB cluster, as outlined in the following. How you do so depends on the version of MySQL that your Aurora MySQL DB cluster uses.

- For Aurora MySQL 3 (MySQL 8.0 compatible), database users must be granted the appropriate **database role**. For more information about MySQL 3 database roles, see [Using Roles](mysql_reference) in the MySQL 8.0 Reference Manual.

- For Aurora MySQL 2 (MySQL 5.7 compatible), database users are granted **privileges**. For more information, see [Access Control and Account Management](mysql_reference) in the MySQL 5.7 Reference Manual.

In the following table you can find the role or privilege that database users need to work with Amazon Comprehend and SageMaker functions.
Using Aurora machine learning with Aurora MySQL

Granting access to Amazon Comprehend functions

To give database users access to Amazon Comprehend functions, use the appropriate statement for your Aurora MySQL version.

- **Aurora MySQL version 3 (MySQL 8.0 compatible)**
  
  ```sql
  GRANT AWS_COMPREHEND_ACCESS TO user@domain-or-ip-address
  ```

- **Aurora MySQL version 2 (MySQL 5.7 compatible)**
  
  ```sql
  GRANT INVOKE COMPREHEND ON *.* TO user@domain-or-ip-address
  ```

The Amazon Comprehend functions are now available for use. For usage examples, see [Using Amazon Comprehend with your Aurora MySQL DB cluster](p. 1094).

Granting access to SageMaker functions

To give database users access to SageMaker functions, use the appropriate statement for your Aurora MySQL version.

- **Aurora MySQL version 3 (MySQL 8.0 compatible)**
  
  ```sql
  GRANT AWS_SAGEMAKER_ACCESS TO user@domain-or-ip-address
  ```

- **Aurora MySQL version 2 (MySQL 5.7 compatible)**
  
  ```sql
  GRANT INVOKE SAGEMAKER ON *.* TO user@domain-or-ip-address
  ```

Database users also need to be granted EXECUTE permissions for the functions that you create for working with SageMaker. Suppose that you created two functions, `db1.anomaly_score` and `db2.company_forecasts`, to invoke the services of your SageMaker endpoint. You grant execute privileges as shown following.

```sql
GRANT EXECUTE ON FUNCTION db1.anomaly_score TO user1@domain-or-ip-address1
GRANT EXECUTE ON FUNCTION db2.company_forecasts TO user2@domain-or-ip-address2
```

The SageMaker functions are now available for use. For usage examples, see [Using SageMaker with your Aurora MySQL DB cluster](p. 1096).

**Using Amazon Comprehend with your Aurora MySQL DB cluster**

For Aurora MySQL, Aurora machine learning provides the following two built-in functions for working with Amazon Comprehend and your text data. You provide the text to analyze (input_data) and specify the language (language_code).
aws_comprehend_detect_sentiment

This function identifies the text as having a positive, negative, neutral, or mixed emotional posture. This function's reference documentation is as follows.

```python
aws_comprehend_detect_sentiment(
    input_text,  # required
    language_code=language_code,  # required
    [max_batch_size],  # optional
)
```

To learn more, see Sentiment in the Amazon Comprehend Developer Guide.

aws_comprehend_detect_sentiment_confidence

This function measures the confidence level of the sentiment detected for a given text. It returns a value (type, double) that indicates the confidence of the sentiment assigned by the `aws_comprehend_detect_sentiment` function to the text. Confidence is a statistical metric between 0 and 1. The higher the confidence level, the more weight you can give the result. A summary of the function's documentation is as follows.

```python
aws_comprehend_detect_sentiment_confidence(
    input_text,  # required
    language_code=language_code,  # required
    [max_batch_size],  # optional
)
```

In both functions (`aws_comprehend_detect_sentiment_confidence`, `aws_comprehend_detect_sentiment`) the `max_batch_size` uses a default value of 25 if none is specified. Batch size should always be greater than 0. You can use `max_batch_size` to tune the performance of the Amazon Comprehend function calls. A large batch size trades off faster performance for greater memory usage on the Aurora MySQL DB cluster. For more information, see Performance considerations for using Aurora machine learning with Aurora MySQL (p. 1098).

For more information about parameters and return types for the sentiment detection functions in Amazon Comprehend, see DetectSentiment

Example Example: A simple query using Amazon Comprehend functions

Here's an example of a simple query that invokes these two functions to see how happy your customers are with your support team. Suppose you have a database table (`support`) that stores customer feedback after each request for help. This example query applies both built-in functions to the text in the `feedback` column of the table and outputs the results. The confidence values returned by the function are doubles between 0.0 and 1.0. For more readable output, this query rounds the results to 6 decimal points. For easier comparisons, this query also sorts the results in descending order, from the result having the highest degree of confidence, first.

```sql
SELECT feedback AS 'Customer feedback',
    aws_comprehend_detect_sentiment(feedback, 'en') AS Sentiment,
    ROUND(aws_comprehend_detect_sentiment_confidence(feedback, 'en'), 6) AS Confidence
FROM support
ORDER BY Confidence DESC;
```

<table>
<thead>
<tr>
<th>Customer feedback</th>
<th>Sentiment</th>
<th>Confidence</th>
</tr>
</thead>
<tbody>
<tr>
<td>Thank you for the excellent customer support!</td>
<td>POSITIVE</td>
<td>0.999771</td>
</tr>
<tr>
<td>The latest version of this product stinks!</td>
<td>NEGATIVE</td>
<td>0.999184</td>
</tr>
<tr>
<td>Your support team is just awesome! I am blown away.</td>
<td>POSITIVE</td>
<td>0.997774</td>
</tr>
<tr>
<td>Your product is too complex, but your support is great.</td>
<td>MIXED</td>
<td>0.957958</td>
</tr>
</tbody>
</table>
Example Example: Determining the average sentiment for text above a specific confidence level

A typical Amazon Comprehend query looks for rows where the sentiment is a certain value, with a confidence level greater than a certain number. For example, the following query shows how you can determine the average sentiment of documents in your database. The query considers only documents where the confidence of the assessment is at least 80%.

```
SELECT AVG(CASE aws_comprehend_detect_sentiment(productTable.document, 'en')
    WHEN 'POSITIVE' THEN 1.0
    WHEN 'NEGATIVE' THEN -1.0
    ELSE 0.0 END) AS avg_sentiment, COUNT(*) AS total
FROM productTable
WHERE productTable.productCode = 1302 AND
    aws_comprehend_detect_sentiment_confidence(productTable.document, 'en') >= 0.80;
```

Using SageMaker with your Aurora MySQL DB cluster

To use SageMaker functionality from your Aurora MySQL DB cluster, you need to create stored functions that embed your calls to the SageMaker endpoint and its inference features. You do so by using MySQL's CREATE FUNCTION in generally the same way that you do for other processing tasks on your Aurora MySQL DB cluster. In other words, you create user-defined functions using the familiar MySQL data definition language (DDL) statements for stored functions.

To use models deployed in SageMaker for inference, you create user-defined functions using the familiar MySQL data definition language (DDL) statements for stored functions. Each stored function represents the SageMaker endpoint hosting the model. When you define such a function, you specify the input parameters to the model, the specific SageMaker endpoint to invoke, and the return type. The function returns the inference computed by the SageMaker endpoint after applying the model to the input parameters.

All Aurora machine learning stored functions return numeric types or VARCHAR. You can use any numeric type except BIT. Other types, such as JSON, BLOB, TEXT, and DATE aren't allowed.

In the following example, you can find syntax pattern for the CREATE FUNCTION for working with SageMaker.

```
CREATE FUNCTION function_name (
    arg1 type1,
    arg2 type2, ...)
[DEFINER = user]
RETURNS mysql_type
[SQL SECURITY { DEFINER | INVOKER } ]
ALIAS AWS_SAGEMAKER_INVOKE_ENDPOINT
ENDPOINT NAME 'endpoint_name'
[MAX_BATCH_SIZE max_batch_size];
```

This is an extension of the regular CREATE FUNCTION DDL statement. In the CREATE FUNCTION statement that defines the SageMaker function, you don't specify a function body. Instead, you specify the keyword ALIAS where the function body usually goes. Currently, Aurora machine learning
only supports `aws_sagemaker_invoke_endpoint` for this extended syntax. You must specify the `endpoint_name` parameter. An SageMaker endpoint can have different characteristics for each model.

**Note**

The `max_batch_size` parameter is optional. By default, maximum batch size is 10,000. You can use this parameter in your function to restrict the maximum number of inputs processed in a batched request to SageMaker. The `max_batch_size` parameter can help to avoid an error caused by inputs that are too large, or to make SageMaker return a response more quickly. This parameter affects the size of an internal buffer used for SageMaker request processing. Specifying too large a value for `max_batch_size` might cause substantial memory overhead on your DB instance.

We recommend that you leave the `MANIFEST` setting at its default value of `OFF`. Although you can use the `MANIFEST ON` option, some SageMaker features can't directly use the CSV exported with this option. The manifest format is not compatible with the expected manifest format from SageMaker.

You create a separate stored function for each of your SageMaker models. This mapping of functions to models is required because an endpoint is associated with a specific model, and each model accepts different parameters. Using SQL types for the model inputs and the model output type helps to avoid type conversion errors passing data back and forth between the AWS services. You can control who can apply the model. You can also control the runtime characteristics by specifying a parameter representing the maximum batch size.

Currently, all Aurora machine learning functions have the `NOT DETERMINISTIC` property. If you don't specify that property explicitly, Aurora sets `NOT DETERMINISTIC` automatically. This requirement is because the SageMaker model can be changed without any notification to the database. If that happens, calls to an Aurora machine learning function might return different results for the same input within a single transaction.

You can't use the characteristics `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, or `MODIFIES SQL DATA` in your `CREATE FUNCTION` statement.

Following is an example usage of invoking an SageMaker endpoint to detect anomalies. There is an SageMaker endpoint `random-cut-forest-model`. The corresponding model is already trained by the `random-cut-forest` algorithm. For each input, the model returns an anomaly score. This example shows the data points whose score is greater than 3 standard deviations (approximately the 99.9th percentile) from the mean score.

```sql
CREATE FUNCTION anomaly_score(value real) returns real
    alias aws_sagemaker_invoke_endpoint endpoint name 'random-cut-forest-model-demo';

set @score_cutoff = (select avg(anomaly_score(value)) + 3 * std(anomaly_score(value)) from nyc_taxi);

select *, anomaly_detection(value) score from nyc_taxi
where anomaly_detection(value) > @score_cutoff;
```

### Character set requirement for SageMaker functions that return strings

We recommend specifying a character set of `utf8mb4` as the return type for your SageMaker functions that return string values. If that isn't practical, use a large enough string length for the return type to hold a value represented in the `utf8mb4` character set. The following example shows how to declare the `utf8mb4` character set for your function.

```sql
CREATE FUNCTION my_ml_func(...) RETURNS VARCHAR(5) CHARSET utf8mb4 ALIAS ...;
```

Currently, each SageMaker function that returns a string uses the character set `utf8mb4` for the return value. The return value uses this character set even if your SageMaker function declares a different
character set for its return type implicitly or explicitly. If your SageMaker function declares a different character set for the return value, the returned data might be silently truncated if you store it in a table column that isn't long enough. For example, a query with a DISTINCT clause creates a temporary table. Thus, the SageMaker function result might be truncated due to the way strings are handled internally during a query.

**Exporting data to Amazon S3 for SageMaker model training (Advanced)**

We recommend that you get started with Aurora machine learning and SageMaker by using some of the provided algorithms, and that the data scientists on your team provide you with the SageMaker endpoints that you can use with your SQL code. In the following, you can find minimal information about using your own Amazon S3 bucket with your own SageMaker models and your Aurora MySQL DB cluster.

Machine learning consists of two major steps: training, and inference. To train SageMaker models, you export data to an Amazon S3 bucket. The Amazon S3 bucket is used by a Jupyter SageMaker notebook instance to train your model before it is deployed. You can use the `SELECT INTO OUTFILE` statement to query data from an Aurora MySQL DB cluster and save it directly into text files stored in an Amazon S3 bucket. Then the notebook instance consumes the data from the Amazon S3 bucket for training.

Aurora machine learning extends the existing `SELECT INTO OUTFILE` syntax in Aurora MySQL to export data to CSV format. The generated CSV file can be directly consumed by models that need this format for training purposes.

```
SELECT * INTO OUTFILE S3 's3_uri' [FORMAT {CSV|TEXT} [HEADER]] FROM table_name;
```

The extension supports the standard CSV format.

- Format TEXT is the same as the existing MySQL export format. This is the default format.
- Format CSV is a newly introduced format that follows the specification in RFC-4180.
- If you specify the optional keyword HEADER, the output file contains one header line. The labels in the header line correspond to the column names from the `SELECT` statement.
- You can still use the keywords CSV and HEADER as identifiers.

The extended syntax and grammar of `SELECT INTO` is now as follows:

```
INTO OUTFILE S3 's3_uri'
[CHARACTER SET charset_name]
[FORMAT {CSV|TEXT} [HEADER]]
[[FIELDS | COLUMNS]
 [TERMINATED BY 'string']
 [[OPTIONALLY] ENCLOSED BY 'char']
 [ESCAPED BY 'char']
]
[LINES
 [STARTING BY 'string']
 [TERMINATED BY 'string']
]
```

**Performance considerations for using Aurora machine learning with Aurora MySQL**

The Amazon Comprehend and SageMaker services do most of the work when invoked by an Aurora machine learning function. That means that you can scale those resources as needed, independently. For
your Aurora MySQL DB cluster, you can make your function calls as efficient as possible. Following, you can find some performance considerations to note when working with Aurora machine learning.

Query cache

The Aurora MySQL query cache doesn't work for Aurora machine learning functions. Aurora MySQL doesn't store query results in the query cache for any SQL statements that call Aurora machine learning functions.

Batch optimization for Aurora machine learning function calls

The main Aurora machine learning performance aspect that you can influence from your Aurora cluster is the batch mode setting for calls to the Aurora machine learning stored functions. Machine learning functions typically require substantial overhead, making it impractical to call an external service separately for each row. Aurora machine learning can minimize this overhead by combining the calls to the external Aurora machine learning service for many rows into a single batch. Aurora machine learning receives the responses for all the input rows, and delivers the responses, one row at a time, to the query as it runs. This optimization improves the throughput and latency of your Aurora queries without changing the results.

When you create an Aurora stored function that's connected to an SageMaker endpoint, you define the batch size parameter. This parameter influences how many rows are transferred for every underlying call to SageMaker. For queries that process large numbers of rows, the overhead to make a separate SageMaker call for each row can be substantial. The larger the data set processed by the stored procedure, the larger you can make the batch size.

If the batch mode optimization can be applied to an SageMaker function, you can tell by checking the query plan produced by the \texttt{EXPLAIN PLAN} statement. In this case, the extra column in the execution plan includes \texttt{Batched machine learning}.

```
mysql> CREATE FUNCTION anomaly_score(val real) returns real alias
  aws_sagemaker_invoke_endpoint endpoint name 'my-rcf-model-20191126';
Query OK, 0 rows affected (0.01 sec)
mysql> explain select timestamp, value, anomaly_score(value) from nyc_taxi;
+----+-------------+----------+------------+------+---------------+------+---------+------+
| id | select_type | table    | partitions | type | possible_keys | key  | key_len | ref  |
|    | rows        | filtered | Extra      |     |              |      |         |     |
+----+-------------+----------+------------+------+---------------+------+---------+------+
|  1 | SIMPLE      | nyc_taxi | ALL        | NULL | NULL          | NULL | NULL    | NULL |
|    | 48 | 100.00 | Batched machine learning |
+----+-------------+----------+------------+------+
| 1 row in set, 1 warning (0.01 sec)
```

When you call one of the built-in Amazon Comprehend functions, you can control the batch size by specifying the optional \texttt{max\_batch\_size} parameter. This parameter restricts the maximum number of \texttt{input\_text} values processed in each batch. By sending multiple items at once, it reduces the number of round trips between Aurora and Amazon Comprehend. Limiting the batch size is useful in situations such as a query with a \texttt{LIMIT} clause. By using a small value for \texttt{max\_batch\_size}, you can avoid invoking Amazon Comprehend more times than you have input texts.

The batch optimization for evaluating Aurora machine learning functions applies in the following cases:

* Function calls within the select list or the \texttt{WHERE} clause of \texttt{SELECT} statements. There are some exceptions, as described following.
• Function calls in the VALUES list of INSERT and REPLACE statements.
• SageMaker functions in SET values in UPDATE statements.

```sql
INSERT INTO MY_TABLE (col1, col2, col3) VALUES
  (ML_FUNC(1), ML_FUNC(2), ML_FUNC(3)),
  (ML_FUNC(4), ML_FUNC(5), ML_FUNC(6));
UPDATE MY_TABLE SET col1 = ML_FUNC(col2), SET col3 = ML_FUNC(col4) WHERE ...;
```

Monitoring Aurora machine learning

You can monitor Aurora machine learning batch operations by querying several global variables, as shown following.

```sql
show status like 'Aurora_ml%';
```

You can reset the status variables by using a FLUSH STATUS statement. Thus, all of the figures represent totals, averages, and so on, since the last time the variable was reset.

- **Aurora_ml_logical_request_cnt**
  - The number of logical requests that the DB instance has evaluated to be sent to the Aurora machine learning services since the last status reset. Depending on whether batching has been used, this value can be higher than **Aurora_ml_actual_request_cnt**.

- **Aurora_ml_logical_response_cnt**
  - The aggregate response count that Aurora MySQL receives from the Aurora machine learning services across all queries run by users of the DB instance.

- **Aurora_ml_actual_request_cnt**
  - The aggregate request count that Aurora MySQL makes to the Aurora machine learning services across all queries run by users of the DB instance.

- **Aurora_ml_actual_response_cnt**
  - The aggregate response count that Aurora MySQL receives from the Aurora machine learning services across all queries run by users of the DB instance.

- **Aurora_ml_cache_hit_cnt**
  - The aggregate internal cache hit count that Aurora MySQL receives from the Aurora machine learning services across all queries run by users of the DB instance.

- **Aurora_ml_retry_request_cnt**
  - The number of retried requests that the DB instance has sent to the Aurora machine learning services since the last status reset.

- **Aurora_ml_single_request_cnt**
  - The aggregate count of Aurora machine learning functions that are evaluated by non-batch mode across all queries run by users of the DB instance.

For information about monitoring the performance of the SageMaker operations called from Aurora machine learning functions, see [Monitor Amazon SageMaker](https://aws.amazon.com).
Amazon Aurora MySQL lab mode

Aurora lab mode is used to enable Aurora features that are available in the current Aurora database version, but are not enabled by default. While Aurora lab mode features are not recommended for use in production DB clusters, you can use Aurora lab mode to enable these features for DB clusters in your development and test environments. For more information about Aurora features available when Aurora lab mode is enabled, see Aurora lab mode features (p. 1101).

The `aurora_lab_mode` parameter is an instance-level parameter that is in the default parameter group. The parameter is set to 0 (disabled) in the default parameter group. To enable Aurora lab mode, create a custom parameter group, set the `aurora_lab_mode` parameter to 1 (enabled) in the custom parameter group, and modify one or more DB instances in your Aurora cluster to use the custom parameter group. Then connect to the appropriate instance endpoint to try the lab mode features. For information on modifying a DB parameter group, see Modifying parameters in a DB parameter group (p. 229). For information on parameter groups and Amazon Aurora, see Aurora MySQL configuration parameters (p. 1115).

Aurora lab mode features

The following table lists the Aurora features currently available when Aurora lab mode is enabled. You must enable Aurora lab mode before any of these features can be used.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scan Batching</td>
<td>Aurora MySQL scan batching speeds up in-memory, scan-oriented queries significantly. The feature boosts the performance of table full scans, index full scans, and index range scans by batch processing.</td>
</tr>
<tr>
<td>Hash Joins</td>
<td>This feature can improve query performance when you need to join a large amount of data by using an equijoin. You can use this feature without lab mode in Aurora MySQL version 2. For more information about using this feature, see Optimizing large Aurora MySQL join queries with hash joins (p. 1106).</td>
</tr>
<tr>
<td>Fast DDL</td>
<td>This feature allows you to run an ALTER TABLE <code>tbl_name</code> ADD COLUMN <code>col_name</code> <code>column_definition</code> operation nearly instantaneously. The operation completes without requiring the table to be copied and without materially impacting other DML statements. Since it does not consume temporary storage for a table copy, it makes DDL statements practical even for large tables on small instance classes. Fast DDL is currently only supported for adding a nullable column, without a default value, at the end of a table. For more information about using this feature, see Altering tables in Amazon Aurora using Fast DDL (p. 897).</td>
</tr>
</tbody>
</table>
Best practices with Amazon Aurora MySQL

This topic includes information on best practices and options for using or migrating data to an Amazon Aurora MySQL DB cluster. The information in this topic summarizes and reiterates some of the guidelines and procedures that you can find in Managing an Amazon Aurora DB cluster (p. 248).

Contents

• Determining which DB instance you are connected to (p. 1102)
• Best practices for Aurora MySQL performance and scaling (p. 1103)
  • Using T instance classes for development and testing (p. 1103)
  • Optimizing Aurora MySQL indexed join queries with asynchronous key prefetch (p. 1104)
    • Enabling asynchronous key prefetch (p. 1104)
    • Optimizing queries for asynchronous key prefetch (p. 1105)
  • Optimizing large Aurora MySQL join queries with hash joins (p. 1106)
    • Enabling hash joins (p. 1107)
    • Optimizing queries for hash joins (p. 1107)
  • Using Amazon Aurora to scale reads for your MySQL database (p. 1108)
  • Optimizing timestamp operations (p. 1108)
• Best practices for Aurora MySQL high availability (p. 1109)
  • Using Amazon Aurora for Disaster Recovery with your MySQL databases (p. 1109)
  • Migrating from MySQL to Amazon Aurora MySQL with reduced downtime (p. 1109)
  • Avoiding slow performance, automatic restart, and failover for Aurora MySQL DB instances (p. 1109)
• Recommendations for Aurora MySQL (p. 1110)
  • Using multithreaded replication in Aurora MySQL version 3 (p. 1110)
  • Invoking AWS Lambda functions using native MySQL functions (p. 1110)
  • Avoiding XA transactions with Amazon Aurora MySQL (p. 1111)
  • Keeping foreign keys turned on during DML statements (p. 1111)
  • Configuring how frequently the log buffer is flushed (p. 1111)
  • Minimizing and troubleshooting Aurora MySQL deadlocks (p. 1112)
    • Minimizing InnoDB deadlocks (p. 1112)
    • Monitoring InnoDB deadlocks (p. 1113)

Determining which DB instance you are connected to

To determine which DB instance in an Aurora MySQL DB cluster a connection is connected to, check the innodb_read_only global variable, as shown in the following example.

```sql
SHOW GLOBAL VARIABLES LIKE 'innodb_read_only';
```

The innodb_read_only variable is set to ON if you are connected to a reader DB instance. This setting is OFF if you are connected to a writer DB instance, such as primary instance in a provisioned cluster.

This approach can be helpful if you want to add logic to your application code to balance the workload or to ensure that a write operation is using the correct connection.
Best practices for Aurora MySQL performance and scaling

You can apply the following best practices to improve the performance and scalability of your Aurora MySQL clusters.

Topics

- Using T instance classes for development and testing (p. 1103)
- Optimizing Aurora MySQL indexed join queries with asynchronous key prefetch (p. 1104)
- Optimizing large Aurora MySQL join queries with hash joins (p. 1106)
- Using Amazon Aurora to scale reads for your MySQL database (p. 1108)
- Optimizing timestamp operations (p. 1108)

Using T instance classes for development and testing

Amazon Aurora MySQL instances that use the db.t2, db.t3, or db.t4g DB instance classes are best suited for applications that do not support a high workload for an extended amount of time. The T instances are designed to provide moderate baseline performance and the capability to burst to significantly higher performance as required by your workload. They are intended for workloads that don't use the full CPU often or consistently, but occasionally need to burst. We recommend using the T DB instance classes only for development and test servers, or other non-production servers. For more details on the T instance classes, see Burstable performance instances.

If your Aurora cluster is larger than 40 TB, don't use the T instance classes. When your database has a large volume of data, the memory overhead for managing schema objects can exceed the capacity of a T instance.

Don't enable the MySQL Performance Schema on Amazon Aurora MySQL T instances. If the Performance Schema is enabled, the instance might run out of memory.

Tip

If your database is sometimes idle but at other times has a substantial workload, you can use Aurora Serverless v2 as an alternative to T instances. With Aurora Serverless v2, you define a capacity range and Aurora automatically scales your database up or down depending on the current workload. For usage details, see Using Aurora Serverless v2 (p. 1961). For the database engine versions that you can use with Aurora Serverless v2, see Requirements for Aurora Serverless v2 (p. 1969).

When you use a T instance as a DB instance in an Aurora MySQL DB cluster, we recommend the following:

- Use the same DB instance class for all instances in your DB cluster. For example, if you use db.t2.medium for your writer instance, then we recommend that you use db.t2.medium for your reader instances also.
- Don't adjust any memory-related configuration settings, such as innodb_buffer_pool_size. Aurora uses a highly tuned set of default values for memory buffers on T instances. These special defaults are needed for Aurora to run on memory-constrained instances. If you change any memory-related settings on a T instance, you are much more likely to encounter out-of-memory conditions, even if your change is intended to increase buffer sizes.
- Monitor your CPU Credit Balance (CPUCreditBalance) to ensure that it is at a sustainable level. That is, CPU credits are being accumulated at the same rate as they are being used.

When you have exhausted the CPU credits for an instance, you see an immediate drop in the available CPU and an increase in the read and write latency for the instance. This situation results in a severe decrease in the overall performance of the instance.
If your CPU credit balance is not at a sustainable level, then we recommend that you modify your DB instance to use one of the supported R DB instance classes (scale compute).

For more information on monitoring metrics, see Viewing metrics in the Amazon RDS console (p. 535).

- Monitor the replica lag (AuroraReplicaLag) between the writer instance and the reader instances.

If a reader instance runs out of CPU credits before the writer instance does, the resulting lag can cause the reader instance to restart frequently. This result is common when an application has a heavy load of read operations distributed among reader instances, at the same time that the writer instance has a minimal load of write operations.

If you see a sustained increase in replica lag, make sure that your CPU credit balance for the reader instances in your DB cluster is not being exhausted.

If your CPU credit balance is not at a sustainable level, then we recommend that you modify your DB instance to use one of the supported R DB instance classes (scale compute).

- Keep the number of inserts per transaction below 1 million for DB clusters that have binary logging enabled.

If the DB cluster parameter group for your DB cluster has the binlog_format parameter set to a value other than OFF, then your DB cluster might experience out-of-memory conditions if the DB cluster receives transactions that contain over 1 million rows to insert. You can monitor the freeable memory (FreeableMemory) metric to determine if your DB cluster is running out of available memory. You then check the write operations (VolumeWriteIOPS) metric to see if a writer instance is receiving a heavy load of write operations. If this is the case, then we recommend that you update your application to limit the number of inserts in a transaction to less than 1 million. Alternatively, you can modify your instance to use one of the supported R DB instance classes (scale compute).

### Optimizing Aurora MySQL indexed join queries with asynchronous key prefetch

Aurora MySQL can use the asynchronous key prefetch (AKP) feature to improve the performance of queries that join tables across indexes. This feature improves performance by anticipating the rows needed to run queries in which a JOIN query requires use of the Batched Key Access (BKA) Join algorithm and Multi-Range Read (MRR) optimization features. For more information about BKA and MRR, see Block nested-loop and batched key access joins and Multi-range read optimization in the MySQL documentation.

To take advantage of the AKP feature, a query must use both BKA and MRR. Typically, such a query occurs when the JOIN clause of a query uses a secondary index, but also needs some columns from the primary index. For example, you can use AKP when a JOIN clause represents an equijoin on index values between a small outer and large inner table, and the index is highly selective on the larger table. AKP works in concert with BKA and MRR to perform a secondary to primary index lookup during the evaluation of the JOIN clause. AKP identifies the rows required to run the query during the evaluation of the JOIN clause. It then uses a background thread to asynchronously load the pages containing those rows into memory before running the query.

AKP is available for Aurora MySQL version 2.10 and higher, and version 3. For more information about Aurora MySQL versions, see Database engine updates for Amazon Aurora MySQL (p. 1200).

### Enabling asynchronous key prefetch

You can enable the AKP feature by setting aurora_use_key_prefetch, a MySQL server variable, to on. By default, this value is set to on. However, AKP can't be enabled until you also enable the BKA Join algorithm and disable cost-based MRR functionality. To do so, you must set the following values for optimizer_switch, a MySQL server variable:
- Set `batched_key_access` to on. This value controls the use of the BKA Join algorithm. By default, this value is set to off.
- Set `mrr_cost_based` to off. This value controls the use of cost-based MRR functionality. By default, this value is set to on.

Currently, you can set these values only at the session level. The following example illustrates how to set these values to enable AKP for the current session by executing SET statements.

```
mysql> set @@session.aurora_use_key_prefetch=on;
mysql> set @@session.optimizer_switch='batched_key_access=on,mrr_cost_based=off';
```

Similarly, you can use SET statements to disable AKP and the BKA Join algorithm and re-enable cost-based MRR functionality for the current session, as shown in the following example.

```
mysql> set @@session.aurora_use_key_prefetch=off;
mysql> set @@session.optimizer_switch='batched_key_access=off,mrr_cost_based=on';
```

For more information about the `batched_key_access` and `mrr_cost_based` optimizer switches, see `Switchable optimizations` in the MySQL documentation.

**Optimizing queries for asynchronous key prefetch**

You can confirm whether a query can take advantage of the AKP feature. To do so, use the EXPLAIN statement to profile the query before running it. The EXPLAIN statement provides information about the execution plan to use for a specified query.

In the output for the EXPLAIN statement, the `Extra` column describes additional information included with the execution plan. If the AKP feature applies to a table used in the query, this column includes one of the following values:

- Using Key Prefetching
- Using join buffer (Batched Key Access with Key Prefetching)

The following example shows the use of EXPLAIN to view the execution plan for a query that can take advantage of AKP.

```
mysql> explain select sql_no_cache
   ->   ps_partkey,
   ->   sum(ps_supplycost * ps_availqty) as value
   -> from
   ->   partsupp,
   ->   supplier,
   ->   nation
   -> where
   ->   ps_suppkey = s_suppkey
   ->   and s_nationkey = n_nationkey
   ->   and n_name = 'ETHIOPIA'
   -> group by
   ->   ps_partkey having
   ->   sum(ps_supplycost * ps_availqty) > (select
   ->       sum(ps_supplycost * ps_availqty) * 0.0000003333
   -> from
   ->   partsupp,
   ->   supplier,
```
```sql
-> nation
-> where
-> ps_suppkey = s_suppkey
-> and s_nationkey = n_nationkey
-> and n_name = 'ETHIOPIA'
->
-> order by
-> value desc;
```

For more information about the EXPLAIN output format, see Extended EXPLAIN output format in the MySQL documentation.

### Optimizing large Aurora MySQL join queries with hash joins

When you need to join a large amount of data by using an equijoin, a hash join can improve query performance. You can enable hash joins for Aurora MySQL.

A hash join column can be any complex expression. In a hash join column, you can compare across data types in the following ways:

- You can compare anything across the category of precise numeric data types, such as int, bigint, numeric, and bit.
- You can compare anything across the category of approximate numeric data types, such as float and double.
- You can compare items across string types if the string types have the same character set and collation.
- You can compare items with date and timestamp data types if the types are the same.

**Note**

You can't compare data types in different categories.
The following restrictions apply to hash joins for Aurora MySQL:

- Left-right outer joins aren't supported for Aurora MySQL version 2, but are supported for version 3.
- Semijoins such as subqueries aren't supported, unless the subqueries are materialized first.
- Multiple-table updates or deletes aren't supported.
  
  **Note**
  
  Single-table updates or deletes are supported.

- BLOB and spatial data type columns can't be join columns in a hash join.

### Enabling hash joins

To enable hash joins:

- **Aurora MySQL version 2** – Set the DB parameter or DB cluster parameter `aurora_disable_hash_join` to `0`. Turning off `aurora_disable_hash_join` sets the value of `optimizer_switch` to `hash_join=on`.
- **Aurora MySQL version 3** – Set the MySQL server parameter `optimizer_switch` to `block_nested_loop=on`.

Hash joins are turned on by default in Aurora MySQL version 3 and turned off by default in Aurora MySQL version 2. The following example illustrates how to enable hash joins for Aurora MySQL version 3. You can issue the statement `select @@optimizer_switch` first to see what other settings are present in the `SET` parameter string. Updating one setting in the `optimizer_switch` parameter doesn't erase or modify the other settings.

```sql
mysql> SET optimizer_switch='block_nested_loop=on';
```

**Note**

For Aurora MySQL version 3, hash join support is available in all minor versions and is turned on by default.

For Aurora MySQL version 2, hash join support is available in all minor versions.

In Aurora MySQL version 2, the hash join feature is always controlled by the `aurora_disable_hash_join` value.

With this setting, the optimizer chooses to use a hash join based on cost, query characteristics, and resource availability. If the cost estimation is incorrect, you can force the optimizer to choose a hash join. You do so by setting `hash_join_cost_based`, a MySQL server variable, to `off`. The following example illustrates how to force the optimizer to choose a hash join.

```sql
mysql> SET optimizer_switch='hash_join_cost_based=off';
```

**Note**

This setting overrides the decisions of the cost-based optimizer. While the setting can be useful for testing and development, we recommend that you not use it in production.

### Optimizing queries for hash joins

To find out whether a query can take advantage of a hash join, use the EXPLAIN statement to profile the query first. The EXPLAIN statement provides information about the execution plan to use for a specified query.

In the output for the EXPLAIN statement, the `Extra` column describes additional information included with the execution plan. If a hash join applies to the tables used in the query, this column includes values similar to the following:
• Using where; Using join buffer (Hash Join Outer table `table1_name`)
• Using where; Using join buffer (Hash Join Inner table `table2_name`)

The following example shows the use of EXPLAIN to view the execution plan for a hash join query.

```
mysql> explain SELECT sql_no_cache * FROM hj_small, hj_big, hj_big2
    -> WHERE hj_small.col1 = hj_big.col1 and hj_big.col1=hj_big2.col1 ORDER BY 1;
+----+-------------+----------+------+---------------+------+---------+------+------+
<table>
<thead>
<tr>
<th>id</th>
<th>select_type</th>
<th>table</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>
<th>rows</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SIMPLE</td>
<td>hj_small</td>
<td>ALL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>6</td>
<td>Using</td>
</tr>
</tbody>
</table>
+----+-------------+----------+------|---------------|------|---------+------|------|-------|
| 1  | SIMPLE      | hj_big   | ALL  | NULL          | NULL | NULL    | NULL | 10   | Using |
| 1  | SIMPLE      | hj_big2  | ALL  | NULL          | NULL | NULL    | NULL | 15   | Using |
+----+-------------+----------+------|---------------|------|---------+------|------|-------|
3 rows in set (0.04 sec)
```

In the output, the Hash Join Inner table is the table used to build hash table, and the Hash Join Outer table is the table that is used to probe the hash table.

For more information about the extended EXPLAIN output format, see [Extended EXPLAIN Output Format](https://dev.mysql.com/doc/refman/8.0/en/explain.html) in the MySQL product documentation.

In Aurora MySQL 2.08 and higher, you can use SQL hints to influence whether a query uses hash join or not, and which tables to use for the build and probe sides of the join. For details, see [Aurora MySQL hints](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-mysql-hints.html).

**Using Amazon Aurora to scale reads for your MySQL database**

You can use Amazon Aurora with your MySQL DB instance to take advantage of the read scaling capabilities of Amazon Aurora and expand the read workload for your MySQL DB instance. To use Aurora to read scale your MySQL DB instance, create an Aurora MySQL DB cluster and make it a read replica of your MySQL DB instance. Then connect to the Aurora MySQL cluster to process the read queries. The source database can be an RDS for MySQL DB instance, or a MySQL database running external to Amazon RDS. For more information, see [Using Amazon Aurora to scale reads for your MySQL database](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-mysql-scaling-reads.html).

**Optimizing timestamp operations**

When the value of the system variable `time_zone` is set to `SYSTEM`, each MySQL function call that requires a time zone calculation makes a system library call. When you run SQL statements that return or change such TIMESTAMP values at high concurrency, you might experience increased latency, lock contention, and CPU usage. For more information, see `time_zone` in the MySQL documentation.

To avoid this behavior, we recommend that you change the value of the `time_zone` DB cluster parameter to `UTC`. For more information, see [Modifying parameters in a DB cluster parameter group](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-mysql-parameter-groups.html).

While the `time_zone` parameter is dynamic (doesn't require a database server restart), the new value is used only for new connections. To make sure that all connections are updated to use the new
time_zone value, we recommend that you recycle your application connections after updating the DB cluster parameter.

Best practices for Aurora MySQL high availability

You can apply the following best practices to improve the availability of your Aurora MySQL clusters.

Topics

- Using Amazon Aurora for Disaster Recovery with your MySQL databases (p. 1109)
- Migrating from MySQL to Amazon Aurora MySQL with reduced downtime (p. 1109)
- Avoiding slow performance, automatic restart, and failover for Aurora MySQL DB instances (p. 1109)

Using Amazon Aurora for Disaster Recovery with your MySQL databases

You can use Amazon Aurora with your MySQL DB instance to create an offsite backup for disaster recovery. To use Aurora for disaster recovery of your MySQL DB instance, create an Amazon Aurora DB cluster and make it a read replica of your MySQL DB instance. This applies to an RDS for MySQL DB instance, or a MySQL database running external to Amazon RDS.

**Important**
When you set up replication between a MySQL DB instance and an Amazon Aurora MySQL DB cluster, you should monitor the replication to ensure that it remains healthy and repair it if necessary.

For instructions on how to create an Amazon Aurora MySQL DB cluster and make it a read replica of your MySQL DB instance, follow the procedure in [Using Amazon Aurora to scale reads for your MySQL database](p. 1108).

For more information on disaster recovery models, see [How to choose the best disaster recovery option for your Amazon Aurora MySQL cluster](p. 1108).

Migrating from MySQL to Amazon Aurora MySQL with reduced downtime

When importing data from a MySQL database that supports a live application to an Amazon Aurora MySQL DB cluster, you might want to reduce the time that service is interrupted while you migrate. To do so, you can use the procedure documented in [Importing data to a MySQL or MariaDB DB instance with reduced downtime](p. 1109) in the Amazon Relational Database Service User Guide. This procedure can especially help if you are working with a very large database. You can use the procedure to reduce the cost of the import by minimizing the amount of data that is passed across the network to AWS.

The procedure lists steps to transfer a copy of your database data to an Amazon EC2 instance and import the data into a new RDS for MySQL DB instance. Because Amazon Aurora is compatible with MySQL, you can instead use an Amazon Aurora DB cluster for the target Amazon RDS MySQL DB instance.

Avoiding slow performance, automatic restart, and failover for Aurora MySQL DB instances

If you’re running a heavy workload or workloads that spike beyond the allocated resources of your DB instance, you can exhaust the resources on which you’re running your application and Aurora database. To get metrics on your database instance such as CPU utilization, memory usage, and number of database connections used, you can refer to the metrics provided by Amazon CloudWatch,
Performance Insights, and Enhanced Monitoring. For more information on monitoring your DB instance, see Monitoring metrics in an Amazon Aurora cluster (p. 509).

If your workload exhausts the resources you're using, your DB instance might slow down, restart, or even fail over to another DB instance. To avoid this, monitor your resource utilization, examine the workload running on your DB instance, and make optimizations where necessary. If optimizations don't improve the instance metrics and mitigate the resource exhaustion, consider scaling up your DB instance before you reach its limits. For more information on available DB instance classes and their specifications, see Aurora DB instance classes (p. 84).

Recommendations for Aurora MySQL

The following features are available in Aurora MySQL for MySQL compatibility. However, they have performance, scalability, stability, or compatibility issues in the Aurora environment. Thus, we recommend that you follow certain guidelines in your use of these features. For example, we recommend that you don't use certain features for production Aurora deployments.

Topics
- Using multithreaded replication in Aurora MySQL version 3 (p. 1110)
- Invoking AWS Lambda functions using native MySQL functions (p. 1110)
- Avoiding XA transactions with Amazon Aurora MySQL (p. 1111)
- Keeping foreign keys turned on during DML statements (p. 1111)
- Configuring how frequently the log buffer is flushed (p. 1111)
- Minimizing and troubleshooting Aurora MySQL deadlocks (p. 1112)

Using multithreaded replication in Aurora MySQL version 3

By default, Aurora uses single-threaded replication when an Aurora MySQL DB cluster is used as a read replica for binary log replication.

Although Aurora MySQL doesn't prohibit multithreaded replication, this feature is only supported in Aurora MySQL version 3.

Aurora MySQL version 2 inherited several issues regarding multithreaded replication from MySQL. For that version, we recommend that you not use multithreaded replication in production.

If you do use multithreaded replication, we recommend that you test any use thoroughly.

For more information about using replication in Amazon Aurora, see Replication with Amazon Aurora (p. 104). For information about multithreaded replication in Aurora MySQL version 3, see Multithreaded binary log replication (Aurora MySQL version 3 and higher) (p. 1032).

Invoking AWS Lambda functions using native MySQL functions

We recommend using the native MySQL functions `lambda_sync` and `lambda_async` to invoke Lambda functions.

If you are using the deprecated `mysql.lambda_async` procedure, we recommend that you wrap calls to the `mysql.lambda_async` procedure in a stored procedure. You can call this stored procedure from different sources, such as triggers or client code. This approach can help to avoid impedance mismatch issues and make it easier for your database programmers to invoke Lambda functions.

For more information on invoking Lambda functions from Amazon Aurora, see Invoking a Lambda function from an Amazon Aurora MySQL DB cluster (p. 1075).
Avoiding XA transactions with Amazon Aurora MySQL

We recommend that you don't use eXtended Architecture (XA) transactions with Aurora MySQL, because they can cause long recovery times if the XA was in the PREPARED state. If you must use XA transactions with Aurora MySQL, follow these best practices:

- Don't leave an XA transaction open in the PREPARED state.
- Keep XA transactions as small as possible.

For more information about using XA transactions with MySQL, see XA transactions in the MySQL documentation.

Keeping foreign keys turned on during DML statements

We strongly recommend that you don't run any data definition language (DDL) statements when the foreign_key_checks variable is set to 0 (off).

If you need to insert or update rows that require a transient violation of foreign keys, follow these steps:

1. Set foreign_key_checks to 0.
2. Make your data manipulation language (DML) changes.
3. Make sure that your completed changes don't violate any foreign key constraints.
4. Set foreign_key_checks to 1 (on).

In addition, follow these other best practices for foreign key constraints:

- Make sure that your client applications don't set the foreign_key_checks variable to 0 as a part of the init_connect variable.
- If a restore from a logical backup such as mysqldump fails or is incomplete, make sure that foreign_key_checks is set to 1 before starting any other operations in the same session. A logical backup sets foreign_key_checks to 0 when it starts.

Configuring how frequently the log buffer is flushed

In MySQL Community Edition, to make transactions durable, the InnoDB log buffer must be flushed to durable storage. You use the innodb_flush_log_at_trx_commit parameter to configure how frequently the log buffer is flushed to disk.

When you set the innodb_flush_log_at_trx_commit parameter to the default value of 1, the log buffer is flushed at each transaction commit. This setting helps to keep the database ACID compliant. We recommend that you keep the default setting of 1.

Changing innodb_flush_log_at_trx_commit to a nondefault value, 0 or 2, can help reduce data manipulation language (DML) latency, but sacrifices the durability of the log records. This lack of durability makes the database ACID noncompliant. We recommend that your databases be ACID compliant to avoid the risk of data loss in the event of a server restart. For more information on this parameter, see innodb_flush_log_at_trx_commit in the MySQL documentation.

In Aurora MySQL, redo log processing is offloaded to the storage layer, so no flushing to log files occurs on the DB instance. When a write is issued, redo logs are sent from the writer DB instance directly to the Aurora cluster volume. The only writes that cross the network are redo log records. No pages are ever written from the database tier.

By default, in Aurora MySQL, the innodb_flush_log_at_trx_commit parameter is set to 1. Each thread committing a transaction waits for confirmation from the Aurora cluster volume.
confirmation indicates that this record and all previous redo log records are written and have achieved quorum. Persisting the log records and achieving quorum make the transaction durable, whether through autocommit or explicit commit. For more information on the Aurora storage architecture, see Amazon Aurora storage demystified.

Aurora MySQL doesn't flush logs to data files as MySQL Community Edition does. However, you can use the innodb_flush_log_at_trx_commit parameter to relax durability constraints when writing redo log records to the Aurora cluster volume. When you set innodb_flush_log_at_trx_commit to a nondefault value (0 or 2), the database doesn't wait for confirmation that the redo log records are written to the Aurora cluster volume. While these settings can lower DML latency to the client, they can also result in data loss in the event of a failover or restart. Therefore, we recommend that you keep the innodb_flush_log_at_trx_commit parameter set to the default value of 1.

While data loss can occur in both MySQL Community Edition and Aurora MySQL, behavior differs in each database because of their different architectures. These architectural differences can lead to varying degrees of data loss. To make sure that your database is ACID compliant, always set innodb_flush_log_at_trx_commit to 1.

Note

In Aurora MySQL version 3, before you can change innodb_flush_log_at_trx_commit to a value other than 1, you must first change the value of innodb_trx_commit_allow_data_loss to 1. By doing so, you acknowledge the risk of data loss.

Minimizing and troubleshooting Aurora MySQL deadlocks

Users running workloads that regularly experience constraint violations on unique secondary indexes or foreign keys, when modifying records on the same data page concurrently, might experience increased deadlocks and lock wait timeouts. These deadlocks and timeouts are because of a MySQL Community Edition bug fix.

This fix is included in MySQL Community Edition versions 5.7.26 and higher, and was backported into Aurora MySQL versions 2.10.3 and higher. The fix is necessary for enforcing serializability, by implementing additional locking for these types of data manipulation language (DML) operations, on changes made to records in an InnoDB table. This issue was uncovered as part of an investigation into deadlock issues introduced by a previous MySQL Community Edition bug fix.

The fix changed the internal handling for the partial rollback of a tuple (row) update in the InnoDB storage engine. Operations that generate constraint violations on foreign keys or unique secondary indexes cause partial rollback. This includes, but isn't limited to, concurrent INSERT...ON DUPLICATE KEY UPDATE, REPLACE INTO, and INSERT IGNORE statements (upserts).

In this context, partial rollback doesn't refer to the rollback of application-level transactions, but rather an internal InnoDB rollback of changes to a clustered index, when a constraint violation is encountered. For example, a duplicate key value is found during an upsert operation.

In a normal insert operation, InnoDB atomically creates clustered and secondary index entries for each index. If InnoDB detects a duplicate value on a unique secondary index during an upsert operation, the inserted entry in the clustered index has to be reverted (partial rollback), and the update then has to be applied to the existing duplicate row. During this internal partial rollback step, InnoDB must lock each record seen as part of the operation. The fix ensures transaction serializability by introducing additional locking after the partial rollback.

Minimizing InnoDB deadlocks

You can take the following approaches to reduce the frequency of deadlocks in your database instance. More examples can be found in the MySQL documentation.

1. To reduce the chances of deadlocks, commit transactions immediately after making a related set of changes. You can do this by breaking up large transactions (multiple row updates between commits)
into smaller ones. If you’re batch inserting rows, then try to reduce batch insert sizes, especially when using the upsert operations mentioned previously.

To reduce the number of possible partial rollbacks, you can try some of the following approaches:

a. Replace batch insert operations with inserting one row at a time. This can reduce the amount of time where locks are held by transactions that might have conflicts.

b. Instead of using REPLACE INTO, rewrite the SQL statement as a multistatement transaction such as the following:

```
BEGIN;
DELETE conflicting rows;
INSERT new rows;
COMMIT;
```

c. Instead of using INSERT...ON DUPLICATE KEY UPDATE, rewrite the SQL statement as a multistatement transaction such as the following:

```
BEGIN;
SELECT rows that conflict on secondary indexes;
UPDATE conflicting rows;
INSERT new rows;
COMMIT;
```

2. Avoid long-running transactions, active or idle, that might hold onto locks. This includes interactive MySQL client sessions that might be open for an extended period with an uncommitted transaction. When optimizing transaction sizes or batch sizes, the impact can vary depending on a number of factors such as concurrency, number of duplicates, and table structure. Any changes should be implemented and tested based on your workload.

3. In some situations, deadlocks can occur when two transactions attempt to access the same datasets, either in one or multiple tables, in different orders. To prevent this, you can modify the transactions to access the data in the same order, thereby serializing the access. For example, create a queue of transactions to be completed. This approach can help to avoid deadlocks when multiple transactions occur concurrently.

4. Adding carefully chosen indexes to your tables can improve selectivity and reduce the need to access rows, which leads to less locking.

5. If you encounter gap locking, you can modify the transaction isolation level to READ COMMITTED for the session or transaction to prevent it. For more information on InnoDB isolation levels and their behaviors, see Transaction isolation levels in the MySQL documentation.

**Note**

While you can take precautions to reduce the possibility of deadlocks occurring, deadlocks are an expected database behavior and can still occur. Applications should have the necessary logic to handle deadlocks when they are encountered. For example, implement retry and backing-off logic in the application. It’s best to address the root cause of the issue but if a deadlock does occur, the application has the option to wait and retry.

**Monitoring InnoDB deadlocks**

Deadlocks can occur in MySQL when application transactions try to take table-level and row-level locks in a way that results in circular waiting. An occasional InnoDB deadlock isn’t necessarily an issue, because the InnoDB storage engine detects the condition immediately and rolls back one of the transactions automatically. If you encounter deadlocks frequently, we recommend reviewing and modifying your application to alleviate performance issues and avoid deadlocks. When deadlock detection is turned on (the default), InnoDB automatically detects transaction deadlocks and rolls back a transaction or transactions to break the deadlock. InnoDB tries to pick small transactions to roll back, where the size of a transaction is determined by the number of rows inserted, updated, or deleted.
• **SHOW ENGINE** statement – The **SHOW ENGINE INNODB STATUS \G** statement contains details of the most recent deadlock encountered on the database since the last restart.

• MySQL error log – If you encounter frequent deadlocks where the output of the **SHOW ENGINE** statement is inadequate, you can turn on the `innodb_print_all_deadlocks` DB cluster parameter. When this parameter is turned on, information about all deadlocks in InnoDB user transactions is recorded in the Aurora MySQL error log.

• Amazon CloudWatch metrics – We also recommend that you proactively monitor deadlocks using the CloudWatch metric DeadLocks. For more information, see [Instance-level metrics for Amazon Aurora](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-mysql-instance-level-metrics.html) (p. 643).

• Amazon CloudWatch Logs – With CloudWatch Logs, you can view metrics, analyze log data, and create real-time alarms. For more information, see [Monitor errors in Amazon Aurora MySQL and Amazon RDS for MySQL using Amazon CloudWatch and send notifications using Amazon SNS](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-mysql-cloudwatch-log.html).

Using CloudWatch Logs with `innodb_print_all_deadlocks` turned on, you can configure alarms to notify you when the number of deadlocks exceeds a given threshold. To define a threshold, we recommend that you observe your trends and use a value based on your normal workload.

• Performance Insights – When you use Performance Insights, you can monitor the `innodb_deadlocks` and `innodb_lock_wait_timeout` metrics. For more information on these metrics, see [Non-native counters for Aurora MySQL](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-mysql-counter-list.html) (p. 667).
Amazon Aurora MySQL reference

This reference includes information about Aurora MySQL parameters, status variables, and general SQL extensions or differences from the community MySQL database engine.

Topics
- Aurora MySQL configuration parameters (p. 1115)
- Aurora MySQL wait events (p. 1151)
- Aurora MySQL thread states (p. 1155)
- Aurora MySQL isolation levels (p. 1158)
- Aurora MySQL hints (p. 1162)
- Aurora MySQL stored procedures (p. 1164)
- Aurora MySQL–specific information_schema tables (p. 1195)

Aurora MySQL configuration parameters

You manage your Amazon Aurora MySQL DB cluster in the same way that you manage other Amazon RDS DB instances, by using parameters in a DB parameter group. Amazon Aurora differs from other DB engines in that you have a DB cluster that contains multiple DB instances. As a result, some of the parameters that you use to manage your Aurora MySQL DB cluster apply to the entire cluster. Other parameters apply only to a particular DB instance in the DB cluster.

To manage cluster-level parameters, use DB cluster parameter groups. To manage instance-level parameters, use DB parameter groups. Each DB instance in an Aurora MySQL DB cluster is compatible with the MySQL database engine. However, you apply some of the MySQL database engine parameters at the cluster level, and you manage these parameters using DB cluster parameter groups. You can’t find cluster-level parameters in the DB parameter group for an instance in an Aurora DB cluster. A list of cluster-level parameters appears later in this topic.

You can manage both cluster-level and instance-level parameters using the AWS Management Console, the AWS CLI, or the Amazon RDS API. You use separate commands for managing cluster-level parameters and instance-level parameters. For example, you can use the `modify-db-cluster-parameter-group` CLI command to manage cluster-level parameters in a DB cluster parameter group. You can use the `modify-db-parameter-group` CLI command to manage instance-level parameters in a DB parameter group for a DB instance in a DB cluster.

You can view both cluster-level and instance-level parameters in the console, or by using the CLI or RDS API. For example, you can use the `describe-db-cluster-parameters` AWS CLI command to view cluster-level parameters in a DB cluster parameter group. You can use the `describe-db-parameters` CLI command to view instance-level parameters in a DB parameter group for a DB instance in a DB cluster.

Note
Each default parameter group (p. 212) contains the default values for all parameters in the parameter group. If the parameter has "engine default" for this value, see the version-specific MySQL or PostgreSQL documentation for the actual default value. Unless otherwise noted, parameters listed in the following tables are valid for Aurora MySQL versions 2 and 3.

For more information about DB parameter groups, see Working with parameter groups (p. 212). For rules and restrictions for Aurora Serverless v1 clusters, see Parameter groups for Aurora Serverless v1 (p. 2034).

Topics
- Cluster-level parameters (p. 1116)
- Instance-level parameters (p. 1127)
### Cluster-level parameters

The following table shows all of the parameters that apply to the entire Aurora MySQL DB cluster.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Modifiable</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>aurora_binlog_read_buffer_size</code></td>
<td>Yes</td>
<td>Only affects clusters that use binary log (binlog) replication. For information about binlog replication, see [Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication)](p. 1015). Removed from Aurora MySQL version 3.</td>
</tr>
<tr>
<td><code>aurora_binlog_replication_max_yield_seconds</code></td>
<td>Yes</td>
<td>Only affects clusters that use binary log (binlog) replication. For information about binlog replication, see [Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication)](p. 1015).</td>
</tr>
<tr>
<td><code>aurora_binlog_use_large_read_buffer</code></td>
<td>Yes</td>
<td>Only affects clusters that use binary log (binlog) replication. For information about binlog replication, see [Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication)](p. 1015). Removed from Aurora MySQL version 3.</td>
</tr>
<tr>
<td><code>aurora_disable_hash_join</code></td>
<td>Yes</td>
<td>Set this parameter to ON to turn off hash join optimization in Aurora MySQL version 2.09 or higher. It isn't supported for version 3. For more information, see [Working with parallel query for Amazon Aurora MySQL](p. 948).</td>
</tr>
<tr>
<td><code>aurora_enable_replica_log_compression</code></td>
<td>Yes</td>
<td>For more information, see [Performance considerations for Amazon Aurora MySQL replication](p. 985). Doesn't apply to clusters that are part of an Aurora global database. Removed from Aurora MySQL version 3.</td>
</tr>
<tr>
<td><code>aurora_enable_repl_bin_log_filtering</code></td>
<td>Yes</td>
<td>For more information, see [Performance considerations for Amazon Aurora MySQL replication](p. 985). Doesn't apply to clusters that are part of an Aurora global database. Removed from Aurora MySQL version 3.</td>
</tr>
<tr>
<td><code>aurora_enable_staggered_replica_restart</code></td>
<td>Yes</td>
<td>This setting is available in Aurora MySQL version 3, but it isn't used.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Modifiable</td>
<td>Notes</td>
</tr>
<tr>
<td>--------------------------------------</td>
<td>------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------</td>

### Configuration parameters

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Modifiable</th>
<th>Notes</th>
</tr>
</thead>
</table>
| innodbaurora_instant_alter_column_allowed     | Yes        | Controls whether the INSTANT algorithm can be used for ALTER COLUMN operations at the global level. The allowed values are the following:  
- never (0) – The INSTANT algorithm isn't allowed for ALTER COLUMN operations. Reverts to the IN-PLACE algorithm.  
- instant (1) – ALTER COLUMN operations always use the INSTANT algorithm. This is the default value.  
- no_add_drop (2) – VIRTUAL_ADD_DROP_ONLY and COLUMN_RENAME_ONLY column operations support the INSTANT algorithm. ADD COLUMN and DROP COLUMN operations use the IN-PLACE algorithm.  
For more information, see [Column Operations](https://dev.mysql.com/doc/refman/8.0/en/column-operations.html) in the MySQL documentation.  
This parameter applies to Aurora MySQL version 3.05 and higher. |
<p>| innodb_autoinc_lock_mode                      | Yes        | Removed from Aurora MySQL version 3.                                    |
| innodb_checksums                               | No         | Aurora MySQL uses managed instances where you don't access the file system directly. |
| innodb_cmp_per_index_enabled                  | Yes        |                                                                                  |
| innodb_commit_concurrency                     | Yes        |                                                                                  |
| innodb_data_home_dir                          | No         |                                                                                  |
| innodb_deadlock_detect                        | Yes        |                                                                                  |
| innodb_default_row_format                     | Yes        |                                                                                  |</p>

### Instance-level parameters

The following table shows all of the parameters that apply to a specific DB instance in an Aurora MySQL DB cluster.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Modifiable</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>activate_all_roles_on_login</td>
<td>Yes</td>
<td>This parameter applies to Aurora MySQL version 3.</td>
</tr>
<tr>
<td>allow-suspicious-udfs</td>
<td>No</td>
<td></td>
</tr>
<tr>
<td>aurora_disable_hash_join</td>
<td>Yes</td>
<td>Set this parameter to ON to turn off hash join optimization in Aurora MySQL version 2.09 or higher. It isn't supported for version 3. For more information, see [Working with parallel query for Amazon Aurora MySQL](p. 948).</td>
</tr>
<tr>
<td>aurora_lab_mode</td>
<td>Yes</td>
<td>For more information, see [Amazon Aurora MySQL lab mode](p. 1101). Removed from Aurora MySQL version 3.</td>
</tr>
<tr>
<td>aurora_oom_response</td>
<td>Yes</td>
<td>This parameter is supported for Aurora MySQL versions 2 and 3. For more information, see [Amazon Aurora MySQL out-of-memory issues](p. 2515).</td>
</tr>
<tr>
<td>aurora_parallel_query</td>
<td>Yes</td>
<td>Set to ON to turn on parallel query in Aurora MySQL version 2.09 or higher. The old <code>aurora_pq</code> parameter isn't used in these versions. For more information, see [Working with parallel query for Amazon Aurora MySQL](p. 948).</td>
</tr>
<tr>
<td>aurora_pq</td>
<td>Yes</td>
<td>Set to OFF to turn off parallel query for specific DB instances in Aurora MySQL versions before 2.09. In version 2.09 or higher, turn parallel query on and off with <code>aurora_parallel_query</code> instead. For more information, see [Working with parallel query for Amazon Aurora MySQL](p. 948).</td>
</tr>
<tr>
<td>aurora_read_replica_read_committed</td>
<td>Yes</td>
<td>Enables READ COMMITTED isolation level for Aurora Replicas and changes the isolation behavior to reduce purge lag during long-running queries. Enable this setting only if you understand the behavior changes and how they affect</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Modifiable</td>
<td>Notes</td>
</tr>
<tr>
<td>----------------------------------------------------</td>
<td>------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>your query results. For example, this setting uses less-strict isolation than the MySQL default. When it's enabled, long-running queries might see more than one copy of the same row because Aurora reorganizes the table data while the query is running. For more information, see Aurora MySQL isolation levels (p. 1158).</td>
<td></td>
<td></td>
</tr>
<tr>
<td>aurora_tmptable_enable_per_table_limit</td>
<td>Yes</td>
<td>Determines whether the tmp_table_size parameter controls the maximum size of in-memory temporary tables created by the TempTable storage engine in Aurora MySQL version 3.04 and higher. For more information, see Limiting the size of internal, in-memory temporary tables (p. 785).</td>
</tr>
<tr>
<td>aurora_use_vector_instructions</td>
<td>Yes</td>
<td>When this parameter is enabled, Aurora MySQL uses optimized vector processing instructions provided by modern CPUs to improve performance on I/O-intensive workloads. This setting is enabled by default in Aurora MySQL version 3.05 and higher.</td>
</tr>
<tr>
<td>autocommit</td>
<td>Yes</td>
<td></td>
</tr>
<tr>
<td>automatic_sp_privileges</td>
<td>Yes</td>
<td></td>
</tr>
<tr>
<td>back_log</td>
<td>Yes</td>
<td></td>
</tr>
<tr>
<td>basedir</td>
<td>No</td>
<td>Aurora MySQL uses managed instances where you don't access the file system directly.</td>

MySQL parameters that don’t apply to Aurora MySQL

Because of architectural differences between Aurora MySQL and MySQL, some MySQL parameters don’t apply to Aurora MySQL.
The following MySQL parameters don't apply to Aurora MySQL. This list isn't exhaustive.

- activate_all_roles_on_login – This parameter doesn't apply to Aurora MySQL version 2. It is available in Aurora MySQL version 3.
- big_tables
- bind_address
- character_sets_dir
- innodb_adaptive_flushing
- innodb_adaptive_flushing_lwm
- innodb_buffer_pool_chunk_size
- innodb_buffer_pool_instances
- innodb_change_buffering
- innodb_checksum_algorithm
- innodb_data_file_path
- innodb_dedicated_server
- innodb_doublewrite
- innodb_flush_log_at_timeout – This parameter doesn't apply to Aurora MySQL. For more information, see Configuring how frequently the log buffer is flushed (p. 1111).
- innodb_flush_method
- innodb_flush_neighbors
- innodb_io_capacity
- innodb_io_capacity_max
- innodb_log_buffer_size
- innodb_log_file_size
- innodb_log_files_in_group
- innodb_log_spin_cpu_abs_lwm
- innodb_log_spin_cpu_pct_hwm
- innodb_log_writer_threads
- innodb_max_dirty_pages_pct
- innodb_numa_interleave
- innodb_page_size
- innodb_redo_log_capacity
- innodb_redo_log_encrypt
- innodb_undo_log_encrypt
- innodb_undo_log_truncate
- innodb_undo_logs
- innodb_undo_tablespaces
- innodb_use_native_aio
- innodb_write_io_threads

**Aurora MySQL global status variables**

You can find the current values for Aurora MySQL global status variables by using a statement such as the following:

```
show global status like '%aurora%';
```
The following table describes the global status variables that Aurora MySQL uses.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AuroraDb_commits</td>
<td>The total number of commits since the last restart.</td>
</tr>
<tr>
<td>AuroraDb_commit_latency</td>
<td>The aggregate commit latency since the last restart.</td>
</tr>
<tr>
<td>AuroraDb_ddl_stmt_duration</td>
<td>The aggregate DDL latency since the last restart.</td>
</tr>
<tr>
<td>AuroraDb_select_stmt_duration</td>
<td>The aggregate SELECT statement latency since the last restart.</td>
</tr>
<tr>
<td>AuroraDb_insert_stmt_duration</td>
<td>The aggregate INSERT statement latency since the last restart.</td>
</tr>
<tr>
<td>AuroraDb_update_stmt_duration</td>
<td>The aggregate UPDATE statement latency since the last restart.</td>
</tr>
<tr>
<td>AuroraDb_delete_stmt_duration</td>
<td>The aggregate DELETE statement latency since the last restart.</td>
</tr>
<tr>
<td>Aurora_binlog_io_cache_allocated</td>
<td>The number of bytes allocated to the binlog I/O cache.</td>
</tr>
<tr>
<td>Aurora_binlog_io_cache_read_requests</td>
<td>The number of read requests made to the binlog I/O cache.</td>
</tr>
<tr>
<td>Aurora_binlog_io_cache_reads</td>
<td>The number of read requests that were served from the binlog I/O cache.</td>
</tr>
<tr>
<td>Aurora_enhanced_binlog</td>
<td>Indicates whether enhanced binlog is enabled or disabled for this DB instance. For more information, see Setting up enhanced binlog (p. 1037).</td>
</tr>
<tr>
<td>Aurora_external_connection_count</td>
<td>The number of database connections to the DB instance, excluding RDS service connections used for database health checks.</td>
</tr>
<tr>
<td>Aurora_fast_insert_cache_hits</td>
<td>A counter that’s incremented when the cached cursor is successfully retrieved and verified. For more information on the fast insert cache, see Amazon Aurora MySQL performance enhancements (p. 779).</td>
</tr>
<tr>
<td>Aurora_fast_insert_cache_misses</td>
<td>A counter that’s incremented when the cached cursor is no longer valid and Aurora performs a normal index traversal. For more information on the fast insert cache, see Amazon Aurora MySQL performance enhancements (p. 779).</td>
</tr>
<tr>
<td>Aurora_fwd_master_dml_stmt_count</td>
<td>The total number of DML statements forwarded to this writer DB instance. This variable applies to Aurora MySQL version 2.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Aurora_fwd_master_dml_stmt_duration</td>
<td>The total duration of DML statements forwarded to this writer DB instance. This variable applies to Aurora MySQL version 2.</td>
</tr>
<tr>
<td>Aurora_fwd_master_errors_rpc_timeout</td>
<td>The number of times a forwarded connection failed to be established on the writer.</td>
</tr>
<tr>
<td>Aurora_fwd_master_errors_session_limit</td>
<td>The number of forwarded queries that get rejected due to session full on the writer.</td>
</tr>
<tr>
<td>Aurora_fwd_master_errors_session_timeout</td>
<td>The number of times a forwarding session is ended due to a timeout on the writer.</td>
</tr>
<tr>
<td>Aurora_fwd_master_open_sessions</td>
<td>The number of forwarded sessions on the writer DB instance. This variable applies to Aurora MySQL version 2.</td>
</tr>
<tr>
<td>Aurora_fwd_master_select_stmt_count</td>
<td>The total number of SELECT statements forwarded to this writer DB instance. This variable applies to Aurora MySQL version 2.</td>
</tr>
<tr>
<td>Aurora_fwd_master_select_stmt_duration</td>
<td>The total duration of SELECT statements forwarded to this writer DB instance. This variable applies to Aurora MySQL version 2.</td>
</tr>
<tr>
<td>Aurora_fwd_writer_dml_stmt_count</td>
<td>The total number of DML statements forwarded to this writer DB instance. This variable applies to Aurora MySQL version 3.</td>
</tr>
<tr>
<td>Aurora_fwd_writer_dml_stmt_duration</td>
<td>The total duration of DML statements forwarded to this writer DB instance. This variable applies to Aurora MySQL version 3.</td>
</tr>
<tr>
<td>Aurora_fwd_writer_errors_rpc_timeout</td>
<td>The number of times a forwarded connection failed to be established on the writer.</td>
</tr>
<tr>
<td>Aurora_fwd_writer_errors_session_limit</td>
<td>The number of forwarded queries that get rejected due to session full on the writer.</td>
</tr>
<tr>
<td>Aurora_fwd_writer_errors_session_timeout</td>
<td>The number of times a forwarding session is ended due to a timeout on the writer.</td>
</tr>
<tr>
<td>Aurora_fwd_writer_open_sessions</td>
<td>The number of forwarded sessions on the writer DB instance. This variable applies to Aurora MySQL version 3.</td>
</tr>
<tr>
<td>Aurora_fwd_writer_select_stmt_count</td>
<td>The total number of SELECT statements forwarded to this writer DB instance. This variable applies to Aurora MySQL version 3.</td>
</tr>
<tr>
<td>Aurora_fwd_writer_select_stmt_duration</td>
<td>The total duration of SELECT statements forwarded to this writer DB instance. This variable applies to Aurora MySQL version 3.</td>
</tr>
<tr>
<td>Aurora_lockmgr_memory_used</td>
<td>The amount of memory in bytes that the Aurora MySQL lock manager is using.</td>
</tr>
</tbody>
</table>
### Configuration parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Aurora_ml_actual_request_cnt</strong></td>
<td>The aggregate request count that Aurora MySQL makes to the Aurora machine learning services across all queries run by users of the DB instance. For more information, see [Using Amazon Aurora machine learning with Aurora MySQL](p. 1086).</td>
</tr>
<tr>
<td><strong>Aurora_ml_actual_response_cnt</strong></td>
<td>The aggregate response count that Aurora MySQL receives from the Aurora machine learning services across all queries run by users of the DB instance. For more information, see [Using Amazon Aurora machine learning with Aurora MySQL](p. 1086).</td>
</tr>
<tr>
<td><strong>Aurora_ml_cache_hit_cnt</strong></td>
<td>The aggregate internal cache hit count that Aurora MySQL receives from the Aurora machine learning services across all queries run by users of the DB instance. For more information, see [Using Amazon Aurora machine learning with Aurora MySQL](p. 1086).</td>
</tr>
<tr>
<td><strong>Aurora_ml_logical_request_cnt</strong></td>
<td>The number of logical requests that the DB instance has evaluated to be sent to the Aurora machine learning services since the last status reset. Depending on whether batching has been used, this value can be higher than <code>Aurora_ml_actual_request_cnt</code>. For more information, see [Using Amazon Aurora machine learning with Aurora MySQL](p. 1086).</td>
</tr>
<tr>
<td><strong>Aurora_ml_logical_response_cnt</strong></td>
<td>The aggregate response count that Aurora MySQL receives from the Aurora machine learning services across all queries run by users of the DB instance. For more information, see [Using Amazon Aurora machine learning with Aurora MySQL](p. 1086).</td>
</tr>
<tr>
<td><strong>Aurora_ml_retry_request_cnt</strong></td>
<td>The number of retried requests that the DB instance has sent to the Aurora machine learning services since the last status reset. For more information, see [Using Amazon Aurora machine learning with Aurora MySQL](p. 1086).</td>
</tr>
<tr>
<td><strong>Aurora_ml_single_request_cnt</strong></td>
<td>The aggregate count of Aurora machine learning functions that are evaluated by non-batch mode across all queries run by users of the DB instance. For more information, see [Using Amazon Aurora machine learning with Aurora MySQL](p. 1086).</td>
</tr>
<tr>
<td><strong>Aurora_pq_bytes_returned</strong></td>
<td>The number of bytes for the tuple data structures transmitted to the head node during parallel queries. Divide by 16,384 to compare against <code>Aurora_pq_pages_pushed_down</code>.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Aurora_pq_max_concurrent_requests</td>
<td>The maximum number of parallel query sessions that can run concurrently on this Aurora DB instance. This is a fixed number that depends on the AWS DB instance class.</td>
</tr>
<tr>
<td>Aurora_pq_pages_pushed_down</td>
<td>The number of data pages (each with a fixed size of 16 KiB) where parallel query avoided a network transmission to the head node.</td>
</tr>
<tr>
<td>Aurora_pq_request_attempted</td>
<td>The number of parallel query sessions requested. This value might represent more than one session per query, depending on SQL constructs such as subqueries and joins.</td>
</tr>
<tr>
<td>Aurora_pq_request_executed</td>
<td>The number of parallel query sessions run successfully.</td>
</tr>
<tr>
<td>Aurora_pq_request_failed</td>
<td>The number of parallel query sessions that returned an error to the client. In some cases, a request for a parallel query might fail, for example due to a problem in the storage layer. In these cases, the query part that failed is retried using the nonparallel query mechanism. If the retried query also fails, an error is returned to the client and this counter is incremented.</td>
</tr>
<tr>
<td>Aurora_pq_request_in_progress</td>
<td>The number of parallel query sessions currently in progress. This number applies to the particular Aurora DB instance that you are connected to, not the entire Aurora DB cluster. To see if a DB instance is close to its concurrency limit, compare this value to Aurora_pq_max_concurrent_requests.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen</td>
<td>The number of times parallel query wasn't chosen to satisfy a query. This value is the sum of several other more granular counters. An EXPLAIN statement can increment this counter even though the query isn't actually performed.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_below_min_rows</td>
<td>The number of times parallel query wasn't chosen due to the number of rows in the table. An EXPLAIN statement can increment this counter even though the query isn't actually performed.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_column_bit</td>
<td>The number of parallel query requests that use the nonparallel query processing path because of an unsupported data type in the list of projected columns.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_column_geometry</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the table has columns with the GEOMETRY data type. For information about Aurora MySQL versions that remove this limitation, see Upgrading parallel query clusters to Aurora MySQL version 3 (p. 957).</td>
</tr>
</tbody>
</table>

For information about Aurora MySQL versions that remove this limitation, see Upgrading parallel query clusters to Aurora MySQL version 3 (p. 957).
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora_pq_request_not_chosen_column_lob</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the table has columns with a LOB data type, or VARCHAR columns that are stored externally due to the declared length. For information about Aurora MySQL versions that remove this limitation, see [Upgrading parallel query clusters to Aurora MySQL version 3](p. 957).</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_column_virtual</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the table contains a virtual column.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_custom_charset</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the table has columns with a custom character set.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_fast_ddl</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the table is currently being altered by a fast DDL ALTER statement.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_few_pages_outside_buffer_pool</td>
<td>The number of times parallel query wasn’t chosen, even though less than 95 percent of the table data was in the buffer pool, because there wasn’t enough unbuffered table data to make parallel query worthwhile.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_full_text_index</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the table has full-text indexes.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_high_buffer_pool_pct</td>
<td>The number of times parallel query wasn’t chosen because a high percentage of the table data (currently, greater than 95 percent) was already in the buffer pool. In these cases, the optimizer determines that reading the data from the buffer pool is more efficient. An EXPLAIN statement can increment this counter even though the query isn’t actually performed.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_index_hint</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the query includes an index hint.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_innodb_table_format</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the table uses an unsupported InnoDB row format. Aurora parallel query only applies to the COMPACT, REDUNDANT, and DYNAMIC row formats.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_long_trx</td>
<td>The number of parallel query requests that used the nonparallel query processing path, due to the query being started inside a long-running transaction. An EXPLAIN statement can increment this counter even though the query isn't actually performed.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_no_where_clause</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the query doesn't include any WHERE clause.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_range_scan</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the query uses a range scan on an index.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_row_length_too_long</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the total combined length of all the columns is too long.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_small_table</td>
<td>The number of times parallel query wasn't chosen due to the overall size of the table, as determined by number of rows and average row length. An EXPLAIN statement can increment this counter even though the query isn't actually performed.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_temporary_table</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the query refers to temporary tables that use the unsupported MyISAM or memory table types.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_tx_isolation</td>
<td>The number of parallel query requests that use the nonparallel query processing path because query uses an unsupported transaction isolation level. On reader DB instances, parallel query only applies to the REPEATABLE READ and READ COMMITTED isolation levels.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_update_delete_stmts</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the query is part of an UPDATE or DELETE statement.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_unsupported_access</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the WHERE clause doesn't meet the criteria for parallel query. This result can occur if the query doesn't require a data-intensive scan, or if the query is a DELETE or UPDATE statement.</td>
</tr>
</tbody>
</table>
### Configuration parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora_pq_request_not_chosen_unsupported_storage_type</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the Aurora MySQL DB cluster isn't using a supported Aurora cluster storage configuration. For more information, see [Limitations](p. 950). This parameter applies to Aurora MySQL version 3.04 and higher.</td>
</tr>
<tr>
<td>Aurora_pq_request_throttled</td>
<td>The number of times parallel query wasn't chosen due to the maximum number of concurrent parallel queries already running on a particular Aurora DB instance.</td>
</tr>
<tr>
<td>Aurora_repl_bytes_received</td>
<td>Number of bytes replicated to an Aurora MySQL reader database instance since the last restart. For more information, see [Replication with Amazon Aurora MySQL](p. 984).</td>
</tr>
<tr>
<td>Aurora_reserved_mem_exceeded_incidents</td>
<td>The number of times since the last restart that the engine has exceeded reserved memory limits. If <code>aurora_oom_response</code> is configured, this threshold defines when out-of-memory (OOM) avoidance activities are triggered. For more information on the Aurora MySQL OOM response, see [Amazon Aurora MySQL out-of-memory issues](p. 2515).</td>
</tr>
<tr>
<td>Aurora_thread_pool_thread_count</td>
<td>The current number of threads in the Aurora thread pool. For more information on the thread pool in Aurora MySQL, see [Thread pool](p. 905).</td>
</tr>
<tr>
<td>Aurora_tmz_version</td>
<td>Denotes the current version of the time zone information used by the DB cluster. The values follow the Internet Assigned Numbers Authority (IANA) format: YYYYsuffix, for example 2022a and 2023c. This parameter applies to Aurora MySQL version 2.12 and higher, and version 3.04 and higher.</td>
</tr>
<tr>
<td>server_aurora_das_running</td>
<td>Indicates whether Database Activity Streams (DAS) are enabled or disabled on this DB instance. For more information, see [Monitoring Amazon Aurora with Database Activity Streams](p. 746).</td>
</tr>
</tbody>
</table>

### MySQL status variables that don't apply to Aurora MySQL

Because of architectural differences between Aurora MySQL and MySQL, some MySQL status variables don't apply to Aurora MySQL.

The following MySQL status variables don't apply to Aurora MySQL. This list isn't exhaustive.

- `innodb_buffer_pool_bytes_dirty`
- `innodb_buffer_pool_pages_dirty`
• `innodb_buffer_pool_pages_flushed`

Aurora MySQL version 3 removes the following status variables that were in Aurora MySQL version 2:

• `AuroraDb_lockmgr_bitmaps0_in_use`
• `AuroraDb_lockmgr_bitmaps1_in_use`
• `AuroraDb_lockmgr_bitmaps_mem_used`
• `AuroraDb_thread_deadlocks`
• `available_alter_table_log_entries`
• `Aurora_lockmgr_memory_used`
• `Aurora_missing_history_on_replica_incidents`
• `Aurora_new_lock_manager_lock_release_cnt`
• `Aurora_new_lock_manager_lock_release_total_duration_micro`
• `Aurora_new_lock_manager_lock_timeout_cnt`
• `Aurora_total_op_memory`
• `Aurora_total_op_temp_space`
• `Aurora_used_alter_table_log_entries`
• `Aurora_using_new_lock_manager`
• `Aurora_volume_bytes_allocated`
• `Aurora_volume_bytes_left_extent`
• `Aurora_volume_bytes_left_total`
• `Com_alter_db_upgrade`
• `Compression`
• `External_threads_connected`
• `Innodb_available_undo_logs`
• `Last_query_cost`
• `Last_query_partial_plans`
• `Slave_heartbeat_period`
• `Slave_last_heartbeat`
• `Slave_received_heartbeats`
• `Slave_retried_transactions`
• `Slave_running`
• `Time_since_zero_connections`

These MySQL status variables are available in Aurora MySQL version 2, but they aren't available in Aurora MySQL version 3:

• `Innodb_redo_log_enabled`
• `Innodb_undo_tablespaces_total`
• `Innodb_undo_tablespaces_implicit`
• `Innodb_undo_tablespaces_explicit`
• `Innodb_undo_tablespaces_active`

**Aurora MySQL wait events**

The following are some common wait events for Aurora MySQL.
Note
For information on tuning Aurora MySQL performance using wait events, see Tuning Aurora MySQL with wait events (p. 905).
For information about the naming conventions used in MySQL wait events, see Performance Schema instrument naming conventions in the MySQL documentation.

cpu
The number of active connections that are ready to run is consistently higher than the number of vCPUs. For more information, see cpu (p. 906).

io/aurora_redo_log_flush
A session is persisting data to Aurora storage. Typically, this wait event is for a write I/O operation in Aurora MySQL. For more information, see io/aurora_redo_log_flush (p. 909).

io/aurora_respond_to_client
Query processing has completed and results are being returned to the application client for the following Aurora MySQL versions: 2.10.2 and higher 2.10 versions, 2.09.3 and higher 2.09 versions, and 2.07.7 and higher 2.07 versions. Compare the network bandwidth of the DB instance class with the size of the result set being returned. Also, check client-side response times. If the client is unresponsive and can't process the TCP packets, packet drops and TCP retransmissions can occur. This situation negatively affects network bandwidth. In versions lower than 2.10.2, 2.09.3, and 2.07.7, the wait event erroneously includes idle time. To learn how to tune your database when this wait is prominent, see io/aurora_respond_to_client (p. 912).

io/file/csv/data
Threads are writing to tables in comma-separated value (CSV) format. Check your CSV table usage. A typical cause of this event is setting log_output on a table.

io/file/sql/binlog
A thread is waiting on a binary log (binlog) file that is being written to disk.

io/socket/sql/client_connection
The mysqld program is busy creating threads to handle incoming new client connections. For more information, see io/socket/sql/client_connection (p. 914).

io/table/sql/handler
The engine is waiting for access to a table. This event occurs regardless of whether the data is cached in the buffer pool or accessed on disk. For more information, see io/table/sql/handler (p. 916).

lock/table/sql/handler
This wait event is a table lock wait event handler. For more information about atom and molecule events in the Performance Schema, see Performance Schema atom and molecule events in the MySQL documentation.

synch/cond/innodb/row_lock_wait
Multiple data manipulation language (DML) statements are accessing the same database rows at the same time. For more information, see synch/cond/innodb/row_lock_wait (p. 919).

synch/cond/innodb/row_lock_wait_cond
Multiple DML statements are accessing the same database rows at the same time. For more information, see synch/cond/innodb/row_lock_wait_cond (p. 921).

synch/cond/mysys/my_thread_var::suspend
The thread is suspended while waiting on a table-level lock because another thread issued LOCK TABLES . . . READ.
**synch/cond/sql/MDL_context::COND_wait_status**

Threads are waiting on a table metadata lock. The engine uses this type of lock to manage concurrent access to a database schema and to ensure data consistency. For more information, see [Optimizing locking operations](#) in the MySQL documentation. To learn how to tune your database when this event is prominent, see *synch/cond/sql/MDL_context::COND_wait_status* (p. 924).

**synch/cond/sql/MYSQL_BIN_LOG::COND_done**

You have turned on binary logging. There might be a high commit throughput, large number transactions committing, or replicas reading binlogs. Consider using multirow statements or bundling statements into one transaction. In Aurora, use global databases instead of binary log replication, or use the `aurora_binlog_*` parameters.

**synch/mutex/innodb/aurora_lock_thread_slot_futex**

Multiple DML statements are accessing the same database rows at the same time. For more information, see *synch/mutex/innodb/aurora_lock_thread_slot_futex* (p. 928).

**synch/mutex/innodb/buf_pool_mutex**

The buffer pool isn’t large enough to hold the working data set. Or the workload accesses pages from a specific table, which leads to contention in the buffer pool. For more information, see *synch/mutex/innodb/buf_pool_mutex* (p. 930).

**synch/mutex/innodb/fil_system_mutex**

The process is waiting for access to the tablespace memory cache. For more information, see *synch/mutex/innodb/fil_system_mutex* (p. 932).

**synch/mutex/innodb/trx_sys_mutex**

Operations are checking, updating, deleting, or adding transaction IDs in InnoDB in a consistent or controlled manner. These operations require a `trx_sys` mutex call, which is tracked by Performance Schema instrumentation. Operations include management of the transaction system when the database starts or shuts down, rollbacks, undo cleanups, row read access, and buffer pool loads. High database load with a large number of transactions results in the frequent appearance of this wait event. For more information, see *synch/mutex/innodb/trx_sys_mutex* (p. 935).

**synch/mutex/mysys/KEY_CACHE::cache_lock**

The `keycache->cache_lock` mutex controls access to the key cache for MyISAM tables. While Aurora MySQL doesn’t allow usage of MyISAM tables to store persistent data, they are used to store internal temporary tables. Consider checking the `created_tmp_tables` or `created_tmp_disk_tables` status counters, because in certain situations, temporary tables are written to disk when they no longer fit in memory.

**synch/mutex/sql/FILE_AS_TABLE::LOCK_offsets**

The engine acquires this mutex when opening or creating a table metadata file. When this wait event occurs with excessive frequency, the number of tables being created or opened has spiked.

**synch/mutex/sql/FILE_AS_TABLE::LOCK_shim_lists**

The engine acquires this mutex while performing operations such as `reset_size`, `detach_contents`, or `add_contents` on the internal structure that keeps track of opened tables. The mutex synchronizes access to the list contents. When this wait event occurs with high frequency, it indicates a sudden change in the set of tables that were previously accessed. The engine needs to access new tables or let go of the context related to previously accessed tables.

**synch/mutex/sql/LOCK_open**

The number of tables that your sessions are opening exceeds the size of the table definition cache or the table open cache. Increase the size of these caches. For more information, see [How MySQL opens and closes tables](#).
### synch/mutex/sql/LOCK_table_cache

The number of tables that your sessions are opening exceeds the size of the table definition cache or the table open cache. Increase the size of these caches. For more information, see [How MySQL opens and closes tables](https://dev.mysql.com/doc/refman/8.0/en/session-variables.html#sysvar_table_open_cache).

### synch/mutex/sql/LOG

In this wait event, there are threads waiting on a log lock. For example, a thread might wait for a lock to write to the slow query log file.

### synch/mutex/sql/MYSQL_BIN_LOG::LOCK_commit

In this wait event, there is a thread that is waiting to acquire a lock with the intention of committing to the binary log. Binary logging contention can occur on databases with a very high change rate. Depending on your version of MySQL, there are certain locks being used to protect the consistency and durability of the binary log. In RDS for MySQL, binary logs are used for replication and the automated backup process. In Aurora MySQL, binary logs are not needed for native replication or backups. They are disabled by default but can be enabled and used for external replication or change data capture. For more information, see [The binary log](https://dev.mysql.com/doc/refman/8.0/en/replication-summary.html) in the MySQL documentation.

### synch/mutex/sql/MYSQL_BIN_LOG::LOCK_dump_thread_metrics_collection

If binary logging is turned on, the engine acquires this mutex when it prints active dump threads metrics to the engine error log and to the internal operations map.

### synch/mutex/sql/MYSQL_BIN_LOG::LOCK_inactive_binlogs_map

If binary logging is turned on, the engine acquires this mutex when it adds to, deletes from, or searches through the list of binlog files behind the latest one.

### synch/mutex/sql/MYSQL_BIN_LOG::LOCK_io_cache

If binary logging is turned on, the engine acquires this mutex during Aurora binlog IO cache operations: allocate, resize, free, write, read, purge, and access cache info. If this event occurs frequently, the engine is accessing the cache where binlog events are stored. To reduce wait times, reduce commits. Try grouping multiple statements into a single transaction.

### synch/mutex/sql/MYSQL_BIN_LOG::LOCK_log

You have turned on binary logging. There might be high commit throughput, many transactions committing, or replicas reading binlogs. Consider using multirow statements or bundling statements into one transaction. In Aurora, use global databases instead of binary log replication or use the `aurora_binlog_*` parameters.

### synch/mutex/sql/SERVER_THREAD::LOCK_sync

The mutex `SERVER_THREAD::LOCK_sync` is acquired during the scheduling, processing, or launching of threads for file writes. The excessive occurrence of this wait event indicates increased write activity in the database.

### synch/mutex/sql/TABLESPACES:lock

The engine acquires the `TABLESPACES:lock` mutex during the following tablespace operations: create, delete, truncate, and extend. The excessive occurrence of this wait event indicates a high frequency of tablespace operations. An example is loading a large amount of data into the database.

### synch/rwlock/innodb/dict

In this wait event, there are threads waiting on an rwlock held on the InnoDB data dictionary.

### synch/rwlock/innodb/dict_operation_lock

In this wait event, there are threads holding locks on InnoDB data dictionary operations.
synch/rwlock/innodb/dict sys RW lock

A high number of concurrent data control language statements (DCLs) in data definition language code (DDLs) are triggered at the same time. Reduce the application's dependency on DDLs during regular application activity.

synch/rwlock/innodb/index_tree_rw_lock

A large number of similar data manipulation language (DML) statements are accessing the same database object at the same time. Try using multirow statements. Also, spread the workload over different database objects. For example, implement partitioning.

synch/sxlock/innodb/dict_operation_lock

A high number of concurrent data control language statements (DCLs) in data definition language code (DDLs) are triggered at the same time. Reduce the application's dependency on DDLs during regular application activity.

synch/sxlock/innodb/dict_sys_lock

A high number of concurrent data control language statements (DCLs) in data definition language code (DDLs) are triggered at the same time. Reduce the application's dependency on DDLs during regular application activity.

synch/sxlock/innodb/hash_table_locks

The session couldn't find pages in the buffer pool. The engine either needs to read a file or modify the least-recently used (LRU) list for the buffer pool. Consider increasing the buffer cache size and improving access paths for the relevant queries.

synch/sxlock/innodb/index_tree_rw_lock

Many similar data manipulation language (DML) statements are accessing the same database object at the same time. Try using multirow statements. Also, spread the workload over different database objects. For example, implement partitioning.

For more information on troubleshooting synch wait events, see Why is my MySQL DB instance showing a high number of active sessions waiting on SYNCH wait events in Performance Insights?

Aurora MySQL thread states

The following are some common thread states for Aurora MySQL.

checking permissions

The thread is checking whether the server has the required privileges to run the statement.

checking query cache for query

The server is checking whether the current query is present in the query cache.

cleaned up

This is the final state of a connection whose work is complete but which hasn't been closed by the client. The best solution is to explicitly close the connection in code. Or you can set a lower value for wait_timeout in your parameter group.

closing tables

The thread is flushing the changed table data to disk and closing the used tables. If this isn't a fast operation, verify the network bandwidth consumption metrics against the instance class network bandwidth. Also, check that the parameter values for table_open_cache and table_definition_cache parameter allow for enough tables to be simultaneously open so that the engine doesn't need to open and close tables frequently. These parameters influence the memory consumption on the instance.
converting HEAP to MyISAM

The query is converting a temporary table from in-memory to on-disk. This conversion is necessary because the temporary tables created by MySQL in the intermediate steps of query processing grew too big for memory. Check the values of `tmp_table_size` and `max_heap_table_size`. In later versions, this thread state name is converting HEAP to ondisk.

converting HEAP to ondisk

The thread is converting an internal temporary table from an in-memory table to an on-disk table.

copy to tmp table

The thread is processing an `ALTER TABLE` statement. This state occurs after the table with the new structure has been created but before rows are copied into it. For a thread in this state, you can use the Performance Schema to obtain information about the progress of the copy operation.

creating sort index

Aurora MySQL is performing a sort because it can't use an existing index to satisfy the `ORDER BY` or `GROUP BY` clause of a query. For more information, see [creating sort index](p. 939).

creating table

The thread is creating a permanent or temporary table.

delayed commit ok done

An asynchronous commit in Aurora MySQL has received an acknowledgement and is complete.

delayed commit ok initiated

The Aurora MySQL thread has started the async commit process but is waiting for acknowledgement. This is usually the genuine commit time of a transaction.

delayed send ok done

An Aurora MySQL worker thread that is tied to a connection can be freed while a response is sent to the client. The thread can begin other work. The state `delayed send ok` means that the asynchronous acknowledgement to the client completed.

delayed send ok initiated

An Aurora MySQL worker thread has sent a response asynchronously to a client and is now free to do work for other connections. The transaction has started an async commit process that hasn't yet been acknowledged.

executing

The thread has begun running a statement.

freeing items

The thread has run a command. Some freeing of items done during this state involves the query cache. This state is usually followed by cleaning up.

init

This state occurs before the initialization of `ALTER TABLE`, `DELETE`, `INSERT`, `SELECT`, or `UPDATE` statements. Actions in this state include flushing the binary log or InnoDB log, and some cleanup of the query cache.

master has sent all binlog to slave

The primary node has finished its part of the replication. The thread is waiting for more queries to run so that it can write to the binary log (binlog).

opening tables

The thread is trying to open a table. This operation is fast unless an `ALTER TABLE` or a `LOCK TABLE` statement needs to finish, or it exceeds the value of `table_open_cache`. 
optimizing

The server is performing initial optimizations for a query.

preparing

This state occurs during query optimization.

query end

This state occurs after processing a query but before the freeing items state.

removing duplicates

Aurora MySQL couldn't optimize a DISTINCT operation in the early stage of a query. Aurora MySQL must remove all duplicated rows before sending the result to the client.

searching rows for update

The thread is finding all matching rows before updating them. This stage is necessary if the UPDATE is changing the index that the engine uses to find the rows.

sending binlog event to slave

The thread read an event from the binary log and is sending it to the replica.

sending cached result to client

The server is taking the result of a query from the query cache and sending it to the client.

sending data

The thread is reading and processing rows for a SELECT statement but hasn't yet started sending data to the client. The process is identifying which pages contain the results necessary to satisfy the query. For more information, see sending data (p. 941).

sending to client

The server is writing a packet to the client. In earlier MySQL versions, this wait event was labeled writing to net.

starting

This is the first stage at the beginning of statement execution.

statistics

The server is calculating statistics to develop a query execution plan. If a thread is in this state for a long time, the server is probably disk-bound while performing other work.

storing result in query cache

The server is storing the result of a query in the query cache.

system lock

The thread has called mysql_lock_tables, but the thread state hasn't been updated since the call. This general state occurs for many reasons.

update

The thread is preparing to start updating the table.

updating

The thread is searching for rows and is updating them.

user lock

The thread issued a GET_LOCK call. The thread either requested an advisory lock and is waiting for it, or is planning to request it.
waiting for more updates
The primary node has finished its part of the replication. The thread is waiting for more queries to run so that it can write to the binary log (binlog).

waiting for schema metadata lock
This is a wait for a metadata lock.

waiting for stored function metadata lock
This is a wait for a metadata lock.

waiting for stored procedure metadata lock
This is a wait for a metadata lock.

waiting for table flush
The thread is executing FLUSH TABLES and is waiting for all threads to close their tables. Or the thread received notification that the underlying structure for a table changed, so it must reopen the table to get the new structure. To reopen the table, the thread must wait until all other threads have closed the table. This notification takes place if another thread has used one of the following statements on the table: FLUSH TABLES, ALTER TABLE, RENAME TABLE, REPAIR TABLE, ANALYZE TABLE, or OPTIMIZE TABLE.

waiting for table level lock
One session is holding a lock on a table while another session tries to acquire the same lock on the same table.

waiting for table metadata lock
Aurora MySQL uses metadata locking to manage concurrent access to database objects and to ensure data consistency. In this wait event, one session is holding a metadata lock on a table while another session tries to acquire the same lock on the same table. When the Performance Schema is enabled, this thread state is reported as the wait event synch/cond/sql/MDL_context::COND_wait_status.

writing to net
The server is writing a packet to the network. In later MySQL versions, this wait event is labeled Sending to client.

Aurora MySQL isolation levels
Learn how DB instances in an Aurora MySQL cluster implement the database property of isolation. This topic explains how the Aurora MySQL default behavior balances between strict consistency and high performance. You can use this information to help you decide when to change the default settings based on the traits of your workload.

Available isolation levels for writer instances
You can use the isolation levels REPEATABLE, READ, READ COMMITTED, READ UNCOMMITTED, and SERIALIZABLE on the primary instance of an Aurora MySQL DB cluster. These isolation levels work the same in Aurora MySQL as in RDS for MySQL.

REPEATABLE READ isolation level for reader instances
By default, Aurora MySQL DB instances that are configured as read-only Aurora Replicas always use the REPEATABLE READ isolation level. These DB instances ignore any SET TRANSACTION ISOLATION LEVEL statements and continue using the REPEATABLE READ isolation level.

You can't set the isolation level for reader DB instances using DB parameters or DB cluster parameters.
READ COMMITTED isolation level for reader instances

If your application includes a write-intensive workload on the primary instance and long-running queries on the Aurora Replicas, you might experience substantial purge lag. Purge lag happens when internal garbage collection is blocked by long-running queries. The symptom that you see is a high value for history list length in the output from the SHOW ENGINE INNODB STATUS command. You can monitor this value using the RollbackSegmentHistoryListLength metric in CloudWatch. Substantial purge lag can reduce the effectiveness of secondary indexes, decrease overall query performance, and lead to wasted storage space.

If you experience such issues, you can set an Aurora MySQL session-level configuration setting, aurora_read_replica_read_committed, to use the READ COMMITTED isolation level on Aurora Replicas. When you apply this setting, you can help reduce slowdowns and wasted space that can result from performing long-running queries at the same time as transactions that modify your tables.

We recommend making sure that you understand the specific Aurora MySQL behavior of the READ COMMITTED isolation before using this setting. The Aurora Replica READ COMMITTED behavior complies with the ANSI SQL standard. However, the isolation is less strict than typical MySQL READ COMMITTED behavior that you might be familiar with. Therefore, you might see different query results under READ COMMITTED on an Aurora MySQL read replica than you might see for the same query under READ COMMITTED on the Aurora MySQL primary instance or on RDS for MySQL. You might consider using the aurora_read_replica_read_committed setting for such cases as a comprehensive report that scans a very large database. In contrast, you might avoid it for short queries with small result sets, where precision and repeatability are important.

The READ COMMITTED isolation level isn't available for sessions within a secondary cluster in an Aurora global database that use the write forwarding feature. For information about write forwarding, see Using write forwarding in an Amazon Aurora global database (p. 1831).

Using READ COMMITTED for readers

To use the READ COMMITTED isolation level for Aurora Replicas, set the aurora_read_replica_read_committed configuration setting to ON. Use this setting at the session level while connected to a specific Aurora Replica. To do so, run the following SQL commands.

```sql
set session aurora_read_replica_read_committed = ON;
set session transaction isolation level read committed;
```

You might use this configuration setting temporarily to perform interactive, one-time queries. You might also want to run a reporting or data analysis application that benefits from the READ COMMITTED isolation level, while leaving the default setting unchanged for other applications.

When the aurora_read_replica_read_committed setting is turned on, use the SET TRANSACTION ISOLATION LEVEL command to specify the isolation level for the appropriate transactions.

```sql
set transaction isolation level read committed;
```

Differences in READ COMMITTED behavior on Aurora replicas

The aurora_read_replica_read_committed setting makes the READ COMMITTED isolation level available for an Aurora Replica, with consistency behavior that is optimized for long-running transactions. The READ COMMITTED isolation level on Aurora Replicas has less strict isolation than on Aurora primary instances. For that reason, enable this setting only on Aurora Replicas where you know that your queries can accept the possibility of certain types of inconsistent results.

Your queries can experience certain kinds of read anomalies when the aurora_read_replica_read_committed setting is turned on. Two kinds of anomalies are especially important to understand and handle in your application code. A non-repeatable read occurs when...
another transaction commits while your query is running. A long-running query can see different data
at the start of the query than it sees at the end. A phantom read occurs when other transactions cause
existing rows to be reorganized while your query is running, and one or more rows are read twice by your
query.

Your queries might experience inconsistent row counts as a result of phantom reads. Your queries might
also return incomplete or inconsistent results due to non-repeatable reads. For example, suppose that
a join operation refers to tables that are concurrently modified by SQL statements such as INSERT or
DELETE. In this case, the join query might read a row from one table but not the corresponding row from
another table.

The ANSI SQL standard allows both of these behaviors for the READ COMMITTED isolation level.
However, those behaviors are different than the typical MySQL implementation of READ COMMITTED.
Thus, before enabling the aurora_read_replica_read_committed setting, check any existing SQL
code to verify if it operates as expected under the looser consistency model.

Row counts and other results might not be strongly consistent under the READ COMMITTED isolation
level while this setting is enabled. Thus, you typically enable the setting only while running analytic
queries that aggregate large amounts of data and don't require absolute precision. If you don't have
these kinds of long-running queries alongside a write-intensive workload, you probably don't need the
aurora_read_replica_read_committed setting. Without the combination of long-running queries
and a write-intensive workload, you're unlikely to encounter issues with the length of the history list.

Example Queries showing isolation behavior for READ COMMITTED on Aurora Replicas

The following example shows how READ COMMITTED queries on an Aurora Replica might return non-
repeatable results if transactions modify the associated tables at the same time. The table BIG_TABLE
contains 1 million rows before any queries start. Other data manipulation language (DML) statements
add, remove, or change rows while they are running.

The queries on the Aurora primary instance under the READ COMMITTED isolation level produce
predictable results. However, the overhead of keeping the consistent read view for the lifetime of every
long-running query can lead to expensive garbage collection later.

The queries on the Aurora Replica under the READ COMMITTED isolation level are optimized to minimize
this garbage collection overhead. The tradeoff is that the results might vary depending on whether
the queries retrieve rows that are added, removed, or reorganized by transactions that are committed
while the query is running. The queries are allowed to consider these rows, but aren't required to. For
demonstration purposes, the queries check only the number of rows in the table by using the COUNT(*)
function.

<table>
<thead>
<tr>
<th>Time</th>
<th>DML statement on Aurora primary instance</th>
<th>Query on Aurora primary instance with READ COMMITTED</th>
<th>Query on Aurora Replica with READ COMMITTED</th>
</tr>
</thead>
<tbody>
<tr>
<td>T1</td>
<td>INSERT INTO big_table SELECT * FROM other_table LIMIT 1000000; COMMIT;</td>
<td>Q1: SELECT COUNT(*) FROM big_table;</td>
<td>Q2: SELECT COUNT(*) FROM big_table;</td>
</tr>
<tr>
<td>T2</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>T3</td>
<td>INSERT INTO big_table (c1, c2) VALUES (1, 'one more row'); COMMIT;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

1160
If the queries finish quickly, before any other transactions perform DML statements and commit, the results are predictable and the same between the primary instance and the Aurora Replica. Let's examine the differences in behavior in detail, starting with the first query.

The results for Q1 are highly predictable because `READ COMMITTED` on the primary instance uses a strong consistency model similar to the `REPEATABLE READ` isolation level.
The results for Q2 might vary depending on what transactions are committed while that query is running. For example, suppose that other transactions perform DML statements and commit while the queries are running. In this case, the query on the Aurora Replica with the READ COMMITTED isolation level might or might not take the changes into account. The row counts aren't predictable in the same way as under the REPEATABLE READ isolation level. They also aren't as predictable as queries running under the READ COMMITTED isolation level on the primary instance, or on an RDS for MySQL instance.

The UPDATE statement at T7 doesn't actually change the number of rows in the table. However, by changing the length of a variable-length column, this statement can cause rows to be reorganized internally. A long-running READ COMMITTED transaction might see the old version of a row, and later within the same query see the new version of the same row. The query can also skip both the old and new versions of the row, so the row count might be different than expected.

The results of Q5 and Q6 might be identical or slightly different. Query Q6 on the Aurora Replica under READ COMMITTED is able to see, but is not required to see, the new rows that are committed while the query is running. It might also see the row from one table, but not from the other table. If the join query doesn't find a matching row in both tables, it returns a count of zero. If the query does find both the new rows in PARENT_TABLE and CHILD_TABLE, the query returns a count of one. In a long-running query, the lookups from the joined tables might happen at widely separated times.

Note
These differences in behavior depend on the timing of when transactions are committed and when the queries process the underlying table rows. Thus, you're most likely to see such differences in report queries that take minutes or hours and that run on Aurora clusters processing OLTP transactions at the same time. These are the kinds of mixed workloads that benefit the most from the READ COMMITTED isolation level on Aurora Replicas.

### Aurora MySQL hints

You can use SQL hints with Aurora MySQL queries to fine-tune performance. You can also use hints to prevent execution plans for important queries from changing because of unpredictable conditions.

**Tip**
To verify the effect that a hint has on a query, examine the query plan produced by the EXPLAIN statement. Compare the query plans with and without the hint.

In Aurora MySQL version 3, you can use all the hints that are available in MySQL Community Edition 8.0. For more information about these hints, see Optimizer Hints in the MySQL Reference Manual.

The following hints are available in Aurora MySQL version 2. These hints apply to queries that use the hash join feature in Aurora MySQL version 2, especially queries that use parallel query optimization.

**PQ, NO_PQ**

Specifies whether to force the optimizer to use parallel query on a per-table or per-query basis.

PQ forces the optimizer to use parallel query for specified tables or the whole query (block). NO_PQ prevents the optimizer from using parallel query for specified tables or the whole query (block).

This hint is available in Aurora MySQL version 2.11 and higher. The following examples show you how to use this hint.

**Note**
Specifying a table name forces the optimizer to apply the PQ/NO_PQ hint only on those select tables. Not specifying a table name forces the PQ/NO_PQ hint on all tables affected by the query block.

```sql
EXPLAIN SELECT /*+ PQ() */ f1, f2
   FROM num1 t1 WHERE f1 > 10 and f2 < 100;
```
Hints

EXPLAIN SELECT /*+ PQ(t1) */ f1, f2
FROM num1 t1 WHERE f1 > 10 AND f2 < 100;

EXPLAIN SELECT /*+ PQ(t1,t2) */ f1, f2
FROM num1 t1, num1 t2 WHERE t1.f1 = t2.f21;

EXPLAIN SELECT /*+ NO_PQ() */ f1, f2
FROM num1 t1 WHERE f1 > 10 AND f2 < 100;

EXPLAIN SELECT /*+ NO_PQ(t1) */ f1, f2
FROM num1 t1 WHERE f1 > 10 AND f2 < 100;

EXPLAIN SELECT /*+ NO_PQ(t1,t2) */ f1, f2
FROM num1 t1, num1 t2 WHERE t1.f1 = t2.f21;

HASH JOIN, NO_HASH_JOIN

Turns on or off the ability of the parallel query optimizer to choose whether to use the hash join optimization method for a query. HASH_JOIN lets the optimizer use hash join if that mechanism is more efficient. NO_HASH_JOIN prevents the optimizer from using hash join for the query. This hint is available in Aurora MySQL version 2.08 and higher. It has no effect in Aurora MySQL version 3.

The following examples show you how to use this hint.

EXPLAIN SELECT /*+ HASH_JOIN(t2) */ f1, f2
FROM t1, t2 WHERE t1.f1 = t2.f1;

EXPLAIN SELECT /*+ NO_HASH_JOIN(t2) */ f1, f2
FROM t1, t2 WHERE t1.f1 = t2.f1;

HASH_JOIN_PROBING, NO_HASH_JOIN_PROBING

In a hash join query, specifies whether to use the specified table for the probe side of the join. The query tests if column values from the build table exist in the probe table, instead of reading the entire contents of the probe table. You can use HASH_JOIN_PROBING and HASH_JOIN_BUILDING to specify how hash join queries are processed without reordering the tables within the query text. This hint is available in Aurora MySQL version 2.08 and higher. It has no effect in Aurora MySQL version 3.

The following examples show how to use this hint. Specifying the HASH_JOIN_PROBING hint for the table T2 has the same effect as specifying NO_HASH_JOIN_PROBING for the table T1.

EXPLAIN SELECT /*+ HASH_JOIN(t2) HASH_JOIN_PROBING(t2) */ f1, f2
FROM t1, t2 WHERE t1.f1 = t2.f1;

EXPLAIN SELECT /*+ HASH_JOIN(t2) NO_HASH_JOIN_PROBING(t1) */ f1, f2
FROM t1, t2 WHERE t1.f1 = t2.f1;

HASH_JOIN_BUILDING, NO_HASH_JOIN_BUILDING

In a hash join query, specifies whether to use the specified table for the build side of the join. The query processes all the rows from this table to build the list of column values to cross-reference with the other table. You can use HASH_JOIN_PROBING and HASH_JOIN_BUILDING to specify how hash join queries are processed without reordering the tables within the query text. This hint is available in Aurora MySQL version 2.08 and higher. It has no effect in Aurora MySQL version 3.

The following example shows you how to use this hint. Specifying the HASH_JOIN_BUILDING hint for the table T2 has the same effect as specifying NO_HASH_JOIN_BUILDING for the table T1.

EXPLAIN SELECT /*+ HASH_JOIN(t2) HASH_JOIN_BUILDING(t2) */ f1, f2
JOIN_FIXED_ORDER

Specifies that tables in the query are joined based on the order they are listed in the query. It is useful with queries involving three or more tables. It is intended as a replacement for the MySQL STRAIGHT_JOIN hint and is equivalent to the MySQL JOIN_FIXED_ORDER hint. This hint is available in Aurora MySQL version 2.08 and higher.

The following example shows you how to use this hint.

```sql
EXPLAIN SELECT /*+ JOIN_FIXED_ORDER() */ f1, f2
FROM t1 JOIN t2 USING (id) JOIN t3 USING (id) JOIN t4 USING (id);
```

JOIN_ORDER

Specifies the join order for the tables in the query. It is useful with queries involving three or more tables. It is equivalent to the MySQL JOIN_ORDER hint. This hint is available in Aurora MySQL version 2.08 and higher.

The following example shows you how to use this hint.

```sql
EXPLAIN SELECT /*+ JOIN_ORDER (t4, t2, t1, t3) */ f1, f2
FROM t1 JOIN t2 USING (id) JOIN t3 USING (id) JOIN t4 USING (id);
```

JOIN_PREFIX

Specifies the tables to put first in the join order. It is useful with queries involving three or more tables. It is equivalent to the MySQL JOIN_PREFIX hint. This hint is available in Aurora MySQL version 2.08 and higher.

The following example shows you how to use this hint.

```sql
EXPLAIN SELECT /*+ JOIN_PREFIX (t4, t2) */ f1, f2
FROM t1 JOIN t2 USING (id) JOIN t3 USING (id) JOIN t4 USING (id);
```

JOIN_SUFFIX

Specifies the tables to put last in the join order. It is useful with queries involving three or more tables. It is equivalent to the MySQL JOIN_SUFFIX hint. This hint is available in Aurora MySQL version 2.08 and higher.

The following example shows you how to use this hint.

```sql
EXPLAIN SELECT /*+ JOIN_SUFFIX (t1) */ f1, f2
FROM t1 JOIN t2 USING (id) JOIN t3 USING (id) JOIN t4 USING (id);
```

For information about using hash join queries, see Optimizing large Aurora MySQL join queries with hash joins (p. 1106).

Aurora MySQL stored procedures

You can manage your Aurora MySQL DB cluster by calling built-in stored procedures.
Topics

- Configuring (p. 1166)
- Ending a session or query (p. 1168)
- Logging (p. 1170)
- Managing the Global Status History (p. 1171)
- Replicating (p. 1173)
Configuring

The following stored procedures set and show configuration parameters, such as for binary log file retention.

Topics
- `mysql.rds_set_configuration` (p. 1166)
- `mysql.rds_show_configuration` (p. 1167)

`mysql.rds_set_configuration`

Specifies the number of hours to retain binary logs or the number of seconds to delay replication.

Syntax

```
CALL mysql.rds_set_configuration(name, value);
```

Parameters

- **name**
  
  The name of the configuration parameter to set.

- **value**

  The value of the configuration parameter.

Usage notes

The `mysql.rds_set_configuration` procedure supports the following configuration parameters:

- `binlog retention hours` (p. 1166)

The configuration parameters are stored permanently and survive any DB instance reboot or failover.

`binlog retention hours`

The `binlog retention hours` parameter is used to specify the number of hours to retain binary log files. Amazon Aurora normally purges a binary log as soon as possible, but the binary log might still be required for replication with a MySQL database external to Aurora.

The default value of `binlog retention hours` is NULL. For Aurora MySQL, NULL means binary logs are cleaned up lazily. Aurora MySQL binary logs might remain in the system for a certain period, which is usually not longer than a day.

To specify the number of hours to retain binary logs on a DB cluster, use the `mysql.rds_set_configuration` stored procedure and specify a period with enough time for replication to occur, as shown in the following example.

```
call mysql.rds_set_configuration('binlog retention hours', 24);
```

**Note**

You can't use the value 0 for `binlog retention hours`.

For Aurora MySQL version 2.11.0 and higher and version 3 DB clusters, the maximum `binlog retention hours` value is 2160 (90 days).
After you set the retention period, monitor storage usage for the DB instance to make sure that the retained binary logs don't take up too much storage.

`mysql.rds_show_configuration`

The number of hours that binary logs are retained.

Syntax

```sql
CALL mysql.rds_show_configuration;
```

Usage notes

To verify the number of hours that Amazon RDS retains binary logs, use the `mysql.rds_show_configuration` stored procedure.

Examples

The following example displays the retention period:

```sql
CALL mysql.rds_show_configuration;
```

<table>
<thead>
<tr>
<th>name</th>
<th>value</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>binlog retention hours</td>
<td>24</td>
<td>binlog retention hours specifies the duration in hours before binary logs are automatically deleted.</td>
</tr>
</tbody>
</table>
Ending a session or query

The following stored procedures end a session or query.

*Topics*

- `mysql.rds_kill (p. 1168)`
- `mysql.rds_kill_query (p. 1168)`

**mysql.rds_kill**

Ends a connection to the MySQL server.

**Syntax**

```
CALL mysql.rds_kill(processID);
```

**Parameters**

*processID*

The identity of the connection thread to be ended.

**Usage notes**

Each connection to the MySQL server runs in a separate thread. To end a connection, use the `mysql.rds_kill` procedure and pass in the thread ID of that connection. To obtain the thread ID, use the MySQL `SHOW PROCESSLIST` command.

**Examples**

The following example ends a connection with a thread ID of 4243:

```
CALL mysql.rds_kill(4243);
```

**mysql.rds_kill_query**

Ends a query running against the MySQL server.

**Syntax**

```
CALL mysql.rds_kill_query(processID);
```

**Parameters**

*processID*

The identity of the process or thread that is running the query to be ended.

**Usage notes**

To stop a query running against the MySQL server, use the `mysql_rds_kill_query` procedure and pass in the connection ID of the thread that is running the query. The procedure then terminates the connection.
To obtain the ID, query the MySQL `INFORMATION_SCHEMA.PROCESSLIST` table or use the MySQL `SHOW PROCESSLIST` command. The value in the ID column from `SHOW PROCESSLIST` or `SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST` is the `processID`.

Examples

The following example stops a query with a query thread ID of 230040:

```sql
CALL mysql.rds_kill_query(230040);
```
Logging

The following stored procedures rotate MySQL logs to backup tables. For more information, see [Aurora MySQL database log files](#).

Topics
- `mysql.rds_rotate_general_log (p. 1170)`
- `mysql.rds_rotate_slow_log (p. 1170)`

### mysql.rds_rotate_general_log

Rotates the `mysql.general_log` table to a backup table.

**Syntax**

```sql
CALL mysql.rds_rotate_general_log;
```

**Usage notes**

You can rotate the `mysql.general_log` table to a backup table by calling the `mysql.rds_rotate_general_log` procedure. When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If a backup log table already exists, then it is deleted before the current log table is copied to the backup. You can query the backup log table if needed. The backup log table for the `mysql.general_log` table is named `mysql.general_log_backup`.

You can run this procedure only when the `log_output` parameter is set to `TABLE`.

### mysql.rds_rotate_slow_log

Rotates the `mysql.slow_log` table to a backup table.

**Syntax**

```sql
CALL mysql.rds_rotate_slow_log;
```

**Usage notes**

You can rotate the `mysql.slow_log` table to a backup table by calling the `mysql.rds_rotate_slow_log` procedure. When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If a backup log table already exists, then it is deleted before the current log table is copied to the backup.

You can query the backup log table if needed. The backup log table for the `mysql.slow_log` table is named `mysql.slow_log_backup`.
Managing the Global Status History

Amazon RDS provides a set of procedures that take snapshots of the values of status variables over time and write them to a table, along with any changes since the last snapshot. This infrastructure is called Global Status History. For more information, see Managing the Global Status History.

The following stored procedures manage how the Global Status History is collected and maintained.

Topics
- `mysql.rds_collect_global_status_history` (p. 1171)
- `mysql.rds_disable_gsh_collector` (p. 1171)
- `mysql.rds_disable_gsh_rotation` (p. 1171)
- `mysql.rds_enable_gsh_collector` (p. 1171)
- `mysql.rds_enable_gsh_rotation` (p. 1172)
- `mysql.rds_rotate_global_status_history` (p. 1172)
- `mysql.rds_set_gsh_collector` (p. 1172)
- `mysql.rds_set_gsh_rotation` (p. 1172)

**mysql.rds_collect_global_status_history**

Takes a snapshot on demand for the Global Status History.

**Syntax**

```sql
CALL mysql.rds_collect_global_status_history;
```

**mysql.rds_disable_gsh_collector**

Turns off snapshots taken by the Global Status History.

**Syntax**

```sql
CALL mysql.rds_disable_gsh_collector;
```

**mysql.rds_disable_gsh_rotation**

Turns off rotation of the `mysql.global_status_history` table.

**Syntax**

```sql
CALL mysql.rds_disable_gsh_rotation;
```

**mysql.rds_enable_gsh_collector**

Turns on the Global Status History to take default snapshots at intervals specified by `rds_set_gsh_collector`.

**Syntax**

```sql
CALL mysql.rds_enable_gsh_collector;
```
CALL mysql.rds_enable_gsh_rotation;

**mysql.rds_enable_gsh_rotation**

Turns on rotation of the contents of the `mysql.global_status_history` table to `mysql.global_status_history_old` at intervals specified by `rds_set_gsh_rotation`.

**Syntax**

CALL mysql.rds_enable_gsh_rotation;

**mysql.rds_rotate_global_status_history**

Rotates the contents of the `mysql.global_status_history` table to `mysql.global_status_history_old` on demand.

**Syntax**

CALL mysql.rds_rotate_global_status_history;

**mysql.rds_set_gsh_collector**

Specifies the interval, in minutes, between snapshots taken by the Global Status History.

**Syntax**

CALL mysql.rds_set_gsh_collector(\textit{intervalPeriod});

**Parameters**

\textit{intervalPeriod}

The interval, in minutes, between snapshots. Default value is 5.

**mysql.rds_set_gsh_rotation**

Specifies the interval, in days, between rotations of the `mysql.global_status_history` table.

**Syntax**

CALL mysql.rds_set_gsh_rotation(\textit{intervalPeriod});

**Parameters**

\textit{intervalPeriod}

The interval, in days, between table rotations. Default value is 7.
Replicating

You can call the following stored procedures while connected to the primary instance in an Aurora MySQL cluster. These procedures control how transactions are replicated from an external database into Aurora MySQL, or from Aurora MySQL to an external database. To learn how to use replication based on global transaction identifiers (GTIDs) with Aurora MySQL, see Using GTID-based replication for Amazon Aurora MySQL (p. 1043).

Topics

- `mysql.rds_assign_gtids_to_anonymous_transactions (Aurora MySQL version 3)` (p. 1173)
- `mysql.rds_disable_session_binlog (Aurora MySQL version 2)` (p. 1174)
- `mysql.rds_enable_session_binlog (Aurora MySQL version 2)` (p. 1175)
- `mysql.rds_gtid_purged (Aurora MySQL version 3)` (p. 1175)
- `mysql.rds_import_binlog_ssl_material (p. 1176)
- `mysql.rds_next_master_log (Aurora MySQL version 2)` (p. 1178)
- `mysql.rds_next_source_log (Aurora MySQL version 3)` (p. 1179)
- `mysql.rds_remove_binlog_ssl_material (p. 1181)
- `mysql.rds_reset_external_master (Aurora MySQL version 2)` (p. 1181)
- `mysql.rds_reset_external_source (Aurora MySQL version 3)` (p. 1182)
- `mysql.rds_set_external_master (Aurora MySQL version 2)` (p. 1182)
- `mysql.rds_set_external_master_with_auto_position (Aurora MySQL version 2)` (p. 1184)
- `mysql.rds_set_external_source (Aurora MySQL version 3)` (p. 1186)
- `mysql.rds_set_external_source_with_auto_position (Aurora MySQL version 3)` (p. 1188)
- `mysql.rds_set_master_auto_position (Aurora MySQL version 2)` (p. 1190)
- `mysql.rds_set_session_binlog_format (Aurora MySQL version 2)` (p. 1190)
- `mysql.rds_set_source_auto_position (Aurora MySQL version 3)` (p. 1191)
- `mysql.rds_skip_transaction_with_gtid (Aurora MySQL version 2 and 3)` (p. 1191)
- `mysql.rds_skip_repl_error (p. 1192)
- `mysql.rds_start_replication (p. 1193)
- `mysql.rds_start_replication_until (Aurora MySQL version 3)` (p. 1193)
- `mysql.rds_start_replication_until_gtid (Aurora MySQL version 3)` (p. 1194)
- `mysql.rds_stop_replication (p. 1195)

`mysql.rds_assign_gtids_to_anonymous_transactions (Aurora MySQL version 3)`

Configures the ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS option of the CHANGE REPLICATION SOURCE TO statement. It makes the replication channel assign a GTID to replicated transactions that don't have one. That way, you can perform binary log replication from a source that doesn't use GTID-based replication to a replica that does. For more information, see CHANGE REPLICATION SOURCE TO Statement and Replication From a Source Without GTIDs to a Replica With GTIDs in the MySQL Reference Manual.

**Syntax**

```
CALL mysql.rds_assign_gtids_to_anonymous_transactions(gtid_option);
```

**Parameters**

`gtid_option`

String value. The allowed values are OFF, LOCAL, or a specified UUID.
Usage notes

This procedure has the same effect as issuing the statement CHANGE REPLICATION SOURCE TO ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS = `gtid_option` in community MySQL.

GTID must be turned to ON for `gtid_option` to be set to LOCAL or a specific UUID.

The default is OFF, meaning that the feature isn't used.

LOCAL assigns a GTID including the replica's own UUID (the `server_uuid` setting).

Passing a parameter that is a UUID assigns a GTID that includes the specified UUID, such as the `server_uuid` setting for the replication source server.

Examples

To turn off this feature:

```sql
mysql> call mysql.rds_assign_gtids_to_anonymous_transactions('OFF');
+-------------+
| Message     |
| ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS has been set to: OFF |
+-------------+
1 row in set (0.07 sec)
```

To use the replica's own UUID:

```sql
mysql> call mysql.rds_assign_gtids_to_anonymous_transactions('LOCAL');
+-------------+
| Message     |
| ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS has been set to: LOCAL |
+-------------+
1 row in set (0.07 sec)
```

To use a specified UUID:

```sql
mysql> call mysql.rds_assign_gtids_to_anonymous_transactions('317a4760-f3dd-3b74-8e45-0615ed29de0e');
+-------------+
| Message     |
| ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS has been set to: 317a4760-f3dd-3b74-8e45-0615ed29de0e |
+-------------+
1 row in set (0.07 sec)
```

`mysql.rds_disable_session_binlog (Aurora MySQL version 2)`

Turns off binary logging for the current session by setting the `sql_log_bin` variable to OFF.

Syntax

```sql
CALL mysql.rds_disable_session_binlog;
```
Parameters

None

Usage notes

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance.

For Aurora, this procedure is supported for Aurora MySQL version 2.12 and higher MySQL 5.7-compatible versions.

**Note**

In Aurora MySQL version 3, you can use the following command to disable binary logging for the current session if you have the `SESSION_VARIABLES_ADMIN` privilege:

```
SET SESSION sql_log_bin = OFF;
```

### mysql.rds_enable_session_binlog (Aurora MySQL version 2)

Turns on binary logging for the current session by setting the `sql_log_bin` variable to `ON`.

**Syntax**

```
CALL mysql.rds_enable_session_binlog;
```

Parameters

None

Usage notes

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance.

For Aurora, this procedure is supported for Aurora MySQL version 2.12 and higher MySQL 5.7-compatible versions.

**Note**

In Aurora MySQL version 3, you can use the following command to enable binary logging for the current session if you have the `SESSION_VARIABLES_ADMIN` privilege:

```
SET SESSION sql_log_bin = ON;
```

### mysql.rds_gtid_purged (Aurora MySQL version 3)

Sets the global value of the system variable `gtid_purged` to a given global transaction identifier (GTID) set. The `gtid_purged` system variable is a GTID set that consists of the GTIDs of all transactions that have been committed on the server, but don’t exist in any binary log file on the server.

To allow compatibility with MySQL 8.0, there are two ways to set the value of `gtid_purged`:

- Replace the value of `gtid_purged` with your specified GTID set.
- Append your specified GTID set to the GTID set that `gtid_purged` already contains.

**Syntax**

To replace the value of `gtid_purged` with your specified GTID set:
CALL mysql.rds_gtid_purged (gtid_set);

To append the value of gtid_purged to your specified GTID set:

CALL mysql.rds_gtid_purged (+gtid_set);

**Parameters**

**gtid_set**

The value of gtid_set must be a superset of the current value of gtid_purged, and can't intersect with gtid_subtract(gtid_executed, gtid_purged). That is, the new GTID set must include any GTIDs that were already in gtid_purged, and can't include any GTIDs in gtid_executed that haven't yet been purged. The gtid_set parameter also can't include any GTIDs that are in the global gtid_owned set, the GTIDs for transactions that are currently being processed on the server.

**Usage notes**

The master user must run the mysql.rds_gtid_purged procedure.

This procedure is supported for Aurora MySQL version 3.04 and higher.

**Examples**

The following example assigns the GTID 3E11FA47-71CA-11E1-9E33-C80AA9429562:23 to the gtid_purged global variable.

```sql
CALL mysql.rds_gtid_purged('3E11FA47-71CA-11E1-9E33-C80AA9429562:23');
```

**mysql.rds_import_binlog_ssl_material**

Imports the certificate authority certificate, client certificate, and client key into an Aurora MySQL DB cluster. The information is required for SSL communication and encrypted replication.

**Note**

Currently, this procedure is supported for Aurora MySQL version 2: 2.09.2, 2.10.0, 2.10.1, and 2.11.0; and version 3: 3.01.1 and higher.

**Syntax**

```sql
CALL mysql.rds_import_binlog_ssl_material (ssl_material);
```

**Parameters**

**ssl_material**

JSON payload that contains the contents of the following .pem format files for a MySQL client:

- "ssl_ca":"Certificate authority certificate"
- "ssl_cert":"Client certificate"
- "ssl_key":"Client key"
Usage notes

Prepare for encrypted replication before you run this procedure:

- If you don't have SSL enabled on the external MySQL source database instance and don't have a client key and client certificate prepared, enable SSL on the MySQL database server and generate the required client key and client certificate.

- If SSL is enabled on the external source database instance, supply a client key and certificate for the Aurora MySQL DB cluster. If you don't have these, generate a new key and certificate for the Aurora MySQL DB cluster. To sign the client certificate, you must have the certificate authority key you used to configure SSL on the external MySQL source database instance.

For more information, see [Creating SSL certificates and keys using openssl](#) in the MySQL documentation.

**Important**

After you prepare for encrypted replication, use an SSL connection to run this procedure. The client key must not be transferred across an insecure connection.

This procedure imports SSL information from an external MySQL database into an Aurora MySQL DB cluster. The SSL information is in .pem format files that contain the SSL information for the Aurora MySQL DB cluster. During encrypted replication, the Aurora MySQL DB cluster acts a client to the MySQL database server. The certificates and keys for the Aurora MySQL client are in files in .pem format.

You can copy the information from these files into the `ssl_material` parameter in the correct JSON payload. To support encrypted replication, import this SSL information into the Aurora MySQL DB cluster.

The JSON payload must be in the following format.

```
{"ssl_ca":"-----BEGIN CERTIFICATE-----
ssl_ca_pem_body_code
-----END CERTIFICATE-----
"ssl_cert":"-----BEGIN CERTIFICATE-----
ssl_cert_pem_body_code
-----END CERTIFICATE-----
"ssl_key":"-----BEGIN RSA PRIVATE KEY-----
ssl_key_pem_body_code
-----END RSA PRIVATE KEY-----
}
```

**Examples**

The following example imports SSL information into an Aurora MySQL. In .pem format files, the body code typically is longer than the body code shown in the example.

```sql
call mysql.rds_import_binlog_ssl_material(
  '{"ssl_ca":"-----BEGIN CERTIFICATE-----
AAAAB3NzaC1yc2EAAAADAQABAAABAAGQCIksfKnuSevGj3eYhCeS3pcjqP3maAhDFcvB5706V

```
mysql.rds_next_master_log (Aurora MySQL version 2)

Changes the source database instance log position to the start of the next binary log on the source database instance. Use this procedure only if you are receiving replication I/O error 1236 on a read replica.

Syntax

CALL mysql.rds_next_master_log(
    curr_master_log
);

Parameters

curr_master_log

The index of the current master log file. For example, if the current file is named mysql-bin-changelog.012345, then the index is 12345. To determine the current master log file name, run the SHOW REPLICA STATUS command and view the Master_Log_File field.

Note

Previous versions of MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

Usage notes

The master user must run the mysql.rds_next_master_log procedure.

Warning

Call mysql.rds_next_master_log only if replication fails after a failover of a Multi-AZ DB instance that is the replication source, and the Last_IO_Errno field of SHOW REPLICA STATUS reports I/O error 1236. Calling mysql.rds_next_master_log can result in data loss in the read replica if transactions in the source instance were not written to the binary log on disk before the failover event occurred.

Examples

Assume replication fails on an Aurora MySQL read replica. Running SHOW REPLICA STATUS\G on the read replica returns the following result:

```
*************************** 1. row ***************************
Replica_IO_State: Source_Host: myhost.XXXXXXXXXXXXXX.rr-rrrr-1.rds.amazonaws.com
Source_User: MasterUser
Source_Port: 3306
Connect_Retry: 10
Source_Log_File: mysql-bin-changelog.012345
Read_Source_Log_Pos: 1219393
Relay_Log_File: relaylog.012340
```
The `Last_IO_Errno` field shows that the instance is receiving I/O error 1236. The `Master_Log_File` field shows that the file name is `mysql-bin-changelog.012345`, which means that the log file index is 12345. To resolve the error, you can call `mysql.rds_next_master_log` with the following parameter:

```
CALL mysql.rds_next_master_log(12345);
```

**Note**

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

**mysql.rds_next_source_log (Aurora MySQL version 3)**

Changes the source database instance log position to the start of the next binary log on the source database instance. Use this procedure only if you are receiving replication I/O error 1236 on a read replica.

**Syntax**

```
CALL mysql.rds_next_source_log(
    curr_source_log
);
```
Parameters

curr_source_log

The index of the current source log file. For example, if the current file is named mysql-bin-changelog.012345, then the index is 12345. To determine the current source log file name, run the SHOW REPLICA STATUS command and view the Source_Log_File field.

Usage notes

The master user must run the mysql.rds_next_source_log procedure.

Warning

Call mysql.rds_next_source_log only if replication fails after a failover of a Multi-AZ DB instance that is the replication source, and the Last_IO_Errno field of SHOW REPLICA STATUS reports I/O error 1236.

Calling mysql.rds_next_source_log can result in data loss in the read replica if transactions in the source instance were not written to the binary log on disk before the failover event occurred.

Examples

Assume replication fails on an Aurora MySQL read replica. Running SHOW REPLICA STATUS\G on the read replica returns the following result:

```

| Last_IO_Error: Got fatal error 1236 from source when reading data from binary log: 'Client requested source to start replication from impossible position; the

1180
The Last_IO_Errno field shows that the instance is receiving I/O error 1236. The Source_Log_File field shows that the file name is mysql-bin-changelog.012345, which means that the log file index is 12345. To resolve the error, you can call `mysql.rds_next_source_log` with the following parameter:

```sql
CALL mysql.rds_next_source_log(12345);
```

**mysql.rds_remove_binlog_ssl_material**

Removes the certificate authority certificate, client certificate, and client key for SSL communication and encrypted replication. This information is imported by using `mysql.rds_import_binlog_ssl_material` (p. 1176).

Syntax

```sql
CALL mysql.rds_remove_binlog_ssl_material;
```

**mysql.rds_reset_external_master (Aurora MySQL version 2)**

Reconfigures an Aurora MySQL DB instance to no longer be a read replica of an instance of MySQL running external to Amazon RDS.

**Important**

To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group (p. 229).

Syntax

```sql
CALL mysql.rds_reset_external_master;
```

**Usage notes**

The master user must run the `mysql.rds_reset_external_master` procedure. This procedure must be run on the MySQL DB instance to be removed as a read replica of a MySQL instance running external to Amazon RDS.

**Note**

We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. We recommend that you use Aurora Replicas to manage replication within an Aurora MySQL DB cluster when possible. For information about managing replication in Aurora MySQL DB clusters, see Using Aurora Replicas (p. 984).

For more information about using replication to import data from an instance of MySQL running external to Aurora MySQL, see Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication) (p. 1015).
**mysql.rds_reset_external_source (Aurora MySQL version 3)**

Reconfigures an Aurora MySQL DB instance to no longer be a read replica of an instance of MySQL running external to Amazon RDS.

**Important**
To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see [Modifying parameters in a DB parameter group](p. 229).

**Syntax**

```sql
CALL mysql.rds_reset_external_source;
```

**Usage notes**

The master user must run the `mysql.rds_reset_external_source` procedure. This procedure must be run on the MySQL DB instance to be removed as a read replica of a MySQL instance running external to Amazon RDS.

**Note**
We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. We recommend that you use Aurora Replicas to manage replication within an Aurora MySQL DB cluster when possible. For information about managing replication in Aurora MySQL DB clusters, see [Using Aurora Replicas](p. 984).

**mysql.rds_set_external_master (Aurora MySQL version 2)**

Configures an Aurora MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

The `mysql.rds_set_external_master` procedure is deprecated and will be removed in a future release. Use `mysql.rds_set_external_source` (p. 1186) instead.

**Important**
To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see [Modifying parameters in a DB parameter group](p. 229).

**Syntax**

```sql
CALL mysql.rds_set_external_master (host_name, host_port, replication_user_name, replication_user_password, mysql_binary_log_file_name, mysql_binary_log_file_location, ssl_encryption);
```

**Parameters**

`host_name`

The host name or IP address of the MySQL instance running external to Amazon RDS to become the source database instance.
**host_port**

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

**replication_user_name**

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

**replication_user_password**

The password of the user ID specified in replication_user_name.

**mysql_binary_log_file_name**

The name of the binary log on the source database instance that contains the replication information.

**mysql_binary_log_file_location**

The location in the mysql_binary_log_file_name binary log at which replication starts reading the replication information.

You can determine the binlog file name and location by running `SHOW MASTER STATUS` on the source database instance.

**ssl_encryption**

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

**Note**

The MASTER_SSL_VERIFY_SERVER_CERT option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

**Usage notes**

The master user must run the `mysql.rds_set_external_master` procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

Before you run `mysql.rds_set_external_master`, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify replication_user_name and replication_user_password values that indicate a replication user that has REPLICATION CLIENT and REPLICATION SLAVE permissions on the external instance of MySQL.

**To configure an external instance of MySQL as a source database instance**

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

   **MySQL 5.7**

   ```sql
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
   ```

   **MySQL 8.0**
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY 'password';

**Note**
Specify a password other than the prompt shown here as a security best practice.

2. On the external instance of MySQL, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain.

### MySQL 5.7

```sql
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

### MySQL 8.0

```sql
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

To use encrypted replication, configure source database instance to use SSL connections. Also, import the certificate authority certificate, client certificate, and client key into the DB instance or DB cluster using the `mysql.rds_import_binlog_ssl_material` procedure.

**Note**
We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. We recommend that you use Aurora Replicas to manage replication within an Aurora MySQL DB cluster when possible. For information about managing replication in Aurora MySQL DB clusters, see Using Aurora Replicas (p. 984).

After calling `mysql.rds_set_external_master` to configure an Amazon RDS DB instance as a read replica, you can call `mysql.rds_start_replication` on the read replica to start the replication process. You can call `mysql.rds_reset_external_master` (Aurora MySQL version 2) to remove the read replica configuration.

When `mysql.rds_set_external_master` is called, Amazon RDS records the time, user, and an action of set master in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

### Examples

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

```sql
call mysql.rds_set_external_master(
    'Externaldb.some.com',
    3306,
    'repl_user',
    'password',
    'mysql-bin-changelog.0777',
    128,
    0);
```

**mysql.rds_set_external_master_with_auto_position (Aurora MySQL version 2)**

Configures an Aurora MySQL primary instance to accept incoming replication from an external MySQL instance. This procedure also configures replication based on global transaction identifiers (GTIDs).
This procedure doesn't configure delayed replication, because Aurora MySQL doesn't support delayed replication.

Syntax

```sql
CALL mysql.rds_set_external_master_with_auto_position(
    host_name,
    host_port,
    replication_user_name,
    replication_user_password,
    ssl_encryption
);
```

Parameters

**host_name**

The host name or IP address of the MySQL instance running external to Aurora to become the replication master.

**host_port**

The port used by the MySQL instance running external to Aurora to be configured as the replication master. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

**replication_user_name**

The ID of a user with REPLICATION_CLIENT and REPLICATION_SLAVE permissions on the MySQL instance running external to Aurora. We recommend that you provide an account that is used solely for replication with the external instance.

**replication_user_password**

The password of the user ID specified in replication_user_name.

**ssl_encryption**

This option isn't currently implemented. The default is 0.

Usage notes

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance. The master user must run the `mysql.rds_set_external_master_with_auto_position` procedure. The master user runs this procedure on the primary instance of an Aurora MySQL DB cluster that acts as a replication target. This can be the replication target of an external MySQL DB instance or an Aurora MySQL DB cluster.

This procedure is supported for Aurora MySQL version 2. For Aurora MySQL version 3, use the procedure `mysql.rds_set_external_source_with_auto_position (Aurora MySQL version 3)` instead.

Before you run `mysql.rds_set_external_master_with_auto_position`, configure the external MySQL DB instance to be a replication master. To connect to the external MySQL instance, specify values for `replication_user_name` and `replication_user_password`. These values must indicate a replication user that has REPLICATION_CLIENT and REPLICATION_SLAVE permissions on the external MySQL instance.

**To configure an external MySQL instance as a replication master**

1. Using the MySQL client of your choice, connect to the external MySQL instance and create a user account to be used for replication. The following is an example.
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'

2. On the external MySQL instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain.

GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'

When you call `mysql.rds_set_external_master_with_auto_position`, Amazon RDS records certain information. This information is the time, the user, and an action of "set master" in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

To skip a specific GTID-based transaction that is known to cause a problem, you can use the `mysql.rds_skip_transaction_with_gtid` (p. 1191) stored procedure. For more information about working with GTID-based replication, see Using GTID-based replication for Amazon Aurora MySQL (p. 1043).

Examples

When run on an Aurora primary instance, the following example configures the Aurora cluster to act as a read replica of an instance of MySQL running external to Aurora.

```sql
call mysql.rds_set_external_master_with_auto_position(  'Externaldb.some.com',  3306,  'repl_user'@'mydomain.com',  'SomePassW0rd');
```

`mysql.rds_set_external_source (Aurora MySQL version 3)`

Configures an Aurora MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

**Important**

To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group (p. 229).

Syntax

```sql
CALL mysql.rds_set_external_source (  host_name  , host_port  , replication_user_name  , replication_user_password  , mysql_binary_log_file_name  , mysql_binary_log_file_location  , ssl_encryption  );
```

**Parameters**

*host_name*

The host name or IP address of the MySQL instance running external to Amazon RDS to become the source database instance.
**host_port**

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

**replication_user_name**

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

**replication_user_password**

The password of the user ID specified in replication_user_name.

**mysql_binary_log_file_name**

The name of the binary log on the source database instance that contains the replication information.

**mysql_binary_log_file_location**

The location in the mysql_binary_log_file_name binary log at which replication starts reading the replication information.

You can determine the binlog file name and location by running SHOW MASTER STATUS on the source database instance.

**ssl_encryption**

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

**Note**

The MASTER_SSL_VERIFY_SERVER_CERT option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

**Usage notes**

The master user must run the mysql.rds_set_external_source procedure. This procedure must be run on the Aurora MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

Before you run mysql.rds_set_external_source, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify replication_user_name and replication_user_password values that indicate a replication user that has REPLICATION CLIENT and REPLICATION SLAVE permissions on the external instance of MySQL.

**To configure an external instance of MySQL as a source database instance**

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

   **MySQL 5.7**

   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';

   **MySQL 8.0**

   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY 'password';
2. On the external instance of MySQL, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain.

MySQL 5.7

```sql
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
IDENTIFIED BY 'password';
```

MySQL 8.0

```sql
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

To use encrypted replication, configure source database instance to use SSL connections. Also, import the certificate authority certificate, client certificate, and client key into the DB instance or DB cluster using the `mysql.rds_import_binlog_ssl_material` procedure.

Note
We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. We recommend that you use Aurora Replicas to manage replication within an Aurora MySQL DB cluster when possible. For information about managing replication in Aurora MySQL DB clusters, see Using Aurora Replicas (p. 984).

After calling `mysql.rds_set_external_source` to configure an Aurora MySQL DB instance as a read replica, you can call `mysql.rds_start_replication` on the read replica to start the replication process. You can call `mysql.rds_reset_external_source` to remove the read replica configuration.

When `mysql.rds_set_external_source` is called, Amazon RDS records the time, user, and an action of `set master` in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

Examples

When run on an Aurora MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

```sql
call mysql.rds_set_external_source(
    'Externaldb.some.com',
    3306,
    'repl_user',
    'password',
    'mysql-bin-changelog.0777',
    120,
    0);
```

`mysql.rds_set_external_source_with_auto_position` (Aurora MySQL version 3)

Configures an Aurora MySQL primary instance to accept incoming replication from an external MySQL instance. This procedure also configures replication based on global transaction identifiers (GTIDs).

Syntax

```sql
CALL mysql.rds_set_external_source_with_auto_position (host_name, host_port, replication_user_name)
```

Parameters

`host_name`

The host name or IP address of the MySQL instance running external to Aurora to become the replication source.

`host_port`

The port used by the MySQL instance running external to Aurora to be configured as the replication source. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

`replication_user_name`

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the MySQL instance running external to Aurora. We recommend that you provide an account that is used solely for replication with the external instance.

`replication_user_password`

The password of the user ID specified in replication_user_name.

`ssl_encryption`

This option isn't currently implemented. The default is 0.

Usage notes

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance. The administrative user must run the `mysql.rds_set_external_source_with_auto_position` procedure. The administrative user runs this procedure on the primary instance of an Aurora MySQL DB cluster that acts as a replication target. This can be the replication target of an external MySQL DB instance or an Aurora MySQL DB cluster.

This procedure is supported for Aurora MySQL version 3. This procedure doesn't configure delayed replication, because Aurora MySQL doesn't support delayed replication.

Before you run `mysql.rds_set_external_source_with_auto_position`, configure the external MySQL DB instance to be a replication source. To connect to the external MySQL instance, specify values for `replication_user_name` and `replication_user_password`. These values must indicate a replication user that has REPLICATION CLIENT and REPLICATION SLAVE permissions on the external MySQL instance.

To configure an external MySQL instance as a replication source

1. Using the MySQL client of your choice, connect to the external MySQL instance and create a user account to be used for replication. The following is an example.

    ```sql
    CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'
    ```

2. On the external MySQL instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain.

    ```sql
    GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *:* TO 'repl_user'@'mydomain.com'
    IDENTIFIED BY 'SomePassW0rd'
    ```
When you call `mysql.rds_set_external_source_with_auto_position`, Amazon RDS records certain information. This information is the time, the user, and an action of "set master" in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

To skip a specific GTID-based transaction that is known to cause a problem, you can use the `mysql.rds_skip_transaction_with_gtid` stored procedure. For more information about working with GTID-based replication, see [Using GTID-based replication for Amazon Aurora MySQL](p. 1043).

**Examples**

When run on an Aurora primary instance, the following example configures the Aurora cluster to act as a read replica of an instance of MySQL running external to Aurora.

```sql
CALL mysql.rds_set_external_source_with_auto_position(  
    'Externaldb.some.com',  
    3306,  
    'repl_user'@'mydomain.com',  
    'SomePassW0rd');
```

### `mysql.rds_set_master_auto_position` (Aurora MySQL version 2)

Sets the replication mode to be based on either binary log file positions or on global transaction identifiers (GTIDs).

**Syntax**

```sql
CALL mysql.rds_set_master_auto_position (  
    auto_position_mode
);
```

**Parameters**

`auto_position_mode`

A value that indicates whether to use log file position replication or GTID-based replication:

- 0 – Use the replication method based on binary log file position. The default is 0.
- 1 – Use the GTID-based replication method.

**Usage notes**

The master user must run the `mysql.rds_set_master_auto_position` procedure.

This procedure is supported for Aurora MySQL version 2.

### `mysql.rds_set_session_binlog_format` (Aurora MySQL version 2)

Sets the binary log format for the current session.

**Syntax**

```sql
CALL mysql.rds_set_session_binlog_format(  
    format
);
```

**Parameters**

`format`

A value that indicates the binary log format for the current session:
- **STATEMENT** – The replication source writes events to the binary log based on SQL statements.
- **ROW** – The replication source writes events to the binary log that indicate changes to individual table rows.
- **MIXED** – Logging is generally based on SQL statements, but switches to rows under certain conditions. For more information, see [Mixed Binary Logging Format](#) in the MySQL documentation.

### Usage notes

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance. To use this stored procedure, you must have binary logging configured for the current session. For Aurora, this procedure is supported for Aurora MySQL version 2.12 and higher MySQL 5.7–compatible versions.

#### `mysql.rds_set_source_auto_position (Aurora MySQL version 3)`

Sets the replication mode to be based on either binary log file positions or on global transaction identifiers (GTIDs).

**Syntax**

```sql
CALL mysql.rds_set_source_auto_position (auto_position_mode);
```

**Parameters**

- **auto_position_mode**

  A value that indicates whether to use log file position replication or GTID-based replication:
  - 0 – Use the replication method based on binary log file position. The default is 0.
  - 1 – Use the GTID-based replication method.

### Usage notes

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance. The administrative user must run the `mysql.rds_set_source_auto_position` procedure.

#### `mysql.rds_skip_transaction_with_gtid (Aurora MySQL version 2 and 3)`

Skips replication of a transaction with the specified global transaction identifier (GTID) on an Aurora primary instance.

You can use this procedure for disaster recovery when a specific GTID transaction is known to cause a problem. Use this stored procedure to skip the problematic transaction. Examples of problematic transactions include transactions that disable replication, delete important data, or cause the DB instance to become unavailable.

**Syntax**

```sql
CALL mysql.rds_skip_transaction_with_gtid (gtid_to_skip);
```
Parameters

gtid_to_skip

The GTID of the replication transaction to skip.

Usage notes

The master user must run the mysql.rds_skip_transaction_with_gtid procedure.

This procedure is supported for Aurora MySQL version 2 and 3.

Examples

The following example skips replication of the transaction with the GTID 3E11FA47-71CA-11E1-9E33-C80AA9429562:23.

```sql
CALL mysql.rds_skip_transaction_with_gtid('3E11FA47-71CA-11E1-9E33-C80AA9429562:23');
```

mysql.rds_skip_repl_error

Skips and deletes a replication error on a MySQL DB read replica.

Syntax

```sql
CALL mysql.rds_skip_repl_error;
```

Usage notes

The master user must run the mysql.rds_skip_repl_error procedure on a read replica. For more information about this procedure, see [Skipping the current replication error](#).

To determine if there are errors, run the MySQL SHOW REPLICA STATUS\G command. If a replication error isn't critical, you can run mysql.rds_skip_repl_error to skip the error. If there are multiple errors, mysql.rds_skip_repl_error deletes the first error, then warns that others are present. You can then use SHOW REPLICA STATUS\G to determine the correct course of action for the next error. For information about the values returned, see [SHOW REPLICA STATUS statement](#) in the MySQL documentation.

**Note**

Previous versions of MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

For more information about addressing replication errors with Aurora MySQL, see [Diagnosing and resolving a MySQL read replication failure](#).

Replication stopped error

When you call the mysql.rds_skip_repl_error procedure, you might receive an error message stating that the replica is down or disabled.

This error message appears if you run the procedure on the primary instance instead of the read replica. You must run this procedure on the read replica for the procedure to work.

This error message might also appear if you run the procedure on the read replica, but replication can't be restarted successfully.

If you need to skip a large number of errors, the replication lag can increase beyond the default retention period for binary log (binlog) files. In this case, you might encounter a fatal error due to binlog files.
being purged before they have been replayed on the read replica. This purge causes replication to stop, and you can no longer call the `mysql.rds_skip_repl_error` command to skip replication errors.

You can mitigate this issue by increasing the number of hours that binlog files are retained on your source database instance. After you have increased the binlog retention time, you can restart replication and call the `mysql.rds_skip_repl_error` command as needed.

To set the binlog retention time, use the `mysql.rds_set_configuration` procedure and specify a configuration parameter of `binlog retention hours` along with the number of hours to retain binlog files on the DB cluster. The following example sets the retention period for binlog files to 48 hours.

```sql
CALL mysql.rds_set_configuration('binlog retention hours', 48);
```

### `mysql.rds_start_replication`

Initiates replication from an Aurora MySQL DB cluster.

**Note**

You can use the `mysql.rds_start_replication_until` (Aurora MySQL version 3) or `mysql.rds_start_replication_until_gtid` (Aurora MySQL version 3) stored procedure to initiate replication from an Aurora MySQL DB instance and stop replication at the specified binary log file location.

**Syntax**

```sql
CALL mysql.rds_start_replication;
```

**Usage notes**

The master user must run the `mysql.rds_start_replication` procedure.

To import data from an instance of MySQL external to Amazon RDS, call `mysql.rds_start_replication` on the read replica to start the replication process after you call `mysql.rds_set_external_master` or `mysql.rds_set_external_source` to build the replication configuration. For more information, see [Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication)](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-db-instance-created-or-replica-replication.html).

To export data to an instance of MySQL external to Amazon RDS, call `mysql.rds_start_replication` and `mysql.rds_stop_replication` on the read replica to control some replication actions, such as purging binary logs. For more information, see [Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication)](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-db-instance-created-or-replica-replication.html).

You can also call `mysql.rds_start_replication` on the read replica to restart any replication process that you previously stopped by calling `mysql.rds_stop_replication`. For more information, see [Replication stopped error](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-db-instance-created-or-replica-replication.html).

### `mysql.rds_start_replication_until` (Aurora MySQL version 3)

Initiates replication from an Aurora MySQL DB cluster and stops replication at the specified binary log file location.

**Syntax**

```sql
CALL mysql.rds_start_replication_until (
    replication_log_file,
    replication_stop_point
);
```
Parameters

*replication_log_file*

The name of the binary log on the source database instance contains the replication information.

*replication_stop_point*

The location in the *replication_log_file* binary log at which replication will stop.

Usage notes

The master user must run the `mysql.rds_start_replication_until` procedure.

This procedure is supported for Aurora MySQL version 3.04 and higher.

The file name specified for the *replication_log_file* parameter must match the source database instance binlog file name.

When the *replication_stop_point* parameter specifies a stop location that is in the past, replication is stopped immediately.

Examples

The following example initiates replication and replicates changes until it reaches location 120 in the `mysql-bin-changelog.000777` binary log file.

```sql
CALL mysql.rds_start_replication_until('mysql-bin-changelog.000777', 120);
```

mysql.rds_start_replication_until_gtid (Aurora MySQL version 3)

Initiates replication from an Aurora MySQL DB cluster and stops replication immediately after the specified global transaction identifier (GTID).

Syntax

```sql
CALL mysql.rds_start_replication_until_gtid(gtid);
```

Parameters

*gtid*

The GTID after which replication is to stop.

Usage notes

The master user must run the `mysql.rds_start_replication_until_gtid` procedure.

This procedure is supported for Aurora MySQL version 3.04 and higher.

When the *gtid* parameter specifies a transaction that has already been run by the replica, replication is stopped immediately.

Examples

The following example initiates replication and replicates changes until it reaches GTID 3E11FA47-71CA-11E1-9E33-C80AA9429562:23.
**mysql.rds_stop_replication**

Stops replication from a MySQL DB instance.

**Syntax**

```
call mysql.rds_stop_replication_until_gtid('3E11FA47-71CA-11E1-9E33-C80AA9429562:23');
```

**Usage notes**

The master user must run the `mysql.rds_stop_replication` procedure.

If you are configuring replication to import data from an instance of MySQL running external to Amazon RDS, you call `mysql.rds_stop_replication` on the read replica to stop the replication process after the import has completed. For more information, see [Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication)](p. 1015).

If you are configuring replication to export data to an instance of MySQL external to Amazon RDS, you call `mysql.rds_start_replication` and `mysql.rds_stop_replication` on the read replica to control some replication actions, such as purging binary logs. For more information, see [Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication)](p. 1015).

**Aurora MySQL–specific information_schema tables**

Aurora MySQL has certain `information_schema` tables that are specific to Aurora.

**information_schema.aurora_global_db_instance_status**

The `information_schema.aurora_global_db_instance_status` table contains information about the status of all DB instances in a global database's primary and secondary DB clusters. The following table shows the columns that you can use. The remaining columns are for Aurora internal use only.

<table>
<thead>
<tr>
<th>Column</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SERVER_ID</td>
<td>varchar(100)</td>
<td>The identifier of the DB instance.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>varchar(100)</td>
<td>A unique identifier for the current session. A value of MASTER_SESSION_ID identifies the Writer (primary) DB instance.</td>
</tr>
<tr>
<td>AWS_REGION</td>
<td>varchar(100)</td>
<td>The AWS Region in which this global database instance runs. For a list of Regions, see [Region availability](p. 17).</td>
</tr>
<tr>
<td>Column</td>
<td>Data type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DURABLE_LSN</td>
<td>bigint unsigned</td>
<td>The log sequence number (LSN) made durable in storage. A log sequence number (LSN) is a unique sequential number that identifies a record in the database transaction log. LSNs are ordered such that a larger LSN represents a later transaction.</td>
</tr>
<tr>
<td>HIGHEST_LSN_RCVD</td>
<td>bigint unsigned</td>
<td>The highest LSN received by the DB instance from the writer DB instance.</td>
</tr>
<tr>
<td>OLDEST_READ_VIEW_TRX_ID</td>
<td>bigint unsigned</td>
<td>The ID of the oldest transaction that the writer DB instance can purge to.</td>
</tr>
<tr>
<td>OLDEST_READ_VIEW_LSN</td>
<td>bigint unsigned</td>
<td>The oldest LSN used by the DB instance to read from storage.</td>
</tr>
<tr>
<td>VISIBILITY_LAG_IN_MSEC</td>
<td>float(10,0) unsigned</td>
<td>For readers in the primary DB cluster, how far this DB instance is lagging behind the writer DB instance in milliseconds. For readers in a secondary DB cluster, how far this DB instance is lagging behind the secondary volume in milliseconds.</td>
</tr>
</tbody>
</table>

**information_schema.aurora_global_db_status**

The information_schema.aurora_global_db_status table contains information about various aspects of Aurora global database lag, specifically, lag of the underlying Aurora storage (so called durability lag) and lag between the recovery point objective (RPO). The following table shows the columns that you can use. The remaining columns are for Aurora internal use only.

**Note**
This information schema table is only available with Aurora MySQL version 3.04.0 and higher global databases.

<table>
<thead>
<tr>
<th>Column</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS_REGION</td>
<td>varchar(100)</td>
<td>The AWS Region in which this global database instance runs. For a list of Regions, see Region availability (p. 17).</td>
</tr>
<tr>
<td>HIGHEST_LSN_WRITTEN</td>
<td>bigint unsigned</td>
<td>The highest log sequence number (LSN) that currently exists on this DB cluster. A log sequence number (LSN) is a unique sequential number that identifies a record in the database transaction log.</td>
</tr>
<tr>
<td>Column</td>
<td>Data type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------------</td>
<td>--------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DURABILITY_LAG_IN_MILLISECONDS</td>
<td>float(10,0) unsigned</td>
<td>The difference in the timestamp values between the HIGHEST_LSN_WRITTEN on a secondary DB cluster and the HIGHEST_LSN_WRITTEN on the primary DB cluster. This value is always 0 on the primary DB cluster of the Aurora global database.</td>
</tr>
<tr>
<td>RPO_LAG_IN_MILLISECONDS</td>
<td>float(10,0) unsigned</td>
<td>The recovery point objective (RPO) lag. The RPO lag is the time it takes for the most recent user transaction COMMIT to be stored on a secondary DB cluster after it's been stored on the primary DB cluster of the Aurora global database. This value is always 0 on the primary DB cluster of the Aurora global database. In simple terms, this metric calculates the recovery point objective for each Aurora MySQL DB cluster in the Aurora global database, that is, how much data might be lost if there were an outage. As with lag, RPO is measured in time.</td>
</tr>
<tr>
<td>LAST_LAG CALCULATION_TIMESTAMP</td>
<td>datetime</td>
<td>The timestamp that specifies when values were last calculated for DURABILITY_LAG_IN_MILLISECONDS and RPO_LAG_IN_MILLISECONDS. A time value such as 1970-01-01 00:00:00+00 means this is the primary DB cluster.</td>
</tr>
<tr>
<td>OLDEST_READ_VIEW_TRX_ID</td>
<td>bigint unsigned</td>
<td>The ID of the oldest transaction that the writer DB instance can purge to.</td>
</tr>
</tbody>
</table>

**information_schema.replica_host_status**

The `information_schema.replica_host_status` table contains replication information. The columns that you can use are shown in the following table. The remaining columns are for Aurora internal use only.
### information_schema.tables

<table>
<thead>
<tr>
<th>Column</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU</td>
<td>double</td>
<td>The CPU percentage usage of the replica host.</td>
</tr>
<tr>
<td>IS_CURRENT</td>
<td>tinyint</td>
<td>Whether the replica is current.</td>
</tr>
<tr>
<td>LAST_UPDATE_TIMESTAMP</td>
<td>datetime(6)</td>
<td>The time the last update occurred. Used to determine whether a record is stale.</td>
</tr>
<tr>
<td>REPLICA_LAG_IN_MILLISECONDS</td>
<td>double</td>
<td>The replica lag in milliseconds.</td>
</tr>
<tr>
<td>SERVER_ID</td>
<td>varchar(100)</td>
<td>The ID of the database server.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>varchar(100)</td>
<td>The ID of the database session. Used to determine whether a DB instance is a writer or reader instance.</td>
</tr>
</tbody>
</table>

**Note**
When a replica instance falls behind, the information queried from its `information_schema.replica_host_status` table might be outdated. In this situation, we recommend that you query from the writer instance instead. While the `mysql.ro_replica_status` table has similar information, we don't recommend that you use it.

### information_schema.aurora_forwarding_processlist

The `information_schema.aurora_forwarding_processlist` table contains information about processes involved in write forwarding.

The contents of this table are visible only on the writer DB instance for a DB cluster with global or in-cluster write forwarding turned on. An empty result set is returned on reader DB instances.

<table>
<thead>
<tr>
<th>Field</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>bigint</td>
<td>The identifier of the connection on the writer DB instance. This identifier is the same value displayed in the Id column of the SHOW PROCESSLIST statement and returned by the CONNECTION_ID() function within the thread.</td>
</tr>
<tr>
<td>USER</td>
<td>varchar(32)</td>
<td>The MySQL user that issued the statement.</td>
</tr>
<tr>
<td>HOST</td>
<td>varchar(255)</td>
<td>The MySQL client that issued the statement. For forwarded statements, this field shows the application client host address that established the connection on the forwarding reader DB instance.</td>
</tr>
<tr>
<td>DB</td>
<td>varchar(64)</td>
<td>The default database for the thread.</td>
</tr>
<tr>
<td>COMMAND</td>
<td>varchar(16)</td>
<td>The type of command the thread is executing on behalf of the client, or Sleep if the session is idle. For descriptions of thread commands, see the MySQL documentation on Thread Command Values in the MySQL documentation.</td>
</tr>
<tr>
<td>Field</td>
<td>Data type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>TIME</td>
<td>int</td>
<td>The time in seconds that the thread has been in its current state.</td>
</tr>
<tr>
<td>STATE</td>
<td>varchar(64)</td>
<td>An action, event, or state that indicates what the thread is doing. For descriptions of state values, see General Thread States in the MySQL documentation.</td>
</tr>
<tr>
<td>INFO</td>
<td>longtext</td>
<td>The statement that the thread is executing, or NULL if it isn't executing a statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements.</td>
</tr>
<tr>
<td>IS_FORWARDED</td>
<td>bigint</td>
<td>Indicates whether the thread is forwarded from a reader DB instance.</td>
</tr>
<tr>
<td>REPLICA_SESSION_ID</td>
<td>bigint</td>
<td>The connection identifier on the Aurora Replica. This identifier is the same value displayed in the Id column of the SHOW PROCESSLIST statement on the forwarding Aurora reader DB instance.</td>
</tr>
<tr>
<td>REPLICA_INSTANCE_IDENTIFIER</td>
<td>varchar(64)</td>
<td>The DB instance identifier of the forwarding thread.</td>
</tr>
<tr>
<td>REPLICA_CLUSTER_NAME</td>
<td>varchar(64)</td>
<td>The DB cluster identifier of the forwarding thread. For in-cluster write forwarding, this identifier is the same DB cluster as the writer DB instance.</td>
</tr>
<tr>
<td>REPLICA_REGION</td>
<td>varchar(64)</td>
<td>The AWS Region from which the forwarding thread originates. For in-cluster write forwarding, this Region is the same AWS Region as the writer DB instance.</td>
</tr>
</tbody>
</table>
Database engine updates for Amazon Aurora MySQL

Amazon Aurora releases updates regularly. Updates are applied to Aurora DB clusters during system maintenance windows. The timing when updates are applied depends on the region and maintenance window setting for the DB cluster, as well as the type of update.

Amazon Aurora releases are made available to all AWS Regions over the course of multiple days. Some Regions might temporarily show an engine version that isn't available in a different Region yet.

Updates are applied to all instances in a DB cluster at the same time. An update requires a database restart on all instances in a DB cluster, so you experience 20 to 30 seconds of downtime, after which you can resume using your DB cluster or clusters. You can view or change your maintenance window settings from the AWS Management Console.

For details about the Aurora MySQL versions that are supported by Amazon Aurora, see the Release Notes for Aurora MySQL.

Following, you can learn how to choose the right Aurora MySQL version for your cluster, how to specify the version when you create or upgrade a cluster, and the procedures to upgrade a cluster from one version to another with minimal interruption.

Topics
- Aurora MySQL version numbers and special versions (p. 1200)

- Database engine updates for Amazon Aurora MySQL version 3 (p. 1228)
- Database engine updates for Amazon Aurora MySQL version 2 (p. 1228)
- Database engine updates for Amazon Aurora MySQL version 1 (p. 1228)
- Database engine updates for Aurora MySQL Serverless clusters (p. 1228)
- MySQL bugs fixed by Aurora MySQL database engine updates (p. 1228)
- Security vulnerabilities fixed in Amazon Aurora MySQL (p. 1228)

Aurora MySQL version numbers and special versions

Although Aurora MySQL-Compatible Edition is compatible with the MySQL database engines, Aurora MySQL includes features and bug fixes that are specific to particular Aurora MySQL versions. Application developers can check the Aurora MySQL version in their applications by using SQL. Database administrators can check and specify Aurora MySQL versions when creating or upgrading Aurora MySQL DB clusters and DB instances.

Topics
- Checking or specifying Aurora MySQL engine versions through AWS (p. 1201)
- Checking Aurora MySQL versions using SQL (p. 1202)
- Aurora MySQL long-term support (LTS) releases (p. 1202)
Checking or specifying Aurora MySQL engine versions through AWS

When you perform administrative tasks using the AWS Management Console, AWS CLI, or RDS API, you specify the Aurora MySQL version in a descriptive alphanumeric format.

Starting with Aurora MySQL version 2, Aurora engine versions have the following syntax.

```
mysql-major-version.mysql_aurora.aurora-mysql-version
```

The `mysql-major-version` portion is 5.7 or 8.0. This value represents the version of the client protocol and general level of MySQL feature support for the corresponding Aurora MySQL version.

The `aurora-mysql-version` is a dotted value with three parts: the Aurora MySQL major version, the Aurora MySQL minor version, and the patch level. The major version is 2 or 3. Those values represent Aurora MySQL compatible with MySQL 5.7 or 8.0, respectively. The minor version represents the feature release within the 2.x or 3.x series. The patch level begins at 0 for each minor version, and represents the set of subsequent bug fixes that apply to the minor version. Occasionally, a new feature is incorporated into a minor version but not made visible immediately. In these cases, the feature undergoes fine-tuning and is made public in a later patch level.

All 2.x Aurora MySQL engine versions are wire-compatible with Community MySQL 5.7.12. All 3.x Aurora MySQL engine versions are wire-compatible with MySQL 8.0.23 onwards. You can refer to release notes of the specific 3.x version to find the corresponding MySQL compatible version.

For example, the engine versions for Aurora MySQL 3.02.0 and 2.11.2 are the following.

```
8.0.mysql_aurora.3.02.0
5.7.mysql_aurora.2.11.2
```

**Note**

There isn't a one-to-one correspondence between community MySQL versions and the Aurora MySQL 2.x versions. For Aurora MySQL version 3, there is a more direct mapping. To check which bug fixes and new features are in a particular Aurora MySQL release, see Database engine updates for Amazon Aurora MySQL version 3 and Database engine updates for Amazon Aurora MySQL version 2 in the Release Notes for Aurora MySQL. For a chronological list of new features and releases, see Document history (p. 2522). To check the minimum version required for a security-related fix, see Security vulnerabilities fixed in Aurora MySQL in the Release Notes for Aurora MySQL.

You specify the Aurora MySQL engine version in some AWS CLI commands and RDS API operations. For example, you specify the `--engine-version` option when you run the AWS CLI commands `create-db-cluster` and `modify-db-cluster`. You specify the `EngineVersion` parameter when you run the RDS API operations `CreateDBCluster` and `ModifyDBCluster`.

In Aurora MySQL version 2 and higher, the engine version in the AWS Management Console also includes the Aurora version. Upgrading the cluster changes the displayed value. This change helps you to specify and check the precise Aurora MySQL versions, without the need to connect to the cluster or run any SQL commands.

**Tip**

For Aurora clusters managed through AWS CloudFormation, this change in the `EngineVersion` setting can trigger actions by AWS CloudFormation. For information about how AWS CloudFormation treats changes to the `EngineVersion` setting, see the AWS CloudFormation documentation.
Checking Aurora MySQL versions using SQL

The Aurora version numbers that you can retrieve in your application using SQL queries use the format `<major version>.<minor version>.<patch version>`. You can get this version number for any DB instance in your Aurora MySQL cluster by querying the AURORA_VERSION system variable. To get this version number, use one of the following queries.

```sql
select aurora_version();
select @@aurora_version;
```

Those queries produce output similar to the following.

```
mysql> select aurora_version(), @@aurora_version;
+------------------+------------------+
| aurora_version() | @@aurora_version |
|------------------+------------------|
| 2.11.1           | 2.11.1           |
+------------------+------------------+
```

The version numbers that the console, CLI, and RDS API return by using the techniques described in Checking or specifying Aurora MySQL engine versions through AWS (p. 1201) are typically more descriptive.

Aurora MySQL long-term support (LTS) releases

Each new Aurora MySQL version remains available for a certain amount of time for you to use when you create or upgrade a DB cluster. After this period, you must upgrade any clusters that use that version. You can manually upgrade your cluster before the support period ends, or Aurora can automatically upgrade it for you when its Aurora MySQL version is no longer supported.

Aurora designates certain Aurora MySQL versions as long-term support (LTS) releases. DB clusters that use LTS releases can stay on the same version longer and undergo fewer upgrade cycles than clusters that use non-LTS releases. Aurora supports each LTS release for at least three years after that release becomes available. When a DB cluster that's on an LTS release is required to upgrade, Aurora upgrades it to the next LTS release. That way, the cluster doesn't need to be upgraded again for a long time.

During the lifetime of an Aurora MySQL LTS release, new patch levels introduce fixes to important issues. The patch levels don't include any new features. You can choose whether to apply such patches to DB clusters running the LTS release. For certain critical fixes, Amazon might perform a managed upgrade to a patch level within the same LTS release. Such managed upgrades are performed automatically within the cluster maintenance window.

We recommend that you upgrade to the latest release, instead of using the LTS release, for most of your Aurora MySQL clusters. Doing so takes advantage of Aurora as a managed service and gives you access to the latest features and bug fixes. The LTS releases are intended for clusters with the following characteristics:

- You can't afford downtime on your Aurora MySQL application for upgrades outside of rare occurrences for critical patches.
- The testing cycle for the cluster and associated applications takes a long time for each update to the Aurora MySQL database engine.
- The database version for your Aurora MySQL cluster has all the DB engine features and bug fixes that your application needs.

The current LTS release for Aurora MySQL is the following:
• Aurora MySQL version 3.04.*. For more details about the LTS version, see Database engine updates for Amazon Aurora MySQL version 3 in the Release Notes for Aurora MySQL.

Preparing for Amazon Aurora MySQL-Compatible Edition version 2 end of Standard Support

Amazon Aurora MySQL-Compatible Edition version 2 (with MySQL 5.7 compatibility) is planned to reach end of Standard Support on October 31, 2024. Amazon advises that you upgrade all clusters running Aurora MySQL version 2 to the default Aurora MySQL version 3 (with MySQL 8.0 compatibility) or higher before Aurora MySQL version 2 reaches the end of its Standard Support period. If you want to continue using Aurora MySQL version 2 after the end of the Standard Support, you will need to opt into Amazon RDS Extended Support. If you are running Amazon Aurora MySQL version 2 (with MySQL 5.7 compatibility) in an Aurora Serverless version 1 cluster, this doesn't apply to you. If you want to upgrade your Aurora Serverless version 1 clusters to Aurora MySQL version 3, refer to Upgrade path for Aurora Serverless v1 Clusters.

You can find upcoming end-of-life dates for Aurora major versions in Amazon Aurora versions (p. 4).

If you have clusters running Aurora MySQL version 2, you will receive periodic notices with the latest information on how to conduct an upgrade, or opt into Extended Support, as we get closer to the end of the Standard Support date. We will update this page periodically with the latest information.

End of Standard Support Timeline

1. Now through October 31, 2024 – You can upgrade clusters from Aurora MySQL version 2 (with MySQL 5.7 compatibility) to Aurora MySQL version 3 (with MySQL 8.0 compatibility).
2. October 31, 2024 – At this date, Aurora MySQL version 2 reaches the end of Standard Support. If you want to continue using Aurora MySQL version 2, you will need to opt in to Amazon RDS Extended Support.

If you try to restore an Aurora MySQL version 2 database snapshot after this date, unless you specify you want to restore the cluster in Extended Support, we will try to automatically upgrade the restored cluster to the default version of Aurora MySQL version 3 at the time of restore.

Finding clusters affected by this end-of-life process

To find clusters affected by this end-of-life process, use the following procedures.

Important
Be sure to perform these instructions in every AWS Region and for each AWS account where your resources are located.

Console

To find an Aurora MySQL version 2 cluster
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. In the Filter by databases box, enter 5.7.
4. Check for Aurora MySQL in the engine column.
AWS CLI

To find clusters affected by this end-of-life process using the AWS CLI, call the `describe-db-clusters` command. You can use the sample script following.

**Example**

```
aws rds describe-db-clusters --include-share --query 'DBClusters[?(Engine==`aurora-mysql` && contains(EngineVersion,`5.7.mysql_aurora`))].{EngineVersion:EngineVersion, DBClusterIdentifier:DBClusterIdentifier, EngineMode:EngineMode}' --output table --region us-east-1
```

RDS API

To find Aurora MySQL DB clusters running Aurora MySQL version 2, use the RDS `DescribeDBClusters` API operation with the following required parameters:

- `DescribeDBClusters`
- `Filters.Filter.N`
  - `Name` engine
  - `Values.Value.N` ['aurora']

RDS Extended Support

Amazon Aurora MySQL provides you with one year of free extended support over community MySQL 5.7, that reaches end of life on October 31, 2023. If you need more time to complete the upgrades, you can opt into Amazon RDS Extended Support for Aurora MySQL version 2. RDS Extended Support for Aurora is a paid service that will provide up to 28 additional months of support for Aurora MySQL version 2 until the end of extended support in February 2027. To gain access to extended support, you will need to explicitly opt in to RDS Extended Support. We will reach out to you in early 2024 with detailed instructions for opting into RDS Extended Support through the RDS console, Command Line Interface (CLI), and RDS APIs. RDS Extended Support will only be offered for Aurora MySQL minor versions 2.11 and 2.12. If you plan to use Amazon Aurora MySQL version 2 beyond the end of Standard Support, plan to be running your databases on one of these minor versions before October 31, 2024.

Performing an Upgrade

Upgrading between major versions requires more extensive planning and testing than for a minor version. The process can take substantial time. We want to look at the upgrade as a three-step process, with activities before the upgrade, for the upgrade, and after the upgrade.

Before the upgrade:

Before the upgrade, we recommend that you check for application compatibility, performance, maintenance procedures, and similar considerations for the upgraded cluster, thereby confirming that
post-upgrade your applications will work as expected. Here are five recommendations that will help provide you a better upgrade experience.

- First, it's critical to understand how the Aurora MySQL in-place major version upgrade works.
- Next, explore the upgrade techniques that are available when Upgrading from Aurora MySQL 2.x to 3.x.
- To help you decide the right time and approach to upgrade, you can learn the differences between Aurora MySQL version 3 and your current environment with Upgrade planning for Aurora MySQL version 3.
- After you have decided on the option that is convenient and works best, try a mock in-place upgrade on a cloned cluster, using Planning a major version upgrade for an Aurora MySQL cluster. The pre-checker can run and determine if your database can be upgraded successfully, and if there is any application incompatibility issue post-upgrade as well as performance, maintenance procedures, and similar considerations.
- Not all kinds or versions of Aurora MySQL clusters can use the in-place upgrade mechanism. For more information, see Aurora MySQL major version upgrade paths.

If you have any questions or concerns, the AWS Support Team is available on the community forums and Premium Support.

Doing the upgrade:

Upgrades may be performed using in-place, snapshot and restore, or a high availability blue-green upgrade technique which can be fully managed using Using Amazon RDS Blue/Green Deployments. The amount of downtime your system will experience depends on the upgrade technique chosen.

- **In Place Upgrades:** You can perform an in-place upgrade where Aurora will automatically perform a pre-check process for you, take the cluster offline, backup your cluster, perform the upgrade, and put your cluster back online. An in-place major version upgrade can be performed in a few clicks and doesn't involve other coordination or failovers with other clusters, but does involve downtime.

- **Snapshot and Restore:** You can upgrade your Aurora MySQL version 2 cluster by restoring from an Aurora MySQL version 2 snapshot into an Aurora MySQL version 3 cluster. To do this, you should follow the process for taking a snapshot and restoring from it. This process involves database interruption since you are restoring from a snapshot.

- **Blue Green Deployments:** For situations where the top priority is to reduce application downtime, you can use Amazon RDS Blue/Green deployments for performing the major version upgrade in provisioned Amazon Aurora DB clusters. A blue/green deployment creates a staging environment that copies the production environment. You can make certain changes to the Aurora DB cluster in the green (staging) environment without affecting production workloads. The switchover typically takes under a minute with no data loss. For more information, see Overview of Amazon RDS Blue/Green Deployments for Aurora. This minimizes downtime, but requires you to run additional resources while performing the upgrade.

You can review the latest features of Aurora MySQL version 3 and plan for Upgrading to Aurora MySQL version 3. For details about major version upgrades, refer to Upgrading from Aurora MySQL 2.x to 3.x. For details regarding feature differences, refer to Aurora MySQL version 2 and Aurora MySQL version 3 differences.

After the upgrade:

After the upgrade, you need to closely monitor your system (application and database) and make fine-tune changes if necessary. Following the pre-upgrade steps closely will minimize the required changes needed.

Above, you can find a high level summary of the three steps to upgrade. To learn more about the methods, planning, testing, and troubleshooting of Aurora MySQL major version upgrades, be sure to
Preparing for Amazon Aurora MySQL-Compatible Edition version 1 end of life

Amazon Aurora MySQL-Compatible Edition version 1 (with MySQL 5.6 compatibility) is planned to reach end of life on February 28, 2023. Amazon advises that you upgrade all clusters (provisioned and Aurora Serverless) running Aurora MySQL version 1 to Aurora MySQL version 2 (with MySQL 5.7 compatibility) or Aurora MySQL version 3 (with MySQL 8.0 compatibility). Do this before Aurora MySQL version 1 reaches the end of its support period.

For Aurora provisioned DB clusters, you can complete upgrades from Aurora MySQL version 1 to Aurora MySQL version 2 by several methods. You can find instructions for the in-place upgrade mechanism in How to perform an in-place upgrade (p. 1217). Another way to complete the upgrade is to take a snapshot of an Aurora MySQL version 1 cluster and restore the snapshot to an Aurora MySQL version 2 cluster. Or you can follow a multistep process that runs the old and new clusters side by side. For more details about each method, see Upgrading the major version of an Amazon Aurora MySQL DB cluster (p. 1213).

For Aurora Serverless v1 DB clusters, you can perform an in-place upgrade from Aurora MySQL version 1 to Aurora MySQL version 2. For more details about this method, see Modifying an Aurora Serverless v1 DB cluster (p. 2051).

For Aurora provisioned DB clusters, you can complete upgrades from Aurora MySQL version 1 to Aurora MySQL version 3 by using a two-stage upgrade process:

1. Upgrade from Aurora MySQL version 1 to Aurora MySQL version 2 using the methods described preceding.
2. Upgrade from Aurora MySQL version 2 to Aurora MySQL version 3 using the same methods as for upgrading from version 1 to version 2. For more details, see Upgrading from Aurora MySQL 2.x to 3.x (p. 1213). Note the Feature differences between Aurora MySQL version 2 and 3 (p. 791).

You can find upcoming end-of-life dates for Aurora major versions in Amazon Aurora versions (p. 4). Amazon automatically upgrades any clusters that you don't upgrade yourself before the end-of-life date. After the end-of-life date, these automatic upgrades to the subsequent major version occur during a scheduled maintenance window for clusters.
The following are additional milestones for upgrading Aurora MySQL version 1 clusters (provisioned and Aurora Serverless) that are reaching end of life. For each, the start time is 00:00 Universal Coordinated Time (UTC).

1. Now through February 28, 2023 – You can at any time start upgrades of Aurora MySQL version 1 (with MySQL 5.6 compatibility) clusters to Aurora MySQL version 2 (with MySQL 5.7 compatibility). From Aurora MySQL version 2, you can do a further upgrade to Aurora MySQL version 3 (with MySQL 8.0 compatibility) for Aurora provisioned DB clusters.

2. January 16, 2023 – After this time, you can't create new Aurora MySQL version 1 clusters or instances from either the AWS Management Console or the AWS Command Line Interface (AWS CLI). You also can't add new secondary Regions to an Aurora global database. This might affect your ability to recover from an unplanned outage as outlined in Recovering an Amazon Aurora global database from an unplanned outage (p. 1855), because you can't complete steps 5 and 6 after this time. You will also be unable to create a new cross-Region read replica running Aurora MySQL version 1. You can still do the following for existing Aurora MySQL version 1 clusters until February 28, 2023:
   - Restore a snapshot taken of an Aurora MySQL version 1 cluster to the same version as the original snapshot cluster.
   - Add read replicas (not applicable for Aurora Serverless DB clusters).
   - Change instance configuration.
   - Perform point-in-time restore.
   - Create clones of existing version 1 clusters.
   - Create a new cross-Region read replica running Aurora MySQL version 2 or higher.

3. February 28, 2023 – After this time, we plan to automatically upgrade Aurora MySQL version 1 clusters to the default version of Aurora MySQL version 2 within a scheduled maintenance window that follows. Restoring Aurora MySQL version 1 DB snapshots results in an automatic upgrade of the restored cluster to the default version of Aurora MySQL version 2 at that time.

Upgrading between major versions requires more extensive planning and testing than for a minor version. The process can take substantial time.

For situations where the top priority is to reduce downtime, you can also use blue/green deployments for performing the major version upgrade in provisioned Amazon Aurora DB clusters. A blue/green deployment creates a staging environment that copies the production environment. You can make changes to the Aurora DB cluster in the green (staging) environment without affecting production workloads. The switchover typically takes under a minute with no data loss and no need for application changes. For more information, see Overview of Amazon RDS Blue/Green Deployments for Aurora (p. 400).

After the upgrade is finished, you also might have follow-up work to do. For example, you might need to follow up due to differences in SQL compatibility, the way certain MySQL-related features work, or parameter settings between the old and new versions.

To learn more about the methods, planning, testing, and troubleshooting of Aurora MySQL major version upgrades, be sure to thoroughly read Upgrading the major version of an Amazon Aurora MySQL DB cluster (p. 1213).

Finding clusters affected by this end-of-life process

To find clusters affected by this end-of-life process, use the following procedures.

Important
   Be sure to perform these instructions in every AWS Region and for each AWS account where your resources are located.
Console

To find an Aurora MySQL version 1 cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. In the Filter by databases box, enter 5.6.
4. Check for Aurora MySQL in the engine column.

AWS CLI

To find clusters affected by this end-of-life process using the AWS CLI, call the describe-db-clusters command. You can use the sample script following.

Example

```bash
aws rds describe-db-clusters --include-share --query 'DBClusters[?Engine=='aurora'].
{EV:EngineVersion, DBCI:DBClusterIdentifier, EM:EngineMode}' --output table --region us-east-1
```

RDS API

To find Aurora MySQL DB clusters running Aurora MySQL version 1, use the RDS DescribeDBClusters API operation with the following required parameters:

- DescribeDBClusters
  - Filters.Filter.N
    - Name
      - engine
    - Values.Value.N
      - ['aurora']

Upgrading Amazon Aurora MySQL DB clusters

You can upgrade an Aurora MySQL DB cluster to get bug fixes, new Aurora MySQL features, or to change to an entirely new version of the underlying database engine. The following sections show how.

Note

The type of upgrade that you do depends on how much downtime you can afford for your cluster, how much verification testing you plan to do, how important the specific bug fixes or new features are for your use case, and whether you plan to do frequent small upgrades or occasional upgrades that skip several intermediate versions. For each upgrade, you can change the major version, the minor version, and the patch level for your cluster. If you aren’t familiar with the distinction between Aurora MySQL major versions, minor versions, and patch levels, you can read the background information at Aurora MySQL version numbers and special versions (p. 1200).
Tip
You can minimize the downtime required for a DB cluster upgrade by using a blue/green deployment. For more information, see Using Amazon RDS Blue/Green Deployments for database updates (p. 399).

Topics
- Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1209)
- Upgrading the major version of an Amazon Aurora MySQL DB cluster (p. 1213)

Upgrading the minor version or patch level of an Aurora MySQL DB cluster

You can use the following methods to upgrade the minor version of a DB cluster or to patch a DB cluster:

- Upgrading Aurora MySQL by modifying the engine version (p. 1209) (for Aurora MySQL version 2 and 3)
- Enabling automatic upgrades between minor Aurora MySQL versions (p. 1210)

For information about how zero-downtime patching can reduce interruptions during the upgrade process, see Using zero-downtime patching (p. 1211).

Upgrading Aurora MySQL by modifying the engine version

Upgrading the minor version of an Aurora MySQL cluster applies additional fixes and new features to an existing cluster.

This kind of upgrade applies to Aurora MySQL clusters where the original version and the upgraded version are both in the Aurora MySQL 2.x series. The process is fast and straightforward because it doesn't involve any conversion for the Aurora MySQL metadata or reorganization of your table data.

You perform this kind of upgrade by modifying the engine version of the DB cluster using the AWS Management Console, AWS CLI, or the RDS API. If your cluster is running Aurora MySQL 2.x, choose a higher 2.x version.

If you're performing a minor upgrade on an Aurora global database, upgrade all of the secondary clusters before you upgrade the primary cluster.

Note
To perform a minor version upgrade to Aurora MySQL version 3.03.* or higher, or version 2.12.*, use the following process:

1. Remove all secondary Regions from the global cluster. Follow the steps in Removing a cluster from an Amazon Aurora global database (p. 1826).
2. Upgrade the engine version of the primary Region to version 3.03.* or higher, or version 2.12.*, as applicable. Follow the steps in To modify the engine version of a DB cluster.
3. Add secondary Regions to the global cluster. Follow the steps in Adding an AWS Region to an Amazon Aurora global database (p. 1817).

To modify the engine version of a DB cluster

- By using the console – Modify the properties of your cluster. In the Modify DB cluster window, change the Aurora MySQL engine version in the DB engine version box. If you aren't familiar with the general procedure for modifying a cluster, follow the instructions at Modifying the DB cluster by using the console, CLI, and API (p. 269).
• **By using the AWS CLI** – Call the `modify-db-cluster` AWS CLI command, and specify the name of your DB cluster for the `--db-cluster-identifier` option and the engine version for the `--engine-version` option.

  For example, to upgrade to Aurora MySQL version 2.11.1, set the `--engine-version` option to `5.7.mysql_aurora.2.11.1`. Specify the `--apply-immediately` option to immediately update the engine version for your DB cluster.

• **By using the RDS API** – Call the `ModifyDBCluster` API operation, and specify the name of your DB cluster for the `DBClusterIdentifier` parameter and the engine version for the `EngineVersion` parameter. Set the `ApplyImmediately` parameter to `true` to immediately update the engine version for your DB cluster.

Enabling automatic upgrades between minor Aurora MySQL versions

For an Amazon Aurora MySQL DB cluster, you can specify that Aurora upgrades the DB cluster automatically to new minor versions. You do so by using the automatic minor version upgrade property of the DB cluster using the AWS Management Console, AWS CLI, or the RDS API.

Automatic upgrades occur during the maintenance window. If the individual DB instances in the DB cluster have different maintenance windows from the cluster maintenance window, then the cluster maintenance window takes precedence.

Automatic minor version upgrade doesn't apply to the following kinds of Aurora MySQL clusters:

• Clusters that are part of an Aurora global database
• Clusters that have cross-Region replicas

The outage duration varies depending on workload, cluster size, the amount of binary log data, and if Aurora can use the zero-downtime patching (ZDP) feature. Aurora restarts the database cluster, so you might experience a short period of unavailability before resuming use of your cluster. In particular, the amount of binary log data affects recovery time. The DB instance processes the binary log data during recovery. Thus, a high volume of binary log data increases recovery time.

**Note**

Aurora only performs the automatic upgrade if all DB instances in your DB cluster have this setting turned on. For information on how to set Auto minor version upgrade, and how the setting works when applied at the cluster and instance levels, see [Automatic minor version upgrades for Aurora DB clusters](p. 351).

Auto minor version upgrades are performed to the default minor version.

You can use a CLI command such as the following to check the status of the AutoMinorVersionUpgrade setting for all of the DB instances in your Aurora MySQL clusters.

```bash
aws rds describe-db-instances \
  --query '*[].
  {DBClusterIdentifier:DBClusterIdentifier, DBInstanceIdentifier:DBInstanceIdentifier, AutoMinorVersionUpgrade:AutoMinorVersionUpgrade}]
```

That command produces output similar to the following:

```json
[
  {
    "DBInstanceIdentifier": "db-t2-medium-instance",
    "DBClusterIdentifier": "cluster-57-2020-06-05-6411",
    "AutoMinorVersionUpgrade": true
  },
  {
    "DBInstanceIdentifier": "db-t2-small-original-size",
```
In this example, **Enable auto minor version upgrade** is turned off for the DB cluster `cluster-57-2020-06-03-6411`, because it's turned off for one of the DB instances in the cluster.

**Using zero-downtime patching**

Performing upgrades for Aurora MySQL DB clusters involves the possibility of an outage when the database is shut down and while it's being upgraded. By default, if you start the upgrade while the database is busy, you lose all the connections and transactions that the DB cluster is processing. If you wait until the database is idle to perform the upgrade, you might have to wait a long time.

The zero-downtime patching (ZDP) feature attempts, on a best-effort basis, to preserve client connections through an Aurora MySQL upgrade. If ZDP completes successfully, application sessions are preserved and the database engine restarts while the upgrade is in progress. The database engine restart can cause a drop in throughput lasting for a few seconds to approximately one minute.

ZDP doesn't apply to the following:

- Operating system (OS) patches and upgrades
- Major version upgrades
- Upgrades from versions lower than 2.11.0 to version 2.11.0 and higher, and from versions lower than 3.03.0 to version 3.03.0 and higher

These upgrades require a host replacement due to underlying Amazon EC2 instance operating system patching or upgrades.

ZDP isn't supported for Aurora Serverless v1 or Aurora global databases.

The following table shows the Aurora MySQL versions and DB instance classes where ZDP is available.

<table>
<thead>
<tr>
<th>Version</th>
<th>db.r* instance classes</th>
<th>db.t* instance classes</th>
<th>db.x* instance classes</th>
<th>db.serverless instance class</th>
</tr>
</thead>
<tbody>
<tr>

<td>3.04.0 and higher</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Note**

We recommend using the T DB instance classes only for development and test servers, or other non-production servers. For more details on the T instance classes, see [Using T instance classes for development and testing](p. 1103).

You can see metrics of important attributes during ZDP in the MySQL error log. You can also see information about when Aurora MySQL uses ZDP or chooses not to use ZDP on the **Events** page in the AWS Management Console.

In Aurora MySQL version 2.10 and higher and version 3, Aurora can perform a zero-downtime patch whether or not binary log replication is enabled. If binary log replication is enabled, Aurora MySQL automatically drops the connection to the binlog target during a ZDP operation. Aurora MySQL automatically reconnects to the binlog target and resumes replication after the restart finishes.

ZDP also works in combination with the reboot enhancements in Aurora MySQL 2.10 and higher. Patching the writer DB instance automatically patches readers at the same time. After performing the patch, Aurora restores the connections on both the writer and reader DB instances. Before Aurora MySQL 2.10, ZDP applies only to the writer DB instance of a cluster.

ZDP might not complete successfully under the following conditions:

- Long-running queries or transactions are in progress. If Aurora can perform ZDP in this case, any open transactions are canceled.
- Temporary tables or table locks are in use, for example while data definition language (DDL) statements run. If Aurora can perform ZDP in this case, any open transactions are canceled.
- Pending parameter changes exist.

If no suitable time window for performing ZDP becomes available because of one or more of these conditions, patching reverts to the standard behavior.

**Note**

For Aurora MySQL version 2 lower than 2.11.0 and version 3 lower than 3.04.0, ZDP might not complete successfully when there are open Secure Socket Layer (SSL) or Transport Layer Security (TLS) connections.

Although connections remain intact following a successful ZDP operation, some variables and features are reinitialized. The following kinds of information aren't preserved through a restart caused by zero-downtime patching:

- Global variables. Aurora restores session variables, but it doesn't restore global variables after the restart.
- Status variables. In particular, the uptime value reported by the engine status is reset after a restart that uses the ZDR or ZDP mechanisms.
- LAST_INSERT_ID.
- In-memory auto_increment state for tables. The in-memory auto-increment state is reinitialized.

For more information about auto-increment values, see [MySQL Reference Manual](#).
Diagnostic information from INFORMATION_SCHEMA and PERFORMANCE_SCHEMA tables. This diagnostic information also appears in the output of commands such as SHOW PROFILE and SHOW PROFILES.

The following activities related to zero-downtime restart are reported on the Events page:

- Attempting to upgrade the database with zero downtime.
- Attempting to upgrade the database with zero downtime finished. The event reports how long the process took. The event also reports how many connections were preserved during the restart and how many connections were dropped. You can consult the database error log to see more details about what happened during the restart.

Alternative blue/green upgrade technique

In some situations, your top priority is to perform an immediate switchover from the old cluster to an upgraded one. In such situations, you can use a multistep process that runs the old and new clusters side-by-side. Here, you replicate data from the old cluster to the new one until you are ready for the new cluster to take over. For details, see Using Amazon RDS Blue/Green Deployments for database updates (p. 399).

Upgrading the major version of an Amazon Aurora MySQL DB cluster

In an Aurora MySQL version number such as 2.11.1, the 2 represents the major version. Aurora MySQL version 2 is compatible with MySQL 5.7. Aurora MySQL version 3 is compatible with MySQL 8.0.

Upgrading between major versions requires more extensive planning and testing than for a minor version. The process can take substantial time. After the upgrade is finished, you also might have followup work to do. For example, this might occur because of differences in SQL compatibility or the way certain MySQL-related features work. Or it might occur because of differing parameter settings between the old and new versions.

- Alternative blue-green upgrade technique (p. 1228)

Upgrading from Aurora MySQL 2.x to 3.x

If you have a MySQL 5.7–compatible cluster and want to upgrade it to a MySQL–8.0 compatible cluster, you can do so by running an upgrade process on the cluster itself. This kind of upgrade is an in-place upgrade, in contrast to upgrades that you do by creating a new cluster. This technique keeps the same
endpoint and other characteristics of the cluster. The upgrade is relatively fast because it doesn’t require copying all your data to a new cluster volume. This stability helps to minimize any configuration changes in your applications. It also helps to reduce the amount of testing for the upgraded cluster. This is because the number of DB instances and their instance classes all stay the same.

The in-place upgrade mechanism involves shutting down your DB cluster while the operation takes place. Aurora performs a clean shutdown and completes outstanding operations such as transaction rollback and undo purge. For more information, see How the Aurora MySQL in-place major version upgrade works (p. 1216).

The in-place upgrade method is convenient, because it is simple to perform and minimizes configuration changes to associated applications. For example, an in-place upgrade preserves the endpoints and set of DB instances for your cluster. However, the time needed for an in-place upgrade can vary depending on the properties of your schema and how busy the cluster is. Thus, depending on the needs for your cluster, you might want to choose among the multiple upgrade techniques. These include in-place upgrade and snapshot restore, described in Restoring from a DB cluster snapshot (p. 439). They also include other upgrade techniques such as the one described in Alternative blue-green upgrade technique (p. 1228).

**Note**
If you use the AWS CLI or RDS API for the snapshot restore upgrade method, you must run a subsequent operation to create a writer DB instance in the restored DB cluster.

For general information about Aurora MySQL version 3 and its new features, see Aurora MySQL version 3 compatible with MySQL 8.0 (p. 781). For details about planning an upgrade, see Upgrade planning for Aurora MySQL version 3 (p. 800) and Upgrading to Aurora MySQL version 3 (p. 799).

**Tip**
When you upgrade the major version of your cluster from 2.x to 3.x, the original cluster and the upgraded one both use the same `aurora-mysql` value for the `engine` attribute.

**Planning a major version upgrade for an Aurora MySQL cluster**

To make sure that your applications and administration procedures work smoothly after upgrading a cluster between major versions, do some advance planning and preparation. To see what sorts of management code to update for your AWS CLI scripts or RDS API–based applications, see How in-place upgrades affect the parameter groups for a cluster (p. 1220). Also see Changes to cluster properties between Aurora MySQL versions (p. 1220).

To learn the sorts of issues that you might encounter during the upgrade, see Troubleshooting for Aurora MySQL in-place upgrade (p. 1222). For issues that might cause the upgrade to take a long time, you can test those conditions in advance and correct them.

You can check application compatibility, performance, maintenance procedures, and similar considerations for the upgraded cluster. To do so, you can perform a simulation of the upgrade before doing the real upgrade. This technique can be especially useful for production clusters. Here, it’s important to minimize downtime and have the upgraded cluster ready to go as soon as the upgrade has finished.

Use the following steps:

1. Create a clone of the original cluster. Follow the procedure in Cloning a volume for an Amazon Aurora DB cluster (p. 303).
2. Set up a similar set of writer and reader DB instances as in the original cluster.
3. Perform an in-place upgrade of the cloned cluster. Follow the procedure in How to perform an in-place upgrade (p. 1217).

Start the upgrade immediately after creating the clone. That way, the cluster volume is still identical to the state of the original cluster. If the clone sits idle before you do the upgrade, Aurora performs
4. Test application compatibility, performance, administration procedures, and so on, using the cloned cluster.

5. If you encounter any issues, adjust your upgrade plans to account for them. For example, adapt any application code to be compatible with the feature set of the higher version. Estimate how long the upgrade is likely to take based on the amount of data in your cluster. You might also choose to schedule the upgrade for a time when the cluster isn’t busy.

6. After you’re satisfied that your applications and workload work properly with the test cluster, you can perform the in-place upgrade for your production cluster.

7. Work to minimize the total downtime of your cluster during a major version upgrade. To do so, make sure that the workload on the cluster is low or zero at the time of the upgrade. In particular, make sure that there are no long running transactions in progress when you start the upgrade.

For information specific to upgrading to Aurora MySQL version 3, see Upgrade planning for Aurora MySQL version 3 (p. 800).

Aurora MySQL major version upgrade paths

Not all kinds or versions of Aurora MySQL clusters can use the in-place upgrade mechanism. You can learn the appropriate upgrade path for each Aurora MySQL cluster by consulting the following table.

<table>
<thead>
<tr>
<th>Type of Aurora MySQL DB cluster</th>
<th>Can it use in-place upgrade?</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL provisioned cluster, 2.0 or higher</td>
<td>Yes</td>
<td>In-place upgrade is supported for 5.7-compatible Aurora MySQL clusters. For information about upgrading to Aurora MySQL version 3, see Upgrade planning for Aurora MySQL version 3 (p. 800) and Upgrading to Aurora MySQL version 3 (p. 799).</td>
</tr>
<tr>
<td>Aurora MySQL provisioned cluster, 3.01.0 or higher</td>
<td>N/A</td>
<td>Use a minor version upgrade procedure to upgrade between Aurora MySQL version 3 versions.</td>
</tr>
<tr>
<td>Aurora Serverless v1 cluster</td>
<td>Yes</td>
<td>You can upgrade from a MySQL 5.6-compatible Aurora Serverless v1 version to a MySQL 5.7-compatible one by performing an in-place upgrade. For more information, see Modifying an Aurora Serverless v1 DB cluster (p. 2051).</td>
</tr>
<tr>
<td>Aurora Serverless v2 cluster</td>
<td>N/A</td>
<td>Currently, Aurora Serverless v2 is supported for Aurora MySQL only on version 3.</td>
</tr>
<tr>
<td>Cluster in an Aurora global database</td>
<td>Yes</td>
<td>To upgrade Aurora MySQL from version 2 to version 3, follow the procedure for doing an in-place upgrade for clusters in an Aurora global database. Perform the upgrade on the global cluster. Aurora upgrades the primary cluster and all the secondary clusters in the global database at the same time. If you use the AWS CLI or RDS API, call the modify-global-cluster command or ModifyGlobalCluster operation instead of modify-db-cluster or ModifyDBCluster.</td>
</tr>
<tr>
<td>Type of Aurora MySQL DB cluster</td>
<td>Can it use in-place upgrade?</td>
<td>Action</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>-----------------------------</td>
<td>--------</td>
</tr>
<tr>
<td>Parallel query cluster</td>
<td>Yes</td>
<td>You can't perform an in-place upgrade from Aurora MySQL version 2 to version 3 if the lower_case_table_names parameter is turned on. For more information, see Major version upgrades (p. 1876).</td>
</tr>
<tr>
<td>Cluster that is the target of binary log replication</td>
<td>Maybe</td>
<td>If the binary log replication is from an Aurora MySQL cluster, you can perform an in-place upgrade. You can't perform the upgrade if the binary log replication is from an RDS for MySQL or an on-premises MySQL DB instance. In that case, you can upgrade using the snapshot restore mechanism.</td>
</tr>
<tr>
<td>Cluster with zero DB instances</td>
<td>No</td>
<td>Using the AWS CLI or the RDS API, you can create an Aurora MySQL cluster without any attached DB instances. In the same way, you can also remove all DB instances from an Aurora MySQL cluster while leaving the data in the cluster volume intact. While a cluster has zero DB instances, you can't perform an in-place upgrade. The upgrade mechanism requires a writer instance in the cluster to perform conversions on the system tables, data files, and so on. In this case, use the AWS CLI or the RDS API to create a writer instance for the cluster. Then you can perform an in-place upgrade.</td>
</tr>
<tr>
<td>Cluster with backtrack enabled</td>
<td>Yes</td>
<td>You can perform an in-place upgrade for an Aurora MySQL cluster that uses the backtrack feature. However, after the upgrade, you can't backtrack the cluster to a time before the upgrade.</td>
</tr>
</tbody>
</table>

How the Aurora MySQL in-place major version upgrade works

Aurora MySQL performs a major version upgrade as a multistage process. You can check the current status of an upgrade. Some of the upgrade steps also provide progress information. As each stage begins, Aurora MySQL records an event. You can examine events as they occur on the Events page in the RDS console. For more information about working with events, see Working with Amazon RDS event notification (p. 690).

Important

Once the process begins, it runs until the upgrade either succeeds or fails. You can't cancel the upgrade while it's underway. If the upgrade fails, Aurora rolls back all the changes and your cluster has the same engine version, metadata, and so on as before.

The upgrade process consists of these stages:

1. Aurora performs a series of checks before beginning the upgrade process. Your cluster keeps running while Aurora does these checks. For example, the cluster can't have any XA transactions in the prepared state or be processing any data definition language (DDL) statements. For example, you might need to shut down applications that are submitting certain kinds of SQL statements. Or you might simply wait until certain long-running statements are finished. Then try the upgrade again.
Some checks test for conditions that don't prevent the upgrade but might make the upgrade take a long time.

If Aurora detects that any required conditions aren't met, modify the conditions identified in the event details. Follow the guidance in Troubleshooting for Aurora MySQL in-place upgrade (p. 1222). If Aurora detects conditions that might cause a slow upgrade, plan to monitor the upgrade over an extended period.

2. Aurora takes your cluster offline. Then Aurora performs a similar set of tests as in the previous stage, to confirm that no new issues arose during the shutdown process. If Aurora detects any conditions at this point that would prevent the upgrade, Aurora cancels the upgrade and brings the cluster back online. In this case, confirm when the conditions no longer apply and start the upgrade again.

3. Aurora creates a snapshot of your cluster volume. Suppose that you discover compatibility or other kinds of issues after the upgrade is finished. Or suppose that you want to perform testing using both the original and upgraded clusters. In such cases, you can restore from this snapshot to create a new cluster with the original engine version and the original data.

   Tip
   This snapshot is a manual snapshot. However, Aurora can create it and continue with the upgrade process even if you have reached your quota for manual snapshots. This snapshot remains permanently until you delete it. After you finish all post-upgrade testing, you can delete this snapshot to minimize storage charges.

4. Aurora clones your cluster volume. Cloning is a fast operation that doesn't involve copying the actual table data. If Aurora encounters an issue during the upgrade, it reverts to the original data from the cloned cluster volume and brings the cluster back online. The temporary cloned volume during the upgrade isn't subject to the usual limit on the number of clones for a single cluster volume.

5. Aurora performs a clean shutdown for the writer DB instance. During the clean shutdown, progress events are recorded every 15 minutes for the following operations. You can examine events as they occur on the Events page in the RDS console.
   - Aurora purges the undo records for old versions of rows.
   - Aurora rolls back any uncommitted transactions.

6. Aurora upgrades the engine version on the writer DB instance:
   - Aurora installs the binary for the new engine version on the writer DB instance.
   - Aurora uses the writer DB instance to upgrade your data to MySQL 5.7-compatible format. During this stage, Aurora modifies the system tables and performs other conversions that affect the data in your cluster volume. In particular, Aurora upgrades the partition metadata in the system tables to be compatible with the MySQL 5.7 partition format. This stage can take a long time if the tables in your cluster have a large number of partitions.

   If any errors occur during this stage, you can find the details in the MySQL error logs. After this stage starts, if the upgrade process fails for any reason, Aurora restores the original data from the cloned cluster volume.

7. Aurora upgrades the engine version on the reader DB instances.

8. The upgrade process is completed. Aurora records a final event to indicate that the upgrade process completed successfully. Now your DB cluster is running the new major version.

How to perform an in-place upgrade

We recommend that you review the background material in How the Aurora MySQL in-place major version upgrade works (p. 1216).

Perform any preupgrade planning and testing, as described in the following:

- Planning a major version upgrade for an Aurora MySQL cluster (p. 1214)
- Upgrade planning for Aurora MySQL version 3 (p. 800)
To upgrade the major version of an Aurora MySQL DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. If you used a custom parameter group for the original DB cluster, create a corresponding parameter group compatible with the new major version. Make any necessary adjustments to the configuration parameters in that new parameter group. For more information, see How in-place upgrades affect the parameter groups for a cluster (p. 1220).
3. In the navigation pane, choose Databases.
4. In the list, choose the DB cluster that you want to modify.
5. Choose Modify.
6. For Version, choose a new Aurora MySQL major version. We generally recommend using the latest minor version of the major version.
7. Choose Continue.
8. On the next page, specify when to perform the upgrade. Choose During the next scheduled maintenance window or Immediately.
9. (Optional) Periodically examine the Events page in the RDS console during the upgrade. Doing so helps you to monitor the progress of the upgrade and identify any issues. If the upgrade encounters any issues, consult Troubleshooting for Aurora MySQL in-place upgrade (p. 1222) for the steps to take.
10. If you created a new parameter group at the start of this procedure, associate the custom parameter group with your upgraded cluster. For more information, see How in-place upgrades affect the parameter groups for a cluster (p. 1220).
   
   **Note**
   Performing this step requires you to restart the cluster again to apply the new parameter group.
11. (Optional) After you complete any post-upgrade testing, delete the manual snapshot that Aurora created at the beginning of the upgrade.
AWS CLI

To upgrade the major version of an Aurora MySQL DB cluster, use the AWS CLI `modify-db-cluster` command with the following required parameters:

- `--db-cluster-identifier`
- `--engine aurora-mysql`
- `--engine-version`
- `--allow-major-version-upgrade`
- `--apply-immediately` or `--no-apply-immediately`

If your cluster uses any custom parameter groups, also include one or both of the following options:

- `--db-cluster-parameter-group-name`, if the cluster uses a custom cluster parameter group
- `--db-instance-parameter-group-name`, if any instances in the cluster use a custom DB parameter group

The following example upgrades the `sample-cluster` DB cluster to Aurora MySQL version 2.10.2. The upgrade happens immediately, instead of waiting for the next maintenance window.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster \
  --db-cluster-identifier sample-cluster \
  --engine aurora-mysql \
  --engine-version 5.7.mysql_aurora.2.10.2 \
  --allow-major-version-upgrade \
  --apply-immediately
```

For Windows:

```bat
aws rds modify-db-cluster ^
  --db-cluster-identifier sample-cluster ^
  --engine aurora-mysql ^
  --engine-version 5.7.mysql_aurora.2.10.2 ^
  --allow-major-version-upgrade ^
  --apply-immediately
```

You can combine other CLI commands with `modify-db-cluster` to create an automated end-to-end process for performing and verifying upgrades. For more information and examples, see [Aurora MySQL in-place upgrade tutorial](p. 1223).

**Note**

If your cluster is part of an Aurora global database, the in-place upgrade procedure is slightly different. You call the `modify-global-cluster` command operation instead of `modify-db-cluster`. For more information, see [In-place major upgrades for global databases](p. 1220).

RDS API

To upgrade the major version of an Aurora MySQL DB cluster, use the RDS API operation `ModifyDBCluster` with the following required parameters:
• DBClusterIdentifier
• Engine
• EngineVersion
• AllowMajorVersionUpgrade
• ApplyImmediately (set to true or false)

**Note**
If your cluster is part of an Aurora global database, the in-place upgrade procedure is slightly different. You call the `ModifyGlobalCluster` operation instead of `ModifyDBCluster`. For more information, see In-place major upgrades for global databases (p. 1220).

How in-place upgrades affect the parameter groups for a cluster

Aurora parameter groups have different sets of configuration settings for clusters that are compatible with MySQL 5.7 or 8.0. When you perform an in-place upgrade, the upgraded cluster and all its instances must use the corresponding cluster and instance parameter groups:

Your cluster and instances might use the default 5.7-compatible parameter groups. If so, the upgraded cluster and instance start with the default 8.0-compatible parameter groups. If your cluster and instances use any custom parameter groups, make sure to create corresponding or 8.0-compatible parameter groups. Also make sure to specify those during the upgrade process.

**Important**
If you specify any custom parameter group during the upgrade process, make sure to manually reboot the cluster after the upgrade finishes. Doing so makes the cluster begin using your custom parameter settings.

Changes to cluster properties between Aurora MySQL versions

When you upgrade from Aurora MySQL version 2 to version 3, make sure to check any applications or scripts that you use to set up or manage Aurora MySQL clusters and DB instances.

Also, change your code that manipulates parameter groups to account for the fact that the default parameter group names are different for 5.7- and 8.0-compatible clusters. The default parameter group names for Aurora MySQL version 2 and 3 clusters are `default.aurora-mysql5.7` and `default.aurora-mysql8.0`, respectively.

For example, you might have code like the following that applies to your cluster before an upgrade.

```bash
# Check the default parameter values for MySQL 5.7-compatible clusters.
aws rds describe-db-parameters --db-parameter-group-name default.aurora-mysql5.7 --region us-east-1
```

After upgrading the major version of the cluster, modify that code as follows.

```bash
# Check the default parameter values for MySQL 8.0-compatible clusters.
aws rds describe-db-parameters --db-parameter-group-name default.aurora-mysql8.0 --region us-east-1
```

In-place major upgrades for global databases

For an Aurora global database, you upgrade the global database cluster. Aurora automatically upgrades all of the clusters at the same time and makes sure that they all run the same engine version. This
The requirement is because any changes to system tables, data file formats, and so on, are automatically replicated to all the secondary clusters.

Follow the instructions in How the Aurora MySQL in-place major version upgrade works (p. 1216). When you specify what to upgrade, make sure to choose the global database cluster instead of one of the clusters it contains.

If you use the AWS Management Console, choose the item with the role Global database.

If you use the AWS CLI or RDS API, start the upgrade process by calling the modify-global-cluster command or ModifyGlobalCluster operation. You use one of these instead of modify-db-cluster or ModifyDBCluster.

Note
You can't specify a custom parameter group for the global database cluster while you're performing a major version upgrade of that Aurora global database. Create your custom parameter groups in each Region of the global cluster. Then apply them manually to the Regional clusters after the upgrade.

To upgrade the major version of an Aurora MySQL global database cluster by using the AWS CLI, use the modify-global-cluster command with the following required parameters:

- --global-cluster-identifier
- --engine aurora-mysql
- --engine-version
- --allow-major-version-upgrade

The following example upgrades the global database cluster to Aurora MySQL version 2.10.2.

Example
For Linux, macOS, or Unix:

```bash
aws rds modify-global-cluster \
    --global-cluster-identifier global_cluster_identifier \
    --engine aurora-mysql \
    --engine-version 5.7.mysql_aurora.2.10.2 \
    --allow-major-version-upgrade
```
For Windows:

```plaintext
aws rds modify-global-cluster ^
  --global-cluster-identifier global_cluster_identifier ^
  --engine aurora-mysql ^
  --engine-version 5.7.mysql_aurora.2.10.2 ^
  --allow-major-version-upgrade
```

**After the upgrade**

If the cluster that you upgraded had the Backtrack feature enabled, you can’t backtrack the upgraded cluster to a time that's before the upgrade.

**Troubleshooting for Aurora MySQL in-place upgrade**

Use the following tips to help troubleshoot problems with Aurora MySQL in-place upgrades. These tips don't apply to Aurora Serverless DB clusters.

<table>
<thead>
<tr>
<th>Reason for in-place upgrade being canceled or slow</th>
<th>Effect</th>
<th>Solution to allow in-place upgrade to complete within maintenance window</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cluster has XA transactions in the prepared state</td>
<td>Aurora cancels the upgrade.</td>
<td>Commit or roll back all prepared XA transactions.</td>
</tr>
<tr>
<td>Cluster is processing any data definition language (DDL) statements</td>
<td>Aurora cancels the upgrade.</td>
<td>Consider waiting and performing the upgrade after all DDL statements are finished.</td>
</tr>
<tr>
<td>Cluster has uncommitted changes for many rows</td>
<td>Upgrade might take a long time.</td>
<td>The upgrade process rolls back the uncommitted changes. The indicator for this condition is the value of TRX_ROWS_MODIFIED in the INFORMATION_SCHEMA.INNODB_TRX table. Consider performing the upgrade only after all large transactions are committed or rolled back.</td>
</tr>
<tr>
<td>Cluster has high number of undo records</td>
<td>Upgrade might take a long time.</td>
<td>Even if the uncommitted transactions don't affect a large number of rows, they might involve a large volume of data. For example, you might be inserting large BLOBs. Aurora doesn't automatically detect or generate an event for this kind of transaction activity. The indicator for this condition is the history list length. The upgrade process rolls back the uncommitted changes. Consider performing the upgrade only after the history list length is smaller.</td>
</tr>
<tr>
<td>Cluster is in the process of committing a large binary log transaction</td>
<td>Upgrade might take a long time.</td>
<td>The upgrade process waits until the binary log changes are applied. More transactions or DDL statements could start during this period, further slowing down the upgrade process. Schedule the upgrade process when the cluster isn't busy with generating binary log replication changes. Aurora doesn't automatically detect or generate an event for this condition.</td>
</tr>
</tbody>
</table>
### Reason for in-place upgrade being canceled or slow

<table>
<thead>
<tr>
<th>Effect</th>
<th>Solution to allow in-place upgrade to complete within maintenance window</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora cancels the upgrade.</td>
<td>Change the default storage engine for temporary tables from MyISAM to InnoDB. Perform the following steps:</td>
</tr>
<tr>
<td></td>
<td>1. Modify the <code>default_tmp_storage_engine</code> DB parameter to InnoDB.</td>
</tr>
<tr>
<td></td>
<td>2. Reboot the DB cluster.</td>
</tr>
<tr>
<td></td>
<td>3. After rebooting, confirm that the <code>default_tmp_storage_engine</code> DB parameter is set to InnoDB. Use the following command:</td>
</tr>
<tr>
<td></td>
<td><code>show global variables like 'default_tmp_storage_engine';</code></td>
</tr>
<tr>
<td></td>
<td>4. Make sure not to create any temporary tables that use the MyISAM storage engine. We recommend that you pause any database workload and not create any new database connections, because you're upgrading soon.</td>
</tr>
<tr>
<td></td>
<td>5. Try the in-place upgrade again.</td>
</tr>
</tbody>
</table>

You can use the following steps to perform your own checks for some of the conditions in the preceding table. That way, you can schedule the upgrade at a time when you know the database is in a state where the upgrade can complete successfully and quickly.

- You can check for open XA transactions by executing the `XA RECOVER` statement. You can then commit or roll back the XA transactions before starting the upgrade.
- You can check for DDL statements by executing a `SHOW PROCESSLIST` statement and looking for `CREATE`, `DROP`, `ALTER`, `RENAME`, and `TRUNCATE` statements in the output. Allow all DDL statements to finish before starting the upgrade.
- You can check the total number of uncommitted rows by querying the `INFORMATION_SCHEMA.INNODB_TRX` table. The table contains one row for each transaction. The `TRX_ROWS_MODIFIED` column contains the number of rows modified or inserted by the transaction.
- You can check the length of the InnoDB history list by executing the `SHOW ENGINE INNODB STATUS` SQL statement and looking for the `History list length` in the output. You can also check the value directly by running the following query:

```sql
SELECT count FROM information_schema.innodb_metrics WHERE name = 'trx_rseg_history_len';
```

The length of the history list corresponds to the amount of undo information stored by the database to implement multi-version concurrency control (MVCC).

### Aurora MySQL in-place upgrade tutorial

The following Linux examples show how you might perform the general steps of the in-place upgrade procedure using the AWS CLI.

This first example creates an Aurora DB cluster that's running a 2.x version of Aurora MySQL. The cluster includes a writer DB instance and a reader DB instance. The `wait db-instance-available` command pauses until the writer DB instance is available. That's the point when the cluster is ready to be upgraded.
aws rds create-db-cluster --db-cluster-identifier mynewdbcluster --engine aurora-mysql
--db-cluster-version 5.7.mysql_aurora.2.10.2
...
aws rds create-db-instance --db-instance-identifier mynewdbcluster-instance1
--db-cluster-identifier mynewdbcluster --db-instance-class db.t4g.medium --engine aurora-mysql
...
aws rds wait db-instance-available --db-instance-identifier mynewdbcluster-instance1

The Aurora MySQL 3.x versions that you can upgrade the cluster to depend on the 2.x version that the
cluster is currently running and on the AWS Region where the cluster is located. The first command, with
--output text, just shows the available target version. The second command shows the full JSON
output of the response. In that response, you can see details such as the aurora-mysql value that you
use for the engine parameter. You can also see the fact that upgrading to 3.02.0 represents a major
version upgrade.

aws rds describe-db-clusters --db-cluster-identifier mynewdbcluster
--query "[*].{EngineVersion:EngineVersion}" --output text
5.7.mysql_aurora.2.10.2
aws rds describe-db-engine-versions --engine aurora-mysql --engine-version
5.7.mysql_aurora.2.10.2
--query "[*].[ValidUpgradeTarget]"
...
{
  "Engine": "aurora-mysql",
  "EngineVersion": "8.0.mysql_aurora.3.02.0",
  "Description": "Aurora MySQL 3.02.0 (compatible with MySQL 8.0.23)",
  "AutoUpgrade": false,
  "IsMajorVersionUpgrade": true,
  "SupportedEngineModes": [
    "provisioned"
  ],
  "SupportsParallelQuery": true,
  "SupportsGlobalDatabases": true,
  "SupportsBabelfish": false
},
...

This example shows how if you enter a target version number that isn't a valid upgrade target for the
cluster, Aurora doesn't perform the upgrade. Aurora also doesn't perform a major version upgrade
unless you include the --allow-major-version-upgrade parameter. That way, you can't accidentally
perform an upgrade that has the potential to require extensive testing and changes to your application
code.

aws rds modify-db-cluster --db-cluster-identifier mynewdbcluster
--engine-version 5.7.mysql_aurora.2.09.2 --apply-immediately
An error occurred (InvalidParameterCombination) when calling the ModifyDBCluster
operation: Cannot find upgrade target from 5.7.mysql_aurora.2.10.2 with requested version
5.7.mysql_aurora.2.09.2.
aws rds modify-db-cluster --db-cluster-identifier mynewdbcluster
--engine-version 8.0.mysql_aurora.3.02.0 --region us-east-1 --apply-immediately
An error occurred (InvalidParameterCombination) when calling the ModifyDBCluster operation:
The AllowMajorVersionUpgrade flag must be present when upgrading to a new major version.
aws rds modify-db-cluster --db-cluster-identifier mynewdbcluster
--engine-version 8.0.mysql_aurora.3.02.0 --apply-immediately --allow-major-version-upgrade
{
  "DBClusterIdentifier": "mynewdbcluster",
}
It takes a few moments for the status of the cluster and associated DB instances to change to upgrading. The version numbers for the cluster and DB instances only change when the upgrade is finished. Again, you can use the `wait db-instance-available` command for the writer DB instance to wait until the upgrade is finished before proceeding.

```
aws rds describe-db-clusters --db-cluster-identifier mynewdbcluster \
    --query '[].[Status,EngineVersion]' --output text
upgrading 5.7.mysql_aurora.2.10.2
```

```
aws rds describe-db-instances --db-instance-identifier mynewdbcluster-instance1 \
    --query '[].
        {DBInstanceIdentifier:DBInstanceIdentifier,\n        DBInstanceStatus:DBInstanceStatus} | [0]'
    {
        "DBInstanceIdentifier": "mynewdbcluster-instance1",
        "DBInstanceStatus": "upgrading"
    }
```

```
aws rds wait db-instance-available --db-instance-identifier mynewdbcluster-instance1
```

At this point, the version number for the cluster matches the one that was specified for the upgrade.

```
aws rds describe-db-clusters --db-cluster-identifier mynewdbcluster \
    --query '[].[EngineVersion]' --output text
8.0.mysql_aurora.3.02.0
```

The preceding example did an immediate upgrade by specifying the `--apply-immediately` parameter. To let the upgrade happen at a convenient time when the cluster isn't expected to be busy, you can specify the `--no-apply-immediately` parameter. Doing so makes the upgrade start during the next maintenance window for the cluster. The maintenance window defines the period during which maintenance operations can start. A long-running operation might not finish during the maintenance window. Thus, you don't need to define a larger maintenance window even if you expect that the upgrade might take a long time.

The following example upgrades a cluster that's initially running Aurora MySQL version 2.10.2. In the `describe-db-engine-versions` output, the False and True values represent the `IsMajorVersionUpgrade` property. From version 2.10.2, you can upgrade to some other 2.*, but those upgrades aren't considered major version upgrades and so don't require an in-place upgrade. In-place upgrade is only available for upgrades to the 3.* versions that are shown in the list.

```
aws rds describe-db-clusters --db-cluster-identifier mynewdbcluster \
    --query '[].[EngineVersion:EngineVersion]' --output text
5.7.mysql_aurora.2.10.2
```

```
aws rds describe-db-engine-versions --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.10.2 \
    --query '[].[ValidUpgradeTarget][0][0][*].[EngineVersion,IsMajorVersionUpgrade]' --output text
5.7.mysql_aurora.2.10.3 False
5.7.mysql_aurora.2.11.0 False
5.7.mysql_aurora.2.11.1 False
8.0.mysql_aurora.3.01.1 True
8.0.mysql_aurora.3.02.0 True
8.0.mysql_aurora.3.02.2 True
```
When a cluster is created without a specified maintenance window, Aurora picks a random day of the week. In this case, the `modify-db-cluster` command is submitted on a Monday. Thus, we change the maintenance window to be Tuesday morning. All times are represented in the UTC time zone. The `tue:10:00-tue:10:30` window corresponds to 2:00-2:30 AM Pacific time. The change in the maintenance window takes effect immediately.

```plaintext
aws rds describe-db-clusters --db-cluster-identifier mynewdbcluster --query '[]
[PreferredMaintenanceWindow]
[
  "sat:08:20-sat:08:50"
]
]
aws rds modify-db-cluster --db-cluster-identifier mynewdbcluster --preferred-maintenance-window tue:10:00-tue:10:30
aws rds describe-db-clusters --db-cluster-identifier mynewdbcluster --query '[]
[PreferredMaintenanceWindow]
[
  "tue:10:00-tue:10:30"
]
]
```

The following example shows how to get a report of the events generated by the upgrade. The `--duration` argument represents the number of minutes to retrieve the event information. This argument is needed because by default, `describe-events` only returns events from the last hour.

```plaintext
aws rds describe-events --source-type db-cluster --source-identifier mynewdbcluster --duration 20160
{
  "Events": [
    {
      "SourceIdentifier": "mynewdbcluster",
      "SourceType": "db-cluster",
      "Message": "DB cluster created",
      "EventCategories": [
        "creation"
      ],
      "Date": "2022-11-17T01:24:11.093000+00:00",

  "Message": "Database cluster major version has been upgraded",
  "EventCategories": [  "maintenance"
],  "Date": "2022-11-18T23:00:22.318000+00:00",
"SourceArn": "arn:aws:rds:us-east-1:123456789012:cluster:mynewdbcluster"
}
Alternative blue-green upgrade technique

In some situations, your top priority is to perform an immediate switchover from the old cluster to an upgraded one. In such situations, you can use a multistep process that runs the old and new clusters side-by-side. Here, you replicate data from the old cluster to the new one until you are ready for the new cluster to take over. For details, see Using Amazon RDS Blue/Green Deployments for database updates (p. 399).

Working with Amazon Aurora PostgreSQL

Amazon Aurora PostgreSQL is a fully managed, PostgreSQL–compatible, and ACID–compliant relational database engine that combines the speed, reliability, and manageability of Amazon Aurora with the simplicity and cost-effectiveness of open-source databases. Aurora PostgreSQL is a drop-in replacement for PostgreSQL and makes it simple and cost-effective to set up, operate, and scale your new and existing PostgreSQL deployments, thus freeing you to focus on your business and applications. To learn more about Aurora in general, see [What is Amazon Aurora?](#) (p. 1).

In addition to the benefits of Aurora, Aurora PostgreSQL offers a convenient migration pathway from Amazon RDS into Aurora, with push-button migration tools that convert your existing RDS for PostgreSQL applications to Aurora PostgreSQL. Routine database tasks such as provisioning, patching, backup, recovery, failure detection, and repair are also easy to manage with Aurora PostgreSQL.

Aurora PostgreSQL can work with many industry standards. For example, you can use Aurora PostgreSQL databases to build HIPAA-compliant applications and to store healthcare related information, including protected health information (PHI), under a completed Business Associate Agreement (BAA) with AWS.

Aurora PostgreSQL is FedRAMP HIGH eligible. For details about AWS and compliance efforts, see [AWS services in scope by compliance program](#).

Working with the database preview environment

The PostgreSQL community releases new major version of PostgreSQL annually. Similarly, Amazon Aurora makes PostgreSQL major versions available as Preview releases. This allows you to create DB cluster using the Preview version and test out its features in the Database Preview Environment.

Aurora PostgreSQL DB clusters in the Database Preview Environment are functionally similar to other Aurora PostgreSQL DB clusters. However, you can't use a Preview version for production.

Keep in mind the following important limitations:

- All DB instances and DB clusters are deleted 60 days after you create them, along with any backups and snapshots.
- You can only create a DB instance in a virtual private cloud (VPC) based on the Amazon VPC service.
- You can't copy a snapshot of a DB instance to a production environment.

The following options are supported by the Preview.

- You can create DB instances using r5, r6g, r6i, r7g, x2g, t3 and t4g instance types only. For more information about instance classes, see Aurora DB instance classes (p. 84).
- You can use both single-AZ and multi-AZ deployments.
- You can use standard PostgreSQL dump and load functions to export databases from or import databases to the Database Preview Environment.

Supported DB instance class types

Amazon Aurora PostgreSQL supports the following DB instance classes in the preview region:

**Memory Optimized Classes**

- db.r5 – memory-optimized instance classes
- db.r6g – memory-optimized instance classes powered by AWS Graviton2 processors
- db.r6i – memory-optimized instance classes
- db.x2g – memory-optimized instance classes powered by AWS Graviton2 processors

**Note**
For more information on the list of instance classes, see DB instance class types (p. 84).

**Burstable classes**

- db.t3.medium
- db.t3.large
- db.t4g.medium
- db.t4g.large

Unsupported features in the preview environment

The following features aren't available in the preview environment:

- Aurora Serverless v1 and v2
Creating a new DB cluster in the preview environment

Use the following procedure to create a DB cluster in the preview environment.

To create a DB cluster in the preview environment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.  
2. Choose Dashboard from the navigation pane.  
3. In the Dashboard page, locate the Database Preview Environment section on the Dashboard page, as shown in the following image.
4. To create the Aurora PostgreSQL DB cluster, follow the same process as that for creating any Aurora DB cluster. For more information, see Creating an Amazon Aurora DB cluster (p. 179).

To create an instance in the Database Preview Environment using the Aurora API or the AWS CLI, use the following endpoint.

```
rds-preview.us-east-2.amazonaws.com
```

**PostgreSQL version 16 in the Database Preview environment**

This is preview documentation for Aurora PostgreSQL version 16. It is subject to change.

PostgreSQL version 16.0 is now available in the Amazon RDS Database Preview environment. PostgreSQL version 16 contains several improvements that are described in the following PostgreSQL documentation:

- PostgreSQL 16 Released

For information on the Database Preview Environment, see Working with the database preview environment (p. 1230). To access the Preview Environment from the console, select https://console.aws.amazon.com/rds-preview/.
Security with Amazon Aurora PostgreSQL

For a general overview of Aurora security, see Security in Amazon Aurora (p. 2367). You can manage security for Amazon Aurora PostgreSQL at a few different levels:

- To control who can perform Amazon RDS management actions on Aurora PostgreSQL DB clusters and DB instances, use AWS Identity and Access Management (IAM). IAM handles the authentication of user identity before the user can access the service. It also handles authorization, that is, whether the user is allowed to do what they're trying to do. IAM database authentication is an additional authentication method that you can choose when you create your Aurora PostgreSQL DB cluster. For more information, see Identity and access management for Amazon Aurora (p. 2400).

  If you do use IAM with your Aurora PostgreSQL DB cluster, sign in to the AWS Management Console with your IAM credentials first, before opening the Amazon RDS console at https://console.aws.amazon.com/rds/.

- Make sure to create Aurora DB clusters in a virtual private cloud (VPC) based on the Amazon VPC service. To control which devices and Amazon EC2 instances can open connections to the endpoint and port of the DB instance for Aurora DB clusters in a VPC, use a VPC security group. You can make these endpoint and port connections by using Secure Sockets Layer (SSL). In addition, firewall rules at your company can control whether devices running at your company can open connections to a DB instance. For more information on VPCs, see Amazon VPC VPCs and Amazon Aurora (p. 2478).

  The supported VPC tenancy depends on the DB instance class used by your Aurora PostgreSQL DB clusters. With default VPC tenancy, the DB cluster runs on shared hardware. With dedicated VPC tenancy, the DB cluster runs on a dedicated hardware instance. The burstable performance DB instance classes support default VPC tenancy only. The burstable performance DB instance classes include the db.t3 and db.t4g DB instance classes. All other Aurora PostgreSQL DB instance classes support both default and dedicated VPC tenancy.

  For more information about instance classes, see Aurora DB instance classes (p. 84). For more information about default and dedicated VPC tenancy, see Dedicated instances in the Amazon Elastic Compute Cloud User Guide.

- To grant permissions to the PostgreSQL databases running on your Amazon Aurora DB cluster, you can take the same general approach as with stand-alone instances of PostgreSQL. Commands such as CREATE ROLE, ALTER ROLE, GRANT, and REVOKE work just as they do in on-premises databases, as does directly modifying databases, schemas, and tables.

  PostgreSQL manages privileges by using roles. The rds_superuser role is the most privileged role on an Aurora PostgreSQL DB cluster. This role is created automatically, and it's granted to the user that creates the DB cluster (the master user account, postgres by default). To learn more, see Understanding PostgreSQL roles and permissions (p. 1233).

All available Aurora PostgreSQL versions, including versions 10, 11, 12, 13, 14, and higher releases support the Salted Challenge Response Authentication Mechanism (SCRAM) for passwords as an alternative to message digest (MD5). We recommend that you use SCRAM because it's more secure than MD5. For more information, including how to migrate database user passwords from MD5 to SCRAM, see Using SCRAM for PostgreSQL password encryption (p. 1238).

Understanding PostgreSQL roles and permissions

When you create an Aurora PostgreSQL DB cluster using the AWS Management Console, an administrator account is created at the same time. By default, its name is postgres, as shown in the following screenshot:
You can choose another name rather than accept the default (postgres). If you do, the name you choose must start with a letter and be between 1 and 16 alphanumeric characters. For simplicity's sake, we refer to this main user account by its default value (postgres) throughout this guide.

If you use the `create-db-cluster` AWS CLI rather than the AWS Management Console, you create the user name by passing it with the `master-username` parameter. For more information, see Step 2: Create an Aurora PostgreSQL DB cluster (p. 142).

Whether you use the AWS Management Console, the AWS CLI, or the Amazon RDS API, and whether you use the default `postgres` name or choose a different name, this first database user account is a member of the `rds_superuser` group and has `rds_superuser` privileges.

Topics

- Understanding the `rds_superuser` role (p. 1234)
- Controlling user access to the PostgreSQL database (p. 1236)
- Delegating and controlling user password management (p. 1237)
- Using SCRAM for PostgreSQL password encryption (p. 1238)

**Understanding the `rds_superuser` role**

In PostgreSQL, a *role* can define a user, a group, or a set of specific permissions granted to a group or user for various objects in the database. PostgreSQL commands to `CREATE USER` and `CREATE GROUP` have been replaced by the more general, `CREATE ROLE` with specific properties to distinguish database users. A database user can be thought of as a role with the LOGIN privilege.

**Note**

The `CREATE USER` and `CREATE GROUP` commands can still be used. For more information, see Database Roles in the PostgreSQL documentation.

The `postgres` user is the most highly privileged database user on your Aurora PostgreSQL DB cluster. It has the characteristics defined by the following `CREATE ROLE` statement.

```
CREATE ROLE postgres WITH LOGIN NOSUPERUSER INHERIT CREATEDB CREATEROLE NOREPLICATION VALID UNTIL 'infinity'
```

The properties NOSUPERUSER, NOREPLICATION, INHERIT, and VALID UNTIL `infinity` are the default options for `CREATE ROLE`, unless otherwise specified.

By default, `postgres` has privileges granted to the `rds_superuser` role, and permissions to create roles and databases. The `rds_superuser` role allows the `postgres` user to do the following:
• Add extensions that are available for use with Aurora PostgreSQL. For more information, see Working with extensions and foreign data wrappers (p. 1616).

• Create roles for users and grant privileges to users. For more information, see CREATE ROLE and GRANT in the PostgreSQL documentation.

• Create databases. For more information, see CREATE DATABASE in the PostgreSQL documentation.

• Grant rds_superuser privileges to user roles that don't have these privileges, and revoke privileges as needed. We recommend that you grant this role only to those users who perform superuser tasks. In other words, you can grant this role to database administrators (DBAs) or system administrators.

• Grant (and revoke) the rds_replication role to database users that don't have the rds_superuser role.

• Grant (and revoke) the rds_password role to database users that don't have the rds_superuser role.

• Obtain status information about all database connections by using the pg_stat_activity view. When needed, rds_superuser can stop any connections by using pg_terminate_backend or pg_cancel_backend.

In the CREATE ROLE postgres... statement, you can see that the postgres user role specifically disallows PostgreSQL superuser permissions. Aurora PostgreSQL is a managed service, so you can't access the host OS, and you can't connect using the PostgreSQL superuser account. Many of the tasks that require superuser access on a stand-alone PostgreSQL are managed automatically by Aurora.

For more information about granting privileges, see GRANT in the PostgreSQL documentation.

The rds_superuser role is one of several predefined roles in an Aurora PostgreSQL DB cluster.

**Note**
In PostgreSQL 13 and earlier releases, predefined roles are known as default roles.

In the following list, you find some of the other predefined roles that are created automatically for a new Aurora PostgreSQL DB cluster. Predefined roles and their privileges can't be changed. You can't drop, rename, or modify privileges for these predefined roles. Attempting to do so results in an error.

• **rds_password** – A role that can change passwords and set up password constraints for database users. The rds_superuser role is granted this role by default, and can grant the role to database users.

  For more information, see Controlling user access to the PostgreSQL database (p. 1236).

• **rdsadmin** – A role that's created to handle many of the management tasks that the administrator with superuser privileges would perform on a standalone PostgreSQL database. This role is used internally by Aurora PostgreSQL for many management tasks.

To see all predefined roles, you can connect to the primary instance of your Aurora PostgreSQL DB cluster and use the psql \du metacommand. The output looks as follows:

<table>
<thead>
<tr>
<th>Role name</th>
<th>Attributes</th>
<th>Member of</th>
</tr>
</thead>
<tbody>
<tr>
<td>postgres</td>
<td>Create role, Create DB</td>
<td>{rds_superuser}</td>
</tr>
<tr>
<td></td>
<td>Password valid until infinity</td>
<td></td>
</tr>
<tr>
<td>rds_superuser</td>
<td>Cannot login</td>
<td>{pg_monitor,pg_signal_backend,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>rds_replication,rds_password}</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In the output, you can see that rds_superuser isn't a database user role (it can't login), but it has the privileges of many other roles. You can also see that database user postgres is a member of the rds_superuser role. As mentioned previously, postgres is the default value in the Amazon RDS
console's **Create database** page. If you chose another name, that name is shown in the list of roles instead.

**Note**
Aurora PostgreSQL versions 15.2 and 14.7 introduced restrictive behavior of the `rds_superuser` role. An Aurora PostgreSQL user needs to be granted the CONNECT privilege on the corresponding database to connect even if the user is granted the `rds_superuser` role. Prior to Aurora PostgreSQL versions 14.7 and 15.2, a user was able to connect to any database and system table if the user was granted the `rds_superuser` role. This restrictive behavior aligns with the AWS and Amazon Aurora commitments to the continuous improvement of security. Please update the respective logic in your applications if the above enhancement has an impact.

### Controlling user access to the PostgreSQL database

New databases in PostgreSQL are always created with a default set of privileges in the database's public schema that allow all database users and roles to create objects. These privileges allow database users to connect to the database, for example, and create temporary tables while connected.

To better control user access to the databases instances that you create on your Aurora PostgreSQL DB cluster primary node, we recommend that you revoke these default public privileges. After doing so, you then grant specific privileges for database users on a more granular basis, as shown in the following procedure.

**To set up roles and privileges for a new database instance**

Suppose you're setting up a database on a newly created Aurora PostgreSQL DB cluster for use by several researchers, all of whom need read-write access to the database.

1. Use `psql` (or pgAdmin) to connect to the primary DB instance on your Aurora PostgreSQL DB cluster:

   ```
   psql --host=your-cluster-instance-1.666666666666.aws-region.rds.amazonaws.com --
   port=5432 --username=postgres --password
   ```

   When prompted, enter your password. The `psql` client connects and displays the default administrative connection database, `postgres=>`, as the prompt.

2. To prevent database users from creating objects in the public schema, do the following:

   ```
   postgres=> REVOKE CREATE ON SCHEMA public FROM PUBLIC;
   ```

3. Next, you create a new database instance:

   ```
   postgres=> CREATE DATABASE lab_db;
   ```

4. Revoke all privileges from the PUBLIC schema on this new database.

   ```
   postgres=> REVOKE ALL ON DATABASE lab_db FROM public;
   ```

5. Create a role for database users.

   ```
   postgres=> CREATE ROLE lab_tech;
   ```
6. Give database users that have this role the ability to connect to the database.

   postgres=> GRANT CONNECT ON DATABASE lab_db TO lab_tech;

7. Grant all users with the lab_tech role all privileges on this database.

   postgres=> GRANT ALL PRIVILEGES ON DATABASE lab_db TO lab_tech;

8. Create database users, as follows:

   postgres=> CREATE ROLE lab_user1 LOGIN PASSWORD 'change_me';
   postgres=> CREATE ROLE lab_user2 LOGIN PASSWORD 'change_me';

9. Grant these two users the privileges associated with the lab_tech role:

   postgres=> GRANT lab_tech TO lab_user1;
   postgres=> GRANT lab_tech TO lab_user2;

At this point, lab_user1 and lab_user2 can connect to the lab_db database. This example doesn't follow best practices for enterprise usage, which might include creating multiple database instances, different schemas, and granting limited permissions. For more complete information and additional scenarios, see Managing PostgreSQL Users and Roles.

For more information about privileges in PostgreSQL databases, see the GRANT command in the PostgreSQL documentation.

Delegating and controlling user password management

As a DBA, you might want to delegate the management of user passwords. Or, you might want to prevent database users from changing their passwords or reconfiguring password constraints, such as password lifetime. To ensure that only the database users that you choose can change password settings, you can turn on the restricted password management feature. When you activate this feature, only those database users that have been granted the rds_password role can manage passwords.

   Note
   To use restricted password management, your Aurora PostgreSQL DB cluster must be running Amazon Aurora PostgreSQL 10.6 or higher.

By default, this feature is off, as shown in the following:

   postgres=> SHOW rds.restrict_password_commands;
   rds.restrict_password_commands
   -----------------------------------
   off
   (1 row)

To turn on this feature, you use a custom parameter group and change the setting for rds.restrict_password_commands to 1. Be sure to reboot your Aurora PostgreSQL's primary DB instance so that the setting takes effect.

With this feature active, rds_password privileges are needed for the following SQL commands:
Renaming a role (ALTER ROLE myrole RENAME TO newname) is also restricted if the password uses the MD5 hashing algorithm.

With this feature active, attempting any of these SQL commands without the rds_password role permissions generates the following error:

```
ERROR: must be a member of rds_password to alter passwords
```

We recommend that you grant the rds_password to only a few roles that you use solely for password management. If you grant rds_password privileges to database users that don't have rds_superuser privileges, you need to also grant them the CREATEROLE attribute.

Make sure that you verify password requirements such as expiration and needed complexity on the client side. If you use your own client-side utility for password related changes, the utility needs to be a member of rds_password and have CREATE ROLE privileges.

### Using SCRAM for PostgreSQL password encryption

The *Salted Challenge Response Authentication Mechanism (SCRAM)* is an alternative to PostgreSQL's default message digest (MD5) algorithm for encrypting passwords. The SCRAM authentication mechanism is considered more secure than MD5. To learn more about these two different approaches to securing passwords, see [Password Authentication](#) in the PostgreSQL documentation.

We recommend that you use SCRAM rather than MD5 as the password encryption scheme for your Aurora PostgreSQL DB cluster. As of the Aurora PostgreSQL 14 release, SCRAM is supported in all available Aurora PostgreSQL versions, including versions 10, 11, 12, 13, and 14. It's a cryptographic challenge-response mechanism that uses the scram-sha-256 algorithm for password authentication and encryption.

You might need to update libraries for your client applications to support SCRAM. For example, JDBC versions before 42.2.0 don't support SCRAM. For more information, see [PostgreSQL JDBC Driver](#) in the PostgreSQL JDBC Driver documentation. For a list of other PostgreSQL drivers and SCRAM support, see [List of drivers](#) in the PostgreSQL documentation.

**Note**

Aurora PostgreSQL version 14 and higher support scram-sha-256 for password encryption by default for new DB clusters. That is, the default DB cluster parameter group (default.aurora-postgresql14) has its password_encryption value set to scram-sha-256.

### Setting up Aurora PostgreSQL DB cluster to require SCRAM

For Aurora PostgreSQL 14.3 and higher versions, you can require the Aurora PostgreSQL DB cluster to accept only passwords that use the scram-sha-256 algorithm.

**Important**

For existing RDS Proxies with PostgreSQL databases, if you modify the database authentication to use SCRAM only, the proxy becomes unavailable for up to 60 seconds. To avoid the issue, do one of the following:

- Ensure that the database allows both SCRAM and MD5 authentication.
To use only SCRAM authentication, create a new proxy, migrate your application traffic to the new proxy, then delete the proxy previously associated with the database.

Before making changes to your system, be sure you understand the complete process, as follows:

- Get information about all roles and password encryption for all database users.
- Double-check the parameter settings for your Aurora PostgreSQL DB cluster for the parameters that control password encryption.
- If your Aurora PostgreSQL DB cluster uses a default parameter group, you need to create a custom DB cluster parameter group and apply it to your Aurora PostgreSQL DB cluster so that you can modify parameters when needed. If your Aurora PostgreSQL DB cluster uses a custom parameter group, you can modify the necessary parameters later in the process, as needed.
- Change the password_encryption parameter to scram-sha-256.
- Notify all database users that they need to update their passwords. Do the same for your postgres account. The new passwords are encrypted and stored using the scram-sha-256 algorithm.
- Verify that all passwords are encrypted using the type of encryption.
- If all passwords use scram-sha-256, you can change the rds.accepted_password_auth_method parameter from md5+scram to scram-sha-256.

**Warning**
After you change rds.accepted_password_auth_method to scram-sha-256 alone, any users (roles) with md5–encrypted passwords can't connect.

**Getting ready to require SCRAM for your Aurora PostgreSQL DB cluster**

Before making any changes to your Aurora PostgreSQL DB cluster, check all existing database user accounts. Also, check the type of encryption used for passwords. You can do these tasks by using the rds_tools extension. This extension is supported on Aurora PostgreSQL 13.1 and higher releases.

**To get a list of database users (roles) and password encryption methods**

1. Use psql to connect to the primary instance of your Aurora PostgreSQL DB cluster, as shown in the following.

```
psql --host=cluster-name-instance-1.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
```

2. Install the rds_tools extension.

```
postgres=> CREATE EXTENSION rds_tools;
CREATE EXTENSION
```

3. Get a listing of roles and encryption.

```
postgres=> SELECT * FROM
       rds_tools.role_password_encryption_type();
```

You see output similar to the following.

```
<table>
<thead>
<tr>
<th>rolname</th>
<th>encryption_type</th>
</tr>
</thead>
<tbody>
<tr>
<td>pg_monitor</td>
<td>-----------------</td>
</tr>
<tr>
<td>pg_read_all_settings</td>
<td>-----------------</td>
</tr>
<tr>
<td>pg_read_all_stats</td>
<td>-----------------</td>
</tr>
</tbody>
</table>
```

1239
Creating a custom DB cluster parameter group

**Note**

If your Aurora PostgreSQL DB cluster already uses a custom parameter group, you don’t need to create a new one.

For an overview of parameter groups for Aurora, see Creating a DB cluster parameter group (p. 216).

The password encryption type used for passwords is set in one parameter, password_encryption. The encryption that the Aurora PostgreSQL DB cluster allows is set in another parameter, rds.accepted_password_auth_method. Changing either of these from the default values requires that you create a custom DB cluster parameter group and apply it to your cluster.

You can also use the AWS Management Console or the RDS API to create a custom DB cluster parameter group. For more information, see Creating a DB cluster parameter group (p. 216).

You can now associate the custom parameter group with your DB instance.

**To create a custom DB cluster parameter group**

1. Use the `create-db-cluster-parameter-group` CLI command to create the custom parameter group for the cluster. The following example uses `aurora-postgresql13` as the source for this custom parameter group.

   For Linux, macOS, or Unix:
   
   ```bash
   aws rds create-db-cluster-parameter-group --db-cluster-parameter-group-name 'docs-lab-scram-passwords' 
   --db-parameter-group-family aurora-postgresql13 --description 'Custom DB cluster parameter group for SCRAM'
   ```

   For Windows:
   
   ```bash
   aws rds create-db-cluster-parameter-group --db-cluster-parameter-group-name "docs-lab-scram-passwords" 
   --db-parameter-group-family aurora-postgresql13 --description "Custom DB cluster parameter group for SCRAM"
   ```

   You can now associate the custom parameter group with your cluster.

2. Use the `modify-db-cluster` CLI command to apply this custom parameter group to your Aurora PostgreSQL DB cluster.

   For Linux, macOS, or Unix:
   
   ```bash
   aws rds modify-db-cluster --db-cluster-identifier 'your-instance-name' 
   --db-cluster-parameter-group-name 'docs-lab-scram-passwords'
   ```

   For Windows:
   
   ```bash
   aws rds modify-db-cluster --db-cluster-identifier "your-instance-name" 
   --db-cluster-parameter-group-name "docs-lab-scram-passwords"
   ```
Configuring password encryption to use SCRAM

The password encryption mechanism used by an Aurora PostgreSQL DB cluster is set in the DB cluster parameter group in the password_encryption parameter. Allowed values are unset, md5, or scram-sha-256. The default value depends on the Aurora PostgreSQL version, as follows:

- Aurora PostgreSQL 14 – Default is scram-sha-256
- Aurora PostgreSQL 13 – Default is md5

With a custom DB cluster parameter group attached to your Aurora PostgreSQL DB cluster, you can modify values for the password encryption parameter.

<table>
<thead>
<tr>
<th>Name</th>
<th>Values</th>
<th>Allowed values</th>
<th>Modifiable</th>
<th>Source</th>
<th>Apply type</th>
</tr>
</thead>
<tbody>
<tr>
<td>password_encryption</td>
<td>scram-sha-256</td>
<td>md5, scram-sha-256</td>
<td>true</td>
<td>system</td>
<td>dynamic</td>
</tr>
<tr>
<td>rdls accepted_password_auth_method</td>
<td>md5,scram</td>
<td>md5</td>
<td>scram, scram</td>
<td>true</td>
<td>system</td>
</tr>
</tbody>
</table>

To change password encryption setting to scram-sha-256

- Change the value of the password encryption to scram-sha-256, as shown following. The change can be applied immediately because the parameter is dynamic, so a restart isn't required for the change to take effect.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name "docs-lab-scram-passwords" --parameters "ParameterName=password_encryption,ParameterValue=scram-sha-256,ApplyMethod=immediate"
```

For Windows:

```bash
aws rds modify-db-parameter-group --db-parameter-group-name "docs-lab-scram-passwords" --parameters "ParameterName=password_encryption,ParameterValue=scram-sha-256,ApplyMethod=immediate"
```

Migrating passwords for user roles to SCRAM

You can migrate passwords for user roles to SCRAM as described following.

To migrate database user (role) passwords from MD5 to SCRAM

1. Log in as the administrator user (default user name, postgres) as shown following.

   ```bash
   psql --host=cluster-name-instance-1.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   ```

2. Check the setting of the password_encryption parameter on your RDS for PostgreSQL DB instance by using the following command.
3. Change the value of this parameter to scram-sha-256. This is a dynamic parameter, so you don't need to reboot the instance after making this change. Check the value again to make sure that it's now set to scram-sha-256, as follows.

```sql
postgres=> SHOW password_encryption;
password_encryption
--------------------
scram-sha-256
(1 row)
```

4. Notify all database users to change their passwords. Be sure to also change your own password for account postgres (the database user with rds_superuser privileges).

```
labdb=> ALTER ROLE postgres WITH LOGIN PASSWORD 'change_me';
ALTER ROLE
```

5. Repeat the process for all databases on your Aurora PostgreSQL DB cluster.

**Changing parameter to require SCRAM**

This is the final step in the process. After you make the change in the following procedure, any user accounts (roles) that still use md5 encryption for passwords can't log in to the Aurora PostgreSQL DB cluster.

The `rds.accepted_password_auth_method` specifies the encryption method that the Aurora PostgreSQL DB cluster accepts for a user password during the login process. The default value is `md5+scram`, meaning that either method is accepted. In the following image, you can find the default setting for this parameter.

<table>
<thead>
<tr>
<th>Name</th>
<th>Values</th>
<th>Allowed values</th>
<th>Modifiable</th>
<th>Source</th>
<th>Apply type</th>
</tr>
</thead>
<tbody>
<tr>
<td>password_encryption</td>
<td>scram-sha-256</td>
<td>md5, scram-sha-256</td>
<td>true</td>
<td>system</td>
<td>dynamic</td>
</tr>
<tr>
<td>rds.accepted_password_auth_method</td>
<td>md5+scram</td>
<td>md5+scram</td>
<td>true</td>
<td>system</td>
<td>dynamic</td>
</tr>
</tbody>
</table>

The allowed values for this parameter are `md5+scram` or `scram` alone. Changing this parameter value to `scram` makes this a requirement.

**To change the parameter value to require SCRAM authentication for passwords**

1. Verify that all database user passwords for all databases on your Aurora PostgreSQL DB cluster use `scram-sha-256` for password encryption. To do so, query `rds_tools` for the role (user) and encryption type, as follows.

```sql
postgres=> SELECT * FROM rds_tools.role_password_encryption_type();
rolname        | encryption_type
-----------------+-----------------
pg_monitor      |               
pg_read_all_settings |         
pg_read_all_stats  |         
pg_stat_scan_tables |         
```

1242
Securing Aurora PostgreSQL data with SSL/TLS

Amazon RDS supports Secure Socket Layer (SSL) and Transport Layer Security (TLS) encryption for Aurora PostgreSQL DB clusters. Using SSL/TLS, you can encrypt a connection between your applications and your Aurora PostgreSQL DB clusters. You can also force all connections to your Aurora PostgreSQL DB cluster to use SSL/TLS. Amazon Aurora PostgreSQL supports Transport Layer Security (TLS) versions 1.1 and 1.2. We recommend using TLS 1.2 for encrypted connections. We have added support for TLSv1.3 from the following versions of Aurora PostgreSQL:

- 15.3 and all higher versions
- 14.8 and higher 14 versions
- 13.11 and higher 13 versions
- 12.15 and higher 12 versions
- 11.20 and higher 11 versions

For general information about SSL/TLS support and PostgreSQL databases, see SSL support in the PostgreSQL documentation. For information about using an SSL/TLS connection over JDBC, see Configuring the client in the PostgreSQL documentation.

Topics

- Requiring an SSL/TLS connection to an Aurora PostgreSQL DB cluster (p. 1244)
- Determining the SSL/TLS connection status (p. 1245)
- Configuring cipher suites for connections to Aurora PostgreSQL DB clusters (p. 1245)

SSL/TLS support is available in all AWS Regions for Aurora PostgreSQL. Amazon RDS creates an SSL/TLS certificate for your Aurora PostgreSQL DB cluster when the DB cluster is created. If you enable SSL/TLS certificate verification, then the SSL/TLS certificate includes the DB cluster endpoint as the Common Name (CN) for the SSL/TLS certificate to guard against spoofing attacks.
To connect to an Aurora PostgreSQL DB cluster over SSL/TLS

1. Download the certificate.
   
   For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 2385).

2. Import the certificate into your operating system.

3. Connect to your Aurora PostgreSQL DB cluster over SSL/TLS.

   When you connect using SSL/TLS, your client can choose to verify the certificate chain or not. If your connection parameters specify `sslmode=verify-ca` or `sslmode=verify-full`, then your client requires the RDS CA certificates to be in their trust store or referenced in the connection URL. This requirement is to verify the certificate chain that signs your database certificate.

   When a client, such as psql or JDBC, is configured with SSL/TLS support, the client first tries to connect to the database with SSL/TLS by default. If the client can't connect with SSL/TLS, it reverts to connecting without SSL/TLS. By default, the `sslmode` option for JDBC and libpq-based clients is set to `prefer`.

   Use the `sslrootcert` parameter to reference the certificate, for example `sslrootcert=rds-ssl-ca-cert.pem`.

The following is an example of using psql to connect to an Aurora PostgreSQL DB cluster.

```
$ psql -h testpg.cdhmuqifdpib.us-east-1.rds.amazonaws.com -p 5432 "dbname=testpg user=testuser sslrootcert=rds-ca-2015-root.pem sslmode=verify-full"
```

Requiring an SSL/TLS connection to an Aurora PostgreSQL DB cluster

You can require that connections to your Aurora PostgreSQL DB cluster use SSL/TLS by using the `rds.force_ssl` parameter. By default, the `rds.force_ssl` parameter is set to 0 (off). You can set the `rds.force_ssl` parameter to 1 (on) to require SSL/TLS for connections to your DB cluster. Updating the `rds.force_ssl` parameter also sets the PostgreSQL `ssl` parameter to 1 (on) and modifies your DB cluster's `pg_hba.conf` file to support the new SSL/TLS configuration.

You can set the `rds.force_ssl` parameter value by updating the DB cluster parameter group for your DB cluster. If the DB cluster parameter group isn't the default one, and the `ssl` parameter is already set to 1 when you set `rds.force_ssl` to 1, you don't need to reboot your DB cluster. Otherwise, you must reboot your DB cluster for the change to take effect. For more information on parameter groups, see Working with parameter groups (p. 212).

When the `rds.force_ssl` parameter is set to 1 for a DB cluster, you see output similar to the following when you connect, indicating that SSL/TLS is now required:

```
$ psql postgres -h SOMEHOST.amazonaws.com -p 8192 -U someuser
psql (9.3.12, server 9.4.4)
Some psql features might not work.
SSL connection (cipher: DHE-RSA-AES256-SHA, bits: 256)
Type "help" for help.

postgres=>
```

1244
Determining the SSL/TLS connection status

The encrypted status of your connection is shown in the logon banner when you connect to the DB cluster.

Password for user master: 
psql (9.3.12) 
SSL connection (cipher: DHE-RSA-AES256-SHA, bits: 256) 
Type "help" for help. 

postgres=>

You can also load the sslinfo extension and then call the ssl_is_used() function to determine if SSL/TLS is being used. The function returns t if the connection is using SSL/TLS, otherwise it returns f.

postgres=> create extension sslinfo; 
CREATE EXTENSION

postgres=> select ssl_is_used(); 
ssl_is_used
---------
t
(1 row)

You can use the select ssl_cipher() command to determine the SSL/TLS cipher:

postgres=> select ssl_cipher(); 
ssl_cipher
--------------------
DHE-RSA-AES256-SHA
(1 row)

If you enable set rds.force_ssl and restart your DB cluster, non-SSL connections are refused with the following message:

$ export PGSSLMODE=disable
$ psql postgres -h SOMEHOST.amazonaws.com -p 8192 -U someuser 
psql: FATAL: no pg_hba.conf entry for host "host.ip", user "someuser", database "postgres", SSL off
$

For information about the sslmode option, see Database connection control functions in the PostgreSQL documentation.

Configuring cipher suites for connections to Aurora PostgreSQL DB clusters

By using configurable cipher suites, you can have more control over the security of your database connections. You can specify a list of cipher suites that you want to allow to secure client SSL/TLS connections to your database. With configurable cipher suites, you can control the connection encryption that your database server accepts. Doing this helps prevent the use of insecure or deprecated ciphers.

Configurable cipher suites is supported in Aurora PostgreSQL versions 11.8 and higher.
To specify the list of permissible ciphers for encrypting connections, modify the `ssl_ciphers` cluster parameter. Set the `ssl_ciphers` parameter to a string of comma-separated cipher values in a cluster parameter group using the AWS Management Console, the AWS CLI, or the RDS API. To set cluster parameters, see [Modifying parameters in a DB cluster parameter group](p. 219).

The following table shows the supported ciphers for the valid Aurora PostgreSQL engine versions.

<table>
<thead>
<tr>
<th>Aurora PostgreSQL engine versions</th>
<th>Supported ciphers</th>

• TLS_RSA_WITH_AES_128_CBC_SHA  
• TLS_RSA_WITH_AES_128_CBC_SHA256  
• TLS_RSA_WITH_AES_128_GCM_SHA256  
• TLS_RSA_WITH_AES_256_CBC_SHA  
• TLS_RSA_WITH_AES_256_CBC_SHA256  
• TLS_RSA_WITH_AES_256_GCM_SHA384  
• TLS_AES_128_GCM_SHA256  
• TLS_AES_256_GCM_SHA384 |

You can also use the `describe-engine-default-cluster-parameters` CLI command to determine which cipher suites are currently supported for a specific parameter group family. The following example shows how to get the allowed values for the `ssl_cipher` cluster parameter for Aurora PostgreSQL 11.

```bash
aws rds describe-engine-default-cluster-parameters --db-parameter-group-family aurora-postgresql11

...some output truncated...
{
  "ParameterName": "ssl_ciphers",
  "Description": "Sets the list of allowed TLS ciphers to be used on secure connections.",
  "Source": "engine-default",
  "ApplyType": "dynamic",
  "DataType": "list",
}
```
The `ssl_ciphers` parameter defaults to all allowed cipher suites. For more information about ciphers, see the `ssl_ciphers` variable in the PostgreSQL documentation.

### Updating applications to connect to Aurora PostgreSQL DB clusters using new SSL/TLS certificates

As of January 13, 2023, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your Aurora DB clusters using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB clusters. If they do, you can further check whether those applications require certificate verification to connect.

**Note**

Some applications are configured to connect to Aurora PostgreSQL DB clusters only if they can successfully verify the certificate on the server.

For such applications, you must update your client application trust stores to include the new CA certificates.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB clusters. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see [Rotating your SSL/TLS certificate](p. 2391). For more information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB cluster](p. 2385). For information about using SSL/TLS with PostgreSQL DB clusters, see [Securing Aurora PostgreSQL data with SSL/TLS](p. 1243).

**Topics**

- Determining whether applications are connecting to Aurora PostgreSQL DB clusters using SSL (p. 1250)
- Determining whether a client requires certificate verification in order to connect (p. 1250)
- Updating your application trust store (p. 1251)
- Using SSL/TLS connections for different types of applications (p. 1251)
Determining whether applications are connecting to Aurora PostgreSQL DB clusters using SSL

Check the DB cluster configuration for the value of the rds.force_ssl parameter. By default, the rds.force_ssl parameter is set to 0 (off). If the rds.force_ssl parameter is set to 1 (on), clients are required to use SSL/TLS for connections. For more information about parameter groups, see Working with parameter groups (p. 212).

If rds.force_ssl isn't set to 1 (on), query the pg_stat_ssl view to check connections using SSL. For example, the following query returns only SSL connections and information about the clients using SSL.

```
select datname, usename, ssl, client_addr from pg_stat_ssl inner join pg_stat_activity on pg_stat_ssl.pid = pg_stat_activity.pid where ssl is true and usename<>'rdsadmin';
```

Only rows using SSL/TLS connections are displayed with information about the connection. The following is sample output.

```
<table>
<thead>
<tr>
<th>datname</th>
<th>usename</th>
<th>ssl</th>
<th>client_addr</th>
</tr>
</thead>
<tbody>
<tr>
<td>benchdb</td>
<td>pgadmin</td>
<td>t</td>
<td>53.95.6.13</td>
</tr>
<tr>
<td>postgres</td>
<td>pgadmin</td>
<td>t</td>
<td>53.95.6.13</td>
</tr>
</tbody>
</table>
```

The preceding query displays only the current connections at the time of the query. The absence of results doesn't indicate that no applications are using SSL connections. Other SSL connections might be established at a different time.

Determining whether a client requires certificate verification in order to connect

When a client, such as psql or JDBC, is configured with SSL support, the client first tries to connect to the database with SSL by default. If the client can't connect with SSL, it reverts to connecting without SSL. The default sslmode mode used is different between libpq-based clients (such as psql) and JDBC. The libpq-based clients default to prefer, where JDBC clients default to verify-full. The certificate on the server is verified only when sslrootcert is provided with sslmode set to verify-ca or verify-full. An error is thrown if the certificate is invalid.

Use PGSSLROOTCERT to verify the certificate with the PGSSLMODE environment variable, with PGSSLMODE set to verify-ca or verify-full.

```
PGSSLMODE=verify-full PGSSLROOTCERT=/fullpath/ssl-cert.pem psql -h pgdbidentifier.cxxxxxxxx.us-east-2.rds.amazonaws.com -U primaryuser -d postgres
```

Use the sslrootcert argument to verify the certificate with sslmode in connection string format, with sslmode set to verify-ca or verify-full.

```
psql "host=pgdbidentifier.cxxxxxxxx.us-east-2.rds.amazonaws.com sslmode=verify-full sslrootcert=/full/path/ssl-cert.pem user=primaryuser dbname=postgres"
```

For example, in the preceding case, if you use an invalid root certificate, you see an error similar to the following on your client.

```
psql: SSL error: certificate verify failed
```
Updating your application trust store

For information about updating the trust store for PostgreSQL applications, see Secure TCP/IP connections with SSL in the PostgreSQL documentation.

**Note**
When you update the trust store, you can retain older certificates in addition to adding the new certificates.

Updating your application trust store for JDBC

You can update the trust store for applications that use JDBC for SSL/TLS connections.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 2385).

For sample scripts that import certificates, see Sample script for importing certificates into your trust store (p. 2397).

Using SSL/TLS connections for different types of applications

The following provides information about using SSL/TLS connections for different types of applications:

- **psql**

  The client is invoked from the command line by specifying options either as a connection string or as environment variables. For SSL/TLS connections, the relevant options are `sslmode` (environment variable `PGSSLMODE`), `sslrootcert` (environment variable `PGSSLROOTCERT`).

  For the complete list of options, see Parameter key words in the PostgreSQL documentation. For the complete list of environment variables, see Environment variables in the PostgreSQL documentation.

- **pgAdmin**

  This browser-based client is a more user-friendly interface for connecting to a PostgreSQL database.

  For information about configuring connections, see the pgAdmin documentation.

- **JDBC**

  JDBC enables database connections with Java applications.

  For general information about connecting to a PostgreSQL database with JDBC, see Connecting to the database in the PostgreSQL documentation. For information about connecting with SSL/TLS, see Configuring the client in the PostgreSQL documentation.

- **Python**

  A popular Python library for connecting to PostgreSQL databases is psycopg2.

  For information about using psycopg2, see the psycopg2 documentation. For a short tutorial on how to connect to a PostgreSQL database, see Psycopg2 tutorial. You can find information about the options the connect command accepts in The psycopg2 module content.

**Important**
After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-rsa2048-g1...
certificates. For instructions, see step 3 in Updating your CA certificate by modifying your DB instance (p. 2391).

Using Kerberos authentication with Aurora PostgreSQL

You can use Kerberos to authenticate users when they connect to your DB cluster running PostgreSQL. To do so, configure your DB cluster to use AWS Directory Service for Microsoft Active Directory for Kerberos authentication. AWS Directory Service for Microsoft Active Directory is also called AWS Managed Microsoft AD. It's a feature available with AWS Directory Service. To learn more, see What is AWS Directory Service? in the AWS Directory Service Administration Guide.

To start, create an AWS Managed Microsoft AD directory to store user credentials. Then, provide to your PostgreSQL DB cluster the Active Directory's domain and other information. When users authenticate with the PostgreSQL DB cluster, authentication requests are forwarded to the AWS Managed Microsoft AD directory.

Keeping all of your credentials in the same directory can save you time and effort. You have a centralized location for storing and managing credentials for multiple DB clusters. Using a directory can also improve your overall security profile.

In addition, you can access credentials from your own on-premises Microsoft Active Directory. To do so, create a trusting domain relationship so that the AWS Managed Microsoft AD directory trusts your on-premises Microsoft Active Directory. In this way, your users can access your PostgreSQL clusters with the same Windows single sign-on (SSO) experience as when they access workloads in your on-premises network.

A database can use Kerberos, AWS Identity and Access Management (IAM), or both Kerberos and IAM authentication. However, because Kerberos and IAM authentication provide different authentication methods, a specific database user can log in to a database using only one or the other authentication method but not both. For more information about IAM authentication, see IAM database authentication (p. 2432).

Topics

- Region and version availability (p. 1252)
- Overview of Kerberos authentication for PostgreSQL DB clusters (p. 1252)
- Setting up Kerberos authentication for PostgreSQL DB clusters (p. 1253)
- Managing a DB cluster in a Domain (p. 1263)
- Connecting to PostgreSQL with Kerberos authentication (p. 1264)

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of Aurora PostgreSQL with Kerberos authentication, see Kerberos authentication with Aurora PostgreSQL (p. 38).

Overview of Kerberos authentication for PostgreSQL DB clusters

To set up Kerberos authentication for a PostgreSQL DB cluster, take the following steps, described in more detail later:
1. Use AWS Managed Microsoft AD to create an AWS Managed Microsoft AD directory. You can use the AWS Management Console, the AWS CLI, or the AWS Directory Service API to create the directory. Make sure to open the relevant outbound ports on the directory security group so that the directory can communicate with the cluster.

2. Create a role that provides Amazon Aurora access to make calls to your AWS Managed Microsoft AD directory. To do so, create an AWS Identity and Access Management (IAM) role that uses the managed IAM policy AmazonRDSDirectoryServiceAccess.

   For the IAM role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the correct AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Activating and deactivating AWS STS in an AWS Region in the IAM User Guide.

3. Create and configure users in the AWS Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users in your Active Directory, see Manage users and groups in AWS Managed Microsoft AD in the AWS Directory Service Administration Guide.

4. If you plan to locate the directory and the DB instance in different AWS accounts or virtual private clouds (VPCs), configure VPC peering. For more information, see What is VPC peering? in the Amazon VPC Peering Guide.

5. Create or modify a PostgreSQL DB cluster either from the console, CLI, or RDS API using one of the following methods:
   - Creating and connecting to an Aurora PostgreSQL DB cluster (p. 137)
   - Modifying an Amazon Aurora DB cluster (p. 269)
   - Restoring from a DB cluster snapshot (p. 439)
   - Restoring a DB cluster to a specified time (p. 490)

   You can locate the cluster in the same Amazon Virtual Private Cloud (VPC) as the directory or in a different AWS account or VPC. When you create or modify the PostgreSQL DB cluster, do the following:
   - Provide the domain identifier (d-* identifier) that was generated when you created your directory.
   - Provide the name of the IAM role that you created.
   - Ensure that the DB instance security group can receive inbound traffic from the directory security group.

6. Use the RDS master user credentials to connect to the PostgreSQL DB cluster. Create the user in PostgreSQL to be identified externally. Externally identified users can log in to the PostgreSQL DB cluster using Kerberos authentication.

## Setting up Kerberos authentication for PostgreSQL DB clusters

You use AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to set up Kerberos authentication for a PostgreSQL DB cluster. To set up Kerberos authentication, take the following steps.

### Topics
- Step 1: Create a directory using AWS Managed Microsoft AD (p. 1254)
- Step 2: (Optional) Create a trust relationship between your on-premises Active Directory and AWS Directory Service (p. 1257)
- Step 3: Create an IAM role for Amazon Aurora to access the AWS Directory Service (p. 1258)
- Step 4: Create and configure users (p. 1259)
- Step 5: Enable cross-VPC traffic between the directory and the DB instance (p. 1259)
Step 1: Create a directory using AWS Managed Microsoft AD

AWS Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and DNS servers for you. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

- Sets up an Active Directory within your VPC.
- Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.
  
  **Important**
  
  Make sure to save this password. AWS Directory Service doesn't store this password, and it can't be retrieved or reset.

- Creates a security group for the directory controllers. The security group must permit communication with the PostgreSQL DB cluster.

When you launch AWS Directory Service for Microsoft Active Directory, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU, which has the NetBIOS name that you entered when you created your directory, is located in the domain root. The domain root is owned and managed by AWS.

The Admin account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
- Create additional OUs and containers
- Delegate authority
- Restore deleted objects from the Active Directory Recycle Bin
- Run Active Directory and Domain Name Service (DNS) modules for Windows PowerShell on the Active Directory Web Service

The Admin account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders)
- View DNS event logs
- View security event logs

**To create a directory with AWS Managed Microsoft AD**

1. In the AWS Directory Service console navigation pane, choose **Directories**, and then choose **Set up directory**.
2. Choose **AWS Managed Microsoft AD**. AWS Managed Microsoft AD is the only option currently supported for use with Amazon Aurora.

3. Choose **Next**.

4. On the **Enter directory information** page, provide the following information:

   **Edition**
   
   Choose the edition that meets your requirements.

   **Directory DNS name**
   
   The fully qualified name for the directory, such as `corp.example.com`.

   **Directory NetBIOS name**
   
   An optional short name for the directory, such as CORP.

   **Directory description**
   
   An optional description for the directory.

   **Admin password**
   
   The password for the directory administrator. The directory creation process creates an administrator account with the user name `Admin` and this password.

   The directory administrator password can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:
   - Lowercase letters (a–z)
   - Uppercase letters (A–Z)
   - Numbers (0–9)
   - Nonalphanumeric characters (~!@#$%^&*_-+=`\|(){}[]:;"'<>,.?/)

   **Confirm password**
   
   Retype the administrator password.

   **Important**
   
   Make sure that you save this password. AWS Directory Service doesn't store this password, and it can't be retrieved or reset.

5. Choose **Next**.

6. On the **Choose VPC and subnets** page, provide the following information:

   **VPC**
   
   Choose the VPC for the directory. You can create the PostgreSQL DB cluster in this same VPC or in a different VPC.

   **Subnets**
   
   Choose the subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Choose **Next**.

8. Review the directory information. If changes are needed, choose **Previous** and make the changes. When the information is correct, choose **Create directory**.
It takes several minutes for the directory to be created. When it has been successfully created, the Status value changes to Active.

To see information about your directory, choose the directory ID in the directory listing. Make a note of the Directory ID value. You need this value when you create or modify your PostgreSQL DB instance.
Step 2: (Optional) Create a trust relationship between your on-premises Active Directory and AWS Directory Service

If you don’t plan to use your own on-premises Microsoft Active Directory, skip to Step 3: Create an IAM role for Amazon Aurora to access the AWS Directory Service (p. 1258).

To get Kerberos authentication using your on-premises Active Directory, you need to create a trusting domain relationship using a forest trust between your on-premises Microsoft Active Directory and the AWS Managed Microsoft AD directory (created in Step 1: Create a directory using AWS Managed Microsoft AD (p. 1254)). The trust can be one-way, where the AWS Managed Microsoft AD directory trusts the on-premises Microsoft Active Directory. The trust can also be two-way, where both Active Directories trust each other. For more information about setting up trusts using AWS Directory Service, see When to create a trust relationship in the AWS Directory Service Administration Guide.

Note
If you use an on-premises Microsoft Active Directory:

- Windows clients must connect using the domain name of the AWS Directory Service in the endpoint rather than rds.amazonaws.com. For more information, see Connecting to PostgreSQL with Kerberos authentication (p. 1264).
• Windows clients can't connect using Aurora custom endpoints. To learn more, see Amazon Aurora connection management (p. 62).

• For global databases (p. 1800):
  • Windows clients can connect using instance endpoints or cluster endpoints in the primary AWS Region of the global database only.
  • Windows clients can't connect using cluster endpoints in secondary AWS Regions.

Make sure that your on-premises Microsoft Active Directory domain name includes a DNS suffix routing that corresponds to the newly created trust relationship. The following screenshot shows an example.

Step 3: Create an IAM role for Amazon Aurora to access the AWS Directory Service

For Amazon Aurora to call AWS Directory Service for you, your AWS account needs an IAM role that uses the managed IAM policy AmazonRDSDirectoryServiceAccess. This role allows Amazon Aurora to make calls to AWS Directory Service. (Note that this IAM role to access the AWS Directory Service is different than the IAM role used for IAM database authentication (p. 2432).)

When you create a DB instance using the AWS Management Console and your console user account has the `iam:CreateRole` permission, the console creates the needed IAM role automatically. In this case, the role name is `rds-directoryservice-kerberos-access-role`. Otherwise, you must create the IAM role manually. When you create this IAM role, choose Directory Service, and attach the AWS managed policy `AmazonRDSDirectoryServiceAccess` to it.

For more information about creating IAM roles for a service, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

Note
The IAM role used for Windows Authentication for RDS for Microsoft SQL Server can't be used for Amazon Aurora.

As an alternative to using the AmazonRDSDirectoryServiceAccess managed policy, you can create policies with the required permissions. In this case, the IAM role must have the following IAM trust policy.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
```
"Service": [
    "directoryservice.rds.amazonaws.com",
    "rds.amazonaws.com"
],

"Action": "sts:AssumeRole"
}

The role must also have the following IAM role policy.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "ds:DescribeDirectories",
                "ds:AuthorizeApplication",
                "ds:UnauthorizeApplication",
                "ds:GetAuthorizedApplicationDetails"
            ],
            "Effect": "Allow",
            "Resource": "*"
        }
    ]
}
```

**Step 4: Create and configure users**

You can create users by using the Active Directory Users and Computers tool. This is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. For more information, see Add Users and Computers to the Active Directory domain in the Microsoft documentation. In this case, users are individuals or other entities, such as their computers that are part of the domain and whose identities are being maintained in the directory.

To create users in an AWS Directory Service directory, you must be connected to a Windows-based Amazon EC2 instance that's a member of the AWS Directory Service directory. At the same time, you must be logged in as a user that has privileges to create users. For more information, see Create a user in the AWS Directory Service Administration Guide.

**Step 5: Enable cross-VPC traffic between the directory and the DB instance**

If you plan to locate the directory and the DB cluster in the same VPC, skip this step and move on to Step 6: Create or modify a PostgreSQL DB cluster (p. 1260).

If you plan to locate the directory and the DB instance in different VPCs, configure cross-VPC traffic using VPC peering or AWS Transit Gateway.

The following procedure enables traffic between VPCs using VPC peering. Follow the instructions in What is VPC peering? in the Amazon Virtual Private Cloud Peering Guide.

To enable cross-VPC traffic using VPC peering

1. Set up appropriate VPC routing rules to ensure that network traffic can flow both ways.
2. Ensure that the DB instance security group can receive inbound traffic from the directory security group.
3. Ensure that there is no network access control list (ACL) rule to block traffic.
Setting up

If a different AWS account owns the directory, you must share the directory.

To share the directory between AWS accounts

1. Start sharing the directory with the AWS account that the DB instance will be created in by following the instructions in Tutorial: Sharing your AWS Managed Microsoft AD directory for seamless EC2 Domain-join in the AWS Directory Service Administration Guide.
2. Sign in to the AWS Directory Service console using the account for the DB instance, and ensure that the domain has the SHARED status before proceeding.
3. While signed into the AWS Directory Service console using the account for the DB instance, note the Directory ID value. You use this directory ID to join the DB instance to the domain.

Step 6: Create or modify a PostgreSQL DB cluster

Create or modify a PostgreSQL DB cluster for use with your directory. You can use the console, CLI, or RDS API to associate a DB cluster with a directory. You can do this in one of the following ways:

- Create a new PostgreSQL DB cluster using the console, the create-db-cluster CLI command, or the CreateDBCluster RDS API operation. For instructions, see Creating and connecting to an Aurora PostgreSQL DB cluster (p. 137).
- Modify an existing PostgreSQL DB cluster using the console, the modify-db-cluster CLI command, or the ModifyDBCluster RDS API operation. For instructions, see Modifying an Amazon Aurora DB cluster (p. 269).
- Restore a PostgreSQL DB cluster from a DB snapshot using the console, the restore-db-cluster-from-db-snapshot CLI command, or the RestoreDBClusterFromDBSnapshot RDS API operation. For instructions, see Restoring from a DB cluster snapshot (p. 439).
- Restore a PostgreSQL DB cluster to a point-in-time using the console, the restore-db-instance-to-point-in-time CLI command, or the RestoreDBClusterToPointInTime RDS API operation. For instructions, see Restoring a DB cluster to a specified time (p. 490).

Kerberos authentication is only supported for PostgreSQL DB clusters in a VPC. The DB cluster can be in the same VPC as the directory, or in a different VPC. The DB cluster must use a security group that allows ingress and egress within the directory's VPC so the DB cluster can communicate with the directory.

Console

When you use the console to create, modify, or restore a DB cluster, choose Kerberos authentication in the Database authentication section. Then choose Browse Directory. Select the directory or choose Create a new directory to use the Directory Service.
AWS CLI

When you use the AWS CLI, the following parameters are required for the DB cluster to be able to use the directory that you created:

- For the **--domain** parameter, use the domain identifier ("d-*" identifier) generated when you created the directory.
- For the **--domain-iam-role-name** parameter, use the role you created that uses the managed IAM policy AmazonRDSDirectoryServiceAccess.

For example, the following CLI command modifies a DB cluster to use a directory.

```
aws rds  modify-db-cluster --db-cluster-identifier mydbinstance --domain d-Directory-ID --domain-iam-role-name role-name
```

**Important**

If you modify a DB cluster to enable Kerberos authentication, reboot the DB cluster after making the change.

**Step 7: Create PostgreSQL users for your Kerberos principals**

At this point, your Aurora PostgreSQL DB cluster is joined to the AWS Managed Microsoft AD domain. The users that you created in the directory in [Step 4: Create and configure users](p. 1259) need to be set up as PostgreSQL database users and granted privileges to login to the database. You do that by signing in as the database user with `rds_superuser` privileges. For example, if you accepted the defaults when you created your Aurora PostgreSQL DB cluster, you use `postgres`, as shown in the following steps.

**To create PostgreSQL database users for Kerberos principals**

1. Use `psql` to connect to your Aurora PostgreSQL DB cluster's DB instance endpoint using `psql`. The following example uses the default `postgres` account for the `rds_superuser` role.

   ```
   psql --host=cluster-instance-1.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   ```

2. Create a database user name for each Kerberos principal (Active Directory username) that you want to have access to the database. Use the canonical username (identity) as defined in the Active Directory instance, that is, a lower-case alias (username in Active Directory) and the upper-case name of the Active Directory domain for that user name. The Active Directory user name is an externally authenticated user, so use quotes around the name as shown following.

   ```
   postgres=> CREATE USER "username@CORP.EXAMPLE.COM" WITH LOGIN;
   CREATE ROLE
   ```

3. Grant the `rds_ad` role to the database user.

   ```
   postgres=> GRANT rds_ad TO "username@CORP.EXAMPLE.COM";
   GRANT ROLE
   ```

After you finish creating all the PostgreSQL users for your Active Directory user identities, users can access the Aurora PostgreSQL DB cluster by using their Kerberos credentials.

It's assumed that the database users who authenticate using Kerberos are doing so from client machines that are members of the Active Directory domain.
Database users that have been granted the rds_ad role can't also have the rds_iam role. This also applies to nested memberships. For more information, see IAM database authentication (p. 2432).

Configuring your Aurora PostgreSQL DB cluster for case-insensitive user names

Aurora PostgreSQL versions 14.5, 13.8, 12.12, and 11.17 support the krb_caseins_users PostgreSQL parameter. This parameter supports case-insensitive Active Directory user names. By default, this parameter is set to false, so user names are interpreted case-sensitively by Aurora PostgreSQL. That's the default behavior in all older versions of Aurora PostgreSQL. However, you can set this parameter to true in your custom DB cluster parameter group and allow your Aurora PostgreSQL DB cluster to interpret user names, case-insensitively. Consider doing this as a convenience for your database users, who might sometimes mis-type the casing of their user name when authenticating using Active Directory.

To change the krb_caseins_users parameter, your Aurora PostgreSQL DB cluster must be using a custom DB cluster parameter group. For information about working with a custom DB cluster parameter group, see Working with parameter groups (p. 212).

You can use the AWS CLI or the AWS Management Console to change the setting. For more information, see Modifying parameters in a DB cluster parameter group (p. 219).

Step 8: Configure a PostgreSQL client

To configure a PostgreSQL client, take the following steps:

- Create a krb5.conf file (or equivalent) to point to the domain.
- Verify that traffic can flow between the client host and AWS Directory Service. Use a network utility such as Netcat for the following:
  - Verify traffic over DNS for port 53.
  - Verify traffic over TCP/UDP for port 53 and for Kerberos, which includes ports 88 and 464 for AWS Directory Service.
  - Verify that traffic can flow between the client host and the DB instance over the database port. For example, use psql to connect and access the database.

The following is sample krb5.conf content for AWS Managed Microsoft AD.

```
[libdefaults]
default_realm = EXAMPLE.COM
[realms]
EXAMPLE.COM = {
  kdc = example.com
  admin_server = example.com
}
[domain_realm]
.example.com = EXAMPLE.COM
example.com = EXAMPLE.COM
```

The following is sample krb5.conf content for an on-premises Microsoft Active Directory.

```
[libdefaults]
default_realm = EXAMPLE.COM
[realms]
EXAMPLE.COM = {
  kdc = example.com
  admin_server = example.com
}
ONPREM.COM = {
```

1262
Managing a DB cluster in a Domain

You can use the console, the CLI, or the RDS API to manage your DB cluster and its relationship with your Microsoft Active Directory. For example, you can associate an Active Directory to enable Kerberos authentication. You can also remove the association for an Active Directory to disable Kerberos authentication. You can also move a DB cluster to be externally authenticated by one Microsoft Active Directory to another.

For example, using the CLI, you can do the following:

- To reattempt enabling Kerberos authentication for a failed membership, use the `modify-db-cluster` CLI command. Specify the current membership's directory ID for the `--domain` option.
- To disable Kerberos authentication on a DB instance, use the `modify-db-cluster` CLI command. Specify `none` for the `--domain` option.
- To move a DB instance from one domain to another, use the `modify-db-cluster` CLI command. Specify the domain identifier of the new domain for the `--domain` option.

Understanding Domain membership

After you create or modify your DB cluster, the DB instances become members of the domain. You can view the status of the domain membership in the console or by running the `describe-db-instances` CLI command. The status of the DB instance can be one of the following:

- `kerberos-enabled` – The DB instance has Kerberos authentication enabled.
- `enabling-kerberos` – AWS is in the process of enabling Kerberos authentication on this DB instance.
- `pending-enable-kerberos` – Enabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-enable-kerberos` – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `pending-disable-kerberos` – Disabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-disable-kerberos` – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `enable-kerberos-failed` – A configuration problem prevented AWS from enabling Kerberos authentication on the DB instance. Correct the configuration problem before reissuing the command to modify the DB instance.
- `disabling-kerberos` – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. In some cases, the attempt to enable Kerberos authentication might fail when you create or modify a DB cluster. If so, make sure that you are using the correct IAM role, then modify the DB cluster to join the domain.
Connecting to PostgreSQL with Kerberos authentication

You can connect to PostgreSQL with Kerberos authentication with the pgAdmin interface or with a command-line interface such as psql. For more information about connecting, see Connecting to an Amazon Aurora PostgreSQL DB cluster (p. 209). For information about obtaining the endpoint, port number, and other details needed for connection, see Viewing the endpoints for an Aurora cluster (p. 64).

pgAdmin

To use pgAdmin to connect to PostgreSQL with Kerberos authentication, take the following steps:

1. Launch the pgAdmin application on your client computer.
3. In the Create - Server dialog box, enter a name on the General tab to identify the server in pgAdmin.
4. On the Connection tab, enter the following information from your Aurora PostgreSQL database.
   - For Host, enter the endpoint for the Writer instance of your Aurora PostgreSQL DB cluster. An endpoint looks similar to the following:
     
     AUR-cluster-instance.111122223333.aws-region.rds.amazonaws.com

     To connect to an on-premises Microsoft Active Directory from a Windows client, you use the domain name of the AWS Managed Active Directory instead of rds.amazonaws.com in the host endpoint. For example, suppose that the domain name for the AWS Managed Active Directory is corp.example.com. Then for Host, the endpoint would be specified as follows:

     AUR-cluster-instance.111122223333.aws-region.corp.example.com

     - For Port, enter the assigned port.
     - For Maintenance database, enter the name of the initial database to which the client will connect.
     - For Username, enter the user name that you entered for Kerberos authentication in Step 7: Create PostgreSQL users for your Kerberos principals (p. 1261).
5. Choose Save.

psql

To use psql to connect to PostgreSQL with Kerberos authentication, take the following steps:

1. At a command prompt, run the following command.

   
kinit username

   Replace username with the user name. At the prompt, enter the password stored in the Microsoft Active Directory for the user.

2. If the PostgreSQL DB cluster is using a publicly accessible VPC, put IP address for your DB cluster endpoint in your /etc/hosts file on the EC2 client. For example, the following commands obtain the IP address and then put it in the /etc/hosts file.

   % dig +short PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com
   ;; Truncated, retrying in TCP mode.
   ec2-34-210-197-118.AWS-Region.compute.amazonaws.com.
   34.210.197.118

1264
If you're using an on-premises Microsoft Active Directory from a Windows client, then you need to connect using a specialized endpoint. Instead of using the Amazon domain rds.amazonaws.com in the host endpoint, use the domain name of the AWS Managed Active Directory.

For example, suppose that the domain name for your AWS Managed Active Directory is corp.example.com. Then use the format PostgreSQL-endpoint.AWS-Region.corp.example.com for the endpoint and put it in the /etc/hosts file.

```
% echo " 34.210.197.118 PostgreSQL-endpoint.AWS-Region.corp.example.com" >> /etc/hosts
```

3. Use the following psql command to log in to a PostgreSQL DB cluster that is integrated with Active Directory. Use a cluster or instance endpoint.

```
psql -U username@CORP.EXAMPLE.COM -p 5432 -h PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com postgres
```

To log in to the PostgreSQL DB cluster from a Windows client using an on-premises Active Directory, use the following psql command with the domain name from the previous step (corp.example.com):

```
psql -U username@CORP.EXAMPLE.COM -p 5432 -h PostgreSQL-endpoint.AWS-Region.corp.example.com postgres
```

### Migrating data to Amazon Aurora with PostgreSQL compatibility

You have several options for migrating data from your existing database to an Amazon Aurora PostgreSQL-Compatible Edition DB cluster. Your migration options also depend on the database that you are migrating from and the size of the data that you are migrating. Following are your options:

**Migrating an RDS for PostgreSQL DB instance using a snapshot (p. 1266)**

You can migrate data directly from an RDS for PostgreSQL DB snapshot to an Aurora PostgreSQL DB cluster.

**Migrating an RDS for PostgreSQL DB instance using an Aurora read replica (p. 1270)**

You can also migrate from an RDS for PostgreSQL DB instance by creating an Aurora PostgreSQL read replica of an RDS for PostgreSQL DB instance. When the replica lag between the RDS for PostgreSQL DB instance and the Aurora PostgreSQL read replica is zero, you can stop replication. At this point, you can make the Aurora read replica a standalone Aurora PostgreSQL DB cluster for reading and writing.

**Importing data from Amazon S3 into Aurora PostgreSQL (p. 1514)**

You can migrate data by importing it from Amazon S3 into a table belonging to an Aurora PostgreSQL DB cluster.

**Migrating from a database that is not PostgreSQL-compatible**

You can use AWS Database Migration Service (AWS DMS) to migrate data from a database that is not PostgreSQL-compatible. For more information on AWS DMS, see What is AWS Database Migration Service? in the AWS Database Migration Service User Guide.
Migrating a snapshot of an RDS for PostgreSQL DB instance to an Aurora PostgreSQL DB cluster

To create an Aurora PostgreSQL DB cluster, you can migrate a DB snapshot of an RDS for PostgreSQL DB instance. The new Aurora PostgreSQL DB cluster is populated with the data from the original RDS for PostgreSQL DB instance. For information about creating a DB snapshot, see Creating a DB snapshot.

In some cases, the DB snapshot might not be in the AWS Region where you want to locate your data. If so, use the Amazon RDS console to copy the DB snapshot to that AWS Region. For information about copying a DB snapshot, see Copying a DB snapshot.

You can migrate RDS for PostgreSQL snapshots that are compatible with the Aurora PostgreSQL versions available in the given AWS Region. For example, you can migrate a snapshot from an RDS for PostgreSQL 11.1 DB instance to Aurora PostgreSQL version 11.4, 11.7, 11.8, or 11.9 in the US West (N. California) Region. You can migrate RDS for PostgreSQL 10.11 snapshot to Aurora PostgreSQL 10.11, 10.12, 10.13, and 10.14. In other words, the RDS for PostgreSQL snapshot must use the same or a lower minor version as the Aurora PostgreSQL.

You can also choose for your new Aurora PostgreSQL DB cluster to be encrypted at rest by using an AWS KMS key. This option is available only for unencrypted DB snapshots.

To migrate an RDS for PostgreSQL DB snapshot to an Aurora PostgreSQL DB cluster, you can use the AWS Management Console, the AWS CLI, or the RDS API. When you use the AWS Management Console, the console takes the actions necessary to create both the DB cluster and the primary instance.

**Console**

**To migrate a PostgreSQL DB snapshot by using the RDS console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Snapshots.
3. On the Snapshots page, choose the RDS for PostgreSQL snapshot that you want to migrate into an Aurora PostgreSQL DB cluster.
4. Choose Actions then choose Migrate snapshot.
5. Set the following values on the Migrate database page:

   - **DB engine version**: Choose a DB engine version you want to use for the new migrated instance.
   - **DB instance identifier**: Enter a name for the DB cluster that is unique for your account in the AWS Region that you chose. This identifier is used in the endpoint addresses for the instances in your DB cluster. You might choose to add some intelligence to the name, such as including the AWS Region and DB engine that you chose, for example aurora-cluster1.

The DB instance identifier has the following constraints:
• It must contain 1–63 alphanumeric characters or hyphens.
• Its first character must be a letter.
• It can't end with a hyphen or contain two consecutive hyphens.
• It must be unique for all DB instances per AWS account, per AWS Region.

• **DB instance class:** Choose a DB instance class that has the required storage and capacity for your database, for example \texttt{db.r6g.large}. Aurora cluster volumes automatically grow as the amount of data in your database increases. So you only need to choose a DB instance class that meets your current storage requirements. For more information, see Overview of Amazon Aurora storage (p. 97).

• **Virtual private cloud (VPC):** If you have an existing VPC, then you can use that VPC with your Aurora PostgreSQL DB cluster by choosing your VPC identifier, for example \texttt{vpc-a464d1c1}. For information about creating a VPC, see Tutorial: Create a VPC for use with a DB cluster (IPv4 only) (p. 2494). Otherwise, you can choose to have Amazon RDS create a VPC for you by choosing Create new VPC.

• **DB subnet group:** If you have an existing subnet group, then you can use that subnet group with your Aurora PostgreSQL DB cluster by choosing your subnet group identifier, for example \texttt{gs-subnet-group1}.

• **Public access:** Choose No to specify that instances in your DB cluster can only be accessed by resources inside of your VPC. Choose Yes to specify that instances in your DB cluster can be accessed by resources on the public network.

  **Note**
Your production DB cluster might not need to be in a public subnet, because only your application servers require access to your DB cluster. If your DB cluster doesn't need to be in a public subnet, set Public access to No.

• **VPC security group:** Choose a VPC security group to allow access to your database.

• **Availability Zone:** Choose the Availability Zone to host the primary instance for your Aurora PostgreSQL DB cluster. To have Amazon RDS choose an Availability Zone for you, choose No preference.

• **Database port:** Enter the default port to be used when connecting to instances in the Aurora PostgreSQL DB cluster. The default is 5432.

  **Note**
You might be behind a corporate firewall that doesn't allow access to default ports such as the PostgreSQL default port, 5432. In this case, provide a port value that your corporate firewall allows. Remember that port value later when you connect to the Aurora PostgreSQL DB cluster.

• **Enable Encryption:** Choose Enable Encryption for your new Aurora PostgreSQL DB cluster to be encrypted at rest. Also choose a KMS key as the AWS KMS key value.

• **Auto minor version upgrade:** Choose Enable auto minor version upgrade to enable your Aurora PostgreSQL DB cluster to receive minor PostgreSQL DB engine version upgrades automatically when they become available.

The **Auto minor version upgrade** option only applies to upgrades to PostgreSQL minor engine versions for your Aurora PostgreSQL DB cluster. It doesn't apply to regular patches applied to maintain system stability.

6. Choose **Migrate** to migrate your DB snapshot.

7. Choose **Databases** to see the new DB cluster. Choose the new DB cluster to monitor the progress of the migration. When the migration completes, the Status for the cluster is Available. On the Connectivity & security tab, you can find the cluster endpoint to use for connecting to the primary writer instance of the DB cluster. For more information on connecting to an Aurora PostgreSQL DB cluster, see Connecting to an Amazon Aurora DB cluster (p. 204).
AWS CLI

Using the AWS CLI to migrate an RDS for PostgreSQL DB snapshot to an Aurora PostgreSQL involves two separate AWS CLI commands. First, you use the `restore-db-cluster-from-snapshot` AWS CLI command to create a new Aurora PostgreSQL DB cluster. You then use the `create-db-instance` command to create the primary DB instance in the new cluster to complete the migration. The following procedure creates an Aurora PostgreSQL DB cluster with a primary DB instance that has the same configuration as the DB instance used to create the snapshot.

**To migrate an RDS for PostgreSQL DB snapshot to an Aurora PostgreSQL DB cluster**

1. Use the `describe-db-snapshots` command to obtain information about the DB snapshot you want to migrate. You can specify either the `--db-instance-identifier` parameter or the `--db-snapshot-identifier` in the command. If you don't specify one of these parameters, you get all snapshots.

```bash
aws rds describe-db-snapshots --db-instance-identifier <your-db-instance-name>
```

2. The command returns all configuration details for any snapshots created from the DB instance specified. In the output, find the snapshot that you want to migrate and locate its Amazon Resource Name (ARN). To learn more about Amazon RDS ARNs, see Amazon Relational Database Service (Amazon RDS). An ARN looks similar to the output following.

```
"DBSnapshotArn": "arn:aws:rds:aws-region:111122223333:snapshot:<snapshot_name>"
```

Also in the output you can find configuration details for the RDS for PostgreSQL DB instance, such as the engine version, allocated storage, whether or not the DB instance is encrypted, and so on.

3. Use the `restore-db-cluster-from-snapshot` command to start the migration. Specify the following parameters:

   - `--db-cluster-identifier` – The name that you want to give to the Aurora PostgreSQL DB cluster. This Aurora DB cluster is the target for your DB snapshot migration.
   - `--snapshot-identifier` – The Amazon Resource Name (ARN) of the DB snapshot to migrate.
   - `--engine` – Specify `aurora-postgresql` for the Aurora DB cluster engine.
   - `--kms-key-id` – This optional parameter lets you create an encrypted Aurora PostgreSQL DB cluster from an unencrypted DB snapshot. It also lets you choose a different encryption key for the DB cluster than the key used for the DB snapshot.

   **Note**
   You can't create an unencrypted Aurora PostgreSQL DB cluster from an encrypted DB snapshot.

   Without the `--kms-key-id` parameter specified as shown following, the `restore-db-cluster-from-snapshot` AWS CLI command creates an empty Aurora PostgreSQL DB cluster that's either encrypted using the same key as the DB snapshot or is unencrypted if the source DB snapshot isn't encrypted.

   For Linux, macOS, or Unix:

   ```bash
   aws rds restore-db-cluster-from-snapshot \
   --db-cluster-identifier cluster-name \
   --snapshot-identifier arn:aws:rds:aws-region:111122223333:snapshot:<snapshot_name> \
   --engine aurora-postgresql
   ```

   For Windows:

   ```bash
   ```

1268
aws rds restore-db-cluster-from-snapshot ^
  --db-cluster-identifier new_cluster ^
  --engine aurora-postgresql

4. The command returns details about the Aurora PostgreSQL DB cluster that's being created for the migration. You can check the status of the Aurora PostgreSQL DB cluster by using the `describe-db-clusters` AWS CLI command.

aws rds describe-db-clusters --db-cluster-identifier cluster-name

5. When the DB cluster becomes "available", you use `create-db-instance` command to populate the Aurora PostgreSQL DB cluster with the DB instance based on your Amazon RDS DB snapshot. Specify the following parameters:

- `--db-cluster-identifier` – The name of the new Aurora PostgreSQL DB cluster that you created in the previous step.
- `--db-instance-identifier` – The name you want to give to the DB instance. This instance becomes the primary node in your Aurora PostgreSQL DB cluster.
- `--db-instance-class` – Specify the DB instance class to use. Choose from among the DB instance classes supported by the Aurora PostgreSQL version to which you're migrating. For more information, see [DB instance class types](p. 84) and [Supported DB engines for DB instance classes](p. 86).
- `--engine` – Specify `aurora-postgresql` for the DB instance.

You can also create the DB instance with a different configuration than the source DB snapshot, by passing in the appropriate options in the `create-db-instance` AWS CLI command. For more information, see the `create-db-instance` command.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \ 
  --db-cluster-identifier cluster-name \ 
  --db-instance-identifier --db-instance-class db.instance.class \ 
  --engine aurora-postgresql
```

For Windows:

```
aws rds create-db-instance ^
  --db-cluster-identifier cluster-name ^
  --db-instance-identifier --db-instance-class db.instance.class ^
  --engine aurora-postgresql
```

When the migration process completes, the Aurora PostgreSQL cluster has a populated primary DB instance.
Migrating from an RDS for PostgreSQL DB instance to an Aurora PostgreSQL DB cluster using an Aurora read replica

You can use an RDS for PostgreSQL DB instance as the basis for a new Aurora PostgreSQL DB cluster by using an Aurora read replica for the migration process. The Aurora read replica option is available only for migrating within the same AWS Region and account, and it's available only if the Region offers a compatible version of Aurora PostgreSQL for your RDS for PostgreSQL DB instance. By *compatible*, we mean that the Aurora PostgreSQL version is the same as the RDS for PostgreSQL version, or that it is a higher minor version in the same major version family.

For example, to use this technique to migrate an RDS for PostgreSQL 11.14 DB instance, the Region must offer Aurora PostgreSQL version 11.14 or a higher minor version in the PostgreSQL version 11 family.

Topics
- Overview of migrating data by using an Aurora read replica (p. 1270)
- Preparing to migrate data by using an Aurora read replica (p. 1270)
- Creating an Aurora read replica (p. 1271)
- Promoting an Aurora read replica (p. 1277)

Overview of migrating data by using an Aurora read replica

Migrating from an RDS for PostgreSQL DB instance to an Aurora PostgreSQL DB cluster is a multistep procedure. First, you create an Aurora read replica of your source RDS for PostgreSQL DB instance. That starts a replication process from your RDS for PostgreSQL DB instance to a special-purpose DB cluster known as a Replica cluster. The Replica cluster consists solely of an Aurora read replica (a reader instance).

Once the Replica cluster exists, you monitor the lag between it and the source RDS for PostgreSQL DB instance. When the replica lag is zero (0), you can promote the Replica cluster. Replication stops, the Replica cluster is promoted to a standalone Aurora DB cluster, and the reader is promoted to writer instance for the cluster. You can then add instances to the Aurora PostgreSQL DB cluster to size your Aurora PostgreSQL DB cluster for your use case. You can also delete the RDS for PostgreSQL DB instance if you have no further need of it.

**Note**

It can take several hours per terabyte of data for the migration to complete.

You can't create an Aurora read replica if your RDS for PostgreSQL DB instance already has an Aurora read replica or if it has a cross-Region read replica.

Preparing to migrate data by using an Aurora read replica

During the migration process using Aurora read replica, updates made to the source RDS for PostgreSQL DB instance are asynchronously replicated to the Aurora read replica of the Replica cluster. The process uses PostgreSQL's native streaming replication functionality which stores write-ahead logs (WAL) segments on the source instance. Before starting this migration process, make sure that your instance has sufficient storage capacity by checking values for the metrics listed in the table.

<table>
<thead>
<tr>
<th>Metric</th>

</tr>
</tbody>
</table>

For more information about monitoring your RDS instance, see Monitoring in the Amazon RDS User Guide.

Creating an Aurora read replica

You can create an Aurora read replica for an RDS for PostgreSQL DB instance by using the AWS Management Console or the AWS CLI. The option to create an Aurora read replica using the AWS Management Console is available only if the AWS Region offers a compatible Aurora PostgreSQL version. That is, it's available only if there's an Aurora PostgreSQL version that is the same as the RDS for PostgreSQL version or a higher minor version in the same major version family.

Console

To create an Aurora read replica from a source PostgreSQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the RDS for PostgreSQL DB instance that you want to use as the source for your Aurora read replica. For Actions, choose Create Aurora read replica. If this choice doesn't display, it means that a compatible Aurora PostgreSQL version isn't available in the Region.
4. On the Create Aurora read replica settings page, you configure the properties for the Aurora PostgreSQL DB cluster as shown in the following table. The Replica DB cluster is created from a
snapshot of the source DB instance using the same 'master' user name and password as the source, so you can't change these at this time.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DB instance class</strong></td>
<td>Choose a DB instance class that meets the processing and memory requirements primary instance in the DB cluster. For more information, see [Aurora DB instance classes](p. 84).</td>
</tr>
<tr>
<td><strong>Multi-AZ deployment</strong></td>
<td>Not available during the migration</td>

Amazon Aurora User Guide for Aurora
Migrating an RDS for PostgreSQL DB instance using an Aurora read replica

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Auto minor version upgrade**       | Choose Yes to enable your Aurora PostgreSQL DB cluster to receive minor PostgreSQL DB engine version upgrades automatically when they become available.
|                                      | The **Auto minor version upgrade** option only applies to upgrades to PostgreSQL minor engine versions for your Aurora PostgreSQL DB cluster. It doesn't apply to regular patches applied to maintain system stability. |
| **Maintenance window**               | Choose the weekly time range during which system maintenance can occur.     |

5. Choose **Create read replica**.

**AWS CLI**

To create an Aurora read replica from a source RDS for PostgreSQL DB instance by using the AWS CLI, you first use the `create-db-cluster` CLI command to create an empty Aurora DB cluster. Once the DB cluster exists, you then use the `create-db-instance` command to create the primary instance for your DB cluster. The primary instance is the first instance that's created in an Aurora DB cluster. In this case, it's created initially as an Aurora read replica of your RDS for PostgreSQL DB instance. When the process concludes, your RDS for PostgreSQL DB instance has effectively been migrated to an Aurora PostgreSQL DB cluster.

You don't need to specify the main user account (typically, postgres), its password, or the database name. The Aurora read replica obtains these automatically from the source RDS for PostgreSQL DB instance that you identify when you invoke the AWS CLI commands.

You do need to specify the engine version to use for the Aurora PostgreSQL DB cluster and the DB instance. The version you specify should match the source RDS for PostgreSQL DB instance. If the source RDS for PostgreSQL DB instance is encrypted, you need to also specify encryption for the Aurora PostgreSQL DB cluster primary instance. Migrating an encrypted instance to an unencrypted Aurora DB cluster isn't supported.

The following examples create an Aurora PostgreSQL DB cluster named `my-new-aurora-cluster` that's going to use an unencrypted RDS DB source instance. You first create the Aurora PostgreSQL DB cluster by calling the `create-db-cluster` CLI command. The example shows how to use the optional `--storage-encrypted` parameter to specify that the DB cluster should be encrypted. Because the source DB isn't encrypted, the `-kms-key-id` is used to specify the key to use. For more information about required and optional parameters, see the list following the example.

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster  \
    --db-cluster-identifier my-new-aurora-cluster  \
    --db-subnet-group-name my-db-subnet  \
    --vpc-security-group-ids sg-11111111  \
    --engine aurora-postgresql  \
    --engine-version same-as-your-rds-instance-version  \
    --storage-encrypted  \
    --kms-key-id arn:aws:kms:aws-region:111122223333:key/11111111-2222-3333-444444444444
```

For Windows:

```bash
aws rds create-db-cluster ^
```
In the following list you can find more information about some of the options shown in the example. Unless otherwise specified, these parameters are required.

- `--db-cluster-identifier` – You need to give your new Aurora PostgreSQL DB cluster a name.
- `--db-subnet-group-name` – Create your Aurora PostgreSQL DB cluster in the same DB subnet as the source DB instance.
- `--vpc-security-group-ids` – Specify the security group for your Aurora PostgreSQL DB cluster.
- `--engine-version` – Specify the version to use for the Aurora PostgreSQL DB cluster. This should be the same as the version used by your source RDS for PostgreSQL DB instance.
- `--replication-source-identifier` – Identify your RDS for PostgreSQL DB instance using its Amazon Resource Name (ARN). For more information about Amazon RDS ARNs, see Amazon Relational Database Service (Amazon RDS) in the AWS General Reference. of your DB cluster.
- `--storage-encrypted` – Optional. Use only when needed to specify encryption as follows:
  - Use this parameter when the source DB instance has encrypted storage. The call to `create-db-cluster` fails if you don't use this parameter with a source DB instance that has encrypted storage. If you want to use a different key for the Aurora PostgreSQL DB cluster than the key used by the source DB instance, you need to also specify the `--kms-key-id`.
  - Use if the source DB instance's storage is unencrypted but you want the Aurora PostgreSQL DB cluster to use encryption. If so, you also need to identify the encryption key to use with the `--kms-key-id` parameter.
- `--kms-key-id` – Optional. When used, you can specify the key to use for storage encryption (`--storage-encrypted`) by using the key's ARN, ID, alias ARN, or its alias name. This parameter is needed only for the following situations:
  - To choose a different key for the Aurora PostgreSQL DB cluster than that used by the source DB instance.
  - To create an encrypted cluster from an unencrypted source. In this case, you need to specify the key that Aurora PostgreSQL should use for encryption.

After creating the Aurora PostgreSQL DB cluster, you then create the primary instance by using the `create-db-instance` CLI command, as shown in the following:

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
--db-cluster-identifier my-new-aurora-cluster \
--db-instance-class db.x2g.16xlarge \
--db-instance-identifier rpg-for-migration \
--engine aurora-postgresql
```

For Windows:

```powershell
aws rds create-db-instance ^
--db-cluster-identifier my-new-aurora-cluster ^
--db-instance-class db.x2g.16xlarge ^
--db-instance-identifier rpg-for-migration ^
--engine aurora-postgresql
```
In the following list, you can find more information about some of the options shown in the example.

- **--db-cluster-identifier** – Specify the name of the Aurora PostgreSQL DB cluster that you created with the `create-db-instance` command in the previous steps.
- **--db-instance-class** – The name of the DB instance class to use for your primary instance, such as `db.r4.xlarge`, `db.t4g.medium`, `db.x2g.16xlarge`, and so on. For a list of available DB instance classes, see [DB instance class types](#) (p. 84).
- **--db-instance-identifier** – Specify the name to give your primary instance.
- **--engine aurora-postgresql** – Specify `aurora-postgresql` for the engine.

**RDS API**

To create an Aurora read replica from a source RDS for PostgreSQL DB instance, first use the RDS API operation `CreateDBCluster` to create a new Aurora DB cluster for the Aurora read replica that gets created from your source RDS for PostgreSQL DB instance. When the Aurora PostgreSQL DB cluster is available, you then use the `CreateDBInstance` to create the primary instance for the Aurora DB cluster.

You don't need to specify the main user account (typically, `postgres`), its password, or the database name. The Aurora read replica obtains these automatically from the source RDS for PostgreSQL DB instance specified with `ReplicationSourceIdentifier`.

You do need to specify the engine version to use for the Aurora PostgreSQL DB cluster and the DB instance. The version you specify should match the source RDS for PostgreSQL DB instance. If the source RDS for PostgreSQL DB instance is encrypted, you need to also specify encryption for the Aurora PostgreSQL DB cluster primary instance. Migrating an encrypted instance to an unencrypted Aurora DB cluster isn't supported.

To create the Aurora DB cluster for the Aurora read replica, use the RDS API operation `CreateDBCluster` with the following parameters:

- **DBClusterIdentifier** – The name of the DB cluster to create.
- **DBSubnetGroupName** – The name of the DB subnet group to associate with this DB cluster.
- **Engine=aurora-postgresql** – The name of the engine to use.
- **ReplicationSourceIdentifier** – The Amazon Resource Name (ARN) for the source PostgreSQL DB instance. For more information about Amazon RDS ARNs, see [Amazon Relational Database Service (Amazon RDS)](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/Overview.RDS.ARN.html) in the Amazon Web Services General Reference. If `ReplicationSourceIdentifier` identifies an encrypted source, Amazon RDS uses your default KMS key unless you specify a different key using the `KmsKeyId` option.
- **VpcSecurityGroupIds** – The list of Amazon EC2 VPC security groups to associate with this DB cluster.
- **StorageEncrypted** – Indicates that the DB cluster is encrypted. When you use this parameter without also specifying the `ReplicationSourceIdentifier`, Amazon RDS uses your default KMS key.
- **KmsKeyId** – The key for an encrypted cluster. When used, you can specify the key to use for storage encryption by using the key’s ARN, ID, alias ARN, or its alias name.

For more information, see [CreateDBCluster](https://docs.aws.amazon.com/AmazonRDS/latest/APIReference/API_CreateDBCluster.html) in the Amazon RDS API Reference.

Once the Aurora DB cluster is available, you can then create a primary instance for it by using the RDS API operation `CreateDBInstance` with the following parameters:

- **DBClusterIdentifier** – The name of your DB cluster.
- **DBInstanceClass** – The name of the DB instance class to use for your primary instance.
- **DBInstanceIdentifier** – The name of your primary instance.
• Engine=aurora-postgresql – The name of the engine to use.

For more information, see CreateDBInstance in the Amazon RDS API Reference.

Promoting an Aurora read replica

The migration to Aurora PostgreSQL isn't complete until you promote the Replica cluster, so don't delete the RDS for PostgreSQL source DB instance just yet.

Before promoting the Replica cluster, make sure that the RDS for PostgreSQL DB instance doesn't have any in-process transactions or other activity writing to the database. When the replica lag on the Aurora read replica reaches zero (0), you can promote the Replica cluster. For more information about monitoring replica lag, see Monitoring Aurora PostgreSQL replication (p. 1506) and Instance-level metrics for Amazon Aurora (p. 643).

Console

To promote an Aurora read replica to an Aurora DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the Replica cluster.
4. For Actions, choose Promote. This may take a few minutes and can cause downtime.

When the process completes, the Aurora Replica cluster is a Regional Aurora PostgreSQL DB cluster, with a Writer instance containing the data from the RDS for PostgreSQL DB instance.

AWS CLI

To promote an Aurora read replica to a stand-alone DB cluster, use the promote-read-replica-db-cluster AWS CLI command.

Example

For Linux, macOS, or Unix:

```
aws rds promote-read-replica-db-cluster \  
--db-cluster-identifier myreadreplicaclasser
```
RDS API

To promote an Aurora read replica to a stand-alone DB cluster, use the RDS API operation `PromoteReadReplicaDBCluster`.

After you promote the Replica cluster, you can confirm that the promotion has completed by checking the event log, as follows.

**To confirm that the Aurora Replica cluster was promoted**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Events**.
3. On the **Events** page, find the name of your cluster in the **Source** list. Each event has a source, type, time, and message. You can see all events that have occurred in your AWS Region for your account. A successful promotion generates the following message.

   ```
   Promoted Read Replica cluster to a stand-alone database cluster.
   ```

After promotion is complete, the source RDS for PostgreSQL DB instance and the Aurora PostgreSQL DB cluster are unlinked. You can direct your client applications to the endpoint for the Aurora read replica. For more information on the Aurora endpoints, see Amazon Aurora connection management (p. 62). At this point, you can safely delete the DB instance.

---

**Improving query performance for Aurora PostgreSQL with Aurora Optimized Reads**

You can achieve faster query processing for Aurora PostgreSQL with Aurora Optimized Reads. An Aurora PostgreSQL DB instance that uses Aurora Optimized Reads delivers up to 8x improved query latency and up to 30% cost savings for applications with large datasets, that exceed the memory capacity of a DB instance.

**Topics**

- Overview of Aurora Optimized Reads in PostgreSQL (p. 1278)
- Using Aurora Optimized Reads (p. 1279)
- Use cases for Aurora Optimized Reads (p. 1280)
- Monitoring DB instances that use Aurora Optimized Reads (p. 1280)
- Best practices for Aurora Optimized Reads (p. 1281)

**Overview of Aurora Optimized Reads in PostgreSQL**

Aurora Optimized Reads is available by default when you create a DB cluster that uses Graviton-based R6gd and Intel-based R6id instances with non-volatile memory express (NVMe) storage. It is available from the following PostgreSQL versions:

---
Aurora Optimized Reads supports two capabilities: tiered cache and temporary objects.

**Optimized Reads-enabled tiered cache** - Using tiered cache, you can extend your DB instance caching capacity by up to 5x the instance memory. This automatically maintains the cache to contain the most recent, transactionally consistent data, freeing applications from the overhead of managing the data currency of external result-set based caching solutions. It offers up to 8x better latency for queries that were previously fetching data from Aurora storage.

**Optimized Reads-enabled temporary objects** - Using temporary objects, you can achieve faster query processing by placing the temporary files that are generated by PostgreSQL on the local NVMe storage. This reduces the traffic to Elastic Block Storage (EBS) over the network. If offers up to 2x better latency and throughput for advanced queries that sort, join, or merge large volumes of data that do not fit within the memory capacity available on a DB instance.

On an Aurora I/O-Optimized cluster, Optimized Reads makes use of both tiered cache and temporary objects on NVMe storage. With Optimized Reads-enabled tiered cache capability, Aurora allocates 2x the instance memory for temporary objects, approximately 10% of the storage for internal operations and the remaining storage as tiered cache. On an Aurora Standard cluster, Optimized Reads makes use of only temporary objects.

**Note**
A switch between IO-Optimized and Standard clusters on a NVMe-based DB instance class causes an immediate database engine restart.

In Aurora PostgreSQL, use the the `temp_tablespaces` parameter to configure the temporary work area where the temporary objects are stored.

To check whether the temporary workspace is correctly configured, use the following command:

```
postgres=> show temp_tablespaces;
 temp_tablespaces
 -----------
aurora_temp_tablespace
(1 row)
```

The `aurora_temp_tablespace` is a tablespace configured by Aurora that points to the NVMe local storage. You can't modify this parameter or switch back to Amazon EBS storage.

To check whether optimized reads cache is turned on, use the following command:

```
postgres=> show shared_preload_libraries;
 shared_preload_libraries
 ----------------------------------------
 rdsutils,pg_stat_statements,aurora_optimized_reads_cache
```

### Using Aurora Optimized Reads

When you provision an Aurora PostgreSQL DB instance with one of the NVMe-based DB instance, the DB instance automatically uses Aurora Optimized Reads.

To turn on Aurora Optimized Reads, do one of the following:

- Create an Aurora PostgreSQL DB cluster using one of the NVMe-based DB instance classes. For more information, see [Creating an Amazon Aurora DB cluster](p. 179).
• Modify an existing Aurora PostgreSQL DB cluster to use one of the NVMe-based DB instance classes. For more information, see Modifying an Amazon Aurora DB cluster (p. 269).

Aurora Optimized Reads is available in all AWS Regions where one or more of the DB instance classes with local NVMe SSD storage are supported. For more information, see Aurora DB instance classes (p. 84).

To switch back to a non-optimized reads Aurora instance, modify the DB instance class of your Aurora instance to the similar instance class that only supports EBS storage for your database workloads. For example, if the current DB instance class is db.r6gd.4xlarge, choose db.r6g.4xlarge to switch back. For more information, see Modifying an Aurora DB instance.

Use cases for Aurora Optimized Reads

Optimized Reads-enabled tiered cache

The following are some use cases that can benefit from Optimized Reads with tiered cache:

• Internet scale applications such as payments processing, billing, e-commerce with strict performance SLAs.
• Real-time reporting dashboards that run hundreds of point queries for metrics/data collection.
• Generative AI applications with the pgvector extension to search exact or nearest neighbors across millions of vector embeddings.

Optimized Reads-enabled temporary objects

The following are some use cases that can benefit from Optimized Reads with temporary objects:

• Analytical queries that include Common Table Expressions (CTEs), derived tables, and grouping operations.
• Read replicas that handle the unoptimized queries for an application.
• On-demand or dynamic reporting queries with complex operations such as GROUP BY and ORDER BY that can't always use appropriate indexes.
• Other workloads that use internal temporary tables.

Monitoring DB instances that use Aurora Optimized Reads

You can monitor your queries that use Optimized Reads-enabled tiered cache with the EXPLAIN command as shown in the following example:

```
Postgres=> EXPLAIN (ANALYZE, BUFFERS) SELECT c FROM sbtest15 WHERE id=100000000

QUERY PLAN
------------------------------------------------------------------------------------------------------------------------
Index Scan using sbtest15_pkey on sbtest15 (cost=0.57..8.59 rows=1 width=121) (actual time=0.287..0.288 rows=1 loops=1)
  Index Cond: (id = 100000000)
Buffers: shared hit=3 read=2 aurora_orcache_hit=2
I/O Timings: shared/local read=0.264
Planning:
  Buffers: shared hit=33 read=6 aurora_orcache_hit=6
```

1280
I/O Timings: shared/local read=0.607
Planning Time: 0.929 ms
Execution Time: 0.303 ms
(9 rows)
Time: 2.028 ms

**Note**

aurora_orcache_hit and aurora_storage_read fields in the Buffers section of the explain plan are shown only when Optimized Reads is turned on and the hit is greater than zero.

You can monitor DB instances that use Aurora Optimized Reads using the following CloudWatch metrics:

- AuroraOptimizedReadsCacheHitRatio
- FreeEphemeralStorage
- ReadIOPSEphemeralStorage
- ReadLatencyEphemeralStorage
- ReadThroughputEphemeralStorage
- WriteIOPSEphemeralStorage
- WriteLatencyEphemeralStorage
- WriteThroughputEphemeralStorage

These metrics provide data about available instance store storage, IOPS, and throughput. For more information about these metrics, see [Instance-level metrics for Amazon Aurora](p. 643).

You can also use the pg_proctab extension to monitor NVMe storage.

```sql
postgres=> select * from pg_diskusage();
```

(2 rows)

**Best practices for Aurora Optimized Reads**

Use the following best practices for Aurora Optimized Reads:

- Monitor the storage space available on the instance store with the CloudWatch metric FreeEphemeralStorage. If the instance store is reaching its limit because of the workload on the DB instance, tune the concurrency and plan queries which heavily use temporary objects or modify it to use a larger DB instance class.
- Monitor the CloudWatch metric for the Optimized Reads cache hit rate. Operations like VACUUM modify large numbers of blocks very quickly. This can cause a temporary drop in the hit ratio. The pg_prewarm extension can be used to load data into the buffer cache that allows Aurora to proactively write some of those blocks to the Optimized Reads cache.
• You can enable cluster cache management (CCM) to warm up the buffer cache and tiered cache on a tier-0 reader, which will be used as a failover target. When CCM is enabled, the buffer cache is periodically scanned to write pages eligible for eviction in tiered cache. For more information on CCM, see Fast recovery after failover with cluster cache management for Aurora PostgreSQL (p. 1478).
Using Babelfish for Aurora PostgreSQL

Babelfish for Aurora PostgreSQL extends your Aurora PostgreSQL DB cluster with the ability to accept database connections from SQL Server clients. With Babelfish, applications that were originally built for SQL Server can work directly with Aurora PostgreSQL with few code changes compared to a traditional migration and without changing database drivers. For more information about migrating, see Migrating a SQL Server database to Babelfish for Aurora PostgreSQL (p. 1314).

Babelfish provides an additional endpoint for an Aurora PostgreSQL database cluster that allows it to understand the SQL Server wire-level protocol and commonly used SQL Server statements. Client applications that use the Tabular Data Stream (TDS) wire protocol can connect natively to the TDS listener port on Aurora PostgreSQL. To learn more about TDS, see [MS-TDS]: Tabular Data Stream Protocol on the Microsoft website.

**Note**

Babelfish for Aurora PostgreSQL supports TDS versions 7.1 through 7.4.

Babelfish also provides access to data using the PostgreSQL connection. By default, both SQL dialects supported by Babelfish are available through their native wire protocols at the following ports:

- SQL Server dialect (T-SQL), clients connect to port 1433.
- PostgreSQL dialect (PL/pgSQL), clients connect to port 5432.

Babelfish runs the Transact-SQL (T-SQL) language with some differences. For more information, see Differences between Babelfish for Aurora PostgreSQL and SQL Server (p. 1339).

In the following sections, you can find information about setting up and using a Babelfish for Aurora PostgreSQL DB cluster.

**Topics**

- Babelfish limitations (p. 1284)
- Understanding Babelfish architecture and configuration (p. 1284)
- Creating a Babelfish for Aurora PostgreSQL DB cluster (p. 1307)
- Migrating a SQL Server database to Babelfish for Aurora PostgreSQL (p. 1314)
- Database authentication with Babelfish for Aurora PostgreSQL (p. 1322)
- Connecting to a Babelfish DB cluster (p. 1327)
- Working with Babelfish (p. 1336)
- Troubleshooting Babelfish (p. 1361)
- Turning off Babelfish (p. 1362)
- Babelfish version updates (p. 1363)
- Babelfish for Aurora PostgreSQL reference (p. 1374)
Babelfish limitations

The following limitations currently apply to Babelfish for Aurora PostgreSQL:

- Babelfish currently doesn't support the following Aurora features:
  - AWS Identity and Access Management
  - Database Activity Streams (DAS)
  - Query plan management (QPM)
  - Salted challenge response authentication mechanism (SCRAM)
- Babelfish currently doesn't support Kerberos based authentication using Active Directory security groups.
- Babelfish currently doesn't support the following PostgreSQL features:
  - pg_dump/pg_restore utility to move a database from one Aurora PostgreSQL DB cluster to another
- Babelfish doesn't provide the following client driver API support:
  - API requests with the connection attributes related to Microsoft Distributed Transaction Coordinator (MSDTC) aren't supported. These include XA calls by the SQLServerXAResource class in the SQL server JDBC driver.
  - API requests with the connection attributes and methods related to connection pooling aren't supported. Usually, Babelfish for Aurora PostgreSQL performs well when the connection attributes of the connection pooling are removed.
- The open source jTDS driver that is designed as an alternative to the Microsoft JDBC driver is not supported.

Understanding Babelfish architecture and configuration

You manage the Aurora PostgreSQL-Compatible Edition DB cluster running Babelfish much as you would any Aurora DB cluster. That is, you benefit from the scalability, high-availability with failover support, and built-in replication provided by an Aurora DB cluster. To learn more about these capabilities, see Managing performance and scaling for Aurora DB clusters (p. 297), High availability for Amazon Aurora (p. 102), and Replication with Amazon Aurora (p. 104). You also have access to many other AWS tools and utilities, including the following:

- Amazon CloudWatch is a monitoring and observability service that provides you with data and actionable insights. For more information, see Monitoring Amazon Aurora metrics with Amazon CloudWatch (p. 545).
- Performance Insights is a database performance tuning and monitoring feature that helps you quickly assess the load on your database. To learn more, see Monitoring DB load with Performance Insights on Amazon Aurora (p. 559).
- Aurora global databases span multiple AWS Regions, enabling low latency global reads and providing fast recovery from the rare outage that might affect an entire AWS Region. For more information, see Using Amazon Aurora global databases (p. 1800).
- Automatic software patching keeps your database up-to-date with the latest security and feature patches when they become available.
- Amazon RDS events notify you by email or SMS message of important database events, such as an automated failover. For more information, see Monitoring Amazon Aurora events (p. 685).

Following, you can learn about Babelfish architecture and how the SQL Server databases that you migrate are handled by Babelfish. When you create your Babelfish DB cluster, you need to make some decisions up front about single database or multiple databases, collations, and other details.
Babelfish architecture

When you create an Aurora PostgreSQL cluster with Babelfish turned on, Aurora provisions the cluster with a PostgreSQL database named babelfish_db. This database is where all migrated SQL Server objects and structures reside.

**Note**

In an Aurora PostgreSQL cluster, the babelfish_db database name is reserved for Babelfish. Creating your own "babelfish_db" database on a Babelfish DB cluster prevents Aurora from successfully provisioning Babelfish.

When you connect to the TDS port, the session is placed in the babelfish_db database. From T-SQL, the structure looks similar to being connected to a SQL Server instance. You can see the master, msdb, and tempdb databases, and the sys.databases catalog. You can create additional user databases and switch between databases with the USE statement. When you create a SQL Server user database, it's flattened into the babelfish_db PostgreSQL database. Your database retains cross-database syntax and semantics equal to or similar to those provided by SQL Server.

Using Babelfish with a single database or multiple databases

When you create an Aurora PostgreSQL cluster to use with Babelfish, you choose between using a single SQL Server database on its own or multiple SQL Server databases together. Your choice affects how the names of SQL Server schemas inside the babelfish_db database appear from Aurora PostgreSQL. The migration mode is stored in the migration_mode parameter. You must not change this parameter after creating your cluster as you could lose access to all your previously created SQL objects.

In single-db mode, the schema names of the SQL Server database remain the same in the babelfish_db database of the PostgreSQL. If you choose to migrate only a single database, the schema names of the migrated user database can be referenced in PostgreSQL with the same names used in SQL Server. For example, the dbo and smith schemas reside inside the dbA database.

When connecting through TDS, you can run USE dbA to see schemas dbo and smith from T-SQL, as you would in SQL Server. The unchanged schema names are also visible from PostgreSQL.

In multiple-database mode, the schema names of user databases become dbname_schemaname when accessed from PostgreSQL. The schema names remain the same when accessed from T-SQL.
Understanding Babelfish architecture and configuration

As shown in the image, multiple-database mode and single-database mode are the same as SQL Server when connecting through the TDS port and using T-SQL. For example, USE `dbA` lists schemas `dbo` and `smith` just as it does in SQL Server. The mapped schema names, such as `dbA_dbo` and `dbA_smith`, are visible from PostgreSQL.

Each database still contains your schemas. The name of each database is prepended to the name of the SQL Server schema, using an underscore as a delimiter, for example:

- `dbA` contains `dbA_dbo` and `dbA_smith`.
- `dbB` contains `dbB_dbo` and `dbB_jones`.
- `dbC` contains `dbC_dbo` and `dbC_miller`.

Inside the `babelfish_db` database, the T-SQL user still needs to run `USE dbname` to change database context, so the look and feel remains similar to SQL Server.

**Choosing a migration mode**

Each migration mode has advantages and disadvantages. Choose your migration mode based on the number of user databases you have, and your migration plans. After you create a cluster for use with Babelfish, you must not change the migration mode as you might lose access to all your previously created SQL objects. When choosing a migration mode, consider the requirements of your user databases and clients.

When you create a cluster for use with Babelfish, Aurora PostgreSQL creates the system databases, `master` and `tempdb`. If you created or modified objects in the system databases (`master` or `tempdb`), make sure to recreate those objects in your new cluster. Unlike SQL Server, Babelfish doesn't reinitialize `tempdb` after a cluster reboot.

Use single database migration mode in the following cases:

- If you are migrating a single SQL Server database. In single database mode, migrated schema names when accessed from PostgreSQL are identical to those in original SQL Server schema names. This reduces code changes to existing SQL queries if you want to optimize them to run with a PostgreSQL connection.
- If your end goal is a complete migration to native Aurora PostgreSQL. Before migrating, consolidate your schemas into a single schema (`dbo`) and then migrate into a single cluster to lessen required changes.

Use multiple database migration mode in the following cases:

- If you want the default SQL Server experience with multiple user databases in the same instance.
- If multiple user databases need to be migrated together.
DB cluster parameter group settings for Babelfish

When you create an Aurora PostgreSQL DB cluster and choose Turn on Babelfish, a DB cluster parameter group is created for you automatically if you choose Create new. This DB cluster parameter group is based on the Aurora PostgreSQL DB cluster parameter group for the Aurora PostgreSQL version chosen for the install, for example, Aurora PostgreSQL version 14. It’s named using the following general pattern:

custom-aurora-postgresql14-babelfish-compat-3

You can change the following settings during the cluster creation process but some of these can’t be changed once they’re stored in the custom parameter group, so choose carefully:

• Single database or Multiple databases
• Default collation locale
• Collation name
• Babelfish TDS port
• DB parameter group

To use an existing Aurora PostgreSQL DB cluster version 13 or higher parameter group, edit the group and set the babelfish_status parameter to on. Specify any Babelfish options before creating your Aurora PostgreSQL cluster. To learn more, see Working with parameter groups (p. 212).

The following parameters control Babelfish preferences. Unless otherwise stated in the Description, parameters are modifiable. The default value is included in the description. To see the allowable values for any parameter, do as follows:

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Parameter groups from the navigation menu.
3. Choose the default.aurora-postgresql14 DB cluster parameter group from the list.
4. Enter the name of a parameter in the search field. For example, enter babelfishpg_tsql.default_locale in the search field to display this parameter and its default value and allowable settings.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>babelfishpg_tds.tds_default_numeric_scale</td>
<td>Sets the default scale of numeric type to be sent in the TDS column metadata if the engine doesn’t specify one. (Default: 8) (Allowable: 0–38)</td>
</tr>
<tr>
<td>babelfishpg_tds.tds_default_numeric_precision</td>
<td>An integer that sets the default precision of numeric type to be sent in the TDS column metadata if the engine doesn’t specify one. (Default: 38) (Allowable: 1–38)</td>
</tr>
<tr>
<td>babelfishpg_tds.tds_default_packet_size</td>
<td>An integer that sets the default packet size for connecting SQL Server clients. (Default: 4096) (Allowable: 512–32767)</td>
</tr>
<tr>
<td>babelfishpg_tds.tds_default_protocol_version</td>
<td>An integer that sets a default TDS protocol version for connecting clients. (Default: DEFAULT) (Allowable: TDSv7.0, TDSv7.1, TDSv7.1.1, TDSv7.2, TDSv7.3A, TDSv7.3B, TDSv7.4, DEFAULT)</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>babelfishpg_tds.default_server_name</td>
<td>A string that identifies the default name of the Babelfish server. (Default: Microsoft SQL Server) (Allowable: null)</td>
</tr>
<tr>
<td>babelfishpg_tds.enable_tds_debug_log_level</td>
<td>An integer that sets the logging level in TDS; 0 turns off logging. (Default: 1) (Allowable: 0, 1, 2, 3)</td>
</tr>
<tr>
<td>babelfishpg_tds.listen_addresses</td>
<td>A string that sets the host name or IP address or addresses to listen for TDS on. This parameter can't be modified after the Babelfish DB cluster is created. (Default: *) (Allowable: null)</td>
</tr>
<tr>
<td>babelfishpg_tds.port</td>
<td>An integer that specifies the TCP port used for requests in SQL Server syntax. (Default: 1433) (Allowable: 1–65535)</td>
</tr>
<tr>
<td>babelfishpg_tds.tds_ssl_encrypt</td>
<td>A boolean that turns encryption on (0) or off (1) for data traversing the TDS listener port. For detailed information about using SSL for client connections, see Babelfish SSL settings and client connections (p. 1290). (Default: 0) (Allowable: 0, 1)</td>
</tr>
<tr>
<td>babelfishpg_tds.tds_ssl_max_protocol_version</td>
<td>A string that specifies the highest SSL/TLS protocol version to use for the TDS session. (Default: 'TLSv1.2') (Allowable: 'TLSv1', 'TLSv1.1', 'TLSv1.2')</td>
</tr>
<tr>
<td>babelfishpg_tds.tds_ssl_min_protocol_version</td>
<td>A string that specifies the minimum SSL/TLS protocol version to use for the TDS session. (Default: 'TLSv1') (Allowable: 'TLSv1', 'TLSv1.1', 'TLSv1.2')</td>
</tr>
<tr>
<td>babelfishpg_tds.unix_socket_directories</td>
<td>A string that identifies the TDS server Unix socket directory. This parameter can't be modified after the Babelfish DB cluster is created. (Default: /tmp) (Allowable: null)</td>
</tr>
<tr>
<td>babelfishpg_tds.unix_socket_group</td>
<td>A string that identifies the TDS server Unix socket group. This parameter can't be modified after the Babelfish DB cluster is created. (Default: rdsdb) (Allowable: null)</td>
</tr>
<tr>
<td>babelfishpg_tsql.default_locale</td>
<td>A string that specifies the default locale used for Babelfish collations. The default locale is the locale only and doesn't include any qualifiers. Set this parameter when you provision a Babelfish DB cluster. After the DB cluster is provisioned, changes to this parameter are ignored. (Default: en_US) (Allowable: See tables (p. 1294))</td>
</tr>
<tr>
<td>babelfishpg_tsql.migration_mode</td>
<td>A non-modifiable list that specifies support for single- or multiple user databases. Set this parameter when you provision a Babelfish DB cluster. After the DB cluster is provisioned, you can't modify this parameter's value. (Default: single-db) (Allowable: single-db, multi-db,null)</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>babelfishpg_tsql.server_collation_name</td>
<td>A string that specifies the name of the collation used for server-level actions. Set this parameter when you provision a Babelfish DB cluster. After the DB cluster is provisioned, don't modify the value of this parameter. (Default: bbf_unicode_general_ci_as) (Allowable: See tables (p. 1294))</td>
</tr>
<tr>
<td>babelfishpg_tsql.version</td>
<td>A string that sets the output of @@VERSION variable. Don't modify this value for Aurora PostgreSQL DB clusters. (Default: null) (Allowable: default)</td>
</tr>
<tr>
<td>rds.babelfish_status</td>
<td>A string that sets the state of Babelfish functionality. When this parameter is set to datatypesonly, Babelfish is turned off but SQL Server data types are still available. (Default: off) (Allowable: on, off, datatypesonly)</td>
</tr>
<tr>
<td>unix_socket_permissions</td>
<td>An integer that sets the TDS server Unix socket permissions. This parameter can't be modified after the Babelfish DB cluster is created. (Default: 0700) (Allowable: 0–511)</td>
</tr>
</tbody>
</table>
Babelfish SSL settings and client connections

When a client connects to the TDS port (default 1433), Babelfish compares the Secure Sockets Layer (SSL) setting sent during the client handshake to the Babelfish SSL parameter setting (tds_ssl_encrypt). Babelfish then determines if a connection is allowed. If a connection is allowed, encryption behavior is either enforced or not, depending on your parameter settings and the support for encryption offered by the client.

The table following shows how Babelfish behaves for each combination.

<table>
<thead>
<tr>
<th>Client SSL setting</th>
<th>Babelfish SSL setting</th>
<th>Connection allowed?</th>
<th>Value returned to client</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENCRYPT_OFF</td>
<td>tds_ssl_encrypt=0</td>
<td>Allowed, the login packet is encrypted</td>
<td>ENCRYPT_OFF</td>
</tr>
<tr>
<td>ENCRYPT_OFF</td>
<td>tds_ssl_encrypt=1</td>
<td>Allowed, the entire connection is encrypted</td>
<td>ENCRYPT_REQ</td>
</tr>
<tr>
<td>ENCRYPT_ON</td>
<td>tds_ssl_encrypt=0</td>
<td>Allowed, the entire connection is encrypted</td>
<td>ENCRYPT_ON</td>
</tr>
<tr>
<td>ENCRYPT_ON</td>
<td>tds_ssl_encrypt=1</td>
<td>Allowed, the entire connection is encrypted</td>
<td>ENCRYPT_ON</td>
</tr>

</tr>
</tbody>
</table>
Kerberos authentication with Babelfish

Babelfish for Aurora PostgreSQL 15.2 version supports authentication to your DB cluster using Kerberos. This method allows you to use Microsoft Windows Authentication to authenticate users when they connect to your Babelfish database. To do so, you must first configure your DB cluster to use AWS Directory Service for Microsoft Active Directory for Kerberos authentication. For more information, see What is AWS Directory Service? in the AWS Directory Service Administration Guide.

Setting up Kerberos Authentication

Babelfish for Aurora PostgreSQL DB cluster can connect using two different ports, but Kerberos authentication setup is a one-time process. Therefore, you must first set up Kerberos authentication for your DB cluster. For more information, see Setting up Kerberos authentication. After completing the setup, ensure that you can connect with a PostgreSQL client using Kerberos. For more information, see Connecting with Kerberos Authentication.

Login and user provisioning in Babelfish

Windows logins created from the Tabular Data Stream (TDS) port can be used either with the TDS port or the PostgreSQL port. First, the login that can use Kerberos for authentication must be provisioned from the TDS port before it is used by the T-SQL users and applications to connect to a Babelfish database. When creating Windows logins, administrators can provide the login using either the DNS domain name or the NetBIOS domain name. Typically, NetBIOS domain is the subdomain of the DNS domain name. For example, if the DNS domain name is CORP.EXAMPLE.COM, then the NetBIOS domain can be CORP. If the NetBIOS domain name format is provided for a login, a mapping must exist to the DNS domain name.

Managing NetBIOS domain name to DNS domain name mapping

To manage mappings between the NetBIOS domain name and DNS domain name, Babelfish provides system stored procedures to add, remove, and truncate mappings. Only a user with a sysadmin role can run these procedures.

To create mapping between NetBIOS and DNS domain name, use the Babelfish provided system stored procedure babelfish_add_domain_mapping_entry. Both arguments must have a valid value and are not NULL.

Example

```
EXEC babelfish_add_domain_mapping_entry 'netbios_domain_name', 'fully_qualified_domain_name'
```

The following example shows how to create the mapping between the NetBIOS name CORP and DNS domain name CORP.EXAMPLE.COM.

Example

```
EXEC babelfish_add_domain_mapping_entry 'corp', 'corp.example.com'
```

To delete an existing mapping entry, use the system stored procedure babelfish_remove_domain_mapping_entry.

Example

```
EXEC babelfish_remove_domain_mapping_entry 'netbios_domain_name'
```

The following example shows how to remove the mapping for the NetBIOS name CORP.
Example

```sql
EXEC babelfish_remove_domain_mapping_entry 'corp'
```

To remove all existing mapping entries, use the system stored procedure `babelfish_truncate_domain_mapping_table`:

Example

```sql
EXEC babelfish_truncate_domain_mapping_table
```

To view all mappings between NetBIOS and DNS domain name, use the following query.

Example

```sql
SELECT netbios_domain_name, fq_domain_name FROM babelfish_domain_mapping;
```

Managing Logins

Create logins

Connect to the DB through the TDS endpoint using a login that has the correct permissions. If there is no database user created for the login, then the login is mapped to guest user. If the guest user is not enabled, then the login attempt fails.

Create a Windows login using the following query. The `FROM WINDOWS` option allows authentication using Active Directory.

```sql
CREATE LOGIN login_name FROM WINDOWS [WITH DEFAULT_DATABASE=database]
```

Example

The following example shows creating a login for the Active Directory user `[corp\test1]` with a default database of `db1`.

```sql
CREATE LOGIN [corp\test1] FROM WINDOWS WITH DEFAULT_DATABASE=db1
```

This example assumes that there is a mapping between the NetBIOS domain `CORP` and the DNS domain name `CORP.EXAMPLE.COM`. If there is no mapping, then you must provide the DNS domain name `[CORP.EXAMPLE.COM\test1]`.

Note

Logins based on Active Directory users, are limited to names of fewer than 21 characters.

Drop login

To drop a login, use the same syntax as for any login, as shown in the following example:

```sql
DROP LOGIN [DNS domain name\login]
```

Alter login

To alter a login, use the same syntax as for any login, as in the following example:

```
ALTER LOGIN [DNS domain name\login] { ENABLE|DISABLE|WITH DEFAULT_DATABASE=[master] }
The `ALTER LOGIN` command supports limited options for Windows logins, including the following:

- **DISABLE** – To disable a login. You can’t use a disabled login for authentication.
- **ENABLE** – To enable a disabled login.
- **DEFAULT_DATABASE** – To change the default database of a login.

**Note**

All password management is performed through AWS Directory Service, so the `ALTER LOGIN` command doesn’t allow database administrators to change or set passwords for Windows logins.

**Connecting to Babelfish for Aurora PostgreSQL with Kerberos authentication**

Typically, the database users who authenticate using Kerberos are doing so from their client machines. These machines are members of the Active Directory domain. They use Windows Authentication from their client applications to access the Babelfish for Aurora PostgreSQL server on the TDS port.

**Connecting to Babelfish for Aurora PostgreSQL on the PostgreSQL port with Kerberos authentication**

You can use logins created from the TDS port with either the TDS port or the PostgreSQL port. However, PostgreSQL uses case-sensitive comparisons by default for usernames. For Aurora PostgreSQL to interpret Kerberos usernames as case-insensitive, you must set the `krb_caseins_users` parameter as `true` in the custom Babelfish cluster parameter group. This parameter is set to `false` by default. For more information, see [Configuring for case-insensitive user names](#). In addition, you must specify the login username in the format `<login@DNS domain name>` from the PostgreSQL client applications. You can’t use `<DNS domain name\login>` format.

**Frequently occurring errors**

You can configure forest trust relationships between your on-premises Microsoft Active Directory and the AWS Managed Microsoft AD. For more information, see [Create a trust relationship](#). Then, you must connect using a specialized domain specific endpoint instead of using the Amazon domain `rds.amazonaws.com` in the host endpoint. If you don’t use the correct domain specific endpoint, you might encounter the following error:

```
Error: "Authentication method "NTLMSSP" not supported (Microsoft SQL Server, Error: 514)"
```

This error occurs when the TDS client can’t cache the service ticket for the supplied endpoint URL. For more information, see [Connecting with Kerberos](#).
Collations supported by Babelfish

When you create an Aurora PostgreSQL DB cluster with Babelfish, you choose a collation for your data. A **collation** specifies the sort order and bit patterns that produce the text or characters in a given written human language. A collation includes rules comparing data for a given set of bit patterns. Collation is related to localization. Different locales affect character mapping, sort order, and the like. Collation attributes are reflected in the names of various collations. For information about attributes, see the Babelfish collation attributes table.

Babelfish maps SQL Server collations to comparable collations provided by Babelfish. Babelfish predefines Unicode collations with culturally sensitive string comparisons and sort orders. Babelfish also provides a way to translate the collations in your SQL Server DB to the closest-matching Babelfish collation. Locale-specific collations are provided for different languages and regions.

Some collations specify a code page that corresponds to a client-side encoding. Babelfish automatically translates from the server encoding to the client encoding depending on the collation of each output column.

Babelfish supports the collations listed in the Babelfish supported collations table. Babelfish maps SQL Server collations to comparable collations provided by Babelfish.

Babelfish uses version 153.80 of the International Components for Unicode (ICU) collation library. For more information about ICU collations, see Collation in the ICU documentation. To learn more about PostgreSQL and collation, see Collation Support in the Postgres documentation.

**Topics**

- DB cluster parameters that control collation and locale (p. 1294)
- Deterministic and nondeterministic collations and Babelfish (p. 1295)
- Collations supported by Babelfish (p. 1295)
- Default Collation in Babelfish (p. 1298)
- Managing collations (p. 1298)
- Collation limitations and behavior differences (p. 1299)

**DB cluster parameters that control collation and locale**

The following parameters affect collation behavior.

**babelexportpg_tsql.default_locale**

This parameter specifies the default locale used by the collation. This parameter is used in combination with attributes listed in the Babelfish collation attributes table to customize collations for a specific language and region. The default value for this parameter is en-US.

The default locale applies to all Babelfish collation names that start with "BBF" and to all SQL Server collations that are mapped to Babelfish collations. Changing the setting for this parameter on an existing Babelfish DB cluster doesn't affect the locale of existing collations. For the list of collations, see the Babelfish supported collations table.

**babelexportpg_tsql.server_collation_name**

This parameter specifies the default collation for the server (Aurora PostgreSQL DB cluster instance) and the database. The default value is sql_latin1_general_cpi_ci_as. The server_collation_name has to be a CI AS collation because in T-SQL, the server collation determines how identifiers are compared.

When you create your Babelfish DB cluster, you choose the Collation name from the selectable list. These include the collations listed in the Babelfish supported collations table. Don't modify the server_collation_name after the Babelfish database is created.
The settings you choose when you create your Babelfish for Aurora PostgreSQL DB cluster are stored in the DB cluster parameter group associated with the cluster for these parameters and set its collation behavior.

**Deterministic and nondeterministic collations and Babelfish**

Babelfish supports deterministic and nondeterministic collations:

- A **deterministic collation** evaluates characters that have identical byte sequences as equal. That means that $x$ and $X$ aren’t equal in a deterministic collation. Deterministic collations can be case-sensitive (CS) and accent-sensitive (AS).

- A **nondeterministic collation** doesn’t need an identical match. A nondeterministic collation evaluates $x$ and $X$ as equal. Nondeterministic collations are case-insensitive (CI) and accent-insensitive (AI).

In the table following, you can find some behavior differences between Babelfish and PostgreSQL when using nondeterministic collations.

<table>
<thead>
<tr>
<th>Babelfish</th>
<th>PostgreSQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Supports the LIKE clause for CI_AS collations.</td>
<td>Doesn’t support the LIKE clause on nondeterministic collations.</td>
</tr>
<tr>
<td>Doesn’t support the LIKE clause on AI collations.</td>
<td></td>
</tr>
<tr>
<td>Don’t support pattern-matching operations on nondeterministic collations.</td>
<td></td>
</tr>
</tbody>
</table>

For a list of other limitations and behavior differences for Babelfish compared to SQL Server and PostgreSQL, see [Collation limitations and behavior differences (p. 1299)](#).

Babelfish and SQL Server follow a naming convention for collations that describe the collation attributes, as shown in the table following.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AI</td>
<td>Accent-insensitive.</td>
</tr>
<tr>
<td>AS</td>
<td>Accent-sensitive.</td>
</tr>
<tr>
<td>BIN2</td>
<td>BIN2 requests data to be sorted in code point order. Unicode code point order is the same character order for UTF-8, UTF-16, and UCS-2 encodings. Code point order is a fast deterministic collation.</td>
</tr>
<tr>
<td>CI</td>
<td>Case-insensitive.</td>
</tr>
<tr>
<td>CS</td>
<td>Case-sensitive.</td>
</tr>
<tr>
<td>PREF</td>
<td>To sort uppercase letters before lowercase letters, use a PREF collation. If comparison is case-insensitive, the uppercase version of a letter sorts before the lowercase version, if there is no other distinction. The ICU library supports uppercase preference with colCaseFirst=upper, but not for CI_AS collations. PREF can be applied only to CS_AS deterministic collations.</td>
</tr>
</tbody>
</table>

**Collations supported by Babelfish**

Use the following collations as a server collation or an object collation.
<table>
<thead>
<tr>
<th>Collation ID</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>bbf_unicode_general_ci_as</td>
<td>Supports case-insensitive comparison and the LIKE operator.</td>
</tr>
<tr>
<td>bbf_unicode_cp1_ci_as</td>
<td>Nondeterministic collation also known as CP1252.</td>
</tr>
<tr>
<td>bbf_unicode_CP1250_ci_as</td>
<td>Nondeterministic collation used to represent texts in Central European and Eastern European languages that use Latin script.</td>
</tr>
<tr>
<td>bbf_unicode_CP1251_ci_as</td>
<td>Nondeterministic collation for languages that use the Cyrillic script.</td>
</tr>
<tr>
<td>bbf_unicode_cp1253_ci_as</td>
<td>Nondeterministic collation used to represent modern Greek.</td>
</tr>
<tr>
<td>bbf_unicode_cp1254_ci_as</td>
<td>Nondeterministic collation that supports Turkish.</td>
</tr>
<tr>
<td>bbf_unicode_cp1255_ci_as</td>
<td>Nondeterministic collation that supports Hebrew.</td>
</tr>
<tr>
<td>bbf_unicode_cp1256_ci_as</td>
<td>Nondeterministic collation used to write languages that use Arabic script.</td>
</tr>
<tr>
<td>bbf_unicode_cp1257_ci_as</td>
<td>Nondeterministic collation used to support Estonian, Latvian, and Lithuanian languages.</td>
</tr>
<tr>
<td>bbf_unicode_cp1258_ci_as</td>
<td>Nondeterministic collation used to write Vietnamese characters.</td>
</tr>
<tr>
<td>bbf_unicode_cp874_ci_as</td>
<td>Nondeterministic collation used to write Thai characters.</td>
</tr>
<tr>
<td>sql_latin1_general_cp1250_ci_as</td>
<td>Nondeterministic single-byte character encoding used to represent Latin characters.</td>
</tr>
<tr>
<td>sql_latin1_general_cp1251_ci_as</td>
<td>Nondeterministic collation that supports Latin characters.</td>
</tr>
<tr>
<td>sql_latin1_general_cp1_ci_as</td>
<td>Nondeterministic collation that supports Latin characters.</td>
</tr>
<tr>
<td>sql_latin1_general_cp1253_ci_as</td>
<td>Nondeterministic collation that supports Latin characters.</td>
</tr>
<tr>
<td>sql_latin1_general_cp1254_ci_as</td>
<td>Nondeterministic collation that supports Latin characters.</td>
</tr>
<tr>
<td>sql_latin1_general_cp1255_ci_as</td>
<td>Nondeterministic collation that supports Latin characters.</td>
</tr>
<tr>
<td>sql_latin1_general_cp1256_ci_as</td>
<td>Nondeterministic collation that supports Latin characters.</td>
</tr>
<tr>
<td>sql_latin1_general_cp1257_ci_as</td>
<td>Nondeterministic collation that supports Latin characters.</td>
</tr>
<tr>
<td>sql_latin1_general_cp1258_ci_as</td>
<td>Nondeterministic collation that supports Latin characters.</td>
</tr>
<tr>
<td>chinese_prc_ci_as</td>
<td>Nondeterministic collation that supports Chinese (PRC).</td>
</tr>
<tr>
<td>cyrillic_general_ci_as</td>
<td>Nondeterministic collation that supports Cyrillic.</td>
</tr>
<tr>
<td>finnish_swedish_ci_as</td>
<td>Nondeterministic collation that supports Finnish.</td>
</tr>
<tr>
<td>french_ci_as</td>
<td>Nondeterministic collation that supports French.</td>
</tr>
<tr>
<td>japanese_ci_as</td>
<td>Nondeterministic collation that supports Japanese. Supported in Babelfish 2.1.0 and higher releases.</td>
</tr>
<tr>
<td>korean_wansung_ci_as</td>
<td>Nondeterministic collation that supports Korean (with dictionary sort).</td>
</tr>
<tr>
<td>latin1_general_ci_as</td>
<td>Nondeterministic collation that supports Latin characters.</td>
</tr>
<tr>
<td>Collation ID</td>
<td>Notes</td>
</tr>
<tr>
<td>------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>modern_spanish_ci_as</td>
<td>Nondeterministic collation that supports Modern Spanish.</td>
</tr>
<tr>
<td>polish_ci_as</td>
<td>Nondeterministic collation that supports Polish.</td>
</tr>
<tr>
<td>thai_ci_as</td>
<td>Nondeterministic collation that supports Thai.</td>
</tr>
<tr>
<td>traditional_spanish_ci_as</td>
<td>Nondeterministic collation that supports Spanish (traditional sort).</td>
</tr>
<tr>
<td>turkish_ci_as</td>
<td>Nondeterministic collation that supports Turkish.</td>
</tr>
<tr>
<td>ukrainian_ci_as</td>
<td>Nondeterministic collation that supports Ukrainian.</td>
</tr>
<tr>
<td>vietnamese_ci_as</td>
<td>Nondeterministic collation that supports Vietnamese.</td>
</tr>
</tbody>
</table>

You can use the following collations as object collations.

<table>
<thead>
<tr>
<th>Dialect</th>
<th>Deterministic options</th>
<th>Nondeterministic options</th>
</tr>
</thead>
<tbody>
<tr>

**Default Collation in Babelfish**

Earlier, the default collation of the collatable datatypes was `pg_catalog.default`. The datatypes and the objects that depend on these datatypes follows case-sensitive collation. This condition potentially impacts the T-SQL objects of the data set with case-insensitive collation. Starting with Babelfish 2.3.0, the default collation for the collatable data types (except TEXT and NTEXT) is the same as the collation in the `babelfishpg_tsql.server_collation_name` parameter. When you upgrade to Babelfish 2.3.0, the default collation is picked automatically at the time of DB cluster creation, which doesn’t create any visible impact.

**Managing collations**

The ICU library provides collation version tracking to ensure that indexes that depend on collations can be reindexed when a new version of ICU becomes available. To see if your current database has collations that need refreshing, you can use the following query after connecting using `psql` or `pgAdmin`:

```sql
SELECT pg_describe_object(refclassid, refobjid, refobjsubid) AS "Collation",
       pg_describe_object(classid, objid, objsubid) AS "Object"
FROM pg_depend d JOIN pg_collation c ON refclassid = 'pg_collation'::regclass
AND refobjid = c.oid WHERE c.collversion <> pg_collation_actual_version(c.oid)
ORDER BY 1, 2;
```

This query returns output such as the following:

<table>
<thead>
<tr>
<th>Collation</th>
<th>Object</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

(0 rows)

In this example, no collations need to be updated.

To get a listing of the predefined collations in your Babelfish database, you can use `psql` or `pgAdmin` with the following query:

```sql
SELECT * FROM pg_collation;
```

Predefined collations are stored in the `sys.fn_helpcollations` table. You can use the following command to display information about a collation (such as its lcid, style, and collate flags). To get a listing of all collations by using `sqlcmd`, connect to the T-SQL port (1433, by default) and run the following query:

```sql
1> :setvar SQLCMDMAXVARTYPEWIDTH 40
2> :setvar SQLCMDMAXFIXEDTYPEWIDTH 40
3> SELECT * FROM fn_helpcollations()
4> GO
```

<table>
<thead>
<tr>
<th>name</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>arabic_cs_as</td>
<td>Arabic, case-sensitive, accent-sensitive</td>
</tr>
<tr>
<td>arabic_ci_ai</td>
<td>Arabic, case-insensitive, accent-insensitive</td>
</tr>
<tr>
<td>arabic_ci_as</td>
<td>Arabic, case-insensitive, accent-sensitive</td>
</tr>
<tr>
<td>bbf_unicode_bin2</td>
<td>Unicode-General, case-sensitive, accent-sensitive</td>
</tr>
</tbody>
</table>
Collation limitations and behavior differences

Babelfish uses the ICU library for collation support. PostgreSQL is built with a specific version of ICU and can match at most one version of a collation. Variations across versions are unavoidable, as are minor variations across time as languages evolve. In the following list you can find known limitations and behavior variations of Babelfish collations:

- **Indexes and collation type dependency** – An index on a user-defined type that depends on the International Components for Unicode (ICU) collation library (the library used by Babelfish) isn’t invalidated when the library version changes.

- **COLLATIONPROPERTY function** – Collation properties are implemented only for the supported Babelfish BBF collations. For more information, see the Babelfish supported collations table.

- **Unicode sorting rule differences** – SQL collations for SQL Server sort Unicode-encoded data (nchar and nvarchar) differently than data that’s not Unicode-encoded (char and varchar). Babelfish databases are always UTF-8 encoded and always apply Unicode sorting rules consistently, regardless of data type, so the sort order for char or varchar is the same as it is for nchar or nvarchar.

- **Secondary-equal collations and sorting behavior** – The default ICU Unicode secondary-equal (CI_AS) collation sorts punctuation marks and other nonalphanumeric characters before numeric characters, and numeric characters before alphabetic characters. However, the order of punctuation and other special characters is different.

- **Tertiary collations, workaround for ORDER BY** – SQL collations, such as SQL_Latin1_General_Pref_CP1_CI_AS, support the TERTIARY_WEIGHTS function and the ability to sort strings that compare equally in a CI_AS collation to be sorted uppercase first: ABC, ABC, AbC, aBC, and finally abc. Thus, the DENSE_RANK OVER (ORDER BY column) analytic function assesses these strings as having the same rank but orders them uppercase first within a partition.

You can get a similar result with Babelfish by adding a COLLATE clause to the ORDER BY clause that specifies a tertiary CS_AS collation that specifies @colCaseFirst=upper. However, the colCaseFirst modifier applies only to strings that are tertiary-equal (rather than secondary-equal such as with CI_AS collation). Thus, you can’t emulate tertiary SQL collations using a single ICU collation.

As a workaround, we recommend that you modify applications that use the SQL_Latin1_General_Pref_CP1_CI_AS collation to use the
BBF_SQL_Latin1_General_CP1_CI_AS collation first. Then add COLLATE BBF_SQL_Latin1_General_Pref_CP1_CS_AS to any ORDER BY clause for this column.

- **Character expansion** – A character expansion treats a single character as equal to a sequence of characters at the primary level. SQL Server's default CI_AS collation supports character expansion. ICU collations support character expansion for accent-insensitive collations only.

  When character expansion is required, then use a AI collation for comparisons. However, such collations aren't currently supported by the LIKE operator.

- **char and varchar encoding** – When SQL collations are used for char or varchar data types, the sort order for characters preceding ASCII 127 is determined by the specific code page for that SQL collation. For SQL collations, strings declared as char or varchar might sort differently than strings declared as nchar or nvarchar.

  PostgreSQL encodes all strings with the database encoding, so all characters are converted to UTF-8 and sorted using Unicode rules.

  Because SQL collations sort nchar and nvarchar data types using Unicode rules, Babelfish encodes all strings on the server using UTF-8. Babelfish sorts nchar and nvarchar strings the same way it sorts char and varchar strings, using Unicode rules.

- **Supplementary character** – The SQL Server functions NCHAR, UNICODE, and LEN support characters for code-points outside the Unicode Basic Multilingual Plane (BMP). In contrast, non-SC collations use surrogate pair characters to handle supplementary characters. For Unicode data types, SQL Server can represent up to 65,535 characters using UCS-2, or the full Unicode range (1,114,114 characters) if supplementary characters are used.

- **Kana-sensitive (KS) collations** – A Kana-sensitive (KS) collation is one that treats Hiragana and Katakana Japanese Kana characters differently. ICU supports the Japanese collation standard JIS X 4061. The now deprecated colhiraganaQ [on | off] locale modifier might provide the same functionality as KS collations. However, KS collations of the same name as SQL Server aren't currently supported by Babelfish.

- **Width-sensitive (WS) collations** – When a single-byte character (half-width) and the same character represented as a double-byte character (full-width) are treated differently, the collation is called width-sensitive (WS). WS collations with the same name as SQL Server aren't currently supported by Babelfish.

- **Variation-selector sensitive (VSS) collations** – Variation-selector sensitive (VSS) collations distinguish between ideographic variation selectors in Japanese collations Japanese_Bushu_Kakusu_140 and Japanese_XJIS_140. A variation sequence is made up of a base character plus an additional variation selector. If you don't select the _VSS option, the variation selector isn't considered in the comparison.

  VSS collations aren't currently supported by Babelfish.

- **BIN and BIN2 collations** – A BIN2 collation sorts characters according to code point order. The byte-by-byte binary order of UTF-8 preserves Unicode code point order, so this is also likely to be the best-performing collation. If Unicode code point order works for an application, consider using a BIN2 collation. However, using a BIN2 collation can result in data being displayed on the client in an order that is culturally unexpected. New mappings to lowercase characters are added to Unicode as time progresses, so the LOWER function might perform differently on different versions of ICU. This is a special case of the more general collation versioning problem rather than as something specific to the BIN2 collation.

  Babelfish provides the BBF_Latin1_General_BIN2 collation with the Babelfish distribution to collate in Unicode code point order. In a BIN collation only the first character is sorted as a wchar. Remaining characters are sorted byte-by-byte, effectively in code point order according to its encoding. This approach doesn't follow Unicode collation rules and isn't supported by Babelfish.

- **Non-deterministic collations and CHARINDEX limitation** – For Babelfish releases older than version 2.1.0, you can't use CHARINDEX with non-deterministic collations. By default, Babelfish uses a case-
insensitive (non-deterministic) collation. Using CHARINDEX for older versions of Babelfish raises the following runtime error:

| nondeterministic collations are not supported for substring searches |

**Note**
This limitation and workaround apply to Babelfish version 1.x only (Aurora PostgreSQL 13.x versions). Babelfish 2.1.0 and higher releases don't have this issue.

You can work around this issue in one of the following ways:
- Explicitly convert the expression to a case-sensitive collation and case-fold both arguments by applying LOWER or UPPER. For example, `SELECT charindex('x', a) FROM t1` would become the following:

| SELECT charindex(LOWER('x'), LOWER(a COLLATE sql_latin1_general_cpl_cs_as)) FROM t1 |

- Create a SQL function `f_charindex`, and replace CHARINDEX calls with calls to the following function:

| CREATE function f_charindex(@s1 varchar(max), @s2 varchar(max)) RETURNS int AS BEGIN declare @i int = 1 WHILE len(@s2) >= len(@s1) BEGIN if LOWER(@s1) = LOWER(substring(@s2,1,len(@s1))) return @i set @i += 1 set @s2 = substring(@s2,2,999999999) END return 0 END go |
Managing Babelfish error handling with escape hatches

Babelfish mimics SQL behavior for control flow and transaction state whenever possible. When Babelfish encounters an error, it returns an error code similar to the SQL Server error code. If Babelfish can't map the error to a SQL Server code, it returns a fixed error code (33557097) and takes specific actions based on the type of error, as follows:

- For compile time errors, Babelfish rolls back the transaction.
- For runtime errors, Babelfish ends the batch and rolls back the transaction.
- For protocol error between client and server, the transaction isn't rolled back.

If an error code can't be mapped to an equivalent code and the code for a similar error is available, the error code is mapped to the alternative code. For example, the behaviors that cause SQL Server codes 8143 and 8144 are both mapped to 8143.

Errors that can't be mapped don't respect a TRY... CATCH construct.

You can use @@ERROR to return a SQL Server error code, or the @@PGERROR function to return a PostgreSQL error code. You can also use the fn_mapped_system_error_list function to return a list of mapped error codes. For information about PostgreSQL error codes, see the PostgreSQL website.

Modifying Babelfish escape hatch settings

To handle statements that might fail, Babelfish defines certain options called escape hatches. An escape hatch is an option that specifies Babelfish behavior when it encounters an unsupported feature or syntax.

You can use the sp_babelfish_configure stored procedure to control the settings of an escape hatch. Use the script to set the escape hatch to ignore or strict. If it's set to strict, Babelfish returns an error that you need to correct before continuing.

To apply changes to the current session and on the cluster level, include the server keyword.

The usage is as follows:

- To list all escape hatches and their status, plus usage information, run sp_babelfish_configure.
- To list the named escape hatches and their values, for the current session or cluster-wide, run the command sp_babelfish_configure 'hatch_name' where hatch_name is the identifier of one or more escape hatches. hatch_name can use SQL wildcards, such as '%'.
- To set one or more escape hatches to the value specified, run sp_babelfish_configure ['hatch_name' [, 'strict'|'ignore' [, 'server']]. To make the settings permanent on a cluster-wide level, include the server keyword, such as shown in the following:

```sql
EXECUTE sp_babelfish_configure 'escape_hatch_unique_constraint', 'ignore', 'server'
```

To set them for the current session only, don't use server.
- To reset all escape hatches to their default values, run sp_babelfish_configure 'default' (Babelfish 1.2.0 and higher).

The string identifying the hatch (or hatches) can include SQL wildcards. For example, the following sets all syntax escape hatches to ignore for the Aurora PostgreSQL cluster.

```sql
EXECUTE sp_babelfish_configure '%', 'ignore', 'server'
```
In the following table you can find descriptions and default values for the Babelfish predefined escape hatches.

<table>
<thead>
<tr>
<th>Escape hatch</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>escape_hatch_checkpoint</td>
<td>Allows the use of CHECKPOINT statement in the procedural code, but the CHECKPOINT statement is currently not implemented.</td>
<td>ignore</td>
</tr>
<tr>
<td>escape_hatch_constraint_name_for_default</td>
<td>Controls Babelfish behavior related to default constraint names.</td>
<td>ignore</td>
</tr>
<tr>
<td>escape_hatch_database_misc_options</td>
<td>Controls Babelfish behavior related to the following options on CREATE or ALTER DATABASE: CONTAINMENT, DB_CHAINING, TRUSTWORTHY, PERSISTENT_LOG_BUFFER.</td>
<td>ignore</td>
</tr>
<tr>
<td>escape_hatch_for_replication</td>
<td>Controls Babelfish behavior related to the [NOT] FOR REPLICATION clause when creating or altering a table.</td>
<td>strict</td>
</tr>
<tr>
<td>escape_hatch_fulltext</td>
<td>Controls Babelfish behavior related to FULLTEXT features, such a DEFAULT_FULLTEXT_LANGUAGE in CREATE/ALTER DATABASE, CREATE FULLTEXT INDEX, or sp_fulltext_database.</td>
<td>strict</td>
</tr>
<tr>
<td>escape_hatch_ignore_dup_key</td>
<td>Controls Babelfish behavior related to CREATE/ALTER TABLE and CREATE INDEX. When IGNORE_DUP_KEY=ON, raises an error when set to strict (the default) or ignores the error when set to ignore (Babelfish version 1.2.0 and higher).</td>
<td>strict</td>
</tr>
<tr>
<td>escape_hatch_index_clustering</td>
<td>Controls Babelfish behavior related to the CLUSTERED or NONCLUSTERED keywords for indexes and PRIMARY KEY or UNIQUE constraints. When CLUSTERED is ignored, the index or constraint is still created as if NONCLUSTERED was specified.</td>
<td>ignore</td>
</tr>
<tr>
<td>escape_hatch_index_columnstore</td>
<td>Controls Babelfish behavior related to the COLUMNSTORE clause. If you specify ignore, Babelfish creates a regular B-tree index.</td>
<td>strict</td>
</tr>
<tr>
<td>escape_hatch_join_hints</td>
<td>Controls the behavior of keywords in a JOIN operator: LOOP, HASH, MERGE, REMOTE, REDUCE, REDISTRIBUTE, REPLICATE.</td>
<td>ignore</td>
</tr>
<tr>
<td>Escape hatch</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>--------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>escape_hatch_language_non_english</td>
<td>Controls Babelfish behavior related to languages other than English for onscreen messages. Babelfish currently supports only us_english for onscreen messages. SET LANGUAGE might use a variable containing the language name, so the actual language being set can only be detected at run time.</td>
<td>strict</td>
</tr>
<tr>
<td>escape_hatch_login_hashed_password</td>
<td>When ignored, suppresses the error for the HASHED keyword for CREATE LOGIN and ALTER LOGIN.</td>
<td>strict</td>
</tr>
<tr>
<td>escape_hatch_login_misc_options</td>
<td>When ignored, suppresses the error for other keywords besides HASHED, MUST_CHANGE, OLD_PASSWORD, and UNLOCK for CREATE LOGIN and ALTER LOGIN.</td>
<td>strict</td>
</tr>
<tr>
<td>escape_hatch_login_old_password</td>
<td>When ignored, suppresses the error for the OLD_PASSWORD keyword for CREATE LOGIN and ALTER LOGIN.</td>
<td>strict</td>
</tr>
<tr>
<td>escape_hatch_login_password_must_change</td>
<td>When ignored, suppresses the error for the MUST_CHANGE keyword for CREATE LOGIN and ALTER LOGIN.</td>
<td>strict</td>
</tr>
<tr>
<td>escape_hatch_login_password_unlock</td>
<td>When ignored, suppresses the error for the UNLOCK keyword for CREATE LOGIN and ALTER LOGIN.</td>
<td>strict</td>
</tr>
<tr>
<td>escape_hatch_nocheck_add_constraint</td>
<td>Controls Babelfish behavior related to the WITH CHECK or NOCHECK clause for constraints.</td>
<td>strict</td>
</tr>
<tr>
<td>escape_hatch_nocheck_existing_constraint</td>
<td>Controls Babelfish behavior related to FOREIGN KEY or CHECK constraints.</td>
<td>strict</td>
</tr>
<tr>
<td>escape_hatch_query_hints</td>
<td>Controls Babelfish behavior related to query hints. When this option is set to ignore, the server ignores hints that use the OPTION (…) clause to specify query processing aspects. Examples include SELECT FROM … OPTION(MERGE JOIN HASH, MAXRECURSION 10)).</td>
<td>ignore</td>
</tr>
<tr>
<td>escape_hatch_rowversion</td>
<td>Controls the behavior of the ROWVERSION and TIMESTAMP datatypes. For usage information, see Using Babelfish features with limited implementation (p. 1343).</td>
<td>strict</td>
</tr>
<tr>
<td>Escape hatch</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>--------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>escape_hatch_schemabinding_function</td>
<td>Controls Babelfish behavior related to the WITH SCHEMABINDING clause. By default, the WITH SCHEMABINDING clause is ignored when specified with the CREATE or ALTER FUNCTION command.</td>
<td>ignore</td>
</tr>
<tr>
<td>escape_hatch_schemabinding_procedure</td>
<td>Controls Babelfish behavior related to the WITH SCHEMABINDING clause. By default, the WITH SCHEMABINDING clause is ignored when specified with the CREATE or ALTER PROCEDURE command.</td>
<td>ignore</td>
</tr>
<tr>
<td>escape_hatch_rowguidcol_column</td>
<td>Controls Babelfish behavior related to the ROWGUIDCOL clause when creating or altering a table.</td>
<td>strict</td>
</tr>
<tr>
<td>escape_hatch_schemabinding_trigger</td>
<td>Controls Babelfish behavior related to the WITH SCHEMABINDING clause. By default, the WITH SCHEMABINDING clause is ignored when specified with the CREATE or ALTER TRIGGER command.</td>
<td>ignore</td>
</tr>
<tr>
<td>escape_hatch_schemabinding_view</td>
<td>Controls Babelfish behavior related to the WITH SCHEMABINDING clause. By default, the WITH SCHEMABINDING clause is ignored when specified with the CREATE or ALTER VIEW command.</td>
<td>ignore</td>
</tr>
<tr>
<td>escape_hatch_session_settings</td>
<td>Controls Babelfish behavior toward unsupported session-level SET statements.</td>
<td>ignore</td>
</tr>
<tr>
<td>escape_hatch_showplan_all</td>
<td>Controls Babelfish behavior related to SET SHOWPLAN_ALL and SET STATISTICS PROFILE. When set to ignore, they behave like SET BABELFISH_SHOWPLAN_ALL and SET BABELFISH_STATISTICS PROFILE; when set to strict, they are silently ignored.</td>
<td>strict</td>
</tr>
<tr>
<td>escape_hatch_storage_on_partition</td>
<td>Controls Babelfish behavior related to the ON_partition_scheme clause when defining partitioning. Babelfish currently doesn't implement partitioning.</td>
<td>strict</td>
</tr>
<tr>
<td>Escape hatch</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>--------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>escape_hatch_storage_options</td>
<td>Escape hatch on any storage option used in CREATE, ALTER DATABASE, TABLE, INDEX. This includes clauses (LOG) ON, TEXTIMAGE_ON, FILESTREAM_ON that define storage locations (partitions, file groups) for tables, indexes, and constraints, and also for a database. This escape hatch setting applies to all of these clauses (including ON [PRIMARY] and ON &quot;DEFAULT&quot;). The exception is when a partition is specified for a table or index with ON partition_scheme (column).</td>
<td>ignore</td>
</tr>
<tr>
<td>escape_hatch_table_hints</td>
<td>Controls the behavior of table hints specified using the WITH (...) clause.</td>
<td>ignore</td>
</tr>
<tr>
<td>escape_hatch_unique_constraint</td>
<td>When set to strict, an obscure semantic difference between SQL Server and PostgreSQL in handling NULL values on indexed columns can raise errors. The semantic difference only emerges in unrealistic use cases, so you can set this escape hatch to 'ignore' to avoid seeing the error.</td>
<td>strict</td>
</tr>
</tbody>
</table>
Creating a Babelfish for Aurora PostgreSQL DB cluster

Babelfish for Aurora PostgreSQL is supported on Aurora PostgreSQL version 13.4 and higher.

You can use the AWS Management Console or the AWS CLI to create an Aurora PostgreSQL cluster with Babelfish.

**Note**
In an Aurora PostgreSQL cluster, the `babelfish_db` database name is reserved for Babelfish. Creating your own "babelfish_db" database on a Babelfish for Aurora PostgreSQL prevents Aurora from successfully provisioning Babelfish.

**Console**

**To create a cluster with Babelfish running with the AWS Management Console**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/), and choose **Create database**.

2. For **Choose a database creation method**, do one of the following:
   - To specify detailed engine options, choose **Standard create**.
   - To use preconfigured options that support best practices for an Aurora cluster, choose **Easy create**.

3. For **Engine type**, choose **Aurora (PostgreSQL Compatible)**.

4. Choose **Show filters**, and then choose **Show versions that support the Babelfish for PostgreSQL feature** to list the engine types that support Babelfish. Babelfish is currently supported on Aurora PostgreSQL 13.4 and higher versions.

5. For **Available versions**, choose an Aurora PostgreSQL version. To get the latest Babelfish features, choose the highest Aurora PostgreSQL major version.
6. For **Templates**, choose the template that matches your use case.

7. For **DB cluster identifier**, enter a name that you can easily find later in the DB cluster list.

8. For **Master username**, enter an administrator user name. The default value for Aurora PostgreSQL is `postgres`. You can accept the default or choose a different name. For example, to follow the naming convention used on your SQL Server databases, you can enter `sa` (system administrator) for the Master username.

If you don't create a user named `sa` at this time, you can create one later with your choice of client. After creating the user, use the `ALTER SERVER ROLE` command to add it to the `sysadmin` group (role) for the cluster.

**Warning**
Master username must always use lowercase characters failing which the DB cluster can't connect to Babelfish via the TDS port.

9. For **Master password**, create a strong password and confirm the password.

10. For the options that follow, until the **Babelfish settings** section, specify your DB cluster settings. For information about each setting, see *Settings for Aurora DB clusters* (p. 190).

11. To make Babelfish functionality available, select the **Turn on Babelfish** box.

12. For **DB cluster parameter group**, do one of the following:

    - Choose **Create new** to create a new parameter group with Babelfish turned on.
    - Choose **Choose existing** to use an existing parameter group. If you use an existing group, make sure to modify the group before creating the cluster and add values for Babelfish parameters. For information about Babelfish parameters, see *DB cluster parameter group settings for Babelfish* (p. 1287).
If you use an existing group, provide the group name in the box that follows.

13. For **Database migration mode**, choose one of the following:

- **Single database** to migrate a single SQL Server database.

  In some cases, you might migrate multiple user databases together, with your end goal a complete migration to native Aurora PostgreSQL without Babelfish. If the final applications require consolidated schemas (a single dbo schema), make sure to first consolidate your SQL Server databases into a single SQL server database. Then migrate to Babelfish using **Single database** mode.

- **Multiple databases** to migrate multiple SQL Server databases (originating from a single SQL Server installation). Multiple database mode doesn't consolidate multiple databases that don't originate from a single SQL Server installation. For information about migrating multiple databases, see [Using Babelfish with a single database or multiple databases](p. 1285).

14. For **Default collation locale**, enter your server locale. The default is en-US. For detailed information about collations, see [Collations supported by Babelfish](p. 1294).

15. For **Collation name** field, enter your default collation. The default is `sql_latin1_general_cp1_ci_as`. For detailed information, see [Collations supported by Babelfish](p. 1294).

16. For **Babelfish TDS port**, enter the default port 1433. Currently, Babelfish only supports port 1433 for your DB cluster.

17. For **DB parameter group**, choose a parameter group or have Aurora create a new group for you with default settings.

18. For **Failover priority**, choose a failover priority for the instance. If you don't choose a value, the default is **tier-1**. This priority determines the order in which replicas are promoted when
recovering from a primary instance failure. For more information, see Fault tolerance for an Aurora DB cluster (p. 103).

19. For **Backup retention period**, choose the length of time (1–35 days) that Aurora retains backup copies of the database. You can use backup copies for point-in-time restores (PITR) of your database down to the second. The default retention period is seven days.

20. Choose **Copy tags to snapshots** to copy any DB instance tags to a DB snapshot when you create a snapshot.

21. Choose **Enable encryption** to turn on encryption at rest (Aurora storage encryption) for this DB cluster.

22. Choose **Enable Performance Insights** to turn on Amazon RDS Performance Insights.

23. Choose **Enable Enhanced monitoring** to start gathering metrics in real time for the operating system that your DB cluster runs on.

24. Choose **PostgreSQL log** to publish the log files to Amazon CloudWatch Logs.
25. Choose **Enable auto minor version upgrade** to automatically update your Aurora DB cluster when a minor version upgrade is available.

26. For **Maintenance window**, do the following:
   - To choose a time for Amazon RDS to make modifications or perform maintenance, choose **Select window**.
   - To perform Amazon RDS maintenance at an unscheduled time, choose **No preference**.

27. Select the **Enable deletion protection** box to protect your database from being deleted by accident.

   If you turn on this feature, you can't directly delete the database. Instead, you need to modify the database cluster and turn off this feature before deleting the database.

28. Choose **Create database**.

   You can find your new database set up for Babelfish in the **Databases** listing. The **Status** column displays **Available** when the deployment is complete.

   ![Amazon Aurora User Interface](image)

   **AWS CLI**

   When you create an Babelfish for Aurora PostgreSQL; using the AWS CLI, you need to pass the command the name of the DB cluster parameter group to use for the cluster. For more information, see **DB cluster prerequisites** (p. 179).

   Before you can use the AWS CLI to create an Aurora PostgreSQL cluster with Babelfish, do the following:
   - Choose your endpoint URL from the list of services at **Amazon Aurora endpoints and quotas**.
Creating a Babelfish for Aurora PostgreSQL DB cluster

- Create a parameter group for the cluster. For more information about parameter groups, see Working with parameter groups (p. 212).
- Modify the parameter group, adding the parameter that turns on Babelfish.

To create an Aurora PostgreSQL DB cluster with Babelfish using the AWS CLI

The examples that follow use the default Master username, postgres. Replace as needed with the username that you created for your DB cluster, such as sa or whatever username you chose if you didn’t accept the default.

1. Create a parameter group.
   - For Linux, macOS, or Unix:
     ```
     aws rds create-db-cluster-parameter-group
     --endpoint-url endpoint-url
     --db-cluster-parameter-group-name parameter-group
     --db-parameter-group-family aurora-postgresql14
     --description "description"
     ```
   - For Windows:
     ```
     aws rds create-db-cluster-parameter-group
     --endpoint-url endpoint-URL
     --db-cluster-parameter-group-name parameter-group
     --db-parameter-group-family aurora-postgresql14
     --description "description"
     ```

2. Modify your parameter group to turn on Babelfish.
   - For Linux, macOS, or Unix:
     ```
     aws rds modify-db-cluster-parameter-group
     --endpoint-url endpoint-url
     --db-cluster-parameter-group-name parameter-group
     --parameters "ParameterName=rds.babelfish_status,ParameterValue=on,ApplyMethod=pending-reboot"
     ```
   - For Windows:
     ```
     aws rds modify-db-cluster-parameter-group
     --endpoint-url endpoint-url
     --db-cluster-parameter-group-name parameter-group
     --parameters "ParameterName=rds.babelfish_status,ParameterValue=on,ApplyMethod=pending-reboot"
     ```

3. Identify your DB subnet group and the virtual private cloud (VPC) security group ID for your new DB cluster, and then call the create-db-cluster command.
   - For Linux, macOS, or Unix:
     ```
     aws rds create-db-cluster
     --db-cluster-identifier cluster-name
     --master-username postgres
     --manage-master-user-password
     --engine aurora-postgresql
     --engine-version 14.3
     --vpc-security-group-ids security-group
     ```
--db-subnet-group-name subnet-group-name \
--db-cluster-parameter-group-name parameter-group

For Windows:

```bash
aws rds create-db-cluster ^
--db-cluster-identifier cluster-name ^
--master-username postgres ^
--manage-master-user-password ^
--engine aurora-postgresql ^
--engine-version 14.3 ^
--vpc-security-group-ids security-group ^
--db-subnet-group-name subnet-group ^
--db-cluster-parameter-group-name parameter-group
```

This example specifies the `--manage-master-user-password` option to generate the master user password and manage it in Secrets Manager. For more information, see Password management with Amazon Aurora and AWS Secrets Manager (p. 2371). Alternatively, you can use the `--master-password` option to specify and manage the password yourself.

4. Explicitly create the primary instance for your DB cluster. Use the name of the cluster that you created in step 3 for the `--db-cluster-identifier` argument when you call the `create-db-instance` command, as shown following.

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance \
--db-instance-identifier instance-name \
--db-instance-class db.r6g \
--db-subnet-group-name subnet-group \
--db-cluster-identifier cluster-name \
--engine aurora-postgresql
```

For Windows:

```bash
aws rds create-db-instance ^
--db-instance-identifier instance-name ^
--db-instance-class db.r6g ^
--db-subnet-group-name subnet-group ^
--db-cluster-identifier cluster-name ^
--engine aurora-postgresql
```
Migrating a SQL Server database to Babelfish for Aurora PostgreSQL

You can use Babelfish for Aurora PostgreSQL to migrate an SQL Server database to an Amazon Aurora PostgreSQL DB cluster. Before migrating, review Using Babelfish with a single database or multiple databases (p. 1285).

Topics

- Overview of the migration process (p. 1314)
- Evaluating and handling differences between SQL Server and Babelfish (p. 1315)
- Import/export tools for migrating from SQL Server to Babelfish (p. 1318)

Overview of the migration process

The following summary lists the steps required to successfully migrate your SQL Server application and make it work with Babelfish. For information about the tools you can use for the export and import processes and for more detail, see Import/export tools for migrating from SQL Server to Babelfish (p. 1318).

1. Create a new Aurora PostgreSQL DB cluster with Babelfish turned on. To learn how, see Creating a Babelfish for Aurora PostgreSQL DB cluster (p. 1307).

   To import the various SQL artifacts exported from your SQL Server database, connect to the Babelfish cluster using a SQL Server tool such as sqlcmd. For more information, see Using a SQL Server client to connect to your DB cluster (p. 1330).

2. On the SQL Server database that you want to migrate, export the data definition language (DDL). The DDL is SQL code that describes database objects that contain user data (such as tables, indexes, and views) and user-written database code (such as stored procedures, user-defined functions, and triggers).

   For more information, see Using SQL Server Management Studio (SSMS) to migrate to Babelfish (p. 1318).

3. Run an assessment tool to evaluate the scope of any changes that you might need to make so that Babelfish can effectively support the application running on SQL Server. For more information, see Evaluating and handling differences between SQL Server and Babelfish (p. 1315).

4. To load the data, we recommend using the AWS DMS with either Babelfish or Aurora PostgreSQL as a target endpoint based on your migration requirements. Make sure to modify the columns with the recommended Babelfish data types. To do so, see the Prerequisites to using Babelfish as a target for AWS DMS.

5. On your new Babelfish DB cluster, run the DDL within your specified T-SQL database to create only the schemas, user-defined data types, and tables with their primary key constraints.

6. Use AWS DMS to migrate your data from SQL Server to Babelfish tables. For continuous replication using SQL Server Change Data Capture or SQL Replication, use Aurora PostgreSQL instead of Babelfish as the endpoint. To do so, see the Using Babelfish for Aurora PostgreSQL as a target for AWS Database Migration Service.

7. When the data load completes, create all the remaining T-SQL objects that support the application on your Babelfish cluster.

8. Reconfigure your client application to connect to the Babelfish endpoint instead of your SQL Server database. For more information, see Connecting to a Babelfish DB cluster (p. 1527).

9. Modify your application as needed and retest. For more information, see Differences between Babelfish for Aurora PostgreSQL and SQL Server (p. 1339).
You still need to assess your client-side SQL queries. The schemas generated from your SQL Server instance convert only the server-side SQL code. We recommend that you take the following steps:

- Capture client-side queries by using the SQL Server Profiler with the TSQL_Replay predefined template. This template captures T-SQL statement information that you can then replay for iterative tuning and testing. You can start the profiler within SQL Server Management Studio from the Tools menu. Choose SQL Server Profiler to open the profiler and choose the TSQL_Replay template.

To use for your Babelfish migration, start a trace and then run your application using your functional tests. The profiler captures the T-SQL statements. When you finish testing, stop the trace. Save the result to an XML file with your client-side queries (File > Save as > Trace XML File for Replay).

For more information, see SQL Server Profiler in the Microsoft documentation. For more information about the TSQL_Replay template, see SQL Server Profiler Templates.

- For applications with complex client-side SQL queries, we recommend that you use Babelfish Compass to analyze these queries for Babelfish compatibility. If the analysis indicates that the client-side SQL statements contain unsupported SQL features, review the SQL aspects in the client application and modify as needed.

- You can also capture the SQL queries as extended events (.xel format). To do so, use the SSMS XEvent Profiler. After generating the .xel file, extract the SQL statements into .xml files that Compass can then process. For more information, see Use the SSMS XEvent Profiler in the Microsoft documentation.

When you're satisfied with all testing, analysis, and any modifications needed for your migrated application, you can start using your Babelfish database for production. To do so, stop the original database and redirect live client applications to use the Babelfish TDS port.

### Evaluating and handling differences between SQL Server and Babelfish

For best results, we recommend that you evaluate the generated DDL/DML and the client query code before actually migrating your SQL Server database application to Babelfish. Depending on the version of Babelfish and the specific features of SQL Server that your application implements, you might need to refactor your application or use alternatives for functionality that aren't fully supported yet in Babelfish.

- To assess your SQL Server application code, use Babelfish Compass on the generated DDL to determine how much T-SQL code is supported by Babelfish. Identify T-SQL code that might need modifications before running on Babelfish. For more information about this tool, see Babelfish Compass tool on GitHub.

  **Note**
  Babelfish Compass is an open-source tool. Report any issues with Babelfish Compass through GitHub instead of through AWS Support.

You can use Generate Script Wizard with SQL Server Management Studio (SSMS) to generate the SQL file that is assessed by Babelfish Compass or AWS Schema Conversion Tool CLI. We recommend the following steps to streamline the assessment.

1. On the Choose Objects page, choose Script entire database and all database objects.
2. For the **Set Scripting Options**, choose **Save as script file** as a **Single script file**.
3. Choose **Advanced** to change the default scripting options to identify features that normally are set to false for a full assessment:
   - Script Change Tracking to True
   - Script Full-Text Indexes to True
   - Script Triggers to True
   - Script Logins to True
   - Script Owner to True
   - Script Object-Level Permissions to True
   - Script Collations to True
4. Perform the remaining steps in the wizard to generate the file.

**Import/export tools for migrating from SQL Server to Babelfish**

We recommend that you use AWS DMS as the primary tool for migrating from SQL Server to Babelfish. However, Babelfish supports several other ways to migrate data using SQL Server tools that includes the following.

- **SQL Server Integration Services (SSIS)** for all versions of Babelfish. For more information, see [Migrate from SQL Server to Aurora PostgreSQL using SSIS and Babelfish](#).
- **Use the SSMS Import/Export Wizard** for Babelfish versions 2.1.0 and later. This tool is available through the SSMS, but it's also available as a standalone tool. For more information, see [Welcome to SQL Server Import and Export Wizard](#) in the Microsoft documentation.
- The Microsoft bulk data copy program (bcp) utility lets you copy data from a Microsoft SQL Server instance to a data file in the format you specify. For more information, see [bcp Utility](#) in the Microsoft documentation. Babelfish now supports the data migration using the BCP client and the bcp utility now supports **-E** flag (for identity columns) and **-b** flag (for batching inserts). Certain bcp options aren't supported, including **-C**, **-T**, **-G**, **-K**, **-R**, **-V**, and **-h**.

**Using SQL Server Management Studio (SSMS) to migrate to Babelfish**

We recommend generating separate files for each of the specific object types. You can use the Generate Scripts wizard in SSMS for each set of DDL statements first, and then modify the objects as a group to fix any issues found during the assessment.
Perform these steps to migrate the data using AWS DMS or other data migration methods. Run these create script types first for a better and faster approach to load the data on the Babelfish tables in Aurora PostgreSQL.

1. Run `CREATE SCHEMA` statements.
2. Run `CREATE TYPE` statements to create user-defined data types.
3. Run basic `CREATE TABLE` statements with the primary keys or unique constraints.

Perform the data load using the recommended import/export tool. Run the modified scripts for the following steps to add the remaining database objects. You need the create table statements to run these scripts for the constraints, triggers, and indexes. After the scripts generate, delete the create table statements.

1. Run `ALTER TABLE` statements for the check constraints, foreign key constraints, default constraints.
2. Run `CREATE TRIGGER` statements.
3. Run `CREATE INDEX` statements.
4. Run `CREATE VIEW` statements.
5. Run `CREATE STORED PROCEDURE` statements.

**To generate scripts for each object type**

Use the following steps to create the basic create table statements using the Generate Scripts wizard in SSMS. Follow the same steps to generate scripts for the different object types.

1. Connect to your existing SQL Server instance.
2. Open the context (right-click) menu for a database name.
3. Choose Tasks, and then choose Generate Scripts....
4. On the Choose Objects pane, choose Select specific database objects. Choose Tables, select all tables. Choose Next to continue.
5. On the **Set Scripting Options** page, choose **Advanced** to open the **Options** settings. To generate the basic create table statements, change the following default values:

- Script Defaults to False.
- Script Extended Properties to False. Babelfish does not support extended properties.
- Script Check Constraints to False. Script Foreign Keys to False.
6. Choose OK.

7. On the Set Scripting Options page, choose Save as script file and then choose the Single script file option. Enter your File name.
Database authentication with Babelfish for Aurora PostgreSQL

Babelfish for Aurora PostgreSQL supports two ways to authenticate database users. Password authentication is available by default for all Babelfish DB clusters. You can also add Kerberos authentication for the same DB cluster.

8. Choose **Next** to view the **Summary wizard** page.
9. Choose **Next** to start the script generation.

You can continue to generate scripts for the other object types in the wizard. Instead of choosing **Finish** after the file is saved, choose the **Previous** button three times to go back to the **Choose Objects** page. Then repeat the steps in the wizard to generate scripts for the other object types.
Password authentication with Babelfish

Babelfish for Aurora PostgreSQL supports password authentication. Passwords are stored in encrypted form on disk. For more information about authentication on an Aurora PostgreSQL cluster, see Security with Amazon Aurora PostgreSQL (p. 1233).

You might be prompted for credentials each time you connect to Babelfish. Any user migrated to or created on Aurora PostgreSQL can use the same credentials on both the SQL Server port and the PostgreSQL port. Babelfish doesn't enforce password policies, but we recommend that you do the following:

- Require a complex password that's at least eight (8) characters long.
- Enforce a password expiration policy.

To review a complete list of database users, use the command SELECT * FROM pg_user;.
Babelfish for Aurora PostgreSQL 15.2 version supports authentication to your DB cluster using Kerberos. This method allows you to use Microsoft Windows Authentication to authenticate users when they connect to your Babelfish database. To do so, you must first configure your DB cluster to use AWS Directory Service for Microsoft Active Directory for Kerberos authentication. For more information, see What is AWS Directory Service? in the AWS Directory Service Administration Guide.

Setting up Kerberos Authentication

Babelfish for Aurora PostgreSQL DB cluster can connect using two different ports, but Kerberos authentication setup is a one-time process. Therefore, you must first set up Kerberos authentication for your DB cluster. For more information, see Setting up Kerberos authentication. After completing the setup, ensure that you can connect with a PostgreSQL client using Kerberos. For more information, see Connecting with Kerberos Authentication.

Login and user provisioning in Babelfish

Windows logins created from the Tabular Data Stream (TDS) port can be used either with the TDS port or the PostgreSQL port. First, the login that can use Kerberos for authentication must be provisioned from the TDS port before it is used by the T-SQL users and applications to connect to a Babelfish database. When creating Windows logins, administrators can provide the login using either the DNS domain name or the NetBIOS domain name. Typically, NetBIOS domain is the subdomain of the DNS domain name. For example, if the DNS domain name is CORP.EXAMPLE.COM, then the NetBIOS domain can be CORP. If the NetBIOS domain name format is provided for a login, a mapping must exist to the DNS domain name.

Managing NetBIOS domain name to DNS domain name mapping

To manage mappings between the NetBIOS domain name and DNS domain name, Babelfish provides system stored procedures to add, remove, and truncate mappings. Only a user with a sysadmin role can run these procedures.

To create mapping between NetBIOS and DNS domain name, use the Babelfish provided system stored procedure babelfish_add_domain_mapping_entry. Both arguments must have a valid value and are not NULL.

Example

```
EXEC babelfish_add_domain_mapping_entry 'netbios_domain_name', 'fully_qualified_domain_name'
```

The following example shows how to create the mapping between the NetBIOS name CORP and DNS domain name CORP.EXAMPLE.COM.

Example

```
EXEC babelfish_add_domain_mapping_entry 'corp', 'corp.example.com'
```

To delete an existing mapping entry, use the system stored procedure babelfish_remove_domain_mapping_entry.

Example

```
EXEC babelfish_remove_domain_mapping_entry 'netbios_domain_name'
```

The following example shows how to remove the mapping for the NetBIOS name CORP.
Example

EXEC babelfish_remove_domain_mapping_entry 'corp'

To remove all existing mapping entries, use the system stored procedure babelfish_truncate_domain_mapping_table:

Example

EXEC babelfish_truncate_domain_mapping_table

To view all mappings between NetBIOS and DNS domain name, use the following query.

Example

SELECT netbios_domain_name, fq_domain_name FROM babelfish_domain_mapping;

Managing Logins

Create logins

Connect to the DB through the TDS endpoint using a login that has the correct permissions. If there is no database user created for the login, then the login is mapped to guest user. If the guest user is not enabled, then the login attempt fails.

Create a Windows login using the following query. The FROM WINDOWS option allows authentication using Active Directory.

CREATE LOGIN login_name FROM WINDOWS [WITH DEFAULT_DATABASE=database]

Example

The following example shows creating a login for the Active Directory user [corp\test1] with a default database of db1.

CREATE LOGIN [corp\test1] FROM WINDOWS WITH DEFAULT_DATABASE=db

This example assumes that there is a mapping between the NetBIOS domain CORP and the DNS domain name CORP.EXAMPLE.COM. If there is no mapping, then you must provide the DNS domain name [CORP.EXAMPLE.COM\test1].

Note

Logins based on Active Directory users, are limited to names of fewer than 21 characters.

Drop login

To drop a login, use the same syntax as for any login, as shown in the following example:

DROP LOGIN [DNS domain name\login]

Alter login

To alter a login, use the same syntax as for any login, as in the following example:

ALTER LOGIN [DNS domain name\login] { ENABLE|DISABLE|WITH DEFAULT_DATABASE=[master] }
The ALTER LOGIN command supports limited options for Windows logins, including the following:

- **DISABLE** – To disable a login. You can’t use a disabled login for authentication.
- **ENABLE** – To enable a disabled login.
- **DEFAULT_DATABASE** – To change the default database of a login.

**Note**
All password management is performed through AWS Directory Service, so the ALTER LOGIN command doesn’t allow database administrators to change or set passwords for Windows logins.

**Connecting to Babelfish for Aurora PostgreSQL with Kerberos authentication**

Typically, the database users who authenticate using Kerberos are doing so from their client machines. These machines are members of the Active Directory domain. They use Windows Authentication from their client applications to access the Babelfish for Aurora PostgreSQL server on the TDS port.

**Connecting to Babelfish for Aurora PostgreSQL on the PostgreSQL port with Kerberos authentication**

You can use logins created from the TDS port with either the TDS port or the PostgreSQL port. However, PostgreSQL uses case-sensitive comparisons by default for usernames. For Aurora PostgreSQL to interpret Kerberos usernames as case-insensitive, you must set the `krb_caseins_users` parameter as `true` in the custom Babelfish cluster parameter group. This parameter is set to `false` by default. For more information, see [Configuring for case-insensitive user names](#). In addition, you must specify the login username in the format `<login@DNS domain name>` from the PostgreSQL client applications. You can’t use `<DNS domain name\login>` format.

**Frequently occurring errors**

You can configure forest trust relationships between your on-premises Microsoft Active Directory and the AWS Managed Microsoft AD. For more information, see [Create a trust relationship](#). Then, you must connect using a specialized domain specific endpoint instead of using the Amazon domain `rds.amazonaws.com` in the host endpoint. If you don’t use the correct domain specific endpoint, you might encounter the following error:

```
Error: “Authentication method "NTLMSSP" not supported (Microsoft SQL Server, Error: 514)”
```

This error occurs when the TDS client can’t cache the service ticket for the supplied endpoint URL. For more information, see [Connecting with Kerberos](#).
Connecting to a Babelfish DB cluster

To connect to Babelfish, you connect to the endpoint of the Aurora PostgreSQL cluster running Babelfish. Your client can use one of the following client drivers compliant with TDS version 7.1 through 7.4:

- Open Database Connectivity (ODBC)
- OLE DB Driver/MSOLEDBSQL
- Java Database Connectivity (JDBC) version 8.2.2 (mssql-jdbc-8.2.2) and higher
- Microsoft SqlClient Data Provider for SQL Server
- .NET Data Provider for SQL Server
- SQL Server Native Client 11.0 (deprecated)
- OLE DB Provider/SQLOLEDB (deprecated)

With Babelfish, you run the following:

- SQL Server tools, applications, and syntax on the TDS port, by default port 1433.
- PostgreSQL tools, applications, and syntax on the PostgreSQL port, by default port 5432.

To learn more about connecting to Aurora PostgreSQL in general, see Connecting to an Amazon Aurora PostgreSQL DB cluster (p. 209).

Topics

- Finding the writer endpoint and port number (p. 1327)
- Creating C# or JDBC client connections to Babelfish (p. 1329)
- Using a SQL Server client to connect to your DB cluster (p. 1330)
- Using a PostgreSQL client to connect to your DB cluster (p. 1333)

Finding the writer endpoint and port number

To connect to your Babelfish DB cluster, you use the endpoint associated with the DB cluster's writer (primary) instance. The instance must have a status of Available. It can take up to 20 minutes for the instances to be available after creating the Babelfish for Aurora PostgreSQL DB cluster.

To find your database endpoint

1. Open the console for Babelfish.
2. Choose Databases from the navigation pane.
3. Choose your Babelfish for Aurora PostgreSQL DB cluster from those listed to see its details.
4. On the Connectivity & security tab, note the available cluster Endpoints values. Use the cluster endpoint for the writer instance in your connection strings for any applications that perform database write or read operations.
For more information about Aurora DB cluster details, see [Creating an Amazon Aurora DB cluster](p. 179).
Amazon Aurora User Guide for Aurora
Connecting to a Babelﬁsh DB cluster

Creating C# or JDBC client connections to Babelﬁsh
In the following you can ﬁnd some examples of using C# and JDBC classes to connect to an Babelﬁsh for
Aurora PostgreSQL.

Example : Using C# code to connect to a DB cluster
string dataSource = 'babelfishServer_11_24';
//Create connection
connectionString = @"Data Source=" + dataSource
+";Initial Catalog=your-DB-name"
+";User ID=user-id;Password=password";
SqlConnection cnn = new SqlConnection(connectionString);
cnn.Open();

Example : Using generic JDBC API classes and interfaces to connect to a DB cluster
String dbServer =
"database-babelfish.cluster-123abc456def.us-east-1-rds.amazonaws.com";
String connectionUrl = "jdbc:sqlserver://" + dbServer + ":1433;" +
"databaseName=your-DB-name;user=user-id;password=password";
// Load the SQL Server JDBC driver and establish the connection.
System.out.print("Connecting Babelfish Server ... ");
Connection cnn = DriverManager.getConnection(connectionUrl);

Example : Using SQL Server-speciﬁc JDBC classes and interfaces to connect to a DB cluster
// Create datasource.
SQLServerDataSource ds = new SQLServerDataSource();
ds.setUser("user-id");
ds.setPassword("password");
String babelfishServer =
"database-babelfish.cluster-123abc456def.us-east-1-rds.amazonaws.com";
ds.setServerName(babelfishServer);
ds.setPortNumber(1433);
ds.setDatabaseName("your-DB-name");
Connection con = ds.getConnection();

1329


Using a SQL Server client to connect to your DB cluster

You can use a SQL Server client to connect with Babelfish on the TDS port. As of Babelfish 2.1.0 and higher releases, you can use the SSMS Object Explorer or the SSMS Query Editor to connect to your Babelfish cluster.

Limitations

- In Babelfish 2.1.0 and older versions, using PARSE to check SQL syntax doesn't work as it should. Rather than checking the syntax without running the query, the PARSE command runs the query but doesn't display any results. Using the SSMS <Ctrl>+<F5> key combination to check syntax has the same anomalous behavior, that is, Babelfish unexpectedly runs the query without providing any output.

- Babelfish doesn't support MARS (Multiple Active Result Sets). Be sure that any client applications that you use to connect to Babelfish aren't set to use MARS.

- For Babelfish 1.3.0 and older versions, only the Query Editor is supported for SSMS. To use SSMS with Babelfish, be sure to open the Query Editor connection dialog in SSMS, and not the Object Explorer. If the Object Explorer dialog does open, cancel the dialog and re-open the Query Editor. In the following image, you can find the menu options to choose when connecting to Babelfish 1.3.0 or older versions.

For more information about interoperability and behavioral differences between SQL Server and Babelfish, see Differences between Babelfish for Aurora PostgreSQL and SQL Server (p. 1339).

Using sqlcmd to connect to the DB cluster

You can connect to and interact with an Aurora PostgreSQL DB cluster that supports Babelfish by using the SQL Server sqlcmd command line client. Use the following command to connect.

```
sqcmd -S endpoint,port -U login-id -P password -d your-DB-name
```

The options are as follows:

- `-S` is the endpoint and (optional) TDS port of the DB cluster.
- `-U` is the login name of the user.
- `-P` is the password associated with the user.
- `-d` is the name of your Babelfish database.

After connecting, you can use many of the same commands that you use with SQL Server. For some examples, see Getting information from the Babelfish system catalog (p. 1336).

Using SSMS to connect to the DB cluster

You can connect to an Aurora PostgreSQL DB cluster running Babelfish by using Microsoft SQL Server Management Studio (SSMS). SSMS includes a variety of tools, including the SQL Server Import and Export Wizard discussed in Migrating a SQL Server database to Babelfish for Aurora PostgreSQL (p. 1314). For more information about SSMS, see Download SQL Server Management Studio (SSMS) in the Microsoft documentation.
To connect to your Babelfish database with SSMS

1. Start SSMS.
2. Open the Connect to Server dialog box. To continue with the connection, do one of the following:
   - Choose New Query.
   - If the Query Editor is open, choose Query, Connection, Connect.
3. Provide the following information for your database:
   a. For Server type, choose Database Engine.
   b. For Server name, enter the DNS name. For example, your server name should look similar to the following.

   ```
   cluster-name.cluster-555555555555.aws-region.rds.amazonaws.com,1433
   ```
   c. For Authentication, choose SQL Server Authentication.
   d. For Login, enter the user name that you chose when you created your database.
   e. For Password, enter the password that you chose when you created your database.

4. (Optional) Choose Options, and then choose the Connection Properties tab.
5. (Optional) For **Connect to database**, specify the name of the migrated SQL Server database to connect to, and choose **Connect**.

If a message appears indicating that SSMS can't apply connection strings, choose **OK**.

If you are having trouble connecting to Babelfish, see [Connection failure](p. 1361).

For more information about SQL Server connection issues, see [Troubleshooting connections to your SQL Server DB instance](in the Amazon RDS User Guide).
Using a PostgreSQL client to connect to your DB cluster

You can use a PostgreSQL client to connect to Babelfish on the PostgreSQL port.

Using psql to connect to the DB cluster

You can download the PostgreSQL client from the PostgreSQL website. Follow the instructions specific to your operating system version to install psql.

You can query an Aurora PostgreSQL DB cluster that supports Babelfish with the `psql` command line client. When connecting, use the PostgreSQL port (by default, port 5432). Typically, you don't need to specify the port number unless you changed it from the default. Use the following command to connect to Babelfish from the `psql` client:

```
psql -h `bfish-db.cluster-123456789012.aws-region.rds.amazonaws.com` -p 5432 -U postgres -d babelfish_db
```

The parameters are as follows:

- `-h` – The host name of the DB cluster (cluster endpoint) that you want to access.
- `-p` – The PostgreSQL port number used to connect to your DB instance.
- `-d` – The database that you want to connect to. The default is `babelfish_db`.
- `-U` – The database user account that you want to access. (The example shows the default master username.)

When you run a SQL command on the `psql` client, you end the command with a semicolon. For example, the following SQL command queries the `pg_tables` system view to return information about each table in the database.

```
SELECT * FROM pg_tables;
```

The `psql` client also has a set of built-in metacommands. A metacommand is a shortcut that adjusts formatting or provides a shortcut that returns meta-data in an easy-to-use format. For example, the following metacommand returns similar information to the previous SQL command:

```
\d
```

Metacommands don't need to be terminated with a semicolon (`;`).

To exit the `psql` client, enter `\q`.

For more information about using the `psql` client to query an Aurora PostgreSQL cluster, see the PostgreSQL documentation.

Using pgAdmin to connect to the DB cluster

You can use the pgAdmin client to access your data in native PostgreSQL dialect.

To connect to the cluster with the pgAdmin client

1. Download and install the pgAdmin client from the pgAdmin website.
2. Open the client and authenticate with pgAdmin.
3. Open the context (right-click) menu for Servers, and then choose Create, Server.
4. Enter information in the **Create - Server** dialog box.

On the **Connection** tab, add the Aurora PostgreSQL cluster address for **Host** and the PostgreSQL port number (by default, 5432) for **Port**. Provide authentication details, and choose **Save**.
After connecting, you can use pgAdmin functionality to monitor and manage your Aurora PostgreSQL cluster on the PostgreSQL port.

To learn more, see the pgAdmin web page.
Working with Babelfish

Following, you can find usage information for Babelfish, including some of the differences between working with Babelfish and SQL Server, and between Babelfish and PostgreSQL databases.

Topics

- Getting information from the Babelfish system catalog (p. 1336)
- Differences between Babelfish for Aurora PostgreSQL and SQL Server (p. 1339)
- Using Babelfish features with limited implementation (p. 1343)
- Improving Babelfish query performance (p. 1345)
- Using Aurora PostgreSQL extensions with Babelfish (p. 1350)
- Babelfish supports linked servers (p. 1357)

Getting information from the Babelfish system catalog

You can obtain information about the database objects that are stored in your Babelfish cluster by querying many of the same system views as used in SQL Server. Each new release of Babelfish adds support for more system views. For a list of available views currently available, see the SQL Server system catalog views table.

These system views provide information from the system catalog (sys.schemas). In the case of Babelfish, these views contain both SQL Server and PostgreSQL system schemas. To query Babelfish for system catalog information, you can use the TDS port or the PostgreSQL port, as shown in the following examples.

- Query the T-SQL port using sqlcmd or another SQL Server client.

  1> SELECT * FROM sys.schemas  
  2> GO

  This query returns SQL Server and Aurora PostgreSQL system schemas, as shown in the following.

  name
  -------------------------------
demographic_dbo
public
sys
master_dbo
tempdb_dbo
...

- Query the PostgreSQL port using psql or pgAdmin. This example uses the psql list schemas metacommand (\dn):

  babelfish_db=> \dn

  The query returns the same result set as that returned by sqlcmd on the T-SQL port.

<table>
<thead>
<tr>
<th>List of schemas</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>demographic_dbo</td>
</tr>
</tbody>
</table>
**SQL Server system catalogs available in Babelfish**

In the following table you can find the SQL Server views currently implemented in Babelfish. For more information about the system catalogs in SQL Server, see [System Catalog Views (Transact-SQL)](https://docs.microsoft.com/en-us/sql/relational-databases/system-catalog-views) in Microsoft documentation.

<table>
<thead>
<tr>
<th>View name</th>

</tbody>
</table>
### View name | Description or Babelfish limitation (if any)
---|---
``sys.endpoints`` | For information, see `sys.endpoints` in Microsoft Transact-SQL documentation.
``sys.indexes`` | For information, see `sys.indexes` in Microsoft Transact-SQL documentation.
``sys.languages`` | For information, see `sys.languages` in Microsoft Transact-SQL documentation.
``sys.schemas`` | All schemas
``sys.server_principals`` | All logins and roles
``sys.sql_modules`` | For information, see `sys.sql_modules` in Microsoft Transact-SQL documentation.
``sys.sysconfigures`` | Babelfish support limited to a single read-only configuration.
``sys.syscurconfig`` | Babelfish support limited to a single read-only configuration.
``sys.sysprocesses`` | For information, see `sys.sysprocesses` in Microsoft Transact-SQL documentation.
``sys.system_sql_modules`` | For information, see `sys.system_sql_modules` in Microsoft Transact-SQL documentation.
``sys.table_types`` | For information, see `sys.table_types` in Microsoft Transact-SQL documentation.
``sys.tables`` | All tables in a schema
``sys.xml_schema_collections`` | For information, see `sys.xml_schema_collections` in Microsoft Transact-SQL documentation.

PostgreSQL implements system catalogs that are similar to the SQL Server object catalog views. For a complete list of system catalogs, see [System Catalogs](#) in the PostgreSQL documentation.

## DDL exports supported by Babelfish

For Babelfish 2.4.0 and 3.1.0 versions, Babelfish supports DDL exports from various tools. For example, you can use this functionality from SQL Server Management Studio (SSMS) to generate the data definition scripts for various objects in a Babelfish for Aurora PostgreSQL database. You can then use the generated DDL commands in this script to create the same objects in another Babelfish for Aurora PostgreSQL or SQL Server database.

Babelfish supports DDL exports for the following objects in the specified versions.

<table>
<thead>
<tr>

</tbody>
</table>

Limitations with the exported DDLs

- **Use escape hatches before recreating the objects with the exported DDLs** – Babelfish doesn’t support all the commands in the exported DDL script. Use escape hatches to avoid errors caused when recreating the objects from the DDL commands in Babelfish. For more information on escape hatches, see [Managing Babelfish error handling with escape hatches](p. 1302).

- **Objects containing CHECK constraints with explicit COLLATE clauses** – The scripts with these objects generated from a SQL Server database have different but equivalent collations as in the Babelfish database. For example, a few collations, such as `sql_latin1_general_cp1_cs_as`, `sql_latin1_general_cp1251_cs_as`, and `latin1_general_cs_as` are generated as `latin1_general_cs_as`, which is the closest Windows collation.

Differences between Babelfish for Aurora PostgreSQL and SQL Server

Babelfish is an evolving Aurora PostgreSQL feature, with new functionality added in each release since the initial offering in Aurora PostgreSQL 13.4. It’s designed to provide T-SQL semantics on top of PostgreSQL through the T-SQL dialect using the TDS port. Each new version of Babelfish adds features and functions that better align with T-SQL functionality and behavior, as shown in the [Supported functionality in Babelfish by version](p. 1382) table. For best results when working with Babelfish, we recommend that you understand the differences that currently exist between the T-SQL supported by SQL Server and Babelfish for the latest version. To learn more, see [T-SQL differences in Babelfish](p. 1340).

In addition to the differences between T-SQL supported by Babelfish and SQL Server, you might also need to consider interoperability issues between Babelfish and PostgreSQL in the context of the Aurora PostgreSQL DB cluster. As mentioned previously, Babelfish supports T-SQL semantics on top of
PostgreSQL through the T-SQL dialect using the TDS port. At the same time, the Babelfish database can also be accessed through the standard PostgreSQL port with PostgreSQL SQL statements. If you're considering using both PostgreSQL and Babelfish functionality in a production deployment, you need to be aware of the potential interoperability issues between schema names, identifiers, permissions, transactional semantics, multiple result sets, default collations, and so on. In simple terms, when PostgreSQL statements or PostgreSQL access occur in the context of Babelfish, interference between PostgreSQL and Babelfish can occur and can potentially affecting syntax, semantics, and compatibility when new versions of Babelfish are released. For complete information and guidance about all the considerations, see the [Guidance on Babelfish Interoperability](#) in the Babelfish for PostgreSQL documentation.

**Note**

Before using both PostgreSQL native functionality and Babelfish functionality in the same application context, we strongly recommend that you consider the issues discussed in the [Guidance on Babelfish Interoperability](#) in the Babelfish for PostgreSQL documentation. These interoperability issues (Aurora PostgreSQL and Babelfish) are relevant only if you plan to use the PostgreSQL database instance in the same application context as Babelfish.

### T-SQL differences in Babelfish

Following, you can find a table of T-SQL functionality as supported in the current release of Babelfish with some notes about differences in the behavior from that of SQL Server.

For more information about support in various versions, see [Supported functionality in Babelfish by version (p. 1382)](#). For information about features that currently aren't supported, see [Unsupported functionality in Babelfish](#).

Babelfish is available with Aurora PostgreSQL-Compatible Edition. For more information about Babelfish releases, see the [Release Notes for Aurora PostgreSQL](#).

<table>
<thead>
<tr>
<th>Functionality or syntax</th>
<th>Description of behavior or difference</th>
</tr>
</thead>
<tbody>
<tr>
<td>\ (line continuation character)</td>
<td>The line continuation character (a backslash prior to a newline) for character and hexadecimal strings isn't currently supported. For character strings, the backslash-newline is interpreted as characters in the string. For hexadecimal strings, backslash-newline results in a syntax error.</td>
</tr>
<tr>
<td>@@version</td>
<td>The format of the value returned by <code>@version</code> is slightly different from the value returned by SQL Server. Your code might not work correctly if it depends on the formatting of <code>@version</code>.</td>
</tr>
<tr>
<td>Aggregate functions</td>
<td>Aggregate functions are partially supported (AVG, COUNT, COUNT_BIG, GROUPING, MAX, MIN, STRING_AGG, and SUM are supported). For a list of unsupported aggregate functions, see <a href="#">Functions that aren't supported (p. 1378)</a>.</td>
</tr>
<tr>
<td>ALTER TABLE</td>
<td>Supports adding or dropping a single column or constraint only.</td>
</tr>
<tr>
<td>ALTER TABLE..ALTER COLUMN</td>
<td><code>NULL</code> and <code>NOT NULL</code> can't currently be specified. To change the nullability of a column, use the PostgreSQL statement `ALTER TABLE..{SET</td>
</tr>
<tr>
<td>Blank column names with no column alias</td>
<td>The <code>sqlcmd</code> and <code>psql</code> utilities handle columns with blank names differently:</td>
</tr>
<tr>
<td></td>
<td>• SQL Server <code>sqlcmd</code> returns a blank column name.</td>
</tr>
<tr>
<td></td>
<td>• PostgreSQL <code>psql</code> returns a generated column name.</td>
</tr>
<tr>
<td>Functionality or syntax</td>
<td>Description of behavior or difference</td>
</tr>
<tr>
<td>Functionality or syntax</td>
<td>Description of behavior or difference</td>
</tr>
<tr>
<td>-------------------------</td>
<td>----------------------------------------</td>
</tr>
<tr>
<td>Identifiers exceeding 63 characters</td>
<td>PostgreSQL supports a maximum of 63 characters for identifiers. Babelfish converts identifiers longer than 63 characters to a name that includes a hash of the original name. For example, a table created as &quot;AB(ABC1234567890123456789012345678901234567890123456789012345678901234567890&quot; might be converted to &quot;ABC123456789012345678901234567890123456789012345678901234567890&quot;.</td>
</tr>
<tr>
<td>IDENTITY columns support</td>
<td>IDENTITY columns are supported for data types tinyint, smallint, int, bigint, numeric, and decimal. SQL Server supports precision to 38 places for data types numeric and decimal in IDENTITY columns. PostgreSQL supports precision to 19 places for data types numeric and decimal in IDENTITY columns.</td>
</tr>
<tr>
<td>Indexes with IGNORE_DUP_KEY</td>
<td>Syntax that creates an index that includes IGNORE_DUP_KEY creates an index as if this property is omitted.</td>
</tr>
<tr>
<td>Indexes with more than 32 columns</td>
<td>An index can't include more than 32 columns. Included index columns count toward the maximum in PostgreSQL but not in SQL Server.</td>
</tr>
<tr>
<td>Indexes (clustered)</td>
<td>Clustered indexes are created as if NONCLUSTERED was specified.</td>
</tr>
<tr>
<td>Index clauses</td>
<td>The following clauses are ignored: FILLFACTOR, ALLOW_PAGE_LOCKS, ALLOW_ROW_LOCKS, PAD_INDEX, STATISTICS_NORECOMPUTE, OPTIMIZE_FOR_SEQUENTIAL_KEY, SORT_IN_TEMPDB, DROP_EXISTING, ONLINE, COMPRESSION_DELAY, MAXDOP, and DATA_COMPRESSION.</td>
</tr>
<tr>
<td>JSON support</td>
<td>Table aliases can't be used currently to designate the result from the WITH clause. Stored procedures currently don't support the WITH clause. Order of the name-value pairs isn't guaranteed. But the array type remains unaffected.</td>
</tr>
<tr>
<td>LOGIN objects</td>
<td>All options for LOGIN objects are supported except for PASSWORD, DEFAULT_DATABASE, ENABLE, DISABLE.</td>
</tr>
<tr>
<td>NEWSEQUENTIALID function</td>
<td>Implemented as NEWID; sequential behavior isn't guaranteed. When calling NEWSEQUENTIALID, PostgreSQL generates a new GUID value.</td>
</tr>
<tr>
<td>OUTPUT clause is supported with the following limitations</td>
<td>OUTPUT and OUTPUT INTO aren't supported in the same DML query. References to non-target table of UPDATE or DELETE operations in an OUTPUT clause aren't supported. OUTPUT... DELETED *, INSERTED * aren't supported in the same query.</td>
</tr>
<tr>
<td>Procedure or function parameter limit</td>
<td>Babelfish supports a maximum of 100 parameters for a procedure or function.</td>
</tr>
<tr>
<td>ROLLBACK: table variables don't support transactional rollback</td>
<td>Processing might be interrupted if a rollback occurs in a session with table variables.</td>
</tr>
</tbody>
</table>
Using Babelfish features with limited implementation

Each new version of Babelfish adds support for features that better align with T-SQL functionality and behavior. Still, there are some unsupported features and differences in the current implementation. In the following, you can find information about functional differences between Babelfish and T-SQL, with some workarounds or usage notes.

As of version 1.2.0 of Babelfish, the following features currently have limited implementations:

- **SQL Server catalogs (system views)** – The catalogs sys.sysconfigures, sys.syscurconfigs, and sys.configurations support a single read-only configuration only. The sp_configure
isn’t currently supported. For more information about the other SQL Server views implemented by Babelfish, see Getting information from the Babelfish system catalog (p. 1336).

- **GRANT permissions** – GRANT…TO PUBLIC is supported, but GRANT..TO PUBLIC WITH GRANT OPTION is not currently supported.

- **SQL Server ownership chain and permission mechanism limitation** – In Babelfish, the SQL Server ownership chain works for views but not for stored procedures. This means that procedures must be granted explicit access to other objects owned by the same owner as the calling procedures. In SQL Server, granting the caller EXECUTE permissions on the procedure is sufficient to call other objects owned by same owner. In Babelfish, caller must also be granted permissions on the objects accessed by the procedure.

- **Resolution of unqualified (without schema name) object references** – When a SQL object (procedure, view, function or trigger) references an object without qualifying it with a schema name, SQL Server resolves the object’s schema name by using the schema name of the SQL object in which the reference occurs. Currently, Babelfish resolves this differently, by using the default schema of the database user executing the procedure.

- **Default schema changes, sessions, and connections** – If users change their default schema with ALTER USER . . . WITH DEFAULT SCHEMA, the change takes effect immediately in that session. However, for other currently connected sessions belonging to the same user, the timing differs, as follows:
  - For SQL Server: – The change takes effect across all other connections for this user immediately.
  - For Babelfish: – The change takes effect for this user for new connections only.

- **ROWVERSION and TIMESTAMP datatypes implementation and escape hatch setting** – The ROWVERSION and TIMESTAMP datatypes are now supported in Babelfish. To use ROWVERSION or TIMESTAMP in Babelfish, you must change the setting for the escape hatch babelfishpg_tsql.escape_hatch_rowversion from its default (strict) to ignore. The Babelfish implementation of the ROWVERSION and TIMESTAMP datatypes is mostly semantically identical to SQL Server, with the following exceptions:
  - The built-in @@DBTS function behaves similarly to SQL Server, but with small differences. Rather than returning the last-used value for SELECT @@DBTS, Babelfish generates a new timestamp, due to the underlying PostgreSQL database engine and its multi-version concurrency control (MVCC) implementation.
  - In SQL Server, every inserted or updated row gets a unique ROWVERSION/TIMESTAMP value. In Babelfish, every inserted row updated by the same statement is assigned the same ROWVERSION/TIMESTAMP value.

  For example, when an UPDATE statement or INSERT-SELECT statement affects multiple rows, in SQL Server, the affected rows all have different values in their ROWVERSION/TIMESTAMP column. In Babelfish (PostgreSQL), the rows have the same value.

  - In SQL Server, when you create a new table with SELECT-INTO, you can cast an explicit value (such as NULL) to a to-be-created ROWVERSION/TIMESTAMP column. When you do the same thing in Babelfish, an actual ROWVERSION/TIMESTAMP value is assigned to each row in the new table for you, by Babelfish.

  These minor differences in ROWVERSION/TIMESTAMP datatypes shouldn’t have an adverse impact on applications running on Babelfish.

- **Schema creation, ownership, and permissions** – Permissions to create and access objects in a schema owned by a non-DBO user (using CREATE SCHEMA schema name AUTHORIZATION user name) differ for SQL Server and Babelfish non-DBO users, as shown in the following table:
Improving Babelfish query performance

You can achieve faster query processing in Babelfish using query hints and the PostgreSQL optimizer.

Topics
- Using explain plan to improve Babelfish query performance (p. 1345)
- Using T-SQL query hints to improve Babelfish query performance (p. 1349)

You can also improve the query performance using sp_babelfish_volatility procedure. For more information, see sp_babelfish_volatility (p. 1394).

Using explain plan to improve Babelfish query performance

Starting with version 2.1.0, Babelfish includes two functions that transparently use the PostgreSQL optimizer to generate estimated and actual query plans for T-SQL queries on the TDS port. These functions are similar to using SET STATISTICS PROFILE or SET SHOWPLAN_ALL with SQL Server databases to identify and improve slow running queries.

Note
Getting query plans from functions, control flows, and cursors isn't currently supported.

In the table you can find a comparison of query plan explain functions across SQL Server, Babelfish, and PostgreSQL.

<table>
<thead>
<tr>
<th>SQL Server</th>
<th>Babelfish</th>

</tr>
<tr>
<td>• CURSOR</td>
<td>• CREATE</td>
<td>• CURSOR</td>
</tr>
<tr>
<td>• CREATE</td>
<td>• EXECUTE</td>
<td>• CREATE</td>
</tr>
</tbody>
</table>
Use the Babelfish functions as follows:

- **SET BABELFISH_SHOWPLAN_ALL [ON|OFF]** – Set to ON to generate an estimated query execution plan. This function implements the behavior of the PostgreSQL EXPLAIN command. Use this command to obtain the explain plan for given query.
- **SET BABELFISH_STATISTICS PROFILE [ON|OFF]** – Set to ON for actual query execution plans. This function implements the behavior of PostgreSQL's EXPLAIN ANALYZE command.

For more information about PostgreSQL EXPLAIN and EXPLAIN ANALYZE see [EXPLAIN](https://www.postgresql.org/docs/current/plan-visualize.html) in the PostgreSQL documentation.

**Note**
Starting with version 2.2.0, you can set the escape_hatch_showplan_all parameter to ignore in order to avoid the use of BABELFISH_ prefix in the SQL Server syntax for SHOWPLAN_ALL and STATISTICS PROFILE SET commands.

For example, the following command sequence turns on query planning and then returns an estimated query execution plan for the SELECT statement without running the query. This example uses the SQL Server sample northwind database using the sqlcmd command-line tool to query the TDS port:

```
1> SET BABELFISH_SHOWPLAN_ALL ON
2> GO
1> SELECT t.territoryid, e.employeeid FROM
dbo.employeeterritories e, dbo.territories t
3> WHERE e.territoryid=e.territoryid ORDER BY t.territoryid;
4> GO
```

**QUERY PLAN**

```
------------------------------------------------------------------------------------
Query Text: SELECT t.territoryid, e.employeeid FROM
dbo.employeeterritories e, dbo.territories t
WHERE e.territoryid=e.territoryid ORDER BY t.territoryid
Sort (cost=6231.74..6399.22 rows=66992 width=10)
Sort Key: t.territoryid NULLS FIRST
  ->  Nested Loop (cost=0.00..861.76 rows=66992 width=10)
    ->  Seq Scan on employeeterritories e (cost=0.00..22.70 rows=1264 width=4)
      Filter: ((territoryid)::"varchar" IS NOT NULL)
    ->  Materialize (cost=0.00..1.79 rows=53 width=6)
      ->  Seq Scan on territories t (cost=0.00..1.53 rows=53 width=6)
------------------------------------------------------------------------------------
```

When you finish reviewing and adjusting your query, you turn off the function as shown following:

```
1> SET BABELFISH_SHOWPLAN_ALL OFF
```
With BABELFISH_STATISTICS PROFILE set to ON, each executed query returns its regular result set followed by an additional result set that shows actual query execution plans. Babelfish generates the query plan that provides the fastest result set when it invokes the SELECT statement.

```
1> SET BABELFISH_STATISTICS PROFILE ON
2> GO
3> SELECT e.employeeid, t.territoryid FROM
dbo.employeeterritories e, dbo.territories t
4> WHERE t.territoryid=e.territoryid ORDER BY t.territoryid;
5> GO
```

The result set and the query plan are returned (this example shows only the query plan).

```
<table>
<thead>
<tr>
<th>QUERY PLAN</th>
</tr>
</thead>
</table>
| Query Text: SELECT e.employeeid, t.territoryid FROM
dbo.employeeterritories e, dbo.territories t
| WHERE t.territoryid=e.territoryid ORDER BY t.territoryid |
| Sort (cost=42.44..43.28 rows=337 width=10) |
| Sort Key: t.territoryid NULLS FIRST |
| -> Hash Join (cost=2.19..28.29 rows=337 width=10) |
| Hash Cond: ((e.territoryid)::"varchar" = (t.territoryid)::"varchar") |
| -> Seq Scan on employeeterritories e (cost=0.00..22.70 rows=1270 width=36) |
| -> Hash (cost=1.53..1.53 rows=53 width=6) |
| -> Seq Scan on territories t (cost=0.00..1.53 rows=53 width=6) |
```

To learn more about how to analyze your queries and the results returned by the PostgreSQL optimizer, see [explain.depesz.com](https://explain.depesz.com). For more information about PostgreSQL EXPLAIN and EXPLAIN ANALYZE, see [EXPLAIN](https://www.postgresql.org/docs/current/monitoring-explain.html) in the PostgreSQL documentation.

**Parameters that control Babelfish explain options**

You can use the parameters shown in the following table to control the type of information that's displayed by your query plan.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>babelfishpg_tsql.explain_buffers</td>
<td>A boolean that turns on (and off) buffer usage information for the optimizer. (Default: off) (Allowable: off, on)</td>
</tr>
<tr>
<td>babelfishpg_tsql.explain_costs</td>
<td>A boolean that turns on (and off) estimated startup and total cost information for the optimizer. (Default: on) (Allowable: on, off)</td>
</tr>
<tr>
<td>babelfishpg_tsql.explain_format</td>
<td>Specifies the output format for the EXPLAIN plan. (Default: text) (Allowable: text, xml, json, yaml)</td>
</tr>
<tr>
<td>babelfishpg_tsql.explain_settings</td>
<td>A boolean that turns on (or off) the inclusion of information about configuration parameters in the EXPLAIN plan output. (Default: off) (Allowable: off, on)</td>
</tr>
<tr>
<td>babelfishpg_tsql.explain_summary</td>
<td>A boolean that turns on (or off) summary information such as total time after the query plan. (Default: on) (Allowable: off, on)</td>
</tr>
</tbody>
</table>
### Parameter List

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>babelfishpg_tsql.explain_timing</td>
<td>A boolean that turns on (or off) actual startup time and time spent in each node in the output. (Default: on) (Allowable: off, on)</td>
</tr>
<tr>
<td>babelfishpg_tsql.explain_verbose</td>
<td>A boolean that turns on (or off) the most detailed version of an explain plan. (Default: off) (Allowable: off, on)</td>
</tr>
<tr>
<td>babelfishpg_tsql.explain_wal</td>
<td>A boolean that turns on (or off) generation of WAL record information as part of an explain plan. (Default: off) (Allowable: off, on)</td>
</tr>
</tbody>
</table>

You can check the values of any Babelfish-related parameters on your system by using either PostgreSQL client or SQL Server client. Run the following command to get your current parameter values:

```sql
1> execute sp_babelfish_configure '%explain%';
2> GO
```

In the following output, you can see that all settings on this particular Babelfish DB cluster are at their default values. Not all output is shown in this example.

<table>
<thead>
<tr>
<th>name</th>
<th>setting</th>
<th>short_desc</th>
</tr>
</thead>
<tbody>
<tr>
<td>babelfishpg_tsql.explain_buffers</td>
<td>off</td>
<td>Include information on buffer usage</td>
</tr>
<tr>
<td>babelfishpg_tsql.explain_costs</td>
<td>on</td>
<td>Include information on estimated startup and total cost</td>
</tr>
<tr>
<td>babelfishpg_tsql.explain_format</td>
<td>text</td>
<td>Specify the output format, which can be TEXT, XML, JSON, or YAML</td>
</tr>
<tr>
<td>babelfishpg_tsql.explain_settings</td>
<td>off</td>
<td>Include information on configuration parameters</td>
</tr>
<tr>
<td>babelfishpg_tsql.explain_summary</td>
<td>on</td>
<td>Include summary information (e.g., totaled timing information) after the query plan</td>
</tr>
<tr>
<td>babelfishpg_tsql.explain_timing</td>
<td>on</td>
<td>Include actual startup time and time spent in each node in the output</td>
</tr>
<tr>
<td>babelfishpg_tsql.explainVerbose</td>
<td>off</td>
<td>Display additional information regarding the plan</td>
</tr>
<tr>
<td>babelfishpg_tsql.explain_wal</td>
<td>off</td>
<td>Include information on WAL record generation</td>
</tr>
</tbody>
</table>

(8 rows affected)

You can change the setting for these parameters using `sp_babelfish_configure`, as shown in the following example.

```sql
1> execute sp_babelfish_configure 'explain_verbose', 'on';
2> GO
```

If you want make the setting permanent on a cluster-wide level, include the keyword `server`, as shown in the following example.

```sql
1> execute sp_babelfish_configure 'explain_verbose', 'on', 'server';
2> GO
```
Using T-SQL query hints to improve Babelfish query performance

Starting with version 2.3.0, Babelfish supports the use of query hints using pg_hint_plan. In Aurora PostgreSQL, pg_hint_plan is installed by default. For more information about the PostgreSQL extension pg_hint_plan, see https://github.com/ossc-db/pg_hint_plan. For details about the version of this extension supported by Aurora PostgreSQL, see Extension versions for Amazon Aurora PostgreSQL in Release Notes for Aurora PostgreSQL.

The query optimizer is well-designed to find the optimal execution plan for a SQL statement. When selecting a plan, the query optimizer considers both the engine’s cost model, and column and table statistics. However, the suggested plan might not meet the needs of your datasets. Thus, query hints address the performance issues to improve execution plans. A query hint is syntax added to the SQL standard that instructs the database engine about how to execute the query. For example, a hint may instruct the engine to follow a sequential scan and override any plan that the query optimizer had selected.

Turning on T-SQL query hints in Babelfish

Currently, Babelfish ignores all T-SQL hints by default. To apply T-SQL hints, run the command

```sql
EXECUTE sp_babelfish_configure 'enable_pg_hint', 'on' [, 'server']
```

You can make the settings permanent on a cluster-wide level by including the `server` keyword. To configure the setting for the current session only, don’t use `server`.

After `enable_pg_hint` is ON, Babelfish applies the following T-SQL hints.

- INDEX hints
- JOIN hints
- FORCE ORDER hint
- MAXDOP hint

For example, the following command sequence turns on `pg_hint_plan`.

```sql
1> CREATE TABLE t1 (a1 INT PRIMARY KEY, b1 INT);
2> CREATE TABLE t2 (a2 INT PRIMARY KEY, b2 INT);
3> GO
1> EXECUTE sp_babelfish_configure 'enable_pg_hint', 'on';
2> GO
1> SET BABELFISH_SHOWPLAN_ALL ON;
2> GO
1> SELECT * FROM t1 JOIN t2 ON t1.a1 = t2.a2; --NO HINTS (HASH JOIN)
2> GO
```

No hint is applied to the `SELECT` statement. The query plan with no hint is returned.

```
<table>
<thead>
<tr>
<th>QUERY PLAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Query Text: SELECT * FROM t1 JOIN t2 ON t1.a1 = t2.a2</td>
</tr>
<tr>
<td>Hash Join (cost=60.85..99.39 rows=2260 width=16)</td>
</tr>
<tr>
<td>Hash Cond: (t1.a1 = t2.a2)</td>
</tr>
<tr>
<td>-&gt; Seq Scan on t1 (cost=0.00..32.60 rows=2260 width=8)</td>
</tr>
<tr>
<td>-&gt; Hash (cost=32.60..32.60 rows=2260 width=8)</td>
</tr>
<tr>
<td>-&gt; Seq Scan on t2 (cost=0.00..32.60 rows=2260 width=8)</td>
</tr>
</tbody>
</table>
```
The query hint is applied to the SELECT statement. The following output shows that the query plan with merge join is returned.

```
1> SELECT * FROM t1 INNER MERGE JOIN t2 ON t1.a1 = t2.a2;
2> GO
```

```
The query hint is applied to the SELECT statement. The following output shows that the query plan with merge join is returned.

```
QUERY PLAN

----------
Query Text: SELECT/*+ MergeJoin(t1 t2) Leading(t1 t2)*/ * FROM t1 INNER JOIN t2 ON t1.a1 = t2.a2
Merge Join (cost=0.31..190.01 rows=2260 width=16)
  Merge Cond: (t1.a1 = t2.a2)
  -> Index Scan using t1_pkey on t1 (cost=0.15..78.06 rows=2260 width=8)
  -> Index Scan using t2_pkey on t2 (cost=0.15..78.06 rows=2260 width=8)
```

```
1> SET BABELFISH_SHOWPLAN_ALL OFF;
2> GO
```

**Limitations**

While using the query hints, consider the following limitations:

- If a query plan is cached before `enable_pg_hint` is turned on, hints won't be applied in the same session. It will be applied in the new session.
- If schema names are explicitly given, then hints can't be applied. You can use table aliases as a workaround.
- A query hint can't be applied to views and sub-queries.
- Hints don't work for UPDATE/DELETE statements with JOINs.
- An index hint for a non-existing index or table is ignored.
- The FORCE ORDER hint doesn't work for HASH JOINs and non-ANSI JOINs.

**Using Aurora PostgreSQL extensions with Babelfish**

Aurora PostgreSQL provides extensions for working with other AWS services. These are optional extensions that support various use cases, such as using Amazon S3 with your DB cluster for importing or exporting data.

- To import data from an Amazon S3 bucket to your Babelfish DB cluster, you set up the `aws_s3` Aurora PostgreSQL extension. This extension also lets you export data from your Aurora PostgreSQL DB cluster to an Amazon S3 bucket.
- AWS Lambda is a compute service that lets you run code without provisioning or managing servers. You can use Lambda functions to do things like process event notifications from your DB instance. To learn more about Lambda, see [What is AWS Lambda?](https://aws.amazon.com/lambda/) in the [AWS Lambda Developer Guide](https://docs.aws.amazon.com/lambda/latest/dg/). To invoke Lambda functions from your Babelfish DB cluster, you set up the `aws_lambda` Aurora PostgreSQL extension.

To set up these extensions for your Babelfish cluster, you first need to grant permission to the internal Babelfish user to load the extensions. After granting permission, you can then load Aurora PostgreSQL extensions.
Enabling Aurora PostgreSQL extensions in your Babelfish DB cluster

Before you can load the aws_s3 or the aws_lambda extensions, you grant the needed privileges to your Babelfish DB cluster.

The procedure following uses the psql PostgreSQL command line tool to connect to the DB cluster. For more information, see Using psql to connect to the DB cluster (p. 1333). You can also use pgAdmin. For details, see Using pgAdmin to connect to the DB cluster (p. 1333).

This procedure loads both aws_s3 and aws_lambda, one after the other. You don't need to load both if you want to use only one of these extensions. The aws_commons extension is required by each, and it's loaded by default as shown in the output.

To set up your Babelfish DB cluster with privileges for the Aurora PostgreSQL extensions

1. Connect to your Babelfish DB cluster. Use the name for the "master" user (-U) that you specified when you created the Babelfish DB cluster. The default (postgres) is shown in the examples.

   For Linux, macOS, or Unix:
   
   ```
   psql -h your-Babelfish.cluster.444455556666-us-east-1.rds.amazonaws.com \
   -U postgres \
   -d babelfish_db \
   -p 5432
   ```

   For Windows:
   
   ```
   psql -h your-Babelfish.cluster.444455556666-us-east-1.rds.amazonaws.com ^
   -U postgres ^
   -d babelfish_db ^
   -p 5432
   ```

   The command responds with a prompt to enter the password for the user name (-U).

   Password:

   Enter the password for the user name (-U) for the DB cluster. When you successfully connect, you see output similar to the following.

   ```
   psql (13.4)
   Type "help" for help.
   postgres=>
   ```

2. Grant privileges to the internal Babelfish user to create and load extensions.

   ```
   babelfish_db=> GRANT rds_superuser TO master_dbo;
   GRANT ROLE
   ```

3. Create and load the aws_s3 extension. The aws_commons extension is required, and it's installed automatically when the aws_s3 is installed.

   ```
   babelfish_db=> create extension aws_s3 cascade;
   NOTICE:  installing required extension "aws_commons"
   CREATE EXTENSION
   ```
4. Create and load the aws_lambda extension.

```
babelfish_db=> create extension aws_lambda cascade;
CREATE EXTENSION
babelfish_db=>
```

### Using Babelfish with Amazon S3

If you don’t already have an Amazon S3 bucket to use with your Babelfish DB cluster, you can create one. For any Amazon S3 bucket that you want to use, you provide access.

Before trying to import or export data using an Amazon S3 bucket, complete the following one-time steps.

**To set up access for your Babelfish DB instance to your Amazon S3 bucket**

1. Create an Amazon S3 bucket for your Babelfish instance, if needed. To do so, follow the instructions in [Create a bucket](https://docs.aws.amazon.com/AmazonS3/latest/userguide/create-bucket.html) in the Amazon Simple Storage Service User Guide.
2. Upload files to your Amazon S3 bucket. To do so, follow the steps in [Add an object to a bucket](https://docs.aws.amazon.com/AmazonS3/latest/userguide/upload-object.html) in the Amazon Simple Storage Service User Guide.
3. Set up permissions as needed:
   - To import data from Amazon S3, the Babelfish DB cluster needs permission to access the bucket. We recommend using an AWS Identity and Access Management (IAM) role and attaching an IAM policy to that role for your cluster. To do so, follow the steps in [Using an IAM role to access an Amazon S3 bucket](https://docs.aws.amazon.com/AmazonS3/latest/userguide/iam-access-control.html).
   - To export data from your Babelfish DB cluster, your cluster must be granted access to the Amazon S3 bucket. As with importing, we recommend using an IAM role and policy. To do so, follow the steps in [Setting up access to an Amazon S3 bucket](https://docs.aws.amazon.com/AmazonS3/latest/userguide/iam-access-control.html).

You can now use Amazon S3 with the aws_s3 extension with your Babelfish DB cluster.

### To import data from Amazon S3 to Babelfish and to export Babelfish data to Amazon S3

1. Use the aws_s3 extension with your Babelfish DB cluster.

   When you do, make sure to reference the tables as they exist in the context of PostgreSQL. That is, if you want to import into a Babelfish table named `[database]_[schema]_[tableA]`, refer to that table as `database_schema_tableA` in the aws_s3 function:

   - For an example of using an aws_s3 function to import data, see [Importing data from Amazon S3 to your Aurora PostgreSQL DB cluster](https://docs.aws.amazon.com/AmazonAurora/latest/userguide/amazon Aurora Amazon S3).  
   - For examples of using aws_s3 functions to export data, see [Exporting query data using the `aws_s3.query_export_to_s3` function](https://docs.aws.amazon.com/AmazonAurora/latest/userguide/amazon Aurora Amazon S3).

2. Make sure to reference Babelfish tables using PostgreSQL naming when using the aws_s3 extension and Amazon S3, as shown in the following table.

<table>
<thead>
<tr>
<th>Babelfish table</th>
<th>Aurora PostgreSQL table</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>database.schema.table</code></td>
<td><code>database_schema_table</code></td>
</tr>
</tbody>
</table>

1352
To learn more about using Amazon S3 with Aurora PostgreSQL, see Importing data from Amazon S3 into an Aurora PostgreSQL DB cluster (p. 1514) and Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3 (p. 1527).

Using Babelfish with AWS Lambda

After the aws._lambda extension is loaded in your Babelfish DB cluster but before you can invoke Lambda functions, you give Lambda access to your DB cluster by following this procedure.

To set up access for your Babelfish DB cluster to work with Lambda

This procedure uses the AWS CLI to create the IAM policy and role, and associate these with the Babelfish DB cluster.

1. Create an IAM policy that allows access to Lambda from your Babelfish DB cluster.

   ```bash
   aws iam create-policy --policy-name rds-lambda-policy --policy-document '{
   "Version": "2012-10-17",
   "Statement": [
     {
       "Sid": "AllowAccessToExampleFunction",
       "Effect": "Allow",
       "Action": "lambda:InvokeFunction",
     }
   ]
   }
   '}
   ```

2. Create an IAM role that the policy can assume at runtime.

   ```bash
   aws iam create-role --role-name rds-lambda-role --assume-role-policy-document '{
   "Version": "2012-10-17",
   "Statement": [
     {
       "Effect": "Allow",
       "Principal": {
         "Service": "rds.amazonaws.com"
       },
       "Action": "sts:AssumeRole"
     }
   ]
   '}
   ```

3. Attach the policy to the role.

   ```bash
   aws iam attach-role-policy
   --policy-arn arn:aws:iam::444455556666:policy/rds-lambda-policy
   --role-name rds-lambda-role
   --region aws-region
   ```

4. Attach the role to your Babelfish DB cluster

   ```bash
   aws rds add-role-to-db-cluster
   --db-cluster-identifier my-cluster-name
   --feature-name Lambda
   --role-arn arn:aws:iam::444455556666:role/rds-lambda-role
   --region aws-region
   ```

After you complete these tasks, you can invoke your Lambda functions. For more information and examples of setting up AWS Lambda for Aurora PostgreSQL DB cluster with AWS Lambda, see Step 2: Configure IAM for your Aurora PostgreSQL DB cluster and AWS Lambda (p. 1539).
To invoke a Lambda function from your Babelfish DB cluster

AWS Lambda supports functions written in Java, Node.js, Python, Ruby, and other languages. If the function returns text when invoked, you can invoke it from your Babelfish DB cluster. The following example is a placeholder python function that returns a greeting.

```
lambda_function.py
import json
def lambda_handler(event, context):
    #TODO implement
    return {
        'statusCode': 200,
        'body': json.dumps('Hello from Lambda!')
    }
```

Currently, Babelfish doesn't support JSON. If your function returns JSON, you use a wrapper to handle the JSON. For example, say that the `lambda_function.py` shown preceding is stored in Lambda as `my-function`.

1. Connect to your Babelfish DB cluster using the `psql` client (or the pgAdmin client). For more information, see [Using psql to connect to the DB cluster](p. 1333).
2. Create the wrapper. This example uses PostgreSQL's procedural language for SQL, PL/pgSQL. To learn more, see [PL/pgSQL–SQL Procedural Language](p. 1333).

```
create or replace function master_dbo.lambda_wrapper()
returns text
language plpgsql
as $$
declare
    r_status_code integer;
    r_payload text;
begin
    SELECT payload INTO r_payload
    FROM aws_lambda.invoke(  aws_commons.create_lambda_function_arn('my-function',
        'us-east-1')
        ,{"body": "Hello from Postgres!"}::json );
    return r_payload ;
end;
$$;
```

The function can now be run from the Babelfish TDS port (1433) or from the PostgreSQL port (5433).

a. To invoke (call) this function from your PostgreSQL port:

```
SELECT * from aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-function', 'us-east-1'), '{"body": "Hello from Postgres!"'}::json );
```

The output is similar to the following:

```
<table>
<thead>
<tr>
<th>status_code</th>
<th>payload</th>
<th>executed_version</th>
<th>log_result</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>{&quot;statusCode&quot;: 200, &quot;body&quot;: &quot;Hello from Lambda!&quot;}</td>
<td>$LATEST</td>
<td></td>
</tr>
</tbody>
</table>
(1 row)
```
b. To invoke (call) this function from the TDS port, connect to the port using the SQL Server sqlcmd command line client. For details, see Using a SQL Server client to connect to your DB cluster (p. 1330). When connected, run the following:

```
1> select lambda_wrapper();
2> go
```

The command returns output similar to the following:

```
{"statusCode": 200, "body": "\"Hello from Lambda!\""}
```

To learn more about using Lambda with Aurora PostgreSQL, see Invoking an AWS Lambda function from an Aurora PostgreSQL DB cluster (p. 1538). For more information about working with Lambda functions, see Getting started with Lambda in the AWS Lambda Developer Guide.

### Using pg_stat_statements in Babelfish

Babelfish for Aurora PostgreSQL supports pg_stat_statements extension from 3.3.0. To learn more, see pg_stat_statements.

For details about the version of this extension supported by Aurora PostgreSQL, see Extension versions.

#### Creating pg_stat_statements extension

To turn on pg_stat_statements, you must turn on the Query identifier calculation. This is done automatically if compute_query_id is set to on or auto in the parameter group. The default value of compute_query_id parameter is auto. You also need to create this extension to turn on this feature.

Use the following command to install the extension from T-SQL endpoint:

```
1> EXEC sp_execute_postgresql 'CREATE EXTENSION pg_stat_statements WITH SCHEMA sys';
```

You can access the query statistics using the following query:

```
postgres=>select * from pg_stat_statements;
```

**Note**

During installation, if you don't provide the schema name for the extension then by default it will create it in public schema. To access it, you must use square brackets with schema qualifier as shown below:

```
postgres=>select * from [public].pg_stat_statements;
```

You can also create the extension from PSQL endpoint.

#### Authorizing the extension

By default, you can see the statistics for queries performed within your T-SQL database without the need of any authorization.

To access query statistics created by others, you need to have pg_read_all_stats PostgreSQL role. Follow the steps mentioned below to construct GRANT pg_read_all_stats command.
1. In T-SQL, use the following query that returns the internal PG role name.

   ```sql
   SELECT rolname FROM pg_roles WHERE oid = USER_ID();
   ```

2. Connect to Babelfish for Aurora PostgreSQL database with rds_superuser privilege and use the following command:

   ```sql
   GRANT pg_read_all_stats TO <rolname_from_above_query>
   ```

**Example**

**From T-SQL endpoint:**

1>SELECT rolname FROM pg_roles WHERE oid = USER_ID();
2>go

   rolname
   -------
   master_dbo
   (1 rows affected)

**From PSQL endpoint:**

babelfish_db=# grant pg_read_all_stats to master_dbo;

   GRANT ROLE

You can access the query statistics using the `pg_stat_statements` view:

1>create table t1(cola int);
2>go
1>insert into t1 values (1),(2),(3);
2>go

   (3 rows affected)

1>select userid, dbid, queryid, query from pg_stat_statements;
2>go

   userid dbid queryid query
   ------ ---- ------- ----- ------- ---- ------
   37503 34582 6487973085327558478 select * from t1
   37503 34582 6284378402749466286 SET QUOTED_IDENTIFIER OFF
   37503 34582 2864302298511657420 insert into t1 values ($1),($2),($3)
   10 34582 NULL <insufficient privilege>
   37503 34582 5615368793313871642 SET TEXTSIZE 4096
   37503 34582 6394008181530803392 create table t1(cola int)
   (6 rows affected)
Resetting query statistics

You can use `pg_stat_statements_reset()` to reset the statistics gathered so far by `pg_stat_statements`. To learn more, see `pg_stat_statements`. It is currently supported through PSQL endpoint only. Connect to Babelfish for Aurora PostgreSQL with `rds_superuser` privilege, use the following command:

```
SELECT pg_stat_statements_reset();
```

Limitations

- Currently, `pg_stat_statements()` is not supported through T-SQL endpoint. `pg_stat_statements` view is the recommended way to gather the statistics.
- Some of the queries might be re-written by the T-SQL parser implemented by Aurora PostgreSQL engine, `pg_stat_statements` view will show the re-written query and not the original query.

Example

```
select next value for [dbo].[newCounter];
```

The above query is re-written as the following in the `pg_stat_statements` view.

```
select nextval($1);
```

- Based on the execution flow of the statements, some of the queries might not be tracked by `pg_stat_statements` and will not be visible in the view. This includes the following statements: use `dbname`, `goto`, `print`, `raise error`, `set`, `throw`, `declare cursor`.
- For `CREATE LOGIN` and `ALTER LOGIN` statements, `query` and `queryid` will not be shown. It will show insufficient privileges.
- `pg_stat_statements` view always contains the below two entries, as these are executed internally by `sqlcmd` client.
  - SET QUOTED_IDENTIFIER OFF
  - SET TEXTSIZE 4096

Babelfish supports linked servers

Babelfish for Aurora PostgreSQL supports linked servers by using the PostgreSQL `tds_fdw` extension in version 3.1.0. To work with linked servers, you must install the `tds_fdw` extension. For more information about the `tds_fdw` extension, see Working with the supported foreign data wrappers for Amazon Aurora PostgreSQL (p. 1653).

Installing the `tds_fdw` extension

You can install `tds_fdw` extension using the following methods.

Using CREATE EXTENSION from PostgreSQL endpoint

1. Connect to your PostgreSQL DB instance on the Babelfish database in the PostgreSQL port. Use an account that has the `rds_superuser` role.

```
psql --host=your-DB-instance.aws-region.rds.amazonaws.com --port=5432 --username=test --dbname=babelfish_db --password
```
2. Install the `tds_fdw` extension. This is a one-time installation process. You don't need to reinstall when the DB cluster restarts.

```
babelfish_db=> CREATE EXTENSION tds_fdw;
CREATE EXTENSION
```

**Calling sp_execute_postgresql stored procedure from TDS endpoint**

Babelfish supports installing `tds_fdw` extension by calling `sp_execute_postgresql` procedure from version 3.3.0. You can execute PostgreSQL statements from T-SQL endpoint without exiting the T-SQL port. For more information, see [Babelfish for Aurora PostgreSQL procedure reference](p. 1394)

1. Connect to your PostgreSQL DB instance on the Babelfish database in the T-SQL port.

```
sqlcmd -S your-DB-instance.aws-region.rds.amazonaws.com -U test -P password
```

2. Install the `tds_fdw` extension.

```
1>EXEC sp_execute_postgresql N'CREATE EXTENSION tds_fdw';
2>go
```

**Supported functionality**

Babelfish supports adding remote RDS for SQL Server or Babelfish for Aurora PostgreSQL endpoints as the linked server. You can also add other remote SQL Server instances as linked servers. Then, use `OPENQUERY()` to retrieve data from these linked servers. Starting from Babelfish version 3.2.0, four-part names are also supported.

The following stored procedures and catalog views are supported in order to use the linked servers.

**Stored procedures**

- `sp_addlinkedserver` – Babelfish doesn't support the `@provstr` parameter.
- `sp_addlinkedsrvlogin`
  - You must provide an explicit remote username and password to connect to the remote data source. You can't connect with the user's self credentials. Babelfish supports only `@useself = false`.
  - Babelfish doesn't support the `@locallogin` parameter since configuring remote server access specific to local login isn't supported.
- `sp_linkedservers`
- `sp_helplinkedsrvlogin`
- `sp_dropserver`
- `sp_droplinkedsrvlogin` – Babelfish doesn't support the `@locallogin` parameter since configuring remote server access specific to local login isn't supported.
- `sp_serveroption` – Babelfish supports the following server options:
  - query timeout (from Babelfish version 3.2.0)
  - connect timeout (from Babelfish version 3.3.0)
- `sp_testlinkedserver`
- `sp_enum_oledb_providers` (from Babelfish version 3.3.0)

**Catalog views**
Using encryption in transit for the connection

The connection from the source Babelfish for Aurora PostgreSQL server to the target remote server uses encryption in transit (TLS/SSL), depending on the remote server database configuration. If the remote server isn't configured for encryption, the Babelfish server making the request to the remote database falls back to unencrypted.

To enforce connection encryption

- If the target linked server is an RDS for SQL Server instance, set `rds.force_ssl = on` for the target SQL Server instance. For more information about SSL/TLS configuration for RDS for SQL Server, see Using SSL with a Microsoft SQL Server DB instance.
- If the target linked server is a Babelfish for Aurora PostgreSQL cluster, set `babelfishpg_tsql.tds_ssl_encrypt = on` and `ssl = on` for the target server. For more information about SSL/TLS, see Babelfish SSL settings and client connections (p. 1290).

Adding Babelfish as a linked server from SQL Server

Babelfish for Aurora PostgreSQL can be added as a linked server from a SQL Server. On a SQL Server database, you can add Babelfish as a linked server using Microsoft OLE DB provider for ODBC: MSDASQL.

There are two ways to configure Babelfish as a linked server from SQL Server using MSDASQL provider:

- Providing ODBC connection string as the provider string.
- Provide the System DSN of ODBC data source while adding the linked server.

Limitations

- OPENQUERY() works only for SELECT and doesn't work for DML.
- Four-part object names work only for reading and doesn't work for modifying the remote table. An UPDATE can reference a remote table in the FROM clause without modifying it.
- Executing stored procedures against Babelfish linked servers isn't supported.
- Babelfish major version upgrade might not work if there are objects dependent on OPENQUERY() or objects referenced through four-part names. You must ensure that any objects referencing OPENQUERY() or four-part names are dropped before a major version upgrade.
- The following datatypes don't work as expected against remote Babelfish server: `nvarchar(max)`, `varchar(max)`, `varbinary(max)`, `binary(max)` and `time`. We recommend using the CAST function to convert these to the supported datatypes.

Example

In the following example, a Babelfish for Aurora PostgreSQL instance is connecting to an instance of RDS for SQL Server in the cloud.

```sql
EXEC master.dbo.sp_addlinkedserver @server=N'rds_sqlserver', @srvproduct=N'',
    @provider=N'SQLNCLI', @datasrc=N'myserver.CB2KF5FFMY7.US-WEST-2.RDS.AMAZONAWS.COM';
EXEC master.dbo.sp_addlinkedsrvlogin
    @rmtsrvname=N'rds_sqlserver', @useself=N'False', @locallogin=NULL, @rmtuser=N'username', @rmtpassword='pass';
```
When the linked server is in place, you can then use T-SQL OPENQUERY() or standard four-part naming to reference a table, view, or other supported objects, on the remote server:

```sql
SELECT * FROM OPENQUERY(rds_sqlserver, 'SELECT * FROM TestDB.dbo.t1');
SELECT * FROM rds_sqlserver.TestDB.dbo.t1;
```

To drop the linked server and all associated logins:

```sql
EXEC master.dbo.sp_dropserver @server=N'rds_sqlserver', @droplogins=N'droplogins';
```

### Troubleshooting

You can use the same security group for both source and remote servers to allow them to communicate with each other. Security group should allow only inbound traffic on TDS port (1433 by default) and source IP in security group can be set as the security group ID itself. For more information on how to set the rules for connecting to an instance from another instance with the same security group, see [Rules to connect to instances from an instance with the same security group](#).

If access isn't configured correctly, an error message similar to the following example appears when you try to query the remote server.

TDS client library error: DB #: 20009, DB Msg: Unable to connect: server is unavailable or does not exist (mssql2019.aws-region.rds.amazonaws.com), OS #: 110, OS Msg: Connection timed out, Level: 9
Troubleshooting Babelfish

Following, you can find troubleshooting ideas and workarounds for some Babelfish DB cluster issues.

Topics

- Connection failure (p. 1361)

Connection failure

Common causes of connection failures to a new Aurora DB cluster with Babelfish include the following:

- **Security group doesn't allow access** – If you're having trouble connecting to a Babelfish, make sure that you added your IP address to the default Amazon EC2 security group. You can use [https://checkip.amazonaws.com/](https://checkip.amazonaws.com/) to determine your IP address and then add it to your in-bound rule for the TDS port and the PostgreSQL port. For more information, see [Add rules to a security group](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/using-rules.html) in the Amazon EC2 User Guide.

- **Mismatching SSL configurations** – If the `rds.force_ssl` parameter is turned on (set to 1) on Aurora PostgreSQL, then clients must connect to Babelfish over SSL. If your client isn't set up correctly, you see an error message such as the following:

```plaintext
Cannot connect to your-Babelfish-DB-cluster, 1433
---------------------
ADDITIONAL INFORMATION:
no pg_hba_conf entry for host "256.256.256.256", user "your-user-name",
"database babelfish_db", SSL off (Microsoft SQL Server, Error: 33557097)
...
```

This error indicates a possible SSL configuration issue between your local client and the Babelfish DB cluster, and that the cluster requires clients to use SSL (its `rds.force_ssl` parameter is set to 1). For more information about configuring SSL, see [Using SSL with a PostgreSQL DB instance](https://docs.aws.amazon.com/rds/latest/userguide/postgresql-config-ssl.html) in the Amazon RDS User Guide.

If you are using SQL Server Management Studio (SSMS) to connect to Babelfish and you see this error, you can choose **Encrypt connection** and **Trust server certificate** connection options on the Connection Properties pane and try again. These settings handle the SSL connection requirement for SSMS.

For more information about troubleshooting Aurora connection issues, see [Can't connect to Amazon RDS DB instance](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-troubleshooting.html#aurora-troubleshooting-connectivity) (p. 2511).
Turning off Babelfish

When you no longer need Babelfish, you can turn off Babelfish functionality.

Be aware of some considerations:

- In some cases, you might turn off Babelfish before completing a migration to Aurora PostgreSQL. If you do and your DDL depends on SQL Server data types or you use any T-SQL functionality in your code, your code fails.
- If after provisioning a Babelfish instance you turn off the Babelfish extension, you can't provision that same database again on the same cluster.

To turn off Babelfish, modify your parameter group, setting `rds.babelfish_status` to OFF. You can continue to use your SQL Server data types with Babelfish off, by setting `rds.babelfish_status` to `datatypeonly`.

If you turn off Babelfish in parameter group, all clusters that use that parameter group lose Babelfish functionality.

For more information about modifying parameter groups, see [Working with parameter groups](p. 212). For information about Babelfish–specific parameters, see [DB cluster parameter group settings for Babelfish](p. 1287).
Babelfish version updates

Babelfish is an option available with Aurora PostgreSQL version 13.4 and higher releases. Updates to Babelfish become available with certain new releases of the Aurora PostgreSQL database engine. For more information, see the Release Notes for Aurora PostgreSQL.

**Note**

Babelfish DB clusters running on any version of Aurora PostgreSQL 13 can’t be upgraded to Aurora PostgreSQL 14.3, 14.4, and 14.5. Also, Babelfish doesn’t support a direct upgrade from 13.x to 15.x. You must first upgrade your 13.x DB cluster to 14.6 and higher version and then upgrade to 15.x version.

For a list of supported functionality across different Babelfish releases, see Supported functionality in Babelfish by version (p. 1382).

For a list of currently unsupported functionality, see Unsupported functionality in Babelfish (p. 1374).

You can use the describe-db-engine-versions AWS CLI command to get a list of Aurora PostgreSQL versions in your AWS Region that support Babelfish, as shown in the following example.

For Linux, macOS, or Unix:

```
$ aws rds describe-db-engine-versions --region us-east-1 \
   --engine aurora-postgresql \
   --query '*[]|[?SupportsBabelfish==`true`].[EngineVersion]' \
   --output text
```

13.4
13.5
13.6
13.7
13.8
14.3
14.4
14.5
14.6
14.7
15.2
15.3
15.4

For more information, see describe-db-engine-versions in the AWS CLI Command Reference.

In the following topics, you can learn how to identify the version of Babelfish running on your Aurora PostgreSQL DB cluster, and how to upgrade to a new version.

Contents

- Identifying your version of Babelfish (p. 1364)
- Upgrading your Babelfish cluster to a new version (p. 1365)
  - Upgrading Babelfish to a new minor version (p. 1366)
  - Upgrading Babelfish to a new major version (p. 1368)
    - Before upgrading Babelfish to a new major version (p. 1368)
    - Performing major version upgrade (p. 1369)
    - After upgrading to a new major version (p. 1369)
    - Example: Upgrading the Babelfish DB cluster to a major release (p. 1371)
- Using Babelfish product version parameter (p. 1372)
  - Configuring Babelfish product version parameter (p. 1372)
  - Affected queries and parameter (p. 1373)
  - Interface with babelfishpg_tsql.version parameter (p. 1373)
Identifying your version of Babelfish

You can query Babelfish to find details about the Babelfish version, the Aurora PostgreSQL version, and the compatible Microsoft SQL Server version. You can use the TDS port or the PostgreSQL port.

- **To use the TDS port to query for version information**
- **To use the PostgreSQL port to query for version information**

**To use the TDS port to query for version information**

1. Use `sqlcmd` or `ssms` to connect to the endpoint for your Babelfish DB cluster.

   ```
   sqlcmd -S `bfish_db.cluster-123456789012.aws-region.rds.amazonaws.com`,1433 -U login-id -P password -d db_name
   ```

2. To identify the Babelfish version, run the following query:

   ```
   1> SELECT CAST(serverproperty('babelfishversion') AS VARCHAR) AS 'serverproperty'
   2> GO
   ```

   The query returns results similar to the following:

   ```
   serverproperty
   ------------------------
   3.3.0
   (1 rows affected)
   ```

3. To identify the version of the Aurora PostgreSQL DB cluster, run the following query:

   ```
   1> SELECT aurora_version() AS 'aurora_version'
   2> GO
   ```

   The query returns results similar to the following:

   ```
   aurora_version
   ------------------------
   15.4.1
   (1 rows affected)
   ```

4. To identify the compatible Microsoft SQL Server version, run the following query:

   ```
   1> SELECT @@VERSION AS 'version'
   2> GO
   ```

   The query returns results similar to the following:

   ```
   Babelfish for Aurora PostgreSQL with SQL Server Compatibility - 12.0.2000.8
   Oct 21 2023 09:43:06
   Copyright (c) Amazon Web Services
   PostgreSQL 15.4 on x86_64-pc-linux-gnu (Babelfish 3.3.0)
   (1 rows affected)
   ```
As an example that shows one minor difference between Babelfish and Microsoft SQL Server, you can run the following query. On Babelfish, the query returns 1, while on Microsoft SQL Server, the query returns NULL.

```sql
SELECT CAST(serverproperty('babelfish') AS VARCHAR) AS runs_on_babelfish
```

You can also use the PostgreSQL port to obtain version information, as shown in the following procedure.

**To use the PostgreSQL port to query for version information**

1. Use `psql` or `pgAdmin` to connect to the endpoint for your Babelfish DB cluster.

   ```bash
   psql host=bfish_db.cluster-123456789012.aws-region.rds.amazonaws.com port=5432 dbname=babelfish_db user=sa
   ```

2. Turn on the extended feature (`\x`) of `psql` for more readable output.

   ```bash
   babelfish_db=> \x
   babelfish_db=> SELECT babelfish_db=> aurora_version() AS aurora_version,
   babelfish_db=> version() AS postgresql_version,
   babelfish_db=> sys.version() AS Babelfish_compatibility,
   babelfish_db=> sys.SERVERPROPERTY('BabelfishVersion') AS Babelfish_Version;
   ```

The query returns output similar to the following:

```
- [ RECORD 1 ]----------
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>aurora_version</td>
</tr>
</tbody>
</table>
| postgresql_version      | PostgreSQL 15.4 on x86_64-pc-linux-gnu, compiled by x86_64-
|                          | pc-linux-gnu-gcc (GCC) 9.5.0, 64-bit |
| babelfish_compatibility | Babelfish for Aurora Postgres with SQL Server Compatibility -12.0.2000.8 |
|                          | | Oct 21 2023 09:43:06 |
|                          | | Copyright (c) Amazon Web Services |
|                          | | PostgreSQL 15.4 on x86_64-pc-linux-gnu (Babelfish 3.3.0) |
| babelfish_version       | 3.3.0                  |
```

**Upgrading your Babelfish cluster to a new version**

New versions of Babelfish become available with some new releases of the Aurora PostgreSQL database engine after version 13.4. Each new release of Babelfish has its own version number. As with Aurora PostgreSQL, Babelfish uses the `major.minor.patch` naming scheme for versions. For example, the first Babelfish release, Babelfish version 1.0.0, became available as part of Aurora PostgreSQL 13.4.0.

Babelfish doesn't require a separate installation process. As discussed in [Creating a Babelfish for Aurora PostgreSQL DB cluster](p. 1307), Turn on Babelfish is an option that you choose when you create an Aurora PostgreSQL DB cluster.

Likewise, you can't upgrade Babelfish independently from the supporting Aurora DB cluster. To upgrade an existing Babelfish for Aurora PostgreSQL DB cluster to a new version of Babelfish, you upgrade the Aurora PostgreSQL DB cluster to a new version that supports the version of Babelfish that you want to use. The procedure that you follow for the upgrade depends on the version of Aurora PostgreSQL that's supporting your Babelfish deployment, as follows.
**Major version upgrades**

You must upgrade the following Aurora PostgreSQL versions to Aurora PostgreSQL 14.6 and higher version before upgrading to Aurora PostgreSQL 15.2 version.

- Aurora PostgreSQL 13.8 and all higher versions
- Aurora PostgreSQL 13.7.1 and all higher minor versions
- Aurora PostgreSQL 13.6.4 and all higher minor versions

You can upgrade Aurora PostgreSQL 14.6 and higher versions to Aurora PostgreSQL 15.2 and higher versions.

Upgrading an Aurora PostgreSQL DB cluster to a new major version involves several preliminary tasks. For more information, see [How to perform a major version upgrade](p. 1786). To successfully upgrade your Babelfish for Aurora PostgreSQL DB cluster, you need to create a custom DB cluster parameter group for the new Aurora PostgreSQL version. This new parameter group must contain the same Babelfish parameter settings as that of the cluster that you're upgrading. For more information and for a table of major version upgrade sources and targets, see [Upgrading Babelfish to a new major version](p. 1368).

**Minor version upgrades and patches**

Minor versions and patches don't require the creation of a new DB cluster parameter group for the upgrade. Minor versions and patches can use the minor version upgrade process, whether that's applied automatically or manually. For more information and a table of version sources and targets, see [Upgrading Babelfish to a new minor version](p. 1366).

**Note**

Before performing a major or a minor upgrade, apply all pending maintenance tasks to your Babelfish for Aurora PostgreSQL cluster.

**Topics**

- [Upgrading Babelfish to a new minor version](p. 1366)
- [Upgrading Babelfish to a new major version](p. 1368)

### Upgrading Babelfish to a new minor version

A new minor version includes only changes that are backward compatible. A patch version includes important fixes for a minor version after its release. For example, the version label for the first release of Aurora PostgreSQL 13.4 was Aurora PostgreSQL 13.4.0. Several patches for that minor version have been released to date, including Aurora PostgreSQL 13.4.1, 13.4.2, and 13.4.4. You can find the patches available for each Aurora PostgreSQL version in the [Patch releases](p. 1366) list at the top of the Aurora PostgreSQL release notes for that version. For an example, see [PostgreSQL 14.3](p. 1366) in the [Release Notes for Aurora PostgreSQL](p. 1366).

If your Aurora PostgreSQL DB cluster is configured with the [Auto minor version upgrade](p. 1366) option, your Babelfish for Aurora PostgreSQL DB cluster is upgraded automatically during the cluster's maintenance window. To learn more about auto minor version upgrade (AmVU) and how to use it, see [Automatic minor version upgrades for Aurora DB clusters](p. 351). If your cluster isn't using AmVU, you can manually upgrade your Babelfish for Aurora PostgreSQL DB cluster to new minor versions either by responding to maintenance tasks, or by modifying the cluster to use the new version.

When you choose an Aurora PostgreSQL version to install and when you view an existing Aurora PostgreSQL DB cluster in the AWS Management Console, the version displays the major.minor digits only. For example, the following image from the Console for an existing Babelfish for Aurora PostgreSQL DB cluster with Aurora PostgreSQL 13.4 recommends upgrading the cluster to version 13.7, a new minor release of Aurora PostgreSQL.
To get complete version details, including the patch level, you can query the Aurora PostgreSQL DB cluster using the `aurora_version` Aurora PostgreSQL function. For more information, see `aurora_version (p. 1723)` in the `Aurora PostgreSQL functions reference (p. 1692)`. You can find an example of using the function in the `To use the PostgreSQL port to query for version information` procedure in `Identifying your version of Babelfish (p. 1364)`.

The following table shows Aurora PostgreSQL and Babelfish version and the available target versions that can support the minor version upgrade process.

<table>
<thead>
<tr>
<th>Current source versions</th>
<th>Newest upgrade targets</th>
<th>Other available upgrade versions</th>

</table>
Upgrading Babelfish to a new major version

For a major version upgrade, you need to first upgrade your Babelfish for Aurora PostgreSQL DB cluster to a version that supports the major version upgrade. To achieve this, apply patch updates or minor version upgrades to your DB cluster. For more information, see Upgrading Babelfish to a new minor version (p. 1366).

The following table shows Aurora PostgreSQL version and Babelfish version that can support a major version upgrade.

<table>
<thead>
<tr>
<th>Current source versions</th>
<th>Newest available upgrade target</th>
<th>Other available versions (minor version upgrades)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora PostgreSQL</td>
<td>Babelfish</td>
<td>Aurora PostgreSQL version (Babelfish version)</td>
</tr>
<tr>
<td>14.9.1</td>
<td>2.6.0</td>
<td>15.4.1</td>
</tr>
<tr>
<td>14.8</td>
<td>2.4.0</td>
<td>15.3</td>
</tr>
<tr>
<td>14.7</td>

</tr>
<tr>
<td>13.6.4</td>
<td>1.2.2</td>
<td>14.6</td>
</tr>
</tbody>
</table>

Before upgrading Babelfish to a new major version

An upgrade might involve brief outages. For that reason, we recommend that you perform or schedule upgrades during your maintenance window or during other periods of low usage.

Before you perform a major version upgrade

1. Identify the Babelfish version of your existing Aurora PostgreSQL DB cluster by using the commands outlined in Identifying your version of Babelfish (p. 1364). The Aurora PostgreSQL version and Babelfish version information is handled by PostgreSQL, so follow the steps detailed in the To use the PostgreSQL port to query for version information procedure to get the details.

2. Verify if your version supports the major version upgrade. For the list of versions that support the major version upgrade feature, see Upgrading Babelfish to a new minor version (p. 1366) and perform the necessary pre-upgrade tasks.
For example, if your Babelfish version is running on an Aurora PostgreSQL 13.5 DB cluster and you want to upgrade to Aurora PostgreSQL 15.2, then first apply all the minor releases and patches to upgrade your cluster to Aurora PostgreSQL 14.6 or higher version. When your cluster is at version 14.6 or higher, continue with the major version upgrade process.

3. Create a manual snapshot of your current Babelfish DB cluster as a backup. The backup lets you restore the cluster to its Aurora PostgreSQL version, Babelfish version, and restore all data to the state before the upgrade. For more information, see Creating a DB cluster snapshot (p. 437). Be sure to keep your existing custom DB cluster parameter group to use again if you decide to restore this cluster to its pre-upgraded state. For more information, see Restoring from a DB cluster snapshot (p. 439) and Parameter group considerations (p. 439).

4. Prepare a custom DB cluster parameter group for the target Aurora PostgreSQL DB version. Duplicate the settings for the Babelfish parameters from your current Babelfish for Aurora PostgreSQL DB cluster. To find a list of all Babelfish parameters, see DB cluster parameter group settings for Babelfish (p. 1287). For a major version upgrade, the following parameters require the same settings as the source DB cluster. For the upgrade to succeed, all the settings must be the same.

   • rds.babelfish_status
   • babelfishpg_tds.tds_default_numeric_precision
   • babelfishpg_tds.tds_default_numeric_scale
   • babelfishpg_tsql.database_name
   • babelfishpg_tsql.default_locale
   • babelfishpg_tsql.migration_mode
   • babelfishpg_tsql.server_collation_name

   **Warning**
   If the settings for the Babelfish parameters in the custom DB cluster parameter group for the new Aurora PostgreSQL version don't match the parameter values of the cluster you're upgrading, the ModifyDBCluster operation fails. An InvalidParameterCombination error message appears in the AWS Management Console or in the output from the modify-db-cluster AWS CLI command.

5. Use the AWS Management Console or the AWS CLI to create the custom DB cluster parameter group. Choose the applicable Aurora PostgreSQL family for the version of Aurora PostgreSQL that you want for the upgrade.

   **Tip**
   Parameter groups are managed at the AWS Region level. When you work with AWS CLI, you can configure with a default Region instead of specifying the --region in the command. To learn more about using the AWS CLI, see Quick setup in the AWS Command Line Interface User Guide.

**Performing major version upgrade**

1. Upgrade Aurora PostgreSQL DB cluster to a new major version. For more information, see Upgrading the Aurora PostgreSQL engine to a new major version (p. 1790).

2. Reboot the writer instance of the cluster, so that the parameter settings can take effect.

**After upgrading to a new major version**

After a major version upgrade to a new Aurora PostgreSQL version, the IDENTITY value in tables with an IDENTITY column might be larger (+32) than the value was before the upgrade. The result is that when the next row is inserted into such tables, the generated identity column value jumps to the +32
number and starts the sequence from there. This condition won't negatively affect the functions of your Babelfish DB cluster. However, if you want, you can reset the sequence object based on the maximum value of the column. To do so, connect to the T-SQL port on your Babelfish writer instance using sqlcmd or another SQL Server client. For more information, see Using a SQL Server client to connect to your DB cluster (p. 1330).

```
sqlcmd -S bfish-db.cluster-123456789012.aws-region.rds.amazonaws.com,1433 -U sa -P ******** -d dbname
```

When connected, use the following SQL command to generate statements that you can use to seed the associated sequence object. This SQL command works for both single database and multiple database Babelfish configurations. For more information about these two deployment models, see Using Babelfish with a single database or multiple databases (p. 1285).

```
DECLARE @schema_prefix NVARCHAR(200) = ''
IF current_setting('babelfishpg_tsql.migration_mode') = 'multi-db'
    SET @schema_prefix = db_name() + '_'
SELECT 'SELECT setval(pg_get_serial_sequence(''' + @schema_prefix +
    schema_name(tables.schema_id) + '.' + tables.name + ''', ''' + columns.name + '''),(select max(' + columns.name + ')
    FROM ' + schema_name(tables.schema_id) + '.' + tables.name + '));
FROM sys.tables tables JOIN sys.columns columns ON tables.object_id = columns.object_id
WHERE columns.is_identity = 1
GO
```

The query generates a series of SELECT statements that you can then run to reset the maximum IDENTITY value and close any gap. The following shows the output when using the sample SQL Server database, Northwind, running on a Babelfish cluster.

```
--------------------------------------------------------
SELECT setval(pg_get_serial_sequence('northwind_dbo.categories', 'categoryid'),(select max(categoryid)
    FROM dbo.categories));
SELECT setval(pg_get_serial_sequence('northwind_dbo.orders', 'orderid'),(select max(orderid)
    FROM dbo.orders));
SELECT setval(pg_get_serial_sequence('northwind_dbo.products', 'productid'),(select max(productid)
    FROM dbo.products));
SELECT setval(pg_get_serial_sequence('northwind_dbo.shippers', 'shipperid'),(select max(shipperid)
    FROM dbo.shippers));
SELECT setval(pg_get_serial_sequence('northwind_dbo.suppliers', 'supplierid'),(select max(supplierid)
    FROM dbo.suppliers));
(5 rows affected)
```

Run the statements one by one to reset the sequence values.
Example: Upgrading the Babelfish DB cluster to a major release

In this example, you can find the series of AWS CLI commands that explains how to upgrade an Aurora PostgreSQL 13.6.4 DB cluster running Babelfish version 1.2.2 to Aurora PostgreSQL 14.6. First, you create a custom DB cluster parameter group for Aurora PostgreSQL 14. Next, you modify the parameter values to match those of your Aurora PostgreSQL version 13 source. Finally, you perform the upgrade by modifying the source cluster. For more information, see DB cluster parameter group settings for Babelfish (p. 1287). In that topic, you can also find information about using the AWS Management Console to perform the upgrade.

Use the create-db-cluster-parameter-group CLI command to create the DB cluster parameter group for the new version.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster-parameter-group
  --db-cluster-parameter-group-name docs-lab-babelfish-apg-14
  --db-parameter-group-family aurora-postgresql14
  --description 'New custom parameter group for upgrade to new major version'
  --region us-west-1
```

When you issue this command, the custom DB cluster parameter group is created in the AWS Region. You see output similar to the following.

```
{
  "DBClusterParameterGroup": {
    "DBClusterParameterGroupName": "docs-lab-babelfish-apg-14",
    "DBParameterGroupFamily": "aurora-postgresql14",
    "Description": "New custom parameter group for upgrade to new major version",
  }
}
```

For more information, see Creating a DB cluster parameter group (p. 216).

Use the modify-db-cluster-parameter-group CLI command to modify the settings so that they match the source cluster.

For Windows:

```
aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name docs-lab-
babelfish-apg-14
  --parameters "ParameterName=rds.babelfish_status,ParameterValue=on,ApplyMethod=pending-
reboot"
  "ParameterName=babelfishpg_tds.tds_default_numeric_precision,ParameterValue=38,ApplyMethod=pending-
reboot"
  "ParameterName=babelfishpg_tds.tds_default_numeric_scale,ParameterValue=8,ApplyMethod=pending-
reboot"
  "ParameterName=babelfishpg_tsql.database_name,ParameterValue=babelfish_db,ApplyMethod=pending-
reboot"
  "ParameterName=babelfishpg_tsql.default_locale,ParameterValue=en-US,ApplyMethod=pending-
reboot"
  "ParameterName=babelfishpg_tsql.migration_mode,ParameterValue=single-
db,ApplyMethod=pending-reboot"
  "ParameterName=babelfishpg_tsql.server_collation_name,ParameterValue=sql_latin1_general_cpl_ci_as,Apply-
reboot"
```

The response looks similar to the following.

```
1371
```
Use the `modify-db-cluster` CLI command to modify the cluster to use the new version and the new custom DB cluster parameter group. You also specify the `--allow-major-version-upgrade` argument, as shown in the following sample.

```bash
aws rds modify-db-cluster \
  --db-cluster-identifier docs-lab-bfish-apg-14 \
  --engine-version 14.6 \
  --db-cluster-parameter-group-name docs-lab-babelfish-apg-14 \
  --allow-major-version-upgrade \
  --region us-west-1 \
  --apply-immediately
```

Use the `reboot-db-instance` CLI command to reboot the writer instance of the cluster, so that the parameter settings can take effect.

```bash
aws rds reboot-db-instance \
  --db-instance-identifier docs-lab-bfish-apg-14-instance-1\ 
  --region us-west-1
```

### Using Babelfish product version parameter

A new Grand Unified Configuration (GUC) parameter called `babelfishpg_tds.product_version` is introduced from Babelfish 2.4.0 and 3.1.0 versions. This parameter allows you to set the SQL Server product version number as the output of Babelfish.

The parameter is a 4-part version ID string, and each part should be separated by ".".

**Syntax**

```
Major.Minor.Build.Revision
```

- Major Version: A number between 11 and 16.
- Minor Version: A number between 0 and 255.
- Build Version: A number between 0 and 65535.
- Revision: 0 and any positive number.

### Configuring Babelfish product version parameter

You must use the cluster parameter group to set the `babelfishpg_tds.product_version` parameter in the console. For more information on how to modify the DB cluster parameter, see [Modifying parameters in a DB cluster parameter group](#).

When you set the product version parameter to an invalid value, the change will not take effect. Although the console might show you the new value, the parameter retains the previous value. Check the engine log file for details about the error messages.

For Linux, macOS, or Unix:
aws rds modify-db-cluster-parameter-group \
--db-cluster-parameter-group-name mydbparametergroup \
--parameters
"ParameterName=babelfishpg_tds.product_version,ParameterValue=15.2.4000.1,ApplyMethod=immediate"

For Windows:

aws rds modify-db-cluster-parameter-group ^
--db-cluster-parameter-group-name mydbparametergroup ^
--parameters
"ParameterName=babelfishpg_tds.product_version,ParameterValue=15.2.4000.1,ApplyMethod=immediate"

**Affected queries and parameter**

<table>
<thead>
<tr>
<th>Query/Parameter</th>
<th>Result</th>
<th>Effective time</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT @@VERSION</td>
<td>Returns user defined SQL Server version (babelfishpg_tsql.version value = Default)</td>
<td>Immediately</td>
</tr>
<tr>
<td>SELECT SERVERPROPERTY('ProductVersion')</td>
<td>Returns user defined SQL Server version</td>
<td>Immediately</td>
</tr>
<tr>
<td>SELECT SERVERPROPERTY('ProductMajorVersion')</td>
<td>Returns Major Version of the user defined SQL Server version</td>
<td>Immediately</td>
</tr>
<tr>
<td>VERSION tokens in PRELOGIN Response Message</td>
<td>Server returns PRELOGIN messages with user defined SQL Server version</td>
<td>Takes effect when a user creates a new session</td>
</tr>
<tr>
<td>SQLServerVersion in LoginAck when using JDBC</td>
<td>DatabaseMetaData.getDatabaseProductVersion returns user defined SQL Server version</td>
<td>Takes effect when a user creates a new session</td>
</tr>
</tbody>
</table>

**Interface with babelfishpg_tsql.version parameter**

You can set the output of the @@VERSION using the parameters babelfishpg_tsql.version and babelfishpg_tds.product_version. The following examples show how these two parameters interface.

- When babelfishpg_tsql.version parameter is "default" and babelfishpg_tds.product_version is 15.0.2000.8.
- When babelfishpg_tsql.version parameter is set to 13.0.2000.8 and babelfishpg_tds.product_version parameter is 15.0.2000.8.
Babelfish for Aurora PostgreSQL reference

Topics
- Unsupported functionality in Babelfish (p. 1374)
- Supported functionality in Babelfish by version (p. 1382)
- Babelfish for Aurora PostgreSQL procedure reference (p. 1394)

Unsupported functionality in Babelfish

In the following table and lists, you can find functionality that isn't currently supported in Babelfish. Updates to Babelfish are included in Aurora PostgreSQL versions. For more information, see the Release Notes for Aurora PostgreSQL.

Topics
- Functionality that isn't currently supported (p. 1374)
- Settings that aren't supported (p. 1377)
- Commands that aren't supported (p. 1377)
- Column names or attributes that aren't supported (p. 1377)
- Data types that aren't supported (p. 1377)
- Object types that aren't supported (p. 1378)
- Functions that aren't supported (p. 1378)
- Syntax that isn't supported (p. 1379)

Functionality that isn't currently supported

In the table you can find information about certain functionality that isn't currently supported.

<table>
<thead>
<tr>
<th>Functionality or syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Assembly modules and SQL Common Language Runtime (CLR) routines</td>
<td>Functionality related to assembly modules and CLR routines isn't supported.</td>
</tr>
<tr>
<td>Column attributes</td>
<td>ROWGUIDCOL, SPARSE, FILESTREAM, and MASKED aren't supported.</td>
</tr>
<tr>
<td>Contained databases</td>
<td>Contained databases with logins authenticated at the database level rather than at the server level aren't supported.</td>
</tr>
<tr>
<td>Cursors (updatable)</td>
<td>Updatable cursors aren't supported.</td>
</tr>
<tr>
<td>Cursors (global)</td>
<td>GLOBAL cursors aren't supported.</td>
</tr>
<tr>
<td>Cursor (fetch behaviors)</td>
<td>The following cursor fetch behaviors aren't supported: FETCH PRIOR, FIRST, LAST, ABSOLUTE, abd RELATIVE</td>
</tr>
<tr>
<td>Cursor-typed output parameters</td>
<td>Cursor-typed variables and parameters aren't supported for output parameters (an error is raised).</td>
</tr>
<tr>
<td>Cursor options</td>
<td>SCROLL, KEYSET, DYNAMIC, FAST_FORWARD, SCROLL_LOCKS, OPTIMISTIC, TYPE_WARNING, and FOR UPDATE</td>
</tr>
<tr>
<td>Data encryption</td>
<td>Data encryption isn't supported.</td>
</tr>
<tr>
<td>Functionality or syntax</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>Data-tier applications (DAC)</td>
<td>Data-tier applications (DAC) import or export operations with DAC package (.dacpac) or DAC backup (.bacpac) files aren't supported.</td>
</tr>
<tr>
<td>DBCC commands</td>
<td>Microsoft SQL Server Database Console Commands (DBCC) aren't supported.</td>
</tr>
<tr>
<td>DROP IF EXISTS</td>
<td>This syntax isn't supported for USER and SCHEMA objects. It's supported for the objects TABLE, VIEW, PROCEDURE, FUNCTION, and DATABASE.</td>
</tr>
<tr>
<td>Encryption</td>
<td>Built-in functions and statements don't support encryption.</td>
</tr>
<tr>
<td>ENCRYPT_CLIENT_CERT connections</td>
<td>Client certificate connections aren't supported.</td>
</tr>
<tr>
<td>EXECUTE AS statement</td>
<td>This statement isn't supported.</td>
</tr>
<tr>
<td>EXECUTE AS SELF clause</td>
<td>This clause isn't supported in functions, procedures, or triggers.</td>
</tr>
<tr>
<td>EXECUTE AS USER clause</td>
<td>This clause isn't supported in functions, procedures, or triggers.</td>
</tr>
<tr>
<td>Foreign key constraints referencing database name</td>
<td>Foreign key constraints that reference the database name aren't supported.</td>
</tr>
<tr>
<td>Full-text search</td>
<td>Full-text search built-in Functions and statements aren't supported.</td>
</tr>
<tr>
<td>Function declarations with greater than 100 parameters</td>
<td>Function declarations that contain more than 100 parameters aren't supported.</td>
</tr>
<tr>
<td>Function calls that include DEFAULT as a parameter value</td>
<td>DEFAULT isn't a supported parameter value for a function call.</td>
</tr>
<tr>
<td>Functions, externally defined</td>
<td>External functions, including SQL CLR functions, aren't supported.</td>
</tr>
<tr>
<td>Global temporary tables (tables with names that start with ##)</td>
<td>Global temporary tables aren't supported.</td>
</tr>
<tr>
<td>Graph functionality</td>
<td>All SQL graph functionality isn't supported.</td>
</tr>
<tr>
<td>Identifiers (variables or parameters) with multiple leading @ characters</td>
<td>Identifiers that start with more than one leading @ aren't supported.</td>
</tr>
<tr>
<td>Identifiers, table or column names that contain @ or ]</td>
<td>identifiers</td>
</tr>
<tr>
<td>Inline indexes</td>
<td>Inline indexes aren't supported.</td>
</tr>
<tr>
<td>Invoking a procedure whose name is in a variable</td>
<td>Using a variable as a procedure name isn't supported.</td>
</tr>
<tr>
<td>Materialized views</td>
<td>Materialized views aren't supported.</td>
</tr>
<tr>
<td>NOT FOR REPLICATION clause</td>
<td>This syntax is accepted and ignored.</td>
</tr>
<tr>
<td>ODBC escape functions</td>
<td>ODBC escape functions aren't supported.</td>
</tr>
<tr>
<td>Partitioning</td>
<td>Table and index partitioning isn't supported.</td>
</tr>
<tr>
<td>Functionality or syntax</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Procedure calls that includes DEFAULT as a parameter value</td>
<td>DEFAULT isn't a supported parameter value.</td>
</tr>
<tr>
<td>Procedure declarations with more than 100 parameters</td>
<td>Declarations with more than 100 parameters aren't supported.</td>
</tr>
<tr>
<td>Procedures, externally defined</td>
<td>Externally defined procedures, including SQL CLR procedures, aren't supported.</td>
</tr>
<tr>
<td>Procedure versioning</td>
<td>Procedure versioning isn't supported.</td>
</tr>
<tr>
<td>Procedures WITH RECOMPILE</td>
<td>WITH RECOMPILE (when used in conjunction with the DECLARE and EXECUTE statements) isn't supported.</td>
</tr>
<tr>
<td>Remote object references</td>
<td>Objects with four-part names aren't supported. For more information, see [DB cluster parameter group settings for Babelfish](p. 1287).</td>
</tr>
<tr>
<td>Row-level security</td>
<td>Row-level security with CREATE SECURITY POLICY and inline table-valued functions isn't supported.</td>
</tr>
<tr>
<td>Service broker functionality</td>
<td>Service broker functionality isn't supported.</td>
</tr>
<tr>
<td>SESSIONPROPERTY</td>
<td>Unsupported properties: ANSI_NULLS, ANSI_PADDING, ANSI_WARNINGS, ARITHABORT, CONCAT_NULL_YIELDS_NULL, and NUMERIC_ROUNDABORT</td>
</tr>
<tr>
<td>SET LANGUAGE</td>
<td>This syntax isn't supported with any value other than english or us_english.</td>
</tr>
<tr>
<td>SP_CONFIGURE</td>
<td>This system stored procedure isn't supported.</td>
</tr>
<tr>
<td>SQL keyword SPARSE</td>
<td>The keyword SPARSE is accepted and ignored.</td>
</tr>
<tr>
<td>Table value constructor syntax (FROM clause)</td>
<td>The unsupported syntax is for a derived table constructed with the FROM clause.</td>
</tr>
<tr>
<td>Temporal tables</td>
<td>Temporal tables aren't supported.</td>
</tr>
<tr>
<td>Temporary procedures aren't dropped automatically</td>
<td>This functionality isn't supported.</td>
</tr>
<tr>
<td>Transaction isolation levels</td>
<td>READUNCOMMITTED is treated the same as READCOMMITTED, REPEATABLEREAD, and SERIALIZABLE aren't supported.</td>
</tr>
<tr>
<td>Triggers, externally defined</td>
<td>These triggers aren't supported, including SQL Common Language Runtime (CLR).</td>
</tr>
<tr>
<td>Triggers, INSTEAD-OF on views</td>
<td>INSTEAD-OF triggers on views aren't supported. INSTEAD-OF triggers are supported (Babelfish 1.2.0 and higher releases).</td>
</tr>
<tr>
<td>Unquoted string values in stored procedure calls and default values</td>
<td>String parameters to stored procedure calls, and defaults for string parameters in CREATE PROCEDURE, aren't supported.</td>
</tr>
<tr>
<td>Without SCHEMABINDING clause</td>
<td>Creating a view without SCHEMABINDING isn't supported, but the view is created as if WITH SCHEMABINDING was specified. Using SCHEMABINDING when creating functions, procedures, triggers is silently ignored.</td>
</tr>
</tbody>
</table>
Settings that aren't supported

The following settings aren't supported:

- SET ANSI_NULL_DFLT_OFF ON
- SET ANSI_NULL_DFLT_ON OFF
- SET ANSI_PADDING OFF
- SET ANSI_WARNINGS OFF
- SET ARITHABORT OFF
- SET ARITHIGNORE ON
- SET CURSOR_CLOSE_ON_COMMIT ON
- SET NUMERIC_ROUNDABORT ON
- SET PARSEONLY ON (command doesn't work as expected)
- SET FMTONLY ON (command doesn't work as expected. It suppresses only the execution of SELECT statements but not others.)

Commands that aren't supported

Certain functionality for the following commands isn't supported:

- ADD SIGNATURE
- ALTER DATABASE, ALTER DATABASE SET
- BACKUP/RESTORE DATABASE/LOG
- BACPAC and DACPAC FILES RESTORE
- CREATE, ALTER, DROP AUTHORIZATION
- CREATE, ALTER, DROP AVAILABILITY GROUP
- CREATE, ALTER, DROP BROKER PRIORITY
- CREATE, ALTER, DROP COLUMN ENCRYPTION KEY
- CREATE, ALTER, DROP DATABASE ENCRYPTION KEY
- CREATE, ALTER, DROP, BACKUP CERTIFICATE
- CREATE AGGREGATE
- CREATE CONTRACT
- CHECKPOINT

Column names or attributes that aren't supported

The following column names aren't supported:

- $IDENTITY
- $ROWGUID
- IDENTITYCOL

Data types that aren't supported

The following data types aren't supported:

- Geospatial (GEOGRAPHY and GEOMETRY)
- HIERARCHYID
Object types that aren't supported

The following object types aren't supported:

- COLUMN MASTER KEY
- CREATE, ALTER EXTERNAL DATA SOURCE
- CREATE, ALTER, DROP DATABASE AUDIT SPECIFICATION
- CREATE, ALTER, DROP EXTERNAL LIBRARY
- CREATE, ALTER, DROP SERVER AUDIT
- CREATE, ALTER, DROP SERVER AUDIT SPECIFICATION
- CREATE, ALTER, DROP, OPEN/CLOSE SYMMETRIC KEY
- CREATE, DROP DEFAULT
- CREDENTIAL
- CRYPTOGRAPHIC PROVIDER
- DIAGNOSTIC SESSION
- Indexed views
- SERVICE MASTER KEY
- SYNONYM

Functions that aren't supported

The following built-in functions aren't supported:

Aggregate functions

- APPROX_COUNT_DISTINCT
- CHECKSUM_AGG
- GROUPING_ID

Cryptographic functions

- CERTENCODED function
- CERTID function
- CERTPROPERTY function

Metadata functions

- COLUMNPROPERTY
- TYPEPROPERTY
- SERVERPROPERTY function – The following properties aren't supported:
  - BuildClrVersion
  - ComparisonStyle
  - ComputerNamePhysicalNetBIOS
  - HadrManagerStatus
  - InstanceDefaultDataPath
  - InstanceDefaultLogPath
  - IsClustered
  - IsHadrEnabled
• LCID
• NumLicenses
• ProcessID
• ProductBuild
• ProductBuildType
• ProductUpdateReference
• ResourceLastUpdateDateTime
• ResourceVersion
• ServerName
• SqlCharSet
• SqlCharSetName
• SqlSortOrder
• SqlSortOrderName
• FilestreamShareName
• FilestreamConfiguredLevel
• FilestreamEffectiveLevel

Security functions

• CERTPRIVATEKEY
• LOGINPROPERTY

Statements, operators, other functions

• EVENTDATA function
• GET_TRANSMISSION_STATUS
• OPENXML

Syntax that isn't supported

The following syntax isn't supported:

• ALTER DATABASE
• ALTER DATABASE SCOPED CONFIGURATION
• ALTER DATABASE SCOPED CREDENTIAL
• ALTER DATABASE SET HADR
• ALTER FUNCTION
• ALTER INDEX
• ALTER PROCEDURE statement
• ALTER SCHEMA
• ALTER SERVER CONFIGURATION
• ALTER SERVICE, BACKUP/RESTORE SERVICE MASTER KEY clause
• ALTER VIEW
• BEGIN CONVERSATION TIMER
• BEGIN DISTRIBUTED TRANSACTION
• BEGIN DIALOG CONVERSATION
• BULK INSERT

1379
• CREATE COLUMNSTORE INDEX
• CREATE EXTERNAL FILE FORMAT
• CREATE EXTERNAL TABLE
• CREATE, ALTER, DROP APPLICATION ROLE
• CREATE, ALTER, DROP ASSEMBLY
• CREATE, ALTER, DROP ASYMMETRIC KEY
• CREATE, ALTER, DROP CREDENTIAL
• CREATE, ALTER, DROP CRYPTOGRAPHIC PROVIDER
• CREATE, ALTER, DROP ENDPOINT
• CREATE, ALTER, DROP EVENT SESSION
• CREATE, ALTER, DROP EXTERNAL LANGUAGE
• CREATE, ALTER, DROP EXTERNAL RESOURCE POOL
• CREATE, ALTER, DROP FULLTEXT CATALOG
• CREATE, ALTER, DROP FULLTEXT INDEX
• CREATE, ALTER, DROP FULLTEXT STOPLIST
• CREATE, ALTER, DROP MESSAGE TYPE
• CREATE, ALTER, DROP, OPEN/CLOSE, BACKUP/RESTORE MASTER KEY
• CREATE, ALTER, DROP PARTITION FUNCTION
• CREATE, ALTER, DROP PARTITION SCHEME
• CREATE, ALTER, DROP QUEUE
• CREATE, ALTER, DROP RESOURCE GOVERNOR
• CREATE, ALTER, DROP RESOURCE POOL
• CREATE, ALTER, DROP ROUTE
• CREATE, ALTER, DROP SEARCH PROPERTY LIST
• CREATE, ALTER, DROP SECURITY POLICY
• CREATE, ALTER, DROP SELECTIVE XML INDEX clause
• CREATE, ALTER, DROP SERVICE
• CREATE, ALTER, DROP SPATIAL INDEX
• CREATE, ALTER, DROP TYPE
• CREATE, ALTER, DROP XML INDEX
• CREATE, ALTER, DROP XML SCHEMA COLLECTION
• CREATE/DROP RULE
• CREATE, DROP WORKLOAD CLASSIFIER
• CREATE, ALTER, DROP WORKLOAD GROUP
• CREATE/ALTER/ENABLE/DISABLE TRIGGER
• CREATE TABLE... GRANT clause
• CREATE TABLE... IDENTITY clause
• CREATE USER – This syntax isn't supported. The PostgreSQL statement CREATE USER doesn't create
  a user that is equivalent to the SQL Server CREATE USER syntax. For more information, see T-SQL
  differences in Babelfish (p. 1340).
• DENY
• END, MOVE CONVERSATION
• EXECUTE with AS LOGIN or AT option
• GET CONVERSATION GROUP
• GROUP BY ALL clause
• GROUP BY CUBE clause
• GROUP BY ROLLUP clause
• INSERT... DEFAULT VALUES
• KILL
• MERGE
• READTEXT
• REVERT
• SELECT PIVOT/UNPIVOT
• SELECT TOP x PERCENT WHERE x <> 100
• SELECT TOP... WITH TIES
• SELECT... FOR BROWSE
• SELECT... FOR XML AUTO
• SELECT... FOR XML EXPLICIT
• SEND
• SET DATEFORMAT
• SET DEADLOCK_PRIORITY
• SET FMTONLY
• SET FORCEPLAN
• SET NO_BROWSETABLE
• SET NUMERIC_ROUNDABORT ON
• SET OFFSETS
• SET REMOTE_PROC_TRANSACTIONS
• SET SHOWPLAN_ALL
• SET SHOWPLAN_TEXT
• SET SHOWPLAN_XML
• SET STATISTICS
• SET STATISTICS IO
• SET STATISTICS PROFILE
• SET STATISTICS TIME
• SET STATISTICS XML
• SET TRANSACTION ISOLATION LEVEL REPEATABLE READ
• SET TRANSACTION ISOLATION LEVEL SERIALIZABLE
• SHUTDOWN statement
• UPDATE STATISTICS
• UPDATETEXT
• Using EXECUTE to call a SQL function
• VIEW... CHECK OPTION clause
• VIEW... VIEW_METADATA clause
• WAITFOR DELAY
• WAITFOR TIME
• WAITFOR, RECEIVE
• WITH XMLNAMESPACES construct
• WRITETEXT
• XPATH expressions
**Supported functionality in Babelfish by version**

In the following table you can find T-SQL functionality supported by different Babelfish versions. For lists of unsupported functionality, see [Unsupported functionality in Babelfish](p. 1374). For information about various Babelfish releases, see the [Release Notes for Aurora PostgreSQL](#).

<table>

Babelfish for Aurora PostgreSQL procedure reference

Overview
You can use the following procedure for Amazon RDS DB instances running Babelfish for Aurora PostgreSQL for a better query performance:

- `sp_babelfish_volatility` (p. 1394)
- `sp_execute_postgresql` (p. 1396)

`sp_babelfish_volatility`

PostgreSQL function volatility helps the optimizer for a better query execution which when used in parts of certain clauses has a significant impact on query performance.

Syntax

```
sp_babelfish_volatility 'function_name', 'volatility'
```

Arguments

`function_name (optional)`

You can either specify the value of this argument with a two-part name as `schema_name.function_name` or only the `function_name`. If you specify only the `function_name`, the schema name is the default schema for the current user.

`volatility (optional)`

The valid PostgreSQL values of volatility are `stable`, `volatile`, or `immutable`. For more information, see [https://www.postgresql.org/docs/current/xfunc-volatility.html](https://www.postgresql.org/docs/current/xfunc-volatility.html)

Note

When `sp_babelfish_volatility` is called with `function_name` which has multiple definitions, it will throw an error.

Result set

If the parameters are not mentioned then the result set is displayed under the following columns: `schemaname`, `functionname`, `volatility`.

Usage notes

PostgreSQL function volatility helps the optimizer for a better query execution which when used in parts of certain clauses has a significant impact on query performance.
Examples

The following examples shows how to create simple functions and later explains how to use sp_babelfish_volatility on these functions using different methods.

```sql
1> create function f1() returns int as begin return 0 end
2> go
```

```sql
1> create schema test_schema
2> go
```

```sql
1> create function test_schema.f1() returns int as begin return 0 end
2> go
```

The following example displays volatility of the functions:

```sql
1> exec sp_babelfish_volatility
2> go
```

```
schemaname  functionname  volatility
-----------  ------------  ----------
    dbo        f1           volatile
 test_schema f1           volatile
```

The following example shows how to change the volatility of the functions:

```sql
1> exec sp_babelfish_volatility 'f1','stable'
2> go
1> exec sp_babelfish_volatility 'test_schema.f1','immutable'
2> go
```

When you specify only the function_name, it displays the schema name, function name and volatility of that function. The following example displays volatility of functions after changing the values:

```sql
1> exec sp_babelfish_volatility 'test_schema.f1'
2> go
```

```
schemaname  functionname  volatility
-----------  ------------  ----------
 test_schema f1           immutable
```

```sql
1> exec sp_babelfish_volatility 'f1'
2> go
```

```
schemaname  functionname  volatility
-----------  ------------  ----------
    dbo        f1           stable
```

When you don't specify any argument, it displays a list of functions (schema name, function name, volatility of the functions) present in the current database:

```sql
1> exec sp_babelfish_volatility
2> go
```
### sp_execute_postgresql

You can execute PostgreSQL statements from T-SQL endpoint. This simplifies your applications as you don't need to exit T-SQL port to execute these statements.

**Syntax**

```
sp_execute_postgresql [ @stmt = ] statement
```

**Arguments**

`[ @stmt ] statement`

The argument is of datatype varchar. This argument accept PG dialect statements.

**Note**

You can only pass one PG dialect statement as an argument otherwise it will raise the following error.

```
1>exec sp_execute_postgresql 'create extension pg_stat_statements; drop extension pg_stat_statements'
2>go
```

Msg 33557097, Level 16, State 1, Server BABELFISH, Line 1
expected 1 statement but got 2 statements after parsing

**Usage notes**

**CREATE EXTENSION**

Creates and loads a new extension into the current database.

```
1>EXEC sp_execute_postgresql 'create extension [ IF NOT EXISTS ] <extension name> [ WITH ] [SCHEMA schema_name] [VERSION version]';
2>go
```

The following example shows how to create an extension:

```
1>EXEC sp_execute_postgresql 'create extension pg_stat_statements with schema sys version "1.10"';
2>go
```

Use the following command to access extension objects:

```
1>select * from pg_stat_statements;
2>go
```
Note
If schema name is not provided explicitly during extension creation, by default the extensions are installed in the public schema. You must provide the schema qualifier to access the extension objects as mentioned below:

```
1>select * from [public].pg_stat_statements;
2>go
```

Supported extensions
The following extensions available with Aurora PostgreSQL works with Babelfish.

- pg_stat_statements
- tds_fdw
- fuzzystrmatch

Limitations
- Users need to have sysadmin role on T-SQL and rds_superuser on postgres to install the extensions.
- Extensions cannot be installed in user created schemas and also in dbo and guest schemas for master, tempdb and msdb database.
- CASCADE option is not supported.

ALTER EXTENSION
You can upgrade to a new extension version using ALTER extension.

```
1>EXEC sp_execute_postgresql 'alter extension <extension name> UPDATE TO <new_version>'; 
2>go
```

Limitations
- You can upgrade the version of your extension only using the ALTER Extension statement. Other operations aren't supported.

DROP EXTENSION
Drops the specified extension. You can also use if exists or restrict options to drop the extension.

```
1>EXEC sp_execute_postgresql 'drop extension <extension name>'; 
2>go
```

Limitations
- CASCADE option is not supported.

Managing Amazon Aurora PostgreSQL

The following section discusses managing performance and scaling for an Amazon Aurora PostgreSQL DB cluster. It also includes information about other maintenance tasks.
Scaling Aurora PostgreSQL DB instances

You can scale Aurora PostgreSQL DB instances in two ways, instance scaling and read scaling. For more information about read scaling, see Read scaling (p. 301).

You can scale your Aurora PostgreSQL DB cluster by modifying the DB instance class for each DB instance in the DB cluster. Aurora PostgreSQL supports several DB instance classes optimized for Aurora. Don't use db.t2 or db.t3 instance classes for larger Aurora clusters of size greater than 40 terabytes (TB).

Note
We recommend using the T DB instance classes only for development and test servers, or other non-production servers. For more details on the T instance classes, see DB instance class types (p. 84).

Scaling isn't instantaneous. It can take 15 minutes or more to complete the change to a different DB instance class. If you use this approach to modify the DB instance class, you apply the change during the next scheduled maintenance window (rather than immediately) to avoid affecting users.

As an alternative to modifying the DB instance class directly, you can minimize downtime by using the high availability features of Amazon Aurora. First, add an Aurora Replica to your cluster. When creating the replica, choose the DB instance class size that you want to use for your cluster. When the Aurora Replica is synchronized with the cluster, you then failover to the newly added Replica. To learn more, see Aurora Replicas (p. 104) and Fast failover with Amazon Aurora PostgreSQL (p. 1470).

For detailed specifications of the DB instance classes supported by Aurora PostgreSQL, see Supported DB engines for DB instance classes (p. 86).

Maximum connections to an Aurora PostgreSQL DB instance

An Aurora PostgreSQL DB cluster allocates resources based on the DB instance class and its available memory. Each connection to the DB cluster consumes incremental amounts of these resources, such as memory and CPU. Memory consumed per connection varies based on query type, count, and whether temporary tables are used. Even an idle connection consumes memory and CPU. That's because when queries run on a connection, more memory is allocated for each query and it's not released completely, even when processing stops. Thus, we recommend that you make sure your applications aren't holding on to idle connections: each one of these wastes resources and affects performance negatively. For more information, see Resources consumed by idle PostgreSQL connections.

The maximum number of connections allowed by an Aurora PostgreSQL DB instance is determined by the max_connections parameter value specified in the parameter group for that DB instance. The ideal setting for the max_connections parameter is one that supports all the client connections your application needs, without an excess of unused connections, plus at least 3 more connections to support AWS automation. Before modifying the max_connections parameter setting, we recommend that you consider the following:
• If the `max_connections` value is too low, the Aurora PostgreSQL DB instance might not have sufficient connections available when clients attempt to connect. If this happens, attempts to connect using `psql` raise error messages such as the following:

```
psql: FATAL: remaining connection slots are reserved for non-replication superuser connections
```

• If the `max_connections` value exceeds the number of connections that are actually needed, the unused connections can cause performance to degrade.

The default value of `max_connections` is derived from the following Aurora PostgreSQL `LEAST` function:

```
LEAST({DBInstanceClassMemory/9531392},5000).
```

If you want to change the value for `max_connections`, you need to create a custom DB cluster parameter group and change its value there. After applying your custom DB parameter group to your cluster, be sure to reboot the primary instance so the new value takes effect. For more information, see `Amazon Aurora PostgreSQL parameters (p. 1728)` and `Creating a DB cluster parameter group (p. 216)`.

**Tip**

If your applications frequently open and close connections, or keep a large number of long-lived connections open, we recommend that you use Amazon RDS Proxy. RDS Proxy is a fully managed, highly available database proxy that uses connection pooling to share database connections securely and efficiently. To learn more about RDS Proxy, see `Using Amazon RDS Proxy for Aurora (p. 1879)`.

For details about how Aurora Serverless v2 instances handle this parameter, see `Maximum connections for Aurora Serverless v2 (p. 2016)`.

### Temporary storage limits for Aurora PostgreSQL

Aurora PostgreSQL stores tables and indexes in the Aurora storage subsystem. Aurora PostgreSQL uses separate temporary storage for non-persistent temporary files. This includes files that are used for such purposes as sorting large data sets during query processing or for index build operations. For more information, see the article `How can I troubleshoot local storage issues in Aurora PostgreSQL-Compatible instances?`.

These local storage volumes are backed by Amazon Elastic Block Store and can be extended by using a larger DB instance class. For more information about storage, see `Amazon Aurora storage and reliability (p. 97)`.

**Note**

You might see storage-optimization events when scaling DB instances, for example, from `db.r5.2xlarge` to `db.r5.4xlarge`.

The following table shows the maximum amount of temporary storage available for each Aurora PostgreSQL DB instance class. For more information on DB instance class support for Aurora, see `Aurora DB instance classes (p. 84)`.

<table>
<thead>
<tr>

</tbody>
</table>
Huge pages for Aurora PostgreSQL

Huge pages are a memory management feature that reduces overhead when a DB instance is working with large contiguous chunks of memory, such as that used by shared buffers. This PostgreSQL feature is supported by all currently available Aurora PostgreSQL versions.

Huge_pages parameter is turned on by default for all DB instance classes other than t3.medium, db.t3.large, db.t4g.medium, db.t4g.large instance classes. You can't change the huge_pages parameter value or turn off this feature in the supported instance classes of Aurora PostgreSQL.

Testing Amazon Aurora PostgreSQL by using fault injection queries

You can test the fault tolerance of your Aurora PostgreSQL DB cluster by using fault injection queries. Fault injection queries are issued as SQL commands to an Amazon Aurora instance. Fault injection queries let you crash the instance so that you can test failover and recovery. You can also simulate Aurora Replica failure, disk failure, and disk congestion. Fault injection queries are supported by all available Aurora PostgreSQL versions, as follows.

- Aurora PostgreSQL versions 12, 13, 14, and higher
- Aurora PostgreSQL version 11.7 and higher
Testing Amazon Aurora PostgreSQL by using fault injection queries

- Aurora PostgreSQL version 10.11 and higher

Topics
- Testing an instance crash (p. 1402)
- Testing an Aurora Replica failure (p. 1402)
- Testing a disk failure (p. 1403)
- Testing disk congestion (p. 1404)

When a fault injection query specifies a crash, it forces a crash of the Aurora PostgreSQL DB instance. The other fault injection queries result in simulations of failure events, but don’t cause the event to occur. When you submit a fault injection query, you also specify an amount of time for the failure event simulation to occur.

You can submit a fault injection query to one of your Aurora Replica instances by connecting to the endpoint for the Aurora Replica. For more information, see Amazon Aurora connection management (p. 62).

Testing an instance crash

You can force a crash of an Aurora PostgreSQL instance by using the fault injection query function aurora_inject_crash().

For this fault injection query, a failover does not occur. If you want to test a failover, then you can choose the Failover instance action for your DB cluster in the RDS console, or use the failover-db-cluster AWS CLI command or the FailoverDBCluster RDS API operation.

Syntax

```
SELECT aurora_inject_crash ('instance' | 'dispatcher' | 'node');
```

Options

This fault injection query takes one of the following crash types. The crash type is not case sensitive:

- ':instance'
  A crash of the PostgreSQL-compatible database for the Amazon Aurora instance is simulated.
- ':dispatcher'
  A crash of the dispatcher on the primary instance for the Aurora DB cluster is simulated. The dispatcher writes updates to the cluster volume for an Amazon Aurora DB cluster.
- ':node'
  A crash of both the PostgreSQL-compatible database and the dispatcher for the Amazon Aurora instance is simulated.

Testing an Aurora Replica failure

You can simulate the failure of an Aurora Replica by using the fault injection query function aurora_inject_replica_failure().

An Aurora Replica failure blocks replication to the Aurora Replica or all Aurora Replicas in the DB cluster by the specified percentage for the specified time interval. When the time interval completes, the affected Aurora Replicas are automatically synchronized with the primary instance.
Testing Amazon Aurora PostgreSQL by using fault injection queries

**Syntax**

```sql
SELECT aurora_inject_replica_failure(
    percentage_of_failure,
    time_interval,
    'replica_name'
);
```

**Options**

This fault injection query takes the following parameters:

- **percentage_of_failure**
  
  The percentage of replication to block during the failure event. This value can be a double between 0 and 100. If you specify 0, then no replication is blocked. If you specify 100, then all replication is blocked.

- **time_interval**
  
  The amount of time to simulate the Aurora Replica failure. The interval is in seconds. For example, if the value is 20, the simulation runs for 20 seconds.

  **Note**

  Take care when specifying the time interval for your Aurora Replica failure event. If you specify too long an interval, and your writer instance writes a large amount of data during the failure event, then your Aurora DB cluster might assume that your Aurora Replica has crashed and replace it.

- **replica_name**
  
  The Aurora Replica in which to inject the failure simulation. Specify the name of an Aurora Replica to simulate a failure of the single Aurora Replica. Specify an empty string to simulate failures for all Aurora Replicas in the DB cluster.

  To identify replica names, see the `server_id` column from the `aurora_replica_status()` function. For example:

  ```sql
  postgres=> SELECT server_id FROM aurora_replica_status();
  ```

**Testing a disk failure**

You can simulate a disk failure for an Aurora PostgreSQL DB cluster by using the fault injection query function `aurora_inject_disk_failure()`.

During a disk failure simulation, the Aurora PostgreSQL DB cluster randomly marks disk segments as faulting. Requests to those segments are blocked for the duration of the simulation.

**Syntax**

```sql
SELECT aurora_inject_disk_failure(
    percentage_of_failure,
    index,
    is_disk,
    time_interval
);
```

**Options**

This fault injection query takes the following parameters:
/testing Amazon Aurora PostgreSQL by using fault injection queries

**percentage_of_failure**

The percentage of the disk to mark as faulting during the failure event. This value can be a double between 0 and 100. If you specify 0, then none of the disk is marked as faulting. If you specify 100, then the entire disk is marked as faulting.

**index**

A specific logical block of data in which to simulate the failure event. If you exceed the range of available logical blocks or storage nodes data, you receive an error that tells you the maximum index value that you can specify. To avoid this error, see [Displaying volume status for an Aurora PostgreSQL DB cluster (p. 1405)](#).

**is_disk**

Indicates whether the injection failure is to a logical block or a storage node. Specifying true means injection failures are to a logical block. Specifying false means injection failures are to a storage node.

**time_interval**

The amount of time to simulate the Aurora Replica failure. The interval is in seconds. For example, if the value is 20, the simulation runs for 20 seconds.

### Testing disk congestion

You can simulate a disk failure for an Aurora PostgreSQL DB cluster by using the fault injection query function `aurora_inject_disk_congestion()`.

During a disk congestion simulation, the Aurora PostgreSQL DB cluster randomly marks disk segments as congested. Requests to those segments are delayed between the specified minimum and maximum delay time for the duration of the simulation.

**Syntax**

```sql
SELECT aurora_inject_disk_congestion(  
    percentage_of_failure,  
    index,  
    is_disk,  
    time_interval,  
    minimum,  
    maximum  
);
```

**Options**

This fault injection query takes the following parameters:

**percentage_of_failure**

The percentage of the disk to mark as congested during the failure event. This is a double value between 0 and 100. If you specify 0, then none of the disk is marked as congested. If you specify 100, then the entire disk is marked as congested.

**index**

A specific logical block of data or storage node to use to simulate the failure event.

If you exceed the range of available logical blocks or storage nodes of data, you receive an error that tells you the maximum index value that you can specify. To avoid this error, see [Displaying volume status for an Aurora PostgreSQL DB cluster (p. 1405)](#).
**is_disk**

Indicates whether the injection failure is to a logical block or a storage node. Specifying true means injection failures are to a logical block. Specifying false means injection failures are to a storage node.

**time_interval**

The amount of time to simulate the Aurora Replica failure. The interval is in seconds. For example, if the value is 20, the simulation runs for 20 seconds.

**minimum, maximum**

The minimum and maximum amount of congestion delay, in milliseconds. Valid values range from 0.0 to 100.0 milliseconds. Disk segments marked as congested are delayed for a random amount of time within the minimum and maximum range for the duration of the simulation. The maximum value must be greater than the minimum value.

## Displaying volume status for an Aurora PostgreSQL DB cluster

In Amazon Aurora, a DB cluster volume consists of a collection of logical blocks. Each of these represents 10 gigabytes of allocated storage. These blocks are called *protection groups*.

The data in each protection group is replicated across six physical storage devices, called *storage nodes*. These storage nodes are allocated across three Availability Zones (AZs) in the region where the DB cluster resides. In turn, each storage node contains one or more logical blocks of data for the DB cluster volume. For more information about protection groups and storage nodes, see [Introducing the Aurora storage engine](https://aws.amazon.com/blogs/database/introducing-the-aurora-storage-engine/) on the AWS Database Blog. To learn more about Aurora cluster volumes in general, see [Amazon Aurora storage and reliability](p. 97).

Use the `aurora_show_volume_status()` function to return the following server status variables:

- **Disks** — The total number of logical blocks of data for the DB cluster volume.
- **Nodes** — The total number of storage nodes for the DB cluster volume.

You can use the `aurora_show_volume_status()` function to help avoid an error when using the `aurora_inject_disk_failure()` fault injection function. The `aurora_inject_disk_failure()` fault injection function simulates the failure of an entire storage node, or a single logical block of data within a storage node. In the function, you specify the index value of a specific logical block of data or storage node. However, the statement returns an error if you specify an index value greater than the number of logical blocks of data or storage nodes used by the DB cluster volume. For more information about fault injection queries, see [Testing Amazon Aurora PostgreSQL by using fault injection queries](p. 1401).

**Note**

The `aurora_show_volume_status()` function is available for Aurora PostgreSQL version 10.11. For more information about Aurora PostgreSQL versions, see [Amazon Aurora PostgreSQL releases and engine versions](p. 1781).

**Syntax**

```
SELECT * FROM aurora_show_volume_status();
```

**Example**

1405
Specifying the RAM disk for the stats_temp_directory

You can use the Aurora PostgreSQL parameter, rds.pg_stat_ramdisk_size, to specify the system memory allocated to a RAM disk for storing the PostgreSQL stats_temp_directory. The RAM disk parameter is only available in Aurora PostgreSQL 14 and lower versions.

Under certain workloads, setting this parameter can improve performance and decrease IO requirements. For more information about the stats_temp_directory, see Run-time Statistics in the PostgreSQL documentation. From PostgreSQL version 15, the PostgreSQL community switched to use dynamic shared memory. So, there is no need to set stats_temp_directory.

To enable a RAM disk for your stats_temp_directory, set the rds.pg_stat_ramdisk_size parameter to a non-zero value in the DB cluster parameter group used by your DB cluster. This parameter denotes MB, so you must use an integer value. Expressions, formulas, and functions aren't valid for the rds.pg_stat_ramdisk_size parameter. Be sure to restart the DB cluster so that the change takes effect. For information about setting parameters, see Working with parameter groups (p. 212). For more information about restarting the DB cluster, see Rebooting an Amazon Aurora DB cluster or Amazon Aurora DB instance (p. 358).

As an example, the following AWS CLI command sets the RAM disk parameter to 256 MB.

```
aws rds modify-db-cluster-parameter-group
    --db-cluster-parameter-group-name db-cl-pg-ramdisk-testing
    --parameters "ParameterName=rds.pg_stat_ramdisk_size, ParameterValue=256,
    ApplyMethod=pending-reboot"
```

After you restart the DB cluster, run the following command to see the status of the stats_temp_directory:

```
postgres=> SHOW stats_temp_directory;
```

The command should return the following:

```
stats_temp_directory
---------------------------
/rdsdbramdisk/pg_stat_tmp
(1 row)
```

Managing temporary files with PostgreSQL

In PostgreSQL, a query performing sort and hash operations uses the instance memory to store results up to the value specified in the work_mem parameter. When the instance memory is not sufficient, temporary files are created to store the results. These are written to disk to complete the query execution. Later, these files are automatically removed after the query completes. In Aurora PostgreSQL, these files share local storage with other log files. You can monitor your Aurora PostgreSQL DB cluster's local storage space by watching the Amazon CloudWatch metric for FreeLocalStorage. For more information, see Troubleshoot local storage issues.

You can use the following parameters and functions to manage the temporary files in your instance.
• **temp_file_limit** – This parameter cancels any query exceeding the size of temp_files in KB. This limit prevents any query from running endlessly and consuming disk space with temporary files. You can estimate the value using the results from the `log_temp_files` parameter. As a best practice, examine the workload behavior and set the limit according to the estimation. The following example shows how a query is canceled when it exceeds the limit.

```sql
postgres=> select * from pgbench_accounts, pg_class, big_table;
ERROR: temporary file size exceeds temp_file_limit (64kB)
```

• **log_temp_files** – This parameter sends messages to the `postgresql.log` when the temporary files of a session are removed. This parameter produces logs after a query successfully completes. Therefore, it might not help in troubleshooting active, long-running queries.

The following example shows that when the query successfully completes, the entries are logged in the `postgresql.log` file while the temporary files are cleaned up.

```
2023-02-06 23:48:35 UTC:205.251.233.182(12456):adminuser@postgres:[31236]:STATEMENT: select a.aid from pgbench_accounts a, pgbench_accounts b where a.bid=b.bid order by a.bid limit 10;
2023-02-06 23:48:35 UTC:205.251.233.182(12456):adminuser@postgres:[31236]:STATEMENT: select a.aid from pgbench_accounts a, pgbench_accounts b where a.bid=b.bid order by a.bid limit 10;
```

• **pg_ls_tmpdir** – This function that is available from RDS for PostgreSQL 13 and above provides visibility into the current temporary file usage. The completed query doesn't appear in the results of the function. In the following example, you can view the results of this function.

```sql
postgres=> select * from pg_ls_tmpdir();
```

<table>
<thead>
<tr>

- **pg_stat_statements** – If you activate the `pg_stat_statements` parameter, then you can view the average temporary file usage per call. You can identify the query_id of the query and use it to examine the temporary file usage as shown in the following example.

```
postgres=> select queryid from pg_stat_statements where query like 'select a.aid from pgbench%';
```

<table>
<thead>
<tr>
<th>queryid</th>
</tr>
</thead>
<tbody>
<tr>
<td>-7170349228837045701</td>
</tr>
</tbody>
</table>

(1 row)

```
postgres=> select queryid, substr(query,1,25), calls, temp_blks_read/calls temp_blks_read_per_call, temp_blks_written/calls temp_blks_written_per_call from pg_stat_statements where queryid = -7170349228837045701;
```

<table>
<thead>
<tr>
<th>queryid</th>

- **Performance Insights** – In the Performance Insights dashboard, you can view temporary file usage by turning on the metrics `temp_bytes` and `temp_files`. Then, you can see the average of both of these metrics and see how they correspond to the query workload. The view within Performance Insights doesn't show specifically the queries that are generating the temporary files. However, when you combine Performance Insights with the query shown for `pg_ls_tmpdir`, you can troubleshoot, analyze, and determine the changes in your query workload.

For more information about how to analyze metrics and queries with Performance Insights, see [Analyzing metrics with the Performance Insights dashboard (p. 576)](https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUserGuide/aurora-performanceinsights-reference.html).

**To view the temporary file usage with Performance Insights**

1. In the Performance Insights dashboard, choose Manage Metrics.
2. Choose **Database metrics**, and select the **temp_bytes** and **temp_files** metrics as shown in the following image.

![Select metrics shown on the graph](image)

3. In the **Top SQL** tab, choose the **Preferences** icon.

4. In the **Preferences** window, turn on the following statistics to appear in the **Top SQL** tab and choose **Continue**.
   - Temp writes/sec
   - Temp reads/sec
   - Tmp blk write/call
   - Tmp blk read/call

5. The temporary file is broken out when combined with the query shown for `pg_ls_tmpdir`, as shown in the following example.
The IO:BufFileRead and IO:BufFileWrite events occur when the top queries in your workload often create temporary files. You can use Performance Insights to identify top queries waiting on IO:BufFileRead and IO:BufFileWrite by reviewing Average Active Session (AAS) in Database Load and Top SQL sections.

For more information on how to analyze top queries and load by wait event with Performance Insights, see Overview of the Top SQL tab (p. 592). You should identify and tune the queries that cause increase in temporary file usage and related wait events. For more information on these wait events and remediation, see IO:BufFileRead and IO:BufFileWrite.

Note

The work_mem parameter controls when the sort operation runs out of memory and results are written into temporary files. We recommend that you don't change the setting of this parameter higher than the default value because it would permit every database session to consume more memory. Also, a single session that performs complex joins and sorts can perform parallel operations in which each operation consumes memory.

As a best practice, when you have a large report with multiple joins and sorts, set this parameter at the session level by using the SET work_mem command. Then the change is only applied to the current session and doesn't change the value globally.

Tuning with wait events for Aurora PostgreSQL

Wait events are an important tuning tool for Aurora PostgreSQL. When you can find out why sessions are waiting for resources and what they are doing, you're better able to reduce bottlenecks. You can use the information in this section to find possible causes and corrective actions. Before delving into this section, we strongly recommend that you understand basic Aurora concepts, especially the following topics:

- Amazon Aurora storage and reliability (p. 97)
- Managing performance and scaling for Aurora DB clusters (p. 297)

Important

The wait events in this section are specific to Aurora PostgreSQL. Use the information in this section to tune Amazon Aurora only, not RDS for PostgreSQL.

Some wait events in this section have no analogs in the open source versions of these database engines. Other wait events have the same names as events in open source engines, but behave
differently. For example, Amazon Aurora storage works differently from open source storage, so storage-related wait events indicate different resource conditions.

• LWLock:MultiXact (p. 1461)
• Timeout:PgSleep (p. 1463)

Essential concepts for Aurora PostgreSQL tuning

Before you tune your Aurora PostgreSQL database, make sure to learn what wait events are and why they occur. Also review the basic memory and disk architecture of Aurora PostgreSQL. For a helpful architecture diagram, see the PostgreSQL wikibook.

Topics

• Aurora PostgreSQL wait events (p. 1411)
• Aurora PostgreSQL memory (p. 1412)
• Aurora PostgreSQL processes (p. 1413)

Aurora PostgreSQL wait events

A wait event indicates a resource for which a session is waiting. For example, the wait event Client:ClientRead occurs when Aurora PostgreSQL is waiting to receive data from the client. Typical resources that a session waits for include the following:

• Single-threaded access to a buffer, for example, when a session is attempting to modify a buffer
• A row that is currently locked by another session
• A data file read
• A log file write
For example, to satisfy a query, the session might perform a full table scan. If the data isn't already in memory, the session waits for the disk I/O to complete. When the buffers are read into memory, the session might need to wait because other sessions are accessing the same buffers. The database records the waits by using a predefined wait event. These events are grouped into categories.

A wait event doesn't by itself show a performance problem. For example, if requested data isn't in memory, reading data from disk is necessary. If one session locks a row for an update, another session waits for the row to be unlocked so that it can update it. A commit requires waiting for the write to a log file to complete. Waits are integral to the normal functioning of a database.

Large numbers of wait events typically show a performance problem. In such cases, you can use wait event data to determine where sessions are spending time. For example, if a report that typically runs in minutes now runs for hours, you can identify the wait events that contribute the most to total wait time. If you can determine the causes of the top wait events, you can sometimes make changes that improve performance. For example, if your session is waiting on a row that has been locked by another session, you can end the locking session.

**Aurora PostgreSQL memory**

Aurora PostgreSQL memory is divided into shared and local.

**Topics**
- Shared memory in Aurora PostgreSQL (p. 1412)
- Local memory in Aurora PostgreSQL (p. 1413)

**Shared memory in Aurora PostgreSQL**

Aurora PostgreSQL allocates shared memory when the instance starts. Shared memory is divided into multiple subareas. Following, you can find a description of the most important ones.

**Topics**
- Shared buffers (p. 1412)
- Write ahead log (WAL) buffers (p. 1412)

**Shared buffers**

The *shared buffer pool* is an Aurora PostgreSQL memory area that holds all pages that are or were being used by application connections. A *page* is the memory version of a disk block. The shared buffer pool caches the data blocks read from disk. The pool reduces the need to reread data from disk, making the database operate more efficiently.

Every table and index is stored as an array of pages of a fixed size. Each block contains multiple tuples, which correspond to rows. A tuple can be stored in any page.

The shared buffer pool has finite memory. If a new request requires a page that isn't in memory, and no more memory exists, Aurora PostgreSQL evicts a less frequently used page to accommodate the request. The eviction policy is implemented by a clock sweep algorithm.

The `shared_buffers` parameter determines how much memory the server dedicates to caching data.

**Write ahead log (WAL) buffers**

A *write-ahead log (WAL) buffer* holds transaction data that Aurora PostgreSQL later writes to persistent storage. Using the WAL mechanism, Aurora PostgreSQL can do the following:

- Recover data after a failure
- Reduce disk I/O by avoiding frequent writes to disk
When a client changes data, Aurora PostgreSQL writes the changes to the WAL buffer. When the client issues a `COMMIT`, the WAL writer process writes transaction data to the WAL file.

The `wal_level` parameter determines how much information is written to the WAL.

**Local memory in Aurora PostgreSQL**

Every backend process allocates local memory for query processing.

**Topics**

- Work memory area (p. 1413)
- Maintenance work memory area (p. 1413)
- Temporary buffer area (p. 1413)

**Work memory area**

The *work memory area* holds temporary data for queries that performs sorts and hashes. For example, a query with an `ORDER BY` clause performs a sort. Queries use hash tables in hash joins and aggregations.

The `work_mem` parameter the amount of memory to be used by internal sort operations and hash tables before writing to temporary disk files. The default value is 4 MB. Multiple sessions can run simultaneously, and each session can run maintenance operations in parallel. For this reason, the total work memory used can be multiples of the `work_mem` setting.

**Maintenance work memory area**

The *maintenance work memory area* caches data for maintenance operations. These operations include vacuuming, creating an index, and adding foreign keys.

The `maintenance_work_mem` parameter specifies the maximum amount of memory to be used by maintenance operations. The default value is 64 MB. A database session can only run one maintenance operation at a time.

**Temporary buffer area**

The *temporary buffer area* caches temporary tables for each database session.

Each session allocates temporary buffers as needed up to the limit you specify. When the session ends, the server clears the buffers.

The `temp_buffers` parameter sets the maximum number of temporary buffers used by each session. Before the first use of temporary tables within a session, you can change the `temp_buffers` value.

**Aurora PostgreSQL processes**

Aurora PostgreSQL uses multiple processes.

**Topics**

- Postmaster process (p. 1413)
- Backend processes (p. 1414)
- Background processes (p. 1414)

**Postmaster process**

The *postmaster process* is the first process started when you start Aurora PostgreSQL. The postmaster process has the following primary responsibilities:
Fork and monitor background processes
Receive authentication requests from client processes, and authenticate them before allowing the database to service requests

Backend processes
If the postmaster authenticates a client request, the postmaster forks a new backend process, also called a postgres process. One client process connects to exactly one backend process. The client process and the backend process communicate directly without intervention by the postmaster process.

Background processes
The postmaster process forks several processes that perform different backend tasks. Some of the more important include the following:

- WAL writer
  Aurora PostgreSQL writes data in the WAL (write ahead logging) buffer to the log files. The principle of write ahead logging is that the database can't write changes to the data files until after the database writes log records describing those changes to disk. The WAL mechanism reduces disk I/O, and allows Aurora PostgreSQL to use the logs to recover the database after a failure.
- Background writer
  This process periodically write dirty (modified) pages from the memory buffers to the data files. A page becomes dirty when a backend process modifies it in memory.
- Autovacuum daemon
  The daemon consists of the following:
  - The autovacuum launcher
  - The autovacuum worker processes
  When autovacuum is turned on, it checks for tables that have had a large number of inserted, updated, or deleted tuples. The daemon has the following responsibilities:
    - Recover or reuse disk space occupied by updated or deleted rows
    - Update statistics used by the planner
    - Protect against loss of old data because of transaction ID wraparound
  The autovacuum feature automates the execution of VACUUM and ANALYZE commands. VACUUM has the following variants: standard and full. Standard vacuum runs in parallel with other database operations. VACUUM FULL requires an exclusive lock on the table it is working on. Thus, it can't run in parallel with operations that access the same table. VACUUM creates a substantial amount of I/O traffic, which can cause poor performance for other active sessions.

Aurora PostgreSQL wait events
The following table lists the wait events for Aurora PostgreSQL that most commonly indicate performance problems, and summarizes the most common causes and corrective actions. The following wait events are a subset of the list in Amazon Aurora PostgreSQL wait events (p. 1762).

<table>
<thead>
<tr>
<th>Wait event</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Client:ClientRead</td>
<td>This event occurs when Aurora PostgreSQL is waiting to receive data from the client.</td>
</tr>
</tbody>
</table>

1414
<table>
<thead>
<tr>
<th>Wait event</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Client:ClientWrite (p. 1418)</td>
<td>This event occurs when Aurora PostgreSQL is waiting to write data to the client.</td>
</tr>
<tr>
<td>CPU (p. 1420)</td>
<td>This event occurs when a thread is active in CPU or is waiting for CPU.</td>
</tr>
<tr>
<td>IO:BufFileRead and IO:BufFileWrite (p. 1424)</td>
<td>These events occur when Aurora PostgreSQL creates temporary files.</td>
</tr>
<tr>
<td>IO:DataFileRead (p. 1429)</td>
<td>This event occurs when a connection waits on a backend process to read a required page from storage because the page isn't available in shared memory.</td>
</tr>
<tr>
<td>IO:XactSync (p. 1439)</td>
<td>This event occurs when the database is waiting for the Aurora storage subsystem to acknowledge the commit of a regular transaction, or the commit or rollback of a prepared transaction.</td>
</tr>
<tr>
<td>IPC:DamRecordTxAck (p. 1441)</td>
<td>This event occurs when Aurora PostgreSQL in a session using database activity streams generates an activity stream event, then waits for that event to become durable.</td>
</tr>
<tr>
<td>Lock:advisory (p. 1442)</td>
<td>This event occurs when a PostgreSQL application uses a lock to coordinate activity across multiple sessions.</td>
</tr>
<tr>
<td>Lock:extend (p. 1444)</td>
<td>This event occurs when a backend process is waiting to lock a relation to extend it while another process has a lock on that relation for the same purpose.</td>
</tr>
<tr>
<td>Lock:Relation (p. 1445)</td>
<td>This event occurs when a query is waiting to acquire a lock on a table or view that's currently locked by another transaction.</td>
</tr>
<tr>
<td>Lock:transactionid (p. 1449)</td>
<td>This event occurs when a transaction is waiting for a row-level lock.</td>
</tr>
<tr>
<td>Lock:tuple (p. 1451)</td>
<td>This event occurs when a backend process is waiting to acquire a lock on a tuple.</td>
</tr>
<tr>
<td>LWLock:buffer_content (BufferContent) (p. 1454)</td>
<td>This event occurs when a session is waiting to read or write a data page in memory while another session has that page locked for writing.</td>
</tr>
<tr>
<td>LWLock:buffer_mapping (p. 1455)</td>
<td>This event occurs when a session is waiting to associate a data block with a buffer in the shared buffer pool.</td>
</tr>
<tr>
<td>LWLock:BufferIO (IPC:BufferIO) (p. 1457)</td>
<td>This event occurs when Aurora PostgreSQL or RDS for PostgreSQL is waiting for other processes to finish their input/output (I/O) operations when concurrently trying to access a page.</td>
</tr>
<tr>
<td>LWLock:lock_manager (p. 1458)</td>
<td>This event occurs when the Aurora PostgreSQL engine maintains the shared lock's memory area to allocate, check, and deallocate a lock when a fast path lock isn't possible.</td>
</tr>
</tbody>
</table>
Wait event | Definition
--- | ---
LWLock:MultiXact (p. 1461) | This type of event occurs when Aurora PostgreSQL is keeping a session open to complete multiple transactions that involve the same row in a table. The wait event denotes which aspect of multiple transaction processing is generating the wait event, that is, LWLock:MultiXactOffsetSLRU, LWLock:MultiXactOffsetBuffer, LWLock:MultiXactMemberSLRU, or LWLock:MultiXactMemberBuffer.
Timeout:PgSleep (p. 1463) | This event occurs when a server process has called the pg_sleep function and is waiting for the sleep timeout to expire.

### Client:ClientRead

The Client:ClientRead event occurs when Aurora PostgreSQL is waiting to receive data from the client.

**Topics**
- Supported engine versions (p. 1416)
- Context (p. 1416)
- Likely causes of increased waits (p. 1416)
- Actions (p. 1417)

## Supported engine versions

This wait event information is supported for Aurora PostgreSQL version 10 and higher.

## Context

An Aurora PostgreSQL DB cluster is waiting to receive data from the client. The Aurora PostgreSQL DB cluster must receive the data from the client before it can send more data to the client. The time that the cluster waits before receiving data from the client is a Client:ClientRead event.

## Likely causes of increased waits

Common causes for the Client:ClientRead event to appear in top waits include the following:

**Increased network latency**

There might be increased network latency between the Aurora PostgreSQL DB cluster and client. Higher network latency increases the time required for DB cluster to receive data from the client.

**Increased load on the client**

There might be CPU pressure or network saturation on the client. An increase in load on the client can delay transmission of data from the client to the Aurora PostgreSQL DB cluster.

**Excessive network round trips**

A large number of network round trips between the Aurora PostgreSQL DB cluster and the client can delay transmission of data from the client to the Aurora PostgreSQL DB cluster.
Large copy operation

During a copy operation, the data is transferred from the client's file system to the Aurora PostgreSQL DB cluster. Sending a large amount of data to the DB cluster can delay transmission of data from the client to the DB cluster.

Idle client connection

A connection to an Aurora PostgreSQL DB instance is in idle in transaction state and is waiting for a client to send more data or issue a command. This state can lead to an increase in Client:ClientRead events.

PgBouncer used for connection pooling

PgBouncer has a low-level network configuration setting called pkt_buf, which is set to 4,096 by default. If the workload is sending query packets larger than 4,096 bytes through PgBouncer, we recommend increasing the pkt_buf setting to 8,192. If the new setting doesn't decrease the number of Client:ClientRead events, we recommend increasing the pkt_buf setting to larger values, such as 16,384 or 32,768. If the query text is large, the larger setting can be particularly helpful.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Place the clients in the same Availability Zone and VPC subnet as the cluster (p. 1417)
- Scale your client (p. 1417)
- Use current generation instances (p. 1417)
- Increase network bandwidth (p. 1418)
- Monitor maximums for network performance (p. 1418)
- Monitor for transactions in the "idle in transaction" state (p. 1418)

Place the clients in the same Availability Zone and VPC subnet as the cluster

To reduce network latency and increase network throughput, place clients in the same Availability Zone and virtual private cloud (VPC) subnet as the Aurora PostgreSQL DB cluster. Make sure that the clients are as geographically close to the DB cluster as possible.

Scale your client

Using Amazon CloudWatch or other host metrics, determine if your client is currently constrained by CPU or network bandwidth, or both. If the client is constrained, scale your client accordingly.

Use current generation instances

In some cases, you might not be using a DB instance class that supports jumbo frames. If you're running your application on Amazon EC2, consider using a current generation instance for the client. Also, configure the maximum transmission unit (MTU) on the client operating system. This technique might reduce the number of network round trips and increase network throughput. For more information, see Jumbo frames (9001 MTU) in the Amazon EC2 User Guide for Linux Instances.

For information about DB instance classes, see Aurora DB instance classes (p. 84). To determine the DB instance class that is equivalent to an Amazon EC2 instance type, place db. before the Amazon EC2 instance type name. For example, the r5.8xlarge Amazon EC2 instance is equivalent to the db.r5.8xlarge DB instance class.
Increase network bandwidth

Use NetworkReceiveThroughput and NetworkTransmitThroughput Amazon CloudWatch metrics to monitor incoming and outgoing network traffic on the DB cluster. These metrics can help you to determine if network bandwidth is sufficient for your workload.

If your network bandwidth isn't enough, increase it. If the AWS client or your DB instance is reaching the network bandwidth limits, the only way to increase the bandwidth is to increase your DB instance size.

For more information about CloudWatch metrics, see Amazon CloudWatch metrics for Amazon Aurora (p. 638).

Monitor maximums for network performance

If you are using Amazon EC2 clients, Amazon EC2 provides maximums for network performance metrics, including aggregate inbound and outbound network bandwidth. It also provides connection tracking to ensure that packets are returned as expected and link-local services access for services such as the Domain Name System (DNS). To monitor these maximums, use a current enhanced networking driver and monitor network performance for your client.

For more information, see Monitor network performance for your Amazon EC2 instance in the Amazon EC2 User Guide for Linux Instances and Monitor network performance for your Amazon EC2 instance in the Amazon EC2 User Guide for Windows Instances.

Monitor for transactions in the "idle in transaction" state

Check whether you have an increasing number of idle in transaction connections. To do this, monitor the state column in the pg_stat_activity table. You might be able to identify the connection source by running a query similar to the following.

```
select client_addr, state, count(1) from pg_stat_activity
where state like 'idle in transaction%'
group by 1,2
order by 3 desc
```

**Client:ClientWrite**

The Client:ClientWrite event occurs when Aurora PostgreSQL is waiting to write data to the client.

**Topics**

- Supported engine versions (p. 1418)
- Context (p. 1418)
- Likely causes of increased waits (p. 1419)
- Actions (p. 1419)

**Supported engine versions**

This wait event information is supported for Aurora PostgreSQL version 10 and higher.

**Context**

A client process must read all of the data received from an Aurora PostgreSQL DB cluster before the cluster can send more data. The time that the cluster waits before sending more data to the client is a Client:ClientWrite event.
Reduced network throughput between the Aurora PostgreSQL DB cluster and the client can cause this event. CPU pressure and network saturation on the client can also cause this event. **CPU pressure** is when the CPU is fully utilized and there are tasks waiting for CPU time. **Network saturation** is when the network between the database and client is carrying more data than it can handle.

**Likely causes of increased waits**

Common causes for the `Client:ClientWrite` event to appear in top waits include the following:

**Increased network latency**

There might be increased network latency between the Aurora PostgreSQL DB cluster and client. Higher network latency increases the time required for the client to receive the data.

**Increased load on the client**

There might be CPU pressure or network saturation on the client. An increase in load on the client delays the reception of data from the Aurora PostgreSQL DB cluster.

**Large volume of data sent to the client**

The Aurora PostgreSQL DB cluster might be sending a large amount of data to the client. A client might not be able to receive the data as fast as the cluster is sending it. Activities such as a copy of a large table can result in an increase in `Client:ClientWrite` events.

**Actions**

We recommend different actions depending on the causes of your wait event.

**Topics**

- Place the clients in the same Availability Zone and VPC subnet as the cluster (p. 1419)
- Use current generation instances (p. 1419)
- Reduce the amount of data sent to the client (p. 1419)
- Scale your client (p. 1420)

**Place the clients in the same Availability Zone and VPC subnet as the cluster**

To reduce network latency and increase network throughput, place clients in the same Availability Zone and virtual private cloud (VPC) subnet as the Aurora PostgreSQL DB cluster.

**Use current generation instances**

In some cases, you might not be using a DB instance class that supports jumbo frames. If you're running your application on Amazon EC2, consider using a current generation instance for the client. Also, configure the maximum transmission unit (MTU) on the client operating system. This technique might reduce the number of network round trips and increase network throughput. For more information, see [Jumbo frames (9001 MTU)](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/jumbo-frames.html) in the *Amazon EC2 User Guide for Linux Instances*.

For information about DB instance classes, see [Aurora DB instance classes (p. 84)](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-db-instance-classes.html). To determine the DB instance class that is equivalent to an Amazon EC2 instance type, place `db.` before the Amazon EC2 instance type name. For example, the `r5.8xlarge` Amazon EC2 instance is equivalent to the `db.r5.8xlarge` DB instance class.

**Reduce the amount of data sent to the client**

When possible, adjust your application to reduce the amount of data that the Aurora PostgreSQL DB cluster sends to the client. Making such adjustments relieves CPU and network contention on the client.
Scale your client

Using Amazon CloudWatch or other host metrics, determine if your client is currently constrained by CPU or network bandwidth, or both. If the client is constrained, scale your client accordingly.

CPU

This event occurs when a thread is active in CPU or is waiting for CPU.

Topics
- Supported engine versions (p. 1420)
- Context (p. 1420)
- Likely causes of increased waits (p. 1421)
- Actions (p. 1422)

Supported engine versions

This wait event information is relevant for Aurora PostgreSQL version 9.6 and higher.

Context

The central processing unit (CPU) is the component of a computer that runs instructions. For example, CPU instructions perform arithmetic operations and exchange data in memory. If a query increases the number of instructions that it performs through the database engine, the time spent running the query increases. CPU scheduling is giving CPU time to a process. Scheduling is orchestrated by the kernel of the operating system.

Topics
- How to tell when this wait occurs (p. 1420)
- DBLoadCPU metric (p. 1421)
- os.cpuUtilization metrics (p. 1421)
- Likely cause of CPU scheduling (p. 1421)

How to tell when this wait occurs

This CPU wait event indicates that a backend process is active in CPU or is waiting for CPU. You know that it's occurring when a query shows the following information:

- The pg_stat_activity.state column has the value active.
- The wait_event_type and wait_event columns in pg_stat_activity are both null.

To see the backend processes that are using or waiting on CPU, run the following query.

```
SELECT * FROM pg_stat_activity
WHERE state = 'active'
AND wait_event_type IS NULL
AND wait_event IS NULL;
```
**DBLoadCPU metric**

The Performance Insights metric for CPU is DBLoadCPU. The value for DBLoadCPU can differ from the value for the Amazon CloudWatch metric CPUUtilization. The latter metric is collected from the HyperVisor for a database instance.

**os.cpuUtilization metrics**

Performance Insights operating-system metrics provide detailed information about CPU utilization. For example, you can display the following metrics:

- os.cpuUtilization.nice.avg
- os.cpuUtilization.total.avg
- os.cpuUtilization.wait.avg
- os.cpuUtilization.idle.avg

Performance Insights reports the CPU usage by the database engine as os.cpuUtilization.nice.avg.

**Likely cause of CPU scheduling**

From an operating system perspective, the CPU is active when it isn't running the idle thread. The CPU is active while it performs a computation, but it's also active when it waits on memory I/O. This type of I/O dominates a typical database workload.

Processes are likely to wait to get scheduled on a CPU when the following conditions are met:

- The CloudWatch CPUUtilization metric is near 100 percent.
- The average load is greater than the number of vCPUs, indicating a heavy load. You can find the loadAverageMinute metric in the OS metrics section in Performance Insights.

**Likely causes of increased waits**

When the CPU wait event occurs more than normal, possibly indicating a performance problem, typical causes include the following.

**Topics**

- Likely causes of sudden spikes (p. 1421)
- Likely causes of long-term high frequency (p. 1422)
- Corner cases (p. 1422)

**Likely causes of sudden spikes**

The most likely causes of sudden spikes are as follows:

- Your application has opened too many simultaneous connections to the database. This scenario is known as a "connection storm."
- Your application workload changed in any of the following ways:
  - New queries
  - An increase in the size of your dataset
  - Index maintenance or creation
  - New functions
  - New operators
• An increase in parallel query execution
• Your query execution plans have changed. In some cases, a change can cause an increase in buffers. For example, the query is now using a sequential scan when it previously used an index. In this case, the queries need more CPU to accomplish the same goal.

Likely causes of long-term high frequency

The most likely causes of events that recur over a long period:

• Too many backend processes are running concurrently on CPU. These processes can be parallel workers.
• Queries are performing suboptimally because they need a large number of buffers.

Corner cases

If none of the likely causes turn out to be actual causes, the following situations might be occurring:

• The CPU is swapping processes in and out.
• CPU context switching has increased.
• Aurora PostgreSQL code is missing wait events.

Actions

If the CPU wait event dominates database activity, it doesn't necessarily indicate a performance problem. Respond to this event only when performance degrades.

Topics

• Investigate whether the database is causing the CPU increase (p. 1422)
• Determine whether the number of connections increased (p. 1422)
• Respond to workload changes (p. 1423)

Investigate whether the database is causing the CPU increase

Examine the os.cpuUtilization.nice.avg metric in Performance Insights. If this value is far less than the CPU usage, nondatabase processes are the main contributor to CPU.

Determine whether the number of connections increased

Examine the DatabaseConnections metric in Amazon CloudWatch. Your action depends on whether the number increased or decreased during the period of increased CPU wait events.

The connections increased

If the number of connections went up, compare the number of backend processes consuming CPU to the number of vCPUs. The following scenarios are possible:

• The number of backend processes consuming CPU is less than the number of vCPUs.
  In this case, the number of connections isn't an issue. However, you might still try to reduce CPU utilization.
• The number of backend processes consuming CPU is greater than the number of vCPUs.
  In this case, consider the following options:
• Decrease the number of backend processes connected to your database. For example, implement a connection pooling solution such as RDS Proxy. To learn more, see Using Amazon RDS Proxy for Aurora (p. 1879).
• Upgrade your instance size to get a higher number of vCPUs.
• Redirect some read-only workloads to reader nodes, if applicable.

The connections didn't increase

Examine the blks_hit metrics in Performance Insights. Look for a correlation between an increase in blks_hit and CPU usage. The following scenarios are possible:

• CPU usage and blks_hit are correlated.

  In this case, find the top SQL statements that are linked to the CPU usage, and look for plan changes. You can use either of the following techniques:
  • Explain the plans manually and compare them to the expected execution plan.
  • Look for an increase in block hits per second and local block hits per second. In the Top SQL section of Performance Insights dashboard, choose Preferences.

• CPU usage and blks_hit aren't correlated.

  In this case, determine whether any of the following occurs:
  • The application is rapidly connecting to and disconnecting from the database.
    
    Diagnose this behavior by turning on log_connections and log_disconnections, then analyzing the PostgreSQL logs. Consider using the pgbadger log analyzer. For more information, see https://github.com/darold/pgbadger.
  • The OS is overloaded.

    In this case, Performance Insights shows that backend processes are consuming CPU for a longer time than usual. Look for evidence in the Performance Insights os.cpuUtilization metrics or the CloudWatch CPUUtilization metric. If the operating system is overloaded, look at Enhanced Monitoring metrics to diagnose further. Specifically, look at the process list and the percentage of CPU consumed by each process.
  • Top SQL statements are consuming too much CPU.

    Examine statements that are linked to the CPU usage to see whether they can use less CPU. Run an EXPLAIN command, and focus on the plan nodes that have the most impact. Consider using a PostgreSQL execution plan visualizer. To try out this tool, see http://explain.dalibo.com/.

Respond to workload changes

If your workload has changed, look for the following types of changes:

New queries

  Check whether the new queries are expected. If so, ensure that their execution plans and the number of executions per second are expected.

An increase in the size of the data set

  Determine whether partitioning, if it's not already implemented, might help. This strategy might reduce the number of pages that a query needs to retrieve.

Index maintenance or creation

  Check whether the schedule for the maintenance is expected. A best practice is to schedule maintenance activities outside of peak activities.
New functions

Check whether these functions perform as expected during testing. Specifically, check whether the number of executions per second is expected.

New operators

Check whether they perform as expected during the testing.

An increase in running parallel queries

Determine whether any of the following situations has occurred:

• The relations or indexes involved have suddenly grown in size so that they differ significantly from min_parallel_table_scan_size or min_parallel_index_scan_size.
• Recent changes have been made to parallel_setup_cost or parallel_tuple_cost.
• Recent changes have been made to max_parallel_workers or max_parallel_workers_per_gather.

IO:BufFileRead and IO:BufFileWrite

The IO:BufFileRead and IO:BufFileWrite events occur when Aurora PostgreSQL creates temporary files. When operations require more memory than the working memory parameters currently define, they write temporary data to persistent storage. This operation is sometimes called “spilling to disk.”

Topics

• Supported engine versions (p. 1424)
• Context (p. 1424)
• Likely causes of increased waits (p. 1425)
• Actions (p. 1425)

Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

Context

IO:BufFileRead and IO:BufFileWrite relate to the work memory area and maintenance work memory area. For more information about these local memory areas, see Work memory area (p. 1413) and Maintenance work memory area (p. 1413).

The default value for work_mem is 4 MB. If one session performs operations in parallel, each worker handling the parallelism uses 4 MB of memory. For this reason, set work_mem carefully. If you increase the value too much, a database running many sessions might consume too much memory. If you set the value too low, Aurora PostgreSQL creates temporary files in local storage. The disk I/O for these temporary files can reduce performance.

If you observe the following sequence of events, your database might be generating temporary files:

1. Sudden and sharp decreases in availability
2. Fast recovery for the free space

You might also see a “chainsaw” pattern. This pattern can indicate that your database is creating small files constantly.
Likely causes of increased waits

In general, these wait events are caused by operations that consume more memory than the work_mem or maintenance_work_mem parameters allocate. To compensate, the operations write to temporary files. Common causes for the IO:BufFileRead and IO:BufFileWrite events include the following:

Queries that need more memory than exists in the work memory area

Queries with the following characteristics use the work memory area:
- Hash joins
- ORDER BY clause
- GROUP BY clause
- DISTINCT
- Window functions
- CREATE TABLE AS SELECT
- Materialized view refresh

Statements that need more memory than exists in the maintenance work memory area

The following statements use the maintenance work memory area:
- CREATE INDEX
- CLUSTER

Actions

We recommend different actions depending on the causes of your wait event.

Topics
- Identify the problem (p. 1425)
- Examine your join queries (p. 1426)
- Examine your ORDER BY and GROUP BY queries (p. 1426)
- Avoid using the DISTINCT operation (p. 1427)
- Consider using window functions instead of GROUP BY functions (p. 1427)
- Investigate materialized views and CTAS statements (p. 1428)
- Use pg_repack when you create indexes (p. 1428)
- Increase maintenance_work_mem when you cluster tables (p. 1428)
- Tune memory to prevent IO:BufFileRead and IO:BufFileWrite (p. 1428)

Identify the problem

Assume a situation in which Performance Insights isn't turned on and you suspect that IO:BufFileRead and IO:BufFileWrite are occurring more frequently than is normal. Do the following:

1. Examine the FreeLocalStorage metric in Amazon CloudWatch.
2. Look for a chainsaw pattern, which is a series of jagged spikes.

A chainsaw pattern indicates a quick consumption and release of storage, often associated with temporary files. If you notice this pattern, turn on Performance Insights. When using Performance
Insights, you can identify when the wait events occur and which queries are associated with them. Your solution depends on the specific query causing the events.

Or set the parameter `log_temp_files`. This parameter logs all queries generating more than threshold KB of temporary files. If the value is 0, Aurora PostgreSQL logs all temporary files. If the value is 1024, Aurora PostgreSQL logs all queries that produces temporary files larger than 1 MB. For more information about `log_temp_files`, see Error Reporting and Logging in the PostgreSQL documentation.

**Examine your join queries**

Your application probably use joins. For example, the following query joins four tables.

```sql
SELECT *
FROM order
INNER JOIN order_item
  ON (order.id = order_item.order_id)
INNER JOIN customer
  ON (customer.id = order.customer_id)
INNER JOIN customer_address
  ON (customer_address.customer_id = customer.id AND
      order.customer_address_id = customer_address.id)
WHERE customer.id = 1234567890;
```

A possible cause of spikes in temporary file usage is a problem in the query itself. For example, a broken clause might not filter the joins properly. Consider the second inner join in the following example.

```sql
SELECT *
FROM order
INNER JOIN order_item
  ON (order.id = order_item.order_id)
INNER JOIN customer
  ON (customer.id = customer.id)
INNER JOIN customer_address
  ON (customer_address.customer_id = customer.id AND
      order.customer_address_id = customer_address.id)
WHERE customer.id = 1234567890;
```

The preceding query mistakenly joins `customer.id` to `customer.id`, generating a Cartesian product between every customer and every order. This type of accidental join generates large temporary files. Depending on the size of the tables, a Cartesian query can even fill up storage. Your application might have Cartesian joins when the following conditions are met:

- You see large, sharp decreases in storage availability, followed by fast recovery.
- No indexes are being created.
- No `CREATE TABLE FROM SELECT` statements are being issued.
- No materialized views are being refreshed.

To see whether the tables are being joined using the proper keys, inspect your query and object-relational mapping directives. Bear in mind that certain queries of your application are not called all the time, and some queries are dynamically generated.

**Examine your ORDER BY and GROUP BY queries**

In some cases, an ORDER BY clause can result in excessive temporary files. Consider the following guidelines:
• Only include columns in an ORDER BY clause when they need to be ordered. This guideline is especially important for queries that return thousands of rows and specify many columns in the ORDER BY clause.

• Considering creating indexes to accelerate ORDER BY clauses when they match columns that have the same ascending or descending order. Partial indexes are preferable because they are smaller. Smaller indexes are read and traversed more quickly.

• If you create indexes for columns that can accept null values, consider whether you want the null values stored at the end or at the beginning of the indexes.

If possible, reduce the number of rows that need to be ordered by filtering the result set. If you use WITH clause statements or subqueries, remember that an inner query generates a result set and passes it to the outside query. The more rows that a query can filter out, the less ordering the query needs to do.

• If you don't need to obtain the full result set, use the LIMIT clause. For example, if you only want the top five rows, a query using the LIMIT clause doesn't keep generating results. In this way, the query requires less memory and temporary files.

A query that uses a GROUP BY clause can also require temporary files. GROUP BY queries summarize values by using functions such as the following:

• COUNT
• AVG
• MIN
• MAX
• SUM
• STDDEV

To tune GROUP BY queries, follow the recommendations for ORDER BY queries.

**Avoid using the DISTINCT operation**

If possible, avoid using the DISTINCT operation to remove duplicated rows. The more unnecessary and duplicated rows that your query returns, the more expensive the DISTINCT operation becomes. If possible, add filters in the WHERE clause even if you use the same filters for different tables. Filtering the query and joining correctly improves your performance and reduces resource use. It also prevents incorrect reports and results.

If you need to use DISTINCT for multiple rows of a same table, consider creating a composite index. Grouping multiple columns in an index can improve the time to evaluate distinct rows. Also, if you use Amazon Aurora PostgreSQL version 10 or higher, you can correlate statistics among multiple columns by using the CREATE STATISTICS command.

**Consider using window functions instead of GROUP BY functions**

Using GROUP BY, you change the result set, and then retrieve the aggregated result. Using window functions, you aggregate data without changing the result set. A window function uses the OVER clause to perform calculations across the sets defined by the query, correlating one row with another. You can use all the GROUP BY functions in window functions, but also use functions such as the following:

• RANK
• ARRAY_AGG
• ROW_NUMBER
To minimize the number of temporary files generated by a window function, remove duplications for the same result set when you need two distinct aggregations. Consider the following query.

```sql
SELECT sum(salary) OVER (PARTITION BY dept ORDER BY salary DESC) as sum_salary,
      avg(salary) OVER (PARTITION BY dept ORDER BY salary ASC) as avg_salary
FROM empsalary;
```

You can rewrite the query with the WINDOW clause as follows.

```sql
SELECT sum(salary) OVER w as sum_salary,
      avg(salary) OVER w as_avg_salary
FROM empsalary
WINDOW w AS (PARTITION BY dept ORDER BY salary DESC);
```

By default, the Aurora PostgreSQL execution planner consolidates similar nodes so that it doesn't duplicate operations. However, by using an explicit declaration for the window block, you can maintain the query more easily. You might also improve performance by preventing duplication.

### Investigate materialized views and CTAS statements

When a materialized view refreshes, it runs a query. This query can contain an operation such as GROUP BY, ORDER BY, or DISTINCT. During a refresh, you might observe large numbers of temporary files and the wait events IO:BufFileWrite and IO:BufFileRead. Similarly, when you create a table based on a SELECT statement, the CREATE TABLE statement runs a query. To reduce the temporary files needed, optimize the query.

### Use pg_repack when you create indexes

When you create an index, the engine orders the result set. As tables grow in size, and as values in the indexed column become more diverse, the temporary files require more space. In most cases, you can't prevent the creation of temporary files for large tables without modifying the maintenance work memory area. For more information, see Maintenance work memory area (p. 1413).

A possible workaround when recreating a large index is to use the pg_repack tool. For more information, see Reorganize tables in PostgreSQL databases with minimal locks in the pg_repack documentation.

### Increase maintenance_work_mem when you cluster tables

The CLUSTER command clusters the table specified by `table_name` based on an existing index specified by `index_name`. Aurora PostgreSQL physically recreates the table to match the order of a given index.

When magnetic storage was prevalent, clustering was common because storage throughput was limited. Now that SSD-based storage is common, clustering is less popular. However, if you cluster tables, you can still increase performance slightly depending on the table size, index, query, and so on.

If you run the CLUSTER command and observe the wait events IO:BufFileWrite and IO:BufFileRead, tune `maintenance_work_mem`. Increase the memory size to a fairly large amount. A high value means that the engine can use more memory for the clustering operation.

### Tune memory to prevent IO:BufFileRead and IO:BufFileWrite

In some situation, you need to tune memory. Your goal is to balance the following requirements:
The `work_mem` value (see `Work memory area (p. 1413)`)

- The memory remaining after discounting the `shared_buffers` value (see `Buffer pool (p. 904)`)
- The maximum connections opened and in use, which is limited by `max_connections`

## Increase the size of the work memory area

In some situations, your only option is to increase the memory used by your session. If your queries are correctly written and are using the correct keys for joins, consider increasing the `work_mem` value. For more information, see `Work memory area (p. 1413)`.

To find out how many temporary files a query generates, set `log_temp_files` to 0. If you increase the `work_mem` value to the maximum value identified in the logs, you prevent the query from generating temporary files. However, `work_mem` sets the maximum per plan node for each connection or parallel worker. If the database has 5,000 connections, and if each one uses 256 MiB memory, the engine needs 1.2 TiB of RAM. Thus, your instance might run out of memory.

### Reserve sufficient memory for the shared buffer pool

Your database uses memory areas such as the shared buffer pool, not just the work memory area. Consider the requirements of these additional memory areas before you increase `work_mem`. For more information about the buffer pool, see `Buffer pool (p. 904)`.

For example, assume that your Aurora PostgreSQL instance class is `db.r5.2xlarge`. This class has 64 GiB of memory. By default, 75 percent of the memory is reserved for the shared buffer pool. After you subtract the amount allocated to the shared memory area, 16,384 MB remains. Don't allocate the remaining memory exclusively to the work memory area because the operating system and the engine also require memory.

The memory that you can allocate to `work_mem` depends on the instance class. If you use a larger instance class, more memory is available. However, in the preceding example, you can't use more than 16 GiB. Otherwise, your instance becomes unavailable when it runs out of memory. To recover the instance from the unavailable state, the Aurora PostgreSQL automation services automatically restart.

### Manage the number of connections

Suppose that your database instance has 5,000 simultaneous connections. Each connection uses at least 4 MiB of `work_mem`. The high memory consumption of the connections is likely to degrade performance. In response, you have the following options:

- Upgrade to a larger instance class.
- Decrease the number of simultaneous database connections by using a connection proxy or pooler.

For proxies, consider Amazon RDS Proxy, pgBouncer, or a connection pooler based on your application. This solution alleviates the CPU load. It also reduces the risk when all connections require the work memory area. When fewer database connections exist, you can increase the value of `work_mem`. In this way, you reduce the occurrence of the `IO:BufFileRead` and `IO:BufFileWrite` wait events. Also, the queries waiting for the work memory area speed up significantly.

## IO:DataFileRead

The `IO:DataFileRead` event occurs when a connection waits on a backend process to read a required page from storage because the page isn't available in shared memory.

### Topics

- Supported engine versions (p. 1430)
• **Context (p. 1430)**
• **Likely causes of increased waits (p. 1430)**
• **Actions (p. 1431)**

**Supported engine versions**

This wait event information is supported for all versions of Aurora PostgreSQL.

**Context**

All queries and data manipulation (DML) operations access pages in the buffer pool. Statements that can induce reads include SELECT, UPDATE, and DELETE. For example, an UPDATE can read pages from tables or indexes. If the page being requested or updated isn't in the shared buffer pool, this read can lead to the IO:DataFileRead event.

Because the shared buffer pool is finite, it can fill up. In this case, requests for pages that aren't in memory force the database to read blocks from disk. If the IO:DataFileRead event occurs frequently, your shared buffer pool might be too small to accommodate your workload. This problem is acute for SELECT queries that read a large number of rows that don't fit in the buffer pool. For more information about the buffer pool, see **Buffer pool (p. 904)**.

**Likely causes of increased waits**

Common causes for the IO:DataFileRead event include the following:

**Connection spikes**

You might find multiple connections generating the same number of IO:DataFileRead wait events. In this case, a spike (sudden and large increase) in IO:DataFileRead events can occur.

**SELECT and DML statements performing sequential scans**

Your application might be performing a new operation. Or an existing operation might change because of a new execution plan. In such cases, look for tables (particularly large tables) that have a greater seq_scan value. Find them by querying pg_stat_user_tables. To track queries that are generating more read operations, use the extension pg_stat_statements.

**CTAS and CREATE INDEX for large data sets**

A CTAS is a CREATE TABLE AS SELECT statement. If you run a CTAS using a large data set as a source, or create an index on a large table, the IO:DataFileRead event can occur. When you create an index, the database might need to read the entire object using a sequential scan. A CTAS generates IO:DataFile reads when pages aren't in memory.

**Multiple vacuum workers running at the same time**

Vacuum workers can be triggered manually or automatically. We recommend adopting an aggressive vacuum strategy. However, when a table has many updated or deleted rows, the IO:DataFileRead waits increase. After space is reclaimed, the vacuum time spent on IO:DataFileRead decreases.

**Ingesting large amounts of data**

When your application ingests large amounts of data, ANALYZE operations might occur more often. The ANALYZE process can be triggered by an autovacuum launcher or invoked manually.

The ANALYZE operation reads a subset of the table. The number of pages that must be scanned is calculated by multiplying 30 by the default_statistics_target value. For more information,
see the PostgreSQL documentation. The default_statistics_target parameter accepts values between 1 and 10,000, where the default is 100.

Resource starvation

If instance network bandwidth or CPU are consumed, the IO:DataFileRead event might occur more frequently.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Check predicate filters for queries that generate waits (p. 1431)
- Minimize the effect of maintenance operations (p. 1431)
- Respond to high numbers of connections (p. 1439)

Check predicate filters for queries that generate waits

Assume that you identify specific queries that are generating IO:DataFileRead wait events. You might identify them using the following techniques:

- Performance Insights
- Catalog views such as the one provided by the extension pg_stat_statements
- The catalog view pg_stat_all_tables, if it periodically shows an increased number of physical reads
- The pg_statio_all_tables view, if it shows that _read counters are increasing

We recommend that you determine which filters are used in the predicate (WHERE clause) of these queries. Follow these guidelines:

- Run the EXPLAIN command. In the output, identify which types of scans are used. A sequential scan doesn't necessarily indicate a problem. Queries that use sequential scans naturally produce more IO:DataFileRead events when compared to queries that use filters.
  
  Find out whether the column listed in the WHERE clause is indexed. If not, consider creating an index for this column. This approach avoids the sequential scans and reduces the IO:DataFileRead events. If a query has restrictive filters and still produces sequential scans, evaluate whether the proper indexes are being used.

- Find out whether the query is accessing a very large table. In some cases, partitioning a table can improve performance, allowing the query to only read necessary partitions.

- Examine the cardinality (total number of rows) from your join operations. Note how restrictive the values are that you’re passing in the filters for your WHERE clause. If possible, tune your query to reduce the number of rows that are passed in each step of the plan.

Minimize the effect of maintenance operations

Maintenance operations such as VACUUM and ANALYZE are important. We recommend that you don't turn them off because you find IO:DataFileRead wait events related to these maintenance operations. The following approaches can minimize the effect of these operations:

- Run maintenance operations manually during off-peak hours. This technique prevents the database from reaching the threshold for automatic operations.
• For very large tables, consider partitioning the table. This technique reduces the overhead of maintenance operations. The database only accesses the partitions that require maintenance.
• When you ingest large amounts of data, consider disabling the autoanalyze feature.

The autovacuum feature is automatically triggered for a table when the following formula is true.

\[
\text{pg\_stat\_user\_tables.n\_dead\_tup} > (\text{pg\_class.reltuples} \times \text{autovacuum\_vacuum\_scale\_factor}) + \text{autovacuum\_vacuum\_threshold}
\]

The view `pg_stat_user_tables` and catalog `pg_class` have multiple rows. One row can correspond to one row in your table. This formula assumes that the `reltuples` are for a specific table. The parameters `autovacuum\_vacuum\_scale\_factor` (0.20 by default) and `autovacuum\_vacuum\_threshold` (50 tuples by default) are usually set globally for the whole instance. However, you can set different values for a specific table.

Topics
• Find tables consuming space unnecessarily (p. 1432)
• Find indexes consuming unnecessary space (p. 1436)
• Find tables that are eligible to be autovacuumed (p. 1438)

Find tables consuming space unnecessarily

To find tables consuming more space than necessary, run the following query. When this query is run by a database user role that doesn't have the `rds_superuser` role, it returns information about only those tables that the user role has permissions to read. This query is supported by PostgreSQL version 12 and later versions.

```
WITH report AS (
    SELECT schemaname, tblname, n_dead_tup, n_live_tup, block_size*tblpages AS real_size, 
          (tblpages-est_tblpages)*block_size AS extra_size, 
          CASE WHEN tblpages - est_tblpages > 0 
               THEN 100 * (tblpages - est_tblpages)/tblpages::float 
               ELSE 0
          END AS extra_ratio, fillfactor, 
          (tblpages-est_tblpages_ff)*block_size AS bloat_size, 
          CASE WHEN tblpages - est_tblpages_ff > 0 
               THEN 100 * (tblpages - est_tblpages_ff)/tblpages::float 
               ELSE 0
          END AS bloat_ratio, 
          is_na 
    FROM ( 
        SELECT ceil( reltuples / ( (block_size-page_hdr)/tpl_size ) ) + 
                ceil( toasttuples / 4 ) AS est_tblpages, 
        ) 
    )
FROM ( 
    SELECT schemaname, tblname, n_dead_tup, n_live_tup, heappages 
    )
```
IO:DataFileRead

```
SELECT ( 4 + tpl_hdr_size + tpl_data_size + (2*ma) - CASE WHEN tpl_hdr_size%ma = 0 THEN ma ELSE tpl_hdr_size%ma END - CASE WHEN ceil(tpl_data_size)::int%ma = 0 THEN ma ELSE ceil(tpl_data_size)::int%ma END ) AS tpl_size,
block_size - page_hdr AS size_per_block,
(heappages + toastpages) AS tblpages,
,heappages,
,toastpages,

ORDER BY schemaname, tblname
) AS s
```
You can check for table and index bloat in your application. For more information, see

You can use PostgreSQL Multiversion Concurrency Control (MVCC) to help preserve data integrity. PostgreSQL MVCC works by saving an internal copy of updated or deleted rows (also called tuples) until a transaction is either committed or rolled back. This saved internal copy is invisible to users. However, table bloat can occur when those invisible copies aren't cleaned up regularly by the VACUUM or AUTOVACUUM utilities. Unchecked, table bloat can incur increased storage costs and slow your processing speed.

In many cases, the default settings for VACUUM or AUTOVACUUM on Aurora are sufficient for handling unwanted table bloat. However, you may want to check for bloat if your application is experiencing the following conditions:

- Processes a large number of transactions in a relatively short time between VACUUM processes.
- Performs poorly and runs out of storage.

To get started, gather the most accurate information about how much space is used by dead tuples and how much you can recovery by cleaning up the table and index bloat. To do so, use the pgstattuple extension to gather statistics on your Aurora cluster. For more information, see pgstattuple. Privileges to use the pgstattuple extension are limited to the pg_stat_scan_tables role and database superusers.

To create the pgstattuple extension on Aurora, connect a client session to the cluster, for example, psql or pgAdmin, and use the following command:

```
CREATE EXTENSION pgstattuple;
```

Create the extension in each database that you want to profile. After creating the extension, use the command line interface (CLI) to measure how much unusable space you can reclaim. Before gathering statistics, modify the cluster parameter group by setting AUTOVACUUM to 0. A setting of 0 prevents Aurora from automatically cleaning up any dead tuples left behind by your application, which can impact the accuracy of the results. Enter the following command to create a simple table:

```
postgres=> CREATE TABLE lab AS SELECT generate_series (0,100000);
```

In the following example, we run the query with AUTOVACUUM turned on for the DB cluster. The `dead_tuple_count` is 0, which indicates that the AUTOVACUUM has deleted the obsolete data or tuples from the PostgreSQL database.

To use pgstattuple to gather information about the table, specify the name of a table or an object identifier (OID) in the query:
In the following query, we turn off AUTOVACUUM and enter a command that deletes 25,000 rows from the table. As a result, the `dead_tuple_count` increases to 25000.

```sql
postgres=> DELETE FROM lab WHERE generate_series < 25000;
```

`DELETE 25000`

```sql
SELECT * FROM pgstattuple('lab');
```

<table>
<thead>
<tr>
<th>table_len</th>
<th>tuple_count</th>
<th>tuple_len</th>
<th>tuple_percent</th>
<th>dead_tuple_count</th>
<th>dead_tuple_len</th>
<th>dead_tuple_percent</th>
<th>free_space</th>
<th>free_percent</th>
</tr>
</thead>
<tbody>
<tr>
<td>3629056</td>
<td>75001</td>
<td>2100028</td>
<td>57.87</td>
<td>25000</td>

<td>19.29</td>
<td>16616</td>
<td>0.46</td>
</tr>
</tbody>
</table>

(1 row)

To reclaim those dead tuples, start a VACUUM process. Observing bloat without interrupting your application

Settings on an Aurora cluster are optimized to provide the best practices for most workloads. However, you might want to optimize a cluster to better suit your applications and use patterns. In this case, you can use the `pgstattuple` extension without disrupting a busy application. To do so, perform the following steps:

1. Clone your Aurora instance.
2. Modify the parameter file to turn off AUTOVACUUM in the clone.
3. Perform a `pgstattuple` query while testing the clone with a sample workload or with `pgbench`, which is a program for running benchmark tests on PostgreSQL. For more information, see `pgbench`.

After running your applications and viewing the result, use `pg_repack` or VACUUM FULL on the restored copy and compare the differences. If you see a significant drop in the `dead_tuple_count`, `dead_tuple_len`, or `dead_tuple_percent`, then adjust the vacuum schedule on your production cluster to minimize the bloat.
Avoiding bloat in temporary tables

If your application creates temporary tables, make sure that your application removes those temporary tables when they’re no longer needed. Autovacuum processes don’t locate temporary tables. Left unchecked, temporary tables can quickly create database bloat. Moreover, the bloat can extend into the system tables, which are the internal tables that track PostgreSQL objects and attributes, like pg_attribute and pg_depend.

When a temporary table is no longer needed, you can use a TRUNCATE statement to empty the table and free up the space. Then, manually vacuum the pg_attribute and pg_depend tables. Vacuuming these tables ensures that creating and truncating/deleting temporary tables continually isn’t adding tuples and contributing to system bloat.

You can avoid this problem while creating a temporary table by including the following syntax that deletes the new rows when content is committed:

```sql
CREATE TEMP TABLE IF NOT EXISTS table_name(table_description) ON COMMIT DELETE ROWS;
```

The `ON COMMIT DELETE ROWS` clause truncates the temporary table when the transaction is committed.

Avoiding bloat in indexes

When you change an indexed field in a table, the index update results in one or more dead tuples in that index. By default, the autovacuum process cleans up bloat in indexes, but that cleanup uses a significant amount of time and resources. To specify index cleanup preferences when you create a table, include the `vacuum_index_cleanup` clause. By default, at table creation time, the clause is set to AUTO, which means that the server decides if your index requires cleanup when it vacuums the table. You can set the clause to ON to turn on index cleanup for a specific table, or OFF to turn off index cleanup for that table. Remember, turning off index cleanup might save time, but can potentially lead to a bloated index.

You can manually control index cleanup when you VACUUM a table at the command line. To vacuum a table and remove dead tuples from the indexes, include the `INDEX_CLEANUP` clause with a value of ON and the table name:

```sql
acctg=> VACUUM (INDEX_CLEANUP ON) receivables;
```

INFO: aggressively vacuuming "public.receivables"

VACUUM

To vacuum a table without cleaning the indexes, specify a value of OFF:

```sql
acctg=> VACUUM (INDEX_CLEANUP OFF) receivables;
```

INFO: aggressively vacuuming "public.receivables"

VACUUM

Find indexes consuming unnecessary space

To find indexes consuming unnecessary space, run the following query.

```sql
VACUUM ANALYZE INDEXES;
```
-- only indexes on tables you have permissions to read.
-- WARNING: rows with is_na = 't' are known to have bad statistics ("name" type is not supported).
-- This query is compatible with PostgreSQL 8.2 and later.

ORDER BY table_size DESC;
Respond to high numbers of connections

When you monitor Amazon CloudWatch, you might find that the DatabaseConnections metric spikes. This increase indicates an increased number of connections to your database. We recommend the following approach:

• Limit the number of connections that the application can open with each instance. If your application has an embedded connection pool feature, set a reasonable number of connections. Base the number on what the vCPUs in your instance can parallelize effectively.

If your application doesn't use a connection pool feature, considering using Amazon RDS Proxy or an alternative. This approach lets your application open multiple connections with the load balancer. The balancer can then open a restricted number of connections with the database. As fewer connections are running in parallel, your DB instance performs less context switching in the kernel. Queries should progress faster, leading to fewer wait events. For more information, see Using Amazon RDS Proxy for Aurora (p. 1879).

• Whenever possible, take advantage of reader nodes for Aurora PostgreSQL and read replicas for RDS for PostgreSQL. When your application runs a read-only operation, send these requests to the reader-only endpoint. This technique spreads application requests across all reader nodes, reducing the I/O pressure on the writer node.

• Consider scaling up your DB instance. A higher-capacity instance class gives more memory, which gives Aurora PostgreSQL a larger shared buffer pool to hold pages. The larger size also gives the DB instance more vCPUs to handle connections. More vCPUs are particularly helpful when the operations that are generating IO:DataFileRead wait events are writes.

IO:XactSync

The IO:XactSync event occurs when the database is waiting for the Aurora storage subsystem to acknowledge the commit of a regular transaction, or the commit or rollback of a prepared transaction. A prepared transaction is part of PostgreSQL's support for a two-phase commit.

Topics

• Supported engine versions (p. 1439)
• Context (p. 1440)
• Likely causes of increased waits (p. 1440)
• Actions (p. 1440)

Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.
Context

The event IO:XactSync indicates that the instance is spending time waiting for the Aurora storage subsystem to confirm that transaction data was processed.

Likely causes of increased waits

When the IO:XactSync event appears more than normal, possibly indicating a performance problem, typical causes include the following:

Network saturation

Traffic between clients and the DB instance or traffic to the storage subsystem might be too heavy for the network bandwidth.

CPU pressure

A heavy workload might be preventing the Aurora storage daemon from getting sufficient CPU time.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Monitor your resources (p. 1440)
- Scale up the CPU (p. 1440)
- Increase network bandwidth (p. 1440)
- Reduce the number of commits (p. 1441)

Monitor your resources

To determine the cause of the increased IO:XactSync events, check the following metrics:

- WriteThroughput and CommitThroughput – Changes in write throughput or commit throughput can show an increase in workload.
- WriteLatency and CommitLatency – Changes in write latency or commit latency can show that the storage subsystem is being asked to do more work.
- CPUUtilization – If the instance's CPU utilization is above 90 percent, the Aurora storage daemon might not be getting sufficient time on the CPU. In this case, I/O performance degrades.

For information about these metrics, see Instance-level metrics for Amazon Aurora (p. 643).

Scale up the CPU

To address CPU starvation issues, consider changing to an instance type with more CPU capacity. For information about CPU capacity for a DB instance class, see Hardware specifications for DB instance classes for Aurora (p. 94).

Increase network bandwidth

To determine whether the instance is reaching its network bandwidth limits, check for the following other wait events:
• I0:DataFileRead, I0:BufferRead, I0:BufferWrite, and I0:XactWrite – Queries using large amounts of I/O can generate more of these wait events.
• Client:ClientRead and Client:ClientWrite – Queries with large amounts of client communication can generate more of these wait events.

If network bandwidth is an issue, consider changing to an instance type with more network bandwidth. For information about network performance for a DB instance class, see Hardware specifications for DB instance classes for Aurora (p. 94).

Reduce the number of commits
To reduce the number of commits, combine statements into transaction blocks.

**IPC:DamRecordTxAck**

The IPC:DamRecordTxAck event occurs when Aurora PostgreSQL in a session using database activity streams generates an activity stream event, then waits for that event to become durable.

**Topics**
- Relevant engine versions (p. 1441)
- Context (p. 1441)
- Causes (p. 1441)
- Actions (p. 1441)

**Relevant engine versions**

This wait event information is relevant for all Aurora PostgreSQL 10.7 and higher 10 versions, 11.4 and higher 11 versions, and all 12 and 13 versions.

**Context**

In synchronous mode, durability of activity stream events is favored over database performance. While waiting for a durable write of the event, the session blocks other database activity, causing the IPC:DamRecordTxAck wait event.

**Causes**

The most common cause for the IPC:DamRecordTxAck event to appear in top waits is that the Database Activity Streams (DAS) feature is a holistic audit. Higher SQL activity generates activity stream events that need to be recorded.

**Actions**

We recommend different actions depending on the causes of your wait event:

• Reduce the number of SQL statements or turn off database activity streams. Doing this reduces the number of events that require durable writes.
• Change to asynchronous mode. Doing this helps to reduce contention on the IPC:DamRecordTxAck wait event.

However, the DAS feature can't guarantee the durability of every event in asynchronous mode.
Lock:advisory

The Lock:advisory event occurs when a PostgreSQL application uses a lock to coordinate activity across multiple sessions.

Topics

- Relevant engine versions (p. 1442)
- Context (p. 1442)
- Causes (p. 1442)
- Actions (p. 1443)

Relevant engine versions

This wait event information is relevant for Aurora PostgreSQL versions 9.6 and higher.

Context

PostgreSQL advisory locks are application-level, cooperative locks explicitly locked and unlocked by the user's application code. An application can use PostgreSQL advisory locks to coordinate activity across multiple sessions. Unlike regular, object- or row-level locks, the application has full control over the lifetime of the lock. For more information, see Advisory Locks in the PostgreSQL documentation.

Advisory locks can be released before a transaction ends or be held by a session across transactions. This isn't true for implicit, system-enforced locks, such as an access-exclusive lock on a table acquired by a CREATE INDEX statement.

For a description of the functions used to acquire (lock) and release (unlock) advisory locks, see Advisory Lock Functions in the PostgreSQL documentation.

Advisory locks are implemented on top of the regular PostgreSQL locking system and are visible in the pg_locks system view.

Causes

This lock type is exclusively controlled by an application explicitly using it. Advisory locks that are acquired for each row as part of a query can cause a spike in locks or a long-term buildup.

These effects happen when the query is run in a way that acquires locks on more rows than are returned by the query. The application must eventually release every lock, but if locks are acquired on rows that aren't returned, the application can't find all of the locks.

The following example is from Advisory Locks in the PostgreSQL documentation.

<table>
<thead>
<tr>
<th>SQL Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT pg_advisory_lock(id) FROM foo WHERE id &gt; 12345 LIMIT 100;</td>
</tr>
</tbody>
</table>

In this example, the LIMIT clause can only stop the query's output after the rows have already been internally selected and their ID values locked. This can happen suddenly when a growing data volume causes the planner to choose a different execution plan that wasn't tested during development. The buildup in this case happens because the application explicitly calls pg_advisory_unlock for every ID value that was locked. However, in this case it can't find the set of locks acquired on rows that weren't returned. Because the locks are acquired on the session level, they aren't released automatically at the end of the transaction.

Another possible cause for spikes in blocked lock attempts is unintended conflicts. In these conflicts, unrelated parts of the application share the same lock ID space by mistake.
**Actions**

Review application usage of advisory locks and detail where and when in the application flow each type of advisory lock is acquired and released.

Determine whether a session is acquiring too many locks or a long-running session isn't releasing locks early enough, leading to a slow buildup of locks. You can correct a slow buildup of session-level locks by ending the session using `pg_terminate_backend(pid)`.

A client waiting for an advisory lock appears in `pg_stat_activity` with `wait_event_type=Lock` and `wait_event=advisory`. You can obtain specific lock values by querying the `pg_locks` system view for the same `pid`, looking for `locktype=advisory` and `granted=f`.

You can then identify the blocking session by querying `pg_locks` for the same advisory lock having `granted=t`, as shown in the following example.

```sql
SELECT blocked_locks.pid AS blocked_pid,
       blocking_locks.pid AS blocking_pid,
       blocked_activity.usename AS blocked_user,
       blocking_activity.usename AS blocking_user,
       now() - blocked_activity.xact_start AS blocked_transaction_duration,
       now() - blocking_activity.xact_start AS blocking_transaction_duration,
       concat(blocked_activity.wait_event_type,':',blocked_activity.wait_event) AS blocked_wait_event,
       concat(blocking_activity.wait_event_type,':',blocking_activity.wait_event) AS blocking_wait_event,
       blocked_activity.state AS blocked_state,
       blocking_activity.state AS blocking_state,
       blocked_locks.locktype AS blocked_locktype,
       blocking_locks.locktype AS blocking_locktype,
       blocked_activity.query AS blocked_statement,
       blocking_activity.query AS blocking_statement
FROM pg_catalog.pg_locks blocked_locks
JOIN pg_catalog.pg_stat_activity blocked_activity ON blocked_activity.pid = blocked_locks.pid
JOIN pg_catalog.pg_locks blocking_locks
  ON blocking_locks.locktype = blocked_locks.locktype
  AND blocking_locks.DATABASE IS NOT DISTINCT FROM blocked_locks.DATABASE
  AND blocking_locks.relation IS NOT DISTINCT FROM blocked_locks.relation
  AND blocking_locks.page IS NOT DISTINCT FROM blocked_locks.page
  AND blocking_locks.tuple IS NOT DISTINCT FROM blocked_locks.tuple
  AND blocking_locks.virtualxid IS NOT DISTINCT FROM blocked_locks.virtualxid
  AND blocking_locks.transactionid IS NOT DISTINCT FROM blocked_locks.transactionid
  AND blocking_locks.classid IS NOT DISTINCT FROM blocked_locks.classid
  AND blocking_locks.objid IS NOT DISTINCT FROM blocked_locks.objid
  AND blocking_locks.objsubid IS NOT DISTINCT FROM blocked_locks.objsubid
JOIN pg_catalog.pg_stat_activity blocking_activity ON blocking_activity.pid = blocking_locks.pid
WHERE NOT blocked_locks.GRANTED;
```

All of the advisory lock API functions have two sets of arguments, either one bigint argument or two integer arguments:

- For the API functions with one bigint argument, the upper 32 bits are in `pg_locks.classid` and the lower 32 bits are in `pg_locks.objid`.
- For the API functions with two integer arguments, the first argument is `pg_locks.classid` and the second argument is `pg_locks.objid`.

The `pg_locks.objsubid` value indicates which API form was used: 1 means one bigint argument; 2 means two integer arguments.
Lock:extend

The Lock:extend event occurs when a backend process is waiting to lock a relation to extend it while another process has a lock on that relation for the same purpose.

Topics
- Supported engine versions (p. 1444)
- Context (p. 1444)
- Likely causes of increased waits (p. 1444)
- Actions (p. 1444)

Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

Context

The event Lock:extend indicates that a backend process is waiting to extend a relation that another backend process holds a lock on while it's extending that relation. Because only one process at a time can extend a relation, the system generates a Lock:extend wait event. INSERT, COPY, and UPDATE operations can generate this event.

Likely causes of increased waits

When the Lock:extend event appears more than normal, possibly indicating a performance problem, typical causes include the following:

Surge in concurrent inserts or updates to the same table

There might be an increase in the number of concurrent sessions with queries that insert into or update the same table.

Insufficient network bandwidth

The network bandwidth on the DB instance might be insufficient for the storage communication needs of the current workload. This can contribute to storage latency that causes an increase in Lock:extend events.

Actions

We recommend different actions depending on the causes of your wait event.

Topics
- Reduce concurrent inserts and updates to the same relation (p. 1444)
- Increase network bandwidth (p. 1445)

Reduce concurrent inserts and updates to the same relation

First, determine whether there's an increase in tup_inserted and tup_updated metrics and an accompanying increase in this wait event. If so, check which relations are in high contention for insert and update operations. To determine this, query the pg_stat_all_tables view for the values in n_tup_ins and n_tup_upd fields. For information about the pg_stat_all_tables view, see pg_stat_all_tables in the PostgreSQL documentation.
To get more information about blocking and blocked queries, query `pg_stat_activity` as in the following example:

```sql
SELECT
    blocked.pid,
    blocked.usename,
    blocked.query,
    blocking.pid AS blocking_id,
    blocking.query AS blocking_query,
    blocking.wait_event AS blocking_wait_event,
    blocking.wait_event_type AS blocking_wait_event_type
FROM pg_stat_activity AS blocked
JOIN pg_stat_activity AS blocking ON blocking.pid = ANY(pg_blocking_pids(blocked.pid))
WHERE
    blocked.wait_event = 'extend'
    AND blocked.wait_event_type = 'Lock';
```

After you identify relations that contribute to increase `Lock:extend` events, use the following techniques to reduce the contention:

- Find out whether you can use partitioning to reduce contention for the same table. Separating inserted or updated tuples into different partitions can reduce contention. For information about partitioning, see Managing PostgreSQL partitions with the pg_partman extension (p. 1625).
- If the wait event is mainly due to update activity, consider reducing the relation's fillfactor value. This can reduce requests for new blocks during the update. The fillfactor is a storage parameter for a table that determines the maximum amount of space for packing a table page. It's expressed as a percentage of the total space for a page. For more information about the fillfactor parameter, see CREATE TABLE in the PostgreSQL documentation.
  
  **Important**
  
  We highly recommend that you test your system if you change the fillfactor because changing this value can negatively impact performance, depending on your workload.

**Increase network bandwidth**

To see whether there's an increase in write latency, check the WriteLatency metric in CloudWatch. If there is, use the WriteThroughput and ReadThroughput Amazon CloudWatch metrics to monitor the storage related traffic on the DB cluster. These metrics can help you to determine if network bandwidth is sufficient for the storage activity of your workload.

If your network bandwidth isn't enough, increase it. If your DB instance is reaching the network bandwidth limits, the only way to increase the bandwidth is to increase your DB instance size.

For more information about CloudWatch metrics, see Amazon CloudWatch metrics for Amazon Aurora (p. 638). For information about network performance for each DB instance class, see Hardware specifications for DB instance classes for Aurora (p. 94).

**Lock:Relation**

The Lock:Relation event occurs when a query is waiting to acquire a lock on a table or view (relation) that's currently locked by another transaction.
Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

Context

Most PostgreSQL commands implicitly use locks to control concurrent access to data in tables. You can also use these locks explicitly in your application code with the LOCK command. Many lock modes aren't compatible with each other, and they can block transactions when they're trying to access the same object. When this happens, Aurora PostgreSQL generates a Lock:Relation event. Some common examples are the following:

- Exclusive locks such as ACCESS EXCLUSIVE can block all concurrent access. Data definition language (DDL) operations such as DROP TABLE, TRUNCATE, VACUUM FULL, and CLUSTER acquire ACCESS EXCLUSIVE locks implicitly. ACCESS EXCLUSIVE is also the default lock mode for LOCK TABLE statements that don't specify a mode explicitly.
- Using CREATE INDEX (without CONCURRENT) on a table conflicts with data manipulation language (DML) statements UPDATE, DELETE, and INSERT, which acquire ROW EXCLUSIVE locks.

For more information about table-level locks and conflicting lock modes, see Explicit Locking in the PostgreSQL documentation.

Blocking queries and transactions typically unblock in one of the following ways:

- Blocking query – The application can cancel the query or the user can end the process. The engine can also force the query to end because of a session’s statement-timeout or a deadlock detection mechanism.
- Blocking transaction – A transaction stops blocking when it runs a ROLLBACK or COMMIT statement. Rollbacks also happen automatically when sessions are disconnected by a client or by network issues, or are ended. Sessions can be ended when the database engine is shut down, when the system is out of memory, and so forth.

Likely causes of increased waits

When the Lock:Relation event occurs more frequently than normal, it can indicate a performance issue. Typical causes include the following:

Increased concurrent sessions with conflicting table locks

There might be an increase in the number of concurrent sessions with queries that lock the same table with conflicting locking modes.

Maintenance operations

Health maintenance operations such as VACUUM and ANALYZE can significantly increase the number of conflicting locks. VACUUM FULL acquires an ACCESS EXCLUSIVE lock, and ANALYZE acquires a SHARE UPDATE EXCLUSIVE lock. Both types of locks can cause a Lock:Relation wait event.
Application data maintenance operations such as refreshing a materialized view can also increase blocked queries and transactions.

**Locks on reader instances**

There might be a conflict between the relation locks held by the writer and readers. Currently, only ACCESS EXCLUSIVE relation locks are replicated to reader instances. However, the ACCESS EXCLUSIVE relation lock will conflict with any ACCESS SHARE relation locks held by the reader. This can cause an increase in lock relation wait events on the reader.

**Actions**

We recommend different actions depending on the causes of your wait event.

**Topics**

- Reduce the impact of blocking SQL statements (p. 1447)
- Minimize the effect of maintenance operations (p. 1447)
- Check for reader locks (p. 1447)

**Reduce the impact of blocking SQL statements**

To reduce the impact of blocking SQL statements, modify your application code where possible. Following are two common techniques for reducing blocks:

- Use the NOWAIT option – Some SQL commands, such as SELECT and LOCK statements, support this option. The NOWAIT directive cancels the lock-requesting query if the lock can't be acquired immediately. This technique can help prevent a blocking session from causing a pile-up of blocked sessions behind it.

  For example: Assume that transaction A is waiting on a lock held by transaction B. Now, if B requests a lock on a table that's locked by transaction C, transaction A might be blocked until transaction C completes. But if transaction B uses a NOWAIT when it requests the lock on C, it can fail fast and ensure that transaction A doesn't have to wait indefinitely.

- Use SET lock_timeout – Set a lock_timeout value to limit the time a SQL statement waits to acquire a lock on a relation. If the lock isn't acquired within the timeout specified, the transaction requesting the lock is cancelled. Set this value at the session level.

**Minimize the effect of maintenance operations**

Maintenance operations such as VACUUM and ANALYZE are important. We recommend that you don't turn them off because you find Lock:Relation wait events related to these maintenance operations. The following approaches can minimize the effect of these operations:

- Run maintenance operations manually during off-peak hours.
- To reduce Lock:Relation waits caused by autovacuum tasks, perform any needed autovacuum tuning. For information about tuning autovacuum, see Working with PostgreSQL autovacuum on Amazon RDS in the Amazon RDS User Guide.

**Check for reader locks**

You can see how concurrent sessions on a writer and readers might be holding locks that block each other. One way to do this is by running queries that return the lock type and relation. In the table you can find a sequence of queries to two such concurrent sessions, a writer session (left-hand column) and a reader session (right-hand column).
The replay process waits for the duration of `max_standby_streaming_delay` before cancelling the reader query. As shown in the example, the lock timeout of 100ms is well below the default `max_standby_streaming_delay` of 30 seconds. The lock times out before it's an issue.

### Writer session

```bash
export WRITER=aurorapg1.12345678910.us-west-1.rds.amazonaws.com
psql -h $WRITER
psql (15devel, server 10.14)
```

<table>
<thead>
<tr>
<th>Writer session</th>
<th>Reader session</th>
</tr>
</thead>
<tbody>
<tr>
<td>export WRITER=aurorapg1.12345678910.us-west-1.rds.amazonaws.com</td>
<td>export READER=aurorapg2.12345678910.us-west-1.rds.amazonaws.com</td>
</tr>
<tr>
<td>psql -h $WRITER</td>
<td>psql -h $READER</td>
</tr>
<tr>
<td>psql (15devel, server 10.14)</td>
<td>psql (15devel, server 10.14)</td>
</tr>
<tr>
<td>Type &quot;help&quot; for help.</td>
<td>Type &quot;help&quot; for help.</td>
</tr>
</tbody>
</table>

The writer session creates table `t1` on the writer instance. The `ACCESS EXCLUSIVE` lock is acquired on the writer immediately, assuming that there are no conflicting queries on the writer.

```sql
postgres=> CREATE TABLE t1(b integer);
CREATE TABLE
```

The reader session sets a lock timeout interval of 100 milliseconds.

```sql
postgres=> SET lock_timeout=100;
SET
```

The reader session tries to read data from table `t1` on the reader instance.

```sql
postgres=> SELECT * FROM t1;
b
---
(0 rows)
```

The writer session drops `t1`.

```sql
postgres=> BEGIN;
BEGIN
postgres=> DROP TABLE t1;
DROP TABLE
postgres=>
```

The query times out and is canceled on the reader.

```sql
postgres=> SELECT * FROM t1;
ERROR:  canceling statement due to lock timeout
LINE 1: SELECT * FROM t1;
```

The reader session queries `pg_locks` and `pg_stat_activity` to determine the cause of the error. The result indicates that the `aurora wal replay` process is holding an `ACCESS EXCLUSIVE` lock on table `t1`.

```sql
postgres=> SELECT locktype, relation, mode, backend_type
postgres=> FROM pg_locks l, pg_stat_activity t1
postgres=> WHERE l.pid=t1.pid AND relation = 't1'::regclass::oid;
locktype | relation | mode | backend_type
---------|----------|------|------------------
```

1448
Lock:transactionid

The Lock:transactionid event occurs when a transaction is waiting for a row-level lock.

Topics
- Supported engine versions (p. 1449)
- Context (p. 1449)
- Likely causes of increased waits (p. 1449)
- Actions (p. 1450)

Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

Context

The event Lock:transactionid occurs when a transaction is trying to acquire a row-level lock that has already been granted to a transaction that is running at the same time. The session that shows the Lock:transactionid wait event is blocked because of this lock. After the blocking transaction ends in either a COMMIT or ROLLBACK statement, the blocked transaction can proceed.

The multiversion concurrency control semantics of Aurora PostgreSQL guarantee that readers don't block writers and writers don't block readers. For row-level conflicts to occur, blocking and blocked transactions must issue conflicting statements of the following types:

- UPDATE
- SELECT ... FOR UPDATE
- SELECT ... FOR KEY SHARE

The statement SELECT ... FOR KEY SHARE is a special case. The database uses the clause FOR KEY SHARE to optimize the performance of referential integrity. A row-level lock on a row can block INSERT, UPDATE, and DELETE commands on other tables that reference the row.

Likely causes of increased waits

When this event appears more than normal, the cause is typically UPDATE, SELECT ... FOR UPDATE, or SELECT ... FOR KEY SHARE statements combined with the following conditions.

Topics
- High concurrency (p. 1450)
- Idle in transaction (p. 1450)
- Long-running transactions (p. 1450)
High concurrency

Aurora PostgreSQL can use granular row-level locking semantics. The probability of row-level conflicts increases when the following conditions are met:

- A highly concurrent workload contends for the same rows.
- Concurrency increases.

Idle in transaction

Sometimes the `pg_stat_activity.state` column shows the value `idle in transaction`. This value appears for sessions that have started a transaction, but haven't yet issued a COMMIT or ROLLBACK. If the `pg_stat_activity.state` value isn't active, the query shown in `pg_stat_activity` is the most recent one to finish running. The blocking session isn't actively processing a query because an open transaction is holding a lock.

If an idle transaction acquired a row-level lock, it might be preventing other sessions from acquiring it. This condition leads to frequent occurrence of the wait event `Lock:transactionid`. To diagnose the issue, examine the output from `pg_stat_activity` and `pg_locks`.

Long-running transactions

Transactions that run for a long time get locks for a long time. These long-held locks can block other transactions from running.

Actions

Row-locking is a conflict among `UPDATE`, `SELECT ... FOR UPDATE`, or `SELECT ... FOR KEY SHARE` statements. Before attempting a solution, find out when these statements are running on the same row. Use this information to choose a strategy described in the following sections.

Topics

- Respond to high concurrency (p. 1450)
- Respond to idle transactions (p. 1450)
- Respond to long-running transactions (p. 1451)

Respond to high concurrency

If concurrency is the issue, try one of the following techniques:

- Lower the concurrency in the application. For example, decrease the number of active sessions.
- Implement a connection pool. To learn how to pool connections with RDS Proxy, see Using Amazon RDS Proxy for Aurora (p. 1879).
- Design the application or data model to avoid contending `UPDATE` and `SELECT ... FOR UPDATE` statements. You can also decrease the number of foreign keys accessed by `SELECT ... FOR KEY SHARE` statements.

Respond to idle transactions

If `pg_stat_activity.state` shows `idle in transaction`, use the following strategies:

- Turn on autocommit wherever possible. This approach prevents transactions from blocking other transactions while waiting for a COMMIT or ROLLBACK.
- Search for code paths that are missing COMMIT, ROLLBACK, or END.
• Make sure that the exception handling logic in your application always has a path to a valid end of transaction.
• Make sure that your application processes query results after ending the transaction with COMMIT or ROLLBACK.

Respond to long-running transactions

If long-running transactions are causing the frequent occurrence of Lock:transactionid, try the following strategies:

• Keep row locks out of long-running transactions.
• Limit the length of queries by implementing autocommit whenever possible.

Lock:tuple

The Lock:tuple event occurs when a backend process is waiting to acquire a lock on a tuple.

Topics
• Supported engine versions (p. 1451)
• Context (p. 1451)
• Likely causes of increased waits (p. 1452)
• Actions (p. 1452)

Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

Context

The event Lock:tuple indicates that a backend is waiting to acquire a lock on a tuple while another backend holds a conflicting lock on the same tuple. The following table illustrates a scenario in which sessions generate the Lock:tuple event.

<table>
<thead>
<tr>
<th>Time</th>
<th>Session 1</th>
<th>Session 2</th>
<th>Session 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>t1</td>
<td>Starts a transaction.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>t2</td>
<td>Updates row 1.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>t3</td>
<td>Updates row 1. The session acquires an exclusive lock on the tuple and then waits for session 1 to release the lock by committing or rolling back.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>t4</td>
<td></td>
<td></td>
<td>Updates row 1. The session waits for session 2 to release the exclusive lock on the tuple.</td>
</tr>
</tbody>
</table>

Or you can simulate this wait event by using the benchmarking tool pgbench. Configure a high number of concurrent sessions to update the same row in a table with a custom SQL file.
To learn more about conflicting lock modes, see Explicit Locking in the PostgreSQL documentation. To learn more about pgbench, see pgbench in the PostgreSQL documentation.

Likely causes of increased waits

When this event appears more than normal, possibly indicating a performance problem, typical causes include the following:

- A high number of concurrent sessions are trying to acquire a conflicting lock for the same tuple by running UPDATE or DELETE statements.
- Highly concurrent sessions are running a SELECT statement using the FOR UPDATE or FOR NO KEY UPDATE lock modes.
- Various factors drive application or connection pools to open more sessions to execute the same operations. As new sessions are trying to modify the same rows, DB load can spike, and Lock:tuple can appear.

For more information, see Row-Level Locks in the PostgreSQL documentation.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Investigate your application logic (p. 1452)
- Find the blocker session (p. 1452)
- Reduce concurrency when it is high (p. 1453)
- Troubleshoot bottlenecks (p. 1453)

Investigate your application logic

Find out whether a blocker session has been in the idle in transaction state for long time. If so, consider ending the blocker session as a short-term solution. You can use the pg_terminate_backend function. For more information about this function, see Server Signaling Functions in the PostgreSQL documentation.

For a long-term solution, do the following:

- Adjust the application logic.
- Use the idle_in_transaction_session_timeout parameter. This parameter ends any session with an open transaction that has been idle for longer than the specified amount of time. For more information, see Client Connection Defaults in the PostgreSQL documentation.
- Use autocommit as much as possible. For more information, see SET AUTOCOMMIT in the PostgreSQL documentation.

Find the blocker session

While the Lock:tuple wait event is occurring, identify the blocker and blocked session by finding out which locks depend on one another. For more information, see Lock dependency information in the PostgreSQL wiki. To analyze past Lock:tuple events, use the Aurora function aurora_stat_backend_waits.

The following example queries all sessions, filtering on tuple and ordering by wait_time.

```
```
Reduce concurrency when it is high

The Lock:tuple event might occur constantly, especially in a busy workload time. In this situation, consider reducing the high concurrency for very busy rows. Often, just a few rows control a queue or the Boolean logic, which makes these rows very busy.

You can reduce concurrency by using different approaches based in the business requirement, application logic, and workload type. For example, you can do the following:

- Redesign your table and data logic to reduce high concurrency.
- Change the application logic to reduce high concurrency at the row level.
- Leverage and redesign queries with row-level locks.
- Use the NOWAIT clause with retry operations.
- Consider using optimistic and hybrid-locking logic concurrency control.
- Consider changing the database isolation level.

Troubleshoot bottlenecks

The Lock:tuple can occur with bottlenecks such as CPU starvation or maximum usage of Amazon EBS bandwidth. To reduce bottlenecks, consider the following approaches:
• Scale up your instance class type.
• Optimize resource-intensive queries.
• Change the application logic.
• Archive data that is rarely accessed.

LWLock:buffer_content (BufferContent)

The LWLock:buffer_content event occurs when a session is waiting to read or write a data page in memory while another session has that page locked for writing. In Aurora PostgreSQL 13 and higher, this wait event is called BufferContent.

Topics
• Supported engine versions (p. 1454)
• Context (p. 1454)
• Likely causes of increased waits (p. 1454)
• Actions (p. 1455)

Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

Context

To read or manipulate data, PostgreSQL accesses it through shared memory buffers. To read from the buffer, a process gets a lightweight lock (LWLock) on the buffer content in shared mode. To write to the buffer, it gets that lock in exclusive mode. Shared locks allow other processes to concurrently acquire shared locks on that content. Exclusive locks prevent other processes from getting any type of lock on it.

The LWLock:buffer_content (BufferContent) event indicates that multiple processes are attempting to get a lock on contents of a specific buffer.

Likely causes of increased waits

When the LWLock:buffer_content (BufferContent) event appears more than normal, possibly indicating a performance problem, typical causes include the following:

Increased concurrent updates to the same data

There might be an increase in the number of concurrent sessions with queries that update the same buffer content. This contention can be more pronounced on tables with a lot of indexes.

Workload data is not in memory

When data that the active workload is processing is not in memory, these wait events can increase. This effect is because processes holding locks can keep them longer while they perform disk I/O operations.

Excessive use of foreign key constraints

Foreign key constraints can increase the amount of time a process holds onto a buffer content lock. This effect is because read operations require a shared buffer content lock on the referenced key while that key is being updated.
Actions

We recommend different actions depending on the causes of your wait event. You might identify LWLock:buffer_content (BufferContent) events by using Amazon RDS Performance Insights or by querying the view pg_stat_activity.

Topics
- Improve in-memory efficiency (p. 1455)
- Reduce usage of foreign key constraints (p. 1455)
- Remove unused indexes (p. 1455)

Improve in-memory efficiency

To increase the chance that active workload data is in memory, partition tables or scale up your instance class. For information about DB instance classes, see Aurora DB instance classes (p. 84).

Reduce usage of foreign key constraints

Investigate workloads experiencing high numbers of LWLock:buffer_content (BufferContent) wait events for usage of foreign key constraints. Remove unnecessary foreign key constraints.

Remove unused indexes

For workloads experiencing high numbers of LWLock:buffer_content (BufferContent) wait events, identify unused indexes and remove them.

LWLock:buffer_mapping

This event occurs when a session is waiting to associate a data block with a buffer in the shared buffer pool.

Note
This event appears as LWLock:buffer_mapping in Aurora PostgreSQL version 12 and lower, and LWLock:BufferMapping in version 13 and higher.

Topics
- Supported engine versions (p. 1455)
- Context (p. 1455)
- Causes (p. 1456)
- Actions (p. 1456)

Supported engine versions

This wait event information is relevant for Aurora PostgreSQL version 9.6 and higher.

Context

The shared buffer pool is an Aurora PostgreSQL memory area that holds all pages that are or were being used by processes. When a process needs a page, it reads the page into the shared buffer pool. The shared_buffers parameter sets the shared buffer size and reserves a memory area to store the table and index pages. If you change this parameter, make sure to restart the database. For more information, see Shared buffers (p. 1412).

The LWLock:buffer_mapping wait event occurs in the following scenarios:
A process searches the buffer table for a page and acquires a shared buffer mapping lock.
A process loads a page into the buffer pool and acquires an exclusive buffer mapping lock.
A process removes a page from the pool and acquires an exclusive buffer mapping lock.

**Causes**

When this event appears more than normal, possibly indicating a performance problem, the database is paging in and out of the shared buffer pool. Typical causes include the following:

- Large queries
- Bloated indexes and tables
- Full table scans
- A shared pool size that is smaller than the working set

**Actions**

We recommend different actions depending on the causes of your wait event.

**Topics**

- Monitor buffer-related metrics (p. 1456)
- Assess your indexing strategy (p. 1456)
- Reduce the number of buffers that must be allocated quickly (p. 1457)

**Monitor buffer-related metrics**

When LWLock:buffer_mapping waits spike, investigate the buffer hit ratio. You can use these metrics to get a better understanding of what is happening in the buffer cache. Examine the following metrics:

**BufferCacheHitRatio**

This Amazon CloudWatch metric measures the percentage of requests that are served by the buffer cache of a DB instance in your DB cluster. You might see this metric decrease in the lead-up to the LWLock:buffer_mapping wait event.

**blks_hit**

This Performance Insights counter metric indicates the number of blocks that were retrieved from the shared buffer pool. After the LWLock:buffer_mapping wait event appears, you might observe a spike in blks_hit.

**blks_read**

This Performance Insights counter metric indicates the number of blocks that required I/O to be read into the shared buffer pool. You might observe a spike in blks_read in the lead-up to the LWLock:buffer_mapping wait event.

**Assess your indexing strategy**

To confirm that your indexing strategy is not degrading performance, check the following:

**Index bloat**

Ensure that index and table bloat aren't leading to unnecessary pages being read into the shared buffer. If your tables contain unused rows, consider archiving the data and removing the rows from the tables. You can then rebuild the indexes for the resized tables.
Indexes for frequently used queries

To determine whether you have the optimal indexes, monitor DB engine metrics in Performance Insights. The `tup_returned` metric shows the number of rows read. The `tup_fetched` metric shows the number of rows returned to the client. If `tup_returned` is significantly larger than `tup_fetched`, the data might not be properly indexed. Also, your table statistics might not be current.

Reduce the number of buffers that must be allocated quickly

To reduce the `LWLock:buffer_mapping` wait events, try to reduce the number of buffers that must be allocated quickly. One strategy is to perform smaller batch operations. You might be able to achieve smaller batches by partitioning your tables.

**LWLock:BufferIO (IPC:BufferIO)**

The `LWLock:BufferIO` event occurs when Aurora PostgreSQL or RDS for PostgreSQL is waiting for other processes to finish their input/output (I/O) operations when concurrently trying to access a page. Its purpose is for the same page to be read into the shared buffer.

**Topics**
- Relevant engine versions (p. 1457)
- Context (p. 1457)
- Causes (p. 1457)
- Actions (p. 1458)

**Relevant engine versions**

This wait event information is relevant for all Aurora PostgreSQL versions. For Aurora PostgreSQL 12 and earlier versions this wait event is named as `lwlock:buffer_io` whereas in Aurora PostgreSQL 13 version it is named as `lwlock:bufferio`. From Aurora PostgreSQL 14 version BufferIO wait event moved from `LWLock` to IPC wait event type (IPC:BufferIO).

**Context**

Each shared buffer has an I/O lock that is associated with the `LWLock:BufferIO` wait event, each time a block (or a page) has to be retrieved outside the shared buffer pool.

This lock is used to handle multiple sessions that all require access to the same block. This block has to be read from outside the shared buffer pool, defined by the `shared_buffers` parameter.

As soon as the page is read inside the shared buffer pool, the `LWLock:BufferIO` lock is released.

**Note**

The `LWLock:BufferIO` wait event precedes the `IO:DataFileRead` (p. 1429) wait event. The `IO:DataFileRead` wait event occurs while data is being read from storage.

For more information on lightweight locks, see [Locking Overview](#).

**Causes**

Common causes for the `LWLock:BufferIO` event to appear in top waits include the following:

- Multiple backends or connections trying to access the same page that's also pending an I/O operation
• The ratio between the size of the shared buffer pool (defined by the `shared_buffers` parameter) and the number of buffers needed by the current workload
• The size of the shared buffer pool not being well balanced with the number of pages being evicted by other operations
• Large or bloated indexes that require the engine to read more pages than necessary into the shared buffer pool
• Lack of indexes that forces the DB engine to read more pages from the tables than necessary
• Sudden spikes for database connections trying to perform operations on the same page

**Actions**

We recommend different actions depending on the causes of your wait event:

• Observe Amazon CloudWatch metrics for correlation between sharp decreases in the `BufferCacheHitRatio` and `LWLock:BufferIO` wait events. This effect can mean that you have a small shared buffers setting. You might need to increase it or scale up your DB instance class. You can split your workload into more reader nodes.
• Tune `max_wal_size` and `checkpoint_timeout` based on your workload peak time if you see `LWLock:BufferIO` coinciding with `BufferCacheHitRatio` metric dips. Then identify which query might be causing it.
• Verify whether you have unused indexes, then remove them.
• Use partitioned tables (which also have partitioned indexes). Doing this helps to keep index reordering low and reduces its impact.
• Avoid indexing columns unnecessarily.
• Prevent sudden database connection spikes by using a connection pool.
• Restrict the maximum number of connections to the database as a best practice.

**LWLock:lock_manager**

This event occurs when the Aurora PostgreSQL engine maintains the shared lock's memory area to allocate, check, and deallocate a lock when a fast path lock isn't possible.

**Topics**

• Supported engine versions (p. 1458)
• Context (p. 1458)
• Likely causes of increased waits (p. 1459)
• Actions (p. 1460)

**Supported engine versions**

This wait event information is relevant for Aurora PostgreSQL version 9.6 and higher.

**Context**

When you issue a SQL statement, Aurora PostgreSQL records locks to protect the structure, data, and integrity of your database during concurrent operations. The engine can achieve this goal using a fast path lock or a path lock that isn't fast. A path lock that isn't fast is more expensive and creates more overhead than a fast path lock.
Fast path locking

To reduce the overhead of locks that are taken and released frequently, but that rarely conflict, backend processes can use fast path locking. The database uses this mechanism for locks that meet the following criteria:

- They use the DEFAULT lock method.
- They represent a lock on a database relation rather than a shared relation.
- They are weak locks that are unlikely to conflict.
- The engine can quickly verify that no conflicting locks can possibly exist.

The engine can’t use fast path locking when either of the following conditions is true:

- The lock doesn’t meet the preceding criteria.
- No more slots are available for the backend process.

For more information about fast path locking, see fast path in the PostgreSQL lock manager README and pg-locks in the PostgreSQL documentation.

Example of a scaling problem for the lock manager

In this example, a table named purchases stores five years of data, partitioned by day. Each partition has two indexes. The following sequence of events occurs:

1. You query many days worth of data, which requires the database to read many partitions.
2. The database creates a lock entry for each partition. If partition indexes are part of the optimizer access path, the database creates a lock entry for them, too.
3. When the number of requested locks entries for the same backend process is higher than 16, which is the value of FP_LOCK_SLOTS_PER_BACKEND, the lock manager uses the non-fast path lock method.

Modern applications might have hundreds of sessions. If concurrent sessions are querying the parent without proper partition pruning, the database might create hundreds or even thousands of non-fast path locks. Typically, when this concurrency is higher than the number of vCPUs, the LWLock:lock_manager wait event appears.

**Note**

The LWLock:lock_manager wait event isn't related to the number of partitions or indexes in a database schema. Instead, it's related to the number of non-fast path locks that the database must control.

Likely causes of increased waits

When the LWLock:lock_manager wait event occurs more than normal, possibly indicating a performance problem, the most likely causes of sudden spikes are as follows:

- Concurrent active sessions are running queries that don't use fast path locks. These sessions also exceed the maximum vCPU.
- A large number of concurrent active sessions are accessing a heavily partitioned table. Each partition has multiple indexes.
- The database is experiencing a connection storm. By default, some applications and connection pool software create more connections when the database is slow. This practice makes the problem worse. Tune your connection pool software so that connection storms don't occur.
- A large number of sessions query a parent table without pruning partitions.
• A data definition language (DDL), data manipulation language (DML), or a maintenance command exclusively locks either a busy relation or tuples that are frequently accessed or modified.

**Actions**

We recommend different actions depending on the causes of your wait event.

**Topics**

- Use partition pruning (p. 1460)
- Remove unnecessary indexes (p. 1460)
- Tune your queries for fast path locking (p. 1460)
- Tune for other wait events (p. 1460)
- Reduce hardware bottlenecks (p. 1461)
- Use a connection pooler (p. 1461)
- Upgrade your Aurora PostgreSQL version (p. 1461)

**Use partition pruning**

*Partition pruning* is a query optimization strategy that excludes unneeded partitions from table scans, thereby improving performance. Partition pruning is turned on by default. If it is turned off, turn it on as follows.

```
SET enable_partition_pruning = on;
```

Queries can take advantage of partition pruning when their WHERE clause contains the column used for the partitioning. For more information, see [Partition Pruning](#) in the PostgreSQL documentation.

**Remove unnecessary indexes**

Your database might contain unused or rarely used indexes. If so, consider deleting them. Do either of the following:

- Learn how to find unnecessary indexes by reading [Unused Indexes](#) in the PostgreSQL wiki.
- Run PG Collector. This SQL script gathers database information and presents it in a consolidated HTML report. Check the "Unused indexes" section. For more information, see [pg-collector](#) in the AWS Labs GitHub repository.

**Tune your queries for fast path locking**

To find out whether your queries use fast path locking, query the `fastpath` column in the `pg_locks` table. If your queries aren’t using fast path locking, try to reduce number of relations per query to fewer than 16.

**Tune for other wait events**

If `LWLock:lock_manager` is first or second in the list of top waits, check whether the following wait events also appear in the list:

- `Lock:Relation`
- `Lock:transactionid`
- `Lock:tuple`
If the preceding events appear high in the list, consider tuning these wait events first. These events can be a driver for `LWLock:lock_manager`.

**Reduce hardware bottlenecks**

You might have a hardware bottleneck, such as CPU starvation or maximum usage of your Amazon EBS bandwidth. In these cases, consider reducing the hardware bottlenecks. Consider the following actions:

- Scale up your instance class.
- Optimize queries that consume large amounts of CPU and memory.
- Change your application logic.
- Archive your data.

For more information about CPU, memory, and EBS network bandwidth, see [Amazon RDS Instance Types](#).

**Use a connection pooler**

If your total number of active connections exceeds the maximum vCPU, more OS processes require CPU than your instance type can support. In this case, consider using or tuning a connection pool. For more information about the vCPUs for your instance type, see [Amazon RDS Instance Types](#).

For more information about connection pooling, see the following resources:

- [Using Amazon RDS Proxy for Aurora](#)
- [pgbouncer](#)
- [Connection Pools and Data Sources](#) in the *PostgreSQL Documentation*

**Upgrade your Aurora PostgreSQL version**

If your current version of Aurora PostgreSQL is lower than 12, upgrade to version 12 or higher. PostgreSQL versions 12 and 13 have an improved partition mechanism. For more information about version 12, see [PostgreSQL 12.0 Release Notes](#). For more information about upgrading Aurora PostgreSQL, see [Amazon Aurora PostgreSQL updates](#).

**LWLock:MultiXact**

The `LWLock:MultiXactMemberBuffer`, `LWLock:MultiXactOffsetBuffer`, `LWLock:MultiXactMemberSLRU`, and `LWLock:MultiXactOffsetSLRU` wait events indicate that a session is waiting to retrieve a list of transactions that involve the same row in a given table.

- `LWLock:MultiXactMemberBuffer` – A process is waiting for I/O on a simple least-recently used (SLRU) buffer for a multixact member.
- `LWLock:MultiXactMemberSLRU` – A process is waiting to access the simple least-recently used (SLRU) cache for a multixact member.
- `LWLock:MultiXactOffsetBuffer` – A process is waiting for I/O on a simple least-recently used (SLRU) buffer for a multixact offset.
- `LWLock:MultiXactOffsetSLRU` – A process is waiting to access the simple least-recently used (SLRU) cache for a multixact offset.

**Topics**

- [Supported engine versions](#)
Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

Context

A multixact is a secondary data structure that stores a list of transaction IDs (XIDs) that reference the same table row. When a single transaction references a row in a table, the transaction ID is stored in the table. When multiple transactions reference the same row in a table, the list of transaction IDs is stored in the multixact data structure. The multixact wait events indicate that a session is retrieving from the data structure the list of transactions that refer to a given row in a table.

Likely causes of increased waits

Three common causes of multixact use are as follows.

1. Sub-transactions from explicit savepoints. – Explicitly creating a savepoint in your transactions spawns new transactions for the same row. For example, using SELECT FOR UPDATE, then SAVEPOINT, and then UPDATE.

2. Sub-transactions from PL/pgSQL EXCEPTION clauses. – Each EXCEPTION clause that you write in your PL/pgSQL functions or procedures creates a SAVEPOINT internally.

3. Foreign keys – Multiple transactions acquire a shared lock on the parent record.

Some drivers, object-relational mappers (ORMs), and abstraction layers have configuration options for automatically wrapping all operations with savepoints. This can generate many multixact wait events in some workloads. The PostgreSQL JDBC Driver’s autosave option is an example of this. For more information, see pgJDBC in the PostgreSQL JDBC documentation. Another example is the PostgreSQL ODBC driver and its protocol option. For more information, see psqlODBC Configuration Options in the PostgreSQL ODBC driver documentation.

When a given row is included in a multiple transaction operation, processing the row requires retrieving transaction IDs from the multixact listings. If lookups can’t get the multixact from the memory cache, the data structure must be read from the Aurora storage layer. This I/O from storage means that SQL queries can take longer. Memory cache misses can start occurring with heavy usage due to a large number of multiple transactions. All these factors contribute to an increase in this wait event.

Actions

The vacuum process eventually removes multixacts. If your Aurora PostgreSQL DB cluster experiences many LWLock:MultiXact wait events, check that your Aurora PostgreSQL DB cluster’s vacuum process is configured optimally, to run as often as necessary to keep these wait events to a minimum.

Long-running transactions cause the vacuum to retain transaction information until the transaction is committed or until the read-only transaction is closed. We recommend that you proactively monitor and manage long-running transactions. If possible, modify your application to avoid or minimize your use of long-running transactions.

If this wait event spikes suddenly and affects your production environment, you can try using VACUUM FREEZE on the problem table to resolve the issue immediately. However, this is only a temporary
solution. You should analyze the DDL (data definition language) used to create your tables and make sure the table structures and indexes are well designed.

**Timeout:PgSleep**

The Timeout:PgSleep event occurs when a server process has called the `pg_sleep` function and is waiting for the sleep timeout to expire.

**Topics**
- [Supported engine versions](#)
- [Likely causes of increased waits](#)
- [Actions](#)

**Supported engine versions**

This wait event information is supported for all versions of Aurora PostgreSQL.

**Likely causes of increased waits**

This wait event occurs when an application, stored function, or user issues a SQL statement that calls one of the following functions:

- `pg_sleep`
- `pg_sleep_for`
- `pg_sleep_until`

The preceding functions delay execution until the specified number of seconds have elapsed. For example, `SELECT pg_sleep(1)` pauses for 1 second. For more information, see [Delaying Execution](#) in the PostgreSQL documentation.

**Actions**

Identify the statement that was running the `pg_sleep` function. Determine if the use of the function is appropriate.

---

**Tuning Aurora PostgreSQL with Amazon DevOps Guru proactive insights**

DevOps Guru proactive insights detects conditions on your Aurora PostgreSQL DB clusters that can cause problems, and lets you know about them before they occur. DevOps Guru can do the following:

- Prevent many common database issues by cross-checking your database configuration against common recommended settings.
- Alert you to critical issues in your fleet that, if left unchecked, can lead to larger problems later.
- Alert you to newly discovered problems.

Every proactive insight contains an analysis of the cause of the problem and recommendations for corrective actions.
Database has long running idle in transaction connection

A connection to the database has been in the idle in transaction state for more than 1800 seconds.

Supported engine versions

This insight information is supported for all versions of Aurora PostgreSQL.

Context

A transaction in the idle in transaction state can hold locks that block other queries. It can also prevent VACUUM (including autovacuum) from cleaning up dead rows, leading to index or table bloat or transaction ID wraparound.

Likely causes for this issue

A transaction initiated in an interactive session with BEGIN or START TRANSACTION hasn't ended by using a COMMIT, ROLLBACK, or END command. This causes the transaction to move to idle in transaction state.

Actions

You can find idle transactions by querying pg_stat_activity.

In your SQL client, run the following query to list all connections in idle in transaction state and to order them by duration:

```
SELECT now() - state_change as idle_in_transaction_duration, now() - xact_start as xact_duration,*
FROM   pg_stat_activity
WHERE  state  = 'idle in transaction'
AND    xact_start is not null
ORDER BY 1 DESC;
```

We recommend different actions depending on the causes of your insight.

Topics

- End transaction (p. 1465)
- Terminate the connection (p. 1465)
- Configure the idle_in_transaction_session_timeout parameter (p. 1465)
- Check the AUTOCOMMIT status (p. 1465)
- Check the transaction logic in your application code (p. 1466)

End transaction

When you initiate a transaction in an interactive session with BEGIN or START TRANSACTION, it moves to idle in transaction state. It remains in this state until you end the transaction by issuing a COMMIT, ROLLBACK, END command or disconnect the connection completely to roll back the transaction.

Terminate the connection

Terminate the connection with an idle transaction using the following query:

```
SELECT pg_terminate_backend(pid);
```

pid is the process ID of the connection.

Configure the idle_in_transaction_session_timeout parameter

Configure the `idle_in_transaction_session_timeout` parameter in the parameter group. The advantage of configuring this parameter is that it does not require a manual intervention to terminate the long idle in transaction. For more information on this parameter, see the PostgreSQL documentation.

The following message will be reported in the PostgreSQL log file after the connection is terminated, when a transaction is in the `idle_in_transaction` state for longer than the specified time.

```
FATAL: terminating connection due to idle in transaction timeout
```

Check the AUTOCOMMIT status

AUTOCOMMIT is turned on by default. But if it is accidentally turned off in the client ensure that you turn it back on.

- In your psql client, run the following command:

```
postgres=> \set AUTOCOMMIT on
```

- In pgadmin, turn it on by choosing the AUTOCOMMIT option from the down arrow.
Check the transaction logic in your application code

Investigate your application logic for possible problems. Consider the following actions:

- Check if the JDBC auto commit is set true in your application. Also, consider using explicit COMMIT commands in your code.
- Check your error handling logic to see whether it closes a transaction after errors.
- Check whether your application is taking long to process the rows returned by a query while the transaction is open. If so, consider coding the application to close the transaction before processing the rows.
- Check whether a transaction contains many long-running operations. If so, divide a single transaction into multiple transactions.

Relevant metrics

The following PI metrics are related to this insight:

- idle_in_transaction_count - Number of sessions in idle in transaction state.
- idle_in_transaction_max_time - The duration of the longest running transaction in the idle in transaction state.

Best practices with Amazon Aurora PostgreSQL

Following, you can find several best practices for managing your Amazon Aurora PostgreSQL DB cluster. Be sure to also review basic maintenance tasks. For more information, see Managing Amazon Aurora PostgreSQL (p. 1397).

Topics

- Avoiding slow performance, automatic restart, and failover for Aurora PostgreSQL DB instances (p. 1466)
- Diagnosing table and index bloat (p. 1467)
- Improved memory management in Aurora PostgreSQL (p. 1469)
- Fast failover with Amazon Aurora PostgreSQL (p. 1470)
- Fast recovery after failover with cluster cache management for Aurora PostgreSQL (p. 1478)
- Managing Aurora PostgreSQL connection churn with pooling (p. 1482)
- Tuning memory parameters for Aurora PostgreSQL (p. 1488)
- Using Amazon CloudWatch metrics to analyze resource usage for Aurora PostgreSQL (p. 1494)
- Using logical replication to perform a major version upgrade for Aurora PostgreSQL (p. 1497)
- Troubleshooting storage issues (p. 1503)

Avoiding slow performance, automatic restart, and failover for Aurora PostgreSQL DB instances

If you're running a heavy workload or workloads that spike beyond the allocated resources of your DB instance, you can exhaust the resources on which you're running your application and Aurora database. To get metrics on your database instance such as CPU utilization, memory usage, and number of database connections used, you can refer to the metrics provided by Amazon CloudWatch, Performance Insights, and Enhanced Monitoring. For more information on monitoring your DB instance, see Monitoring metrics in an Amazon Aurora cluster (p. 509).
If your workload exhausts the resources you're using, your DB instance might slow down, restart, or even fail over to another DB instance. To avoid this, monitor your resource utilization, examine the workload running on your DB instance, and make optimizations where necessary. If optimizations don't improve the instance metrics and mitigate the resource exhaustion, consider scaling up your DB instance before you reach its limits. For more information on available DB instance classes and their specifications, see *Aurora DB instance classes* (p. 84).

### Diagnosing table and index bloat

You can use PostgreSQL Multiversion Concurrency Control (MVCC) to help preserve data integrity. PostgreSQL MVCC works by saving an internal copy of updated or deleted rows (also called *tuples*) until a transaction is either committed or rolled back. This saved internal copy is invisible to users. However, table bloat can occur when those invisible copies aren't cleaned up regularly by the VACUUM or AUTOVACUUM utilities. Unchecked, table bloat can incur increased storage costs and slow your processing speed.

In many cases, the default settings for VACUUM or AUTOVACUUM on Aurora are sufficient for handling unwanted table bloat. However, you may want to check for bloat if your application is experiencing the following conditions:

- Processes a large number of transactions in a relatively short time between VACUUM processes.
- Performs poorly and runs out of storage.

To get started, gather the most accurate information about how much space is used by dead tuples and how much you can recover by cleaning up the table and index bloat. To do so, use the *pgstattuple* extension to gather statistics on your Aurora cluster. For more information, see *pgstattuple*. Privileges to use the *pgstattuple* extension are limited to the *pg_stat_scan_tables* role and database superusers.

To create the *pgstattuple* extension on Aurora, connect a client session to the cluster, for example, *psql* or *pgAdmin*, and use the following command:

```sql
CREATE EXTENSION pgstattuple;
```

Create the extension in each database that you want to profile. After creating the extension, use the command line interface (CLI) to measure how much unusable space you can reclaim. Before gathering statistics, modify the cluster parameter group by setting AUTOVACUUM to 0. A setting of 0 prevents Aurora from automatically cleaning up any dead tuples left behind by your application, which can impact the accuracy of the results. Enter the following command to create a simple table:

```sql
postgres=> CREATE TABLE lab AS SELECT generate_series (0,100000);
SELECT 100001
```

In the following example, we run the query with AUTOVACUUM turned on for the DB cluster. The *dead_tuple_count* is 0, which indicates that the AUTOVACUUM has deleted the obsolete data or tuples from the PostgreSQL database.

To use *pgstattuple* to gather information about the table, specify the name of a table or an object identifier (OID) in the query:

```sql
postgres=> SELECT * FROM pgstattuple('lab');
```

```sql`
1467
```
In the following query, we turn off AUTOVACUUM and enter a command that deletes 25,000 rows from
the table. As a result, the `dead_tuple_count` increases to 25000.

```
postgres=> DELETE FROM lab WHERE generate_series < 25000;
DELETE 25000
```

```
SELECT * FROM pgstattuple('lab');
```

```
<table>
<thead>
<tr>
<th>table_len</th>
<th>tuple_count</th>
<th>tuple_len</th>
<th>tuple_percent</th>
<th>dead_tuple_count</th>
<th>dead_tuple_len</th>
<th>dead_tuple_percent</th>
<th>free_space</th>
<th>free_percent</th>
</tr>
</thead>
<tbody>
<tr>
<td>3629056</td>
<td>75001</td>
<td>2100028</td>
<td>57.87</td>
<td>25000</td>
<td>700000</td>
<td>19.29</td>
<td>16616</td>
<td>0.46</td>
</tr>
</tbody>
</table>
```

To reclaim those dead tuples, start a VACUUM process.

## Observing bloat without interrupting your application

Settings on an Aurora cluster are optimized to provide the best practices for most workloads. However,
you might want to optimize a cluster to better suit your applications and use patterns. In this case,
you can use the `pgstattuple` extension without disrupting a busy application. To do so, perform the
following steps:

1. Clone your Aurora instance.
2. Modify the parameter file to turn off AUTOVACUUM in the clone.
3. Perform a `pgstattuple` query while testing the clone with a sample workload or with pgbench,
   which is a program for running benchmark tests on PostgreSQL. For more information, see [pgbench](https://www.postgresql.org/docs/current/pgbench.html).

After running your applications and viewing the result, use pg_repack or VACUUM FULL on the restored
copy and compare the differences. If you see a significant drop in the `dead_tuple_count`, `dead_tuple_len`,
or `dead_tuple_percent`, then adjust the vacuum schedule on your production cluster to minimize the
bloat.

## Avoiding bloat in temporary tables

If your application creates temporary tables, make sure that your application removes those temporary
tables when they’re no longer needed. Autovacuum processes don’t locate temporary tables. Left
Unchecked, temporary tables can quickly create database bloat. Moreover, the bloat can extend into the system tables, which are the internal tables that track PostgreSQL objects and attributes, like `pg_attribute` and `pg_depend`.

When a temporary table is no longer needed, you can use a `TRUNCATE` statement to empty the table and free up the space. Then, manually vacuum the `pg_attribute` and `pg_depend` tables. Vacuuming these tables ensures that creating and truncating/deleting temporary tables continually isn't adding tuples and contributing to system bloat.

You can avoid this problem while creating a temporary table by including the following syntax that deletes the new rows when content is committed:

```sql
CREATE TEMP TABLE IF NOT EXISTS table_name(table_description) ON COMMIT DELETE ROWS;
```

The `ON COMMIT DELETE ROWS` clause truncates the temporary table when the transaction is committed.

### Avoiding bloat in indexes

When you change an indexed field in a table, the index update results in one or more dead tuples in that index. By default, the autovacuum process cleans up bloat in indexes, but that cleanup uses a significant amount of time and resources. To specify index cleanup preferences when you create a table, include the `vacuum_index_cleanup` clause. By default, at table creation time, the clause is set to `AUTO`, which means that the server decides if your index requires cleanup when it vacuums the table. You can set the clause to `ON` to turn on index cleanup for a specific table, or `OFF` to turn off index cleanup for that table. Remember, turning off index cleanup might save time, but can potentially lead to a bloated index.

You can manually control index cleanup when you `VACUUM` a table at the command line. To vacuum a table and remove dead tuples from the indexes, include the `INDEX_CLEANUP` clause with a value of `ON` and the table name:

```
acctg=> VACUUM (INDEX_CLEANUP ON) receivables;
INFO: aggressively vacuuming "public.receivables"
VACUUM
```

To vacuum a table without cleaning the indexes, specify a value of `OFF`:

```
acctg=> VACUUM (INDEX_CLEANUP OFF) receivables;
INFO: aggressively vacuuming "public.receivables"
VACUUM
```

### Improved memory management in Aurora PostgreSQL

Customer workloads exhausting the free memory available in the DB instance leads to database restart by the operating system causing database unavailability. Aurora PostgreSQL has introduced improved memory management capabilities that proactively prevents stability issues and database restarts caused by insufficient free memory. This improvement is available by default in the following versions:

- 15.3 and higher 15 versions
- 14.8 and higher 14 versions
- 13.11 and higher 13 versions
• 12.15 and higher 12 versions
• 11.20 and higher 11 versions

To improve the memory management, it does the following:

• Cancelling database transactions that request more memory when the system is approaching critical memory pressure.
• The system is said to be under critical memory pressure, when it exhausts all the physical memory and is about to exhaust the swap. In these circumstances, any transaction that requests memory will be cancelled in an effort to immediately reduce memory pressure in the DB instance.
• Essential PostgreSQL launchers and background workers such as autovacuum workers are always protected.

This feature is turned on by default. An error message is displayed when a transaction is cancelled due to insufficient memory as shown in the following example:

```
ERROR: out of memory
Detail: Failed on request of size 16777216.
```

You can turn off this feature by setting the value of `rds.memory_allocation_guard` to `true` in the DB cluster parameter group. This prevents the queries from being canceled. For more information about DB cluster parameter groups, see Working with parameter groups (p. 212). The default value of this parameter is set to `false` in the Parameter group.

The value of this parameter can also be set at a session level to include or exclude a session in improved memory management. This is a dynamic parameter, so you can change it at the session level. To do this, connect to the Aurora PostgreSQL DB cluster with psql and use the SET statement, as shown in the following example.

```
postgres=>SET rds.memory_allocation_guard = true;
```

**Note**
We don't recommend turning off this feature as it might lead to out-of-memory error that can cause workload induced database restart due to the memory exhaustion in the system.

**Fast failover with Amazon Aurora PostgreSQL**

Following, you can learn how to make sure that failover occurs as fast as possible. To recover quickly after failover, you can use cluster cache management for your Aurora PostgreSQL DB cluster. For more information, see Fast recovery after failover with cluster cache management for Aurora PostgreSQL (p. 1478).

Some of the steps that you can take to make failover perform fast include the following:

• Set Transmission Control Protocol (TCP) keepalives with short time frames, to stop longer running queries before the read timeout expires if there's a failure.
• Set timeouts for Java Domain Name System (DNS) caching aggressively. Doing this helps ensure the Aurora read-only endpoint can properly cycle through read-only nodes on later connection attempts.
• Set the timeout variables used in the JDBC connection string as low as possible. Use separate connection objects for short- and long-running queries.
• Use the read and write Aurora endpoints that are provided to connect to the cluster.
• Use RDS API operations to test application response on server-side failures. Also, use a packet dropping tool to test application response for client-side failures.
• Use the AWS JDBC Driver for PostgreSQL to take full advantage of the failover capabilities of Aurora PostgreSQL. For more information about the AWS JDBC Driver for PostgreSQL and complete instructions for using it, see the AWS JDBC Driver for PostgreSQL GitHub repository.

These are covered in more detail following.

Topics

- Setting TCP keepalives parameters (p. 1471)
- Configuring your application for fast failover (p. 1472)
- Testing failover (p. 1475)
- Fast failover example in Java (p. 1476)

Setting TCP keepalives parameters

When you set up a TCP connection, a set of timers is associated with the connection. When the keepalive timer reaches zero, a keepalive probe packet is sent to the connection endpoint. If the probe receives a reply, you can assume that the connection is still up and running.

Turning on TCP keepalive parameters and setting them aggressively ensures that if your client can't connect to the database, any active connections are quickly closed. The application can then connect to a new endpoint.

Make sure to set the following TCP keepalive parameters:

- `tcp_keepalive_time` controls the time, in seconds, after which a keepalive packet is sent when no data has been sent by the socket. ACKs aren't considered data. We recommend the following setting:
  
  ```
  tcp_keepalive_time = 1
  ```

- `tcp_keepalive_intvl` controls the time, in seconds, between sending subsequent keepalive packets after the initial packet is sent. Set this time by using the `tcp_keepalive_time` parameter. We recommend the following setting:
  
  ```
  tcp_keepalive_intvl = 1
  ```

- `tcp_keepalive_probes` is the number of unacknowledged keepalive probes that occur before the application is notified. We recommend the following setting:
  
  ```
  tcp_keepalive_probes = 5
  ```

These settings should notify the application within five seconds when the database stops responding. If keepalive packets are often dropped within the application's network, you can set a higher `tcp_keepalive_probes` value. Doing this allows for more buffer in less reliable networks, although it increases the time that it takes to detect an actual failure.

To set TCP keepalive parameters on Linux

1. Test how to configure your TCP keepalive parameters.

   We recommend doing so by using the command line with the following commands. This suggested configuration is system-wide. In other words, it also affects all other applications that create sockets with the SO_KEEPALIVE option on.

   ```
   sudo sysctl net.ipv4.tcp_keepalive_time=1
   sudo sysctl net.ipv4.tcp_keepalive_intvl=1
   sudo sysctl net.ipv4.tcp_keepalive_probes=5
   ```
2. After you've found a configuration that works for your application, persist these settings by adding the following lines to `/etc/sysctl.conf`, including any changes you made:

```
tcp_keepalive_time = 1
tcp_keepalive_intvl = 1
tcp_keepalive_probes = 5
```

**Configuring your application for fast failover**

Following, you can find a discussion of several configuration changes for Aurora PostgreSQL that you can make for fast failover. To learn more about PostgreSQL JDBC driver setup and configuration, see the PostgreSQL JDBC Driver documentation.

**Topics**
- Reducing DNS cache timeouts (p. 1472)
- Setting an Aurora PostgreSQL connection string for fast failover (p. 1472)
- Other options for obtaining the host string (p. 1473)

**Reducing DNS cache timeouts**

When your application tries to establish a connection after a failover, the new Aurora PostgreSQL writer will be a previous reader. You can find it by using the Aurora read-only endpoint before DNS updates have fully propagated. Setting the java DNS time to live (TTL) to a low value, such as under 30 seconds, helps cycle between reader nodes on later connection attempts.

```
// Sets internal TTL to match the Aurora RO Endpoint TTL
java.security.Security.setProperty("networkaddress.cache.ttl" , "1");
// If the lookup fails, default to something like small to retry
java.security.Security.setProperty("networkaddress.cache.negative.ttl" , "3");
```

**Setting an Aurora PostgreSQL connection string for fast failover**

To use Aurora PostgreSQL fast failover, make sure that your application's connection string has a list of hosts instead of just a single host. Following is an example connection string that you can use to connect to an Aurora PostgreSQL cluster. In this example, the hosts are in bold.

```
jdbc:postgresql://myauroracluster.cluster-c9bfei4hjlrd.us-east-1-beta.rds.amazonaws.com:5432,
myauroracluster.cluster-ro-c9bfei4hjlrd.us-east-1-beta.rds.amazonaws.com:5432
/postgres?user=<primaryuser>&password=<primarypw>&loginTimeout=2
&connectTimeout=2&cancelSignalTimeout=2&socketTimeout=60
&tcpKeepAlive=true&targetServerType=primary
```

For best availability and to avoid a dependency on the RDS API, we recommend that you maintain a file to connect with. This file contains a host string that your application reads from when you establish a connection to the database. This host string has all the Aurora endpoints available for the cluster. For more information about Aurora endpoints, see Amazon Aurora connection management (p. 62).

For example, you might store your endpoints in a local file as shown following.

```
myauroracluster.cluster-c9bfei4hjlrd.us-east-1-beta.rds.amazonaws.com:5432,
myauroracluster.cluster-ro-c9bfei4hjlrd.us-east-1-beta.rds.amazonaws.com:5432
```
Your application reads from this file to populate the host section of the JDBC connection string. Renaming the DB cluster causes these endpoints to change. Make sure that your application handles this event if it occurs.

Another option is to use a list of DB instance nodes, as follows.

```
my-node1.cksc6lxmcwcyw.us-east-1-beta.rds.amazonaws.com:5432,
my-node2.cksc6lxmcwcyw.us-east-1-beta.rds.amazonaws.com:5432,
my-node3.cksc6lxmcwcyw.us-east-1-beta.rds.amazonaws.com:5432,
my-node4.cksc6lxmcwcyw.us-east-1-beta.rds.amazonaws.com:5432
```

The benefit of this approach is that the PostgreSQL JDBC connection driver loops through all nodes on this list to find a valid connection. In contrast, when you use the Aurora endpoints only two nodes are tried in each connection attempt. However, there's a downside to using DB instance nodes. If you add or remove nodes from your cluster and the list of instance endpoints becomes stale, the connection driver might never find the correct host to connect to.

To help ensure that your application doesn't wait too long to connect to any one host, set the following parameters aggressively:

- **targetServerType** – Controls whether the driver connects to a write or read node. To ensure that your applications reconnect only to a write node, set the *targetServerType* value to *primary*.

  Values for the *targetServerType* parameter include *primary*, *secondary*, *any*, and *preferSecondary*. The *preferSecondary* value attempts to establish a connection to a reader first. It connects to the writer if no reader connection can be established.

- **loginTimeout** – Controls how long your application waits to log in to the database after a socket connection has been established.

- **connectTimeout** – Controls how long the socket waits to establish a connection to the database.

You can modify other application parameters to speed up the connection process, depending on how aggressive you want your application to be:

- **cancelSignalTimeout** – In some applications, you might want to send a "best effort" cancel signal on a query that has timed out. If this cancel signal is in your failover path, consider setting it aggressively to avoid sending this signal to a dead host.

- **socketTimeout** – This parameter controls how long the socket waits for read operations. This parameter can be used as a global "query timeout" to ensure no query waits longer than this value. A good practice is to have two connection handlers. One connection handler runs short-lived queries and sets this value lower. Another connection handler, for long-running queries, has this value set much higher. With this approach, you can rely on TCP keepalive parameters to stop long-running queries if the server goes down.

- **tcpKeepAlive** – Turn on this parameter to ensure the TCP keepalive parameters that you set are respected.

- **loadBalanceHosts** – When set to *true*, this parameter has the application connect to a random host chosen from a list of candidate hosts.

**Other options for obtaining the host string**

You can get the host string from several sources, including the *aurora_replica_status* function and by using the Amazon RDS API.

In many cases, you need to determine who the writer of the cluster is or to find other reader nodes in the cluster. To do this, your application can connect to any DB instance in the DB cluster and query the *aurora_replica_status* function. You can use this function to reduce the amount of time it takes to
find a host to connect to. However, in certain network failure scenarios the `aurora_replica_status` function might show out-of-date or incomplete information.

A good way to ensure that your application can find a node to connect to is to try to connect to the cluster writer endpoint and then the cluster reader endpoint. You do this until you can establish a readable connection. These endpoints don't change unless you rename your DB cluster. Thus, you can generally leave them as static members of your application or store them in a resource file that your application reads from.

After you establish a connection using one of these endpoints, you can get information about the rest of the cluster. To do this, call the `aurora_replica_status` function. For example, the following command retrieves information with `aurora_replica_status`.

```sql
postgres=> SELECT server_id, session_id, highest_lsn_rcvd, cur_replay_latency_in_usec, now(), last_update_timestamp
FROM aurora_replica_status;
```

<table>
<thead>

</tbody>
</table>

For example, the hosts section of your connection string might start with both the writer and reader cluster endpoints, as shown following.

```
myauroracluster.cluster-c9bfei4hjlrd.us-east-1-beta.rds.amazonaws.com:5432,
myauroracluster.cluster-ro-c9bfei4hjlrd.us-east-1-beta.rds.amazonaws.com:5432
```

In this scenario, your application attempts to establish a connection to any node type, primary or secondary. When your application is connected, a good practice is to first examine the read/write status of the node. To do this, query for the result of the command `SHOW transaction_read_only`.

If the return value of the query is `OFF`, then you successfully connected to the primary node. However, suppose that the return value is `ON` and your application requires a read/write connection. In this case, you can call the `aurora_replica_status` function to determine the `server_id` that has `session_id='MASTER_SESSION_ID'`. This function gives you the name of the primary node. You can use this with the `endpointPostfix` described following.

Make sure that you're aware when you connect to a replica that has stale data. When this happens, the `aurora_replica_status` function might show out-of-date information. You can set a threshold for staleness at the application level. To check this, you can look at the difference between the server time and the `last_update_timestamp` value. In general, your application should avoid flipping between two hosts due to conflicting information returned by the `aurora_replica_status` function. Your application should try all known hosts first instead of following the data returned by `aurora_replica_status`.

Listing instances using the DescribeDBClusters API operation, example in Java

You can programmatically find the list of instances by using the [AWS SDK for Java](https://docs.aws.amazon.com/sdk-for-java/v1/developer-guide/java-dynamodb.html), specifically the `DescribeDBClusters` API operation.

Following is a small example of how you might do this in Java 8.

```java
AmazonRDS client = AmazonRDSClientBuilder.defaultClient();
```
DescribeDBClustersRequest request = new DescribeDBClustersRequest()
    .withDBClusterIdentifier(clusterName);
DescribeDBClustersResult result = rdsClient.describeDBClusters(request);

DBCluster singleClusterResult = result.getDBClusters().get(0);

String pgJDBCEndpointStr = singleClusterResult.getDBClusterMembers().stream()
    .sorted(Comparator.comparing(DBClusterMember::getIsClusterWriter)
        .reversed()) // This puts the writer at the front of the list
    .map(m -> m.getDBInstanceIdentifier() + endpointPostfix + ":" +
        singleClusterResult.getPort())
    .collect(Collectors.joining","));

Here, pgJDBCEndpointStr contains a formatted list of endpoints, as shown following.

my-node1.cksc6xlmwcyw.us-east-1-beta.rds.amazonaws.com:5432,
my-node2.cksc6xlmwcyw.us-east-1-beta.rds.amazonaws.com:5432

The variable endpointPostfix can be a constant that your application sets. Or your application can
get it by querying the DescribeDBInstances API operation for a single instance in your cluster. This
value remains constant within an AWS Region and for an individual customer. So it saves an API call to
simply keep this constant in a resource file that your application reads from. In the example preceding,
it's set to the following.

.cksc6xlmwcyw.us-east-1-beta.rds.amazonaws.com

For availability purposes, a good practice is to default to using the Aurora endpoints of your DB cluster
if the API isn’t responding or takes too long to respond. The endpoints are guaranteed to be up to date
within the time it takes to update the DNS record. Updating the DNS record with an endpoint typically
takes less than 30 seconds. You can store the endpoint in a resource file that your application consumes.

Testing failover

In all cases you must have a DB cluster with two or more DB instances in it.

From the server side, certain API operations can cause an outage that can be used to test how your
applications responds:

- **FailoverDBCluster** – This operation attempts to promote a new DB instance in your DB cluster to writer.

  The following code example shows how you can use FailoverDBCluster to cause an outage. For
  more details about setting up an Amazon RDS client, see [Using the AWS SDK for Java](#).

  ```java
  public void causeFailover() {
      final AmazonRDS rdsClient = AmazonRDSClientBuilder.defaultClient();
      FailoverDBClusterRequest request = new FailoverDBClusterRequest();
      request.setDBClusterIdentifier("cluster-identifier");
      rdsClient.failoverDBCluster(request);
  }
  ```

- **RebootDBInstance** – Failover isn’t guaranteed with this API operation. It shuts down the database on
  the writer, however. You can use it to test how your application responds to connections dropping. The
  ForceFailover parameter doesn’t apply for Aurora engines. Instead, use the FailoverDBCluster
  API operation.
• **ModifyDBCluster** – Modifying the `Port` parameter causes an outage when the nodes in the cluster begin listening on a new port. In general, your application can respond to this failure first by ensuring that only your application controls port changes. Also, ensure that it can appropriately update the endpoints it depends on. You can do this by having someone manually update the port when they make modifications at the API level. Or you can do this by using the RDS API in your application to determine if the port has changed.

• **ModifyDBInstance** – Modifying the `DBInstanceClass` parameter causes an outage.

• **DeleteDBInstance** – Deleting the primary (writer) causes a new DB instance to be promoted to writer in your DB cluster.

From the application or client side, if you use Linux, you can test how the application responds to sudden packet drops. You can do this based on whether port, host, or if TCP keepalive packets are sent or received by using the `iptables` command.

**Fast failover example in Java**

The following code example shows how an application might set up an Aurora PostgreSQL driver manager.

The application calls the `getConnection` function when it needs a connection. A call to `getConnection` can fail to find a valid host. An example is when no writer is found but the `targetServerType` parameter is set to `primary`. In this case, the calling application should simply retry calling the function.

To avoid pushing the retry behavior onto the application, you can wrap this retry call into a connection pooler. With most connection poolers, you can specify a JDBC connection string. So your application can call into `getJdbcConnectionString` and pass that to the connection pooler. Doing this means you can use faster failover with Aurora PostgreSQL.

```java
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;
import java.sql.Statement;
import java.util.ArrayList;
import java.util.List;
import java.util.stream.Collectors;
import java.util.stream.IntStream;
import org.joda.time.Duration;

public class FastFailoverDriverManager {
    private static Duration LOGIN_TIMEOUT = Duration.standardSeconds(2);
    private static Duration CONNECT_TIMEOUT = Duration.standardSeconds(2);
    private static Duration CANCEL_SIGNAL_TIMEOUT = Duration.standardSeconds(1);
    private static Duration DEFAULT_SOCKET_TIMEOUT = Duration.standardSeconds(5);

    public FastFailoverDriverManager() {
        try {
            Class.forName("org.postgresql.Driver");
        } catch (ClassNotFoundException e) {
            e.printStackTrace();
        }

        /*
         * RO endpoint has a TTL of 1s, we should honor that here. Setting this aggressively makes sure that when
         * the PG JDBC driver creates a new connection, it will resolve a new different RO endpoint on subsequent attempts
         * (assuming there is > 1 read node in your cluster)
        */
    }
}
```
*/
java.security.Security.setProperty("networkaddress.cache.ttl", "1");
// If the lookup fails, default to something like small to retry
java.security.Security.setProperty("networkaddress.cache.negative.ttl", "3");
}

public Connection getConnection(String targetServerType) throws SQLException {
    return getConnection(targetServerType, DEFAULT_SOCKET_TIMEOUT);
}

public Connection getConnection(String targetServerType, Duration queryTimeout) throws SQLException {
    Connection conn = DriverManager.getConnection(getJdbcConnectionString(targetServerType, queryTimeout));
    /*
     * A good practice is to set socket and statement timeout to be the same thing
     * since both  
     * the client AND server will stop the query at the same time, leaving no running queries
     * on the backend
     */
    Statement st = conn.createStatement();
    st.execute("set statement_timeout to " + queryTimeout.getMillis());
    st.close();
    return conn;
}

private static String urlFormat = "jdbc:postgresql://%s"
        + "/?user=%s"
        + "&password=%s"
        + "&loginTimeout=%d"
        + "&connectTimeout=%d"
        + "&cancelSignalTimeout=%d"
        + "&socketTimeout=%d"
        + "&targetServerType=%s"
        + "&tcpKeepAlive=true"
        + "&ssl=true"
        + "&loadBalanceHosts=true";

public String getJdbcConnectionString(String targetServerType, Duration queryTimeout) {
    return String.format(urlFormat, 
        getFormattedEndpointList(getLocalEndpointList()),
        CredentialManager.getUsername(),
        CredentialManager.getPassword(),
        LOGIN_TIMEOUT.getStandardSeconds(),
        CONNECT_TIMEOUT.getStandardSeconds(),
        CANCEL_SIGNAL_TIMEOUT.getStandardSeconds(),
        queryTimeout.getStandardSeconds(),
        targetServerType
    );
}

private List<String> getLocalEndpointList() {
    /*
     * As mentioned in the best practices doc, a good idea is to read a local resource
     * file and parse the cluster endpoints.
     * For illustration purposes, the endpoint list is hardcoded here
     */
    List<String> newEndpointList = new ArrayList<>();
    newEndpointList.add("myauroracluster.cluster-c9bfei4hjlrds.us-east-1-beta.rds.amazonaws.com:5432");
    newEndpointList.add("myauroracluster.cluster-ro-c9bfei4hjlrds.us-east-1-beta.rds.amazonaws.com:5432");
Fast recovery after failover with cluster cache management for Aurora PostgreSQL

For fast recovery of the writer DB instance in your Aurora PostgreSQL clusters if there's a failover, use cluster cache management for Amazon Aurora PostgreSQL. Cluster cache management ensures that application performance is maintained if there's a failover.

In a typical failover situation, you might see a temporary but large performance degradation after failover. This degradation occurs because when the failover DB instance starts, the buffer cache is empty. An empty cache is also known as a cold cache. A cold cache degrades performance because the DB instance has to read from the slower disk, instead of taking advantage of values stored in the buffer cache.

With cluster cache management, you set a specific reader DB instance as the failover target. Cluster cache management ensures that the data in the designated reader's cache is kept synchronized with the data in the writer DB instance's cache. The designated reader's cache with prefilled values is known as a warm cache. If a failover occurs, the designated reader uses values in its warm cache immediately when it's promoted to the new writer DB instance. This approach provides your application much better recovery performance.

Cluster cache management requires that the designated reader instance have the same instance class type and size (db.r5.2xlarge or db.r5.xlarge, for example) as the writer. Keep this in mind when you create your Aurora PostgreSQL DB clusters so that your cluster can recover during a failover. For a listing of instance class types and sizes, see Hardware specifications for DB instance classes for Aurora.

**Note**
Cluster cache management is not supported for Aurora PostgreSQL DB clusters that are part of Aurora global databases. It is recommended that no workload should run on the designated tier-0 reader.

Contents
- Configuring cluster cache management (p. 1478)
  - Enabling cluster cache management (p. 1479)
  - Setting the promotion tier priority for the writer DB instance (p. 1479)
  - Setting the promotion tier priority for a reader DB instance (p. 1480)
- Monitoring the buffer cache (p. 1481)

Configuring cluster cache management

To configure cluster cache management, do the following processes in order.

Topics
- Enabling cluster cache management (p. 1479)
- Setting the promotion tier priority for the writer DB instance (p. 1479)
• Setting the promotion tier priority for a reader DB instance (p. 1480)

Note
Allow at least 1 minute after completing these steps for cluster cache management to be fully operational.

Enabling cluster cache management

To enable cluster cache management, take the steps described following.

Console

To enable cluster cache management

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. In the list, choose the parameter group for your Aurora PostgreSQL DB cluster.
   The DB cluster must use a parameter group other than the default, because you can’t change values in a default parameter group.
4. For Parameter group actions, choose Edit.
5. Set the value of the apg_ccm_enabled cluster parameter to 1.
6. Choose Save changes.

AWS CLI

To enable cluster cache management for an Aurora PostgreSQL DB cluster, use the AWS CLI modify-db-cluster-parameter-group command with the following required parameters:

• --db-cluster-parameter-group-name
• --parameters

Example

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster-parameter-group \
  --db-cluster-parameter-group-name my-db-cluster-parameter-group \
  --parameters "ParameterName=apg_ccm_enabled,ParameterValue=1,ApplyMethod=immediate"
```

For Windows:

```bash
aws rds modify-db-cluster-parameter-group ^
  --db-cluster-parameter-group-name my-db-cluster-parameter-group ^
  --parameters "ParameterName=apg_ccm_enabled,ParameterValue=1,ApplyMethod=immediate"
```

Setting the promotion tier priority for the writer DB instance

For cluster cache management, make sure that the promotion priority is tier-0 for the writer DB instance of the Aurora PostgreSQL DB cluster. The promotion tier priority is a value that specifies the order in which an Aurora reader is promoted to the writer DB instance after a failure. Valid values are 0–15, where
0 is the first priority and 15 is the last priority. For more information about the promotion tier, see Fault tolerance for an Aurora DB cluster (p. 103).

**Console**

**To set the promotion priority for the writer DB instance to tier-0**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the **Writer** DB instance of the Aurora PostgreSQL DB cluster.
4. Choose **Modify**. The **Modify DB Instance** page appears.
5. On the **Additional configuration** panel, choose **tier-0** for the **Failover priority**.
6. Choose **Continue** and check the summary of modifications.
7. To apply the changes immediately after you save them, choose **Apply immediately**.
8. Choose **Modify DB Instance** to save your changes.

**AWS CLI**

To set the promotion tier priority to 0 for the writer DB instance using the AWS CLI, call the **modify-db-instance** command with the following required parameters:

- `--db-instance-identifier`
- `--promotion-tier` 0
- `--apply-immediately`

**Example**

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
   --db-instance-identifier writer-db-instance \
   --promotion-tier 0 \
   --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
   --db-instance-identifier writer-db-instance ^
   --promotion-tier 0 ^
   --apply-immediately
```

**Setting the promotion tier priority for a reader DB instance**

You set one reader DB instance for cluster cache management. To do so, choose a reader from the Aurora PostgreSQL cluster that is the same instance class and size as the writer DB instance. For example, if the writer uses `db.r5.xlarge`, choose a reader that uses this same instance class type and size. Then set its promotion tier priority to 0.

The **promotion tier priority** is a value that specifies the order in which an Aurora reader is promoted to the writer DB instance after a failure. Valid values are 0–15, where 0 is the first priority and 15 is the last priority.
Console

To set the promotion priority of the reader DB instance to tier-0

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose a Reader DB instance of the Aurora PostgreSQL DB cluster that is the same instance class as the writer DB instance.
5. On the Additional configuration panel, choose tier-0 for the Failover priority.
6. Choose Continue and check the summary of modifications.
7. To apply the changes immediately after you save them, choose Apply immediately.
8. Choose Modify DB Instance to save your changes.

AWS CLI

To set the promotion tier priority to 0 for the reader DB instance using the AWS CLI, call the modify-db-instance command with the following required parameters:

- --db-instance-identifier
- --promotion-tier
- --apply-immediately

Example

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier reader-db-instance \
  --promotion-tier 0 \
  --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier reader-db-instance ^
  --promotion-tier 0 ^
  --apply-immediately
```

Monitoring the buffer cache

After setting up cluster cache management, you can monitor the state of synchronization between the writer DB instance's buffer cache and the designated reader's warm buffer cache. To examine the buffer cache contents on both the writer DB instance and the designated reader DB instance, use the PostgreSQL pg_buffercache module. For more information, see the PostgreSQL pg_buffercache documentation.

Using the aurora_ccm_status Function
Cluster cache management also provides the `aurora_ccm_status` function. Use the `aurora_ccm_status` function on the writer DB instance to get the following information about the progress of cache warming on the designated reader:

- `buffers_sent_last_minute` – How many buffers have been sent to the designated reader in the last minute.
- `buffers_found_last_minute` – The number of frequently accessed buffers identified during the past minute.
- `buffers_sent_last_scan` – How many buffers have been sent to the designated reader during the last complete scan of the buffer cache.
- `buffers_found_last_scan` – How many buffers have been identified as frequently accessed and needed to be sent during the last complete scan of the buffer cache. Buffers already cached on the designated reader aren’t sent.
- `buffers_sent_current_scan` – How many buffers have been sent so far during the current scan.
- `buffers_found_current_scan` – How many buffers have been identified as frequently accessed in the current scan.
- `current_scan_progress` – How many buffers have been visited so far during the current scan.

The following example shows how to use the `aurora_ccm_status` function to convert some of its output into a warm rate and warm percentage.

```sql
SELECT buffers_sent_last_minute*8/60 AS warm_rate_kbps,
       100*(1.0-buffers_sent_last_scan::float/buffers_found_last_scan) AS warm_percent
FROM aurora_ccm_status();
```

Managing Aurora PostgreSQL connection churn with pooling

When client applications connect and disconnect so often that Aurora PostgreSQL DB cluster response time slows, the cluster is said to be experiencing connection churn. Each new connection to the Aurora PostgreSQL DB cluster endpoint consumes resources, thus reducing the resources that can be used to process the actual workload. Connection churn is an issue that we recommend that you manage by following some of the best practices discussed following.

For starters, you can improve response times on Aurora PostgreSQL DB clusters that have high rates of connection churn. To do this, you can use a connection pooler, such as RDS Proxy. A connection pooler provides a cache of ready to use connections for clients. Almost all versions of Aurora PostgreSQL support RDS Proxy. For more information, see Amazon RDS Proxy with Aurora PostgreSQL (p. 51).

If your specific version of Aurora PostgreSQL doesn’t support RDS Proxy, you can use another PostgreSQL–compatible connection pooler, such as PgBouncer. To learn more, see the PgBouncer website.

To see if your Aurora PostgreSQL DB cluster can benefit from connection pooling, you can check the `postgresql.log` file for connections and disconnections. You can also use Performance Insights to find out how much connection churn your Aurora PostgreSQL DB cluster is experiencing. Following, you can find information about both topics.

Logging connections and disconnections

The PostgreSQL `log_connections` and `log_disconnections` parameters can capture connections and disconnections to the writer instance of the Aurora PostgreSQL DB cluster. By default, these parameters are turned off. To turn these parameters on, use a custom parameter group and turn on by
changing the value to 1. For more information about custom parameter groups, see Working with DB cluster parameter groups (p. 214). To check the settings, connect to your DB cluster endpoint for Aurora PostgreSQL by using psql and query as follows.

```
labdb=> SELECT setting FROM pg_settings
    WHERE name = 'log_connections';
setting
---------
on
(1 row)
labdb=> SELECT setting FROM pg_settings
    WHERE name = 'log_disconnections';
setting
---------
on
(1 row)
```

With both of these parameters turned on, the log captures all new connections and disconnections. You see the user and database for each new authorized connection. At disconnection time, the session duration is also logged, as shown in the following example.

```
2022-03-07 21:44:55.718 UTC [16641] LOG: disconnection: session time: 0:00:01.740 user=labtek database=labdb host=[local]
```

To check your application for connection churn, turn on these parameters if they're not on already. Then gather data in the PostgreSQL log for analysis by running your application with a realistic workload and time period. You can view the log file in the RDS console. Choose the writer instance of your Aurora PostgreSQL DB cluster, and then choose the Logs & events tab. For more information, see Viewing and listing database log files (p. 722).

Or you can download the log file from the console and use the following command sequence. This sequence finds the total number of connections authorized and dropped per minute.

```
grep "connection authorized\|disconnection: session time:" postgresql.log.2022-03-21-16|\nawk '{print $1,$2}' |\nsort \|\nuniq -c |\nsort -n -k1
```

In the example output, you can see a spike in authorized connections followed by disconnections starting at 16:12:10.

```
......
......
5 2022-03-21 16:11:55 connection authorized:
9 2022-03-21 16:11:55 disconnection: session
5 2022-03-21 16:11:56 connection authorized:
5 2022-03-21 16:11:57 connection authorized:
5 2022-03-21 16:11:57 disconnection: session
32 2022-03-21 16:12:10 connection authorized:
30 2022-03-21 16:12:10 disconnection: session
31 2022-03-21 16:12:11 connection authorized:
27 2022-03-21 16:12:11 disconnection: session
27 2022-03-21 16:12:12 connection authorized:
27 2022-03-21 16:12:12 disconnection: session
41 2022-03-21 16:12:13 connection authorized:
47 2022-03-21 16:12:13 disconnection: session
```
With this information, you can decide if your workload can benefit from a connection pooler. For more detailed analysis, you can use Performance Insights.

**Detecting connection churn with Performance Insights**

You can use Performance Insights to assess the amount of connection churn on your Aurora PostgreSQL-Compatible Edition DB cluster. When you create an Aurora PostgreSQL DB cluster, the setting for Performance Insights is turned on by default. If you cleared this choice when you created your DB cluster, modify your cluster to turn on the feature. For more information, see [Modifying an Amazon Aurora DB cluster](p. 269).

With Performance Insights running on your Aurora PostgreSQL DB cluster, you can choose the metrics that you want to monitor. You can access Performance Insights from the navigation pane in the console. You can also access Performance Insights from the Monitoring tab of the writer instance for your Aurora PostgreSQL DB cluster, as shown in the following image.

From the Performance Insights console, choose Manage metrics. To analyze your Aurora PostgreSQL DB cluster's connection and disconnection activity, choose the following metrics. These are all metrics from PostgreSQL.

- `xact_commit` – The number of committed transactions.
- `total_auth_attempts` – The number of attempted authenticated user connections per minute.
• `numbackends` – The number of backends currently connected to the database.

To save the settings and display connection activity, choose **Update graph**.

In the following image, you can see the impact of running pgbench with 100 users. The line showing connections is on a consistent upward slope. To learn more about pgbench and how to use it, see `pgbench` in PostgreSQL documentation.

The image shows that running a workload with as few as 100 users without a connection pooler can cause a significant increase in the number of `total_auth_attempts` throughout the duration of workload processing.
Managing connection churn

With RDS Proxy connection pooling, the connection attempts increase at the start of the workload. After setting up the connection pool, the average declines. The resources used by transactions and backend use stays consistent throughout workload processing.

For more information about using Performance Insights with your Aurora PostgreSQL DB cluster, see Monitoring DB load with Performance Insights on Amazon Aurora (p. 559). To analyze the metrics, see Analyzing metrics with the Performance Insights dashboard (p. 576).

Demonstrating the benefits of connection pooling

As mentioned previously, if you determine that your Aurora PostgreSQL DB cluster has a connection churn problem, you can use RDS Proxy for improved performance. Following, you can find an example that shows the differences in processing a workload when connections are pooled and when they're not. The example uses pgbench to model a transaction workload.

As is psql, pgbench is a PostgreSQL client application that you can install and run from your local client machine. You can also install and run it from the Amazon EC2 instance that you use for managing your Aurora PostgreSQL DB cluster. For more information, see pgbench in the PostgreSQL documentation.

To step through this example, you first create the pgbench environment in your database. The following command is the basic template for initializing the pgbench tables in the specified database. This example uses the default main user account, postgres, for the login. Change it as needed for your Aurora PostgreSQL DB cluster. You create the pgbench environment in a database on the writer instance of your cluster.

```
pgebench -U postgres -h db-cluster-instance-1.111122223333.aws-region.rds.amazonaws.com -p 5432 -d -i -s 50 dbname
```

For pgbench, specify the following parameters.

- **-d**
  Outputs a debugging report as pgbench runs.

- **-h**
  Specifies the endpoint of the Aurora PostgreSQL DB cluster's writer instance.

- **-i**
  Initializes the pgbench environment in the database for the benchmark tests.

- **-p**
  Identifies the port used for database connections. The default for Aurora PostgreSQL is typically 5432 or 5433.
Managing connection churn

-s

Specifies the scaling factor to use for populating the tables with rows. The default scaling factor is 1, which generates 1 row in the `pgbench_branches` table, 10 rows in the `pgbench_tellers` table, and 100000 rows in the `pgbench_accounts` table.

-U

Specifies the user account for the Aurora PostgreSQL DB cluster's writer instance.

After the pgbench environment is set up, you can then run benchmarking tests with and without connection pooling. The default test consists of a series of five SELECT, UPDATE, and INSERT commands that run repeatedly for the time specified. You can specify scaling factor, number of clients, and other details to model your own use cases.

As an example, the command that follows runs the benchmark for 60 seconds (-T option, for time) with 20 concurrent connections (the -c option). The -C option makes the test run using a new connection each time, rather than once per client session. This setting gives you an indication of the connection overhead.

```
pgbench -h docs-lab-apg-133-test-instance-1.c3zr2auzukpa.us-west-1.rds.amazonaws.com -U postgres -p 5432 -T 60 -c 20 -C labdb
Password:**********
```

Running `pgbench` on the writer instance of an Aurora PostgreSQL DB cluster without reusing connections shows that only about 8 transactions are processed each second. This gives a total of 495 transactions during the 1-minute test.

If you reuse connections, the response from Aurora PostgreSQL DB cluster for the number of users is almost 20 times faster. With reuse, a total of 9,042 transactions is processed compared to 495 in the same amount of time and for the same number of user connections. The difference is that in the following, each connection is being reused.

```
pgbench -h docs-lab-apg-133-test-instance-1.c3zr2auzukpa.us-west-1.rds.amazonaws.com -U postgres -p 5432 -T 60 -c 20 labdb
Password:**********
```

```

```
Tuning memory parameters for Aurora PostgreSQL

In Amazon Aurora PostgreSQL, you can use several parameters that control the amount of memory used for various processing tasks. If a task takes more memory than the amount set for a given parameter, Aurora PostgreSQL uses other resources for processing, such as by writing to disk. This can cause your Aurora PostgreSQL DB cluster to slow or potentially halt, with an out-of-memory error.

The default setting for each memory parameter can usually handle its intended processing tasks. However, you can also tune your Aurora PostgreSQL DB cluster's memory-related parameters. You do this tuning to ensure that enough memory is allocated for processing your specific workload.

Following, you can find information about parameters that control memory management. You can also learn how to assess memory utilization.

Checking and setting parameter values

The parameters that you can set to manage memory and assess your Aurora PostgreSQL DB cluster's memory usage include the following:

- **work_mem** – Specifies the amount of memory that the Aurora PostgreSQL DB cluster uses for internal sort operations and hash tables before it writes to temporary disk files.
- **log_temp_files** – Logs temporary file creation, file names, and sizes. When this parameter is turned on, a log entry is stored for each temporary file that gets created. Turn this on to see how frequently your Aurora PostgreSQL DB cluster needs to write to disk. Turn it off again after you've gathered information about your Aurora PostgreSQL DB cluster's temporary file generation, to avoid excessive logging.
- **logical_decoding_work_mem** – Specifies the amount of memory (in megabytes) to use for logical decoding. Logical decoding is the process used to create a replica. This process is done by converting data from the write-ahead log (WAL) file to the logical streaming output needed by the target. The value of this parameter creates a single buffer of the size specified for each replication connection. By default, it's 65536 KB. After this buffer is filled, the excess is written to disk as a file. To minimize disk activity, you can set the value of this parameter to a much higher value than that of work_mem.

These are all dynamic parameters, so you can change them for the current session. To do this, connect to the Aurora PostgreSQL DB cluster with psql and using the SET statement, as shown following.

```sql
SET parameter_name TO parameter_value;
```

Session settings last for the duration of the session only. When the session ends, the parameter reverts to its setting in the DB cluster parameter group. Before changing any parameters, first check the current values by querying the pg_settings table, as follows.

```sql
SELECT unit, setting, max_val
FROM pg_settings WHERE name='parameter_name';
```

For example, to find the value of the work_mem parameter, connect to the Aurora PostgreSQL DB cluster's writer instance and run the following query.

```sql
SELECT unit, setting, max_val, pg_size_pretty(max_val::numeric)
```

This example shows you that pooling connections can significantly improve response times. For information about setting up RDS Proxy for your Aurora PostgreSQL DB cluster, see Using Amazon RDS Proxy for Aurora (p. 1879).
Changing parameter settings so that they persist requires using a custom DB cluster parameter group. After exercising your Aurora PostgreSQL DB cluster with different values for these parameters using the SET statement, you can create a custom parameter group and apply to your Aurora PostgreSQL DB cluster. For more information, see Working with parameter groups (p. 212).

Understanding the working memory parameter

The working memory parameter (work_mem) specifies the maximum amount of memory that Aurora PostgreSQL can use to process complex queries. Complex queries include those that involve sorting or grouping operations—in other words, queries that use the following clauses:

- ORDER BY
- DISTINCT
- GROUP BY
- JOIN (MERGE and HASH)

The query planner indirectly affects how your Aurora PostgreSQL DB cluster uses working memory. The query planner generates execution plans for processing SQL statements. A given plan might break up a complex query into multiple units of work that can be run in parallel. When possible, Aurora PostgreSQL uses the amount of memory specified in the work_mem parameter for each session before writing to disk for each parallel process.

Multiple database users running multiple operations concurrently and generating multiple units of work in parallel can exhaust your Aurora PostgreSQL DB cluster's allocated working memory. This can lead to excessive temporary file creation and disk I/O, or worse, it can lead to an out-of-memory error.

Identifying temporary file use

Whenever the memory required to process queries exceeds the value specified in the work_mem parameter, the working data is offloaded to disk in a temporary file. You can see how often this occurs by turning on the log_temp_files parameter. By default, this parameter is off (it's set to -1). To capture all temporary file information, set this parameter to 0. Set log_temp_files to any other positive integer to capture temporary file information for files equal to or greater than that amount of data (in kilobytes). In the following image, you can see an example from AWS Management Console.
After configuring temporary file logging, you can test with your own workload to see if your working memory setting is sufficient. You can also simulate a workload by using pgbench, a simple benchmarking application from the PostgreSQL community.

The following example initializes (-i) pgbench by creating the necessary tables and rows for running the tests. In this example, the scaling factor (-s 50) creates 50 rows in the pgbench_branches table, 500 rows in pgbench_tellers, and 5,000,000 rows in the pgbench_accounts table in the labdb database.

```
pgbench -U postgres -h your-cluster-instance-1.111122223333.aws-regionrds.amazonaws.com -p 5432 -i -s 50 labdb
Password: dropping old tables...
NOTICE: table "pgbench_accounts" does not exist, skipping
NOTICE: table "pgbench_branches" does not exist, skipping
NOTICE: table "pgbench_history" does not exist, skipping
NOTICE: table "pgbench_tellers" does not exist, skipping
creating tables...
generating data (client-side)... 50000000 of 50000000 tuples (100%) done (elapsed 15.46 s, remaining 0.00 s) vacuuming... creating primary keys... done in 61.13 s (drop tables 0.08 s, create tables 0.39 s, client-side generate 54.85 s, vacuum 2.30 s, primary keys 3.51 s)
```

After initializing the environment, you can run the benchmark for a specific time (-T) and the number of clients (-c). This example also uses the -d option to output debugging information as the transactions are processed by the Aurora PostgreSQL DB cluster.

```
pgbench -h -U postgres your-cluster-instance-1.111122223333.aws-regionrds.amazonaws.com -p 5432 -d -T 60 -c 10 labdb
Password:*******
pgbench (14.3)
starting vacuum...end.
transaction type: <builtin: TPC-B (sort of)>
scaling factor: 50
query mode: simple
number of clients: 10
number of threads: 1
duration: 60 s
```
number of transactions actually processed: 1408
latency average = 398.467 ms
initial connection time = 4280.846 ms
tps = 25.096201 (without initial connection time)

For more information about pgbench, see `pgbench` in the PostgreSQL documentation.

You can use the psql metacommand command (`\d`) to list the relations such as tables, views, and indexes created by pgbench.

```
labdb=> \d pgbench_accounts
Table "public.pgbench_accounts"
<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Collation</th>
<th>Nullable</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>aid</td>
<td>integer</td>
<td></td>
<td>not null</td>
<td></td>
</tr>
<tr>
<td>bid</td>
<td>integer</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>abalance</td>
<td>integer</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>filler</td>
<td>character(84)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

As shown in the output, the `pgbench_accounts` table is indexed on the `aid` column. To ensure that this next query uses working memory, query any nonindexed column, such as that shown in the following example.

```
postgres=> SELECT * FROM pgbench_accounts ORDER BY bid;
```

Check the log for the temporary files. To do so, open the AWS Management Console, choose the Aurora PostgreSQL DB cluster instance, and then choose the `Logs & Events` tab. View the logs in the console or download for further analysis. As shown in the following image, the size of the temporary files needed to process the query indicates that you should consider increasing the amount specified for the `work_mem` parameter.

```
2022-07-07 23:00:02 UTC:[Local]:[unknown]:[unknown]:[9698]:LOG: connection received: host=[local]
2022-07-07 23:00:02 UTC:[Local]:[unknown]:[unknown]:[15780]:LOG: connection received: host=[local]

2022-07-07 23:04:16 UTC:[@:[18585]]:STATEMENT: SELECT * FROM pgbench_accounts ORDER by bid;
2022-07-07 23:04:16 UTC:[@:[18585]]:STATEMENT: SELECT * FROM pgbench_accounts ORDER by bid;
2022-07-07 23:04:16 UTC:54.240.198.34 (12098):postgres@labdb:[5700]:STATEMENT: SELECT * FROM pgbench_accounts ORDER by bid;
2022-07-07 23:06:02 UTC:[Local]:[unknown]:[unknown]:[26798]:LOG: connection received: host=[local]
2022-07-07 23:08:02 UTC:[Local]:[unknown]:[unknown]:[3331]:LOG: connection received: host=[local]
2022-07-07 23:10:02 UTC:[Local]:[unknown]:[unknown]:[5938]:LOG: connection received: host=[local]
2022-07-07 23:12:02 UTC:[Local]:[unknown]:[unknown]:[11851]:LOG: connection received: host=[local]
2022-07-07 23:14:02 UTC:[Local]:[unknown]:[unknown]:[17375]:LOG: connection received: host=[local]
2022-07-07 23:16:02 UTC:[Local]:[unknown]:[unknown]:[22962]:LOG: connection received: host=[local]
2022-07-07 23:18:02 UTC:[Local]:[unknown]:[unknown]:[28804]:LOG: connection received: host=[local]
2022-07-07 23:20:02 UTC:[Local]:[unknown]:[unknown]:[312]:LOG: connection received: host=[local]
2022-07-07 23:22:02 UTC:[Local]:[unknown]:[unknown]:[180001]:LOG: connection received: host=[local]
```

You can configure this parameter differently for individuals and groups, based on your operational needs. For example, you can set the `work_mem` parameter to 8 GB for the role named `dev_team`.

```
postgres=> ALTER ROLE dev_team SET work_mem='8GB';
```
With this setting for `work_mem`, any role that's a member of the `dev_team` role is allotted up to 8 GB of working memory.

**Using indexes for faster response time**

If your queries are taking too long to return results, you can verify that your indexes are being used as expected. First, turn on `\timing`, the psql metacommand, as follows.

```
postgres=> \timing on
```

After turning on timing, use a simple SELECT statement.

```
postgres=> SELECT COUNT(*) FROM
        (SELECT * FROM pgbench_accounts
         ORDER BY bid)
        AS accounts;
```

<table>
<thead>
<tr>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>5000000</td>
</tr>
</tbody>
</table>

(1 row)

Time: 3119.049 ms (00:03.119)

As shown in the output, this query took just over 3 seconds to complete. To improve the response time, create an index on `pgbench_accounts`, as follows.

```
postgres=> CREATE INDEX ON pgbench_accounts(bid);
CREATE INDEX
```

Rerun the query, and notice the faster response time. In this example, the query completed about 5 times faster, in about half a second.

```
postgres=> SELECT COUNT(*) FROM (SELECT * FROM pgbench_accounts ORDER BY bid) AS accounts;
```

<table>
<thead>
<tr>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>5000000</td>
</tr>
</tbody>
</table>

(1 row)

Time: 567.095 ms

**Adjusting working memory for logical decoding**

Logical replication has been available in all versions of Aurora PostgreSQL since its introduction in PostgreSQL version 10. When you configure logical replication, you can also set the `logical_decoding_work_mem` parameter to specify the amount of memory that the logical decoding process can use for the decoding and streaming process.

During logical decoding, write-ahead log (WAL) records are converted to SQL statements that are then sent to another target for logical replication or another task. When a transaction is written to the WAL and then converted, the entire transaction must fit into the value specified for `logical_decoding_work_mem`. By default, this parameter is set to 65536 KB. Any overflow is written to disk. This means that it must be reread from the disk before it can be sent to its destination, thus slowing the overall process.

You can assess the amount of transaction overflow in your current workload at a specific point in time by using the `aurora_stat_file` function as shown in the following example.

```
SELECT split_part (filename, '/', 2)
```
AS slot_name, count(1) AS num_spill_files,
         sum(used_bytes) AS slot_total_bytes,
         pg_size_pretty(sum(used_bytes)) AS slot_total_size
FROM aurora_stat_file()
WHERE filename like '%spill%'
GROUP BY 1;
slot_name | num_spill_files | slot_total_bytes | slot_total_size
-------------+-----------------+------------------+-----------------
        |       590       |      411600000    | 393 MB
(1 row)

This query returns the count and size of spill files on your Aurora PostgreSQL DB cluster when the query is invoked. Longer running workloads might not have any spill files on disk yet. To profile long-running workloads, we recommend that you create a table to capture the spill file information as the workload runs. You can create the table as follows.

CREATE TABLE spill_file_tracking AS
SELECT now() AS spill_time, *
FROM aurora_stat_file()
WHERE filename LIKE '%spill%';

To see how spill files are used during logical replication, set up a publisher and subscriber and then start a simple replication. For more information, see Setting up logical replication for your Aurora PostgreSQL DB cluster (p. 1507). With replication under way, you can create a job that captures the result set from the aurora_stat_file() spill file function, as follows.

INSERT INTO spill_file_tracking
SELECT now(), *
FROM aurora_stat_file()
WHERE filename LIKE '%spill%';

Use the following psql command to run the job once per second.

\watch 0.5

As the job is running, connect to the writer instance from another psql session. Use the following series of statements to run a workload that exceeds the memory configuration and causes Aurora PostgreSQL to create a spill file.

labdb=> CREATE TABLE my_table (a int PRIMARY KEY, b int);
CREATE TABLE
labdb=> INSERT INTO my_table SELECT x,x FROM generate_series(0,10000000) x;
INSERT 0 10000001
labdb=> UPDATE my_table SET b=b+1;
UPDATE 10000001

These statements take several minutes to complete. When finished, press the Ctrl key and the C key together to stop the monitoring function. Then use the following command to create a table to hold the information about the Aurora PostgreSQL DB cluster's spill file usage.

SELECT spill_time, split_part (filename, '/', 2)
AS slot_name, count(1)
AS spills, sum(used_bytes)
AS slot_total_bytes, pg_size_pretty(sum(used_bytes))
AS slot_total_size FROM spill_file_tracking
GROUP BY 1,2 ORDER BY 1;
spill_time | slot_name     | spills | slot_total_bytes |
-------------+----------------+-------+------------------
The output shows that running the example created five spill files that used 611 MB of memory. To avoid writing to disk, we recommend setting the `logical_decoding_work_mem` parameter to the next highest memory size, 1024.

### Using Amazon CloudWatch metrics to analyze resource usage for Aurora PostgreSQL

Aurora automatically sends metric data to CloudWatch in 1-minute periods. You can analyze resource usage for Aurora PostgreSQL using CloudWatch metrics. You can evaluate the network throughput and the network usage with the metrics.

#### Evaluating network throughput with CloudWatch

When your system usage approaches the resource limits for your instance type, the processing can slow down. You can use CloudWatch Logs Insights to monitor your storage resource usage and ensure that sufficient resources are available. When needed, you can modify the DB instance to a larger instance class.

Aurora storage processing may be slow because of:

- Insufficient network bandwidth between the client and DB instance.
- Insufficient network bandwidth to the storage subsystem.
- A workload that is large for your instance type.

You can query CloudWatch Logs Insights to generate a graph of Aurora storage resource usage to monitor the resources. The graph shows the CPU utilization and metrics to help you decide whether to scale up to a larger instance size. For information about the query syntax for CloudWatch Logs Insights, see [CloudWatch Logs Insights query syntax](#).

To use CloudWatch, you need to export your Aurora PostgreSQL log files to CloudWatch. You can also modify your existing cluster to export logs to CloudWatch. For information about exporting logs to CloudWatch, see [Turning on the option to publish logs to Amazon CloudWatch](#).

You need the Resource ID of your DB instance to query the CloudWatch Logs Insights. The Resource ID is available in the Configuration tab in your console:
To query your log files for resource storage metrics:

   The CloudWatch overview home page appears.

2. If necessary, change the AWS Region. In the navigation bar, choose the AWS Region where your AWS resources are located. For more information, see Regions and endpoints.

3. In the navigation pane, choose Logs and then Logs Insights.

   The Logs Insights page appears.

4. Select the log files from the drop-down list to analyze.

5. Enter the following query in the field, replacing <resource ID> with the resource ID of your DB cluster:

   ```
   filter @logStream = <resource ID> | parse @message ""Aurora Storage Daemon \""memoryUsedPc\":\",\"cpuUsedPc\":\", as a,memoryUsedPc,cpuUsedPc | display memoryUsedPc,cpuUsedPc #| stats avg(xcpu) as avgCpu by bin(5m) | limit 10000
   ```

6. Click Run query.

   The storage utilization graph is displayed.

   The following image provides the Logs Insights page and the graph display.
Evaluating DB instance usage with CloudWatch metrics

You can use CloudWatch metrics to watch your instance throughput and discover if your instance class provides sufficient resources for your applications. For information about your DB instance class limits, go to Hardware specifications for DB instance classes for Aurora (p. 94) and locate the specifications for your DB instance class to find your network performance.

If your DB instance usage is near the instance class limit, then performance may begin to slow. The CloudWatch metrics can confirm this situation so you can plan to manually scale-up to a larger instance class.

Combine the following CloudWatch metrics values to find out if you are nearing the instance class limit:

- **NetworkThroughput** – The amount of network throughput received and transmitted by the clients for each instance in the Aurora DB cluster. This throughput value doesn't include network traffic between instances in the DB cluster and the cluster volume.
- **StorageNetworkThroughput** – The amount of network throughput received and sent to the Aurora storage subsystem by each instance in your Aurora DB cluster.

Add the **NetworkThroughput** to the **StorageNetworkThroughput** to find the network throughput received from and sent to the Aurora storage subsystem by each instance in your Aurora DB cluster. The instance class limit for your instance should be greater than the sum of these two combined metrics.

You can use the following metrics to review additional details of the network traffic from your client applications when sending and receiving:
• **NetworkReceiveThroughput** – The amount of network throughput received from clients by each instance in the Aurora PostgreSQL DB cluster. This throughput doesn't include network traffic between instances in the DB cluster and the cluster volume.

• **NetworkTransmitThroughput** – The amount of network throughput sent to clients by each instance in the Aurora DB cluster. This throughput doesn't include network traffic between instances in the DB cluster and the cluster volume.

• **StorageNetworkReceiveThroughput** – The amount of network throughput received from the Aurora storage subsystem by each instance in the DB cluster.

• **StorageNetworkTransmitThroughput** – The amount of network throughput sent to the Aurora storage subsystem by each instance in the DB cluster.

Add all of these metrics together to evaluate how your network usage compares to the instance class limit. The instance class limit should be greater than the sum of these combined metrics.

The network limits and CPU utilization for storage are mutual. When the network throughput increases, then the CPU utilization also increases. Monitoring the CPU and network usage provides information about how and why the resources are being exhausted.

To help minimize network usage, you can consider:

• Using a larger instance class.
• Using `pg_partman` partitioning strategies.
• Dividing the write requests in batches to reduce overall transactions.
• Directing the read-only workload to a read-only instance.
• Deleting any unused indexes.
• Checking for bloated objects and VACUUM. In the case of severe bloat, use the PostgreSQL extension `pg_repack`. For more information about `pg_repack`, see Reorganize tables in PostgreSQL databases with minimal locks.

### Using logical replication to perform a major version upgrade for Aurora PostgreSQL

Using logical replication and Aurora fast cloning, you can perform a major version upgrade that uses the current version of Aurora PostgreSQL database while gradually migrating the changing data to the new major version database. This low downtime upgrade process is referred to as a blue/green upgrade. The current version of the database is referred as the "blue" environment and the new database version is referred as the "green" environment.

Aurora fast cloning fully loads the existing data by taking a snapshot of the source database. Fast cloning uses a copy-on-write protocol built on top of the Aurora storage layer, which allows you to create a clone of database in a short time. This method is very effective when upgrading to a large database.

Logical replication in PostgreSQL tracks and transfers your data changes from initial instance to a new instance running in parallel until you move to the newer version of PostgreSQL. Logical replication uses a publish and subscribe model. For more information about Aurora PostgreSQL logical replication, see Replication with Amazon Aurora PostgreSQL (p. 1504).

**Note**

This process describes how you can manually configure a low downtime upgrade process for Aurora PostgreSQL using logical replication. The managed Amazon RDS Blue/Green Deployment feature is not currently available for Aurora PostgreSQL. For more information on the Amazon RDS Blue/Green Deployment, see Using Amazon RDS Blue/Green Deployments for database updates (p. 399).
Requirements

You must meet the following requirements to perform this low downtime upgrade process:

- You must have rds_superuser permissions.
- The Aurora PostgreSQL DB cluster you intend to upgrade must be running a supported version that can perform major version upgrades using logical replication. Make sure to apply any minor version updates and patches to your DB cluster. The `aurora_volume_logical_start_lsn` function that is used in this technique is supported in the following versions of Aurora PostgreSQL:
  - 15.2 and higher 15 versions
  - 14.3 and higher 14 versions
  - 13.6 and higher 13 versions
  - 12.10 and higher 12 versions
  - 11.15 and higher 11 versions
  - 10.20 and higher 10 versions

For more information on `aurora_volume_logical_start_lsn` function, see `aurora_volume_logical_start_lsn (p. 1725)`.

- All of your tables must have a primary key or include a PostgreSQL identity column.
- Configure the security group for your VPC to allow inbound and outbound access between the two Aurora PostgreSQL DB clusters, both old and new. You can grant access to a specific classless inter-domain routing (CIDR) range or to another security group in your VPC or in a peer VPC. (Peer VPC requires a VPC peering connection.)

Note

For detailed information about the permissions required to configure and manage a running logical replication scenario, see the PostgreSQL core documentation.

Limitations

When you are performing low downtime upgrade on your Aurora PostgreSQL DB cluster to upgrade it to a new major version, you are using the native PostgreSQL logical replication feature. It has the same capabilities and limitations as the PostgreSQL logical replication. For more information, see PostgreSQL logical replication.

- Data definition language (DDL) commands are not replicated.
- Replication doesn't support schema changes in a live database. The schema is recreated in its original form during the cloning process. If you change the schema after cloning, but before completing the upgrade, it isn't reflected in the upgraded instance.
- Large objects are not replicated, but you can store data in normal tables.
- Replication is only supported by tables, including partitioned tables. Replication to other types of relations, such as views, materialized views, or foreign tables, is not supported.
- Sequence data is not replicated and requires a manual update post-failover.
**Note**

This upgrade doesn't support auto-scripting. You should perform all the steps manually.

### Setting and checking parameter values

Before upgrading, configure the writer instance of your Aurora PostgreSQL DB cluster to act as a publication server. The instance should use a custom DB cluster parameter group with the following settings:

- **rds.logical_replication** – Set this parameter to 1. The `rds.logical_replication` parameter serves the same purpose as a standalone PostgreSQL server's `wal_level` parameter and other parameters that control the write-ahead log file management.
- **max_replication_slots** – Set this parameter to the total number of subscriptions that you plan to create. If you are using AWS DMS, set this parameter to the number of AWS DMS tasks that you plan to use for changed data capture from this DB cluster.
- **max_wal_senders** – Set to the number of concurrent connections, plus a few extra, to make available for management tasks and new sessions. If you are using AWS DMS, the number of `max_wal_senders` should be equal to the number of concurrent sessions plus the number of AWS DMS tasks that may be working at any given time.
- **max_logical_replication_workers** – Set to the number of logical replication workers and table synchronization workers that you expect. It's generally safe to set the number of replication workers to the same value used for `max_wal_senders`. The workers are taken from the pool of background processes (`max_worker_processes`) allocated for the server.
- **max_worker_processes** – Set to the number of background processes for the server. This number should be large enough to allocate workers for replication, auto-vacuum processes, and other maintenance processes that may take place concurrently.

When you upgrade to a newer version of Aurora PostgreSQL, you need to duplicate any parameters that you modified in the earlier version of the parameter group. These parameters are applied to the upgraded version. You can query the `pg_settings` table to get a list of parameter settings so that you can re-create them on your new Aurora PostgreSQL DB cluster.

For example, to get the settings for replication parameters, run the following query:

```sql
SELECT name, setting FROM pg_settings WHERE name in ('rds.logical_replication', 'max_replication_slots', 'max_wal_senders', 'max_logical_replication_workers', 'max_worker_processes');
```

### Upgrading Aurora PostgreSQL to a new major version

**To prepare the publisher (blue)**

1. In the example that follows, the source writer instance (blue) is an Aurora PostgreSQL DB cluster running PostgreSQL version 11.15. This is the publication node in our replication scenario. For this demonstration, our source writer instance hosts a sample table that holds a series of values:

   ```sql
   CREATE TABLE my_table (a int PRIMARY KEY);
   INSERT INTO my_table VALUES (generate_series(1,100));
   ```

2. To create a publication on the source instance, connect to the writer node of the instance with psql (the CLI for PostgreSQL) or with the client of your choice. Enter the following command in each database:

   ```sql
   CREATE PUBLICATION publication_name FOR ALL TABLES;
   ```
The publication_name specifies the name of the publication.

3. You also need to create a replication slot on the instance. The following command creates a replication slot and loads the pgoutput logical decoding plug-in. The plug-in changes content read from write-ahead logging (WAL) to the logical replication protocol, and filters the data according to the publication specification.

```
SELECT pg_create_logical_replication_slot('replication_slot_name', 'pgoutput');
```

To clone the publisher

1. Use the Amazon RDS Console to create a clone of the source instance. Highlight the instance name in the Amazon RDS Console, and then choose Create clone in the Actions menu.

2. Provide a unique name for the instance. Most of the settings are defaults from the source instance. When you've made changes required for the new instance, choose Create clone.

```
Note that clone operation can take several minutes to complete.
```

3. While the target instance is initiating, the Status column of the writer node displays Creating in the Status column. When the instance is ready, the status changes to Available.

To prepare the clone for an upgrade

1. The clone is the ‘green’ instance in the deployment model. It is the host of the replication subscription node. When the node becomes available, connect with psql and query the new writer node to obtain the log sequence number (LSN). The LSN identifies the beginning of a record in the WAL stream.

```
SELECT aurora_volume_logical_start_lsn();
```
2. In the response from the query, you find the LSN number. You need this number later in the process, so make a note of it.

```
postgres=> SELECT aurora_volume_logical_start_lsn();
aurora_volume_logical_start_lsn
--------------------
0/402E2F0
(1 row)
```

3. Before upgrading the clone, drop the clone's replication slot.

```
SELECT pg_drop_replication_slot('replication_slot_name');
```

### To upgrade the cluster to a new major version

- After cloning the provider node, use the Amazon RDS Console to initiate a major version upgrade on the subscription node. Highlight the instance name in the RDS console, and select the **Modify** button. Select the updated version and your updated parameter groups, and apply the settings immediately to upgrade the target instance.

![Modify DB cluster: target-cluster](image)

- You can also use the CLI to perform an upgrade:

```
aws rds modify-db-cluster --db-cluster-identifier $TARGET_Aurora_ID --engine-version 13.6 --allow-major-version-upgrade --apply-immediately
```

### To prepare the subscriber (green)

1. When the clone becomes available after the upgrade, connect with psql and define the subscription. To do so, you need to specify the following options in the **CREATE SUBSCRIPTION** command:

   - **subscription_name** – The name of the subscription.
Using logical replication for a major version upgrade

- admin_user_name – The name of an administrative user with rds_superuser permissions.
- admin_user_password – The password associated with the administrative user.
- source_instance_URL – The URL of the publication server instance.
- database – The database that the subscription server will connect with.
- publication_name – The name of the publication server.
- replication_slot_name – The name of the replication slot.

```sql
CREATE SUBSCRIPTION subscription_name
CONNECTION 'postgres://admin_user_name:admin_user_password@source_instance_URL/database'
PUBLICATION publication_name
WITH (copy_data = false, create_slot = false, enabled = false, connect = true,
slot_name = 'replication_slot_name');
```

2. After creating the subscription, query the `pg_replication_origin` view to retrieve the roname value, which is the identifier of the replication origin. Each instance has one roname:

```sql
SELECT * FROM pg_replication_origin;
```

For example:

```sql
postgres=
SELECT * FROM pg_replication_origin;
roident | roname
---------+----------
1 | pg_24586
```

3. Provide the LSN that you saved from the earlier query of the publication node and the roname returned from the subscription node [INSTANCE] in the command. This command uses the `pg_replication_origin_advance` function to specify the starting point in the log sequence for replication.

```sql
SELECT pg_replication_origin_advance('roname', 'log_sequence_number');
```

roname is the identifier returned by the `pg_replication_origin` view.

log_sequence_number is the value returned by the earlier query of the `aurora_volume_logical_start_lsn` function.

4. Then, use the `ALTER SUBSCRIPTION... ENABLE` clause to turn on logical replication.

```sql
ALTER SUBSCRIPTION subscription_name ENABLE;
```

5. At this point, you can confirm that replication is working. Add a value to the publication instance, then confirm that the value is replicated to the subscription node.

Then, use the following command to monitor replication lag on the publication node:

```sql
SELECT now() AS CURRENT_TIME, slot_name, active, active_pid,
pg_size_pretty(pg_wal_lsn_diff(pg_current_wal_lsn(),
confirmed_flush_lsn)) AS diff_size, pg_wal_lsn_diff(pg_current_wal_lsn(),
confirmed_flush_lsn) AS diff_bytes FROM pg_replication_slots WHERE slot_type = 'logical';
```

For example:
PostgreSQL=> SELECT now() AS CURRENT_TIME, slot_name, active, active_pid,
pg_size_pretty(pg_wal_lsn_diff(pg_current_wal_lsn(),
confirmed_flush_lsn)) AS diff_size, pg_wal_lsn_diff(pg_current_wal_lsn(),
confirmed_flush_lsn) AS diff_bytes FROM pg_replication_slots WHERE slot_type = 'logical';

<table>
<thead>
<tr>
<th>current_time</th>
<th>slot_name</th>
<th>active</th>
<th>active_pid</th>
</tr>
</thead>
<tbody>
<tr>
<td>+-----------+-------------+-----------------+------------</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2022-04-13 15:11:00.243401+00</td>
<td>replication_slot_name</td>
<td>t</td>
<td>21854</td>
</tr>
<tr>
<td>136</td>
<td>136</td>
<td>bytes</td>
<td>136</td>
</tr>
</tbody>
</table>

(1 row)

You can monitor the replication lag using `diff_size` and `diff_bytes` values. When these values reach 0, the replica has caught up to the source DB instance.

### Performing post-upgrade tasks

When the upgrade is complete, the instance status displays as **Available** in the **Status** column of the console dashboard. On the new instance, we recommend you do the following:

- Redirect your applications to point to the writer node.
- Add reader nodes to manage the caseload and provide high-availability in the event of an issue with the writer node.
- Aurora PostgreSQL DB clusters occasionally require operating system updates. These updates might include a newer version of glibc library. During such updates, we recommend you to follow the guidelines as described in [Collations supported in Aurora PostgreSQL](p. 1692).
- Update user permissions on the new instance to ensure access.

After testing your application and data on the new instance, we recommend that you make a final backup of your initial instance before removing it. For more information about using logical replication on an Aurora host, see [Setting up logical replication for your Aurora PostgreSQL DB cluster](p. 1507).

### Troubleshooting storage issues

If the amount of working memory needed for sort or index-creation operations exceeds the amount allocated by the `work_mem` parameter, Aurora PostgreSQL writes the excess data to temporary disk files. When it writes the data, Aurora PostgreSQL uses the same storage space that it uses for storing error and message logs, that is, local storage. Each instance in your Aurora PostgreSQL DB cluster has an amount of local storage available. The amount of storage is based on its DB instance class. To increase the amount of local storage, you need to modify the instance to use a larger DB instance class. For DB instance class specifications, see [Hardware specifications for DB instance classes for Aurora](p. 94).

You can monitor your Aurora PostgreSQL DB cluster’s local storage space by watching the Amazon CloudWatch metric for `FreeLocalStorage`. This metric reports the amount of storage available to each DB instance in the Aurora DB cluster for temporary tables and logs. For more information, see [Monitoring Amazon Aurora metrics with Amazon CloudWatch](p. 545).

Sorting, indexing, and grouping operations start in working memory but often must be offloaded to local storage. If your Aurora PostgreSQL DB cluster runs out of local storage because of these types of operations, you can resolve the issue by taking one of the following actions:

- Increase the amount of working memory. This reduces the need to use local storage. By default, PostgreSQL allocates 4 MB for each sort, group, and index operation. To check the current working
memory value for your Aurora PostgreSQL DB cluster's writer instance, connect to the instance using 
psql and run the following command.

```sql
postgres=> SHOW work_mem;
work_mem
--------
 4MB
(1 row)
```

You can increase the working memory at the session level before sort, group, and other operations, as 
follows.

```sql
SET work_mem TO '1 GB';
```

For more information about working memory, see Resource Consumption in the PostgreSQL 
documentation.

- Change the log retention period so that logs are stored for shorter timeframes. To learn how, see 
  Aurora PostgreSQL database log files (p. 735).

For Aurora PostgreSQL DB clusters larger than 40 TB, don't use db.t2, db.t3, or db.t4g instance classes. 
We recommend using the T DB instance classes only for development and test servers, or other non-
production servers. For more information, see DB instance class types (p. 84).

---

### Replication with Amazon Aurora PostgreSQL

Following, you can find information about replication with Amazon Aurora PostgreSQL, including how to 
monitor replication.

**Topics**

- Using Aurora Replicas (p. 1504)
- Improving the read availability of Aurora Replicas (p. 1505)
- Monitoring Aurora PostgreSQL replication (p. 1506)
- Using PostgreSQL logical replication with Aurora (p. 1506)

---

### Using Aurora Replicas

An Aurora Replica is an independent endpoint in an Aurora DB cluster, best used for scaling read 
operations and increasing availability. An Aurora DB cluster can include up to 15 Aurora Replicas located 
throughout the Availability Zones of the Aurora DB cluster's AWS Region.

The DB cluster volume is made up of multiple copies of the data for the DB cluster. However, the 
data in the cluster volume is represented as a single, logical volume to the primary writer DB instance 
and to Aurora Replicas in the DB cluster. For more information about Aurora Replicas, see Aurora 
Replicas (p. 104).

Aurora Replicas work well for read scaling because they’re fully dedicated to read operations on your 
cluster volume. The writer DB instance manages write operations. The cluster volume is shared among all 
instances in your Aurora PostgreSQL DB cluster. Thus, no extra work is needed to replicate a copy of the 
data for each Aurora Replica.

With Aurora PostgreSQL, when an Aurora Replica is deleted, its instance endpoint is removed 
immediately, and the Aurora Replica is removed from the reader endpoint. If there are statements
running on the Aurora Replica that is being deleted, there is a three minute grace period. Existing statements can finish gracefully during the grace period. When the grace period ends, the Aurora Replica is shut down and deleted.

Aurora PostgreSQL DB clusters don’t support Aurora Replicas in different AWS Regions, so you can’t use Aurora Replicas for cross-Region replication.

**Note**

With the improved read availability feature, if you want to reboot the Aurora Replicas in the DB cluster, you have to perform it manually. For the DB clusters created prior to this feature rebooting the writer DB instance automatically reboots the Aurora Replicas. The automatic reboot re-establishes an entry point that guarantees read/write consistency across the DB cluster.

### Improving the read availability of Aurora Replicas

Aurora PostgreSQL improves the read availability in the DB cluster by continuously serving the read requests when the writer DB instance restarts or when the Aurora Replica is unable to keep up with the write traffic.

The read availability feature is available by default on the following versions of Aurora PostgreSQL:

- 15.2 and higher 15 versions
- 14.7 and higher 14 versions
- 13.10 and higher 13 versions
- 12.14 and higher 12 versions

To use the read availability feature for a DB cluster created on one of these versions prior to this launch, restart the writer instance of the DB cluster.

When you modify static parameters of your Aurora PostgreSQL DB cluster, you must restart the writer instance so that the parameter changes take effect. For example, you must restart the writer instance when you set the value of `shared_buffers`. With the improved availability of Aurora Replicas, the DB cluster maintains read availability during these restarts, which reduces the impact of changes to the writer instance. The reader instances don’t restart and continue to respond to the read requests. To apply static parameter changes, reboot each individual reader instance.

An Aurora PostgreSQL DB cluster’s Aurora Replica can recover from replication errors such as writer restarts, failover, slow replication, and network issues by quickly recovering to in-memory database state after it reconnects with the writer. This approach allows Aurora Replica instances to reach consistency with the latest storage updates while the client database is still available.

The in-progress transactions that conflict with replication recovery might receive an error but the client can retry these transactions, after the readers catch up with the writer.

### Monitoring Aurora Replicas

You can monitor the Aurora Replicas when recovering from a writer disconnect. Use the metrics below to check for the latest information about the reader instance and to track in-process read-only transactions.

- The `aurora_replica_status` function is updated to return the most up-to-date information for the reader instance when it is still connected. The last update time stamp in `aurora_replica_status` is always empty for the row corresponding to the DB instance that the query is executed on. This indicates that the reader instance has the latest data.
- When the Aurora replica disconnects from the writer instance and reconnects back, the following database event is emitted:
The following limitations apply to Aurora Replicas with improved availability:

- Global DB Aurora Replicas in the secondary AWS Regions aren't supported.
- Aurora Replicas don't support online replication recovery if one is already in progress and will restart.
- Aurora Replicas will restart when your DB instance is nearing the transaction ID wraparound. For more information on transaction ID wraparound, see [Preventing Transaction ID Wraparound Failures](#).
- Aurora Replicas can restart when the replication process is blocked under certain circumstances.

### Monitoring Aurora PostgreSQL replication

Read scaling and high availability depend on minimal lag time. You can monitor how far an Aurora Replica is lagging behind the writer DB instance of your Aurora PostgreSQL DB cluster by monitoring the Amazon CloudWatch ReplicaLag metric. Because Aurora Replicas read from the same cluster volume as the writer DB instance, the ReplicaLag metric has a different meaning for an Aurora PostgreSQL DB cluster. The ReplicaLag metric for an Aurora Replica indicates the lag for the page cache of the Aurora Replica compared to that of the writer DB instance.

For more information on monitoring RDS instances and CloudWatch metrics, see [Monitoring metrics in an Amazon Aurora cluster](#) (p. 509).

### Using PostgreSQL logical replication with Aurora

By using PostgreSQL's logical replication feature with your Aurora PostgreSQL DB cluster, you can replicate and synchronize individual tables rather than the entire database instance. Logical replication uses a publish and subscribe model to replicate changes from a source to one or more recipients. It works by using change records from the PostgreSQL write-ahead log (WAL). The source, or publisher, sends WAL data for the specified tables to one or more recipients (subscriber), thus replicating the changes and keeping a subscriber's table synchronized with the publisher's table. The set of changes from the publisher are identified using a publication. Subscribers get the changes by creating a subscription that defines the connection to the publisher's database and its publications. A replication slot is the mechanism used in this scheme to track progress of a subscription.

For Aurora PostgreSQL DB clusters, the WAL records are saved on Aurora storage. The Aurora PostgreSQL DB cluster that's acting as the publisher in a logical replication scenario reads the WAL data from Aurora storage, decodes it, and sends it to the subscriber so that the changes can be applied to the table on that instance. The publisher uses a logical decoder to decode the data for use by subscribers. By default, Aurora PostgreSQL DB clusters use the native PostgreSQL pgoutput plugin when sending data. Other logical decoders are available. For example, Aurora PostgreSQL also supports the wal2json plugin that converts WAL data to JSON.

As of Aurora PostgreSQL version 14.5, 13.8, 12.12, and 11.17, Aurora PostgreSQL augments the PostgreSQL logical replication process with a write-through cache to improve performance. The WAL transaction logs are cached locally, in a buffer, to reduce the amount of disk I/O, that is, reading from Aurora storage during logical decoding. The write-through cache is used by default whenever you use logical replication for your Aurora PostgreSQL DB cluster. Aurora provides several functions that you can
Logical replication is supported by all currently available Aurora PostgreSQL versions. For more information, Amazon Aurora PostgreSQL updates in the Release Notes for Aurora PostgreSQL.

Note
In addition to the native PostgreSQL logical replication feature introduced in PostgreSQL 10, Aurora PostgreSQL also supports the pglogical extension. For more information, see Using pglogical to synchronize data across instances (p. 1643).

For more information about PostgreSQL logical replication, see Logical replication and Logical decoding concepts in the PostgreSQL documentation.

In the following topics, you can find information about how to set up logical replication between your Aurora PostgreSQL DB clusters.

Topics
- Setting up logical replication for your Aurora PostgreSQL DB cluster (p. 1507)
- Turning off logical replication (p. 1508)
- Managing the Aurora PostgreSQL logical replication write-through cache (p. 1509)
- Managing logical slots for Aurora PostgreSQL (p. 1510)
- Example: Using logical replication with Aurora PostgreSQL DB clusters (p. 1510)
- Example: Logical replication using Aurora PostgreSQL and AWS Database Migration Service (p. 1512)

Setting up logical replication for your Aurora PostgreSQL DB cluster

Setting up logical replication requires rds_superuser privileges. Your Aurora PostgreSQL DB cluster must be configured to use a custom DB cluster parameter group so that you can set the necessary parameters as detailed in the procedure following. For more information, see Working with DB cluster parameter groups (p. 214).

To set up PostgreSQL logical replication for an Aurora PostgreSQL DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose your Aurora PostgreSQL DB cluster.
3. Open the Configuration tab. Among the Instance details, find the Parameter group link with DB cluster parameter group for Type.
4. Choose the link to open the custom parameters associated with your Aurora PostgreSQL DB cluster.
5. In the Parameters search field, type rds to find the rds.logical_replication parameter. The default value for this parameter is 0, meaning that it's turned off by default.
6. Choose Edit parameters to access the property values, and then choose 1 from the selector to turn on the feature. Depending on your expected usage, you might also need to change the settings for the following parameters. However, in many cases, the default values are sufficient.

   - max_replication_slots – Set this parameter to a value that's at least equal to your planned total number of logical replication publications and subscriptions. If you are using AWS DMS, this parameter should equal at least your planned change data capture tasks from the cluster, plus logical replication publications and subscriptions.
   - max_wal_senders and max_logical_replication_workers – Set these parameters to a value that's at least equal to the number of logical replication slots that you intend to be active, or the number of active AWS DMS tasks for change data capture. Leaving a logical replication slot
inactive prevents the vacuum from removing obsolete tuples from tables, so we recommend that you monitor replication slots and remove inactive slots as needed.

- `max_worker_processes` – Set this parameter to a value that’s at least equal to the total of the `max_logical_replication_workers`, `autovacuum_max_workers`, and `max_parallel_workers` values. On small DB instance classes, background worker processes can affect application workloads, so monitor the performance of your database if you set `max_worker_processes` higher than the default value. (The default value is the result of `GREATEST(${DBInstanceVCPU*2}, 8}`, which means that, by default, this is either 8 or twice the CPU equivalent of the DB instance class, whichever is greater).

**Note**
You can modify parameter values in a customer-created DB parameter group. You can't change the parameter values in a default DB parameter group.

7. Choose **Save changes**.

8. Reboot the writer instance of your Aurora PostgreSQL DB cluster so that your changes takes effect. In the Amazon RDS console, choose the primary DB instance of the cluster and choose **Reboot** from the **Actions** menu.

9. When the instance is available, you can verify that logical replication is turned on, as follows.
   a. Use `psql` to connect to the writer instance of your Aurora PostgreSQL DB cluster.

   ```bash
   psql --host=your-db-cluster-instance-1.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
   ```

   b. Verify that logical replication has been enabled by using the following command.

   ```bash
   labdb=> SHOW rds.logical_replication;
   rds.logical_replication
    -------------------------
      on
    (1 row)
   ```

   c. Verify that the `wal_level` is set to `logical`.

   ```bash
   labdb=> SHOW wal_level;
   wal_level
    ---------
      logical
    (1 row)
   ```

For an example of using logical replication to keep a database table synchronized with changes from a source Aurora PostgreSQL DB cluster, see [Example: Using logical replication with Aurora PostgreSQL DB clusters (p. 1510)](#).

### Turning off logical replication

After completing your replication tasks, you should stop the replication process, drop replication slots, and turn off logical replication. Before dropping slots, make sure that they’re no longer needed. Active replication slots can’t be dropped.

**To turn off logical replication**

1. Drop all replication slots.
   
   To drop all of the replication slots, connect to the publisher and run the following SQL command.
SELECT pg_drop_replication_slot(slot_name)
    FROM pg_replication_slots
    WHERE slot_name IN (SELECT slot_name FROM pg_replication_slots);

The replication slots can't be active when you run this command.

2. Modify the custom DB cluster parameter group associated with the publisher as detailed in Setting up logical replication for your Aurora PostgreSQL DB cluster (p. 1507), but set the rds.logical_replication parameter to 0.

   For more information about custom parameter groups, see Modifying parameters in a DB cluster parameter group (p. 219).

3. Restart the publisher Aurora PostgreSQL DB cluster for the change to the rds.logical_replication parameter to take effect.

Managing the Aurora PostgreSQL logical replication write-through cache

By default, Aurora PostgreSQL versions 14.5, 13.8, 12.12, and 11.17 and higher use a write-through cache to improve the performance for logical replication. Without the write-through cache, Aurora PostgreSQL uses the Aurora storage layer in its implementation of the native PostgreSQL logical replication process. It does so by writing WAL data to storage and then reading the data back from storage to decode it and send (replicate) to its targets (subscribers). This can result in bottlenecks during logical replication for Aurora PostgreSQL DB clusters.

The write-through cache reduces the need to use the Aurora storage layer. Instead of always writing and reading from the Aurora storage layer, Aurora PostgreSQL uses a buffer to cache the logical WAL stream so that it can be used during the replication process, rather than always pulling from disk. This buffer is the PostgreSQL native cache used by logical replication, identified in Aurora PostgreSQL DB cluster parameters as rds.logical_wal_cache. By default, this cache uses 1/32 of the Aurora PostgreSQL DB cluster's buffer cache setting (shared_buffers) but not less than 64kB nor more than the size of one WAL segment, typically 16MB.

When you use logical replication with your Aurora PostgreSQL DB cluster (for the versions that support the write-through cache), you can monitor the cache hit ratio to see how well it's working for your use case. To do so, connect to your Aurora PostgreSQL DB cluster's write instance using psql and then use the Aurora function, aurora_stat_logical_wal_cache, as shown in the following example.

```
SELECT * FROM aurora_stat_logical_wal_cache();
```

The function returns output such as the following.

<table>
<thead>
<tr>
<th>name</th>
<th>active_pid</th>
<th>cache_hit</th>
<th>cache_miss</th>
<th>blks_read</th>
<th>hit_rate</th>
<th>last_reset_timestamp</th>
</tr>
</thead>
<tbody>
<tr>
<td>test_slot1</td>
<td>79183</td>
<td>24</td>
<td>0</td>
<td>24</td>
<td>100.00%</td>
<td>2022-08-05 17:39...</td>
</tr>
<tr>
<td>test_slot2</td>
<td></td>
<td>1</td>
<td>0</td>
<td>1</td>
<td>100.00%</td>
<td>2022-08-05 17:34...</td>
</tr>
</tbody>
</table>

(2 rows)

The last_reset_timestamp values have been shortened for readability. For more information about this function, see aurora_stat_logical_wal_cache (p. 1713).

You can get more information by using queries such as the following.
SELECT wal_cache_blks_hit 
   FROM aurora_stat_logical_wal_cache() 
   WHERE wal_cache_blks_hit > 0;

Aurora PostgreSQL provides the following two functions for monitoring the write-through cache.

- The `aurora_stat_logical_wal_cache` function – For reference documentation, see `aurora_stat_logical_wal_cache` (p. 1713).
- The `aurora_stat_reset_wal_cache` function – For reference documentation, see `aurora_stat_reset_wal_cache` (p. 1717).

If you find that the automatically adjusted WAL cache size isn't sufficient for your workloads, you can change the value of the `rds.logical_wal_cache` manually, by modifying the parameter in your custom DB cluster parameter group. Note that any positive value less than 32kB is treated as 32kB. For more information about the `wal_buffers`, see Write Ahead Log in the PostgreSQL documentation.

Managing logical slots for Aurora PostgreSQL

Streaming activity is captured in the `pg_replication_origin_status` view. To see the contents of this view, you can use the `pg_show_replication_origin_status()` function, as shown following:

```
SELECT * FROM pg_show_replication_origin_status();
```

You can get a list of your logical slots by using the following SQL query.

```
SELECT * FROM pg_replication_slots;
```

To drop a logical slot, use the `pg_drop_replication_slot` with the name of the slot, as shown in the following command.

```
SELECT pg_drop_replication_slot('test_slot');
```

Example: Using logical replication with Aurora PostgreSQL DB clusters

The following procedure shows you how to start logical replication between two Aurora PostgreSQL DB clusters. Both the publisher and the subscriber must be configured for logical replication as detailed in Setting up logical replication for your Aurora PostgreSQL DB cluster (p. 1507).

The Aurora PostgreSQL DB cluster that’s the designated publisher must also allow access to the replication slot. To do so, modify the security group associated with the Aurora PostgreSQL DB cluster’s virtual public cloud (VPC) based on the Amazon VPC service. Allow inbound access by adding the security group associated with the subscriber’s VPC to the publisher’s security group. For more information, see Control traffic to resources using security groups in the Amazon VPC User Guide.

With these preliminary steps complete, you can use PostgreSQL commands `CREATE PUBLICATION` on the publisher and the `CREATE SUBSCRIPTION` on the subscriber, as detailed in the following procedure.

To start the logical replication process between two Aurora PostgreSQL DB clusters

These steps assume that your Aurora PostgreSQL DB clusters have a writer instance with a database in which to create the example tables.

1. On the publisher Aurora PostgreSQL DB cluster
a. Create a table using the following SQL statement.

```
CREATE TABLE LogicalReplicationTest (a int PRIMARY KEY);
```

b. Insert data into the publisher database by using the following SQL statement.

```
INSERT INTO LogicalReplicationTest VALUES (generate_series(1,10000));
```

c. Verify that data exists in the table by using the following SQL statement.

```
SELECT count(*) FROM LogicalReplicationTest;
```

d. Create a publication for this table by using the CREATE PUBLICATION statement, as follows.

```
CREATE PUBLICATION testpub FOR TABLE LogicalReplicationTest;
```

2. On the subscriber Aurora PostgreSQL DB cluster

a. Create the same LogicalReplicationTest table on the subscriber that you created on the publisher, as follows.

```
CREATE TABLE LogicalReplicationTest (a int PRIMARY KEY);
```

b. Verify that this table is empty.

```
SELECT count(*) FROM LogicalReplicationTest;
```

c. Create a subscription to get the changes from the publisher. You need to use the following details about the publisher Aurora PostgreSQL DB cluster.

- **host** – The publisher Aurora PostgreSQL DB cluster’s writer DB instance.
- **port** – The port on which the writer DB instance is listening. The default for PostgreSQL is 5432.
- **dbname** – The name of the database.

```
CREATE SUBSCRIPTION testsub CONNECTION 'host=publisher-cluster-writer-endpoint port=5432 dbname=db-name user=user password=password' PUBLICATION testpub;
```

**Note**
Specify a password other than the prompt shown here as a security best practice.

After the subscription is created, a logical replication slot is created at the publisher.

d. To verify for this example that the initial data is replicated on the subscriber, use the following SQL statement on the subscriber database.

```
SELECT count(*) FROM LogicalReplicationTest;
```

Any further changes on the publisher are replicated to the subscriber.

Logical replication affects performance. We recommend that you turn off logical replication after your replication tasks are complete.
Example: Logical replication using Aurora PostgreSQL and AWS Database Migration Service

You can use the AWS Database Migration Service (AWS DMS) to replicate a database or a portion of a database. Use AWS DMS to migrate your data from an Aurora PostgreSQL database to another open source or commercial database. For more information about AWS DMS, see the AWS Database Migration Service User Guide.

The following example shows how to set up logical replication from an Aurora PostgreSQL database as the publisher and then use AWS DMS for migration. This example uses the same publisher and subscriber that were created in Example: Using logical replication with Aurora PostgreSQL DB clusters (p. 1510).

To set up logical replication with AWS DMS, you need details about your publisher and subscriber from Amazon RDS. In particular, you need details about the publisher's writer DB instance and the subscriber's DB instance.

Get the following information for the publisher's writer DB instance:

- The virtual private cloud (VPC) identifier
- The subnet group
- The Availability Zone (AZ)
- The VPC security group
- The DB instance ID

Get the following information for the subscriber's DB instance:

- The DB instance ID
- The source engine

To use AWS DMS for logical replication with Aurora PostgreSQL

1. Prepare the publisher database to work with AWS DMS.

   To do this, PostgreSQL 10.x and later databases require that you apply AWS DMS wrapper functions to the publisher database. For details on this and later steps, see the instructions in Using PostgreSQL version 10.x and later as a source for AWS DMS in the AWS Database Migration Service User Guide.

2. Sign in to the AWS Management Console and open the AWS DMS console at https://console.aws.amazon.com/dms/v2. At top right, choose the same AWS Region in which the publisher and subscriber are located.

3. Create an AWS DMS replication instance.

   Choose values that are the same as for your publisher's writer DB instance. These include the following settings:

   - For VPC, choose the same VPC as for the writer DB instance.
   - For Replication Subnet Group, choose a subnet group with the same values as the writer DB instance. Create a new one if necessary.
   - For Availability zone, choose the same zone as for the writer DB instance.
   - For VPC Security Group, choose the same group as for the writer DB instance.

4. Create an AWS DMS endpoint for the source.

   Specify the publisher as the source endpoint by using the following settings:
For **Endpoint type**, choose **Source endpoint**.
- Choose **Select RDS DB Instance**.
- For **RDS Instance**, choose the DB identifier of the publisher's writer DB instance.
- For **Source engine**, choose **postgres**.

5. Create an AWS DMS endpoint for the target.

Specify the subscriber as the target endpoint by using the following settings:
- For **Endpoint type**, choose **Target endpoint**.
- Choose **Select RDS DB Instance**.
- For **RDS Instance**, choose the DB identifier of the subscriber DB instance.
- Choose a value for **Source engine**. For example, if the subscriber is an RDS PostgreSQL database, choose **postgres**. If the subscriber is an Aurora PostgreSQL database, choose **aurora-postgresql**.

6. Create an AWS DMS database migration task.

You use a database migration task to specify what database tables to migrate, to map data using the target schema, and to create new tables on the target database. At a minimum, use the following settings for **Task configuration**:
- For **Replication instance**, choose the replication instance that you created in an earlier step.
- For **Source database endpoint**, choose the publisher source that you created in an earlier step.
- For **Target database endpoint**, choose the subscriber target that you created in an earlier step.

The rest of the task details depend on your migration project. For more information about specifying all the details for DMS tasks, see **Working with AWS DMS tasks** in the **AWS Database Migration Service User Guide**.

After AWS DMS creates the task, it begins migrating data from the publisher to the subscriber.

## Integrating Amazon Aurora PostgreSQL with other AWS services

Amazon Aurora integrates with other AWS services so that you can extend your Aurora PostgreSQL DB cluster to use additional capabilities in the AWS Cloud. Your Aurora PostgreSQL DB cluster can use AWS services to do the following:

- **Quickly collect, view, and assess performance for your Aurora PostgreSQL DB instances with Amazon RDS Performance Insights.** Performance Insights expands on existing Amazon RDS monitoring features to illustrate your database's performance and help you analyze any issues that affect it. With the Performance Insights dashboard, you can visualize the database load and filter the load by waits, SQL statements, hosts, or users. For more information about Performance Insights, see **Monitoring DB load with Performance Insights on Amazon Aurora** (p. 559).
- **Configure your Aurora PostgreSQL DB cluster to publish log data to Amazon CloudWatch Logs.** CloudWatch Logs provide highly durable storage for your log records. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. For more information, see **Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs** (p. 1548).
- **Import data from an Amazon S3 bucket to an Aurora PostgreSQL DB cluster, or export data from an Aurora PostgreSQL DB cluster to Amazon S3 bucket.** For more information, see **Importing data from Amazon S3 into an Aurora PostgreSQL DB cluster** (p. 1514) and **Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3** (p. 1527).
• Add machine learning-based predictions to database applications using the SQL language. Aurora machine learning uses a highly optimized integration between the Aurora database and the AWS machine learning (ML) services SageMaker and Amazon Comprehend. For more information, see Using Amazon Aurora machine learning with Aurora PostgreSQL (p. 1556).
• Invoke AWS Lambda functions from an Aurora PostgreSQL DB cluster. To do this, use the aws_lambda PostgreSQL extension provided with Aurora PostgreSQL. For more information, see Invoking an AWS Lambda function from an Aurora PostgreSQL DB cluster (p. 1538).
• Integrate queries from Amazon Redshift and Aurora PostgreSQL. For more information, see Getting started with using federated queries to PostgreSQL in the Amazon Redshift Database Developer Guide.

Importing data from Amazon S3 into an Aurora PostgreSQL DB cluster

You can import data that's been stored using Amazon Simple Storage Service into a table on an Aurora PostgreSQL DB cluster instance. To do this, you first install the Aurora PostgreSQL aws_s3 extension. This extension provides the functions that you use to import data from an Amazon S3 bucket. A bucket is an Amazon S3 container for objects and files. The data can be in a comma-separate value (CSV) file, a text file, or a compressed (gzip) file. Following, you can learn how to install the extension and how to import data from Amazon S3 into a table.

Your database must be running PostgreSQL version 10.7 or higher to import from Amazon S3 into Aurora PostgreSQL.

If you don't have data stored on Amazon S3, you need to first create a bucket and store the data. For more information, see the following topics in the Amazon Simple Storage Service User Guide.

• Create a bucket
• Add an object to a bucket

Cross-account import from Amazon S3 is supported. For more information, see Granting cross-account permissions in the Amazon Simple Storage Service User Guide.

You can use the customer managed key for encryption while importing data from S3. For more information, see KMS keys stored in AWS KMS in the Amazon Simple Storage Service User Guide.

Note
Importing data from Amazon S3 isn't supported for Aurora Serverless v1. It is supported for Aurora Serverless v2.

Topics
• Installing the aws_s3 extension (p. 1514)
• Overview of importing data from Amazon S3 data (p. 1515)
• Setting up access to an Amazon S3 bucket (p. 1516)
• Importing data from Amazon S3 to your Aurora PostgreSQL DB cluster (p. 1521)
• Function reference (p. 1523)

Installing the aws_s3 extension

Before you can use Amazon S3 with your Aurora PostgreSQL DB cluster, you need to install the aws_s3 extension. This extension provides functions for importing data from an Amazon S3. It also provides functions for exporting data from an instance of an Aurora PostgreSQL DB cluster to an Amazon S3 bucket. For more information, see Exporting data from an Aurora PostgreSQL DB cluster to Amazon
**S3 (p. 1527)**. The `aws_s3` extension depends on some of the helper functions in the `aws_commons` extension, which is installed automatically when needed.

**To install the `aws_s3` extension**

1. Use `psql` (or `pgAdmin`) to connect to the writer instance of your Aurora PostgreSQL DB cluster as a user that has `rds_superuser` privileges. If you kept the default name during the setup process, you connect as `postgres`.

   ```
   psql --host=111122233333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   ```

2. To install the extension, run the following command.

   ```
   postgres=> CREATE EXTENSION aws_s3 CASCADE;
   NOTICE: installing required extension "aws_commons"
   CREATE EXTENSION
   ```

3. To verify that the extension is installed, you can use the `psql \dx` metacommand.

   ```
   postgres=> \dx
   List of installed extensions
   Name     | Version |   Schema   |                 Description
   -------------+---------+------------+---------------------------------------------
   aws_commons | 1.2     | public     | Common data types across AWS services
   aws_s3      | 1.1     | public     | AWS S3 extension for importing data from S3
   plpgsql     | 1.0     | pg_catalog | PL/pgSQL procedural language
   (3 rows)
   ```

The functions for importing data from Amazon S3 and exporting data to Amazon S3 are now available to use.

**Overview of importing data from Amazon S3 data**

**To import S3 data into Aurora PostgreSQL**

First, gather the details that you need to supply to the function. These include the name of the table on your Aurora PostgreSQL DB cluster’s instance, and the bucket name, file path, file type, and AWS Region where the Amazon S3 data is stored. For more information, see View an object in the Amazon Simple Storage Service User Guide.

**Note**

Multi part data import from Amazon S3 isn’t currently supported.

1. Get the name of the table into which the `aws_s3.table_import_from_s3` function is to import the data. As an example, the following command creates a table `t1` that can be used in later steps.

   ```
   postgres=> CREATE TABLE t1
   (col1 varchar(80),
    col2 varchar(80),
    col3 varchar(80));
   ```

2. Get the details about the Amazon S3 bucket and the data to import. To do this, open the Amazon S3 console at [https://console.aws.amazon.com/s3/](https://console.aws.amazon.com/s3/), and choose Buckets. Find the bucket containing your data in the list. Choose the bucket, open its Object overview page, and then choose Properties.

   Make a note of the bucket name, path, the AWS Region, and file type. You need the Amazon Resource Name (ARN) later, to set up access to Amazon S3 through an IAM role. For more more
3. You can verify the path to the data on the Amazon S3 bucket by using the AWS CLI command `aws s3 cp`. If the information is correct, this command downloads a copy of the Amazon S3 file.

```
aws s3 cp s3://sample_s3_bucket/sample_file_path ./
```

4. Set up permissions on your Aurora PostgreSQL DB cluster to allow access to the file on the Amazon S3 bucket. To do so, you use either an AWS Identity and Access Management (IAM) role or security credentials. For more information, see Setting up access to an Amazon S3 bucket (p. 1516).

5. Supply the path and other Amazon S3 object details gathered (see step 2) to the `create_s3_uri` function to construct an Amazon S3 URI object. To learn more about this function, see `aws_commons.create_s3_uri` (p. 1526). The following is an example of constructing this object during a psql session.

```
postgres=> SELECT aws_commons.create_s3_uri(
    'docs-lab-store-for-rpg',
    'versions_and_jdks_listing.csv',
    'us-west-1'
) AS s3_uri \gset
```

In the next step, you pass this object (aws_commons._s3_uri_1) to the `aws_s3.table_import_from_s3` function to import the data to the table.

6. Invoke the `aws_s3.table_import_from_s3` function to import the data from Amazon S3 into your table. For reference information, see `aws_s3.table_import_from_s3` (p. 1524). For examples, see Importing data from Amazon S3 to your Aurora PostgreSQL DB cluster (p. 1521).

### Setting up access to an Amazon S3 bucket

To import data from an Amazon S3 file, give the Aurora PostgreSQL DB cluster permission to access the Amazon S3 bucket containing the file. You provide access to an Amazon S3 bucket in one of two ways, as described in the following topics.

---

1516
Using an IAM role to access an Amazon S3 bucket

Before you load data from an Amazon S3 file, give your Aurora PostgreSQL DB cluster permission to access the Amazon S3 bucket the file is in. This way, you don't have to manage additional credential information or provide it in the `aws_s3.table_import_from_s3` (p. 1524) function call.

To do this, create an IAM policy that provides access to the Amazon S3 bucket. Create an IAM role and attach the policy to the role. Then assign the IAM role to your DB cluster.

**Note**
You can't associate an IAM role with an Aurora Serverless v1 DB cluster, so the following steps don't apply.

To give an Aurora PostgreSQL DB cluster access to Amazon S3 through an IAM role

1. Create an IAM policy.

   This policy provides the bucket and object permissions that allow your Aurora PostgreSQL DB cluster to access Amazon S3.

   Include in the policy the following required actions to allow the transfer of files from an Amazon S3 bucket to Aurora PostgreSQL:

   - `s3:GetObject`
   - `s3:ListBucket`

   Include in the policy the following resources to identify the Amazon S3 bucket and objects in the bucket. This shows the Amazon Resource Name (ARN) format for accessing Amazon S3.

   - `arn:aws:s3:::your-s3-bucket`
   - `arn:aws:s3:::your-s3-bucket/*`

   For more information on creating an IAM policy for Aurora PostgreSQL, see Creating and using an IAM policy for IAM database access (p. 2436). See also Tutorial: Create and attach your first customer managed policy in the IAM User Guide.

   The following AWS CLI command creates an IAM policy named `rds-s3-import-policy` with these options. It grants access to a bucket named `your-s3-bucket`.

   **Note**
   Make a note of the Amazon Resource Name (ARN) of the policy returned by this command. You need the ARN in a subsequent step when you attach the policy to an IAM role.

   **Example**
   For Linux, macOS, or Unix:

   ```bash
   aws iam create-policy
   --policy-name rds-s3-import-policy
   --policy-document '{
   "Version": "2012-10-17",
   "Statement": [
   {
   "Action": "s3:GetObject",
   "Resource": "arn:aws:s3:::your-s3-bucket",
   "Effect": "Allow"},
   {
   "Action": "s3:ListBucket",
   "Resource": "arn:aws:s3:::your-s3-bucket/*",
   "Effect": "Allow"
   ]
   }
   '}
   ```
"Statement": [
  {
    "Sid": "s3import",
    "Action": [
      "s3:GetObject",
      "s3:ListBucket"
    ],
    "Effect": "Allow",
    "Resource": [
      "arn:aws:s3:::your-s3-bucket",
      "arn:aws:s3:::your-s3-bucket/*"
    ]
  }
],

For Windows:

```
aws iam create-policy ^
--policy-name rds-s3-import-policy ^
--policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "s3import",
      "Action": [
        "s3:GetObject",
        "s3:ListBucket"
      ],
      "Effect": "Allow",
      "Resource": [
        "arn:aws:s3:::your-s3-bucket",
        "arn:aws:s3:::your-s3-bucket/*"
      ]
    }
  ]
}
```

2. Create an IAM role.

You do this so Aurora PostgreSQL can assume this IAM role to access your Amazon S3 buckets. For more information, see [Creating a role to delegate permissions to an IAM user](https://docs.aws.amazon.com/iam/latest/lug/guided-examples.html) in the IAM User Guide.

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the policy, be sure to use the `aws:SourceArn` global condition context key with the full ARN of the resource. The following example shows how to do so using the AWS CLI command to create a role named `rds-s3-import-role`.

```
aws iam create-role ^
--role-name rds-s3-import-role ^
--policy-arn arn:aws:iam::123456789012:policy/rds-s3-import-policy
```
Example

For Linux, macOS, or Unix:

```bash
aws iam create-role \
  --role-name rds-s3-import-role \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
          "StringEquals": {
            "aws:SourceAccount": "111122223333",
          }
        }
      }
    ]
  }'
```

For Windows:

```bash
aws iam create-role ^
  --role-name rds-s3-import-role ^
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
          "StringEquals": {
            "aws:SourceAccount": "111122223333",
          }
        }
      }
    ]
  }'
```

3. Attach the IAM policy that you created to the IAM role that you created.

   The following AWS CLI command attaches the policy created in the previous step to the role named `rds-s3-import-role` Replace `your-policy-arn` with the policy ARN that you noted in an earlier step.

   **Example**

   For Linux, macOS, or Unix:

   ```bash
   aws iam attach-role-policy \
   ```
4. Add the IAM role to the DB cluster.

You do so by using the AWS Management Console or AWS CLI, as described following.

**Console**

To add an IAM role for a PostgreSQL DB cluster using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Choose the PostgreSQL DB cluster name to display its details.
3. On the Connectivity & security tab, in the Manage IAM roles section, choose the role to add under Add IAM roles to this cluster.
4. Under Feature, choose s3Import.
5. Choose Add role.

**AWS CLI**

To add an IAM role for a PostgreSQL DB cluster using the CLI

- Use the following command to add the role to the PostgreSQL DB cluster named my-db-cluster. Replace `your-role-arn` with the role ARN that you noted in a previous step. Use s3Import for the value of the --feature-name option.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds add-role-to-db-cluster \
   --db-cluster-identifier my-db-cluster \
   --feature-name s3Import \
   --role-arn your-role-arn \
   --region your-region
```

For Windows:

```bash
aws rds add-role-to-db-cluster ^
   --db-cluster-identifier my-db-cluster ^
   --feature-name s3Import ^
   --role-arn your-role-arn ^
   --region your-region
```

**RDS API**

To add an IAM role for a PostgreSQL DB cluster using the Amazon RDS API, call the [AddRoleToDBCluster](https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUserGuide/AuroraPostgreSQL.Tutorials.AddRoleToDBCluster.html) operation.
Using security credentials to access an Amazon S3 bucket

If you prefer, you can use security credentials to provide access to an Amazon S3 bucket instead of providing access with an IAM role. You do so by specifying the credentials parameter in the `aws_s3.table_import_from_s3` function call.

The credentials parameter is a structure of type `aws_commons._aws_credentials_1`, which contains AWS credentials. Use the `aws_commons.create.aws_credentials` function to set the access key and secret key in an `aws_commons._aws_credentials_1` structure, as shown following.

```
postgres=> SELECT aws_commons.create.aws_credentials('sample_access_key', 'sample_secret_key', '')
AS creds \gset
```

After creating the `aws_commons._aws_credentials_1` structure, use the `aws_s3.table_import_from_s3` function with the `credentials` parameter to import the data, as shown following.

```
postgres=> SELECT aws_s3.table_import_from_s3('t', '', '(format csv)', 's3_uri', 'creds');
```

Or you can include the `aws_commons.create.aws_credentials` function call inline within the `aws_s3.table_import_from_s3` function call.

```
postgres=> SELECT aws_s3.table_import_from_s3('t', '', '(format csv)', 's3_uri', aws_commons.create.aws_credentials('sample_access_key', 'sample_secret_key', ''));
```

Troubleshooting access to Amazon S3

If you encounter connection problems when attempting to import data from Amazon S3, see the following for recommendations:

- Troubleshooting Amazon Aurora identity and access (p. 2460)
- Troubleshooting Amazon S3 in the Amazon Simple Storage Service User Guide
- Troubleshooting Amazon S3 and IAM in the IAM User Guide

Importing data from Amazon S3 to your Aurora PostgreSQL DB cluster

You import data from your Amazon S3 bucket by using the `table_import_from_s3` function of the `aws_s3` extension. For reference information, see `aws_s3.table_import_from_s3` (p. 1524).

**Note**

The following examples use the IAM role method to allow access to the Amazon S3 bucket. Thus, the `aws_s3.table_import_from_s3` function calls don't include credential parameters.

The following shows a typical example.

```
postgres=> SELECT aws_s3.table_import_from_s3('t', '', '(format csv)', 's3_uri', 'creds');
```
The parameters are the following:

- `t1` – The name for the table in the PostgreSQL DB cluster to copy the data into.
- `'` – An optional list of columns in the database table. You can use this parameter to indicate which columns of the S3 data go in which table columns. If no columns are specified, all the columns are copied to the table. For an example of using a column list, see Importing an Amazon S3 file that uses a custom delimiter (p. 1522).
- `(format csv)` – PostgreSQL COPY arguments. The copy process uses the arguments and format of the PostgreSQL COPY command to import the data. Choices for format include comma-separated value (CSV) as shown in this example, text, and binary. The default is text.
- `s3_uri` – A structure that contains the information identifying the Amazon S3 file. For an example of using the `aws_commons.create_s3_uri` function to create an `s3_uri` structure, see Overview of importing data from Amazon S3 data (p. 1515).

For more information about this function, see `aws_s3.table_import_from_s3` (p. 1524).

The `aws_s3.table_import_from_s3` function returns text. To specify other kinds of files for import from an Amazon S3 bucket, see one of the following examples.

**Note**
Importing 0 bytes file will cause an error.

**Topics**
- Importing an Amazon S3 file that uses a custom delimiter (p. 1522)
- Importing an Amazon S3 compressed (gzip) file (p. 1523)
- Importing an encoded Amazon S3 file (p. 1523)

**Importing an Amazon S3 file that uses a custom delimiter**

The following example shows how to import a file that uses a custom delimiter. It also shows how to control where to put the data in the database table using the `column_list` parameter of the `aws_s3.table_import_from_s3` function.

For this example, assume that the following information is organized into pipe-delimited columns in the Amazon S3 file.

```
1|foo1|bar1|elephant1
2|foo2|bar2|elephant2
3|foo3|bar3|elephant3
4|foo4|bar4|elephant4
...
```

**To import a file that uses a custom delimiter**

1. Create a table in the database for the imported data.

```sql
postgres=> CREATE TABLE test (a text, b text, c text, d text, e text);
```

2. Use the following form of the `aws_s3.table_import_from_s3` function to import data from the Amazon S3 file.
You can include the `aws_commons.create_s3_uri (p. 1526)` function call inline within the `aws_s3.table_import_from_s3` function call to specify the file.

```
postgres=> SELECT aws_s3.table_import_from_s3(  
    'test',  
    'a,b,d,e',  
    'DELIMITER ''|''',  
    aws_commons.create_s3_uri('sampleBucket', 'pipeDelimitedSampleFile', 'us-east-2')  
);
```

The data is now in the table in the following columns.

```
postgres=> SELECT * FROM test;  
a | b | c | d | e  
---+----+---+---+----+-----------  
1 | foo1 | | bar1 | elephant1  
2 | foo2 | | bar2 | elephant2  
3 | foo3 | | bar3 | elephant3  
4 | foo4 | | bar4 | elephant4
```

**Importing an Amazon S3 compressed (gzip) file**

The following example shows how to import a file from Amazon S3 that is compressed with gzip. The file that you import needs to have the following Amazon S3 metadata:

- Key: `Content-Encoding`
- Value: `gzip`

If you upload the file using the AWS Management Console, the metadata is typically applied by the system. For information about uploading files to Amazon S3 using the AWS Management Console, the AWS CLI, or the API, see [Uploading objects](#) in the Amazon Simple Storage Service User Guide.

For more information about Amazon S3 metadata and details about system-provided metadata, see [Editing object metadata in the Amazon S3 console](#) in the Amazon Simple Storage Service User Guide.

Import the gzip file into your Aurora PostgreSQL DB cluster as shown following.

```
postgres=> CREATE TABLE test_gzip(id int, a text, b text, c text, d text);
postgres=> SELECT aws_s3.table_import_from_s3(  
    'test_gzip', '', '(format csv)',  
    'myS3Bucket', 'test-data.gz', 'us-east-2'  
);
```

**Importing an encoded Amazon S3 file**

The following example shows how to import a file from Amazon S3 that has Windows-1252 encoding.

```
postgres=> SELECT aws_s3.table_import_from_s3(  
    'test_table', '', 'encoding ''WIN1252''',  
    aws_commons.create_s3_uri('sampleBucket', 'SampleFile', 'us-east-2')  
);
```

**Function reference**

**Functions**
aws_s3.table_import_from_s3

Imports Amazon S3 data into an Aurora PostgreSQL table. The aws_s3 extension provides the aws_s3.table_import_from_s3 function. The return value is text.

Syntax

The required parameters are table_name, column_list and options. These identify the database table and specify how the data is copied into the table.

You can also use the following parameters:

• The s3_info parameter specifies the Amazon S3 file to import. When you use this parameter, access to Amazon S3 is provided by an IAM role for the PostgreSQL DB cluster.

```sql
aws_s3.table_import_from_s3 (table_name text, column_list text, options text, s3_info aws_commons._s3_uri_1)
```

• The credentials parameter specifies the credentials to access Amazon S3. When you use this parameter, you don't use an IAM role.

```sql
aws_s3.table_import_from_s3 (table_name text, column_list text, options text, s3_info aws_commons._s3_uri_1, credentials aws_commons._aws_credentials_1)
```

Parameters

**table_name**

A required text string containing the name of the PostgreSQL database table to import the data into.

**column_list**

A required text string containing an optional list of the PostgreSQL database table columns in which to copy the data. If the string is empty, all columns of the table are used. For an example, see Importing an Amazon S3 file that uses a custom delimiter (p. 1522).

**options**

A required text string containing arguments for the PostgreSQL COPY command. These arguments specify how the data is to be copied into the PostgreSQL table. For more details, see the PostgreSQL COPY documentation.

**s3_info**

An aws_commons._s3_uri_1 composite type containing the following information about the S3 object:
• bucket – The name of the Amazon S3 bucket containing the file.
• file_path – The Amazon S3 file name including the path of the file.
• region – The AWS Region that the file is in. For a listing of AWS Region names and associated values, see Regions and Availability Zones (p. 16).

credentials

An aws_commons._aws_credentials_1 composite type containing the following credentials to use for the import operation:

• Access key
• Secret key
• Session token

For information about creating an aws_commons._aws_credentials_1 composite structure, see aws_commons.create_aws_credentials (p. 1526).

Alternate syntax

To help with testing, you can use an expanded set of parameters instead of the s3_info and credentials parameters. Following are additional syntax variations for the aws_s3.table_import_from_s3 function:

• Instead of using the s3_info parameter to identify an Amazon S3 file, use the combination of the bucket, file_path, and region parameters. With this form of the function, access to Amazon S3 is provided by an IAM role on the PostgreSQL DB instance.

```python
aws_s3.table_import_from_s3 (  
table_name text,  
column_list text,  
options text,  
bucket text,  
file_path text,  
region text
)
```

• Instead of using the credentials parameter to specify Amazon S3 access, use the combination of the access_key, session_key, and session_token parameters.

```python
aws_s3.table_import_from_s3 (  
table_name text,  
column_list text,  
options text,  
bucket text,  
file_path text,  
region text,  
access_key text,  
secret_key text,  
session_token text
)
```

Alternate parameters

bucket

A text string containing the name of the Amazon S3 bucket that contains the file.

file_path

A text string containing the Amazon S3 file name including the path of the file.
region

A text string identifying the AWS Region location of the file. For a listing of AWS Region names and associated values, see Regions and Availability Zones (p. 16).

access_key

A text string containing the access key to use for the import operation. The default is NULL.

secret_key

A text string containing the secret key to use for the import operation. The default is NULL.

session_token

(Optional) A text string containing the session key to use for the import operation. The default is NULL.

aws_commons.create_s3_uri

Creates an aws_commons._s3_uri_1 structure to hold Amazon S3 file information. Use the results of the aws_commons.create_s3_uri function in the s3_info parameter of the aws_s3.table_import_from_s3 (p. 1524) function.

Syntax

```python
aws_commons.create_s3_uri(
    bucket text,
    file_path text,
    region text
)
```

Parameters

bucket

A required text string containing the Amazon S3 bucket name for the file.

file_path

A required text string containing the Amazon S3 file name including the path of the file.

region

A required text string containing the AWS Region that the file is in. For a listing of AWS Region names and associated values, see Regions and Availability Zones (p. 16).

aws_commons.create_aws_credentials

Sets an access key and secret key in an aws_commons._aws_credentials_1 structure. Use the results of the aws_commons.create_aws_credentials function in the credentials parameter of the aws_s3.table_import_from_s3 (p. 1524) function.

Syntax

```python
aws_commons.create_aws_credentials(
    access_key text,
    secret_key text,
    session_token text
)
```
Parameters

access_key
A required text string containing the access key to use for importing an Amazon S3 file. The default is NULL.

secret_key
A required text string containing the secret key to use for importing an Amazon S3 file. The default is NULL.

session_token
An optional text string containing the session token to use for importing an Amazon S3 file. The default is NULL. If you provide an optional session_token, you can use temporary credentials.

Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3

You can query data from an Aurora PostgreSQL DB cluster and export it directly into files stored in an Amazon S3 bucket. To do this, you first install the Aurora PostgreSQL aws_s3 extension. This extension provides you with the functions that you use to export the results of queries to Amazon S3. Following, you can find out how to install the extension and how to export data to Amazon S3.

You can export from a provisioned or an Aurora Serverless v2 DB instance. These steps aren't supported for Aurora Serverless v1.

Note
Cross-account export to Amazon S3 isn't supported.

All currently available versions of Aurora PostgreSQL support exporting data to Amazon Simple Storage Service. For detailed version information, see Amazon Aurora PostgreSQL updates in the Release Notes for Aurora PostgreSQL.

If you don't have a bucket set up for your export, see the following topics the Amazon Simple Storage Service User Guide.

- Setting up Amazon S3
- Create a bucket

The upload to Amazon S3 uses server-side encryption by default. If you are using encryption, the Amazon S3 bucket must be encrypted with an AWS managed key. You can export data to a bucket that's encrypted with a customer managed key.

Note
You can save DB and DB cluster snapshot data to Amazon S3 using the AWS Management Console, AWS CLI, or Amazon RDS API. For more information, see Exporting DB cluster snapshot data to Amazon S3 (p. 471).

Topics

- Installing the aws_s3 extension (p. 1528)
- Overview of exporting data to Amazon S3 (p. 1528)
- Specifying the Amazon S3 file path to export to (p. 1529)
- Setting up access to an Amazon S3 bucket (p. 1530)
- Exporting query data using the aws_s3.query_export_to_s3 function (p. 1533)
- Troubleshooting access to Amazon S3 (p. 1535)
Installing the aws_s3 extension

Before you can use Amazon Simple Storage Service with your Aurora PostgreSQL DB cluster, you need to install the aws_s3 extension. This extension provides functions for exporting data from the writer instance of an Aurora PostgreSQL DB cluster to an Amazon S3 bucket. It also provides functions for importing data from an Amazon S3. For more information, see Importing data from Amazon S3 into an Aurora PostgreSQL DB cluster (p. 1514). The aws_s3 extension depends on some of the helper functions in the aws_commons extension, which is installed automatically when needed.

To install the aws_s3 extension

1. Use psql (or pgAdmin) to connect to the writer instance of your Aurora PostgreSQL DB cluster as a user that has rds_superuser privileges. If you kept the default name during the setup process, you connect as postgres.

   ```
   psql --host=111122233333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   ```

2. To install the extension, run the following command.

   ```
   postgres=> CREATE EXTENSION aws_s3 CASCADE;
   NOTICE: installing required extension "aws_commons"
   CREATE EXTENSION
   ```

3. To verify that the extension is installed, you can use the psql \dx metacommand.

   ```
   postgres=> \dx
   List of installed extensions
   Name     | Version |   Schema   |                 Description
   -------------+---------+------------+---------------------------------------------
   aws_commons | 1.2     | public     | Common data types across AWS services
   aws_s3      | 1.1     | public     | AWS S3 extension for importing data from S3
   plpgsql     | 1.0     | pg_catalog | PL/pgSQL procedural language
   (3 rows)
   ```

The functions for importing data from Amazon S3 and exporting data to Amazon S3 are now available to use.

Verify that your Aurora PostgreSQL version supports exports to Amazon S3

You can verify that your Aurora PostgreSQL version supports export to Amazon S3 by using the describe-db-engine-versions command. The following example checks to see if version 10.14 can export to Amazon S3.

```
aws rds describe-db-engine-versions --region us-east-1 \ --engine aurora-postgresql --engine-version 10.14 | grep s3Export
```  

If the output includes the string "s3Export", then the engine supports Amazon S3 exports. Otherwise, the engine doesn't support them.

Overview of exporting data to Amazon S3

To export data stored in an Aurora PostgreSQL database to an Amazon S3 bucket, use the following procedure.
To export Aurora PostgreSQL data to S3

1. Identify an Amazon S3 file path to use for exporting data. For details about this process, see Specifying the Amazon S3 file path to export to (p. 1529).
2. Provide permission to access the Amazon S3 bucket.
   
   To export data to an Amazon S3 file, give the Aurora PostgreSQL DB cluster permission to access the Amazon S3 bucket that the export will use for storage. Doing this includes the following steps:
   
   1. Create an IAM policy that provides access to an Amazon S3 bucket that you want to export to.
   2. Create an IAM role.
   3. Attach the policy you created to the role you created.
   4. Add this IAM role to your DB cluster.

   For details about this process, see Setting up access to an Amazon S3 bucket (p. 1530).
3. Identify a database query to get the data. Export the query data by calling the \texttt{aws\_s3.query\_export\_to\_s3} function.

   After you complete the preceding preparation tasks, use the \texttt{aws\_s3.query\_export\_to\_s3} function to export query results to Amazon S3. For details about this process, see Exporting query data using the \texttt{aws\_s3.query\_export\_to\_s3} function (p. 1533).

Specifying the Amazon S3 file path to export to

Specify the following information to identify the location in Amazon S3 where you want to export data to:

- **Bucket name** – A *bucket* is a container for Amazon S3 objects or files.
  
  For more information on storing data with Amazon S3, see Create a bucket and View an object in the Amazon Simple Storage Service User Guide.
- **File path** – The file path identifies where the export is stored in the Amazon S3 bucket. The file path consists of the following:
  - An optional path prefix that identifies a virtual folder path.
  - A file prefix that identifies one or more files to be stored. Larger exports are stored in multiple files, each with a maximum size of approximately 6 GB. The additional file names have the same file prefix but with \_partXX appended. The XX represents 2, then 3, and so on.

  For example, a file path with an exports folder and a query-1-export file prefix is /exports/query-1-export.
- **AWS Region (optional)** – The AWS Region where the Amazon S3 bucket is located. If you don't specify an AWS Region value, then Aurora saves your files into Amazon S3 in the same AWS Region as the exporting DB cluster.

  **Note**
  
  Currently, the AWS Region must be the same as the region of the exporting DB cluster.

  For a listing of AWS Region names and associated values, see Regions and Availability Zones (p. 16).

To hold the Amazon S3 file information about where the export is to be stored, you can use the \texttt{aws\_commons.create\_s3\_uri} function to create an aws\_commons._s3\_uri_1 composite structure as follows.

```sql
psql=> SELECT aws_commons.create_s3_uri(
```
You later provide this `s3_uri_1` value as a parameter in the call to the `aws_s3.query_export_to_s3` function. For examples, see Exporting query data using the `aws_s3.query_export_to_s3` function (p. 1533).

### Setting up access to an Amazon S3 bucket

To export data to Amazon S3, give your PostgreSQL DB cluster permission to access the Amazon S3 bucket that the files are to go in.

To do this, use the following procedure.

**To give a PostgreSQL DB cluster access to Amazon S3 through an IAM role**

1. Create an IAM policy.

    This policy provides the bucket and object permissions that allow your PostgreSQL DB cluster to access Amazon S3.

    As part of creating this policy, take the following steps:

    a. Include in the policy the following required actions to allow the transfer of files from your PostgreSQL DB cluster to an Amazon S3 bucket:
       - `s3:PutObject`
       - `s3:AbortMultipartUpload`

    b. Include the Amazon Resource Name (ARN) that identifies the Amazon S3 bucket and objects in the bucket. The ARN format for accessing Amazon S3 is:
       
       ```
       arn:aws:s3:::your-s3-bucket/*
       ```

    For more information on creating an IAM policy for Aurora PostgreSQL, see Creating and using an IAM policy for IAM database access (p. 2436). See also Tutorial: Create and attach your first customer managed policy in the IAM User Guide.

    The following AWS CLI command creates an IAM policy named `rds-s3-export-policy` with these options. It grants access to a bucket named `your-s3-bucket`.

    **Warning**

    We recommend that you set up your database within a private VPC that has endpoint policies configured for accessing specific buckets. For more information, see Using endpoint policies for Amazon S3 in the Amazon VPC User Guide.

    We strongly recommend that you do not create a policy with all-resource access. This access can pose a threat for data security. If you create a policy that gives `s3:PutObject` access to all resources using "Resource":"*", then a user with export privileges can export data to all buckets in your account. In addition, the user can export data to any publicly writable bucket within your AWS Region.

    After you create the policy, note the Amazon Resource Name (ARN) of the policy. You need the ARN for a subsequent step when you attach the policy to an IAM role.

    ```
    aws iam create-policy --policy-name rds-s3-export-policy --policy-document '{
      "Version": "2012-10-17",
      "Statement": [
        {
          "Sid": "s3export",
```
2. Create an IAM role.

You do this so Aurora PostgreSQL can assume this IAM role on your behalf to access your Amazon S3 buckets. For more information, see Creating a role to delegate permissions to an IAM user in the IAM User Guide.

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the policy, be sure to use the `aws:SourceArn` global condition context key with the full ARN of the resource. The following example shows how to do so using the AWS CLI command to create a role named `rds-s3-export-role`.

**Example**

For Linux, macOS, or Unix:

```bash
aws iam create-role
   --role-name rds-s3-export-role
   --assume-role-policy-document '{
   "Version": "2012-10-17",
   "Statement": [ {
     "Effect": "Allow",
     "Principal": { "Service": "rds.amazonaws.com" },
     "Action": "sts:AssumeRole",
   ]
}',
```

For Windows:

```bash
aws iam create-role
   --role-name rds-s3-export-role
   --assume-role-policy-document '{
   "Version": "2012-10-17",
   "Statement": [ {
     "Effect": "Allow",
     "Principal": { "Service": "rds.amazonaws.com" },
     "Action": "sts:AssumeRole",
   ]
}',
```
aws iam create-role
   --role-name rds-s3-export-role
   --assume-role-policy-document '{
   "Version": "2012-10-17",
   "Statement": [
   {
      "Effect": "Allow",
      "Principal": {
         "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
         "StringEquals": {
            "aws:SourceAccount": "111122223333",
         }
      }
   }
  ]}
}

3. Attach the IAM policy that you created to the IAM role that you created.

The following AWS CLI command attaches the policy created earlier to the role named rds-s3-export-role. Replace `your-policy-arn` with the policy ARN that you noted in an earlier step.

```
aws iam attach-role-policy  --policy-arn your-policy-arn  --role-name rds-s3-export-role
```

4. Add the IAM role to the DB cluster. You do so by using the AWS Management Console or AWS CLI, as described following.

**Console**

**To add an IAM role for a PostgreSQL DB cluster using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Choose the PostgreSQL DB cluster name to display its details.
3. On the Connectivity & security tab, in the Manage IAM roles section, choose the role to add under Add IAM roles to this instance.
4. Under Feature, choose s3Export.
5. Choose Add role.

**AWS CLI**

**To add an IAM role for a PostgreSQL DB cluster using the CLI**

- Use the following command to add the role to the PostgreSQL DB cluster named my-db-cluster. Replace `your-role-arn` with the role ARN that you noted in a previous step. Use s3Export for the value of the --feature-name option.

```
Example
For Linux, macOS, or Unix:
aws rds add-role-to-db-cluster
```
Exporting query data using the `aws_s3.query_export_to_s3` function

Export your PostgreSQL data to Amazon S3 by calling the `aws_s3.query_export_to_s3` function.

**Topics**

- Prerequisites (p. 1533)
- Calling `aws_s3.query_export_to_s3` (p. 1533)
- Exporting to a CSV file that uses a custom delimiter (p. 1535)
- Exporting to a binary file with encoding (p. 1535)

**Prerequisites**

Before you use the `aws_s3.query_export_to_s3` function, be sure to complete the following prerequisites:

- Install the required PostgreSQL extensions as described in Overview of exporting data to Amazon S3 (p. 1528).
- Determine where to export your data to Amazon S3 as described in Specifying the Amazon S3 file path to export to (p. 1529).
- Make sure that the DB cluster has export access to Amazon S3 as described in Setting up access to an Amazon S3 bucket (p. 1530).

The examples following use a database table called `sample_table`. These examples export the data into a bucket called `sample-bucket`. The example table and data are created with the following SQL statements in `psql`.

```sql
psql=> CREATE TABLE sample_table (bid bigint PRIMARY KEY, name varchar(80));
psql=> INSERT INTO sample_table (bid,name) VALUES (1, 'Monday'), (2,'Tuesday'), (3,'Wednesday');
```

**Calling `aws_s3.query_export_to_s3`**

The following shows the basic ways of calling the `aws_s3.query_export_to_s3` function.

These examples use the variable `s3_uri_1` to identify a structure that contains the information identifying the Amazon S3 file. Use the `aws_commons.create_s3_uri` function to create the structure.
Although the parameters vary for the following two `aws_s3.query_export_to_s3` function calls, the results are the same for these examples. All rows of the `sample_table` table are exported into a bucket called `sample-bucket`.

```
psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM sample_table', 's3_uri_1');
psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM sample_table', 's3_uri_1',
            options :='format text');
```

The parameters are described as follows:

- `'SELECT * FROM sample_table'` – The first parameter is a required text string containing an SQL query. The PostgreSQL engine runs this query. The results of the query are copied to the S3 bucket identified in other parameters.
- `'s3_uri_1'` – This parameter is a structure that identifies the Amazon S3 file. This example uses a variable to identify the previously created structure. You can instead create the structure by including the `aws_commons.create_s3_uri` function call inline within the `aws_s3.query_export_to_s3` function call as follows.

```
SELECT * from aws_s3.query_export_to_s3('select * from sample_table',
    aws_commons.create_s3_uri('sample-bucket', 'sample-filepath', 'us-west-2')
);
```

- `options :='format text'` – The `options` parameter is an optional text string containing PostgreSQL `COPY` arguments. The copy process uses the arguments and format of the `PostgreSQL COPY` command.

If the file specified doesn't exist in the Amazon S3 bucket, it's created. If the file already exists, it's overwritten. The syntax for accessing the exported data in Amazon S3 is the following.

```
s3-region://bucket-name[/path-prefix]/file-prefix
```

Larger exports are stored in multiple files, each with a maximum size of approximately 6 GB. The additional file names have the same file prefix but with `_partXX` appended. The `XX` represents 2, then 3, and so on. For example, suppose that you specify the path where you store data files as the following.

```
s3-us-west-2://my-bucket/my-prefix
```

If the export has to create three data files, the Amazon S3 bucket contains the following data files.

```
s3-us-west-2://my-bucket/my-prefix
s3-us-west-2://my-bucket/my-prefix_part2
s3-us-west-2://my-bucket/my-prefix_part3
```

For the full reference for this function and additional ways to call it, see [aws_s3.query_export_to_s3](p. 1535). For more about accessing files in Amazon S3, see [View an object](in the Amazon Simple Storage Service User Guide).
Exporting to a CSV file that uses a custom delimiter

The following example shows how to call the `aws_s3.query_export_to_s3` function to export data to a file that uses a custom delimiter. The example uses arguments of the PostgreSQL `COPY` command to specify the comma-separated value (CSV) format and a colon (:) delimiter.

```sql
SELECT * from aws_s3.query_export_to_s3('select * from basic_test', :'s3_uri_1',
  options :='format csv, delimiter $$:$$');
```

Exporting to a binary file with encoding

The following example shows how to call the `aws_s3.query_export_to_s3` function to export data to a binary file that has Windows-1253 encoding.

```sql
SELECT * from aws_s3.query_export_to_s3('select * from basic_test', :'s3_uri_1',
  options :='format binary, encoding WIN1253');
```

Troubleshooting access to Amazon S3

If you encounter connection problems when attempting to export data to Amazon S3, first confirm that the outbound access rules for the VPC security group associated with your DB instance permit network connectivity. Specifically, the security group must have a rule that allows the DB instance to send TCP traffic to port 443 and to any IPv4 addresses (0.0.0.0/0). For more information, see [Provide access to the DB cluster in the VPC by creating a security group](p. 122).

See also the following for recommendations:

- [Troubleshooting Amazon Aurora identity and access](p. 2460)
- [Troubleshooting Amazon S3](p. 122)
- [Troubleshooting Amazon S3 and IAM](p. 1537)

Function reference

Functions

- `aws_s3.query_export_to_s3` (p. 1535)
- `aws_commons.create_s3_uri` (p. 1537)

`aws_s3.query_export_to_s3`

Exports a PostgreSQL query result to an Amazon S3 bucket. The `aws_s3` extension provides the `aws_s3.query_export_to_s3` function.

The two required parameters are `query` and `s3_info`. These define the query to be exported and identify the Amazon S3 bucket to export to. An optional parameter called `options` provides for defining various export parameters. For examples of using the `aws_s3.query_export_to_s3` function, see [Exporting query data using the `aws_s3.query_export_to_s3` function](p. 1533).

Syntax

```sql
aws_s3.query_export_to_s3(
  query text,
  s3_info aws_commons._s3_uri_1,
```

1535
Input parameters

query

A required text string containing an SQL query that the PostgreSQL engine runs. The results of this query are copied to an S3 bucket identified in the s3_info parameter.

s3_info

An aws_commons._s3_uri_1 composite type containing the following information about the S3 object:
- bucket – The name of the Amazon S3 bucket to contain the file.
- file_path – The Amazon S3 file name and path.
- region – The AWS Region that the bucket is in. For a listing of AWS Region names and associated values, see Regions and Availability Zones (p. 16).

Currently, this value must be the same AWS Region as that of the exporting DB cluster. The default is the AWS Region of the exporting DB cluster.

To create an aws_commons._s3_uri_1 composite structure, see the aws_commons.create_s3_uri (p. 1537) function.

options

An optional text string containing arguments for the PostgreSQL COPY command. These arguments specify how the data is to be copied when exported. For more details, see the PostgreSQL COPY documentation.

Alternate input parameters

To help with testing, you can use an expanded set of parameters instead of the s3_info parameter. Following are additional syntax variations for the aws_s3.query_export_to_s3 function.

Instead of using the s3_info parameter to identify an Amazon S3 file, use the combination of the bucket, file_path, and region parameters.

```python
aws_s3.query_export_to_s3(
    query text,
    bucket text,
    file_path text,
    region text,
    options text
)
```

query

A required text string containing an SQL query that the PostgreSQL engine runs. The results of this query are copied to an S3 bucket identified in the s3_info parameter.

bucket

A required text string containing the name of the Amazon S3 bucket that contains the file.

file_path

A required text string containing the Amazon S3 file name including the path of the file.
**region**

An optional text string containing the AWS Region that the bucket is in. For a listing of AWS Region names and associated values, see [Regions and Availability Zones](p. 16).

Currently, this value must be the same AWS Region as that of the exporting DB cluster. The default is the AWS Region of the exporting DB cluster.

**options**

An optional text string containing arguments for the PostgreSQL COPY command. These arguments specify how the data is to be copied when exported. For more details, see the [PostgreSQL COPY documentation](

**Output parameters**

```sql
aws_s3.query_export_to_s3(
    OUT rows_uploaded bigint,
    OUT files_uploaded bigint,
    OUT bytes_uploaded bigint
)
```

**rows_uploaded**

The number of table rows that were successfully uploaded to Amazon S3 for the given query.

**files_uploaded**

The number of files uploaded to Amazon S3. Files are created in sizes of approximately 6 GB. Each additional file created has _partXX appended to the name. The XX represents 2, then 3, and so on as needed.

**bytes_uploaded**

The total number of bytes uploaded to Amazon S3.

**Examples**

```sql
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'sample-bucket', 'sample-filepath');
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'sample-bucket', 'sample-filepath','us-west-2');
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'sample-bucket', 'sample-filepath','us-west-2','format text');
```

**aws_commons.create_s3_uri**

Creates an [aws_commons._s3_uri_1](structure to hold Amazon S3 file information. You use the results of the [aws_commons.create_s3_uri](function in the s3_info parameter of the [aws_s3.query_export_to_s3](p. 1535) function. For an example of using the [aws_commons.create_s3_uri](function, see [Specifying the Amazon S3 file path to export to](p. 1529).

**Syntax**

```python
aws_commons.create_s3_uri(
    bucket text,
    file_path text,
    region text
)
```
Input parameters

bucket

A required text string containing the Amazon S3 bucket name for the file.

file_path

A required text string containing the Amazon S3 file name including the path of the file.

region

A required text string containing the AWS Region that the file is in. For a listing of AWS Region names and associated values, see Regions and Availability Zones (p. 16).

Invoking an AWS Lambda function from an Aurora PostgreSQL DB cluster

AWS Lambda is an event-driven compute service that lets you run code without provisioning or managing servers. It's available for use with many AWS services, including Aurora PostgreSQL. For example, you can use Lambda functions to process event notifications from a database, or to load data from files whenever a new file is uploaded to Amazon S3. To learn more about Lambda, see What is AWS Lambda? in the AWS Lambda Developer Guide.

Note

Invoking AWS Lambda functions is supported in Aurora PostgreSQL 11.9 and higher (including Aurora Serverless v2).

Setting up Aurora PostgreSQL to work with Lambda functions is a multi-step process involving AWS Lambda, IAM, your VPC, and your Aurora PostgreSQL DB cluster. Following, you can find summaries of the necessary steps.

For more information about Lambda functions, see Getting started with Lambda and AWS Lambda foundations in the AWS Lambda Developer Guide.

Topics

- Step 1: Configure your Aurora PostgreSQL DB cluster for outbound connections to AWS Lambda (p. 1538)
- Step 2: Configure IAM for your Aurora PostgreSQL DB cluster and AWS Lambda (p. 1539)
- Step 3: Install the aws_lambda extension for an Aurora PostgreSQL DB cluster (p. 1540)
- Step 4: Use Lambda helper functions with your Aurora PostgreSQL DB cluster (Optional) (p. 1541)
- Step 5: Invoke a Lambda function from your Aurora PostgreSQL DB cluster (p. 1541)
- Step 6: Grant other users permission to invoke Lambda functions (p. 1542)
- Examples: Invoking Lambda functions from your Aurora PostgreSQL DB cluster (p. 1543)
- Lambda function error messages (p. 1545)
- AWS Lambda function reference (p. 1545)

Step 1: Configure your Aurora PostgreSQL DB cluster for outbound connections to AWS Lambda

Lambda functions always run inside an Amazon VPC that's owned by the AWS Lambda service. Lambda applies network access and security rules to this VPC and it maintains and monitors the VPC automatically. Your Aurora PostgreSQL DB cluster sends network traffic to the Lambda service's VPC. How you configure this depends on whether your Aurora DB cluster's primary DB instance is public or private.
• **Public Aurora PostgreSQL DB cluster** – A DB cluster’s primary DB instance is public if it’s located in a public subnet on your VPC, and if the instance’s "PubliclyAccessible" property is true. To find the value of this property, you can use the `describe-db-instances` AWS CLI command. Or, you can use the AWS Management Console to open the Connectivity & security tab and check that Publicly accessible is Yes. To verify that the instance is in the public subnet of your VPC, you can use the AWS Management Console or the AWS CLI.

To set up access to Lambda, you use the AWS Management Console or the AWS CLI to create an outbound rule on your VPC’s security group. The outbound rule specifies that TCP can use port 443 to send packets to any IPv4 addresses (0.0.0.0/0).

• **Private Aurora PostgreSQL DB cluster** – In this case, the instance’s "PubliclyAccessible" property is false or it’s in a private subnet. To allow the instance to work with Lambda, you can use a Network Address Translation) NAT gateway. For more information, see [NAT gateways](http://example.com). Or, you can configure your VPC with a VPC endpoint for Lambda. For more information, see [VPC endpoints](http://example.com) in the [Amazon VPC User Guide](http://example.com). The endpoint responds to calls made by your Aurora PostgreSQL DB cluster to your Lambda functions.

Your VPC can now interact with the AWS Lambda VPC at the network level. Next, you configure the permissions using IAM.

**Step 2: Configure IAM for your Aurora PostgreSQL DB cluster and AWS Lambda**

Invoking Lambda functions from your Aurora PostgreSQL DB cluster requires certain privileges. To configure the necessary privileges, we recommend that you create an IAM policy that allows invoking Lambda functions, assign that policy to a role, and then apply the role to your DB cluster. This approach gives the DB cluster privileges to invoke the specified Lambda function on your behalf. The following steps show you how to do this using the AWS CLI.

**To configure IAM permissions for using your cluster with Lambda**

1. Use the `create-policy` AWS CLI command to create an IAM policy that allows your Aurora PostgreSQL DB cluster to invoke the specified Lambda function. (The statement ID (Sid) is an optional description for your policy statement and has no effect on usage.) This policy gives your Aurora DB cluster the minimum permissions needed to invoke the specified Lambda function.

```bash
aws iam create-policy --policy-name rds-lambda-policy --policy-document '{
    "Version": "2012-10-17",
    "Statement": [
    {
        "Sid": "AllowAccessToExampleFunction",
        "Effect": "Allow",
        "Action": "lambda:InvokeFunction",
    }
    ]
}
'
```

Alternatively, you can use the predefined AWSLambdaRole policy that allows you to invoke any of your Lambda functions. For more information, see [Identity-based IAM policies for Lambda](http://example.com)

2. Use the `create-role` AWS CLI command to create an IAM role that the policy can assume at runtime.

```bash
aws iam create-role --role-name rds-lambda-role --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
    {
        "Sid": "AllowAccessToExampleFunction",
        "Effect": "Allow",
        "Action": "lambda:InvokeFunction",
    }
    ]
}
'
```

1539
3. Apply the policy to the role by using the `attach-role-policy` AWS CLI command.

```bash
aws iam attach-role-policy
--policy-arn arn:aws:iam::444455556666:policy/rds-lambda-policy
--role-name rds-lambda-role --region aws-region
```

4. Apply the role to your Aurora PostgreSQL DB cluster by using the `add-role-to-db-cluster` AWS CLI command. This last step allows your DB cluster's database users to invoke Lambda functions.

```bash
aws rds add-role-to-db-cluster
--db-cluster-identifier my-cluster-name
--feature-name Lambda
--role-arn arn:aws:iam::444455556666:role/rds-lambda-role
--region aws-region
```

With the VPC and the IAM configurations complete, you can now install the `aws_lambda` extension. (Note that you can install the extension at any time, but until you set up the correct VPC support and IAM privileges, the `aws_lambda` extension adds nothing to your Aurora PostgreSQL DB cluster's capabilities.)

**Step 3: Install the `aws_lambda` extension for an Aurora PostgreSQL DB cluster**

To use AWS Lambda with your Aurora PostgreSQL DB cluster, add the `aws_lambda` PostgreSQL extension to your Aurora PostgreSQL DB cluster. This extension provides your Aurora PostgreSQL DB cluster with the ability to call Lambda functions from PostgreSQL.

**To install the `aws_lambda` extension in your Aurora PostgreSQL DB cluster**

Use the PostgreSQL `psql` command-line or the pgAdmin tool to connect to your Aurora PostgreSQL DB cluster.

1. Connect to your Aurora PostgreSQL DB cluster instance as a user with `rds_superuser` privileges. The default `postgres` user is shown in the example.

   ```bash
   psql -h cluster-instance.444455556666.aws-region.rds.amazonaws.com -U postgres -p 5432
   ```

2. Install the `aws_lambda` extension. The `aws_commons` extension is also required. It provides helper functions to `aws_lambda` and many other Aurora extensions for PostgreSQL. If it's not already on your Aurora PostgreSQL DB cluster, it's installed with `aws_lambda` as shown following.

   ```sql
   CREATE EXTENSION IF NOT EXISTS aws_lambda CASCADE;
   NOTICE: installing required extension "aws_commons"
   CREATE EXTENSION
   ```

The `aws_lambda` extension is installed in your Aurora PostgreSQL DB cluster's primary DB instance. You can now create convenience structures for invoking your Lambda functions.
Step 4: Use Lambda helper functions with your Aurora PostgreSQL DB cluster (Optional)

You can use the helper functions in the aws_commons extension to prepare entities that you can more easily invoke from PostgreSQL. To do this, you need to have the following information about your Lambda functions:

- **Function name** – The name, Amazon Resource Name (ARN), version, or alias of the Lambda function. The IAM policy created in Step 2: Configure IAM for your cluster and Lambda (p. 1539) requires the ARN, so we recommend that you use your function’s ARN.

- **AWS Region** – (Optional) The AWS Region where the Lambda function is located if it’s not in the same Region as your Aurora PostgreSQL DB cluster.

To hold the Lambda function name information, you use the
aws_commons.create_lambda_function_arn (p. 1548) function. This helper function creates an aws_commons._lambda_function_arn_1 composite structure with the details needed by the invoke function. Following, you can find three alternative approaches to setting up this composite structure.

```sql
SELECT aws_commons.create_lambda_function_arn(
   'my-function',
   'aws-region'
) AS aws_lambda_arn_1 \gset
```

```sql
SELECT aws_commons.create_lambda_function_arn(
   '111122223333:function:my-function',
   'aws-region'
) AS lambda_partial_arn_1 \gset
```

```sql
SELECT aws_commons.create_lambda_function_arn(
) AS lambda_arn_1 \gset
```

Any of these values can be used in calls to the aws_lambda.invoke (p. 1545) function. For examples, see Step 5: Invoke a Lambda function from your Aurora PostgreSQL DB cluster (p. 1541).

Step 5: Invoke a Lambda function from your Aurora PostgreSQL DB cluster

The aws._lambda.invoke function behaves synchronously or asynchronously, depending on the invocation_type. The two alternatives for this parameter are RequestResponse (the default) and Event, as follows.

- **RequestResponse** – This invocation type is **synchronous**. It's the default behavior when the call is made without specifying an invocation type. The response payload includes the results of the aws._lambda.invoke function. Use this invocation type when your workflow requires receiving results from the Lambda function before proceeding.

- **Event** – This invocation type is **asynchronous**. The response doesn't include a payload containing results. Use this invocation type when your workflow doesn't need a result from the Lambda function to continue processing.

As a simple test of your setup, you can connect to your DB instance using psql and invoke an example function from the command line. Suppose that you have one of the basic functions set up on your Lambda service, such as the simple Python function shown in the following screenshot.
To invoke an example function

1. Connect to your primary DB instance using psql or pgAdmin.

   ```
   psql -h cluster.444455556666.aws-region.rds.amazonaws.com -U postgres -p 5432
   ```

2. Invoke the function using its ARN.

   ```
   SELECT * from aws_lambda.invoke(aws_commons.create_lambda_function_arn('arn:aws:lambda:aws-region:444455556666:function:simple', 'us-west-1'), '{"body": "Hello from Postgres!"'}::json );
   ```

   The response looks as follows.

<table>
<thead>
<tr>
<th>status_code</th>
<th>payload</th>
<th>executed_version</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>{&quot;statusCode&quot;: 200, &quot;body&quot;: &quot;Hello from Lambda!&quot;}</td>
<td>$LATEST</td>
</tr>
</tbody>
</table>
   (1 row)

If your invocation attempt doesn't succeed, see [Lambda function error messages](p. 1545).

**Step 6: Grant other users permission to invoke Lambda functions**

At this point in the procedures, only you as `rds_superuser` can invoke your Lambda functions. To allow other users to invoke any functions that you create, you need to grant them permission.

**To grant others permission to invoke Lambda functions**

1. Connect to your primary DB instance using psql or pgAdmin.

   ```
   psql -h cluster.444455556666.aws-region.rds.amazonaws.com -U postgres -p 5432
   ```

2. Run the following SQL commands:
Examples: Invoking Lambda functions from your Aurora PostgreSQL DB cluster

Following, you can find several examples of calling the `aws_lambda.invoke` function. Most all the examples use the composite structure `aws_lambda_arn_1` that you create in Step 4: Use Lambda helper functions with your Aurora PostgreSQL DB cluster (Optional) to simplify passing the function details. For an example of asynchronous invocation, see Example: Asynchronous (Event) invocation of Lambda functions. All the other examples listed use synchronous invocation.

Examples list

- Example: Synchronous (RequestResponse) invocation of Lambda functions (p. 1543)
- Example: Asynchronous (Event) invocation of Lambda functions (p. 1544)
- Example: Capturing the Lambda execution log in a function response (p. 1544)
- Example: Including client context in a Lambda function (p. 1544)
- Example: Invoking a specific version of a Lambda function (p. 1544)

Example: Synchronous (RequestResponse) invocation of Lambda functions

Following are two examples of a synchronous Lambda function invocation. The results of these `aws_lambda.invoke` function calls are the same.

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}');
```

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}', 'RequestResponse');
```

The parameters are described as follows:

- `'aws_lambda_arn_1'` – This parameter identifies the composite structure created in Step 4: Use Lambda helper functions with your Aurora PostgreSQL DB cluster (Optional), with the `aws_commons.create_lambda_function_arn` helper function. You can also create this structure inline within your `aws_lambda.invoke` call as follows.

```
SELECT * FROM aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-function', 'aws-region'), '{"body": "Hello from Postgres!"}');
```

- `{"body": "Hello from PostgreSQL!"}` – The JSON payload to pass to the Lambda function.
- `'RequestResponse'` – The Lambda invocation type.
Example: Asynchronous (Event) invocation of Lambda functions

Following is an example of an asynchronous Lambda function invocation. The Event invocation type schedules the Lambda function invocation with the specified input payload and returns immediately. Use the Event invocation type in certain workflows that don't depend on the results of the Lambda function.

```
SELECT * FROM aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"}'::json, 'Event');
```

Example: Capturing the Lambda execution log in a function response

You can include the last 4 KB of the execution log in the function response by using the log_type parameter in your `aws_lambda.invoke` function call. By default, this parameter is set to `None`, but you can specify `Tail` to capture the results of the Lambda execution log in the response, as shown following.

```
SELECT *, select convert_from(decode(log_result, 'base64'), 'utf-8') as log FROM aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"}'::json, 'RequestResponse', 'Tail');
```

Set the `aws_lambda.invoke` function's log_type parameter to `Tail` to include the execution log in the response. The default value for the log_type parameter is `None`.

The log_result that's returned is a base64 encoded string. You can decode the contents using a combination of the `decode` and `convert_from` PostgreSQL functions.

For more information about log_type, see `aws_lambda.invoke (p. 1545)`.

Example: Including client context in a Lambda function

The `aws_lambda.invoke` function has a context parameter that you can use to pass information separate from the payload, as shown following.

```
SELECT *, convert_from(decode(log_result, 'base64'), 'utf-8') as log FROM aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"}'::json, 'RequestResponse', 'Tail');
```

To include client context, use a JSON object for the `aws_lambda.invoke (p. 1545)` function's context parameter.

For more information about the context parameter, see the `aws_lambda.invoke (p. 1545)` reference.

Example: Invoking a specific version of a Lambda function

You can specify a particular version of a Lambda function by including the qualifier parameter with the `aws_lambda.invoke` call. Following, you can find an example that does this using 'custom_version' as an alias for the version.

```
SELECT * FROM aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"}'::json, 'RequestResponse', 'None', NULL, 'custom_version');
```

You can also supply a Lambda function qualifier with the function name details instead, as follows.

```
SELECT * FROM aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-function:custom_version', 'us-west-2'), '{"body": "Hello from Postgres!"}'::json);
```

For more information about qualifier and other parameters, see the `aws_lambda.invoke (p. 1545)` reference.
Lambda function error messages

In the following list you can find information about error messages, with possible causes and solutions.

- **VPC configuration issues**
  
  VPC configuration issues can raise the following error messages when trying to connect:

  ```
  ERROR: invoke API failed
  DETAIL: AWS Lambda client returned 'Unable to connect to endpoint'.
  CONTEXT: SQL function "invoke" statement 1
  ```

  A common cause for this error is improperly configured VPC security group. Make sure you have an outbound rule for TCP open on port 443 of your VPC security group so that your VPC can connect to the Lambda VPC.

- **Lack of permissions needed to invoke Lambda functions**
  
  If you see either of the following error messages, the user (role) invoking the function doesn't have proper permissions.

  ```
  ERROR: permission denied for schema aws_lambda
  ```

  ```
  ERROR: permission denied for function invoke
  ```

  A user (role) must be given specific grants to invoke Lambda functions. For more information, see Step 6: Grant other users permission to invoke Lambda functions (p. 1542).

- **Improper handling of errors in your Lambda functions**
  
  If a Lambda function throws an exception during request processing, `aws_lambda.invoke` fails with a PostgreSQL error such as the following.

  ```
  SELECT * FROM aws_lambda.invoke(aws_lambda_arn_1', 'Hello from Postgres!')
  ERROR: lambda invocation failed
  ```

  Be sure to handle errors in your Lambda functions or in your PostgreSQL application.

AWS Lambda function reference

Following is the reference for the functions to use for invoking Lambda functions with Aurora PostgreSQL.

**Functions**

- [aws_lambda.invoke](p. 1545)
- [aws_commons.create_lambda_function_arn](p. 1548)

**aws_lambda.invoke**

Runs a Lambda function for an Aurora PostgreSQL DB cluster.

For more details about invoking Lambda functions, see also **Invoke** in the AWS Lambda Developer Guide.
Syntax

**JSON**

```python
aws_lambda.invoke(  
    IN function_name TEXT,  
    IN payload JSON,  
    IN region TEXT DEFAULT NULL,  
    IN invocation_type TEXT DEFAULT 'RequestResponse',  
    IN log_type TEXT DEFAULT 'None',  
    IN context JSON DEFAULT NULL,  
    IN qualifier VARCHAR(128) DEFAULT NULL,  
    OUT status_code INT,  
    OUT payload JSON,  
    OUT executed_version TEXT,  
    OUT log_result TEXT)
```

```python
aws_lambda.invoke(  
    IN function_name aws_commons._lambda_function_arn_1,  
    IN payload JSON,  
    IN region TEXT DEFAULT NULL,  
    IN invocation_type TEXT DEFAULT 'RequestResponse',  
    IN log_type TEXT DEFAULT 'None',  
    IN context JSON DEFAULT NULL,  
    IN qualifier VARCHAR(128) DEFAULT NULL,  
    OUT status_code INT,  
    OUT payload JSON,  
    OUT executed_version TEXT,  
    OUT log_result TEXT)
```

**JSONB**

```python
aws_lambda.invoke(  
    IN function_name TEXT,  
    IN payload JSONB,  
    IN region TEXT DEFAULT NULL,  
    IN invocation_type TEXT DEFAULT 'RequestResponse',  
    IN log_type TEXT DEFAULT 'None',  
    IN context JSONB DEFAULT NULL,  
    IN qualifier VARCHAR(128) DEFAULT NULL,  
    OUT status_code INT,  
    OUT payload JSONB,  
    OUT executed_version TEXT,  
    OUT log_result TEXT)
```

```python
aws_lambda.invoke(  
    IN function_name aws_commons._lambda_function_arn_1,  
    IN payload JSONB,  
    IN region TEXT DEFAULT NULL,  
    IN invocation_type TEXT DEFAULT 'RequestResponse',  
    IN log_type TEXT DEFAULT 'None',  
    IN context JSONB DEFAULT NULL,  
    IN qualifier VARCHAR(128) DEFAULT NULL,  
    OUT status_code INT,  
    OUT payload JSONB,  
    OUT executed_version TEXT,  
    OUT log_result TEXT)
```

1546
Input parameters

function_name

The identifying name of the Lambda function. The value can be the function name, an ARN, or a partial ARN. For a listing of possible formats, see Lambda function name formats in the AWS Lambda Developer Guide.

payload

The input for the Lambda function. The format can be JSON or JSONB. For more information, see JSON Types in the PostgreSQL documentation.

region

(Optional) The Lambda Region for the function. By default, Aurora resolves the AWS Region from the full ARN in the function_name or it uses the Aurora PostgreSQL DB instance Region. If this Region value conflicts with the one provided in the function_name ARN, an error is raised.

invocation_type

The invocation type of the Lambda function. The value is case-sensitive. Possible values include the following:

- RequestResponse – The default. This type of invocation for a Lambda function is synchronous and returns a response payload in the result. Use the RequestResponse invocation type when your workflow depends on receiving the Lambda function result immediately.
- Event – This type of invocation for a Lambda function is asynchronous and returns immediately without a returned payload. Use the Event invocation type when you don’t need results of the Lambda function before your workflow moves on.
- DryRun – This type of invocation tests access without running the Lambda function.

log_type

The type of Lambda log to return in the log_result output parameter. The value is case-sensitive. Possible values include the following:

- Tail – The returned log_result output parameter will include the last 4 KB of the execution log.
- None – No Lambda log information is returned.

context

Client context in JSON or JSONB format. Fields to use include than custom and env.

qualifier

A qualifier that identifies a Lambda function's version to be invoked. If this value conflicts with one provided in the function_name ARN, an error is raised.

Output parameters

status_code

An HTTP status response code. For more information, see Lambda Invoke response elements in the AWS Lambda Developer Guide.

payload

The information returned from the Lambda function that ran. The format is in JSON or JSONB.

executed_version

The version of the Lambda function that ran.
log_result

The execution log information returned if the log_type value is Tail when the Lambda function was invoked. The result contains the last 4 KB of the execution log encoded in Base64.

aws_commons.create_lambda_function_arn

Creates an aws_commons._lambda_function_arn_1 structure to hold Lambda function name information. You can use the results of the aws_commons.create_lambda_function_arn function in the function_name parameter of the aws_lambda.invoke aws_lambda.invoke (p. 1545) function.

Syntax

```python
aws_commons.create_lambda_function_arn(
    function_name TEXT,
    region TEXT DEFAULT NULL
) 
RETURNS aws_commons._lambda_function_arn_1
```

Input parameters

**function_name**

A required text string containing the Lambda function name. The value can be a function name, a partial ARN, or a full ARN.

**region**

An optional text string containing the AWS Region that the Lambda function is in. For a listing of Region names and associated values, see Regions and Availability Zones (p. 16).

Publishing Aurora PostgreSQL logs to Amazon
CloudWatch Logs

You can configure your Aurora PostgreSQL DB cluster to export log data to Amazon CloudWatch Logs on a regular basis. When you do so, events from your Aurora PostgreSQL DB cluster's PostgreSQL log are automatically published to Amazon CloudWatch, as Amazon CloudWatch Logs. In CloudWatch, you can find the exported log data in a Log group for your Aurora PostgreSQL DB cluster. The log group contains one or more log streams that contain the events from the PostgreSQL log from each instance in the cluster.

Publishing the logs to CloudWatch Logs allows you to keep your cluster's PostgreSQL log records in highly durable storage. With the log data available in CloudWatch Logs, you can evaluate and improve your cluster's operations. You can also use CloudWatch to create alarms and view metrics. To learn more, see Monitoring log events in Amazon CloudWatch (p. 1551).

**Note**

Publishing your PostgreSQL logs to CloudWatch Logs consumes storage, and you incur charges for that storage. Be sure to delete any CloudWatch Logs that you no longer need.

Turning the export log option off for an existing Aurora PostgreSQL DB cluster doesn't affect any data that's already held in CloudWatch Logs. Existing logs remain available in CloudWatch Logs based on your log retention settings. To learn more about CloudWatch Logs, see What is Amazon CloudWatch Logs?

Aurora PostgreSQL supports publishing logs to CloudWatch Logs for the following versions.

- 14.3 and higher 14 versions
• 13.3 and higher 13 versions
• 12.8 and higher 12 versions
• 11.12 and higher 11 versions

Turning on the option to publish logs to Amazon CloudWatch

To publish your Aurora PostgreSQL DB cluster's PostgreSQL log to CloudWatch Logs, choose the Log export option for the cluster. You can choose the Log export setting when you create your Aurora PostgreSQL DB cluster. Or, you can modify the cluster later on. When you modify an existing cluster, its PostgreSQL logs from each instance are published to CloudWatch cluster from that point on. For Aurora PostgreSQL, the PostgreSQL log (postgresql.log) is the only log that gets published to Amazon CloudWatch.

You can use the AWS Management Console, the AWS CLI, or the RDS API to turn on the Log export feature for your Aurora PostgreSQL DB cluster.

**Console**

You choose the Log exports option to start publishing the PostgreSQL logs from your Aurora PostgreSQL DB cluster to CloudWatch Logs.

**To turn on the Log export feature from the console**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the Aurora PostgreSQL DB cluster whose log data you want to publish to CloudWatch Logs.
4. Choose Modify.
5. In the Log exports section, choose PostgreSQL log.
6. Choose Continue, and then choose Modify cluster on the summary page.

**AWS CLI**

You can turn on the log export option to start publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs with the AWS CLI. To do so, run the `modify-db-cluster` AWS CLI command with the following options:

• `--db-cluster-identifier`—The DB cluster identifier.
• `--cloudwatch-logs-export-configuration`—The configuration setting for the log types to be set for export to CloudWatch Logs for the DB cluster.

You can also publish Aurora PostgreSQL logs by running one of the following AWS CLI commands:

• `create-db-cluster`
• `restore-db-cluster-from-s3`
• `restore-db-cluster-from-snapshot`
• `restore-db-cluster-to-point-in-time`

Run one of these AWS CLI commands with the following options:

• `--db-cluster-identifier`—The DB cluster identifier.
• `--engine`—The database engine.
• `--enable-cloudwatch-logs-exports`—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

Other options might be required depending on the AWS CLI command that you run.

**Example**

The following command creates an Aurora PostgreSQL DB cluster to publish log files to CloudWatch Logs.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \
    --db-cluster-identifier my-db-cluster \
    --engine aurora-postgresql \
    --enable-cloudwatch-logs-exports postgresql
```

For Windows:

```
aws rds create-db-cluster ^
    --db-cluster-identifier my-db-cluster ^
    --engine aurora-postgresql ^
    --enable-cloudwatch-logs-exports postgresql
```

**Example**

The following command modifies an existing Aurora PostgreSQL DB cluster to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `EnableLogTypes`, and its value is `postgresql`.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
    --db-cluster-identifier my-db-cluster \
    --cloudwatch-logs-export-configuration '{"EnableLogTypes":["postgresql"]}'
```

For Windows:

```
aws rds modify-db-cluster ^
    --db-cluster-identifier my-db-cluster ^
    --cloudwatch-logs-export-configuration '{"EnableLogTypes":["postgresql"]}'
```

**Note**

When using the Windows command prompt, make sure to escape double quotation marks (") in JSON code by prefixing them with a backslash (\).

**Example**

The following example modifies an existing Aurora PostgreSQL DB cluster to disable publishing log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `DisableLogTypes`, and its value is `postgresql`.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
    --db-cluster-identifier mydbinstance \
    --cloudwatch-logs-export-configuration '{"DisableLogTypes":["postgresql"]}'
```

For Windows:

```
aws rds modify-db-cluster ^
    --db-cluster-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration '{"DisableLogTypes":["postgresql"]}'
```
For Windows:

```
aws rds modify-db-cluster ^
--db-cluster-identifier mydbinstance ^
--cloudwatch-logs-export-configuration "{"DisableLogTypes":["postgresql"]}"
```

**Note**

When using the Windows command prompt, you must escape double quotes (""), in JSON code by prefixing them with a backslash (\).

**RDS API**

You can turn on the log export option to start publishing Aurora PostgreSQL logs with the RDS API. To do so, run the **ModifyDBCluster** operation with the following options:

- **DBClusterIdentifier** – The DB cluster identifier.
- **CloudwatchLogsExportConfiguration** – The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

You can also publish Aurora PostgreSQL logs with the RDS API by running one of the following RDS API operations:

- **CreateDBCluster**
- **RestoreDBClusterFromS3**
- **RestoreDBClusterFromSnapshot**
- **RestoreDBClusterToPointInTime**

Run the RDS API action with the following parameters:

- **DBClusterIdentifier**—The DB cluster identifier.
- **Engine**—The database engine.
- **EnableCloudwatchLogsExports**—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

Other parameters might be required depending on the AWS CLI command that you run.

**Monitoring log events in Amazon CloudWatch**

With Aurora PostgreSQL log events published and available as Amazon CloudWatch Logs, you can view and monitor events using Amazon CloudWatch. For more information about monitoring, see **View log data sent to CloudWatch Logs**.

When you turn on Log exports, a new log group is automatically created using the prefix `/aws/rds/cluster/` with the name of your Aurora PostgreSQL and the log type, as in the following pattern.

```
/aws/rds/cluster/your-cluster-name/postgresql
```

As an example, suppose that an Aurora PostgreSQL DB cluster named `docs-lab-apg-small` exports its log to Amazon CloudWatch Logs. Its log group name in Amazon CloudWatch is shown following.

```
/aws/rds/cluster/docs-lab-apg-small/postgresql
```

If a log group with the specified name exists, Aurora uses that log group to export log data for the Aurora DB cluster. Each DB instance in the Aurora PostgreSQL DB cluster uploads its PostgreSQL log.
Publishing Aurora PostgreSQL logs to CloudWatch Logs
to the log group as a distinct log stream. You can examine the log group and its log streams using the various graphical and analytical tools available in Amazon CloudWatch.

For example, you can search for information within the log events from your Aurora PostgreSQL DB cluster, and filter events by using the CloudWatch Logs console, the AWS CLI, or the CloudWatch Logs API. For more information, [Searching and filtering log data](https://docs.aws.amazon.com/AmazonCloudWatch/latest/logs/log-data-access.html) in the *Amazon CloudWatch Logs User Guide*.

By default, new log groups are created using **Never expire** for their retention period. You can use the CloudWatch Logs console, the AWS CLI, or the CloudWatch Logs API to change the log retention period. To learn more, see [Change log data retention in CloudWatch Logs](https://docs.aws.amazon.com/AmazonCloudWatch/latest/logs/log-data-access.html) in the *Amazon CloudWatch Logs User Guide*.

**Tip**
You can use automated configuration, such as AWS CloudFormation, to create log groups with predefined log retention periods, metric filters, and access permissions.

### Analyzing PostgreSQL logs using CloudWatch Logs Insights

With the PostgreSQL logs from your Aurora PostgreSQL DB cluster published as CloudWatch Logs, you can use CloudWatch Logs Insights to interactively search and analyze your log data in Amazon CloudWatch Logs. CloudWatch Logs Insights includes a query language, sample queries, and other tools for analyzing your log data so that you can identify potential issues and verify fixes. To learn more, see [Analyzing log data with CloudWatch Logs Insights](https://docs.aws.amazon.com/AmazonCloudWatch/latest/logs/log-data-access.html) in the *Amazon CloudWatch Logs User Guide*.

**To analyze PostgreSQL logs with CloudWatch Logs Insights**

2. In the navigation pane, open **Logs** and choose **Log insights**.
3. In **Select log group(s)**, select the log group for your Aurora PostgreSQL DB cluster.
4. In the query editor, delete the query that is currently shown, enter the following, and then choose **Run query**.

```sql
##Autovacuum execution time in seconds per 5 minute fields @message
| parse @message "elapsed: * s" as @duration_sec
| filter @message like / automatic vacuum /
```
Publishing Aurora PostgreSQL logs to CloudWatch Logs

1. Choose the **Visualization** tab.

2. Choose **Add to dashboard**.

3. In **Select a dashboard**, either select a dashboard or enter a name to create a new dashboard.

4. In **Widget type**, choose a widget type for your visualization.

5. Choose the **Visualization** tab.

6. Choose **Add to dashboard**.

7. In **Select a dashboard**, either select a dashboard or enter a name to create a new dashboard.

8. In **Widget type**, choose a widget type for your visualization.

```sql
| display @duration_sec
| sort @timestamp
| stats avg(@duration_sec) as avg_duration_sec,
  max(@duration_sec) as max_duration_sec
by bin(5 min)
```
9. (Optional) Add more widgets based on your log query results.
   
a. Choose **Add widget**.
   
b. Choose a widget type, such as **Line**.
   
c. In the **Add to this dashboard** window, choose **Logs**.
d. In **Select log group(s)**, select the log group for your DB cluster.

e. In the query editor, delete the query that is currently shown, enter the following, and then choose **Run query**.

```
##Autovacuum tuples statistics per 5 min
fields @timestamp, @message
  | parse @message "tuples: " as @tuples_temp
  | parse @tuples_temp "* removed," as @tuples_removed
  | parse @tuples_temp "remain, * are dead but not yet removable, " as @tuples_not_removable
  | filter @message like / automatic vacuum /
  | sort @timestamp
  | stats avg(@tuples_removed) as avg_tuples_removed,
  | avg(@tuples_not_removable) as avg_tuples_not_removable
  | by bin(5 min)
```

f. Choose **Create widget**.

Your dashboard should look similar to the following image.
Using Amazon Aurora machine learning with Aurora PostgreSQL

By using Amazon Aurora machine learning with your Aurora PostgreSQL DB cluster, you can Amazon Comprehend or Amazon SageMaker or both, depending on your needs. Amazon Comprehend and SageMaker each support specific machine learning use cases, as follows.

Amazon Comprehend

Amazon Comprehend is a managed natural language processing (NLP) service that's used to extract insights from documents. With Amazon Comprehend, you can deduce sentiment based on the content of documents, by analyzing entities, key phrases, language, and other features. To learn more, see What is Amazon Comprehend? in the Amazon Comprehend Developer Guide.

SageMaker

Amazon SageMaker is a fully managed machine learning service. Data scientists and developers use Amazon SageMaker to build, train, and test machine learning models for a variety of inference tasks, such as fraud detection and product recommendation. When a machine learning model is ready for use in production, it can be deployed to the Amazon SageMaker hosted environment. For more information, see What Is Amazon SageMaker? in the Amazon SageMaker Developer Guide.

Using Amazon Comprehend with your Aurora DB cluster has less preliminary setup than using SageMaker. If you're new to both AWS machine learning and to Aurora machine learning, we recommend that you start by exploring Amazon Comprehend.

Aurora machine learning is supported in certain AWS Regions and for specific versions of Aurora PostgreSQL only. Before trying to set up Aurora machine learning, check availability for your Aurora PostgreSQL version and your Region. For details, see Aurora machine learning with Aurora PostgreSQL (p. 42).

Topics

• Requirements for using Aurora machine learning with Aurora PostgreSQL (p. 1556)
• Supported features and limitations of Aurora machine learning with Aurora PostgreSQL (p. 1557)
• Setting up your Aurora PostgreSQL DB cluster to use Aurora machine learning (p. 1557)
• Using Amazon Comprehend with your Aurora PostgreSQL DB cluster (p. 1564)
• Using SageMaker with your Aurora PostgreSQL DB cluster (p. 1565)
• Exporting data to Amazon S3 for SageMaker model training (Advanced) (p. 1568)
• Performance considerations for using Aurora machine learning with Aurora PostgreSQL (p. 1568)
• Monitoring Aurora machine learning (p. 1572)

Requirements for using Aurora machine learning with Aurora PostgreSQL

AWS machine learning services are managed services that are set up and run in their own production environments. Aurora machine learning supports integration with Amazon Comprehend and SageMaker. Before trying to set up your Aurora PostgreSQL DB cluster to use Aurora machine learning, be sure you understand the following requirements and prerequisites.

• The Amazon Comprehend and SageMaker services must be running in the same AWS Region as your Aurora PostgreSQL DB cluster. You can't use Amazon Comprehend or SageMaker services from an Aurora PostgreSQL DB cluster in a different Region.
• If your Aurora PostgreSQL DB cluster is in a different virtual public cloud (VPC) based on the Amazon VPC service than your Amazon Comprehend and SageMaker services, the VPC’s Security group needs to allow outbound connections to the target Aurora machine learning service. For more information, see Enabling network communication from Amazon Aurora MySQL to other AWS services (p. 1058).

• For SageMaker, the machine learning components that you want to use for inferences must be setup and ready to use. During the configuration process for your Aurora PostgreSQL DB cluster, you need to have the Amazon Resource Name (ARN) of the SageMaker endpoint available. The data scientists on your team are likely best able to handle working with SageMaker to prepare the models and handle the other such tasks. To get started with Amazon SageMaker, see Get Started with Amazon SageMaker. For more information about inferences and endpoints, see Real-time inference.

Supported features and limitations of Aurora machine learning with Aurora PostgreSQL

Aurora machine learning supports any SageMaker endpoint that can read and write the comma-separated value (CSV) format through a ContentType value of text/csv. The built-in SageMaker algorithms that currently accept this format are the following.

• Linear Learner
• Random Cut Forest
• XGBoost

To learn more about these algorithms, see Choose an Algorithm in the Amazon SageMaker Developer Guide.

Setting up your Aurora PostgreSQL DB cluster to use Aurora machine learning

For Aurora machine learning to work with your Aurora PostgreSQL DB cluster, you need to create an AWS Identity and Access Management (IAM) role for each of the services that you want to use. The IAM role allows your Aurora PostgreSQL DB cluster to use the Aurora machine learning service on the cluster's behalf. You also need to install the Aurora machine learning extension. In the following topics, you can find setup procedures for each of these Aurora machine learning services.

Topics
• Setting up Aurora PostgreSQL to use Amazon Comprehend (p. 1557)
• Setting up Aurora PostgreSQL to use Amazon SageMaker (p. 1561)
  • Setting up Aurora PostgreSQL to use Amazon S3 for SageMaker (Advanced) (p. 1563)
• Installing the Aurora machine learning extension (p. 1563)

Setting up Aurora PostgreSQL to use Amazon Comprehend

In the procedure following, you first create the IAM role and policy that gives your Aurora PostgreSQL permission to use Amazon Comprehend on the cluster's behalf. You then attach the policy to an IAM role that your Aurora PostgreSQL DB cluster uses to work with Amazon Comprehend. For simplicity's sake, this procedure uses the AWS Management Console to complete all tasks.

To set up your Aurora PostgreSQL DB cluster to use Amazon Comprehend

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. Open the IAM console at https://console.aws.amazon.com/iam/.

4. Choose Create policy. In the Visual editor page, choose Service and then enter Comprehend in the Select a service field. Expand the Read access level. Choose BatchDetectSentiment and DetectSentiment from the Amazon Comprehend read settings.

5. Choose Next: Tags and define any tags (this is optional). Choose Next: Review. Enter a Name for the policy and description, as shown in the image.
6. Choose **Create policy**. The Console displays an alert when the policy has been saved. You can find it in the list of Policies.

7. Choose **Roles** (under Access management) on the IAM Console.

8. Choose **Create role**.

9. On the Select trusted entity page, choose the **AWS service** tile, and then choose **RDS** to open the selector.

10. Choose **RDS – Add Role to Database**.
11. Choose **Next**. On the Add permissions page, find the policy that you created in the previous step and choose it from among those listed. Choose **Next**

12. **Next: Review**. Enter a name for the IAM role and a description.

14. Navigate to the AWS Region where your Aurora PostgreSQL DB cluster is located.

15. In the navigation pane, choose **Databases**, and then choose the Aurora PostgreSQL DB cluster that you want to use with Amazon Comprehend.

16. Choose the **Connectivity & security** tab and scroll to find the **Manage IAM roles** section of the page. From the **Add IAM roles to this cluster** selector, choose the role that you created in the previous steps. In the **Feature** selector, choose Comprehend, and then choose **Add role**.

The role (with its policy) are associated with the Aurora PostgreSQL DB cluster. When the process completes, the role is listed in the Current IAM roles for this cluster listing, as shown following.
The IAM setup for Amazon Comprehend is complete. Continue setting up your Aurora PostgreSQL to work with Aurora machine learning by installing the extension as detailed in Installing the Aurora machine learning extension (p. 1563)

**Setting up Aurora PostgreSQL to use Amazon SageMaker**

Before you can create the IAM policy and role for your Aurora PostgreSQL DB cluster, you need to have your SageMaker model setup and your endpoint available.

**To set up your Aurora PostgreSQL DB cluster to use SageMaker**

1. Sign in to the AWS Management Console and open the IAM console at [https://console.aws.amazon.com/iam/](https://console.aws.amazon.com/iam/).

2. Choose Policies (under Access management) on the AWS Identity and Access Management (IAM) Console menu, and then choose Create policy. In the Visual editor, choose SageMaker for the Service. For Actions, open the Read selector (under Access level) and choose InvokeEndpoint. When you this, a warning icon displays.

3. Open the Resources selector and choose the Add ARN to restrict access link under the Specify endpoint resource ARN for the InvokeEndpoint action.

4. Enter the AWS Region of your SageMaker resources and the name of your endpoint. Your AWS account is prefilled.
5. Choose Add to save. Choose Next: Tags and Next: Review to get to the last page of the policy creation process.

6. Enter a Name and Description for this policy, and then choose Create policy. The policy is created and is added to the Policies list. You see an alert in the Console as this occurs.

7. On the IAM Console, choose Roles.

8. Choose Create role.

9. On the Select trusted entity page, choose the AWS service tile, and then choose RDS to open the selector.

10. Choose RDS – Add Role to Database.

11. Choose Next. On the Add permissions page, find the policy that you created in the previous step and choose it from among those listed. Choose Next

12. Next: Review. Enter a name for the IAM role and a description.

14. Navigate to the AWS Region where your Aurora PostgreSQL DB cluster is located.

15. In the navigation pane, choose Databases, and then choose the Aurora PostgreSQL DB cluster that you want to use with SageMaker.

16. Choose the Connectivity & security tab and scroll to find the Manage IAM roles section of the page. From the Add IAM roles to this cluster selector, choose the role that you created in the previous steps. In the Feature selector, choose SageMaker, and then choose Add role.

The role (with its policy) are associated with the Aurora PostgreSQL DB cluster. When the process completes, the role is listed in the Current IAM roles for this cluster listing.
The IAM setup for SageMaker is complete. Continue setting up your Aurora PostgreSQL to work with Aurora machine learning by installing the extension as detailed in [Installing the Aurora machine learning extension](p. 1563).

### Setting up Aurora PostgreSQL to use Amazon S3 for SageMaker (Advanced)

To use SageMaker with your own models rather than using the pre-built components provided by SageMaker, you need to set up an Amazon Simple Storage Service (Amazon S3) bucket for Aurora PostgreSQL DB cluster to use. This is an advanced topic, and isn't fully documented in this *Amazon Aurora User Guide*. The general process is the same as for integrating support for SageMaker, as follows.

1. Create the IAM policy and role for Amazon S3.
2. Add the IAM role and the Amazon S3 import or export as a feature on the Connectivity & security tab of your Aurora PostgreSQL DB cluster.
3. Add the ARN of the role to your custom DB cluster parameter group for your Aurora DB cluster.

For basic usage information, see [Exporting data to Amazon S3 for SageMaker model training (Advanced)](p. 1568).

### Installing the Aurora machine learning extension

The Aurora machine learning extension, `aws_ml`, provides two functions that you can use to invoke Amazon Comprehend and SageMaker services. Installing the extension on your Aurora PostgreSQL DB cluster also creates an administrative role for the feature.

**Note**

Using these functions depends on having the IAM setup for the Aurora machine learning service (Amazon Comprehend, SageMaker) complete, as detailed in [Setting up your Aurora PostgreSQL DB cluster to use Aurora machine learning](p. 1557).

- `aws_comprehend.detect_sentiment` – You use this function to apply sentiment analysis to text stored in the database on your Aurora PostgreSQL DB cluster.
- `aws_sagemaker.invoke_endpoint` – You use this function in your SQL code to communicate with the SageMaker endpoint from your cluster.

### To install the Aurora machine learning extension in your Aurora PostgreSQL DB cluster

- Use `psql` to connect to the writer instance of your Aurora PostgreSQL DB cluster. Connect to the specific database in which to install the `aws_ml` extension.

  ```sql
  psql --host=cluster-instance-1.11112223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
  ```

  ```sql
  labdb=> CREATE EXTENSION IF NOT EXISTS aws_ml CASCADE;
  NOTICE:  installing required extension "aws_commons"
  CREATE EXTENSION
  labdb=>
  ```

Installing the `aws_ml` extension also creates the `aws_ml` administrative role and two new schemas, as follows.

- `aws_comprehend` – Schema for the Amazon Comprehend service and source of the `detect_sentiment` function (`aws_comprehend.detect_sentiment`).
- `aws_sagemaker` – Schema for the SageMaker service and source of the `invoke_endpoint` function (`aws_sagemaker.invoke_endpoint`).
The rds_superuser role is granted the aws_ml administrative role and is made the OWNER of these two Aurora machine learning schemas. To allow other database users to access the Aurora machine learning functions, the rds_superuser needs to grant EXECUTE privileges on the Aurora machine learning functions. By default, EXECUTE privileges are revoked from PUBLIC on the functions in the two Aurora machine learning schemas.

In a multi-tenant database configuration, you can prevent tenants from accessing Aurora machine learning functions by using REVOKE USAGE on the specific Aurora machine learning schema that you want to protect.

### Using Amazon Comprehend with your Aurora PostgreSQL DB cluster

For Aurora PostgreSQL, Aurora machine learning provides the following Amazon Comprehend function for working with your text data. This function is available only after you install the aws_ml extension and complete all setup procedures. For more information, see Setting up your Aurora PostgreSQL DB cluster to use Aurora machine learning (p. 1557).

**aws_comprehend.detect_sentiment**

This function takes text as input and evaluates whether the text has a positive, negative, or neutral sentiment. It outputs this sentiment along with a confidence level for its evaluation. A summary of the function's documentation is as follows.

```
aws_comprehend.detect_sentiment(
    IN input_text varchar,
    IN language_code varchar,
    IN max_rows_per_batch int,
    OUT sentiment varchar,
    OUT confidence real)
```

The inputs and outputs of this function are as follows.

- **input_text** – The text to evaluate and to assign sentiment (negative, positive, neutral, mixed).
- **language_code** – The language of the input_text identified using the 2-letter ISO 639-1 identifier with regional subtag (as needed) or the ISO 639-2 three-letter code, as appropriate. For example, en is the code for English, zh is the code for simplified Chinese. For more information, see Supported languages in the Amazon Comprehend Developer Guide.
- **max_rows_per_batch** – The maximum number of rows per batch for batch-mode processing. For more information, see Understanding batch mode and Aurora machine learning functions (p. 1569).
- **sentiment** – The sentiment of the input text, identified as POSITIVE, NEGATIVE, NEUTRAL, or MIXED.
- **confidence** – The degree of confidence in the accuracy of the specified sentiment. Values range from 0.0 to 1.0.

In the following, you can find examples of how to use this function.

**Example Example: A simple query using Amazon Comprehend functions**

Here's an example of a simple query that invokes this function to assess customer satisfaction with your support team. Suppose you have a database table (support) that stores customer feedback after each request for help. This example query applies the aws_comprehend.detect_sentiment function to the text in the feedback column of the table and outputs the sentiment and the confidence level for that sentiment. This query also outputs results in descending order.

```
SELECT feedback, s.sentiment, s.confidence
```
FROM support, aws_comprehend.detect_sentiment(feedback, 'en') s
ORDER BY s.confidence DESC;

<table>
<thead>
<tr>
<th>feedback</th>
<th>sentiment</th>
<th>confidence</th>
</tr>
</thead>
<tbody>
<tr>
<td>Thank you for the excellent customer support!</td>
<td>POSITIVE</td>
<td>0.999771</td>
</tr>
<tr>
<td>The latest version of this product stinks!</td>
<td>NEGATIVE</td>
<td>0.999184</td>
</tr>
<tr>
<td>Your support team is just awesome! I am blown away.</td>
<td>POSITIVE</td>
<td>0.997774</td>
</tr>
<tr>
<td>Your product is too complex, but your support is great.</td>
<td>MIXED</td>
<td>0.957958</td>
</tr>
<tr>
<td>Your support tech helped me in fifteen minutes.</td>
<td>POSITIVE</td>
<td>0.949491</td>
</tr>
<tr>
<td>My problem was never resolved!</td>
<td>NEGATIVE</td>
<td>0.920644</td>
</tr>
<tr>
<td>When will the new version of this product be released?</td>
<td>NEUTRAL</td>
<td>0.902706</td>
</tr>
<tr>
<td>I cannot stand that chatbot.</td>
<td>NEGATIVE</td>
<td>0.895219</td>
</tr>
<tr>
<td>Your support tech talked down to me.</td>
<td>NEGATIVE</td>
<td>0.868598</td>
</tr>
<tr>
<td>It took me way too long to get a real person.</td>
<td>NEGATIVE</td>
<td>0.481805</td>
</tr>
</tbody>
</table>

(10 rows)

To avoid being charged for sentiment detection more than once per table row, you can materialize the results. Do this on the rows of interest. For example, the clinician's notes are being updated so that only those in French (fr) use the sentiment detection function.

UPDATE clinician_notes
SET sentiment = (aws_comprehend.detect_sentiment (french_notes, 'fr')).sentiment,
   confidence = (aws_comprehend.detect_sentiment (french_notes, 'fr')).confidence
WHERE
   clinician_notes.french_notes IS NOT NULL AND
   LENGTH(TRIM(clinician_notes.french_notes)) > 0 AND
   clinician_notes.sentiment IS NULL;

For more information on optimizing your function calls, see Performance considerations for using Aurora machine learning with Aurora PostgreSQL (p. 1568).

Using SageMaker with your Aurora PostgreSQL DB cluster

After setting up your SageMaker environment and integrating with Aurora PostgreSQL as outlined in Setting up Aurora PostgreSQL to use Amazon SageMaker (p. 1561), you can invoke operations by using the aws_sagemaker.invoke_endpoint function. The aws_sagemaker.invoke_endpoint function connects only to a model endpoint in the same AWS Region. If your database instance has replicas in multiple AWS Regions be sure that you setup and deploy each SageMaker model to every AWS Region.

Calls to aws_sagemaker.invoke_endpoint are authenticated using the IAM role that you set up to associated your Aurora PostgreSQL DB cluster with the SageMaker service and the endpoint that you provided during the setup process. SageMaker model endpoints are scoped to an individual account and are not public. The endpoint_name URL doesn't contain the account ID. SageMaker determines the account ID from the authentication token that is supplied by the SageMaker IAM role of the database instance.

aws_sagemaker.invoke_endpoint

This function takes the SageMaker endpoint as input and the number of rows that should be processed as a batch. It also takes as input the various parameters expected by the SageMaker model endpoint. This function's reference documentation is as follows.

aws_sagemaker.invoke_endpoint(
   IN endpoint_name varchar,
   IN max_rows_per_batch int,
   VARIADIC model_input "any",
   OUT model_output varchar
)
The inputs and outputs of this function are as follows.

- **endpoint_name** – An endpoint URL that is AWS Region-independent.
- **max_rows_per_batch** – The maximum number of rows per batch for batch-mode processing. For more information, see Understanding batch mode and Aurora machine learning functions (p. 1569).
- **model_input** – One or more input parameters for the model. These can be any data type needed by the SageMaker model. PostgreSQL allows you to specify up to 100 input parameters for a function. Array data types must be one-dimensional, but can contain as many elements as are expected by the SageMaker model. The number of inputs to a SageMaker model is limited only by the SageMaker 6 MB message size limit.
- **model_output** – The SageMaker model's output as text.

**Creating a user-defined function to invoke a SageMaker model**

Create a separate user-defined function to call `aws_sagemaker.invoke_endpoint` for each of your SageMaker models. Your user-defined function represents the SageMaker endpoint hosting the model. The `aws_sagemaker.invoke_endpoint` function runs within the user-defined function. User-defined functions provide many advantages:

- You can give your SageMaker model its own name instead of only calling `aws_sagemaker.invoke_endpoint` for all of your SageMaker models.
- You can specify the model endpoint URL in just one place in your SQL application code.
- You can control EXECUTE privileges to each Aurora machine learning function independently.
- You can declare the model input and output types using SQL types. SQL enforces the number and type of arguments passed to your SageMaker model and performs type conversion if necessary. Using SQL types will also translate SQL NULL to the appropriate default value expected by your SageMaker model.
- You can reduce the maximum batch size if you want to return the first few rows a little faster.

To specify a user-defined function, use the SQL data definition language (DDL) statement CREATE FUNCTION. When you define the function, you specify the following:

- The input parameters to the model.
- The specific SageMaker endpoint to invoke.
- The return type.

The user-defined function returns the inference computed by the SageMaker endpoint after running the model on the input parameters. The following example creates a user-defined function for an SageMaker model with two input parameters.

```sql
CREATE FUNCTION classify_event (IN arg1 INT, IN arg2 DATE, OUT category INT) AS $$
SELECT aws_sagemaker.invoke_endpoint (  
    'sagemaker_model_endpoint_name',  
    NULL,  
    arg1, arg2  
)::INT  
$$ LANGUAGE SQL PARALLEL SAFE COST 5000;
```

Note the following:
The `aws_sagemaker.invoke_endpoint` function input can be one or more parameters of any data type.

This example uses an INT output type. If you cast the output from a `varchar` type to a different type, then it must be cast to a PostgreSQL built-in scalar type such as `INTEGER`, `REAL`, `FLOAT`, or `NUMERIC`. For more information about these types, see Data types in the PostgreSQL documentation.

Specify `PARALLEL SAFE` to enable parallel query processing. For more information, see Improving response times with parallel query processing (p. 1570).

Specify `COST 5000` to estimate the cost of running the function. Use a positive number giving the estimated run cost for the function, in units of `cpu_operator_cost`.

### Passing an array as input to a SageMaker model

The `aws_sagemaker.invoke_endpoint` function can have up to 100 input parameters, which is the limit for PostgreSQL functions. If the SageMaker model requires more than 100 parameters of the same type, pass the model parameters as an array.

The following example defines a function that passes an array as input to the SageMaker regression model. The output is cast to a `REAL` value.

```sql
CREATE FUNCTION regression_model (params REAL[], OUT estimate REAL) AS $$
SELECT aws_sagemaker.invoke_endpoint (  
    'sagemaker_model_endpoint_name',  
    NULL,  
    params  
) :: REAL
$$ LANGUAGE SQL PARALLEL SAFE COST 5000;
```

### Specifying batch size when invoking a SageMaker model

The following example creates a user-defined function for a SageMaker model that sets the batch size default to NULL. The function also allows you to provide a different batch size when you invoke it.

```sql
CREATE FUNCTION classify_event (IN event_type INT, IN event_day DATE, IN amount REAL, -- model inputs  
max_rows_per_batch INT DEFAULT NULL,  -- optional batch size limit  
OUT category INT)                     -- model output  
AS $$
SELECT aws_sagemaker.invoke_endpoint (  
    'sagemaker_model_endpoint_name',  
    max_rows_per_batch,  
    event_type, event_day, COALESCE(amount, 0.0)  
) :: INT  
-- casts output to type INT
$$ LANGUAGE SQL PARALLEL SAFE COST 5000;
```

Note the following:

- Use the optional `max_rows_per_batch` parameter to provide control of the number of rows for a batch-mode function invocation. If you use a value of NULL, then the query optimizer automatically chooses the maximum batch size. For more information, see Understanding batch mode and Aurora machine learning functions (p. 1569).
- By default, passing NULL as a parameter's value is translated to an empty string before passing to SageMaker. For this example the inputs have different types.
- If you have a non-text input, or text input that needs to default to some value other than an empty string, use the `COALESCE` statement. Use `COALESCE` to translate NULL to the desired null replacement value in the call to `aws_sagemaker.invoke_endpoint`. For the amount parameter in this example, a NULL value is converted to 0.0.
**Invoking a SageMaker model that has multiple outputs**

The following example creates a user-defined function for a SageMaker model that returns multiple outputs. Your function needs to cast the output of the `aws_sagemaker.invoke_endpoint` function to a corresponding data type. For example, you could use the built-in PostgreSQL point type for (x,y) pairs or a user-defined composite type.

This user-defined function returns values from a model that returns multiple outputs by using a composite type for the outputs.

```sql
CREATE TYPE company_forecasts AS (
    six_month_estimated_return real,
    one_year_bankruptcy_probability float);

CREATE FUNCTION analyze_company (
    IN free_cash_flow NUMERIC(18, 6),
    IN debt NUMERIC(18, 6),
    IN max_rows_per_batch INT DEFAULT NULL,
    OUT prediction company_forecasts)
AS $$
    SELECT (aws_sagemaker.invoke_endpoint('endpt_name',
        max_rows_per_batch,free_cash_flow, debt))::company_forecasts;
$$ LANGUAGE SQL PARALLEL SAFE COST 5000;
```

For the composite type, use fields in the same order as they appear in the model output and cast the output of `aws_sagemaker.invoke_endpoint` to your composite type. The caller can extract the individual fields either by name or with PostgreSQL ".*" notation.

**Exporting data to Amazon S3 for SageMaker model training (Advanced)**

We recommend that you become familiar with Aurora machine learning and SageMaker by using the provided algorithms and examples rather than trying to train your own models. For more information, see [Get Started with Amazon SageMaker](#).

To train SageMaker models, you export data to an Amazon S3 bucket. The Amazon S3 bucket is used by SageMaker to train your model before it is deployed. You can query data from an Aurora PostgreSQL DB cluster and save it directly into text files stored in an Amazon S3 bucket. Then SageMaker consumes the data from the Amazon S3 bucket for training. For more about SageMaker model training, see [Train a model with Amazon SageMaker](#).

**Note**

When you create an Amazon S3 bucket for SageMaker model training or batch scoring, use `sagemaker` in the Amazon S3 bucket name. For more information, see [Specify a Amazon S3 Bucket to Upload Training Datasets and Store Output Data](#) in the Amazon SageMaker Developer Guide.

For more information about exporting your data, see [Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3](p. 1527).

**Performance considerations for using Aurora machine learning with Aurora PostgreSQL**

The Amazon Comprehend and SageMaker services do most of the work when invoked by an Aurora machine learning function. That means that you can scale those resources as needed, independently. For your Aurora PostgreSQL DB cluster, you can make your function calls as efficient as possible. Following, you can find some performance considerations to note when working with Aurora machine learning from Aurora PostgreSQL.
Understanding batch mode and Aurora machine learning functions

Typically, PostgreSQL runs functions one row at a time. Aurora machine learning can reduce this overhead by combining the calls to the external Aurora machine learning service for many rows into batches with an approach called batch-mode execution. In batch mode, Aurora machine learning receives the responses for a batch of input rows, and then delivers the responses back to the running query one row at a time. This optimization improves the throughput of your Aurora queries without limiting the PostgreSQL query optimizer.

Aurora automatically uses batch mode if the function is referenced from the SELECT list, a WHERE clause, or a HAVING clause. Note that top-level simple CASE expressions are eligible for batch-mode execution. Top-level searched CASE expressions are also eligible for batch-mode execution provided that the first WHEN clause is a simple predicate with a batch-mode function call.

Your user-defined function must be a LANGUAGE SQL function and should specify PARALLEL SAFE and COST 5000.

Function migration from the SELECT statement to the FROM clause

Usually, an aws_ml function that is eligible for batch-mode execution is automatically migrated by Aurora to the FROM clause.

The migration of eligible batch-mode functions to the FROM clause can be examined manually on a per-query level. To do this, you use EXPLAIN statements (and ANALYZE and VERBOSE) and find the "Batch Processing" information below each batch-mode Function Scan. You can also use EXPLAIN (with VERBOSE) without running the query. You then observe whether the calls to the function appear as a Function Scan under a nested loop join that was not specified in the original statement.

In the following example, the nested loop join operator in the plan shows that Aurora migrated the anomaly_score function. It migrated this function from the SELECT list to the FROM clause, where it's eligible for batch-mode execution.

```
EXPLAIN (VERBOSE, COSTS false)
SELECT anomaly_score(ts.R.description) from ts.R;
QUERY PLAN
-------------------------------------------------------------
Nested Loop
  Output: anomaly_score((r.description)::text)
    ->  Seq Scan on ts.r
      Output: r.id, r.description, r.score
    ->  Function Scan on public.anomaly_score
      Output: anomaly_score.anomaly_score
      Function Call: anomaly_score((r.description)::text)
```

To disable batch-mode execution, set the apg_enable_function_migration parameter to false. This prevents the migration of aws_ml functions from the SELECT to the FROM clause. The following shows how.

```
SET apg_enable_function_migration = false;
```

The apg_enable_function_migration parameter is a Grand Unified Configuration (GUC) parameter that is recognized by the Aurora PostgreSQL apg_plan_mgmt extension for query plan
management. To disable function migration in a session, use query plan management to save the resulting plan as an approved plan. At runtime, query plan management enforces the approved plan with its \texttt{apg_enable_function_migration} setting. This enforcement occurs regardless of the \texttt{apg_enable_function_migration} GUC parameter setting. For more information, see Managing query execution plans for Aurora PostgreSQL (p. 1573).

**Using the \texttt{max\_rows\_per\_batch} parameter**

Both the \texttt{aws\_comprehend\_detect\_sentiment} and the \texttt{aws\_sagemaker\_invoke\_endpoint} functions have a \texttt{max\_rows\_per\_batch} parameter. This parameter specifies the number of rows that can be sent to the Aurora machine learning service. The larger the dataset processed by your function, the larger you can make the batch size.

Batch-mode functions improve efficiency by building batches of rows that spread the cost of the Aurora machine learning function calls over a large number of rows. However, if a \texttt{SELECT} statement finishes early due to a \texttt{LIMIT} clause, then the batch can be constructed over more rows than the query uses. This approach can result in additional charges to your AWS account. To gain the benefits of batch-mode execution but avoid building batches that are too large, use a smaller value for the \texttt{max\_rows\_per\_batch} parameter in your function calls.

If you do an \texttt{EXPLAIN (VERBOSE, ANALYZE)} of a query that uses batch-mode execution, you see a FunctionScan operator that is below a nested loop join. The number of loops reported by \texttt{EXPLAIN} equals the number of times a row was fetched from the FunctionScan operator. If a statement uses a \texttt{LIMIT} clause, the number of fetches is consistent. To optimize the size of the batch, set the \texttt{max\_rows\_per\_batch} parameter to this value. However, if the batch-mode function is referenced in a predicate in the \texttt{WHERE} clause or \texttt{HAVING} clause, then you probably can't know the number of fetches in advance. In this case, use the loops as a guideline and experiment with \texttt{max\_rows\_per\_batch} to find a setting that optimizes performance.

**Verifying batch-mode execution**

To see if a function ran in batch mode, use \texttt{EXPLAIN ANALYZE}. If batch-mode execution was used, then the query plan will include the information in a "Batch Processing" section.

```
EXPLAIN ANALYZE SELECT user-defined-function();
Batch Processing: num batches=1 avg/min/max batch size=3333.000/3333.000/3333.000
avg/min/max batch call time=146.273/146.273/146.273
```

In this example, there was 1 batch that contained 3,333 rows, which took 146.273 ms to process. The "Batch Processing" section shows the following:

- How many batches there were for this function scan operation
- The batch size average, minimum, and maximum
- The batch execution time average, minimum, and maximum

Typically the final batch is smaller than the rest, which often results in a minimum batch size that is much smaller than the average.

To return the first few rows more quickly, set the \texttt{max\_rows\_per\_batch} parameter to a smaller value.

To reduce the number of batch mode calls to the ML service when you use a \texttt{LIMIT} in your user-defined function, set the \texttt{max\_rows\_per\_batch} parameter to a smaller value.

**Improving response times with parallel query processing**

To get results as fast as possible from a large number of rows, you can combine parallel query processing with batch mode processing. You can use parallel query processing for \texttt{SELECT}, \texttt{CREATE TABLE AS SELECT}, and \texttt{CREATE MATERIALIZED VIEW} statements.
Note

PostgreSQL doesn't yet support parallel query for data manipulation language (DML) statements.

Parallel query processing occurs both within the database and within the ML service. The number of cores in the instance class of the database limits the degree of parallelism that can be used when running a query. The database server can construct a parallel query execution plan that partitions the task among a set of parallel workers. Then each of these workers can build batched requests containing tens of thousands of rows (or as many as are allowed by each service).

The batched requests from all of the parallel workers are sent to the SageMaker endpoint. The degree of parallelism that the endpoint can support is constrained by the number and type of instances that support it. For $K$ degrees of parallelism, you need a database instance class that has at least $K$ cores. You also need to configure the SageMaker endpoint for your model to have $K$ initial instances of a sufficiently high-performing instance class.

To use parallel query processing, you can set the `parallel_workers` storage parameter of the table that contains the data that you plan to pass. You set `parallel_workers` to a batch-mode function such as `aws_comprehend.detect_sentiment`. If the optimizer chooses a parallel query plan, the AWS ML services can be called both in batch and in parallel.

You can use the following parameters with the `aws_comprehend.detect_sentiment` function to get a plan with four-way parallelism. If you change either of the following two parameters, you must restart the database instance for the changes to take effect:

```sql
-- SET max_worker_processes to 8; -- default value is 8
-- SET max_parallel_workers to 8; -- not greater than max_worker_processes
SET max_parallel_workers_per_gather to 4; -- not greater than max_parallel_workers

-- You can set the parallel_workers storage parameter on the table that the data
-- for the Aurora machine learning function is coming from in order to manually override
-- the degree of
-- parallelism that would otherwise be chosen by the query optimizer
--
ALTER TABLE yourTable SET (parallel_workers = 4);

-- Example query to exploit both batch-mode execution and parallel query
EXPLAIN (verbose, analyze, buffers, hashes)
SELECT aws_comprehend.detect_sentiment(description, 'en')).* FROM yourTable WHERE id < 100;
```

For more information about controlling parallel query, see [Parallel plans](https://postgresdoc.com/parallel_plans) in the PostgreSQL documentation.

**Using materialized views and materialized columns**

When you invoke an AWS service such as SageMaker or Amazon Comprehend from your database, your account is charged according to the pricing policy of that service. To minimize charges to your account, you can materialize the result of calling the AWS service into a materialized column so that the AWS service is not called more than once per input row. If desired, you can add a `materializedAt` timestamp column to record the time at which the columns were materialized.

The latency of an ordinary single-row `INSERT` statement is typically much less than the latency of calling a batch-mode function. Thus, you might not be able to meet the latency requirements of your application if you invoke the batch-mode function for every single-row `INSERT` that your application performs. To materialize the result of calling an AWS service into a materialized column, high-performance applications generally need to populate the materialized columns. To do this, they periodically issue an `UPDATE` statement that operates on a large batch of rows at the same time.
UPDATE takes a row-level lock that can impact a running application. So you might need to use 
SELECT ... FOR UPDATE SKIP LOCKED, or use MATERIALIZED VIEW.

Analytic queries that operate on a large number of rows in real time can combine batch-mode 
materialization with real-time processing. To do this, these queries assemble a UNION ALL of the pre- 
materialized results with a query over the rows that don’t yet have materialized results. In some cases, 
such a UNION ALL is needed in multiple places, or the query is generated by a third-party application. 
If so, you can create a VIEW to encapsulate the UNION ALL operation so this detail isn’t exposed to the 
rest of the SQL application.

You can use a materialized view to materialize the results of an arbitrary SELECT statement at a 
snapshot in time. You can also use it to refresh the materialized view at any time in the future. Currently 
PostgreSQL doesn’t support incremental refresh, so each time the materialized view is refreshed the 
materialized view is fully recomputed.

You can refresh materialized views with the CONCURRENTLY option, which updates the contents of the 
materialized view without taking an exclusive lock. Doing this allows a SQL application to read from the 
materialized view while it's being refreshed.

**Monitoring Aurora machine learning**

You can monitor the aws_ml functions by setting the track_functions parameter in your custom DB 
cluster parameter group to all. By default, this parameter is set to pl which means that only procedure- 
language functions are tracked. By changing this to all, the aws_ml functions are also tracked. For 
more information, see Run-time Statistics in the PostgreSQL documentation.

For information about monitoring the performance of the SageMaker operations called from Aurora 
machine learning functions, see Monitor Amazon SageMaker in the Amazon SageMaker Developer Guide.

With track_functions set to all, you can query the pg_stat_user_functions view to get 
statistics about the functions that you define and use to invoke Aurora machine learning services. For 
each function, the view provides the number of calls, total_time, and self_time.

To view the statistics for the aws_sagemaker.invoke_endpoint and the 
aws_comprehend.detect_sentiment functions, you can filter results by schema name using the 
following query.

```
SELECT * FROM pg_stat_user_functions
    WHERE schemaname
    LIKE 'aws_%';
```

To clear the statistics, do as follows.

```
SELECT pg_stat_reset();
```

You can get the names of your SQL functions that call the aws_sagemaker.invoke_endpoint 
function by querying the PostgreSQL pg_proc system catalog. This catalog stores information about 
functions, procedures, and more. For more information, see pg_proc in the PostgreSQL documentation. 
Following is an example of querying the table to get the names of functions (proname) whose source 
(prosrc) includes the text invoke_endpoint.

```
SELECT proname FROM pg_proc WHERE prosrc LIKE '%invoke_endpoint%';
```
Managing query execution plans for Aurora PostgreSQL

Aurora PostgreSQL query plan management is an optional feature that you can use with your Amazon Aurora PostgreSQL-Compatible Edition DB cluster. This feature is packaged as the apg_plan_mgmt extension that you can install in your Aurora PostgreSQL DB cluster. Query plan management allows you to manage the query execution plans generated by the optimizer for your SQL applications. The apg_plan_mgmt AWS extension builds on the native query processing functionality of the PostgreSQL database engine.

Following, you can find information about Aurora PostgreSQL query plan management features, how to set it up, and how to use it with your Aurora PostgreSQL DB cluster. Before you get started, we recommend that you review any release notes for the specific version of the apg_plan_mgmt extension available for your Aurora PostgreSQL version. For more information, see Aurora PostgreSQL apg_plan_mgmt extension versions in the Release Notes for Aurora PostgreSQL.

Topics
- Overview of Aurora PostgreSQL query plan management (p. 1573)

Overview of Aurora PostgreSQL query plan management

Aurora PostgreSQL query plan management is designed to ensure plan stability regardless of changes to the database that might cause query plan regression. Query plan regression occurs when the optimizer chooses a sub-optimal plan for a given SQL statement after system or database changes. Changes to statistics, constraints, environment settings, query parameter bindings, and upgrades to the PostgreSQL database engine can all cause plan regression.

With Aurora PostgreSQL query plan management, you can control how and when query execution plans change. The benefits of Aurora PostgreSQL query plan management include the following.

- Improve plan stability by forcing the optimizer to choose from a small number of known, good plans.
- Optimize plans centrally and then distribute the best plans globally.
- Identify indexes that aren't used and assess the impact of creating or dropping an index.
- Automatically detect a new minimum-cost plan discovered by the optimizer.
- Try new optimizer features with less risk, because you can choose to approve only the plan changes that improve performance.

You can use the tools provided by query plan management proactively, to specify the best plan for certain queries. Or you can use query plan management to react to changing circumstances and
avoid plan regressions. For more information, see Best practices for Aurora PostgreSQL query plan management (p. 1578).

Topics
- Supported SQL statements (p. 1574)
- Query plan management limitations (p. 1574)
- Query plan management terminology (p. 1575)
- Aurora PostgreSQL query plan management versions (p. 1575)
- Turning on Aurora PostgreSQL query plan management (p. 1576)
- Upgrading Aurora PostgreSQL query plan management (p. 1577)
- Turning off Aurora PostgreSQL query plan management (p. 1578)

Supported SQL statements

Query plan management supports the following types of SQL statements.

- Any SELECT, INSERT, UPDATE, or DELETE statement, regardless of complexity.
- Prepared statements. For more information, see PREPARE in the PostgreSQL documentation.
- Dynamic statements, including those run in immediate-mode. For more information, see Dynamic SQL and EXECUTE IMMEDIATE in PostgreSQL documentation.
- Embedded SQL commands and statements. For more information, see Embedded SQL Commands in the PostgreSQL documentation.
- Statements inside named functions. For more information, see CREATE FUNCTION in the PostgreSQL documentation.
- Statements containing temp tables.
- Statements inside procedures and DO-blocks.

You can use query plan management with EXPLAIN in manual mode to capture a plan without actually running it. For more information, see Analyzing the optimizer's chosen plan (p. 1584). To learn more about query plan management’s modes (manual, automatic), see Capturing Aurora PostgreSQL execution plans (p. 1581).

Aurora PostgreSQL query plan management supports all PostgreSQL language features, including partitioned tables, inheritance, row-level security, and recursive common table expressions (CTEs). To learn more about these PostgreSQL language features, see Table Partitioning, Row Security Policies, and WITH Queries (Common Table Expressions) and other topics in the PostgreSQL documentation.

For information about different versions of the Aurora PostgreSQL query plan management feature, see Aurora PostgreSQL apg_plan_mgmt extension versions in the Release Notes for Aurora PostgreSQL.

Query plan management limitations

The current release of Aurora PostgreSQL query plan management has the following limitations.

- Plans aren't captured for statements that reference system relations – Statements that reference system relations, such as pg_class, aren't captured. This is by design, to prevent a large number of system-generated plans that are used internally from being captured. This also applies to system tables inside views.
- Larger DB instance class might be needed for your Aurora PostgreSQL DB cluster – Depending on the workload, query plan management might need a DB instance class that has more than 2 vCPUs. The number of max_worker_processes is limited by the DB instance class size. The number of
max_worker_processes provided by a 2-vCPU DB instance class (db.t3.medium, for example) might not be sufficient for a given workload. We recommend that you choose a DB instance class with more than 2 vCPUs for your Aurora PostgreSQL DB cluster if you use query plan management.

When the DB instance class can't support the workload, query plan management raises an error message such as the following.

```
WARNING: could not register plan insert background process
HINT: You may need to increase max_worker_processes.
```

In this case, you should scale up your Aurora PostgreSQL DB cluster to a DB instance class size with more memory. For more information, see Supported DB engines for DB instance classes (p. 86).

- **Plans already stored in sessions aren't affected** – Query plan management provides a way to influence query plans without changing the application code. However, when a generic plan is already stored in an existing session and if you want to change its query plan, then you must first set `plan_cache_mode` to `force_custom_plan` in the DB cluster parameter group.

- `queryid` in `apg_plan_mgmt.dba_plans` and `pg_stat_statements` can diverge when:
  - Objects are dropped and recreated after storing in `apg_plan_mgmt.dba_plans`.
  - `apg_plan_mgmt.plans` table is imported from another cluster.

For information about different versions of the Aurora PostgreSQL query plan management feature, see Aurora PostgreSQL `apg_plan_mgmt` extension versions in the Release Notes for Aurora PostgreSQL.

**Query plan management terminology**

The following terms are used throughout this topic.

**managed statement**

A SQL statement captured by the optimizer under query plan management. A managed statement has one or more query execution plans stored in the `apg_plan_mgmt.dba_plans` view.

**plan baseline**

The set of approved plans for a given managed statement. That is, all the plans for the managed statement that have "Approved" for their `status` column in the `dba_plan` view.

**plan history**

The set of all captured plans for a given managed statement. The plan history contains all plans captured for the statement, regardless of status.

**query plan regression**

The case when the optimizer chooses a less optimal plan than it did before a given change to the database environment, such as a new PostgreSQL version or changes to statistics.

**Aurora PostgreSQL query plan management versions**

Query plan management is supported by all currently available Aurora PostgreSQL releases. For more information, see the list of Amazon Aurora PostgreSQL updates in the Release Notes for Aurora PostgreSQL.

Query plan management functionality is added to your Aurora PostgreSQL DB cluster when you install the `apg_plan_mgmt` extension. Different versions of Aurora PostgreSQL support different versions of the `apg_plan_mgmt` extension. We recommend that you upgrade the query plan management extension to the latest release for your version of Aurora PostgreSQL.
Note
For release notes for each apg_plan_mgmt extension versions, see Aurora PostgreSQL apg_plan_mgmt extension versions in the Release Notes for Aurora PostgreSQL.

You can identify the version running on your cluster by connecting to an instance using psql and using the metacommand \dx to list extensions as shown following.

```
labdb=> \dx
List of installed extensions
Name      | Version |    Schema     |                            Description
---------------+---------+---------------+-------------------------------------------------------------------
               +-------------------------------------------------------------------
apg_plan_mgmt | 1.0     | apg_plan_mgmt | Amazon Aurora with PostgreSQL compatibility Query Plan Management
plpgsql       | 1.0     | pg_catalog    | PL/pgSQL procedural language
(2 rows)
```

The output shows that this cluster is using 1.0 version of the extension. Only certain apg_plan_mgmt versions are available for a given Aurora PostgreSQL version. In some cases, you might need to upgrade the Aurora PostgreSQL DB cluster to a new minor release or apply a patch so that you can upgrade to the most recent version of query plan management. The apg_plan_mgmt version 1.0 shown in the output is from an Aurora PostgreSQL version 10.17 DB cluster, which doesn't have a newer version of apg_plan_mgmt available. In this case, the Aurora PostgreSQL DB cluster should be upgraded to a more recent version of PostgreSQL.

For more information about upgrading your Aurora PostgreSQL DB cluster to a new version of PostgreSQL, see Amazon Aurora PostgreSQL updates (p. 1780).

To learn how to upgrade the apg_plan_mgmt extension, see Upgrading Aurora PostgreSQL query plan management (p. 1577).

Turning on Aurora PostgreSQL query plan management

Setting up query plan management for your Aurora PostgreSQL DB cluster involves installing an extension and changing several DB cluster parameter settings. You need rds_superuser permissions to install the apg_plan_mgmt extension and to turn on the feature for the Aurora PostgreSQL DB cluster.

Installing the extension creates a new role, apg_plan_mgmt. This role allows database users to view, manage, and maintain query plans. As an administrator with rds_superuser privileges, be sure to grant the apg_plan_mgmt role to database users as needed.

Only users with the rds_superuser role can complete the following procedure. The rds_superuser is required for creating the apg_plan_mgmt extension and its apg_plan_mgmt role. Users must be granted the apg_plan_mgmt role to administer the apg_plan_mgmt extension.

To turn on query plan management for your Aurora PostgreSQL DB cluster

The following steps turn on query plan management for all SQL statements that get submitted to the Aurora PostgreSQL DB cluster. This is known as automatic mode. To learn more about the difference between modes, see Capturing Aurora PostgreSQL execution plans (p. 1581).

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Create a custom DB cluster parameter group for your Aurora PostgreSQL DB cluster. You need to change certain parameters to activate query plan management and to set its behavior. For more information, see Creating a DB parameter group (p. 226).
3. Open the custom DB cluster parameter group and set the rds.enable_plan_management parameter to 1, as shown in the following image.
Overview of Aurora PostgreSQL query plan management

For more information, see Modifying parameters in a DB cluster parameter group (p. 219).

4. Create a custom DB parameter group that you can use to set query plan parameters at the instance level. For more information, see Creating a DB cluster parameter group (p. 216).

5. Modify the writer instance of the Aurora PostgreSQL DB cluster to use the custom DB parameter group. For more information, see Modifying a DB instance in a DB cluster (p. 270).

6. Modify the Aurora PostgreSQL DB cluster to use the custom DB parameter group. For more information, see Modifying the DB cluster by using the console, CLI, and API (p. 269).

7. Reboot your DB instance to enable the custom parameter group settings.

8. Connect to your Aurora PostgreSQL DB cluster's DB instance endpoint using psql or pgAdmin. The following example uses the default postgres account for the rds_superuser role.

```
psql --host=cluster-instance-1.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=my-db
```

9. Create the `apg_plan_mgmt` extension for your DB instance, as shown following.

```
labdb=> CREATE EXTENSION apg_plan_mgmt;
CREATE EXTENSION
```

**Tip**
Install the `apg_plan_mgmt` extension in the template database for your application. The default template database is named `template1`. To learn more, see Template Databases in the PostgreSQL documentation.

10. Change the `apg_plan_mgmt.capture_plan_baselines` parameter to `automatic`. This setting causes the optimizer to generate plans for every SQL statement that is either planned or executed two or more times.

**Note**
Query plan management also has a `manual` mode that you can use for specific SQL statements. To learn more, see Capturing Aurora PostgreSQL execution plans (p. 1581).

11. Change the value of `apg_plan_mgmt.use_plan_baselines` parameter to "on." This parameter causes the optimizer to choose a plan for the statement from its plan baseline. To learn more, see Using Aurora PostgreSQL managed plans (p. 1584).

**Note**
You can modify the value of either of these dynamic parameters for the session without needing to reboot the instance.

When your query plan management set up is complete, be sure to grant the `apg_plan_mgmt` role to any database users that need to view, manage, or maintain query plans.

## Upgrading Aurora PostgreSQL query plan management

We recommend that you upgrade the query plan management extension to the latest release for your version of Aurora PostgreSQL.
1. Connect to the writer instance of your Aurora PostgreSQL DB cluster as a user that has `rds_superuser` privileges. If you kept the default name when you set up your instance, you connect as `postgres`. This example shows how to use `psql`, but you can also use `pgAdmin` if you prefer.

   ```
   psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   ```

2. Run the following query to upgrade the extension.

   ```
   ALTER EXTENSION apg_plan_mgmt UPDATE TO '2.1';
   ```

3. Use the `apg_plan_mgmt.validate_plans (p. 1603)` function to update the hashes of all plans. The optimizer validates all Approved, Unapproved, and Rejected plans to ensure that they're still viable plans for new version of the extension.

   ```
   SELECT apg_plan_mgmt.validate_plans('update_plan_hash');
   ```

   To learn more about using this function, see Validating plans (p. 1589).

4. Use the `apg_plan_mgmt.reload (p. 1601)` function to refresh any plans in the shared memory with the validated plans from the `dba_plans` view.

   ```
   SELECT apg_plan_mgmt.reload();
   ```

To learn more about all functions available for query plan management, see Function reference for Aurora PostgreSQL query plan management (p. 1597).

Turning off Aurora PostgreSQL query plan management

You can disable query plan management at any time by turning off the `apg_plan_mgmt.use_plan_baselines` and `apg_plan_mgmt.capture_plan_baselines`.

   ```
   labdb=> SET apg_plan_mgmt.use_plan_baselines = off;
   labdb=> SET apg_plan_mgmt.capture_plan_baselines = off;
   ```

Best practices for Aurora PostgreSQL query plan management

Query plan management lets you control how and when query execution plans change. As a DBA, your main goals when using QPM include preventing regressions when there are changes to your database, and controlling whether to allow the optimizer to use a new plan. In the following, you can find some recommended best practices for using query plan management. Proactive and reactive plan management approaches differ in how and when new plans get approved for use.

Contents

- Proactive plan management to help prevent performance regression (p. 1579)
  - Ensuring plan stability after a major version upgrade (p. 1579)
- Reactive plan management to detect and repair performance regressions (p. 1580)
Proactive plan management to help prevent performance regression

To prevent plan performance regressions from occurring, you evolve plan baselines by running a procedure that compares the performance of newly discovered plans to the performance of the existing baseline of Approved plans, and then automatically approves the fastest set of plans as the new baseline. In this way, the baseline of plans improves over time as faster plans are discovered.

1. In a development environment, identify the SQL statements that have the greatest impact on performance or system throughput. Then capture the plans for these statements as described in Manually capturing plans for specific SQL statements (p. 1582) and Automatically capturing plans (p. 1582).
2. Export the captured plans from the development environment and import them into the production environment. For more information, see Exporting and importing plans (p. 1591).
3. In production, run your application and enforce the use of approved managed plans. For more information, see Using Aurora PostgreSQL managed plans (p. 1584). While the application runs, also add new plans as the optimizer discovers them. For more information, see Automatically capturing plans (p. 1582).
4. Analyze the unapproved plans and approve those that perform well. For more information, see Evaluating plan performance (p. 1588).
5. While your application continues to run, the optimizer begins to use the new plans as appropriate.

Ensuring plan stability after a major version upgrade

Each major version of PostgreSQL includes enhancements and changes to the query optimizer that are designed to improve performance. However, query execution plans generated by the optimizer in earlier versions might cause performance regressions in newer upgraded versions. You can use query plan management to resolve these performance issues and to ensure plan stability after a major version upgrade.

The optimizer always uses a minimum-cost Approved plan, even if more than one Approved plan for the same statement exists. After an upgrade the optimizer might discover new plans but they will be saved as Unapproved plans. These plans are performed only if approved using the reactive style of plan management with the unapproved_plan_execution_threshold parameter. You can maximize plan stability using the proactive style of plan management with the evolve_plan_baselines parameter. This compares the performance of the new plans to the old plans and approves or rejects plans that are at least 10% faster than the next best plan.

After upgrading, you can use the evolve_plan_baselines function to compare plan performance before and after the upgrade using your query parameter bindings. The following steps assume that you have been using approved managed plans in your production environment, as detailed in Using Aurora PostgreSQL managed plans (p. 1584).

1. Before upgrading, run your application with the query plan manager running. While the application runs, add new plans as the optimizer discovers them. For more information, see Automatically capturing plans (p. 1582).
2. Evaluate each plan's performance. For more information, see Evaluating plan performance (p. 1588).
3. After upgrading, analyze your approved plans again using the evolve_plan_baselines function. Compare performance before and after using your query parameter bindings. If the new plan is fast, you can add it to your approved plans. If it's faster than another plan for the same parameter bindings, then you can mark the slower plan as Rejected.

For more information, see Approving better plans (p. 1588). For reference information about this function, see apg_plan_mgmt.evolve_plan_baselines (p. 1598).
For more information, see Ensuring consistent performance after major version upgrades with Amazon Aurora PostgreSQL-Compatible Edition Query Plan Management.

**Note**
When you perform a major version upgrade using logical replication or AWS DMS, make sure that you replicate the `apg_plan_mgmt` schema to ensure existing plans are copied to the upgraded instance. For more information on logical replication, see Using logical replication to perform a major version upgrade for Aurora PostgreSQL (p. 1497).

**Reactive plan management to detect and repair performance regressions**

By monitoring your application as it runs, you can detect plans that cause performance regressions. When you detect regressions, you manually reject or fix the bad plans by following these steps:

1. While your application runs, enforce the use of managed plans and automatically add newly discovered plans as unapproved. For more information, see Using Aurora PostgreSQL managed plans (p. 1584) and Automatically capturing plans (p. 1582).
3. When you discover a plan regression, set the plan's status to rejected. The next time the optimizer runs the SQL statement, it automatically ignores the rejected plan and uses a different approved plan instead. For more information, see Rejecting or disabling slower plans (p. 1588).

In some cases, you might prefer to fix a bad plan rather than reject, disable, or delete it. Use the `pg_hint_plan` extension to experiment with improving a plan. With `pg_hint_plan`, you use special comments to tell the optimizer to override how it normally creates a plan. For more information, see Fixing plans using `pg_hint_plan` (p. 1589).

**Understanding Aurora PostgreSQL query plan management**

With query plan management turned on for your Aurora PostgreSQL DB cluster, the optimizer generates and stores query execution plans for any SQL statement that it processes more than once. The optimizer always sets the status of a managed statement's first generated plan to Approved, and stores it in the `dba_plans` view.

The set of approved plans saved for a managed statement is known as its **plan baseline**. As your application runs, the optimizer might generate additional plans for managed statements. The optimizer sets additional captured plans to a status of Unapproved.

Later, you can decide if the Unapproved plans perform well and change them to Approved, Rejected, or Preferred. To do so, you use the `apg_plan_mgmt.evolve_plan_baselines` function or the `apg_plan_mgmt.set_plan_status` function.

When the optimizer generates a plan for a SQL statement, query plan management saves the plan in the `apg_plan_mgmt.plans` table. Database users that have been granted the `apg_plan_mgmt` role can see the plan details by querying the `apg_plan_mgmt.dba_plans` view. For example, the following query lists details for plans currently in the view for a non-production Aurora PostgreSQL DB cluster.

- `sql_hash` – An identifier for the SQL statement that's the hash value for the normalized text of the SQL statement.
- `plan_hash` – A unique identifier for the plan that's a combination of the `sql_hash` and a hash of the plan.
- `status` – The status of the plan. The optimizer can run an approved plan.
- `enabled` – Indicates whether the plan is ready to use (true) or not (false).
Capturing Aurora PostgreSQL execution plans

Aurora PostgreSQL query plan management offers two different modes for capturing query execution plans, automatic or manual. You choose the mode by setting the value of the `apg_plan_mgmt.capture_plans_baselines` to automatic or to manual. You can capture execution plans for specific SQL statements by using manual plan capture. Alternatively, you can capture all (or the slowest) plans that are executed two or more times as your application runs by using automatic plan capture.

When capturing plans, the optimizer sets the status of a managed statement's first captured plan to approved. The optimizer sets the status of any additional plans captured for a managed statement to approved.
Capturing Aurora PostgreSQL execution plans

unapproved. However, more than one plan might occasionally be saved with the approved status. This can happen when multiple plans are created for a statement in parallel and before the first plan for the statement is committed.

To control the maximum number of plans that can be captured and stored in the dba_plans view, set the apg_plan_mgmt.max_plans parameter in your DB instance-level parameter group. A change to the apg_plan_mgmt.max_plans parameter requires a DB instance reboot for a new value to take effect. For more information, see the apg_plan_mgmt.max_plans (p. 1594) parameter.

Manually capturing plans for specific SQL statements

If you have a known set of SQL statements to manage, put the statements into a SQL script file and then manually capture plans. The following shows a psql example of how to capture query plans manually for a set of SQL statements.

| psql> SET apg_plan_mgmt.capture_plan_baselines = manual;  
| psql> \\i my-statements.sql  
| psql> SET apg_plan_mgmt.capture_plan_baselines = off;  

After capturing a plan for each SQL statement, the optimizer adds a new row to the apg_plan_mgmt.dba_plans view.

We recommend that you use either EXPLAIN or EXPLAIN EXECUTE statements in the SQL script file. Make sure that you include enough variations in parameter values to capture all the plans of interest.

If you know of a better plan than the optimizer's minimum cost plan, you might be able to force the optimizer to use the better plan. To do so, specify one or more optimizer hints. For more information, see Fixing plans using pg_hint_plan (p. 1589). To compare the performance of the unapproved and approved plans and approve, reject, or delete them, see Evaluating plan performance (p. 1588).

Automatically capturing plans

Use automatic plan capture for situations such as the following:

- You don't know the specific SQL statements that you want to manage.
- You have hundreds or thousands of SQL statements to manage.
- Your application uses a client API. For example, JDBC uses unnamed prepared statements or bulk-mode statements that can't be expressed in psql.

To capture plans automatically

1. Turn on automatic plan capture by setting apg_plan_mgmt.capture_plan_baselines to automatic in the DB instance-level parameter group. For more information, see Modifying parameters in a DB parameter group (p. 229).
2. Reboot your DB instance.
3. As the application runs, the optimizer captures plans for each SQL statement that runs at least twice.

   As the application runs with default query plan management parameter settings, the optimizer captures plans for each SQL statement that runs at least twice. Capturing all plans while using the defaults has very little run-time overhead and can be enabled in production.

To turn off automatic plan capture

- Set the apg_plan_mgmt.capture_plan_baselines parameter to off from the DB instance-level parameter group.
To measure the performance of the unapproved plans and approve, reject, or delete them, see Evaluating plan performance (p. 1588).
Using Aurora PostgreSQL managed plans

To get the optimizer to use captured plans for your managed statements, set the parameter `apg_plan_mgmt.use_plan_baselines` to `true`. The following is a local instance example.

```
SET apg_plan_mgmt.use_plan_baselines = true;
```

While the application runs, this setting causes the optimizer to use the minimum-cost, preferred, or approved plan that is valid and enabled for each managed statement.

Analyzing the optimizer's chosen plan

When the `apg_plan_mgmt.use_plan_baselines` parameter is set to `true`, you can use `EXPLAIN ANALYZE` SQL statements to cause the optimizer to show the plan it would use if it were to run the statement. The following is an example.

```
EXPLAIN ANALYZE EXECUTE rangeQuery (1,10000);
```

The output shows the Approved plan from the baseline that would run. However, the output also shows that it found a lower-cost plan. In this case, you capture this new minimum cost plan by turning on automatic plan capture as described in [Automatically capturing plans](#) (p. 1582).

New plans are always captured by the optimizer as Unapproved. Use the `apg_plan_mgmt.evolve_plan_baselines` function to compare plans and change them to approved, rejected, or disabled. For more information, see [Evaluating plan performance](#) (p. 1588).

How the optimizer chooses which plan to run

The cost of an execution plan is an estimate that the optimizer makes to compare different plans. When calculating a plan's cost, the optimizer includes factors such as CPU and I/O operations required by that plan. To learn more about PostgreSQL query planner cost estimates, see [Query Planning](#) in the PostgreSQL documentation.

The following image shows how a plan is chosen for a given SQL statement when query plan management is active, and when it's not.
The flow is as follows:

1. The optimizer generates a minimum-cost plan for the SQL statement.
2. If query plan management isn't active, the optimizer's plan is run immediately (A. Run Optimizer's plan). Query plan management is inactive when the `apg_plan_mgmt.capture_plan_baselines` and the `apg_plan_mgmt.use_plan_baselines` parameters are both at their default settings ("off" and "false," respectively).

Otherwise, query plan management is active. In this case, the SQL statement and the optimizer's plan for it are further assessed before a plan is chosen.

   **Tip**
   Database users with the `apg_plan_mgmt` role can pro-actively compare plans, change status of plans, and force the use of specific plans as needed. For more information, see [Maintaining Aurora PostgreSQL execution plans](p. 1587).

3. The SQL statement might already have plans that were stored by query plan management in the past. Plans are stored in the `apg_plan_mgmt.dba_plans`, along with information about the SQL statements that were used to create them. Information about a plan includes its status. A plan's status can determine whether it's used or not, as follows.
   a. If the plan isn't among the stored plans for the SQL statement, it means that it's the first time this particular plan was generated by the optimizer for the given SQL statement. The plan is sent to Capture Plan Processing (4).
   b. If the plan is among the stored plans and its status is Approved or Preferred, the plan is run (A. Run Optimizer's plan).

If the plan is among the stored plans but it's neither Approved nor Preferred, the plan is sent to Capture Plan Processing (4).

4. When a plan is captured for the first time for a given SQL statement, the plan's status is always set to Approved (P1). If the optimizer subsequently generates the same plan for the same SQL statement, the status of that plan is changed to Unapproved (P1+n).

With the plan captured and its status updated, the evaluation continues at the next step (5).

5. A plan's baseline consists of the history of the SQL statement and its plans at various states. Query plan management can take the baseline into account when choosing a plan, depending on whether the use plan baselines option is turned on or not, as follows.
   - Use plan baselines is "off" when the `apg_plan_mgmt.use_plan_baselines` parameter is set to its default value (false). The plan isn't compared to the baseline before it's run (A. Run Optimizer's plan).
   - Use plan baselines is "on" when the `apg_plan_mgmt.use_plan_baselines` parameter is set to true. The plan is further assessed using the baseline (6).

6. The plan is compared to other plans for the statement in the baseline.
   a. If the optimizer's plan is among the plans in the baseline, its status is checked (7a).
   b. If the optimizer's plan isn't among plans in the baseline, the plan is added to the plans for the statement as a new Unapproved plan.

7. The plan's status is checked to determine only if it's Unapproved.
   a. If the plan's status is Unapproved, the plan's estimated cost is compared to the cost estimate specified for the unapproved execution plan threshold.
      - If the plan's estimated cost is below the threshold, the optimizer uses it even though it's an Unapproved plan (A. Run Optimizer's plan). Generally, the optimizer won't run an Unapproved plan. However, when the `apg_plan_mgmt.unapproved_plan_execution_threshold` parameter specifies a cost threshold value, the optimizer compares the Unapproved plan's cost to the threshold. If the estimated cost is less than the threshold, the optimizer runs the plan. For more information, see `apg_plan_mgmt.unapproved_plan_execution_threshold` (p. 1596).
      - If the plan's estimated cost isn't below the threshold, the plan's other attributes are checked (8a).
   b. If the plan's status is anything other than Unapproved, its other attributes are checked (8a).

8. The optimizer won't use a plan that's disabled. That is, the plan that has its `enable` attribute set to 'f' (false). The optimizer also won't use a plan that has a status of Rejected.
The optimizer can't use any plans that aren't valid. Plans can become invalid over time when the objects that they depend on, such as indexes and table partitions, are removed or deleted.

a. If the statement has any enabled and valid Preferred plans, the optimizer chooses the minimum-cost plan from among the Preferred plans stored for this SQL statement. The optimizer then runs the minimum-cost Preferred plan.

b. If the statement doesn't have any enabled and valid Preferred plans, it's assessed in the next step (9).

9. If the statement has any enabled and valid Approved plans, the optimizer chooses the minimum-cost plan from among the Approved plans stored for this SQL statement. The optimizer then runs the minimum-cost Approved plan.

If the statement doesn't have any valid and enabled Approved plans, the optimizer uses the minimum cost plan (A. Run Optimizer's plan).

Examining Aurora PostgreSQL query plans in the dba_plans view

Database users and administrators that have been granted the apg_plan_mgmt role can view and manage the plans stored in the apg_plan_mgmt.dba_plans. An Aurora PostgreSQL DB cluster's administrator (someone with rds_superuser permissions) must explicitly grant this role to the database users who need to work with query plan management.

The apg_plan_mgmt view contains the plan history for all managed SQL statements for every database on the writer instance of the Aurora PostgreSQL DB cluster. This view lets you examine plans, their state, when last used, and all other relevant details.

As discussed in Normalization and the SQL hash (p. 1581), each managed plan is identified by the combined SQL hash value and a plan hash value. With these identifiers, you can use tools such as Amazon RDS Performance Insights to track individual plan performance. For more information about Performance Insights, see Using Amazon RDS performance insights.

Listing managed plans

To list the managed plans, use a SELECT statement on the apg_plan_mgmt.dba_plans view. The following example displays some columns in the dba_plans view such as the status, which identifies the approved and unapproved plans.

```
SELECT sql_hash, plan_hash, status, enabled, stmt_name
FROM apg_plan_mgmt.dba_plans;
```

<table>
<thead>
<tr>
<th>sql_hash</th>
<th>plan_hash</th>
<th>status</th>
<th>enabled</th>
<th>stmt_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1984047223</td>
<td>512153379</td>
<td>Approved</td>
<td>t</td>
<td>rangequery</td>
</tr>
<tr>
<td>1984047223</td>
<td>512284451</td>
<td>Unapproved</td>
<td>t</td>
<td>rangequery</td>
</tr>
</tbody>
</table>

(2 rows)

For readability, the query and the output shown list just a few of the columns from the dba_plans view. For complete information, see Reference for the apg_plan_mgmt.dba_plans view (p. 1604).

Maintaining Aurora PostgreSQL execution plans

Query plan management provides techniques and functions to add, maintain, and improve execution plans.
Evaluating plan performance

After the optimizer captures plans as unapproved, use the `apg_plan_mgmt.evolve_plan_baselines` function to compare plans based on their actual performance. Depending on the outcome of your performance experiments, you can change a plan's status from unapproved to either approved or rejected. You can instead decide to use the `apg_plan_mgmt.evolve_plan_baselines` function to temporarily disable a plan if it does not meet your requirements.

Approving better plans

The following example demonstrates how to change the status of managed plans to approved using the `apg_plan_mgmt.evolve_plan_baselines` function.

```sql
SELECT apg_plan_mgmt.evolve_plan_baselines(
    sql_hash,
    plan_hash,
    min_speedup_factor := 1.0,
    action := 'approve'
) FROM apg_plan_mgmt.dba_plans WHERE status = 'Unapproved';
```

The output shows a performance report for the `rangequery` statement with parameter bindings of 1 and 10,000. The new unapproved plan (`Baseline+1`) is better than the best previously approved plan (`Baseline`). To confirm that the new plan is now Approved, check the `apg_plan_mgmt.dba_plans` view.

```sql
SELECT sql_hash, plan_hash, status, enabled, stmt_name
FROM apg_plan_mgmt.dba_plans;
```

The managed plan now includes two approved plans that are the statement's plan baseline. You can also call the `apg_plan_mgmt.set_plan_status` function to directly set a plan's status field to 'Approved', 'Rejected', 'Unapproved', or 'Preferred'.

Rejecting or disabling slower plans

To reject or disable plans, pass 'reject' or 'disable' as the action parameter to the `apg_plan_mgmt.evolve_plan_baselines` function. This example disables any captured Unapproved plan that is slower by at least 10 percent than the best Approved plan for the statement.

```sql
SELECT apg_plan_mgmt.evolve_plan_baselines(
    sql_hash,
    plan_hash,
    min_speedup_factor := 1.0,
    action := 'disable'
) FROM apg_plan_mgmt.dba_plans WHERE status = 'Unapproved' AND (COMPARISON);
sql_hash, -- The managed statement ID
plan_hash, -- The plan ID
1.1, -- number of times faster the plan must be
'disable' -- The action to take. This sets the enabled field to false.
)
FROM apg_plan_mgmt.dba_plans
WHERE status = 'Unapproved' AND -- plan is Unapproved
origin = 'Automatic'; -- plan was auto-captured

You can also directly set a plan to rejected or disabled. To directly set a plan's enabled field
to true or false, call the apg_plan_mgmt.set_plan_enabled function. To directly set a
plan's status field to 'Approved', 'Rejected', 'Unapproved', or 'Preferred', call the
apg_plan_mgmt.set_plan_status function.

Validating plans

Use the apg_plan_mgmt.validate_plans function to delete or disable plans that are invalid.

Plans can become invalid or stale when objects that they depend on are removed, such as an index or
a table. However, a plan might be invalid only temporarily if the removed object gets recreated. If an
invalid plan can become valid later, you might prefer to disable an invalid plan or do nothing rather than
delete it.

To find and delete all plans that are invalid and haven't been used in the past week, use the
apg_plan_mgmt.validate_plans function as follows.

SELECT apg_plan_mgmt.validate_plans(sql_hash, plan_hash, 'delete')
FROM apg_plan_mgmt.dba_plans
WHERE last_used < (current_date - interval '7 days');

To enable or disabled a plan directly, use the apg_plan_mgmt.set_plan_enabled function.

Fixing plans using pg_hint_plan

The query optimizer is well-designed to find an optimal plan for all statements, and in most cases the
optimizer finds a good plan. However, occasionally you might know that a much better plan exists than
that generated by the optimizer. Two recommended ways to get the optimizer to generate a desired plan
include using the pg_hint_plan extension or setting Grand Unified Configuration (GUC) variables in
PostgreSQL:

• pg_hint_plan extension – Specify a "hint" to modify how the planner works by using PostgreSQL's
  pg_hint_plan extension. To install and learn more about how to use the pg_hint_plan extension,
  see the pg_hint_plan documentation.

• GUC variables – Override one or more cost model parameters or other optimizer parameters, such as
  the fromCollapseLimit or GEQO_threshold.

When you use one of these techniques to force the query optimizer to use a plan, you can also use query
plan management to capture and enforce use of the new plan.

You can use the pg_hint_plan extension to change the join order, the join methods, or the access paths
for a SQL statement. You use a SQL comment with special pg_hint_plan syntax to modify how the
optimizer creates a plan. For example, assume the problem SQL statement has a two-way join.

SELECT *
FROM t1, t2
WHERE t1.id = t2.id;
Then suppose that the optimizer chooses the join order (t1, t2), but you know that the join order (t2, t1) is faster. The following hint forces the optimizer to use the faster join order, (t2, t1). Include EXPLAIN so that the optimizer generates a plan for the SQL statement but without running the statement. (Output not shown.)

```sql
/*+ Leading ((t2 t1)) */ EXPLAIN SELECT *
FROM t1, t2
WHERE t1.id = t2.id;
```

The following steps show how to use `pg_hint_plan`.

**To modify the optimizer's generated plan and capture the plan using `pg_hint_plan`**

1. Turn on the manual capture mode.

   ```sql
   SET apg_plan_mgmt.capture_plan_baselines = manual;
   ```

2. Specify a hint for the SQL statement of interest.

   ```sql
   /*+ Leading ((t2 t1)) */ EXPLAIN SELECT *
   FROM t1, t2
   WHERE t1.id = t2.id;
   ```

   After this runs, the optimizer captures the plan in the `apg_plan_mgmt.dba_plans` view. The captured plan doesn't include the special `pg_hint_plan` comment syntax because query plan management normalizes the statement by removing leading comments.

3. View the managed plans by using the `apg_plan_mgmt.dba_plans` view.

   ```sql
   SELECT sql_hash, plan_hash, status, sql_text, plan_outline
   FROM apg_plan_mgmt.dba_plans;
   ```

4. Set the status of the plan to Preferred. Doing so makes sure that the optimizer chooses to run it, instead of selecting from the set of approved plans, when the minimum-cost plan isn't already Approved or Preferred.

   ```sql
   SELECT apg_plan_mgmt.set_plan_status(sql-hash, plan-hash, 'preferred');
   ```

5. Turn off manual plan capture and enforce the use of managed plans.

   ```sql
   SET apg_plan_mgmt.capture_plan_baselines = false;
   SET apg_plan_mgmt.use_plan_baselines = true;
   ```

Now, when the original SQL statement runs, the optimizer chooses either an Approved or Preferred plan. If the minimum-cost plan isn't Approved or Preferred, then the optimizer chooses the Preferred plan.

**Deleting plans**

Plans are automatically deleted if they haven't been used in over a month, specifically, 32 days. That's the default setting for the `apg_plan_mgmt.plan_retention_period` parameter. You can change the plan retention period to a longer period of time, or to a shorter period of time starting from the value of 1. Determining the number of days since a plan was last used is calculated by subtracting the `last_used` date from the current date. The `last_used` date is the most recent date that the optimizer chose the plan as the minimum cost plan or that the plan was run. The date is stored for the plan in the `apg_plan_mgmt.dba_plans` view.
We recommend that you delete plans that haven't been used for a long time or that aren't useful. Every plan has a last_used date that the optimizer updates each time it executes a plan or chooses the plan as the minimum-cost plan for a statement. Check the last_last_used dates to identify the plans that you can safely delete.

The following query returns a three column table with the count on the total number of plans, plans failed to delete, and the plans successfully deleted. It has a nested query that is an example of how to use the apg_plan_mgmt.delete_plan function to delete all plans that haven't been chosen as the minimum-cost plan in the last 31 days and its status is not Rejected.

```
SELECT (SELECT COUNT(*) from apg_plan_mgmt.dba_plans) total_plans,
        COUNT(*) FILTER (WHERE result = -1) failed_to_delete,
        COUNT(*) FILTER (WHERE result = 0) successfully_deleted
FROM (SELECT apg_plan_mgmt.delete_plan(sql_hash, plan_hash) as result
       FROM apg_plan_mgmt.dba_plans
       WHERE last_used < (current_date - interval '31 days')
       AND status <> 'Rejected') as dba_plans;
```

```
total_plans | failed_to_delete | successfully_deleted
-------------+------------------+----------------------
            3 |                0 |                    2
```

For more information, see apg_plan_mgmt.delete_plan (p. 1598).

To delete plans that aren't valid and that you expect to remain invalid, use the apg_plan_mgmt.validate_plans function. This function lets you delete or disable invalid plans. For more information, see Validating plans (p. 1589).

**Important**
If you don't delete extraneous plans, you might eventually run out of shared memory that's set aside for query plan management. To control how much memory is available for managed plans, use the apg_plan_mgmt.max_plans parameter. Set this parameter in your custom DB parameter group and reboot your DB instance for changes to take effect. For more information, see the apg_plan_mgmt.max_plans (p. 1594) parameter.

## Exporting and importing plans

You can export your managed plans and import them into another DB instance.

### To export managed plans

An authorized user can copy any subset of the apg_plan_mgmt.plans table to another table, and then save it using the pg_dump command. The following is an example.

```
CREATE TABLE plans_copy AS SELECT *
FROM apg_plan_mgmt.plans [ WHERE predicates ];

% pg_dump --table apg_plan_mgmt.plans_copy -Ft mysourcedatabase > plans_copy.tar

DROP TABLE apg_plan_mgmt.plans_copy;
```

### To import managed plans

1. Copy the .tar file of the exported managed plans to the system where the plans are to be restored.
2. Use the `pg_restore` command to copy the tar file into a new table.

```bash
% pg_restore --dbname mytargetdatabase -Ft plans_copy.tar
```

3. Merge the `plans_copy` table with the `apg_plan_mgmt.plans` table, as shown in the following example.

```
INSERT INTO apg_plan_mgmt.plans SELECT * FROM plans_copy
ON CONFLICT ON CONSTRAINT plans_pkey
DO UPDATE SET
  status = EXCLUDED.status,
  enabled = EXCLUDED.enabled,
  -- Save the most recent last_used date
  last_used = CASE WHEN EXCLUDED.last_used > plans.last_used
  THEN EXCLUDED.last_used ELSE plans.last_used END,
  -- Save statistics gathered by evolve_plan_baselines, if it ran:
  estimated_startup_cost = EXCLUDED.estimated_startup_cost,
  estimated_total_cost = EXCLUDED.estimated_total_cost,
  planning_time_ms = EXCLUDED.planning_time_ms,
  execution_time_ms = EXCLUDED.execution_time_ms,
  total_time_benefit_ms = EXCLUDED.total_time_benefit_ms,
  execution_time_benefit_ms = EXCLUDED.execution_time_benefit_ms;
```

4. Reload the managed plans into shared memory and remove the temporary plans table.

```
SELECT apg_plan_mgmt.reload(); -- refresh shared memory
DROP TABLE plans_copy;
```

Reference for Aurora PostgreSQL query plan management

Following, you can find reference information for several Aurora PostgreSQL query plan management features and functionality.

Topics

- Parameter reference for Aurora PostgreSQL query plan management (p. 1592)
- Function reference for Aurora PostgreSQL query plan management (p. 1597)
- Reference for the `apg_plan_mgmt.dba_plans` view (p. 1604)

Parameter reference for Aurora PostgreSQL query plan management

You can set your preferences for the `apg_plan_mgmt` extension by using the parameters listed in this section. These are available in the custom DB cluster parameter and the DB parameter group associated with your Aurora PostgreSQL DB cluster. These parameters control the behavior of the query plan management feature and how it affects the optimizer. For information about setting up query plan management, see Turning on Aurora PostgreSQL query plan management (p. 1576). Changing
the parameters following has no effect if the `apg_plan_mgmt` extension isn't set up as detailed in that section. For information about modifying parameters, see Modifying parameters in a DB cluster parameter group (p. 219) and Working with DB parameter groups (p. 226).

### Parameters

- `apg_plan_mgmt.capture_plan_baselines` (p. 1593)
- `apg_plan_mgmt.plan_capture_threshold` (p. 1593)
- `apg_plan_mgmt.explain_hashes` (p. 1594)
- `apg_plan_mgmt.log_plan_enforcement_result` (p. 1594)
- `apg_plan_mgmt.max_databases` (p. 1594)
- `apg_plan_mgmt.max_plans` (p. 1594)
- `apg_plan_mgmt.plan_hash_version` (p. 1595)
- `apg_plan_mgmt.plan_retention_period` (p. 1595)
- `apg_plan_mgmt.unapproved_plan_execution_threshold` (p. 1596)
- `apg_plan_mgmt.use_plan_baselines` (p. 1596)
- `auto_explain.hashes` (p. 1596)

### `apg_plan_mgmt.capture_plan_baselines`

Captures query execution plans generated by the optimizer for each SQL statement and stores them in the `dba_plans` view. By default, the maximum number of plans that can be stored is 10,000 as specified by the `apg_plan_mgmt.max_plans` parameter. For reference information, see `apg_plan_mgmt.max_plans` (p. 1594).

You can set this parameter in the custom DB cluster parameter group or in the custom DB parameter group. Changing the value of this parameter doesn't require a reboot.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>off</td>
<td>automatic</td>
<td>Turns on plan capture for all databases on the DB instance. Collects a plan for each SQL statement that runs two or more times. Use this setting for large or evolving workloads to provide plan stability.</td>
</tr>
<tr>
<td>manual</td>
<td></td>
<td>Turns on plan capture for subsequent statements only, until you turn it off again. Using this setting lets you capture query execution plans for specific critical SQL statements only or for known problematic queries.</td>
</tr>
<tr>
<td>off</td>
<td></td>
<td>Turns off plan capture.</td>
</tr>
</tbody>
</table>

For more information, see Capturing Aurora PostgreSQL execution plans (p. 1581).

### `apg_plan_mgmt.plan_capture_threshold`

Specifies a threshold so that if the total cost of the query execution plan is below the threshold, the plan won't be captured in the `apg_plan_mgmt.dba_plans` view.

Changing the value of this parameter doesn't require a reboot.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0 - 1.79769e+308</td>
<td>Sets the threshold of the <code>apg_plan_mgmt</code> query plan total execution cost for capturing plans.</td>
</tr>
</tbody>
</table>
For more information, see Examining Aurora PostgreSQL query plans in the dba_plans view (p. 1587).

**apg_plan_mgmt.explain_hashes**

Specifies if the EXPLAIN [ANALYZE] shows sql_hash and plan_hash at the end of its output. Changing the value of this parameter doesn't require a reboot.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0 (off)</td>
<td>EXPLAIN does not show sql_hash and plan_hash without hashes true option.</td>
</tr>
<tr>
<td></td>
<td>1 (on)</td>
<td>EXPLAIN shows sql_hash and plan_hash without hashes true option.</td>
</tr>
</tbody>
</table>

**apg_plan_mgmt.log_plan_enforcement_result**

Specifies if the results has to be recorded to see if the QPM managed plans are used properly. When a stored generic plan is used, there will be no records written in the log files. Changing the value of this parameter doesn't require a reboot.

<table>
<thead>
<tr>
<th>Default</th>

<td>none</td>
<td>Does not show any plan enforcement result in log files.</td>
</tr>
<tr>
<td></td>
<td>on_error</td>
<td>Only shows plan enforcement result in log files when QPM fails to use managed plans.</td>
</tr>
<tr>
<td></td>
<td>all</td>
<td>Shows all plan enforcement results in log files including both successes and failures.</td>
</tr>
</tbody>
</table>

**apg_plan_mgmt.max_databases**

Specifies the maximum number of databases on your Aurora PostgreSQL DB cluster's Writer instance that can use query plan management. By default, up to 10 databases can use query plan management. If you have more than 10 databases on the instance, you can change the value of this setting. To find out how many databases are on a given instance, connect to the instance using psql. Then, use the psql metacommand, \l, to list the databases.

Changing the value of this parameter requires that you reboot the instance for the setting to take effect.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>10-2147483647</td>
<td>Maximum number of databases that can use query plan management on the instance.</td>
</tr>
</tbody>
</table>

You can set this parameter in the custom DB cluster parameter group or in the custom DB parameter group.

**apg_plan_mgmt.max_plans**

Sets the maximum number of SQL statements that the query plan manager can maintain in the apg_plan_mgmt.dba_plans view. We recommend setting this parameter to 10000 or higher for all Aurora PostgreSQL versions.
You can set this parameter in the custom DB cluster parameter group or in the custom DB parameter group. Changing the value of this parameter requires that you reboot the instance for the setting to take effect.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>10000</td>
<td>10-2147483647</td>
<td>Maximum number of plans that can be stored in the apg_plan_mgmt.dba_plans view. Default for Aurora PostgreSQL version 10 and older versions is 1000.</td>
</tr>
</tbody>
</table>

For more information, see [Examining Aurora PostgreSQL query plans in the dba_plans view](p. 1587).

**apg_plan_mgmt.plan_hash_version**

Specifies the use cases that the plan_hash calculation is designed to cover. A higher version of apg_plan_mgmt.plan_hash_version covers all the functionality of the lower version. For example, version 3 covers the use cases supported by version 2.

Changing the value of this parameter must be followed by a call to apg_plan_mgmt.validate_plans('update_plan_hash'). It updates the plan_hash values in each database with apg_plan_mgmt installed and entries in the plans table. For more information, see [Validating plans](p. 1589).

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Default plan_hash calculation.</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>plan_hash calculation modified for multi-schema support.</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>plan_hash calculation modified for multi-schema support and partitioned table support.</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>plan_hash calculation modified for parallel operators and to support materialize nodes.</td>
<td></td>
</tr>
</tbody>
</table>

**apg_plan_mgmt.plan_retention_period**

Specifies the number of days to keep plans in the apg_plan_mgmt.dba_plans view, after which they're automatically deleted. By default, a plan is deleted when 32 days have elapsed since the plan was last used (the last_used column in the apg_plan_mgmt.dba_plans view). You can change this setting to any number, 1 and over.

Changing the value of this parameter requires that you reboot the instance for the setting to take effect.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>32</td>
<td>1-2147483647</td>
<td>Maximum number of days since a plan was last used before it's deleted.</td>
</tr>
</tbody>
</table>

For more information, see [Examining Aurora PostgreSQL query plans in the dba_plans view](p. 1587).
**apg_plan_mgmt.unapproved_plan_execution_threshold**

Specifies a cost threshold below which an Unapproved plan can be used by the optimizer. By default the threshold is 0, so the optimizer doesn’t run Unapproved plans. Setting this parameter to a trivially low cost threshold such as 100 avoids plan enforcement overhead on trivial plans. You can also set this parameter to an extremely large value like 10000000 using the reactive style of plan management. This allows the optimizer to use all chosen plans with no plan enforcement overhead. But, when a bad plan is found, you can manually mark it as "rejected" so that it is not used next time.

The value of this parameter represents a cost estimate for running a given plan. If an Unapproved plan is below that estimated cost, the optimizer uses it for the SQL statement. You can see captured plans and their status (Approved, Unapproved) in the `dba_plans` view. To learn more, see [Examining Aurora PostgreSQL query plans in the dba_plans view](p. 1587).

Changing the value of this parameter doesn't require a reboot.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0-2147483647</td>
<td>Estimated plan cost below which an Unapproved plan is used.</td>
</tr>
</tbody>
</table>

For more information, see [Using Aurora PostgreSQL managed plans](p. 1584).

**apg_plan_mgmt.use_plan_baselines**

Specifies that the optimizer should use one of the Approved plans captured and stored in the `apg_plan_mgmt.dba_plans` view. By default, this parameter is off (false), causing the optimizer to use the minimum-cost plan that it generates without any further assessment. Turning this parameter on (setting it to true) forces the optimizer to choose a query execution plan for the statement from its plan baseline. For more information, see [Using Aurora PostgreSQL managed plans](p. 1584). To find an image detailing this process, see [How the optimizer chooses which plan to run](p. 1584).

You can set this parameter in the custom DB cluster parameter group or in the custom DB parameter group. Changing the value of this parameter doesn't require a reboot.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>false</td>
<td>true</td>
<td>Use an Approved, Preferred, or Unapproved plan from the <code>apg_plan_mgmt.dba_plans</code>. If none of those meet all evaluation criterion for the optimizer, it can then use its own generated minimum-cost plan. For more information, see [How the optimizer chooses which plan to run](p. 1584).</td>
</tr>
<tr>
<td>false</td>
<td></td>
<td>Use the minimum cost plan generated by the optimizer.</td>
</tr>
</tbody>
</table>

You can evaluate response times of different captured plans and change plan status, as needed. For more information, see [Maintaining Aurora PostgreSQL execution plans](p. 1587).

**auto_explain.hashes**

Specifies if the auto_explain output shows sql_hash and plan_hash. Changing the value of this parameter doesn't require a reboot.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0(off)</td>
<td>0(off)</td>
<td>auto_explain result does not show sql_hash and plan_hash.</td>
</tr>
</tbody>
</table>
Function reference for Aurora PostgreSQL query plan management

The `apg_plan_mgmt` extension provides the following functions.

**Functions**
- `apg_plan_mgmt.copy_outline` (p. 1597)
- `apg_plan_mgmt.delete_plan` (p. 1598)
- `apg_plan_mgmt.evolve_plan_baselines` (p. 1598)
- `apg_plan_mgmt.get_explain_plan` (p. 1599)
- `apg_plan_mgmt.plan_last_used` (p. 1600)
- `apg_plan_mgmt.reload` (p. 1601)
- `apg_plan_mgmt.set_plan_enabled` (p. 1601)
- `apg_plan_mgmt.set_plan_status` (p. 1601)
- `apg_plan_mgmt.update_plans_last_used` (p. 1602)
- `apg_plan_mgmt.validate_plans` (p. 1603)

**apg_plan_mgmt.copy_outline**

Copy a given SQL plan hash and plan outline to a target SQL plan hash and outline, thereby overwriting the target's plan hash and outline. This function is available in `apg_plan_mgmt 2.3` and higher releases.

**Syntax**

```sql
apg_plan_mgmt.copy_outline(
    source_sql_hash,
    source_plan_hash,
    target_sql_hash,
    target_plan_hash
)
```

**Return value**

Returns 0 when the copy is successful. Raises exceptions for invalid inputs.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source_sql_hash</td>
<td>The sql_hash ID associated with the plan_hash to copy to the target query.</td>
</tr>
<tr>
<td>source_plan_hash</td>
<td>The plan_hash ID to copy to the target query.</td>
</tr>
<tr>
<td>target_sql_hash</td>
<td>The sql_hash ID of the query to update with the source plan hash and outline.</td>
</tr>
<tr>
<td>target_plan_hash</td>
<td>The plan_hash ID of the query to update with the source plan hash and outline.</td>
</tr>
</tbody>
</table>
Usage notes
This function allows you to copy a plan hash and plan outline that uses hints to other, similar statements, and thus saves you from needing to use in-line hint statements at every occurrence in the target statements. If the updated target query results in an invalid plan, this function raises an error and rolls back the attempted update.

`apg_plan_mgmt.delete_plan`
Delete a managed plan.

**Syntax**

```
apg_plan_mgmt.delete_plan(
    sql_hash,
    plan_hash
)
```

**Return value**
Returns 0 if the delete was successful or -1 if the delete failed.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sql_hash</td>
<td>The <code>sql_hash</code> ID of the plan's managed SQL statement.</td>
</tr>
<tr>
<td>plan_hash</td>
<td>The managed plan's <code>plan_hash</code> ID.</td>
</tr>
</tbody>
</table>

`apg_plan_mgmt.evolve_plan_baselines`
Verifies whether an already approved plan is faster or whether a plan identified by the query optimizer as a minimum cost plan is faster.

**Syntax**

```
apg_plan_mgmt.evolve_plan_baselines(
    sql_hash,
    plan_hash,
    min_speedup_factor,
    action
)
```

**Return value**
The number of plans that were not faster than the best approved plan.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sql_hash</td>
<td>The <code>sql_hash</code> ID of the plan's managed SQL statement.</td>
</tr>
<tr>
<td>plan_hash</td>
<td>The managed plan's <code>plan_hash</code> ID. Use NULL to mean all plans that have the same <code>sql_hash</code> ID value.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>min_speedup_factor</td>
<td>The <em>minimum speedup factor</em> can be the number of times faster that a plan must be than the best of the already approved plans to approve it. Alternatively, this factor can be the number of times slower that a plan must be to reject or disable it.</td>
</tr>
<tr>
<td></td>
<td>This is a positive float value.</td>
</tr>
<tr>
<td>action</td>
<td>The action the function is to perform. Valid values include the following. Case does not matter.</td>
</tr>
<tr>
<td></td>
<td>• 'disable' – Disable each matching plan that does not meet the minimum speedup factor.</td>
</tr>
<tr>
<td></td>
<td>• 'approve' – Enable each matching plan that meets the minimum speedup factor and set its status to approved.</td>
</tr>
<tr>
<td></td>
<td>• 'reject' – For each matching plan that does not meet the minimum speedup factor, set its status to rejected.</td>
</tr>
<tr>
<td></td>
<td>• NULL – The function simply returns the number of plans that have no performance benefit because they do not meet the minimum speedup factor.</td>
</tr>
</tbody>
</table>

**Usage notes**

Set specified plans to approved, rejected, or disabled based on whether the planning plus execution time is faster than the best approved plan by a factor that you can set. The action parameter might be set to 'approve' or 'reject' to automatically approve or reject a plan that meets the performance criteria. Alternatively, it might be set to " (empty string) to do the performance experiment and produce a report, but take no action.

You can avoid pointlessly rerunning of the `apg_plan_mgmt.evolve_plan_baselines` function for a plan on which it was recently run. To do so, restrict the plans to just the recently created unapproved plans. Alternatively, you can avoid running the `apg_plan_mgmt.evolve_plan_baselines` function on any approved plan that has a recent `last_verified` timestamp.

Conduct a performance experiment to compare the planning plus execution time of each plan relative to the other plans in the baseline. In some cases, there is only one plan for a statement and the plan is approved. In such a case, compare the planning plus execution time of the plan to the planning plus execution time of using no plan.

The incremental benefit (or disadvantage) of each plan is recorded in the `apg_plan_mgmt.dba_plans` view in the `total_time_benefit_ms` column. When this value is positive, there is a measurable performance advantage to including this plan in the baseline.

In addition to collecting the planning and execution time of each candidate plan, the `last_verified` column of the `apg_plan_mgmt.dba_plans` view is updated with the `current_timestamp`. The `last_verified` timestamp might be used to avoid running this function again on a plan that recently had its performance verified.

**apg_plan_mgmt.get_explain_plan**

Generates the text of an EXPLAIN statement for the specified SQL statement.

**Syntax**

```sql
apg_plan_mgmt.get_explain_plan(
    sql_hash,
    plan_hash,
)```
Return value

Returns runtime statistics for the specified SQL statements. Use without explainOptionList to return a simple EXPLAIN plan.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sql_hash</td>
<td>The sql_hash ID of the plan's managed SQL statement.</td>
</tr>
<tr>
<td>plan_hash</td>
<td>The managed plan's plan_hash ID.</td>
</tr>
<tr>
<td>explainOptionList</td>
<td>A comma-separated list of explain options. Valid values include 'analyze', 'verbose', 'buffers', 'hashes', and 'format json'. If the explainOptionList is NULL or an empty string (''), this function generates an EXPLAIN statement, without any statistics.</td>
</tr>
</tbody>
</table>

Usage notes

For the explainOptionList, you can use any of the same options that you would use with an EXPLAIN statement. The Aurora PostgreSQL optimizer concatenates the list of options that you provide to the EXPLAIN statement.

`apg_plan_mgmt.plan_last_used`

Returns the last_used date of the specified plan from shared memory.

Note

The value in shared memory is always current on the primary DB instance in the DB cluster. The value is only periodically flushed to the last_used column of the `apg_plan_mgmt.dba_plans` view.

Syntax

```sql
apg_plan_mgmt.plan_last_used(
    sql_hash,
    plan_hash
)
```

Return value

Returns the last_used date.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sql_hash</td>
<td>The sql_hash ID of the plan's managed SQL statement.</td>
</tr>
<tr>
<td>plan_hash</td>
<td>The managed plan's plan_hash ID.</td>
</tr>
</tbody>
</table>
**apg_plan_mgmt.reload**

Reload plans into shared memory from the `apg_plan_mgmt.dba_plans` view.

**Syntax**

```python
apg_plan_mgmt.reload()
```

**Return value**

None.

**Parameters**

None.

**Usage notes**

Call `reload` for the following situations:

- Use it to refresh the shared memory of a read-only replica immediately, rather than wait for new plans to propagate to the replica.
- Use it after importing managed plans.

**apg_plan_mgmt.set_plan_enabled**

Enable or disable a managed plan.

**Syntax**

```python
apg_plan_mgmt.set_plan_enabled(
    sql_hash,
    plan_hash,
    [true | false]
)
```

**Return value**

Returns 0 if the setting was successful or -1 if the setting failed.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sql_hash</td>
<td>The <code>sql_hash</code> ID of the plan's managed SQL statement.</td>
</tr>
<tr>
<td>plan_hash</td>
<td>The managed plan's <code>plan_hash</code> ID.</td>
</tr>
<tr>
<td>enabled</td>
<td>Boolean value of true or false:</td>
</tr>
<tr>
<td></td>
<td>• A value of true enables the plan.</td>
</tr>
<tr>
<td></td>
<td>• A value of false disables the plan.</td>
</tr>
</tbody>
</table>

**apg_plan_mgmt.set_plan_status**

Set a managed plan's status to Approved, Unapproved, Rejected, or Preferred.
**Syntax**

```python
apkg_plan_mgmt.set_plan_status(
    sql_hash,
    plan_hash,
    status
)
```

**Return value**

Returns 0 if the setting was successful or -1 if the setting failed.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sql_hash</td>
<td>The sql_hash ID of the plan's managed SQL statement.</td>
</tr>
<tr>
<td>plan_hash</td>
<td>The managed plan's plan_hash ID.</td>
</tr>
</tbody>
</table>
| status    | A string with one of the following values:  
  • 'Approved'  
  • 'Unapproved'  
  • 'Rejected'  
  • 'Preferred'  
  The case you use does not matter, however the status value is set to initial uppercase in the apkg_plan_mgmt.dba_plans view. For more information about these values, see status in [Reference for the apkg_plan_mgmt.dba_plans view](p. 1604). |

**apg_plan_mgmt.update_plans_last_used**

Immediately updates the plans table with the last_used date stored in shared memory.

**Syntax**

```python
apkg_plan_mgmt.update_plans_last_used()
```

**Return value**

None.

**Parameters**

None.

**Usage notes**

Call `update_plans_last_used` to make sure queries against the `dba_plans.last_used` column use the most current information. If the last_used date isn't updated immediately, a background process updates the plans table with the last_used date once every hour (by default).

For example, if a statement with a certain sql_hash begins to run slowly, you can determine which plans for that statement were executed since the performance regression began. To do that, first flush the data in shared memory to disk so that the last_used dates are current, and then query for all
plans of the sql_hash of the statement with the performance regression. In the query, make sure the 
last_used date is greater than or equal to the date on which the performance regression began. The 
query identifies the plan or set of plans that might be responsible for the performance regression. You 
can use apg_plan_mgmt.get_explain_plan with explainOptionList set to verbose, hashes. 
You can also use apg_plan_mgmt.evolve_plan_baselines to analyze the plan and any alternative 
plans that might perform better.

The update_plans_last_used function has an effect only on the primary DB instance of the DB 
cluster.

**apg_plan_mgmt.validate_plans**

Validate that the optimizer can still recreate plans. The optimizer validates Approved, Unapproved, 
and Preferred plans, whether the plan is enabled or disabled. Rejected plans are not validated. 
Optionally, you can use the apg_plan_mgmt.validate_plans function to delete or disable invalid 
plans.

**Syntax**

```
apg_plan_mgmt.validate_plans(
    sql_hash, 
    plan_hash, 
    action)
```

```
apg_plan_mgmt.validate_plans(
    action)
```

**Return value**

The number of invalid plans.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sql_hash</td>
<td>The sql_hash ID of the plan's managed SQL statement.</td>
</tr>
<tr>
<td>plan_hash</td>
<td>The managed plan's plan_hash ID. Use NULL to mean all plans for the same sql_hash ID value.</td>
</tr>
<tr>
<td>action</td>
<td>The action the function is to perform for invalid plans. Valid string values include the following. Case does not matter.</td>
</tr>
<tr>
<td></td>
<td>'disable' − Each invalid plan is disabled.</td>
</tr>
<tr>
<td></td>
<td>'delete' − Each invalid plan is deleted.</td>
</tr>
<tr>
<td></td>
<td>'update_plan_hash' − Updates the plan_hash ID for plans that can't be reproduced exactly. It also allows you to fix a plan by rewriting the SQL. You can then register the good plan as an Approved plan for the original SQL.</td>
</tr>
<tr>
<td></td>
<td>NULL − The function simply returns the number of invalid plans. No other action is performed.</td>
</tr>
<tr>
<td></td>
<td>&quot; − An empty string produces a message indicating the number of both valid and invalid plans.</td>
</tr>
<tr>
<td></td>
<td>Any other value is treated like the empty string.</td>
</tr>
</tbody>
</table>

**Usage notes**
Use the form `validate_plans(action)` to validate all the managed plans for all the managed statements in the entire `apg_plan_mgmt.dba_plans` view.

Use the form `validate_plans(sql_hash, plan_hash, action)` to validate a managed plan specified with `plan_hash`, for a managed statement specified with `sql_hash`.

Use the form `validate_plans(sql_hash, NULL, action)` to validate all the managed plans for the managed statement specified with `sql_hash`.

**Reference for the `apg_plan_mgmt.dba_plans` view**

The columns of plan information in the `apg_plan_mgmt.dba_plans` view include the following.

<table>
<thead>
<tr>
<th><code>dba_plans column</code></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cardinality_error</td>
<td>A measure of the error between the estimated cardinality versus the actual cardinality. <em>Cardinality</em> is the number of table rows that the plan is to process. If the cardinality error is large, then it increases the likelihood that the plan isn't optimal. This column is populated by the <code>apg_plan_mgmt.evolve_plan_baselines</code> function.</td>
</tr>
<tr>
<td>compatibility_level</td>
<td>The feature level of the Aurora PostgreSQL optimizer.</td>
</tr>
<tr>
<td>created_by</td>
<td>The authenticated user (<code>session_user</code>) who created the plan.</td>
</tr>
<tr>
<td>enabled</td>
<td>An indicator of whether the plan is enabled or disabled. All plans are enabled by default. You can disable plans to prevent them from being used by the optimizer. To modify this value, use the <code>apg_plan_mgmt.set_plan_enabled</code> function.</td>
</tr>
<tr>
<td>environment_variables</td>
<td>The PostgreSQL Grand Unified Configuration (GUC) parameters and values that the optimizer has overridden at the time the plan was captured.</td>
</tr>
<tr>
<td>estimated_startup_cost</td>
<td>The estimated optimizer setup cost before the optimizer delivers rows of a table.</td>
</tr>
<tr>
<td>estimated_total_cost</td>
<td>The estimated optimizer cost to deliver the final table row.</td>
</tr>
<tr>
<td>execution_time_benefit_ms</td>
<td>The execution time benefit in milliseconds of enabling the plan. This column is populated by the <code>apg_plan_mgmt.evolve_plan_baselines</code> function.</td>
</tr>
<tr>
<td>execution_time_ms</td>
<td>The estimated time in milliseconds that the plan would run. This column is populated by the <code>apg_plan_mgmt.evolve_plan_baselines</code> function.</td>
</tr>
<tr>
<td>has_side_effects</td>
<td>A value that indicates that the SQL statement is a data manipulation language (DML) statement or a SELECT statement that contains a VOLATILE function.</td>
</tr>
<tr>
<td>last_used</td>
<td>This value is updated to the current date whenever the plan is either executed or when the plan is the query optimizer's minimum-cost plan. This value is stored in shared memory and periodically flushed to disk. To get the most up-to-date value, read the date from shared memory by calling the function <code>apg_plan_mgmt.plan_last_used(sql_hash, plan_hash)</code> instead of reading the <code>last_used</code> value. For additional information, see the <code>apg_plan_mgmt.plan_retention_period</code> parameter.</td>
</tr>
<tr>
<td><strong>dba_plans column</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>----------------------</td>
<td>----------------</td>
</tr>
<tr>
<td><code>last_validated</code></td>
<td>The most recent date and time when it was verified that the plan could be recreated by either the <code>apg_plan_mgmt.validate_plans</code> function or the <code>apg_plan_mgmt.evolve_plan_baselines</code> function.</td>
</tr>
<tr>
<td><code>last_verified</code></td>
<td>The most recent date and time when a plan was verified to be the best-performing plan for the specified parameters by the <code>apg_plan_mgmt.evolve_plan_baselines</code> function.</td>
</tr>
<tr>
<td><code>origin</code></td>
<td>How the plan was captured with the <code>apg_plan_mgmt.capture_plan_baselines</code> parameter. Valid values include the following: M – The plan was captured with manual plan capture. A – The plan was captured with automatic plan capture.</td>
</tr>
<tr>
<td><code>param_list</code></td>
<td>The parameter values that were passed to the statement if this is a prepared statement.</td>
</tr>
<tr>
<td><code>plan_created</code></td>
<td>The date and time the plan that was created.</td>
</tr>
<tr>
<td><code>plan_hash</code></td>
<td>The plan identifier. The combination of <code>plan_hash</code> and <code>sql_hash</code> uniquely identifies a specific plan.</td>
</tr>
<tr>
<td><code>plan_outline</code></td>
<td>A representation of the plan that is used to recreate the actual execution plan, and that is database-independent. Operators in the tree correspond to operators that appear in the EXPLAIN output.</td>
</tr>
<tr>
<td><code>planning_time_ms</code></td>
<td>The actual time to run the planner, in milliseconds. This column is populated by the <code>apg_plan_mgmt.evolve_plan_baselines</code> function.</td>
</tr>
<tr>
<td><code>queryId</code></td>
<td>A statement hash, as calculated by the <code>pg_stat_statements</code> extension. This isn't a stable or database-independent identifier because it depends on object identifiers (OIDs). The value will be 0 if <code>compute_query_id</code> is off when capturing the query plan.</td>
</tr>
<tr>
<td><code>sql_hash</code></td>
<td>A hash value of the SQL statement text, normalized with literals removed.</td>
</tr>
<tr>
<td><code>sql_text</code></td>
<td>The full text of the SQL statement.</td>
</tr>
</tbody>
</table>
**dba_plans column** | **Description**
--- | ---
**status** | A plan's status, which determines how the optimizer uses a plan. Valid values include the following.
- **Approved** – A usable plan that the optimizer can choose to run. The optimizer runs the least-cost plan from a managed statement's set of approved plans (baseline). To reset a plan to approved, use the `apg_plan_mgmt.evolve_plan_baselines` function.
- **Unapproved** – A captured plan that you have not verified for use. For more information, see [Evaluating plan performance](p. 1588).
- **Rejected** – A plan that the optimizer won't use. For more information, see [Rejecting or disabling slower plans](p. 1588).
- **Preferred** – A plan that you have determined is a preferred plan to use for a managed statement.

If the optimizer's minimum-cost plan isn't an approved or preferred plan, you can reduce plan enforcement overhead. To do so, make a subset of the approved plans preferred. When the optimizer's minimum cost isn't an approved plan, a preferred plan is chosen before an approved plan.

To reset a plan to preferred, use the `apg_plan_mgmt.set_plan_status` function.

**stmt_name** | The name of the SQL statement within a PREPARE statement. This value is an empty string for an unnamed prepared statement. This value is NULL for a nonprepared statement.

**total_time_benefit_ms** | The total time benefit in milliseconds of enabling this plan. This value considers both planning time and execution time.

If this value is negative, there is a disadvantage to enabling this plan. This column is populated by the `apg_plan_mgmt.evolve_plan_baselines` function.

---

**Advanced features in Query Plan Management**

Following you can find information about the advanced Aurora PostgreSQL Query Plan Management (QPM) features:

**Topics**
- [Capturing Aurora PostgreSQL execution plans in Replicas](p. 1606)
- [Supporting table partition](p. 1608)

**Capturing Aurora PostgreSQL execution plans in Replicas**

QPM (Query Plan Management) allows you to capture the query plans generated by Aurora Replicas and stores them on the primary DB instance of the Aurora DB cluster. You can collect the query plans from all the Aurora Replicas, and maintain a set of optimal plans in a central persistent table on the primary instance. You can then apply these plans on other Replicas when needed. This helps you to maintain the stability of execution plans and improve performance of the queries across the DB clusters and engine versions.
Prerequisites

Turn on capture_plan_baselines parameter in Aurora Replica - Set capture_plan_baselines parameter to automatic or manual to capture plans in Aurora Replicas. For more information, see apg_plan_mgmt.capture_plan_baselines (p. 1593).

Install postgres_fdw extension - You must install postgres_fdw foreign data wrapper extension to capture plans in Aurora Replicas. Run the following command in each database, to install the extension.

```
postgres=> CREATE EXTENSION IF NOT EXISTS postgres_fdw;
```

Managing plan capture for Aurora Replicas

Turn on plan capture for Aurora Replicas

You must have rds_superuser privileges to create or remove Plan Capture in Aurora Replicas. For more information on user roles and permissions, see Understanding PostgreSQL roles and permissions.

To capture plans, call the function apg_plan_mgmt.create_replica_plan_capture in the writer DB instance, as shown in the following:

```
postgres=> CALL apg_plan_mgmt.create_replica_plan_capture('cluster_endpoint', 'password');
```

- `cluster_endpoint` - `cluster_endpoint` (writer endpoint) provides failover support for Plan Capture in Aurora Replicas.
- `password` - We recommend you to follow the below guidelines while creating the password to enhance the security:
  - It must contain at least 8 characters.
  - It must contain at least one uppercase, one lowercase letter, and one number.
  - It must have at least one special character (, !, #, <, >, *, and so on).

Note

If you change the cluster endpoint, password, or port number, you must run apg_plan_mgmt.create_replica_plan_capture() again with the cluster endpoint and password to re-initialize the plan capture. If not, capturing plans from Aurora Replicas will fail.

Turn off plan capture for Aurora Replicas

You can turn off capture_plan_baselines parameter in Aurora Replica by setting its value to off in the Parameter group.

Remove plan capture for Aurora Replicas

You can completely remove Plan Capture in Aurora Replicas but make sure before you do. To remove plan capture, call apg_plan_mgmt.remove_replica_plan_capture as shown:

```
postgres=> CALL apg_plan_mgmt.remove_replica_plan_capture();
```
You must call `apg_plan_mgmt.create_replica_plan_capture()` again to turn on plan capture in Aurora Replicas with the cluster endpoint and password.

**Troubleshooting**

Following, you can find troubleshooting ideas and workarounds if the plan is not captured in Aurora Replicas as expected.

- **Parameter settings** - Check if the `capture_plan_baselines` parameter is set to proper value to turn on plan capture.

- **`postgres_fdw` extension is installed** - Use the following query to check if `postgres_fdw` is installed.

  ```
  postgres=> SELECT * FROM pg_extension WHERE extname = 'postgres_fdw'
  ```

- **`create_replica_plan_capture()` is called** - Use the following command to check if the user mapping exits. Otherwise, call `create_replica_plan_capture()` to initialize the feature.

  ```
  postgres=> SELECT * FROM pgForeignServer WHERE srvname = 'apg_plan_mgmt_writer_foreign_server';
  ```

- **Cluster endpoint and port number** - Check if the cluster endpoint and port number if appropriate. There won’t be any error message displayed if these values are incorrect.

  Use the following command to verify if the endpoint used in the `create()` and to check which database it resides in:

  ```
  postgres=> SELECT srvoptions FROM pgForeignServer WHERE srvname = 'apg_plan_mgmt_writer_foreign_server';
  ```

- **`reload()`** - You must call `apg_plan_mgmt.reload()` after calling `apg_plan_mgmt.delete_plan()` in Aurora Replicas to make the delete function effective. This ensures that the change has been successfully implemented.

- **Password** - You must enter password in `create_replica_plan_capture()` as per the guidelines mentioned. Otherwise, you will receive an error message. For more information, see [Managing plan capture for Aurora Replicas (p. 1607)](https://docs.aws.amazon.com/aurora/latest/userguide/advanced-query-plan-management.html). Use another password that aligns with the requirements.

- **Cross-Region connection** - Plan capture in Aurora Replicas is also supported in Aurora global database, where writer instance and Aurora Replicas can be in different regions. The writer instance and cross-Region Replica must be able to communicate, using VPC Peering. For more information, see [VPC peering](https://docs.aws.amazon.com/aurora/latest/userguide/advanced-query-plan-management.html). If a cross-Region failover happens, you must reconfigure the endpoint to new primary DB cluster endpoint.

**Supporting table partition**

Aurora PostgreSQL Query Plan Management (QPM) supports table partitioning in the following versions:

- 15.3 and higher 15 versions
- 14.8 and higher 14 versions
- 13.11 and higher 13 versions

For more information, see [Table Partitioning](https://docs.aws.amazon.com/aurora/latest/userguide/advanced-query-plan-management.html).

**Topics**

- [Setting up table partition (p. 1609)](https://docs.aws.amazon.com/aurora/latest/userguide/advanced-query-plan-management.html)
Capturing plans for table partition (p. 1609)
Enforcing a table partition plan (p. 1612)
Naming Convention (p. 1614)

Setting up table partition

To set up table partition in Aurora PostgreSQL QPM, do as follows:

1. Set `apg_plan_mgmt.plan_hash_version` to 3 or more in the DB cluster parameter group.
2. Navigate to a database that uses Query Plan Management and has entries in `apg_plan_mgmt.dba_plans` view.
3. Call `apg_plan_mgmt.validate_plans('update_plan_hash')` to update the `plan_hash` value in the plans table.
4. Repeat steps 2-3 for all databases with Query Plan Management enabled that have entries in `apg_plan_mgmt.dba_plans` view.

For more information on these parameters, see Parameter reference for Aurora PostgreSQL query plan management (p. 1592).

Capturing plans for table partition

In QPM, different plans are distinguished by their `plan_hash` value. To understand how the `plan_hash` changes, you must first understand similar kind of plans.

The combination of access methods, digit-stripped index names and digit-stripped partition names, accumulated at the Append node level must be constant for plans to be considered the same. The specific partitions accessed in the plans are not significant. In the following example, a table `tbl_a` is created with 4 partitions.

```
postgres=>create table tbl_a(i int, j int, k int, l int, m int) partition by range(i);
CREATE TABLE
postgres=>create table tbl_a1 partition of tbl_a for values from (0) to (1000);
CREATE TABLE
postgres=>create table tbl_a2 partition of tbl_a for values from (1001) to (2000);
CREATE TABLE
postgres=>create table tbl_a3 partition of tbl_a for values from (2001) to (3000);
CREATE TABLE
postgres=>create table tbl_a4 partition of tbl_a for values from (3001) to (4000);
CREATE TABLE
postgres=>create index t_i on tbl_a using btree (i);
CREATE INDEX
postgres=>create index t_j on tbl_a using btree (j);
CREATE INDEX
postgres=>create index t_k on tbl_a using btree (k);
CREATE INDEX
```

The following plans are considered the same because a single scan method is being used to scan `tbl_a` irrespective of the number of partitions that the query looks up.

```
postgres=>explain (hashes true, costs false) select j, k from tbl_a where i between 990 and 999 and j < 9910 and k > 50;
_QUERY PLAN
Seq Scan on tbl_a1 tbl_a
| Filter: ((i >= 990) AND (i <= 999) AND (j < 9910) AND (k > 50))
```
SQL Hash: 1553185667, Plan Hash: -694232056
(3 rows)

postgres=>explain (hashes true, costs false) select j, k from tbl_a where i between 990 and 1100 and j < 9910 and k > 50;

QUERY PLAN

Append
  -> Seq Scan on tbl_a1 tbl_a_1
  Filter: ((i >= 990) AND (i <= 1100) AND (j < 9910) AND (k > 50))
  -> Seq Scan on tbl_a2 tbl_a_2
  Filter: ((i >= 990) AND (i <= 1100) AND (j < 9910) AND (k > 50))
SQL Hash: 1553185667, Plan Hash: -694232056
(6 rows)

postgres=>explain (hashes true, costs false) select j, k from tbl_a where i between 990 and 2100 and j < 9910 and k > 50;

QUERY PLAN

Append
  -> Seq Scan on tbl_a1 tbl_a_1
  Filter: ((i >= 990) AND (i <= 2100) AND (j < 9910) AND (k > 50))
  -> Seq Scan on tbl_a2 tbl_a_2
  Filter: ((i >= 990) AND (i <= 2100) AND (j < 9910) AND (k > 50))
  -> Seq Scan on tbl_a3 tbl_a_3
  Filter: ((i >= 990) AND (i <= 2100) AND (j < 9910) AND (k > 50))
SQL Hash: 1553185667, Plan Hash: -993736942
(8 rows)

The following 3 plans are also considered the same because at the parent level, the access methods, digit-stripped index names and digit-stripped partition names are SeqScan tbl_a, IndexScan (i_idx) tbl_a.

postgres=>explain (hashes true, costs false) select j, k from tbl_a where i between 990 and 1100 and j < 9910 and k > 50;

QUERY PLAN

Append
  -> Seq Scan on tbl_a1 tbl_a_1
  Filter: ((i >= 990) AND (i <= 1100) AND (j < 9910) AND (k > 50))
  -> Index Scan using tbl_a2_i_idx on tbl_a2 tbl_a_2
  Index Cond: ((i >= 990) AND (i <= 1100))
  Filter: ((j < 9910) AND (k > 50))
SQL Hash: 1553185667, Plan Hash: -993736942
(7 rows)

postgres=>explain (hashes true, costs false) select j, k from tbl_a where i between 990 and 2100 and j < 9910 and k > 50;

QUERY PLAN

Append
  -> Index Scan using tbl_a1_i_idx on tbl_a1 tbl_a_1
  Index Cond: ((i >= 990) AND (i <= 2100))
  Filter: ((j < 9910) AND (k > 50))
  -> Seq Scan on tbl_a2 tbl_a_2
  Filter: ((i >= 990) AND (i <= 2100) AND (j < 9910) AND (k > 50))
  -> Index Scan using tbl_a3_i_idx on tbl_a3 tbl_a_3
Irrespective of different order and number of occurrences in child partitions, the access methods, digit-stripped index names and digit-stripped partition names are constant at the parent level for each of the above plans.

However, the plans would be considered different if any of the following conditions are met:

- Any additional access methods are used in the plan.

- Any of the access methods in the plan are not used anymore.
The index associated with an index method is changed.

```
postgres=> explain (hashes true, costs false) select j, k from tbl_a where i between 990 and 1100 and j < 9910 and k > 50;

QUERY PLAN

Append
  ->  Seq Scan on tbl_a1 tbl_a_1
      Filter: ((i >= 990) AND (i <= 1100) AND (j < 9910) AND (k > 50))
  ->  Index Scan using tbl_a2_j_idx on tbl_a2 tbl_a_2
      Index Cond: (j < 9910)
      Filter: ((i >= 990) AND (i <= 1100) AND (k > 50))
```

Enforcing a table partition plan

Approved plans for partitioned tables are enforced with positional correspondence. The plans are not specific to the partitions, and can be enforced on partitions other than the plans referenced in the original query. Plans also have the capability of being enforced for queries accessing a different number of partitions than the original approved outline.

For example, if the approved outline is for the following plan:

```
postgres=> explain (hashes true, costs false) select j, k from tbl_a where i between 990 and 2100 and j < 9910 and k > 50;

QUERY PLAN

Append
  ->  Index Scan using tbl_a1_i_idx on tbl_a1 tbl_a_1
      Index Cond: ((i >= 990) AND (i <= 2100))
      Filter: ((j < 9910) AND (k > 50))
  ->  Seq Scan on tbl_a2 tbl_a_2
      Filter: ((i >= 990) AND (i <= 2100) AND (j < 9910) AND (k > 50))
  ->  Index Scan using tbl_a3_i_idx on tbl_a3 tbl_a_3
      Index Cond: ((i >= 990) AND (i <= 2100))
      Filter: ((j < 9910) AND (k > 50))
```

Then, this plan can be enforced on SQL queries referencing 2, 4, or more partitions as well. The possible plans that could arise from these scenarios for 2 and 4 partition access are:

```
postgres=> explain (hashes true, costs false) select j, k from tbl_a where i between 990 and 1100 and j < 9910 and k > 50;

QUERY PLAN

Append
  ->  Index Scan using tbl_a1_i_idx on tbl_a1 tbl_a_1
      Index Cond: ((i >= 990) AND (i <= 1100))
      Filter: ((j < 9910) AND (k > 50))
  ->  Seq Scan on tbl_a2 tbl_a_2
      Filter: ((i >= 990) AND (i <= 1100) AND (j < 9910) AND (k > 50))
Note: An Approved plan was used instead of the minimum cost plan.
```

SQL Hash: 1553185667, Plan Hash: -993736942, Minimum Cost Plan Hash: -1873216041

(10 rows)
postgres=\texttt{explain} (hashes true, costs false) select j, k from tbl_a where i between 990 and 3100 and j < 9910 and k > 50;

\textbf{QUERY PLAN}

\begin{itemize}
\item Append
\item Index Scan using tbl_a1_i_idx on tbl_a1 tbl_a_1
  Index Cond: ((i >= 990) AND (i <= 3100))
  Filter: ((j < 9910) AND (k > 50))
\item Seq Scan on tbl_a2 tbl_a_2
  Filter: ((i >= 990) AND (i <= 3100) AND (j < 9910) AND (k > 50))
\item Index Scan using tbl_a3_i_idx on tbl_a3 tbl_a_3
  Index Cond: ((i >= 990) AND (i <= 3100))
  Filter: ((j < 9910) AND (k > 50))
\item Seq Scan on tbl_a4 tbl_a_4
  Filter: ((i >= 990) AND (i <= 3100) AND (j < 9910) AND (k > 50))
\end{itemize}

Note: An Approved plan was used instead of the minimum cost plan.
SQL Hash: 1553185667, Plan Hash: -993736942, Minimum Cost Plan Hash: -1873216041

Consider another approved plan with different access methods for each partition:

postgres=\texttt{explain} (hashes true, costs false) select j, k from tbl_a where i between 990 and 2100 and j < 9910 and k > 50;

\textbf{QUERY PLAN}

\begin{itemize}
\item Append
\item Index Scan using tbl_a1_i_idx on tbl_a1 tbl_a_1
  Index Cond: ((i >= 990) AND (i <= 3100))
  Filter: ((j < 9910) AND (k > 50))
\item Seq Scan on tbl_a2 tbl_a_2
  Filter: ((i >= 990) AND (i <= 3100) AND (j < 9910) AND (k > 50))
\item Index Scan using tbl_a3_i_idx on tbl_a3 tbl_a_3
  Index Cond: ((i >= 990) AND (i <= 3100))
  Filter: ((j < 9910) AND (k > 50))
\item Index Scan using tbl_a4_i_idx on tbl_a4 tbl_a_4
  Index Cond: ((i >= 990) AND (i <= 3100))
  Filter: ((j < 9910) AND (k > 50))
\end{itemize}

Note: An Approved plan was used instead of the minimum cost plan.
SQL Hash: 1553185667, Plan Hash: -993736942, Minimum Cost Plan Hash: -1873216041
In this case, any plan that reads from two partitions would fail to be enforced. Unless all of the (access method, index name) combinations from the approved plan are usable, the plan cannot be enforced. For example, the following plans have different plan hashes and the approved plan can’t be enforced in these cases:

```sql
postgres=> explain (hashes true, costs false) select j, k from tbl_a where i between 990 and 1900 and j < 9910 and k > 50;

QUERY PLAN
-------------------------------------------------------------------------
|     Append | Bitmap Heap Scan on tbl_a1 tbl_a_1 |
|           | Recheck Cond: (((i >= 990) AND (i <= 1900)) |
|           | Filter: ((j < 9910) AND (k > 50))   |
|           | -> Bitmap Index Scan on tbl_a1_i_idx |
|           | Index Cond: (((i >= 990) AND (i <= 1900)) |
|           | -> Bitmap Heap Scan on tbl_a2 tbl_a_2 |
|           | Recheck Cond: (((i >= 990) AND (i <= 1900)) |
|           | Filter: ((j < 9910) AND (k > 50))   |
|           | -> Bitmap Index Scan on tbl_a2_i_idx |
|           | Index Cond: (((i >= 990) AND (i <= 1900)) |
| Note: This is not an Approved plan. No usable Approved plan was found. |
SQL Hash: 1553185667, Plan Hash: -568647260
(13 rows)
```

```sql
postgres=> explain (hashes true, costs false) select j, k from tbl_a where i between 990 and 1900 and j < 9910 and k > 50;

QUERY PLAN
-------------------------------------------------------------------------
|     Append | Index Scan using tbl_a1_i_idx on tbl_a1 tbl_a_1 |
|           | Index Cond: (((i >= 990) AND (i <= 1900)) |
|           | Filter: ((j < 9910) AND (k > 50))   |
|           | -> Seq Scan on tbl_a2 tbl_a_2 |
|           | Filter: (((i >= 990) AND (i <= 1900)) AND (j < 9910) AND (k > 50)) |
| Note: This is not an Approved plan. No usable Approved plan was found. |
SQL Hash: 1553185667, Plan Hash: -496793743
(8 rows)
```

**Naming Convention**

For table partition plan enforcement in QPM, parent tables must conform to the following naming rules:

- Parent table names must differ by alphabets or special characters, and not by just digits. For example, `ta`, `tb`, and `tc` are acceptable names for separate parent tables while `t1`, `t2`, and `t3` are not.
- Partitions of the same parent should differ from one another by digits only. For example, acceptable partition names of `ta` could be `tA1`, `tA2` or `t1A`, `t2A` or even multiple digits.

Any other differences (letters, special characters) will not guarantee plan enforcement. Inherited tables must follow the same naming conventions as partitioned tables.

Indexes follow naming conventions that are similar to parent tables.

- Index names on parent tables should differ by alphabets or special characters, and not just by digits. For example, if parent table `ta` has an index `i_idx`, then parent table `tb` should not have an index such as `i_idx2` or `i2_idx`. However, names such as `i_idx_2` (differentiating underscore) or `icol_idx` (differentiating letters `col`) would conform to the naming convention.
Failure to adhere to the above naming conventions may result in failure of approved plans enforcement. The following example illustrates such a failed enforcement:

```
postgres=> create table t1(i int, j int, k int, l int, m int) partition by range(i);
CREATE TABLE
postgres=> create table t1a partition of t1 for values from (0) to (1000);
CREATE TABLE
postgres=> create table t1b partition of t1 for values from (1001) to (2000);
CREATE TABLE
postgres=> SET apg_plan_mgmt.capture_plan_baselines TO 'manual';
SET
postgres=> explain (hashes true, costs false) select count(*) from t1 where i > 0;
QUERY PLAN
-------------------------------------------------------------------------
Aggregate
  ->  Append
    ->  Seq Scan on t1a t1_1
        Filter: (i > 0)
    ->  Seq Scan on t1b t1_2
        Filter: (i > 0)
SQL Hash: -1720232281, Plan Hash: -1010664377
(7 rows)

postgres=> SET apg_plan_mgmt.use_plan_baselines TO 'on';
SET
postgres=> explain (hashes true, costs false) select count(*) from t1 where i > 1000;
QUERY PLAN
-------------------------------------------------------------------------
Aggregate
  ->  Seq Scan on t1b t1
      Filter: (i > 1000)
Note: This is not an Approved plan. No usable Approved plan was found.
SQL Hash: -1720232281, Plan Hash: 335531806
(5 rows)
```

Even though the above two plans should be considered the same, they are different because the child table names are not the same after removing digits, which doesn't follow the naming convention rules.
Working with extensions and foreign data wrappers

To extend the functionality to your Aurora PostgreSQL-Compatible Edition DB cluster, you can install and use various PostgreSQL extensions. For example, if your use case calls for intensive data entry across very large tables, you can install the `pg_partman` extension to partition your data and thus spread the workload.

**Note**
As of Aurora PostgreSQL 14.5, Aurora PostgreSQL supports Trusted Language Extensions for PostgreSQL. This feature is implemented as the extension `pg_tle`, which you can add to your Aurora PostgreSQL. By using this extension, developers can create their own PostgreSQL extensions in a safe environment that simplifies the setup and configuration requirements, as well as much of the preliminary testing for new extensions. For more information, see [Working with Trusted Language Extensions for PostgreSQL](p. 1663).

In some cases, rather than installing an extension, you might add a specific module to the list of `shared_preload_libraries` in your Aurora PostgreSQL DB cluster's custom DB cluster parameter group. Typically, the default DB cluster parameter group loads only the `pg_stat_statements`, but several other modules are available to add to the list. For example, you can add scheduling capability by adding the `pg_cron` module, as detailed in [Scheduling maintenance with the PostgreSQL pg_cron extension](p. 1629). As another example, you can log query execution plans by loading the `auto_explain` module. To learn more, see [Logging execution plans of queries](p. 1635) in the AWS knowledge center.

An extension that provides access to external data is more specifically known as a foreign data wrapper (FDW). As one example, the `oracle_fdw` extension allows your Aurora PostgreSQL DB cluster to work with Oracle databases.

You can also specify precisely which extensions can be installed on your Aurora PostgreSQL DB instance, by listing them in the `rds.allowed_extensions` parameter. For more information, see [Restricting installation of PostgreSQL extensions](p. 1629).

Following, you can find information about setting up and using some of the extensions, modules, and FDWs available for Aurora PostgreSQL. For simplicity's sake, these are all referred to as "extensions." You can find listings of extensions that you can use with the currently available Aurora PostgreSQL versions, see [Extension versions for Amazon Aurora PostgreSQL](p. 1616) in the Release Notes for Aurora PostgreSQL.

- Managing large objects with the lo module (p. 1616)
- Managing spatial data with the PostGIS extension (p. 1618)
- Managing PostgreSQL partitions with the pg_partman extension (p. 1625)
- Scheduling maintenance with the PostgreSQL pg_cron extension (p. 1629)
- Using pgAudit to log database activity (p. 1635)
- Using pglogical to synchronize data across instances (p. 1643)
- Working with Oracle databases by using the oracle_fdw extension (p. 1658)
- Working with SQL Server databases by using the tds_fdw extension (p. 1661)

Managing large objects with the lo module

The lo module (extension) is for database users and developers working with PostgreSQL databases through JDBC or ODBC drivers. Both JDBC and ODBC expect the database to handle deletion of large objects when references to them change. However, PostgreSQL doesn't work that way. PostgreSQL
doesn't assume that an object should be deleted when its reference changes. The result is that objects remain on disk, unreferenced. The lo extension includes a function that you use to trigger on reference changes to delete objects if needed.

Tip
To determine if your database can benefit from the lo extension, use the vacuumlo utility to check for orphaned large objects. To get counts of orphaned large objects without taking any action, run the utility with the -n option (no-op). To learn how, see vacuumlo utility following.

The lo module is available for Aurora PostgreSQL 13.7, 12.11, 11.16, 10.21 and higher minor versions.

To install the module (extension), you need rds_superuser privileges. Installing the lo extension adds the following to your database:

- lo – This is a large object (lo) data type that you can use for binary large objects (BLOBs) and other large objects. The lo data type is a domain of the oid data type. In other words, it's an object identifier with optional constraints. For more information, see Object identifiers in the PostgreSQL documentation. In simple terms, you can use the lo data type to distinguish your database columns that hold large object references from other object identifiers (OIDs).
- lo_manage – This is a function that you can use in triggers on table columns that contain large object references. Whenever you delete or modify a value that references a large object, the trigger unlinks the object (lo_unlink) from its reference. Use the trigger on a column only if the column is the sole database reference to the large object.

For more information about the large objects module, see lo in the PostgreSQL documentation.

Installing the lo extension

Before installing the lo extension, make sure that you have rds_superuser privileges.

To install the lo extension

1. Use psql to connect to the primary DB instance of your Aurora PostgreSQL DB cluster.

   ```sh
   psql --host=your-cluster-instance-1.666666666666.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   ```

   When prompted, enter your password. The psql client connects and displays the default administrative connection database, postgres=>, as the prompt.

2. Install the extension as follows.

   ```sql
   postgres=> CREATE EXTENSION lo;
   CREATE EXTENSION
   ```

   You can now use the lo data type to define columns in your tables. For example, you can create a table (images) that contains raster image data. You can use the lo data type for a column raster, as shown in the following example, which creates a table.

   ```sql
   postgres=> CREATE TABLE images (image_name text, raster lo);
   ```

Using the lo_manage trigger function to delete objects

You can use the lo_manage function in a trigger on a lo or other large object columns to clean up (and prevent orphaned objects) when the lo is updated or deleted.
To set up triggers on columns that reference large objects

- Do one of the following:
  - Create a BEFORE UPDATE OR DELETE trigger on each column to contain unique references to large objects, using the column name for the argument.
    
    ```sql
    postgres=> CREATE TRIGGER t_raster BEFORE UPDATE OR DELETE ON images
                FOR EACH ROW EXECUTE FUNCTION lo_manage(raster);
    ```
  - Apply a trigger only when the column is being updated.
    
    ```sql
    postgres=> CREATE TRIGGER t_raster BEFORE UPDATE OF images
                FOR EACH ROW EXECUTE FUNCTION lo_manage(raster);
    ```

The `lo_manage` trigger function works only in the context of inserting or deleting column data, depending on how you define the trigger. It has no effect when you perform a DROP or TRUNCATE operation on a database. That means that you should delete object columns from any tables before dropping, to prevent creating orphaned objects.

For example, suppose that you want to drop the database containing the `images` table. You delete the column as follows.

```sql
postgres=> DELETE FROM images COLUMN raster
```

Assuming that the `lo_manage` function is defined on that column to handle deletes, you can now safely drop the table.

### Using the vacuumlo utility

The `vacuumlo` utility identifies and can remove orphaned large objects from databases. This utility has been available since PostgreSQL 9.1.24. If your database users routinely work with large objects, we recommend that you run `vacuumlo` occasionally to clean up orphaned large objects.

Before installing the `lo` extension, you can use `vacuumlo` to assess whether your Aurora PostgreSQL DB cluster can benefit. To do so, run `vacuumlo` with the `-n` option (no-op) to show what would be removed, as shown in the following:

```
$ vacuumlo -v -n -h your-cluster-instance-1.6666666666666666.aws-region.rds.amazonaws.com -p 5433 -U postgres docs-lab.spatial-db
Password:*****
Connected to database "docs-lab.spatial-db"
Test run: no large objects will be removed!
Would remove 0 large objects from database "docs-lab.spatial-db".
```

As the output shows, orphaned large objects aren't a problem for this particular database.

For more information about this utility, see `vacuumlo` in the PostgreSQL documentation.

### Managing spatial data with the PostGIS extension

PostGIS is an extension to PostgreSQL for storing and managing spatial information. To learn more about PostGIS, see [PostGIS.net](https://postgis.net).

Starting with version 10.5, PostgreSQL supports the libprotobuf 1.3.0 library used by PostGIS for working with map box vector tile data.
Setting up the PostGIS extension requires `rds_superuser` privileges. We recommend that you create a user (role) to manage the PostGIS extension and your spatial data. The PostGIS extension and its related components add thousands of functions to PostgreSQL. Consider creating the PostGIS extension in its own schema if that makes sense for your use case. The following example shows how to install the extension in its own database, but this isn’t required.

Topics

- Step 1: Create a user (role) to manage the PostGIS extension (p. 1619)
- Step 2: Load the PostGIS extensions (p. 1620)
- Step 3: Transfer ownership of the extensions (p. 1620)
- Step 4: Transfer ownership of the PostGIS objects (p. 1621)
- Step 5: Test the extensions (p. 1621)
- Step 6: Upgrade the PostGIS extension (p. 1622)
- PostGIS extension versions (p. 1622)
- Upgrading PostGIS 2 to PostGIS 3 (p. 1623)

Step 1: Create a user (role) to manage the PostGIS extension

First, connect to your RDS for PostgreSQL DB instance as a user that has `rds_superuser` privileges. If you kept the default name when you set up your instance, you connect as `postgres`.

```bash
psql --host=<111122223333.aws-region.rds.amazonaws.com> --port=5432 --username=postgres --password
```

Create a separate role (user) to administer the PostGIS extension.

```bash
postgres=> CREATE ROLE gis_admin LOGIN PASSWORD 'change_me';
```

Grant this role `rds_superuser` privileges, to allow the role to install the extension.

```bash
postgres=> GRANT rds_superuser TO gis_admin;
```

Create a database to use for your PostGIS artifacts. This step is optional. Or you can create a schema in your user database for the PostGIS extensions, but this also isn’t required.

```bash
postgres=> CREATE DATABASE lab_gis;
```

Give the `gis_admin` all privileges on the `lab_gis` database.

```bash
postgres=> GRANT ALL PRIVILEGES ON DATABASE lab_gis TO gis_admin;
```

Exit the session and reconnect to your RDS for PostgreSQL DB instance as `gis_admin`.

```bash
postgres=> psql --host=<111122223333.aws-region.rds.amazonaws.com> --port=5432 --username=gis_admin --password --dbname=lab_gis
```

Password for user gis_admin:...

```bash
lab_gis=>
```

Continue setting up the extension as detailed in the next steps.
Step 2: Load the PostGIS extensions

The PostGIS extension includes several related extensions that work together to provide geospatial functionality. Depending on your use case, you might not need all the extensions created in this step.

Use `CREATE EXTENSION` statements to load the PostGIS extensions.

```
CREATE EXTENSION postgis;
CREATE EXTENSION postgis_raster;
CREATE EXTENSION fuzzystrmatch;
CREATE EXTENSION postgis_tiger_geocoder;
CREATE EXTENSION postgis_topology;
CREATE EXTENSION address_standardizer_data_us;
```

You can verify the results by running the SQL query shown in the following example, which lists the extensions and their owners.

```
SELECT n.nspname AS "Name",
       pg_catalog.pg_get_userbyid(n.nspowner) AS "Owner"
FROM pg_catalog.pg_namespace n
WHERE n.nspname !~ '^pg_' AND n.nspname <> 'information_schema'
ORDER BY 1;
```

List of schemas

<table>
<thead>
<tr>
<th>Name</th>
<th>Owner</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>postgres</td>
</tr>
<tr>
<td>tiger</td>
<td>rdsadmin</td>
</tr>
<tr>
<td>tiger_data</td>
<td>rdsadmin</td>
</tr>
<tr>
<td>topology</td>
<td>rdsadmin</td>
</tr>
</tbody>
</table>

(4 rows)

Step 3: Transfer ownership of the extensions

Use the `ALTER SCHEMA` statements to transfer ownership of the schemas to the `gis_admin` role.

```
ALTER SCHEMA tiger OWNER TO gis_admin;
ALTER SCHEMA tiger_data OWNER TO gis_admin;
ALTER SCHEMA topology OWNER TO gis_admin;
```

You can confirm the ownership change by running the following SQL query. Or you can use the `\dn` metacommand from the `psql` command line.

```
SELECT n.nspname AS "Name",
       pg_catalog.pg_get_userbyid(n.nspowner) AS "Owner"
FROM pg_catalog.pg_namespace n
WHERE n.nspname !~ '^pg_' AND n.nspname <> 'information_schema'
ORDER BY 1;
```

List of schemas

<table>
<thead>
<tr>
<th>Name</th>
<th>Owner</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
**Step 4: Transfer ownership of the PostGIS objects**

Use the following function to transfer ownership of the PostGIS objects to the `gis_admin` role. Run the following statement from the psql prompt to create the function.

```
CREATE FUNCTION exec(text) returns text language plpgsql volatile AS $f$
BEGIN EXECUTE $1;
RETURN $1;
END;
$f$;
```

Next, run the following query to run the `exec` function that in turn runs the statements and alters the permissions.

```
SELECT exec('ALTER TABLE ' || quote_ident(s.nspname) || '.' || quote_ident(s.relname) || 
  ' OWNER TO gis_admin;')
FROM ( 
  SELECT nspname, relname 
  FROM pg_class c JOIN pg_namespace n ON (c.relnamespace = n.oid) 
  WHERE nspname in ('tiger','topology') AND 
  relkind IN ('r','S','v') ORDER BY relkind = 'S')
s;
```

**Step 5: Test the extensions**

To avoid needing to specify the schema name, add the `tiger` schema to your search path using the following command.

```
SET search_path=public,tiger;
```

Test the `tiger` schema by using the following SELECT statement.

```
SELECT address, streetname, streettypeabbrev, zip 
FROM normalize_address('1 Devonshire Place, Boston, MA 02109') AS na;
```

```
<table>
<thead>
<tr>
<th>address</th>
<th>streetname</th>
<th>streettypeabbrev</th>
<th>zip</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Devonshire</td>
<td>Pl</td>
<td>02109</td>
</tr>
</tbody>
</table>
```

To learn more about this extension, see [Tiger Geocoder](https://postgis.net/docs/TigerGeocoder.html) in the PostGIS documentation.

Test access to the `topology` schema by using the following SELECT statement. This calls the `createtopology` function to register a new topology object (`my_new_topo`) with the specified spatial reference identifier (26986) and default tolerance (0.5). To learn more, see [CreateTopology](https://postgis.net/docs/PostGIS_SpatialExtensions.html) in the PostGIS documentation.

```
SELECT topology.createtopology('my_new_topo',26986,0.5);
```

```
createtopology
----------------
1
```

---

<table>
<thead>
<tr>
<th>public</th>
<th>postgres</th>
</tr>
</thead>
<tbody>
<tr>
<td>tiger</td>
<td>gis_admin</td>
</tr>
<tr>
<td>tiger_data</td>
<td>gis_admin</td>
</tr>
<tr>
<td>topology</td>
<td>gis_admin</td>
</tr>
<tr>
<td>(4 rows)</td>
<td></td>
</tr>
</tbody>
</table>
Step 6: Upgrade the PostGIS extension

Each new release of PostgreSQL supports one or more versions of the PostGIS extension compatible with that release. Upgrading the PostgreSQL engine to a new version doesn't automatically upgrade the PostGIS extension. Before upgrading the PostgreSQL engine, you typically upgrade PostGIS to the newest available version for the current PostgreSQL version. For details, see PostGIS extension versions (p. 1622).

After the PostgreSQL engine upgrade, you then upgrade the PostGIS extension again, to the version supported for the newly upgraded PostgreSQL engine version. For more information about upgrading the PostgreSQL engine, see Testing an upgrade of your production DB cluster to a new major version (p. 1786).

You can check for available PostGIS extension version updates on your Aurora PostgreSQL DB cluster at any time. To do so, run the following command. This function is available with PostGIS 2.5.0 and higher versions.

```sql
SELECT postGIS_extensions_upgrade();
```

If your application doesn't support the latest PostGIS version, you can install an older version of PostGIS that's available in your major version as follows.

```sql
CREATE EXTENSION postgis VERSION "2.5.5";
```

If you want to upgrade to a specific PostGIS version from an older version, you can also use the following command.

```sql
ALTER EXTENSION postgis UPDATE TO "2.5.5";
```

Depending on the version that you're upgrading from, you might need to use this function again. The result of the first run of the function determines if an additional upgrade function is needed. For example, this is the case for upgrading from PostGIS 2 to PostGIS 3. For more information, see Upgrading PostGIS 2 to PostGIS 3 (p. 1623).

If you upgraded this extension to prepare for a major version upgrade of the PostgreSQL engine, you can continue with other preliminary tasks. For more information, see Testing an upgrade of your production DB cluster to a new major version (p. 1786).

PostGIS extension versions

We recommend that you install the versions of all extensions such as PostGIS as listed in Extension versions for Aurora PostgreSQL-Compatible Edition in the Release Notes for Aurora PostgreSQL. To get a list of versions that are available in your release, use the following command.

```sql
SELECT * FROM pg_available_extension_versions WHERE name='postgis';
```

You can find version information in the following sections in the Release Notes for Aurora PostgreSQL:

- Extension versions for Aurora PostgreSQL 14
- Extension versions for Aurora PostgreSQL-Compatible Edition 13
- Extension versions for Aurora PostgreSQL-Compatible Edition 12
- Extension versions for Aurora PostgreSQL-Compatible Edition 11
- Extension versions for Aurora PostgreSQL-Compatible Edition 10
Upgrading PostGIS 2 to PostGIS 3

Starting with version 3.0, the PostGIS raster functionality is now a separate extension, `postgis_raster`. This extension has its own installation and upgrade path. This removes dozens of functions, data types, and other artifacts required for raster image processing from the core `postgis` extension. That means that if your use case doesn't require raster processing, you don't need to install the `postgis_raster` extension.

In the following upgrade example, the first upgrade command extracts raster functionality into the `postgis_raster` extension. A second upgrade command is then required to upgrade `postgres_raster` to the new version.

To upgrade from PostGIS 2 to PostGIS 3

1. Identify the default version of PostGIS that's available to the PostgreSQL version on your Aurora PostgreSQL DB cluster. To do so, run the following query.

```
SELECT * FROM pg_available_extensions
WHERE default_version > installed_version;
```

<table>
<thead>
<tr>
<th>name</th>
<th>default_version</th>
<th>installed_version</th>
<th>comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>postgis</td>
<td>3.1.4</td>
<td>2.3.7</td>
<td>PostGIS geometry and geography spatial types and functions</td>
</tr>
</tbody>
</table>

This mismatch between the default version (PostGIS 3.1.4) and the installed version (PostGIS 2.3.7) means that you need to upgrade the PostGIS extension.

```
ALTER EXTENSION postgis UPDATE;
```

```
ALTER EXTENSION
WARNING: unpackaging raster
WARNING: PostGIS Raster functionality has been unpackaged
```
3. Run the following query to verify that the raster functionality is now in its own package.

```sql
SELECT probin, count(*)
FROM pg_proc
WHERE probin LIKE '%postgis%'
GROUP BY probin;
```

<table>
<thead>
<tr>
<th>probin</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>$libdir/rtpostgis-2.3</td>
<td>107</td>
</tr>
<tr>
<td>$libdir/postgis-3</td>
<td>487</td>
</tr>
</tbody>
</table>

(2 rows)

The output shows that there's still a difference between versions. The PostGIS functions are version 3 (postgis-3), while the raster functions (rtpostgis) are version 2 (rtpostgis-2.3). To complete the upgrade, you run the upgrade command again, as follows.

```sql
postgres=> SELECT postgis_extensions_upgrade();
```

You can safely ignore the warning messages. Run the following query again to verify that the upgrade is complete. The upgrade is complete when PostGIS and all related extensions aren't marked as needing upgrade.

```sql
SELECT postgis_full_version();
```

4. Use the following query to see the completed upgrade process and the separately packaged extensions, and verify that their versions match.

```sql
SELECT e.extname AS "Name",
       e.extversion AS "Version",
       n.nspname AS "Schema",
       c.description AS "Description"
FROM pg_catalog.pg_extension e
     LEFT JOIN pg_catalog.pg_namespace n ON n.oid = e.extnamespace
     LEFT JOIN pg_catalog.pg_description c ON c.objoid = e.oid
       AND c.classoid = 'pg_catalog.pg_extension'::pg_catalog.regclass
WHERE e.extname LIKE '%postgis%'
ORDER BY 1;
```

<table>
<thead>
<tr>
<th>Name</th>
<th>Version</th>
<th>Schema</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>postgis</td>
<td>3.1.5</td>
<td>public</td>
<td>PostGIS geometry, geography, and raster spatial types and functions</td>
</tr>
<tr>
<td>postgis_raster</td>
<td>3.1.5</td>
<td>public</td>
<td>PostGIS raster types and functions</td>
</tr>
</tbody>
</table>

(2 rows)

The output shows that the PostGIS 2 extension was upgraded to PostGIS 3, and both postgis and the now separate postgis_raster extension are version 3.1.5.

After this upgrade completes, if you don't plan to use the raster functionality, you can drop the extension as follows.
Managing PostgreSQL partitions with the pg_partman extension

PostgreSQL table partitioning provides a framework for high-performance handling of data input and reporting. Use partitioning for databases that require very fast input of large amounts of data. Partitioning also provides for faster queries of large tables. Partitioning helps maintain data without impacting the database instance because it requires less I/O resources.

By using partitioning, you can split data into custom-sized chunks for processing. For example, you can partition time-series data for ranges such as hourly, daily, weekly, monthly, quarterly, yearly, custom, or any combination of these. For a time-series data example, if you partition the table by hour, each partition contains one hour of data. If you partition the time-series table by day, the partitions holds one day's worth of data, and so on. The partition key controls the size of a partition.

When you use an INSERT or UPDATE SQL command on a partitioned table, the database engine routes the data to the appropriate partition. PostgreSQL table partitions that store the data are child tables of the main table.

During database query reads, the PostgreSQL optimizer examines the WHERE clause of the query and, if possible, directs the database scan to only the relevant partitions.

Starting with version 10, PostgreSQL uses declarative partitioning to implement table partitioning. This is also known as native PostgreSQL partitioning. Before PostgreSQL version 10, you used triggers to implement partitions.

PostgreSQL table partitioning provides the following features:

- Creation of new partitions at any time.
- Variable partition ranges.
- Detachable and reattachable partitions using data definition language (DDL) statements.
  
  For example, detachable partitions are useful for removing historical data from the main partition but keeping historical data for analysis.
- New partitions inherit the parent database table properties, including the following:
  
  - Indexes
  - Primary keys, which must include the partition key column
  - Foreign keys
  - Check constraints
  - References
  - Creating indexes for the full table or each specific partition.

You can't alter the schema for an individual partition. However, you can alter the parent table (such as adding a new column), which propagates to partitions.

Topics

- Overview of the PostgreSQL pg_partman extension (p. 1626)
- Enabling the pg_partman extension (p. 1626)
- Configuring partitions using the create_parent function (p. 1627)
- Configuring partition maintenance using the run_maintenance_proc function (p. 1628)
Overview of the PostgreSQL pg_partman extension

You can use the PostgreSQL pg_partman extension to automate the creation and maintenance of table partitions. For more general information, see PG Partition Manager in the pg_partman documentation.

Note
The pg_partman extension is supported on Aurora PostgreSQL versions 12.6 and higher.

Instead of having to manually create each partition, you configure pg_partman with the following settings:

- Table to be partitioned
- Partition type
- Partition key
- Partition granularity
- Partition precreation and management options

After you create a PostgreSQL partitioned table, you register it with pg_partman by calling the create_parent function. Doing this creates the necessary partitions based on the parameters you pass to the function.

The pg_partman extension also provides the run_maintenance_proc function, which you can call on a scheduled basis to automatically manage partitions. To ensure that the proper partitions are created as needed, schedule this function to run periodically (such as hourly). You can also ensure that partitions are automatically dropped.

Enabling the pg_partman extension

If you have multiple databases inside the same PostgreSQL DB instance for which you want to manage partitions, enable the pg_partman extension separately for each database. To enable the pg_partman extension for a specific database, create the partition maintenance schema and then create the pg_partman extension as follows.

```
CREATE SCHEMA partman;
CREATE EXTENSION pg_partman WITH SCHEMA partman;
```

Note
To create the pg_partman extension, make sure that you have rds_superuser privileges.

If you receive an error such as the following, grant the rds_superuser privileges to the account or use your superuser account.

```
ERROR: permission denied to create extension "pg_partman"
HINT: Must be superuser to create this extension.
```

To grant rds_superuser privileges, connect with your superuser account and run the following command.

```
GRANT rds_superuser TO user-or-role;
```

For the examples that show using the pg_partman extension, we use the following sample database table and partition. This database uses a partitioned table based on a timestamp. A schema data_mart contains a table named events with a column named created_at. The following settings are included in the events table:
• Primary keys event_id and created_at, which must have the column used to guide the partition.
• A check constraint ck_valid_operation to enforce values for an operation table column.
• Two foreign keys, where one (fk_orga_membership) points to the external table organization and the other (fk_parent_event_id) is a self-referenced foreign key.
• Two indexes, where one (idx_org_id) is for the foreign key and the other (idx_event_type) is for the event type.

The following DDL statements create these objects, which are automatically included on each partition.

```
CREATE SCHEMA data_mart;
CREATE TABLE data_mart.organization ( org_id BIGSERIAL, 
  org_name TEXT, 
  CONSTRAINT pk_organization PRIMARY KEY (org_id) );

CREATE TABLE data_mart.events( 
  event_id        BIGSERIAL, 
  operation       CHAR(1), 
  value           FLOAT(24), 
  parent_event_id BIGINT, 
  event_type      VARCHAR(25), 
  org_id          BIGSERIAL, 
  created_at      timestamp, 
  CONSTRAINT pk_data_mart_event PRIMARY KEY (event_id, created_at), 
  CONSTRAINT ck_valid_operation CHECK (operation = 'C' OR operation = 'D'), 
  CONSTRAINT fk_orga_membership 
    REFERENCES data_mart.organization (org_id), 
  CONSTRAINT fk_parent_event_id 
    REFERENCES data_mart.events (event_id,created_at) 
) PARTITION BY RANGE (created_at);

CREATE INDEX idx_org_id     ON  data_mart.events(org_id);
CREATE INDEX idx_event_type ON  data_mart.events(event_type);
```

Configuring partitions using the create_parent function

After you enable the pg_partman extension, use the create_parent function to configure partitions inside the partition maintenance schema. The following example uses the events table example created in Enabling the pg_partman extension (p. 1626). Call the create_parent function as follows.

```
SELECT partman.create_parent( p_parent_table => 'data_mart.events', 
  p_control => 'created_at', 
  p_type => 'native', 
  p_interval => 'daily', 
  p_premake => 30);
```

The parameters are as follows:

• p_parent_table – The parent partitioned table. This table must already exist and be fully qualified, including the schema.
• p_control – The column on which the partitioning is to be based. The data type must be an integer or time-based.
• p_type – The type is either 'native' or 'partman'. You typically use the native type for its performance improvements and flexibility. The partman type relies on inheritance.
• `p_interval` – The time interval or integer range for each partition. Example values include daily, hourly, and so on.
• `p_premake` – The number of partitions to create in advance to support new inserts.

For a complete description of the `create_parent` function, see [Creation Functions](#) in the `pg_partman` documentation.

**Configuring partition maintenance using the `run_maintenance_proc` function**

You can run partition maintenance operations to automatically create new partitions, detach partitions, or remove old partitions. Partition maintenance relies on the `run_maintenance_proc` function of the `pg_partman` extension and the `pg_cron` extension, which initiates an internal scheduler. The `pg_cron` scheduler automatically executes SQL statements, functions, and procedures defined in your databases.

The following example uses the `events` table example created in [Enabling the `pg_partman` extension](p. 1626) to set partition maintenance operations to run automatically. As a prerequisite, add `pg_cron` to the `shared_preload_libraries` parameter in the DB instance's parameter group.

```sql
CREATE EXTENSION pg_cron;

UPDATE partman.part_config
SET infinite_time_partitions = true,
    retention = '3 months',
    retention_keep_table=true
WHERE parent_table = 'data_mart.events';
SELECT cron.schedule('@hourly', $$CALL partman.run_maintenance_proc()$$);
```

Following, you can find a step-by-step explanation of the preceding example:

1. Modify the parameter group associated with your DB instance and add `pg_cron` to the `shared_preload_libraries` parameter value. This change requires a DB instance restart for it to take effect. For more information, see [Modifying parameters in a DB parameter group](p. 229).
2. Run the command `CREATE EXTENSION pg_cron`; using an account that has the `rds_superuser` permissions. Doing this enables the `pg_cron` extension. For more information, see [Scheduling maintenance with the PostgreSQL `pg_cron` extension](p. 1629).
3. Run the command `UPDATE partman.part_config` to adjust the `pg_partman` settings for the `data_mart.events` table.
4. Run the command `SET ...` to configure the `data_mart.events` table, with these clauses:
   a. `infinite_time_partitions = true`, – Configures the table to be able to automatically create new partitions without any limit.
   b. `retention = '3 months'`, – Configures the table to have a maximum retention of three months.
   c. `retention_keep_table=true` – Configures the table so that when the retention period is due, the table isn't deleted automatically. Instead, partitions that are older than the retention period are only detached from the parent table.
5. Run the command `SELECT cron.schedule ...` to make a `pg_cron` function call. This call defines how often the scheduler runs the `pg_partman` maintenance procedure, `partman.run_maintenance_proc`. For this example, the procedure runs every hour.

For a complete description of the `run_maintenance_proc` function, see [Maintenance Functions](#) in the `pg_partman` documentation.
Scheduling maintenance with the PostgreSQL pg_cron extension

You can use the PostgreSQL pg_cron extension to schedule maintenance commands within a PostgreSQL database. For more information about the extension, see What is pg_cron? in the pg_cron documentation.

The pg_cron extension is supported on Aurora PostgreSQL engine versions 12.6 and higher version.

To learn more about using pg_cron, see Schedule jobs with pg_cron on your RDS for PostgreSQL or your Aurora PostgreSQL-Compatible Edition databases.

Topics
- Setting up the pg_cron extension (p. 1629)
- Granting database users permissions to use pg_cron (p. 1629)
- Scheduling pg_cron jobs (p. 1630)
- Reference for the pg_cron extension (p. 1632)

Setting up the pg_cron extension

Set up the pg_cron extension as follows:

1. Modify the custom parameter group associated with your PostgreSQL DB instance by adding pg_cron to the shared_preload_libraries parameter value.

   Restart the PostgreSQL DB instance to have changes to the parameter group take effect. To learn more about working with parameter groups, see Amazon Aurora PostgreSQL parameters (p. 1728).

2. After the PostgreSQL DB instance has restarted, run the following command using an account that has rds_superuser permissions. For example, if you used the default settings when you created your Aurora PostgreSQL DB cluster, connect as user postgres and create the extension.

   `CREATE EXTENSION pg_cron;`

   The pg_cron scheduler is set in the default PostgreSQL database named postgres. The pg_cron objects are created in this postgres database and all scheduling actions run in this database.

3. You can use the default settings, or you can schedule jobs to run in other databases within your PostgreSQL DB instance. To schedule jobs for other databases within your PostgreSQL DB instance, see the example in Scheduling a cron job for a database other than the default database (p. 1631).

Granting database users permissions to use pg_cron

Installing the pg_cron extension requires the rds_superuser privileges. However, permissions to use the pg_cron can be granted (by a member of the rds_superuser group/role) to other database users, so that they can schedule their own jobs. We recommend that you grant permissions to the cron schema only as needed if it improves operations in your production environment.

To grant a database user permission in the cron schema, run the following command:

`postgres=> GRANT USAGE ON SCHEMA cron TO db-user;`
This gives *db-user* permission to access the `cron` schema to schedule cron jobs for the objects that they have permissions to access. If the database user doesn't have permissions, the job fails after posting the error message to the `postgresql.log` file, as shown in the following:

```
2020-12-08 16:41:00 UTC::@:[30647]:ERROR: permission denied for table table-name
2020-12-08 16:41:00 UTC::@:[27071]:LOG: background worker "pg_cron" (PID 30647) exited with exit code 1
```

In other words, make sure that database users that are granted permissions on the `cron` schema also have permissions on the objects (tables, schemas, and so on) that they plan to schedule.

The details of the cron job and it success or failure are also captured in the `cron.job_run_details` table. For more information, see [Tables for scheduling jobs and capturing status](p. 1634).

### Scheduling pg_cron jobs

The following sections show how you can schedule various management tasks using `pg_cron` jobs.

**Note**

When you create `pg_cron` jobs, check that the `max_worker_processes` setting is larger than the number of `cron.max_running_jobs`. A `pg_cron` job fails if it runs out of background worker processes. The default number of `pg_cron` jobs is 5. For more information, see [Parameters for managing the pg_cron extension](p. 1632).

#### Topics

- [Vacuuming a table](p. 1630)
- [Purging the pg_cron history table](p. 1631)
- [Logging errors to the postgresql.log file only](p. 1631)
- [Scheduling a cron job for a database other than the default database](p. 1631)

### Vacuuming a table

Autovacuum handles vacuum maintenance for most cases. However, you might want to schedule a vacuum of a specific table at a time of your choosing.

Following is an example of using the `cron.schedule` function to set up a job to use `VACUUM FREEZE` on a specific table every day at 22:00 (GMT).

```
SELECT cron.schedule('manual vacuum', '0 22 * * *', 'VACUUM FREEZE pgbench_accounts');
```

```
schedule
-------
1 (1 row)
```

After the preceding example runs, you can check the history in the `cron.job_run_details` table as follows.

```
postgres=> SELECT * FROM cron.job_run_details;
jobid | runid | job_pid | database | username | command                        | status
|------|-------|---------|----------|----------|--------------------------------|
| 1    | 1     | 3395    | postgres | adminuser| vacuum freeze pgbench_accounts | succeeded
|      |       |         |          |          | VACUUM                         |
|      | 3395  |         |          |          | 2020-12-04 21:10:00.0000000000  |
```

1630
Following is an querying the `cron.job_run_details` table to see failed jobs.

```
postgres=> SELECT * FROM cron.job_run_details WHERE status = 'failed';
          jobid | runid | job_pid | database | username | command                       | status    
             |       |         |          |          |                              | start_time | end_time

|      5 |     4 |   30339 | postgres | adminuser| vacuum freeze pgbench_account | failed     
| ERROR: relation "pgbench_account" does not exist | 2020-12-04 21:48:00.015145+00 | 2020-12-04 21:48:00.029567+00
(1 row)
```

For more information, see `Tables for scheduling jobs and capturing status (p. 1634)`.`

### Purging the pg_cron history table

The `cron.job_run_details` table contains a history of cron jobs that can become very large over time. We recommend that you schedule a job that purges this table. For example, keeping a week's worth of entries might be sufficient for troubleshooting purposes.

The following example uses the `cron.schedule (p. 1633)` function to schedule a job that runs every day at midnight to purge the `cron.job_run_details` table. The job keeps only the last seven days. Use your `rds_superuser` account to schedule the job such as the following.

```
SELECT cron.schedule('0 0 * * *', '$$DELETE
FROM cron.job_run_details
WHERE end_time < now() - interval '7 days'$$);
```

For more information, see `Tables for scheduling jobs and capturing status (p. 1634)`.`

### Logging errors to the postgresql.log file only

To prevent writing to the `cron.job_run_details` table, modify the parameter group associated with the PostgreSQL DB instance and set the `cron.log_run` parameter to off. The `pg_cron` extension no longer writes to the table and captures errors to the `postgresql.log` file only. For more information, see `Modifying parameters in a DB parameter group (p. 229)`.

Use the following command to check the value of the `cron.log_run` parameter.

```
postgres=> SHOW cron.log_run;
```

For more information, see `Parameters for managing the pg_cron extension (p. 1632)`.`

### Scheduling a cron job for a database other than the default database

The metadata for `pg_cron` is all held in the PostgreSQL default database named `postgres`. Because background workers are used for running the maintenance cron jobs, you can schedule a job in any of your databases within the PostgreSQL DB instance:

1. In the cron database, schedule the job as you normally do using the `cron.schedule (p. 1633)`.

```
postgres=> SELECT cron.schedule('database1 manual vacuum', '29 03 * * *', 'vacuum freeze
test_table');
```
2. As a user with the `rds_superuser` role, update the database column for the job that you just created so that it runs in another database within your PostgreSQL DB instance.

```
postgres=> UPDATE cron.job SET database = 'database1' WHERE jobid = 106;
```

3. Verify by querying the `cron.job` table.

```
postgres=> SELECT * FROM cron.job;
+-----------+--------+-------------------------+-----------+----------+----------+
<table>
<thead>
<tr>
<th>jobid</th>
<th>schedule</th>
<th>command</th>
<th>nodename</th>
<th>nodeport</th>
<th>database</th>
</tr>
</thead>
<tbody>
<tr>
<td>106</td>
<td>29 03 * * *</td>
<td>vacuum freeze test_table</td>
<td>localhost</td>
<td>8192</td>
<td>database1</td>
</tr>
<tr>
<td>adminuser</td>
<td>t</td>
<td>database1 manual vacuum</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>59 23 * * *</td>
<td>vacuum freeze pgbench_accounts</td>
<td>localhost</td>
<td>8192</td>
<td>postgres</td>
</tr>
<tr>
<td>adminuser</td>
<td>t</td>
<td>manual vacuum</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
(2 rows)
```

**Note**
In some situations, you might add a cron job that you intend to run on a different database. In such cases, the job might try to run in the default database (`postgres`) before you update the correct database column. If the user name has permissions, the job successfully runs in the default database.

### Reference for the pg_cron extension

You can use the following parameters, functions, and tables with the `pg_cron` extension. For more information, see [What is pg_cron?](#) in the pg_cron documentation.

**Topics**

- Parameters for managing the `pg_cron` extension (p. 1632)
- Function reference: `cron.schedule` (p. 1633)
- Function reference: `cron.unschedule` (p. 1634)
- Tables for scheduling jobs and capturing status (p. 1634)

### Parameters for managing the `pg_cron` extension

Following is a list of parameters that control the `pg_cron` extension behavior.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cron.database_name</code></td>
<td>The database in which <code>pg_cron</code> metadata is kept.</td>
</tr>
<tr>
<td><code>cron.host</code></td>
<td>The hostname to connect to PostgreSQL. You can't modify this value.</td>
</tr>
<tr>
<td><code>cron.log_run</code></td>
<td>Log every job that runs in the <code>job_run_details</code> table. Values are on or off. For more information, see <a href="#">Tables for scheduling jobs and capturing status</a>.</td>
</tr>
<tr>
<td><code>cron.log_statement</code></td>
<td>Log all cron statements before running them. Values are on or off.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>cron.max_running_jobs</td>
<td>The maximum number of jobs that can run concurrently.</td>
</tr>
<tr>
<td>cron.use_background_workers</td>
<td>Use background workers instead of client sessions. You can't modify this value.</td>
</tr>
</tbody>
</table>

Use the following SQL command to display these parameters and their values.

```
postgres=> SELECT name, setting, short_desc FROM pg_settings WHERE name LIKE 'cron.%' ORDER BY name;
```

**Function reference: cron.schedule**

This function schedules a cron job. The job is initially scheduled in the default postgres database. The function returns a bigint value representing the job identifier. To schedule jobs to run in other databases within your PostgreSQL DB instance, see the example in [Scheduling a cron job for a database other than the default database](p. 1631).

The function has two syntax formats.

**Syntax**

```
cron.schedule (job_name, schedule, command);
cron.schedule (schedule, command);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_name</td>
<td>The name of the cron job.</td>
</tr>
<tr>
<td>schedule</td>
<td>Text indicating the schedule for the cron job. The format is the standard cron format.</td>
</tr>
<tr>
<td>command</td>
<td>Text of the command to run.</td>
</tr>
</tbody>
</table>

**Examples**

```
postgres=> SELECT cron.schedule ('test', '0 10 * * *', 'VACUUM pgbench_history');
schedule   ----------
           145
(1 row)
postgres=> SELECT cron.schedule ('0 15 * * *', 'VACUUM pgbench_accounts');
schedule   ----------
           146
```
Function reference: cron.unschedule

This function deletes a cron job. You can specify either the job_name or the job_id. A policy makes sure that you are the owner to remove the schedule for the job. The function returns a Boolean indicating success or failure.

The function has the following syntax formats.

Syntax

```sql
cron.unschedule (job_id);
cron.unschedule (job_name);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_id</td>
<td>A job identifier that was returned from the cron.schedule function when the cron job was scheduled.</td>
</tr>
<tr>
<td>job_name</td>
<td>The name of a cron job that was scheduled with the cron.schedule function.</td>
</tr>
</tbody>
</table>

Examples

```sql
postgres=> SELECT cron.unschedule(108);
schedule
-------
t
(1 row)
postgres=> SELECT cron.unschedule('test');
schedule
-------
t
(1 row)
```

Tables for scheduling jobs and capturing status

The following tables are used to schedule the cron jobs and record how the jobs completed.

<table>
<thead>
<tr>
<th>Table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cron.job</td>
<td>Contains the metadata about each scheduled job. Most interactions with this table should be done by using the cron.schedule and cron.unschedule functions.</td>
</tr>
</tbody>
</table>

**Important**

We recommend that you don't give update or insert privileges directly to this table. Doing so would allow the
Using pgAudit to log database activity

Financial institutions, government agencies, and many industries need to keep audit logs to meet regulatory requirements. By using the PostgreSQL Audit extension (pgAudit) with your Aurora PostgreSQL DB cluster, you can capture the detailed records that are typically needed by auditors or to meet regulatory requirements. For example, you can set up the pgAudit extension to track changes made to specific databases and tables, to record the user who made the change, and many other details.

The pgAudit extension builds on the functionality of the native PostgreSQL logging infrastructure by extending the log messages with more detail. In other words, you use the same approach to view your audit log as you do to view any log messages. For more information about PostgreSQL logging, see Aurora PostgreSQL database log files (p. 735).

The pgAudit extension redacts sensitive data such as cleartext passwords from the logs. If your Aurora PostgreSQL DB cluster is configured to log data manipulation language (DML) statements as detailed in Turning on query logging for your Aurora PostgreSQL DB cluster (p. 738), you can avoid the cleartext password issue by using the PostgreSQL Audit extension.

You can configure auditing on your database instances with a great degree of specificity. You can audit all databases and all users. Or, you can choose to audit only certain databases, users, and other objects. You can also explicitly exclude certain users and databases from being audited. For more information, see Excluding users or databases from audit logging (p. 1640).

Given the amount of detail that can be captured, we recommend that if you do use pgAudit, you monitor your storage consumption.

The pgAudit extension is supported on all available Aurora PostgreSQL versions. For a list of pgAudit versions supported by Aurora PostgreSQL version, see Extension versions for Amazon Aurora PostgreSQL in the Release Notes for Aurora PostgreSQL.

Topics
- Setting up the pgAudit extension (p. 1635)
- Auditing database objects (p. 1639)
- Excluding users or databases from audit logging (p. 1640)
- Reference for the pgAudit extension (p. 1642)

Setting up the pgAudit extension

To set up the pgAudit extension on your Aurora PostgreSQL DB cluster, you first add pgAudit to the shared libraries on the custom DB cluster parameter group for your Aurora PostgreSQL DB cluster.
For information about creating a custom DB cluster parameter group, see Working with parameter groups (p. 212). Next, you install the pgAudit extension. Finally, you specify the databases and objects that you want to audit. The procedures in this section show you how. You can use the AWS Management Console or the AWS CLI.

You must have permissions as the rds_superuser role to perform all these tasks.

The steps following assume that your Aurora PostgreSQL DB cluster is associated with a custom DB cluster parameter group.

**Console**

**To set up the pgAudit extension**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose your Aurora PostgreSQL DB cluster's Writer instance.
3. Open the Configuration tab for your Aurora PostgreSQL DB cluster writer instance. Among the Instance details, find the Parameter group link.
4. Choose the link to open the custom parameters associated with your Aurora PostgreSQL DB cluster.
5. In the Parameters search field, type shared_pre to find the shared_preload_libraries parameter.
6. Choose Edit parameters to access the property values.
7. Add pgaudit to the list in the Values field. Use a comma to separate items in the list of values.

8. Reboot the writer instance of your Aurora PostgreSQL DB cluster so that your change to the shared_preload_libraries parameter takes effect.

9. When the instance is available, verify that pgAudit has been initialized. Use psql to connect to the writer instance of your Aurora PostgreSQL DB cluster, and then run the following command.

   ```sql
   SHOW shared_preload_libraries;
   shared_preload_libraries
   --------------------------
   rdsutils,pgaudit
   (1 row)
   ```

10. With pgAudit initialized, you can now create the extension. You need to create the extension after initializing the library because the pgaudit extension installs event triggers for auditing data definition language (DDL) statements.

    ```sql
    CREATE EXTENSION pgaudit;
    ```

11. Close the psql session.
12. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

13. Find the `pgaudit.log` parameter in the list and set to the appropriate value for your use case. For example, setting the `pgaudit.log` parameter to `write` as shown in the following image captures inserts, updates, deletes, and some other types changes to the log.

![Parameter List with `write` value](image)

You can also choose one of the following values for the `pgaudit.log` parameter.

- **none** – This is the default. No database changes are logged.
- **all** – Logs everything (read, write, function, role, ddl, misc).
- **ddl** – Logs all data definition language (DDL) statements that aren’t included in the ROLE class.
- **function** – Logs function calls and D0 blocks.
- **misc** – Logs miscellaneous commands, such as DISCARD, FETCH, CHECKPOINT, VACUUM, and SET.
- **read** – Logs SELECT and COPY when the source is a relation (such as a table) or a query.
- **role** – Logs statements related to roles and privileges, such as GRANT, REVOKE, CREATE ROLE, ALTER ROLE, and DROP ROLE.
- **write** – Logs INSERT, UPDATE, DELETE, TRUNCATE, and COPY when the destination is a relation (table).

14. Choose **Save changes**.

15. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.

16. Choose your Aurora PostgreSQL DB cluster's writer instance from the Databases list to select it, and then choose **Reboot** from the Actions menu.

### AWS CLI

#### To setup pgAudit

To setup pgAudit using the AWS CLI, you call the `modify-db-parameter-group` operation to modify the audit log parameters in your custom parameter group, as shown in the following procedure.

1. Use the following AWS CLI command to add `pgaudit` to the `shared_preload_libraries` parameter.

   ```bash
   aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters "ParameterName=shared_preload_libraries,ParameterValue=pgaudit,ApplyMethod=pending-reboot"
   ```
2. Use the following AWS CLI command to reboot the writer instance of your Aurora PostgreSQL DB cluster so that the pgaudit library is initialized.

```bash
aws rds reboot-db-instance \
   --db-instance-identifier writer-instance \
   --region aws-region
```

3. When the instance is available, you can verify that pgaudit has been initialized. Use psql to connect to the writer instance of your Aurora PostgreSQL DB cluster, and then run the following command.

```sql
SHOW shared_preload_libraries;
```

```
shared_preload_libraries
--------------------------
rdsutils,pgaudit
(1 row)
```

With pgAudit initialized, you can now create the extension.

```sql
CREATE EXTENSION pgaudit;
```

4. Close the psql session so that you can use the AWS CLI.

```
labdb=> \q
```

5. Use the following AWS CLI command to specify the classes of statement that want logged by session audit logging. The example sets the pgaudit.log parameter to write, which captures inserts, updates, and deletes to the log.

```bash
aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters "ParameterName=pgaudit.log,ParameterValue=write,ApplyMethod=pending-reboot" \
   --region aws-region
```

You can also choose one of the following values for the pgaudit.log parameter.

- none – This is the default. No database changes are logged.
- all – Logs everything (read, write, function, role, ddl, misc).
- ddl – Logs all data definition language (DDL) statements that aren’t included in the ROLE class.
- function – Logs function calls and DO blocks.
- misc – Logs miscellaneous commands, such as DISCARD, FETCH, CHECKPOINT, VACUUM, and SET.
- read – Logs SELECT and COPY when the source is a relation (such as a table) or a query.
- role – Logs statements related to roles and privileges, such as GRANT, REVOKE, CREATE ROLE, ALTER ROLE, and DROP ROLE.
- write – Logs INSERT, UPDATE, DELETE, TRUNCATE, and COPY when the destination is a relation (table).

Reboot the writer instance of your Aurora PostgreSQL DB cluster using the following AWS CLI command.

```bash
aws rds reboot-db-instance \
   --db-instance-identifier writer-instance \
```
Auditing database objects

With pgAudit set up on your Aurora PostgreSQL DB cluster and configured for your requirements, more detailed information is captured in the PostgreSQL log. For example, while the default PostgreSQL logging configuration identifies the date and time that a change was made in a database table, with the pgAudit extension the log entry can include the schema, user who made the change, and other details depending on how the extension parameters are configured. You can set up auditing to track changes in the following ways.

- For each session, by user. For the session level, you can capture the fully qualified command text.
- For each object, by user and by database.

The object auditing capability is activated when you create the `rds_pgaudit` role on your system and then add this role to the `pgaudit.role` parameter in your custom parameter parameter group. By default, the `pgaudit.role` parameter is unset and the only allowable value is `rds_pgaudit`. The following steps assume that pgAudit has been initialized and that you have created the `pgaudit` extension by following the procedure in Setting up the pgAudit extension (p. 1635).

As shown in this example, the "LOG: AUDIT: SESSION" line provides information about the table and its schema, among other details.

To set up object auditing

1. Use `psql` to connect to the writer instance of your Aurora PostgreSQL DB cluster.

   ```bash
   psql --host=your-instance-name.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
   ```

2. Create a database role named `rds_pgaudit` using the following command.

   ```bash
   labdb=> CREATE ROLE rds_pgaudit;
   CREATE ROLE
   labdb=>
   ```

3. Close the `psql` session.

   ```bash
   labdb=> \q
   ```

   In the next few steps, use the AWS CLI to modify the audit log parameters in your custom parameter group.

4. Use the following AWS CLI command to set the `pgaudit.role` parameter to `rds_pgaudit`. By default, this parameter is empty, and `rds_pgaudit` is the only allowable value.

   ```bash
   aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   ```
5. Use the following AWS CLI command to reboot the writer instance of your Aurora PostgreSQL DB cluster so that your changes to the parameters take effect.

```bash
aws rds reboot-db-instance \
  --db-instance-identifier writer-instance \
  --region aws-region
```

6. Run the following command to confirm that the `pgaudit.role` is set to `rds_pgaudit`.

```sql
SHOW pgaudit.role;
pgaudit.role
------------------
rds_pgaudit
```

To test pgAudit logging, you can run several example commands that you want to audit. For example, you might run the following commands.

```sql
CREATE TABLE t1 (id int);
GRANT SELECT ON t1 TO rds_pgaudit;
SELECT * FROM t1;
```

The database logs should contain an entry similar to the following.

```
2017-06-12 19:09:49 UTC:...:rds_test@postgres:[11701]:LOG: AUDIT: OBJECT,1,1,READ,SELECT,TABLE,public.t1,select * from t1;
```

For information on viewing the logs, see [Monitoring Amazon Aurora log files](#) (p. 722).

To learn more about the pgAudit extension, see [pgAudit](#) on GitHub.

### Excluding users or databases from audit logging

As discussed in [Aurora PostgreSQL database log files](#), PostgreSQL logs consume storage space. Using the pgAudit extension adds to the volume of data gathered in your logs to varying degrees, depending on the changes that you track. You might not need to audit every user or database in your Aurora PostgreSQL DB cluster.

To minimize impacts to your storage and to avoid needlessly capturing audit records, you can exclude users and databases from being audited. You can also change logging within a given session. The following examples show you how.

**Note**

Parameter settings at the session level take precedence over the settings in the custom DB cluster parameter group for the Aurora PostgreSQL DB cluster's writer instance. If you don't want database users to bypass your audit logging configuration settings, be sure to change their permissions.

Suppose that your Aurora PostgreSQL DB cluster is configured to audit the same level of activity for all users and databases. You then decide that you don't want to audit the user `myuser`. You can turn off auditing for `myuser` with the following SQL command.
ALTER USER myuser SET pgaudit.log TO 'NONE';

Then, you can use the following query to check the user_specific_settings column for pgaudit.log to confirm that the parameter is set to NONE.

```
SELECT  
  usename AS user_name,  
  useconfig AS user_specific_settings  
FROM    
  pg_user  
WHERE   
  usename = 'myuser';
```

You see output such as the following.

```
user_name | user_specific_settings
-----------+------------------------
myuser    | {pgaudit.log=NONE}
(1 row)
```

You can turn off logging for a given user in the midst of their session with the database with the following command.

```
ALTER USER myuser IN DATABASE mydatabase SET pgaudit.log TO 'none';
```

Use the following query to check the settings column for pgaudit.log for a specific user and database combination.

```
SELECT  
  usename AS "user_name",  
  datname AS "database_name",  
  pg_catalog.array_to_string(setconfig, E'\n') AS "settings"  
FROM    
  pg_catalog.pg_db_role_setting s  
  LEFT JOIN pg_catalog.pg_database d ON d.oid = setdatabase  
  LEFT JOIN pg_catalog.pg_user r ON r.usesysid = setrole  
WHERE   
  usename = 'myuser'  
  AND datname = 'mydatabase'  
ORDER BY  
  1,  
  2;
```

You see output similar to the following.

```
user_name | database_name |     settings
-----------+---------------+------------------
myuser    | mydatabase    | pgaudit.log=none
(1 row)
```

After turning off auditing for `myuser`, you decide that you don't want to track changes to `mydatabase`. You turn off auditing for that specific database by using the following command.

```
ALTER DATABASE mydatabase SET pgaudit.log to 'NONE';
```

Then, use the following query to check the database_specific_settings column to confirm that pgaudit.log is set to NONE.

```
```
```sql
SELECT
a.datname AS database_name,
b.setconfig AS database_specific_settings
FROM
pg_database a
FULL JOIN pg_db_role_setting b ON a.oid = b.setdatabase
WHERE
a.datname = 'mydatabase';
```

You see output such as the following.

<table>
<thead>
<tr>
<th>database_name</th>
<th>database_specific_settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>mydatabase</td>
<td>{pgaudit.log=NONE}</td>
</tr>
</tbody>
</table>

(1 row)

To return settings to the default setting for myuser, use the following command:

```sql
ALTER USER myuser RESET pgaudit.log;
```

To return settings to their default setting for a database, use the following command.

```sql
ALTER DATABASE mydatabase RESET pgaudit.log;
```

To reset user and database to the default setting, use the following command.

```sql
ALTER USER myuser IN DATABASE mydatabase RESET pgaudit.log;
```

You can also capture specific events to the log by setting the `pgaudit.log` to one of the other allowed values for the `pgaudit.log` parameter. For more information, see [List of allowable settings for the `pgaudit.log` parameter](p. 1643).

```sql
ALTER USER myuser SET pgaudit.log TO 'read';
ALTER DATABASE mydatabase SET pgaudit.log TO 'function';
ALTER USER myuser IN DATABASE mydatabase SET pgaudit.log TO 'read, function'
```

**Reference for the pgAudit extension**

You can specify the level of detail that you want for your audit log by changing one or more of the parameters listed in this section.

**Controlling pgAudit behavior**

You can control the audit logging by changing one or more of the parameters listed in the following table.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pgaudit.log</code></td>
<td>Specifies the statement classes that will be logged by session audit logging. Allowable values include ddl, function, misc, read, role, write, none, all. For more information, see [List of allowable settings for the <code>pgaudit.log</code> parameter](p. 1643).</td>
</tr>
<tr>
<td><code>pgaudit.log_catalog</code></td>
<td>When turned on (set to 1), adds statements to audit trail if all relations in a statement are in <code>pg_catalog</code>.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>pgaudit.log_level</td>
<td>Specifies the log level to use for log entries. Allowed values: debug5, debug4, debug3, debug2, debug1, info, notice, warning, log</td>
</tr>
<tr>
<td>pgaudit.log_parameter</td>
<td>When turned on (set to 1), parameters passed with the statement are captured in the audit log.</td>
</tr>
<tr>
<td>pgaudit.log_relation</td>
<td>When turned on (set to 1), the audit log for the session creates a separate log entry for each relation (TABLE, VIEW, and so on) referenced in a SELECT or DML statement.</td>
</tr>
<tr>
<td>pgaudit.log_statement_once</td>
<td>Specifies whether logging will include the statement text and parameters with the first log entry for a statement/substatement combination or with every entry.</td>
</tr>
<tr>
<td>pgaudit.role</td>
<td>Specifies the master role to use for object audit logging. The only allowable entry is rds_pgaudit.</td>
</tr>
</tbody>
</table>

List of allowable settings for the `pgaudit.log` parameter

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

To log multiple event types with session auditing, use a comma-separated list. To log all event types, set `pgaudit.log` to ALL. Reboot your DB instance to apply the changes.

With object auditing, you can refine audit logging to work with specific relations. For example, you can specify that you want audit logging for READ operations on one or more tables.

Using pglogical to synchronize data across instances

All currently available Aurora PostgreSQL versions support the pglogical extension. The pglogical extension predates the functionally similar logical replication feature that was introduced by PostgreSQL in version 10. For more information, see Using PostgreSQL logical replication with Aurora (p. 1506).
The pglogical extension supports logical replication between two or more Aurora PostgreSQL DB clusters. It also supports replication between different PostgreSQL versions, and between databases running on RDS for PostgreSQL DB instances and Aurora PostgreSQL DB clusters. The pglogical extension uses a publish-subscribe model to replicate changes to tables and other objects, such as sequences, from a publisher to a subscriber. It relies on a replication slot to ensure that changes are synchronized from a publisher node to a subscriber node, defined as follows.

- **The publisher node** is the Aurora PostgreSQL DB cluster that's the source of data to be replicated to other nodes. The publisher node defines the tables to be replicated in a publication set.
- **The subscriber node** is the Aurora PostgreSQL DB cluster that receives WAL updates from the publisher. The subscriber creates a subscription to connect to the publisher and get the decoded WAL data. When the subscriber creates the subscription, the replication slot is created on the publisher node.

Following, you can find information about setting up the pglogical extension.

### Requirements and limitations for the pglogical extension

All currently available releases of Aurora PostgreSQL support the pglogical extension.

Both the publisher node and the subscriber node must be set up for logical replication.

The tables that you want to replicate from subscriber to publisher must have the same names and the same schema. These tables must also contain the same columns, and the columns must use the same data types. Both publisher and subscriber tables must have the same primary keys. We recommend that you use only the PRIMARY KEY as the unique constraint.

The tables on the subscriber node can have more permissive constraints than those on the publisher node for CHECK constraints and NOT NULL constraints.

The pglogical extension provides features such as two-way replication that aren't supported by the logical replication feature built into PostgreSQL (version 10 and higher). For more information, see [PostgreSQL bi-directional replication using pglogical](https://github.com/postgres/pglogical).

### Setting up the pglogical extension

To set up the pglogical extension on your Aurora PostgreSQL DB cluster, you add pglogical to the shared libraries on the custom DB cluster parameter group for your Aurora PostgreSQL DB cluster. You also need to set the value of the `rds.logical_replication` parameter to 1, to turn on logical decoding. Finally, you create the extension in the database. You can use the AWS Management Console or the AWS CLI for these tasks.

You must have permissions as the `rds_superuser` role to perform these tasks.

The steps following assume that your Aurora PostgreSQL DB cluster is associated with a custom DB cluster parameter group. For information about creating a custom DB cluster parameter group, see [Working with parameter groups](https://docs.aws.amazon.com/AmazonRDS/latest/AuroraPostgreSQLUserGuide/aurora-upgrade-postgresql.html#aurora-postgresql-paramgroups).
Console

To set up the pglogical extension

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose your Aurora PostgreSQL DB cluster's Writer instance.
3. Open the Configuration tab for your Aurora PostgreSQL DB cluster writer instance. Among the Instance details, find the Parameter group link.
4. Choose the link to open the custom parameters associated with your Aurora PostgreSQL DB cluster.
5. In the Parameters search field, type shared_pre to find the shared_preload_libraries parameter.
6. Choose Edit parameters to access the property values.
7. Add pglogical to the list in the Values field. Use a comma to separate items in the list of values.
8. Find the rds.logical_replication parameter and set it to 1, to turn on logical replication.
9. Reboot the writer instance of your Aurora PostgreSQL DB cluster so that your changes take effect.
10. When the instance is available, you can use psql (or pgAdmin) to connect to the writer instance of your Aurora PostgreSQL DB cluster.

   psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb

11. To verify that pglogical is initialized, run the following command.

    SHOW shared_preload_libraries;
    shared_preload_libraries
    --------------------------
    rdutils,pglogical
    (1 row)

12. Verify the setting that enables logical decoding, as follows.

    SHOW wal_level;
    wal_level
    ----------
    logical
    (1 row)

13. Create the extension, as follows.
Choose **Save changes**.

15. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.

16. Choose your Aurora PostgreSQL DB cluster’s writer instance from the Databases list to select it, and then choose **Reboot** from the Actions menu.

**AWS CLI**

**To setup the pglogical extension**

To setup pglogical using the AWS CLI, you call the `modify-db-parameter-group` operation to modify certain parameters in your custom parameter group as shown in the following procedure.

1. Use the following AWS CLI command to add `pglogical` to the `shared_preload_libraries` parameter.

   ```bash
   aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters "ParameterName=shared_preload_libraries,ParameterValue=pglogical,ApplyMethod=pending-reboot" \
   --region aws-region
   ```

2. Use the following AWS CLI command to set `rds.logical_replication` to 1 to turn on the logical decoding capability for the writer instance of the Aurora PostgreSQL DB cluster.

   ```bash
   aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters "ParameterName=rds.logical_replication,ParameterValue=1,ApplyMethod=pending-reboot" \
   --region aws-region
   ```

3. Use the following AWS CLI command to reboot the writer instance of your Aurora PostgreSQL DB cluster so that the pglogical library is initialized.

   ```bash
   aws rds reboot-db-instance \
   --db-instance-identifier writer-instance \
   --region aws-region
   ```

4. When the instance is available, use `psql` to connect to the writer instance of your Aurora PostgreSQL DB cluster.

   ```bash
   psql --host=11112223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres \n   --password --dbname=labdb
   ```

5. Create the extension, as follows.

   ```sql
   CREATE EXTENSION pglogical;
   EXTENSION CREATED
   ```

6. Reboot the writer instance of your Aurora PostgreSQL DB cluster using the following AWS CLI command.

   ```bash
   aws rds reboot-db-instance \
   ```
Setting up logical replication for Aurora PostgreSQL DB cluster

The following procedure shows you how to start logical replication between two Aurora PostgreSQL DB clusters. The steps assume that both the source (publisher) and the target (subscriber) have the pglogical extension set up as detailed in Setting up the pglogical extension (p. 1644).

To create the publisher node and define the tables to replicate

These steps assume that your Aurora PostgreSQL DB cluster has a writer instance with a database that has one or more tables that you want to replicate to another node. You need to recreate the table structure from the publisher on the subscriber, so first, get the table structure if necessary. You can do that by using the psql metacommand `\d tablename` and then creating the same table on the subscriber instance. The following procedure creates an example table on the publisher (source) for demonstration purposes.

1. Use psql to connect to the instance that has the table you want to use as a source for subscribers.

   ```
   psql --host=source-instance.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
   ```

   If you don't have an existing table that you want to replicate, you can create a sample table as follows.

   a. Create an example table using the following SQL statement.

   ```
   CREATE TABLE docs_lab_table (a int PRIMARY KEY);
   ```

   b. Populate the table with generated data by using the following SQL statement.

   ```
   INSERT INTO docs_lab_table VALUES (generate_series(1,5000));
   INSERT 0 5000
   ```

   c. Verify that data exists in the table by using the following SQL statement.

   ```
   SELECT count(*) FROM docs_lab_table;
   ```

2. Identify this Aurora PostgreSQL DB cluster as the publisher node, as follows.

   ```
   SELECT pglogical.create_node('node_name := 'docs_lab_provider', 'dsn := 'host=source-instance.aws-region.rds.amazonaws.com port=5432 dbname=labdb');
   create_node
   ------------------
   3410995529
   (1 row)
   ```

3. Add the table that you want to replicate to the default replication set. For more information about replication sets, see Replication sets in the pglogical documentation.

   ```
   SELECT pglogical.replication_set_add_table('default', 'docs_lab_table', 'true', NULL, NULL);
   replication_set_add_table
   ---------------------------
   t
   ```
The publisher node setup is complete. You can now set up the subscriber node to receive the updates from the publisher.

**To set up the subscriber node and create a subscription to receive updates**

These steps assume that the Aurora PostgreSQL DB cluster has been set up with the pglogical extension. For more information, see Setting up the pglogical extension (p. 1644).

1. Use `psql` to connect to the instance that you want to receive updates from the publisher.

   ```bash
   psql --host=target-instance.aws-region.rds.amazonaws.com --port=5432 --username=postgres --dbname=labdb
   ```

2. On the subscriber Aurora PostgreSQL DB cluster, create the same table that exists on the publisher. For this example, the table is `docs_lab_table`. You can create the table as follows.

   ```sql
   CREATE TABLE docs_lab_table (a int PRIMARY KEY);
   ```

3. Verify that this table is empty.

   ```sql
   SELECT count(*) FROM docs_lab_table;
   count
   -------
   0
   (1 row)
   ```

4. Identify this Aurora PostgreSQL DB cluster as the subscriber node, as follows.

   ```sql
   SELECT pglogical.create_node(
       node_name := 'docs_lab_target',
       dsn := 'host=target-instance.aws-region.rds.amazonaws.com port=5432 sslmode=require dbname=labdb user=postgres password=********');
   create_node
   -------------
   2182738256
   (1 row)
   ```

5. Create the subscription.

   ```sql
   SELECT pglogical.create_subscription(
       subscription_name := 'docs_lab_subscription',
       provider_dsn := 'host=source-instance.aws-region.rds.amazonaws.com port=5432 sslmode=require dbname=labdb user=postgres password=******',
       replication_sets := ARRAY['default'],
       synchronize_data := true,
       forward_origins := '{}');
   create_subscription
   ---------------------
   1038357190
   (1 row)
   ```

When you complete this step, the data from the table on the publisher is created in the table on the subscriber. You can verify that this has occurred by using the following SQL query.

```sql
SELECT count(*) FROM docs_lab_table;
count
-------
```
From this point forward, changes made to the table on the publisher are replicated to the table on the subscriber.

## Reestablishing logical replication after a major upgrade

Before you can perform a major version upgrade of an Aurora PostgreSQL DB cluster that's set up as a publisher node for logical replication, you must drop all replication slots, even those that aren't active. We recommend that you temporarily divert database transactions from the publisher node, drop the replication slots, upgrade the Aurora PostgreSQL DB cluster, and then re-establish and restart replication.

The replication slots are hosted on the publisher node only. The Aurora PostgreSQL subscriber node in a logical replication scenario has no slots to drop. The Aurora PostgreSQL major version upgrade process supports upgrading the subscriber to a new major version of PostgreSQL independent of the publisher node. However, the upgrade process does disrupt the replication process and interferes with the synchronization of WAL data between publisher node and subscriber node. You need to re-establish logical replication between publisher and subscriber after upgrading the publisher, the subscriber, or both. The following procedure shows you how to determine that replication has been disrupted and how to resolve the issue.

### Determining that logical replication has been disrupted

You can determine that the replication process has been disrupted by querying either the publisher node or the subscriber node, as follows.

#### To check the publisher node

- Use `psql` to connect to the publisher node, and then query the `pg_replication_slots` function. Note the value in the `active` column. Normally, this will return `t` (true), showing that replication is active. If the query returns `f` (false), it's an indication that replication to the subscriber has stopped.

```sql
SELECT slot_name, plugin, slot_type, active FROM pg_replication_slots;
```

### To check the subscriber node

On the subscriber node, you can check the status of replication in three different ways.

- Look through the PostgreSQL logs on the subscriber node to find failure messages. The log identifies failure with messages that include exit code 1, as shown following.

```bash
2022-07-06 16:17:03 UTC::@::[7361]:LOG: background worker "pglogical apply 16404:2880255011" (PID 14610) exited with exit code 1
2022-07-06 16:19:44 UTC::@::[7361]:LOG: background worker "pglogical apply 16404:2880255011" (PID 21783) exited with exit code 1
```

- Query the `pg_replication_origin` function. Connect to the database on the subscriber node using `psql` and query the `pg_replication_origin` function, as follows.

```sql
SELECT * FROM pg_replication_origin;
```
The empty result set means that replication has been disrupted. Normally, you see output such as the following.

```
roident | roname
---------+--------
(0 rows)
```

To reestablish logical replication between publisher and subscriber nodes

To re-establish replication, you first disconnect the subscriber from the publisher node and then re-establish the subscription, as outlined in these steps.

1. Connect to the subscriber node using `psql` as follows.

   ```
   psql --host=222222222222.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
   ```

2. Deactivate the subscription by using the `pglogical.alter_subscription_disable` function.

   ```
   SELECT pglogical.alter_subscription_disable('docs_lab_subscription',true);
   ```

3. Get the publisher node's identifier by querying the `pg_replication_origin`, as follows.

   ```
   SELECT * FROM pg_replication_origin;
   ```

4. Use the response from the previous step with the `pg_replication_origin_create` command to assign the identifier that can be used by the subscription when re-established.

   ```
   SELECT pg_replication_origin_create('pgl_labdb_docs_labcb4fa94_docs_lab3de412c');
   ```
5. Turn on the subscription by passing its name with a status of true, as shown in the following example.

```sql
SELECT pglogical.alter_subscription_enable('docs_lab_subscription',true);
```

```
alter_subscription_enable
---------------------------
t
```

Check the status of the node. Its status should be replicating as shown in this example.

```sql
SELECT subscription_name,status,slot_name
FROM pglogical.show_subscription_status();
```

```
subscription_name |   status    |              slot_name
-------------------------------+-------------+-------------------------------------
docs_lab_subscription         | replicating | pgl_labdb_docs_lab98f517b_docs_lab3de412c
```

Check the status of the subscriber's replication slot on the publisher node. The slot's active column should return t (true), indicating that replication has been re-established.

```sql
SELECT slot_name,plugin,slot_type,active
FROM pg_replication_slots;
```

```
slot_name              |      plugin      | slot_type | active
-------------------------------------------+------------------+-----------+--------
pgl_labdb_docs_lab98f517b_docs_lab3de412c | pglogical_output | logical   | t
```

### Managing logical replication slots for Aurora PostgreSQL

Before you can perform a major version upgrade on an Aurora PostgreSQL DB cluster's writer instance that's serving as a publisher node in a logical replication scenario, you must drop the replication slots on the instance. The major version upgrade pre-check process notifies you that the upgrade can't proceed until the slots are dropped.

To identify replication slots that were created using the pglogical extension, log in to each database and get the name of the nodes. When you query the subscriber node, you get both the publisher and the subscriber nodes in the output, as shown in this example.

```sql
SELECT * FROM pglogical.node;
```

```
node_id   |     node_name
------------+-------------------
2182738256 | docs_lab_target
3410995529 | docs_lab_provider
```

You can get the details about the subscription with the following query.

```sql
SELECT sub_name,sub_slot_name,sub_target
FROM pglogical.subscription;
```

```
sub_name |         sub_slot_name          | sub_target
----------+--------------------------------+------------
docs_lab_subscription     | pgl_labdb_docs_labcb4fa94_docs_lab3de412c | 2182738256
```
You can now drop the subscription, as follows.

```
SELECT pglogical.drop_subscription(subscription_name := 'docs_lab_subscription');
```

You can verify that the node no longer exists, as follows.

```
SELECT * FROM pglogical.node;
```

You can drop the subscription, as follows.

```
SELECT pglogical.drop_subscription(subscription_name := 'docs_lab_subscription')
```

(1 row)

After dropping the subscription, you can delete the node.

```
SELECT pglogical.drop_node(node_name := 'docs-lab-subscriber');
```

You can verify that the node no longer exists, as follows.

```
SELECT * FROM pglogical.node;
```

(0 rows)

### Parameter reference for the pglogical extension

In the table you can find parameters associated with the pglogical extension. Parameters such as `pglogical.conflict_log_level` and `pglogical.conflict_resolution` are used to handle update conflicts. Conflicts can emerge when changes are made locally to the same tables that are subscribed to changes from the publisher. Conflicts can also occur during various scenarios, such as two-way replication or when multiple subscribers are replicating from the same publisher. For more information, see [PostgreSQL bi-directional replication using pglogical](https://www.postgresql.org/docs/current/pglogical.html).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pglogical.batch_inserts</code></td>
<td>Batch inserts if possible. Not set by default. Change to '1' to turn on, '0' to turn off.</td>
</tr>
<tr>
<td><code>pglogical.conflict_log_level</code></td>
<td>Sets the log level to use for logging resolved conflicts. Supported string values are debug5, debug4, debug3, debug2, debug1, info, notice, warning, error, log, fatal, panic.</td>
</tr>
<tr>
<td><code>pglogical.conflict_resolution</code></td>
<td>Sets method to use to resolve conflicts when conflicts are resolvable. Supported string values are error, apply_remote, keep_local, last_update_wins, first_update_wins.</td>
</tr>
<tr>
<td><code>pglogical.extra_connection_options</code></td>
<td>Connection options to add to all peer node connections.</td>
</tr>
<tr>
<td><code>pglogical.synchronous_commit</code></td>
<td>pglogical specific synchronous commit value</td>
</tr>
<tr>
<td><code>pglogical.use_spi</code></td>
<td>Use SPI (server programming interface) instead of low-level API to apply changes. Set to '1' to turn on, '0' to turn off. For more information about SPI, see <a href="https://www.postgresql.org/docs/current/serverspi.html">Server Programming Interface</a> in the PostgreSQL documentation.</td>
</tr>
</tbody>
</table>
Working with the supported foreign data wrappers for Amazon Aurora PostgreSQL

A foreign data wrapper (FDW) is a specific type of extension that provides access to external data. For example, the oracle_fdw extension allows your Aurora PostgreSQL DB instance to work with Oracle databases.

Following, you can find information about several supported PostgreSQL foreign data wrappers.

Topics

• Using the log_fdw extension to access the DB log using SQL (p. 1653)
• Using the postgres_fdw extension to access external data (p. 1654)
• Working with MySQL databases by using the mysql_fdw extension (p. 1655)
• Working with Oracle databases by using the oracle_fdw extension (p. 1658)
• Working with SQL Server databases by using the tds_fdw extension (p. 1661)

Using the log_fdw extension to access the DB log using SQL

Aurora PostgreSQL DB cluster supports the log_fdw extension, which you can use to access your database engine log using a SQL interface. The log_fdw extension provides two functions that make it easy to create foreign tables for database logs:

• list_postgres_log_files – Lists the files in the database log directory and the file size in bytes.
• create_foreign_table_for_log_file(table_name text, server_name text, log_file_name text) – Builds a foreign table for the specified file in the current database.

All functions created by log_fdw are owned by rds_superuser. Members of the rds_superuser role can grant access to these functions to other database users.

By default, the log files are generated by Amazon Aurora in stderr (standard error) format, as specified in log_destination parameter. There are only two options for this parameter, stderr and csvlog (comma-separated values, CSV). If you add the csvlog option to the parameter, Amazon Aurora generates both stderr and csvlog logs. This can affect the storage capacity on your DB cluster, so you need to be aware of the other parameters that affect log handling. For more information, see Setting the log destination (stderr, csvlog) (p. 737).

One benefit of generating csvlog logs is that the log_fdw extension lets you build foreign tables with the data neatly split into several columns. To do this, your instance needs to be associated with a custom DB parameter group so that you can change the setting for log_destination. For more information about how to do so, see Working with parameter groups (p. 212).

The following example assumes that the log_destination parameter includes csvlog.

To use the log_fdw extension

1. Install the log_fdw extension.

   postgres=> CREATE EXTENSION log_fdw;
   CREATE EXTENSION

2. Create the log server as a foreign data wrapper.

   postgres=> CREATE SERVER log_server FOREIGN DATA WRAPPER log_fdw;
CREATE SERVER

3. Select all from a list of log files.

```
postgres=> SELECT * FROM list_postgres_log_files() ORDER BY 1;
```

A sample response is as follows.

<table>
<thead>
<tr>
<th>file_name</th>
<th>file_size_bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>postgresql.log.2023-08-09-22.csv</td>
<td>1111</td>
</tr>
<tr>
<td>postgresql.log.2023-08-09-23.csv</td>
<td>1172</td>
</tr>
<tr>
<td>postgresql.log.2023-08-10-00.csv</td>
<td>1744</td>
</tr>
<tr>
<td>postgresql.log.2023-08-10-01.csv</td>
<td>1102</td>
</tr>
</tbody>
</table>

(4 rows)

4. Create a table with a single 'log_entry' column for the selected file.

```
postgres=> SELECT create_foreign_table_for_log_file('my_postgres_error_log',
'log_server', 'postgresql.log.2023-08-09-22.csv');
```

The response provides no detail other than that the table now exists.

```
(1 row)
```

5. Select a sample of the log file. The following code retrieves the log time and error message description.

```
postgres=> SELECT log_time, message FROM my_postgres_error_log ORDER BY 1;
```

A sample response is as follows.

<table>
<thead>
<tr>
<th>log_time</th>
<th>message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tue Aug 09 15:45:18.172 2023 PDT</td>
<td>ending log output to stderr</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.175 2023 PDT</td>
<td>database system was interrupted; last known up at 2023-08-09 22:43:34 UTC</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.223 2023 PDT</td>
<td>checkpoint record is at 0/90002E0</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.223 2023 PDT</td>
<td>redo record is at 0/90002A8; shutdown FALSE</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.223 2023 PDT</td>
<td>next transaction ID: 0/1879; next OID: 24578</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.223 2023 PDT</td>
<td>next MultiXactId: 1; next MultiXactOffset: 0</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.223 2023 PDT</td>
<td>oldest unfrozen transaction ID: 1822, in database 1</td>
</tr>
</tbody>
</table>

(7 rows)

### Using the postgres_fdw extension to access external data

You can access data in a table on a remote database server with the `postgres_fdw` extension. If you set up a remote connection from your PostgreSQL DB instance, access is also available to your read replica.

**To use postgres_fdw to access a remote database server**

1. Install the postgres_fdw extension.

```
CREATE EXTENSION postgres_fdw;
```
2. Create a foreign data server using CREATE SERVER.

```
CREATE SERVER foreign_server
FOREIGN DATA WRAPPER postgres_fdw
OPTIONS (host 'xxx.xx.xxx.xx', port '5432', dbname 'foreign_db');
```

3. Create a user mapping to identify the role to be used on the remote server.

```
CREATE USER MAPPING FOR local_user
SERVER foreign_server
OPTIONS (user 'foreign_user', password 'password');
```

4. Create a table that maps to the table on the remote server.

```
CREATE FOREIGN TABLE foreign_table (
    id integer NOT NULL,
    data text)
SERVER foreign_server
OPTIONS (schema_name 'some_schema', table_name 'some_table');
```

**Working with MySQL databases by using the mysql_fdw extension**

To access a MySQL-compatible database from your Aurora PostgreSQL DB cluster, you can install and use the `mysql_fdw` extension. This foreign data wrapper lets you work with RDS for MySQL, Aurora MySQL, MariaDB, and other MySQL-compatible databases. The connection from Aurora PostgreSQL DB cluster to the MySQL database is encrypted on a best-effort basis, depending on the client and server configurations. However, you can enforce encryption if you like. For more information, see [Using encryption in transit with the extension](p. 1657).

The `mysql_fdw` extension is supported on Amazon Aurora PostgreSQL version 15.4, 14.9, 13.12, 12.16, and higher releases. It supports selects, inserts, updates, and deletes from an RDS for PostgreSQL DB to tables on a MySQL-compatible database instance.

**Topics**

- [Setting up your Aurora PostgreSQL DB to use the mysql_fdw extension](p. 1655)
- [Example: Working with an Aurora MySQL database from Aurora PostgreSQL](p. 1656)
- [Using encryption in transit with the extension](p. 1657)

**Setting up your Aurora PostgreSQL DB to use the mysql_fdw extension**

Setting up the `mysql_fdw` extension on your Aurora PostgreSQL DB cluster involves loading the extension in your DB cluster and then creating the connection point to the MySQL DB instance. For that task, you need to have the following details about the MySQL DB instance:

- Hostname or endpoint. For an Aurora MySQL DB cluster, you can find the endpoint by using the Console. Choose the Connectivity & security tab and look in the "Endpoint and port" section.
- Port number. The default port number for MySQL is 3306.
- Name of the database. The DB identifier.

You also need to provide access on the security group or the access control list (ACL) for the MySQL port, 3306. Both the Aurora PostgreSQL DB cluster and the Aurora MySQL DB cluster need access to port
3306. If access isn’t configured correctly, when you try to connect to MySQL-compatible table you see an error message similar to the following:

```
ERROR: failed to connect to MySQL: Can't connect to MySQL server on 'hostname.aws-region.rds.amazonaws.com:3306' (110)
```

In the following procedure, you (as the rds_superuser account) create the foreign server. You then grant access to the foreign server to specific users. These users then create their own mappings to the appropriate MySQL user accounts to work with the MySQL DB instance.

**To use mysql_fdw to access a MySQL database server**

1. Connect to your PostgreSQL DB instance using an account that has the rds_superuser role. If you accepted the defaults when you created your Aurora PostgreSQL DB cluster, the user name is postgres, and you can connect using the psql command line tool as follows:

   ```bash
   psql --host=your-DB-instance.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   ```

2. Install the mysql_fdw extension as follows:

   ```sql
   postgres=> CREATE EXTENSION mysql_fdw;
   CREATE EXTENSION
   ```

   After the extension is installed on your Aurora PostgreSQL DB cluster, you set up the foreign server that provides the connection to a MySQL database.

**To create the foreign server**

Perform these tasks on the Aurora PostgreSQL DB cluster. The steps assume that you’re connected as a user with rds_superuser privileges, such as postgres.

1. Create a foreign server in the Aurora PostgreSQL DB cluster:

   ```sql
   postgres=> CREATE SERVER mysql-db FOREIGN DATA WRAPPER mysql_fdw OPTIONS (host 'db-name.111122223333.aws-region.rds.amazonaws.com', port '3306');
   CREATE SERVER
   ```

2. Grant the appropriate users access to the foreign server. These should be non-administrator users, that is, users without the rds_superuser role.

   ```sql
   postgres=> GRANT USAGE ON FOREIGN SERVER mysql-db to user1;
   GRANT
   ```

PostgreSQL users create and manage their own connections to the MySQL database through the foreign server.

**Example: Working with an Aurora MySQL database from Aurora PostgreSQL**

Suppose that you have a simple table on an Aurora PostgreSQL DB instance. Your Aurora PostgreSQL users want to query (SELECT), INSERT, UPDATE, and DELETE items on that table. Assume that the mysql_fdw extension was created on your RDS for PostgreSQL DB instance, as detailed in the preceding procedure. After you connect to the RDS for PostgreSQL DB instance as a user that has rds_superuser privileges, you can proceed with the following steps.

1. On the Aurora PostgreSQL DB instance, create a foreign server:
test=> CREATE SERVER mysql_fdw FOREIGN DATA WRAPPER mysql_fdw OPTIONS (host 'your-DB.aws-region.rds.amazonaws.com', port '3306');

2. Grant usage to a user who doesn't have rds_superuser permissions, for example, user1:

```sql
test=> GRANT USAGE ON FOREIGN SERVER mysql_fdw TO user1;
GRANT
```

3. Connect as `user1`, and then create a mapping to the MySQL user:

```sql
test=> CREATE USER MAPPING FOR user1 SERVER mysql_fdw OPTIONS (username 'myuser', password 'mypassword');
CREATE USER MAPPING
```

4. Create a foreign table linked to the MySQL table:

```sql
test=> CREATE FOREIGN TABLE mytab (a int, b text) SERVER mysql_fdw OPTIONS (dbname 'test', table_name '');
CREATE FOREIGN TABLE
```

5. Run a simple query against the foreign table:

```sql
test=> SELECT * FROM mytab;
 a |   b
---+-------
 1 | apple
(1 row)
```

6. You can add, change, and remove data from the MySQL table. For example:

```sql
test=> INSERT INTO mytab values (2, 'mango');
INSERT 0 1
```

Run the SELECT query again to see the results:

```sql
test=> SELECT * FROM mytab ORDER BY 1;
 a |   b
---+-------
 1 | apple
 2 | mango
(2 rows)
```

**Using encryption in transit with the extension**

The connection to MySQL from Aurora PostgreSQL uses encryption in transit (TLS/SSL) by default. However, the connection falls back to non-encrypted when the client and server configuration differ. You can enforce encryption for all outgoing connections by specifying the REQUIRE_SSL option on the RDS for MySQL user accounts. This same approach also works for MariaDB and Aurora MySQL user accounts.

For MySQL user accounts configured to REQUIRE_SSL, the connection attempt fails if a secure connection can't be established.

To enforce encryption for existing MySQL database user accounts, you can use the ALTER_USER command. The syntax varies, depending on the MySQL version, as shown in the following table. For more information, see ALTER USER in MySQL Reference Manual.
Amazon Aurora User Guide for Aurora
Supported foreign data wrappers

<table>
<thead>
<tr>
<th>MySQL 5.7, MySQL 8.0</th>
<th>MySQL 5.6</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTER USER 'user'@'%' REQUIRE SSL;</td>
<td>GRANT USAGE ON <em>.</em> to 'user'@'%' REQUIRE SSL;</td>
</tr>
</tbody>
</table>

For more information about the mysql_fdw extension, see the mysql_fdw documentation.

**Working with Oracle databases by using the oracle_fdw extension**

To access an Oracle database from your Aurora PostgreSQL DB cluster you can install and use the oracle_fdw extension. This extension is a foreign data wrapper for Oracle databases. To learn more about this extension, see the oracle_fdw documentation.

The oracle_fdw extension is supported on Aurora PostgreSQL 12.7 (Amazon Aurora release 4.2) and higher versions.

**Topics**
- Turning on the oracle_fdw extension (p. 1658)
- Example: Using a foreign server linked to an Amazon RDS for Oracle database (p. 1658)
- Working with encryption in transit (p. 1659)
- Understanding the pg_user_mappings view and permissions (p. 1659)

**Turning on the oracle_fdw extension**

To use the oracle_fdw extension, perform the following procedure.

**To turn on the oracle_fdw extension**

- Run the following command using an account that has rds_superuser permissions.

  ```sql
  CREATE EXTENSION oracle_fdw;
  ```

**Example: Using a foreign server linked to an Amazon RDS for Oracle database**

The following example shows the use of a foreign server linked to an Amazon RDS for Oracle database.

**To create a foreign server linked to an RDS for Oracle database**

1. Note the following on the RDS for Oracle DB instance:
   - Endpoint
   - Port
   - Database name

2. Create a foreign server.

  ```sql
  test=> CREATE SERVER oradb FOREIGN DATA WRAPPER oracle_fdw OPTIONS (dbserver '//endpoint:port/DB_name');
  ```

1658
3. Grant usage to a user who doesn't have rds_superuser privileges, for example user1.

```sql
test=> GRANT USAGE ON FOREIGN SERVER oradb TO user1;
GRANT
```

4. Connect as user1, and create a mapping to an Oracle user.

```sql
test=> CREATE USER MAPPING FOR user1 SERVER oradb OPTIONS (user 'oracleuser', password 'mypassword');
CREATE USER MAPPING
```

5. Create a foreign table linked to an Oracle table.

```sql
test=> CREATE FOREIGN TABLE mytab (a int) SERVER oradb OPTIONS (table 'MYTABLE');
CREATE FOREIGN TABLE
```

6. Query the foreign table.

```sql
test=> SELECT * FROM mytab;
a
---
1
(1 row)
```

If the query reports the following error, check your security group and access control list (ACL) to make sure that both instances can communicate.

```sql
ERROR: connection for foreign table "mytab" cannot be established
DETAIL: ORA-12170: TNS:Connect timeout occurred
```

### Working with encryption in transit

PostgreSQL-to-Oracle encryption in transit is based on a combination of client and server configuration parameters. For an example using Oracle 21c, see About the Values for Negotiating Encryption and Integrity in the Oracle documentation. The client used for oracle_fdw on Amazon RDS is configured with ACCEPTED, meaning that the encryption depends on the Oracle database server configuration.

If your database is on RDS for Oracle, see Oracle native network encryption to configure the encryption.

### Understanding the pg_user_mappings view and permissions

The PostgreSQL catalog pg_user_mapping stores the mapping from an Aurora PostgreSQL user to the user on a foreign data (remote) server. Access to the catalog is restricted, but you use the pg_user_mappings view to see the mappings. In the following, you can find an example that shows how permissions apply with an example Oracle database, but this information applies more generally to any foreign data wrapper.

In the following output, you can find roles and permissions mapped to three different example users. Users rdsusu1 and rdsusu2 are members of the rds_superuser role, and user1 isn't. The example uses the psql metacommand `\du` to list existing roles.

```sql
test=> \du
<table>
<thead>
<tr>
<th>Role name</th>
<th>Attributes</th>
<th>List of roles</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Member of</td>
<td></td>
</tr>
</tbody>
</table>
```
All users, including users that have rds_superuser privileges, are allowed to view their own user mappings (umoptions) in the pg_user_mappings table. As shown in the following example, when rdssu1 tries to obtain all user mappings, an error is raised even though rdssu1 rds_superuser privileges:

```
test=> SELECT * FROM pg_user_mapping;
ERROR: permission denied for table pg_user_mapping
```

Following are some examples.

```
test=> SET SESSION AUTHORIZATION rdssu1;
SET
...test=> SELECT * FROM pg_user_mappings;
   umid | srvid | srvname | umuser | usename    | umoptions
-------+-------+---------+--------+------------+----------------------------------
     16414 | 16411 | oradb   | 16412  | user1      |
     16423 | 16411 | oradb   | 16421  | rdssu1     | {user=oracleuser,password=mypwd}
     16424 | 16411 | oradb   | 16422  | rdssu2     |
(3 rows)
```

```
test=> SET SESSION AUTHORIZATION rdssu2;
SET
...test=> SELECT * FROM pg_user_mappings;
   umid | srvid | srvname | umuser | usename    | umoptions
-------+-------+---------+--------+------------+----------------------------------
     16414 | 16411 | oradb   | 16412  | user1      |
     16423 | 16411 | oradb   | 16421  | rdssu1     |
     16424 | 16411 | oradb   | 16422  | rdssu2     | {user=oracleuser,password=mypwd}
(3 rows)
```

```
test=> SET SESSION AUTHORIZATION user1;
SET
...test=> SELECT * FROM pg_user_mappings;
   umid | srvid | srvname | umuser | usename    | umoptions
-------+-------+---------+--------+------------+----------------------------------
     16414 | 16411 | oradb   | 16412  | user1      | {user=oracleuser,password=mypwd}
     16423 | 16411 | oradb   | 16421  | rdssu1     |
     16424 | 16411 | oradb   | 16422  | rdssu2     |
(3 rows)
```

Because of implementation differences between information_schema._pg_user_mappings and pg_catalog.pg_user_mappings, a manually created rds_superuser requires additional permissions to view passwords in pg_catalog.pg_user_mappings.

No additional permissions are required for an rds_superuser to view passwords in information_schema._pg_user_mappings.

Users who don't have the rds_superuser role can view passwords in pg_user_mappings only under the following conditions:

- The current user is the user being mapped and owns the server or holds the USAGE privilege on it.
- The current user is the server owner and the mapping is for PUBLIC.
Working with SQL Server databases by using the tds_fdw extension

You can use the PostgreSQL tds_fdw extension to access databases that support the tabular data stream (TDS) protocol, such as Sybase and Microsoft SQL Server databases. This foreign data wrapper lets you connect from your Aurora PostgreSQL DB cluster to databases that use the TDS protocol, including Amazon RDS for Microsoft SQL Server. For more information, see tds-fdw/tds_fdw documentation on GitHub.

The tds_fdw extension is supported on Amazon Aurora PostgreSQL version 13.6 and higher releases.

Setting up your Aurora PostgreSQL DB to use the tds_fdw extension

In the following procedures, you can find an example of setting up and using the tds_fdw with an Aurora PostgreSQL DB cluster. Before you can connect to a SQL Server database using tds_fdw, you need to get the following details for the instance:

- Hostname or endpoint. For an RDS for SQL Server DB instance, you can find the endpoint by using the Console. Choose the Connectivity & security tab and look in the "Endpoint and port" section.
- Port number. The default port number for Microsoft SQL Server is 1433.
- Name of the database. The DB identifier.

You also need to provide access on the security group or the access control list (ACL) for the SQL Server port, 1433. Both the Aurora PostgreSQL DB cluster and the RDS for SQL Server DB instance need access to port 1433. If access isn’t configured correctly, when you try to query the Microsoft SQL Server you see the following error message:

```plaintext
ERROR: DB-Library error: DB #: 20009, DB Msg: Unable to connect: Adaptive Server is unavailable or does not exist (mssql2019.aws-region.rds.amazonaws.com), OS #: 0, OS Msg: Success, Level: 9
```

To use tds_fdw to connect to a SQL Server database

1. Connect to your Aurora PostgreSQL DB cluster’s primary instance using an account that has the rds_superuser role:

   ```bash
   psql --host=your-cluster-name-instance-1.aws-region.rds.amazonaws.com --port=5432 --username=test --password
   ```

2. Install the tds_fdw extension:

   ```bash
   test=> CREATE EXTENSION tds_fdw;
   CREATE EXTENSION
   ```

After the extension is installed on your Aurora PostgreSQL DB cluster, you set up the foreign server.

To create the foreign server

Perform these tasks on the Aurora PostgreSQL DB cluster using an account that has rds_superuser privileges.

1. Create a foreign server in the Aurora PostgreSQL DB cluster:

   ```bash
   test=> CREATE SERVER sqlserverdb FOREIGN DATA WRAPPER tds_fdw OPTIONS (servername 'mssql2019.aws-region.rds.amazonaws.com', port '1433', database 'tds_fdw_testing');
   ```
CREATE SERVER

To access non-ASCII data on the SQLServer side, create a server link with the character_set option in the Aurora PostgreSQL DB cluster:

```
CREATE SERVER sqlserverdb FOREIGN DATA WRAPPER tds_fdw OPTIONS (servername 'mssql2019.aws-region.rds.amazonaws.com', port '1433', database 'tds_fdw_testing', character_set 'UTF-8');
```

2. Grant permissions to a user who doesn't have rds_superuser role privileges, for example, user1:

```
GRANT USAGE ON FOREIGN SERVER sqlserverdb TO user1;
```

3. Connect as user1 and create a mapping to a SQL Server user:

```
CREATE USER MAPPING FOR user1 SERVER sqlserverdb OPTIONS (username 'sqlserveruser', password 'password');
```

4. Create a foreign table linked to a SQL Server table:

```
CREATE FOREIGN TABLE mytab (a int) SERVER sqlserverdb OPTIONS (table 'MYTABLE');
```

5. Query the foreign table:

```
SELECT * FROM mytab;
a ---
1
(1 row)
```

Using encryption in transit for the connection

The connection from Aurora PostgreSQL to SQL Server uses encryption in transit (TLS/SSL) depending on the SQL Server database configuration. If the SQL Server isn't configured for encryption, the RDS for PostgreSQL client making the request to the SQL Server database falls back to unencrypted.

You can enforce encryption for the connection to RDS for SQL Server DB instances by setting the rds.force_ssl parameter. To learn how, see Forcing connections to your DB instance to use SSL. For more information about SSL/TLS configuration for RDS for SQL Server, see Using SSL with a Microsoft SQL Server DB instance.
Working with Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL is an open source development kit for building PostgreSQL extensions. It allows you to build high performance PostgreSQL extensions and safely run them on your Aurora PostgreSQL DB cluster. By using Trusted Language Extensions (TLE) for PostgreSQL, you can create PostgreSQL extensions that follow the documented approach for extending PostgreSQL functionality. For more information, see Packaging Related Objects into an Extension in the PostgreSQL documentation.

One key benefit of TLE is that you can use it in environments that don't provide access to the file system underlying the PostgreSQL instance. Previously, installing a new extension required access to the file system. TLE removes this constraint. It provides a development environment for creating new extensions for any PostgreSQL database, including those running on your Aurora PostgreSQL DB clusters.

TLE is designed to prevent access to unsafe resources for the extensions that you create using TLE. Its runtime environment limits the impact of any extension defect to a single database connection. TLE also gives database administrators fine-grained control over who can install extensions, and it provides a permissions model for running them.

TLE is supported on Aurora PostgreSQL version 14.5 and higher versions.

The Trusted Language Extensions development environment and runtime are packaged as the pg_tle PostgreSQL extension, version 1.0.1. It supports creating extensions in JavaScript, Perl, Tcl, PL/pgSQL, and SQL. You install the pg_tle extension in your Aurora PostgreSQL DB cluster in the same way that you install other PostgreSQL extensions. After the pg_tle is set up, developers can use it to create new PostgreSQL extensions, known as TLE extensions.

In the following topics, you can find information about how to set up Trusted Language Extensions and how to get started creating your own TLE extensions.

Topics
- Terminology (p. 1663)
- Requirements for using Trusted Language Extensions for PostgreSQL (p. 1664)
- Setting up Trusted Language Extensions in your Aurora PostgreSQL DB cluster (p. 1666)
- Overview of Trusted Language Extensions for PostgreSQL (p. 1669)
- Creating TLE extensions for Aurora PostgreSQL (p. 1670)
- Dropping your TLE extensions from a database (p. 1673)
- Uninstalling Trusted Language Extensions for PostgreSQL (p. 1674)
- Using PostgreSQL hooks with your TLE extensions (p. 1675)
- Functions reference for Trusted Language Extensions for PostgreSQL (p. 1679)
- Hooks reference for Trusted Language Extensions for PostgreSQL (p. 1689)

Terminology

To help you better understand Trusted Language Extensions, view the following glossary for terms used in this topic.
Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL is the official name of the open source development kit that's packaged as the pg_tle extension. It's available for use on any PostgreSQL system. For more information, see aws/pg_tle on GitHub.

Trusted Language Extensions

Trusted Language Extensions is the short name for Trusted Language Extensions for PostgreSQL. This shortened name and its abbreviation (TLE) are also used in this documentation.

trusted language

A trusted language is a programming or scripting language that has specific security attributes. For example, trusted languages typically restrict access to the file system, and they limit use of specified networking properties. The TLE development kit is designed to support trusted languages. PostgreSQL supports several different languages that are used to create trusted or untrusted extensions. For an example, see Trusted and Untrusted PL/Perl in the PostgreSQL documentation. When you create an extension using Trusted Language Extensions, the extension inherently uses trusted language mechanisms.

TLE extension

A TLE extension is a PostgreSQL extension that's been created by using the Trusted Language Extensions (TLE) development kit.

Requirements for using Trusted Language Extensions for PostgreSQL

The following are requirements for setting up and using the TLE development kit.

- **Aurora PostgreSQL versions** – Trusted Language Extensions is supported on Aurora PostgreSQL version 14.5 and higher versions only.
  - If you need to upgrade your Aurora PostgreSQL DB cluster, see Upgrading Amazon Aurora PostgreSQL DB clusters (p. 1782).
  - If you don't yet have an Aurora DB cluster running PostgreSQL, you can create one. For more information, see Creating and connecting to an Aurora PostgreSQL DB cluster (p. 137).

- Requires **rds_superuser privileges** – To set up and configure the pg_tle extension, your database user role must have the permissions of the rds_superuser role. By default, this role is granted to the postgres user that creates the Aurora PostgreSQL DB cluster.

- **Requires a custom DB parameter group** – Your Aurora PostgreSQL DB cluster must be configured with a custom DB parameter group. You use the custom DB parameter group for the writer instance of your Aurora PostgreSQL DB cluster.
  - If your Aurora PostgreSQL DB cluster isn't configured with a custom DB parameter group, you should create one and associate it with the writer instance of your Aurora PostgreSQL DB cluster. For a short summary of steps, see Creating and applying a custom DB parameter group (p. 1664).
  - If your Aurora PostgreSQL DB cluster is already configured using a custom DB parameter group, you can set up Trusted Language Extensions. For details, see Setting up Trusted Language Extensions in your Aurora PostgreSQL DB cluster (p. 1666).

Creating and applying a custom DB parameter group

Use the following steps to create a custom DB parameter group and configure your Aurora PostgreSQL DB cluster to use it.
Console

To create a custom DB parameter group and use it with your Aurora PostgreSQL DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Parameter groups from the Amazon RDS menu.
3. Choose Create parameter group.
4. In the Parameter group details page, enter the following information.
   - For Parameter group family, choose aurora-postgresql14.
   - For Type, choose DB Parameter Group.
   - For Group name, give your parameter group a meaningful name in the context of your operations.
   - For Description, enter a useful description so that others on your team can easily find it.
5. Choose Create. Your custom DB parameter group is created in your AWS Region. You can now modify your Aurora PostgreSQL DB cluster to use it by following the next steps.
6. Choose Databases from the Amazon RDS menu.
7. Choose the Aurora PostgreSQL DB cluster that you want to use with TLE from among those listed, and then choose Modify.
8. In the Modify DB cluster settings page, find Database options and use the selector to choose your custom DB parameter group.
9. Choose Continue to save the change.
10. Choose Apply immediately so that you can continue setting up the Aurora PostgreSQL DB cluster to use TLE.

To continue setting up your system for Trusted Language Extensions, see Setting up Trusted Language Extensions in your Aurora PostgreSQL DB cluster (p. 1666).

For more information working with DB cluster and DB parameter groups, see Working with DB cluster parameter groups (p. 214).

AWS CLI

You can avoid specifying the --region argument when you use CLI commands by configuring your AWS CLI with your default AWS Region. For more information, see Configuration basics in the AWS Command Line Interface User Guide.

To create a custom DB parameter group and use it with your Aurora PostgreSQL DB cluster

1. Use the create-db-parameter-group AWS CLI command to create a custom DB parameter group based on aurora-postgresql14 for your AWS Region. Note that in this step you create a DB parameter group to apply to the writer instance of your Aurora PostgreSQL DB cluster.

   For Linux, macOS, or Unix:

   ```bash
   aws rds create-db-parameter-group \
   --region aws-region \
   --db-parameter-group-name custom-params-for-pg-tle \
   --db-parameter-group-family aurora-postgresql14 \
   --description "My custom DB parameter group for Trusted Language Extensions"
   ```

   For Windows:

   ```bash
   aws rds create-db-parameter-group ^
   --region aws-region ^
   ```
--db-parameter-group-name custom-params-for-pg-tle ^
--db-parameter-group-family aurora-postgresql114 ^
--description "My custom DB parameter group for Trusted Language Extensions"

Your custom DB parameter group is available in your AWS Region, so you can modify the writer instance of your Aurora PostgreSQL DB cluster to use it.

2. Use the `modify-db-instance` AWS CLI command to apply your custom DB parameter group to the writer instance of your Aurora PostgreSQL DB cluster. This command immediately reboots the active instance.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --region aws-region \ 
  --db-instance-identifier your-writer-instance-name \ 
  --db-parameter-group-name custom-params-for-pg-tle \ 
  --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
  --region aws-region ^ 
  --db-instance-identifier your-writer-instance-name ^ 
  --db-parameter-group-name custom-params-for-pg-tle ^ 
  --apply-immediately
```

To continue setting up your system for Trusted Language Extensions, see [Setting up Trusted Language Extensions in your Aurora PostgreSQL DB cluster](p. 1666).

For more information, see [Working with DB parameter groups](p. 226).

**Setting up Trusted Language Extensions in your Aurora PostgreSQL DB cluster**

The following steps assume that your Aurora PostgreSQL DB cluster is associated with a custom DB cluster parameter group. You can use the AWS Management Console or the AWS CLI for these steps.

When you set up Trusted Language Extensions in your Aurora PostgreSQL DB cluster, you install it in a specific database for use by the database users who have permissions on that database.

**Console**

To set up Trusted Language Extensions

Perform the following steps using an account that's a member of the `rds_superuser` group (role).

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose your Aurora PostgreSQL DB cluster's Writer instance.
3. Open the Configuration tab for your Aurora PostgreSQL DB cluster writer instance. Among the Instance details, find the Parameter group link.
4. Choose the link to open the custom parameters associated with your Aurora PostgreSQL DB cluster.
5. In the Parameters search field, type `shared_pre` to find the `shared_preload_libraries` parameter.
6. Choose **Edit parameters** to access the property values.

7. Add `pg_tle` to the list in the **Values** field. Use a comma to separate items in the list of values.

8. Reboot the writer instance of your Aurora PostgreSQL DB cluster so that your change to the `shared_preload_libraries` parameter takes effect.

9. When the instance is available, verify that `pg_tle` has been initialized. Use `psql` to connect to the writer instance of your Aurora PostgreSQL DB cluster, and then run the following command.

   ```
   SHOW shared_preload_libraries;
   shared_preload_libraries
   --------------------------
   rdsutils,pg_tle
   (1 row)
   ```

10. With the `pg_tle` extension initialized, you can now create the extension.

    ```
    CREATE EXTENSION pg_tle;
    ```

    You can verify that the extension is installed by using the following `psql` metacommand.

    ```
    labdb=> \dx
    List of installed extensions
    Name   | Version |   Schema   |                Description
    ---------+---------+------------+--------------------------------------------
    pg_tle  | 1.0.1   | pgtle      | Trusted-Language Extensions for PostgreSQL
    plpgsql | 1.0     | pg_catalog | PL/pgSQL procedural language
    ```

11. Grant the `pgtle_admin` role to the primary user name that you created for your Aurora PostgreSQL DB cluster when you set it up. If you accepted the default, it's `postgres`.

    ```
    labdb=> GRANT pgtle_admin TO postgres;
    ```

    You can verify that the grant has occurred by using the `psql` metacommand as shown in the following example. Only the `pgtle_admin` and `postgres` roles are shown in the output. For more information, see [Understanding PostgreSQL roles and permissions](p. 1233).

    ```
    labdb=> \du
    List of roles
    Role name    |           Attributes            |               Member of
    -----------------+---------------------------------+-----------------------------------
    pgtle_admin     | Cannot login                     | {}
    postgres        | Create role, Create DB +| {rds_superuser,pgtle_admin}
    | Password valid until infinity    |...
    ```
12. Close the `psql` session using the `\q` metacommand.

\q

To get started creating TLE extensions, see Example: Creating a trusted language extension using SQL (p. 1670).

**AWS CLI**

You can avoid specifying the `--region` argument when you use CLI commands by configuring your AWS CLI with your default AWS Region. For more information, see Configuration basics in the AWS Command Line Interface User Guide.

**To set up Trusted Language Extensions**

1. Use the `modify-db-parameter-group` AWS CLI command to add `pg_tle` to the `shared_preload_libraries` parameter.

   ```bash
   aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters "ParameterName=shared_preload_libraries,ParameterValue=pg_tle,ApplyMethod=pending-reboot" \
   --region aws-region
   ```

2. Use the `reboot-db-instance` AWS CLI command to reboot the writer instance of your Aurora PostgreSQL DB cluster and initialize the `pg_tle` library.

   ```bash
   aws rds reboot-db-instance \
   --db-instance-identifier writer-instance \
   --region aws-region
   ```

3. When the instance is available, you can verify that `pg_tle` has been initialized. Use `psql` to connect to the writer instance of your Aurora PostgreSQL DB cluster, and then run the following command.

   ```
   SHOW shared_preload_libraries;
   shared_preload_libraries
   --------------------------
   rdsutils,pg_tle
   (1 row)
   ```

   With `pg_tle` initialized, you can now create the extension.

   ```
   CREATE EXTENSION pg_tle;
   ```

4. Grant the `pgtle_admin` role to the primary user name that you created for your Aurora PostgreSQL DB cluster when you set it up. If you accepted the default, it's `postgres`.

   ```
   GRANT pgtle_admin TO postgres;
   GRANT ROLE
   ```

5. Close the `psql` session as follows.

   ```
   labdb=> \q
   ```
To get started creating TLE extensions, see Example: Creating a trusted language extension using SQL (p. 1670).

Overview of Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL is a PostgreSQL extension that you install in your Aurora PostgreSQL DB cluster in the same way that you set up other PostgreSQL extensions. In the following image of an example database in the pgAdmin client tool, you can view some of the components that comprise the pg_tle extension.

You can see the following details.

1. The Trusted Language Extensions (TLE) for PostgreSQL development kit is packaged as the pg_tle extension. As such, pg_tle is added to the available extensions for the database in which it's installed.

2. TLE has its own schema, pgtle. This schema contains helper functions (3) for installing and managing the extensions that you create.

3. TLE provides over a dozen helper functions for installing, registering, and managing your extensions. To learn more about these functions, see Functions reference for Trusted Language Extensions for PostgreSQL (p. 1679).

Other components of the pg_tle extension include the following:
• The pgtle_admin role – The pgtle_admin role is created when the pg_tle extension is installed. This role is privileged and should be treated as such. We strongly recommend that you follow the principle of least privilege when granting the pgtle_admin role to database users. In other words, grant the pgtle_admin role only to database users that are allowed to create, install, and manage new TLE extensions, such as postgres.

• The pgtle.feature_info table – The pgtle.feature_info table is a protected table that contains information about your TLEs, hooks, and the custom stored procedures and functions that they use. If you have pgtle_admin privileges, you use the following Trusted Language Extensions functions to add and update that information in the table.

  • pgtle.register_feature (p. 1683)
  • pgtle.register_feature_if_not_exists (p. 1683)
  • pgtle.unregister_feature (p. 1687)
  • pgtle.unregister_feature_if_exists (p. 1688)

Creating TLE extensions for Aurora PostgreSQL

You can install any extensions that you create with TLE in any Aurora PostgreSQL DB cluster that has the pg_tle extension installed. The pg_tle extension is scoped to the PostgreSQL database in which it's installed. The extensions that you create using TLE are scoped to the same database.

Use the various pgtle functions to install the code that makes up your TLE extension. The following Trusted Language Extensions functions all require the pgtle_admin role.

  • pgtle.install_extension (p. 1681)
  • pgtle.install_update_path (p. 1682)
  • pgtle.register_feature (p. 1683)
  • pgtle.register_feature_if_not_exists (p. 1683)
  • pgtle.set_default_version (p. 1684)
  • pgtle.uninstall_extension(name) (p. 1685)
  • pgtle.uninstall_extension(name, version) (p. 1685)
  • pgtle.uninstall_extension_if_exists (p. 1686)
  • pgtle.uninstall_update_path (p. 1686)
  • pgtle.uninstall_update_path_if_exists (p. 1687)
  • pgtle.unregister_feature (p. 1687)
  • pgtle.unregister_feature_if_exists (p. 1688)

Example: Creating a trusted language extension using SQL

The following example shows you how to create a TLE extension named pg_distance that contains a few SQL functions for calculating distances using different formulas. In the listing, you can find the function for calculating the Manhattan distance and the function for calculating the Euclidean distance. For more information about the difference between these formulas, see Taxicab geometry and Euclidean geometry in Wikipedia.

You can use this example in your own Aurora PostgreSQL DB cluster if you have the pg_tle extension set up as detailed in Setting up Trusted Language Extensions in your Aurora PostgreSQL DB cluster (p. 1666).

Note
You need to have the privileges of the pgtle_admin role to follow this procedure.
To create the example TLE extension

The following steps use an example database named labdb. This database is owned by the postgres primary user. The postgres role also has the permissions of the pgtle_admin role.

1. Use psql to connect to the writer instance of your Aurora PostgreSQL DB cluster.

   ```
   psql --host=db-instance-123456789012.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
   ```

2. Create a TLE extension named `pg_distance` by copying the following code and pasting it into your psql session console.

   ```
   SELECT pgtle.install_extension
   ('pg_distance',
   '0.1',
   'Distance functions for two points',
   $pg_tle$_
   CREATE FUNCTION dist(x1 float8, y1 float8, x2 float8, y2 float8, norm int)
     RETURNS float8
     AS $$_$
     SELECT (abs(x2 - x1) ^ norm + abs(y2 - y1) ^ norm) ^ (1::float8 / norm);
     $$ LANGUAGE SQL;

   CREATE FUNCTION manhattan_dist(x1 float8, y1 float8, x2 float8, y2 float8)
     RETURNS float8
     AS $$
     SELECT dist(x1, y1, x2, y2, 1);
     $$ LANGUAGE SQL;

   CREATE FUNCTION euclidean_dist(x1 float8, y1 float8, x2 float8, y2 float8)
     RETURNS float8
     AS $$
     SELECT dist(x1, y1, x2, y2, 2);
     $$ LANGUAGE SQL;
   $pg_tle$_
   );
   ```

   You see the output, such as the following.

   ```
   install_extension
   ---------------
   t (1 row)
   ```

   The artifacts that make up the `pg_distance` extension are now installed in your database. These artifacts include the control file and the code for the extension, which are items that need to be present so that the extension can be created using the `CREATE EXTENSION` command. In other words, you still need to create the extension to make its functions available to database users.

3. To create the extension, use the `CREATE EXTENSION` command as you do for any other extension. As with other extensions, the database user needs to have the `CREATE` permissions in the database.

   ```
   CREATE EXTENSION pg_distance;
   ```

4. To test the `pg_distance` TLE extension, you can use it to calculate the Manhattan distance between four points.

   ```
   labdb=> SELECT manhattan_dist(1, 1, 5, 5);
   1671
   ```
To calculate the Euclidean distance between the same set of points, you can use the following.

```
labdb=> SELECT euclidean_dist(1, 1, 5, 5);
5.656854249492381
```

The `pg_distance` extension loads the functions in the database and makes them available to any users with permissions on the database.

## Modifying your TLE extension

To improve query performance for the functions packaged in this TLE extension, add the following two PostgreSQL attributes to their specifications.

- **IMMUTABLE** – The **IMMUTABLE** attribute ensures that the query optimizer can use optimizations to improve query response times. For more information, see [Function Volatility Categories](#) in the PostgreSQL documentation.
- **PARALLEL SAFE** – The **PARALLEL SAFE** attribute is another attribute that allows PostgreSQL to run the function in parallel mode. For more information, see [CREATE FUNCTION](#) in the PostgreSQL documentation.

In the following example, you can see how the `pgtle.install_update_path` function is used to add these attributes to each function to create a version 0.2 of the `pg_distance` TLE extension. For more information about this function, see `pgtle.install_update_path (p. 1682)`. You need to have the `pgtle_admin` role to perform this task.

### To update an existing TLE extension and specify the default version

1. Connect to the writer instance of your Aurora PostgreSQL DB cluster using `psql` or another client tool, such as pgAdmin.
   ```
   psql --host=db-instance-123456789012.aws-region.rds.amazonaws.com
   --port=5432 --username=postgres --password --dbname=labdb
   ```

2. Modify the existing TLE extension by copying the following code and pasting it into your `psql` session console.
   ```
   SELECT pgtle.install_update_path
   (  
     'pg_distance',  
     '0.1',  
     '0.2',  
     '$_pg_tle_$'  
   
CREATE OR REPLACE FUNCTION dist(x1 float8, y1 float8, x2 float8, y2 float8, norm int)
RETURNS float8
AS $$
  SELECT (abs(x2 - x1) ^ norm + abs(y2 - y1) ^ norm) ^ (1::float8 / norm);
$$ LANGUAGE SQL IMMUTABLE PARALLEL SAFE;

CREATE OR REPLACE FUNCTION manhattan_dist(x1 float8, y1 float8, x2 float8, y2 float8)
RETURNS float8
AS $$
  SELECT dist(x1, y1, x2, y2, 1);
$$ LANGUAGE SQL IMMUTABLE PARALLEL SAFE;
   ```
You see a response similar to the following.

```
install_update_path
---------------------
t (1 row)
```

You can make this version of the extension the default version, so that database users don't have to specify a version when they create or update the extension in their database.

3. To specify that the modified version (version 0.2) of your TLE extension is the default version, use the `pgtle.set_default_version` function as shown in the following example.

```
SELECT pgtle.set_default_version('pg_distance', '0.2');
```

For more information about this function, see `pgtle.set_default_version (p. 1684)`.

4. With the code in place, you can update the installed TLE extension in the usual way, by using ALTER EXTENSION ... UPDATE command, as shown here:

```
ALTER EXTENSION pg_distance UPDATE;
```

## Dropping your TLE extensions from a database

You can drop your TLE extensions by using the DROP EXTENSION command in the same way that you do for other PostgreSQL extensions. Dropping the extension doesn't remove the installation files that make up the extension, which allows users to re-create the extension. To remove the extension and its installation files, do the following two-step process.

### To drop the TLE extension and remove its installation files

1. Use `psql` or another client tool to connect to the writer instance of your Aurora PostgreSQL DB cluster.

   ```bash
   psql --host=cluster-instance-1.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=dbname
   ```

2. Drop the extension as you would any PostgreSQL extension.

   ```sql
   DROP EXTENSION your-TLE-extension
   ```

   For example, if you create the `pg_distance` extension as detailed in Example: Creating a trusted language extension using SQL (p. 1670), you can drop the extension as follows.

   ```sql
   DROP EXTENSION pg_distance;
   ```
You see output confirming that the extension has been dropped, as follows.

```
DROP EXTENSION
```

At this point, the extension is no longer active in the database. However, its installation files and control file are still available in the database, so database users can create the extension again if they like.

- If you want to leave the extension files intact so that database users can create your TLE extension, you can stop here.
- If you want to remove all files that make up the extension, continue to the next step.

3. To remove all installation files for your extension, use the `pgtle.uninstall_extension` function. This function removes all the code and control files for your extension.

```
SELECT pgtle.uninstall_extension('your-tle-extension-name');
```

For example, to remove all `pg_distance` installation files, use the following command.

```
SELECT pgtle.uninstall_extension('pg_distance');
```

---

**Uninstalling Trusted Language Extensions for PostgreSQL**

If you no longer want to create your own TLE extensions using TLE, you can drop the `pg_tle` extension and remove all artifacts. This action includes dropping any TLE extensions in the database and dropping the `pgtle` schema.

**To drop the `pg_tle` extension and its schema from a database**

1. Use `psql` or another client tool to connect to the writer instance of your Aurora PostgreSQL DB cluster.

   ```
   psql --host=cluster-instance-1.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=dbname
   ```

2. Drop the `pg_tle` extension from the database. If the database has your own TLE extensions still running in the database, you need to also drop those extensions. To do so, you can use the `CASCADE` keyword, as shown in the following.

   ```
   DROP EXTENSION pg_tle CASCADE;
   ```

   If the `pg_tle` extension isn't still active in the database, you don't need to use the `CASCADE` keyword.

3. Drop the `pgtle` schema. This action removes all the management functions from the database.

   ```
   DROP SCHEMA pgtle CASCADE;
   ```
Using PostgreSQL hooks with your TLE extensions

A hook is a callback mechanism available in PostgreSQL that allows developers to call custom functions or other routines during regular database operations. The TLE development kit supports PostgreSQL hooks so that you can integrate custom functions with PostgreSQL behavior at runtime. For example, you can use a hook to associate the authentication process with your own custom code, or to modify the query planning and execution process for your specific needs.

Your TLE extensions can use hooks. If a hook is global in scope, it applies across all databases. Therefore, if your TLE extension uses a global hook, then you need to create your TLE extension in all databases that your users can access.

When you use the pg_tle extension to build your own Trusted Language Extensions, you can use the available hooks from a SQL API to build out the functions of your extension. You should register any hooks with pg_tle. For some hooks, you might also need to set various configuration parameters. For example, the passcode check hook can be set to on, off, or require. For more information about specific requirements for available pg_tle hooks, see Hooks reference for Trusted Language Extensions for PostgreSQL (p. 1689).

Example: Creating an extension that uses a PostgreSQL hook

The example discussed in this section uses a PostgreSQL hook to check the password provided during specific SQL operations and prevents database users from setting their passwords to any of those contained in the password_check.bad_passwords table. The table contains the top-ten most commonly used, but easily breakable choices for passwords.

To set up this example in your Aurora PostgreSQL DB cluster, you must have already installed Trusted Language Extensions. For details, see Setting up Trusted Language Extensions in your Aurora PostgreSQL DB cluster (p. 1666).

To set up the password-check hook example

1. Use psql to connect to the writer instance of your Aurora PostgreSQL DB cluster.

```
psql --host=database-instance-123456789012.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
```

2. Copy the code from the Password-check hook code listing (p. 1678) and paste it into your database.

```
SELECT pg_tle.install_extension (  
  'my_password_check_rules',  
  '1.0',  
  'Do not let users use the 10 most commonly used passwords',  
  $pg_tle$  
CREATE SCHEMA password_check;  
REVOKE ALL ON SCHEMA password_check FROM PUBLIC;  
GRANT USAGE ON SCHEMA password_check TO PUBLIC;  
CREATE TABLE password_check.bad_passwords (plaintext) AS
```
VALUES
('123456'),
('password'),
('12345678'),
('qwert'),
('123456789'),
('12345'),
('1234'),
('111111'),
('1234567'),
('dragon');

CREATE UNIQUE INDEX ON password_check.bad_passwords (plaintext);

CREATE FUNCTION password_check.passcheck_hook(username text, password text,
password_type pgtle.password_types, valid_until timestamp, valid_null boolean)
RETURNS void AS $$
DECLARE
invalid bool := false;
BEGIN
IF password_type = 'PASSWORD_TYPE_MD5' THEN
SELECT EXISTS(
SELECT 1
FROM password_check.bad_passwords bp
WHERE ('md5' || md5(bp.plaintext || username)) = password
) INTO invalid;
IF invalid THEN
RAISE EXCEPTION 'Cannot use passwords from the common password dictionary';
END IF;
ELSIF password_type = 'PASSWORD_TYPE_PLAINTEXT' THEN
SELECT EXISTS(
SELECT 1
FROM password_check.bad_passwords bp
WHERE bp.plaintext = password
) INTO invalid;
IF invalid THEN
RAISE EXCEPTION 'Cannot use passwords from the common common password

dictionary';
END IF;
END IF;
END
$$ LANGUAGE plpgsql SECURITY DEFINER;

GRANT EXECUTE ON FUNCTION password_check.passcheck_hook TO PUBLIC;

SELECT pgtle.register_feature('password_check.passcheck_hook', 'passcheck');
$_pgtle_$);

When the extension has been loaded into your database, you see the output such as the following.

install_extension
-------------------
t
(1 row)

3. While still connected to the database, you can now create the extension.

CREATE EXTENSION my_password_check_rules;

4. You can confirm that the extension has been created in the database by using the following psql metacommand.

\dx
5. Open another terminal session to work with the AWS CLI. You need to modify your custom DB parameter group to turn on the password-check hook. To do so, use the **modify-db-parameter-group** CLI command as shown in the following example.

```
aws rds modify-db-parameter-group \
  --region aws-region \
  --db-parameter-group-name your-custom-parameter-group \
  --parameters "ParameterName=pgtle.enable_password_check,ParameterValue=on,ApplyMethod=immediate"
```

It might take a few minutes for the change to the parameter group setting to take effect. This parameter is dynamic, however, so you don't need to restart the writer instance of the Aurora PostgreSQL DB cluster for the setting to take effect.

6. Open the `psql` session and query the database to verify that the password_check hook has been turned on.

```
labdb=> SHOW pgtle.enable_password_check;
pgle.enable_password_check
-----------------------------
on
(1 row)
```

The password-check hook is now active. You can test it by creating a new role and using one of the bad passwords, as shown in the following example.

```
CREATE ROLE test_role PASSWORD 'password';
ERROR:  Cannot use passwords from the common password dictionary
CONTEXT:  PL/pgSQL function password_check.passcheck_hook(text,text,pgtle.password_types,timestamptz,boolean) line 21 at RAISE
SQL statement "SELECT password_check.passcheck_hook("
  $1::pg_catalog.text,
  $2::pg_catalog.text,
  $3::pgtle.password_types,
  $4::pg_catalog.timestamptz,
  $5::pg_catalog.bool)"
```

The output has been formatted for readability.

The following example shows that `psql` interactive metacommand `\password` behavior is also affected by the password_check hook.

```
postgres=> SET password_encryption TO 'md5';
SET
postgres=> \password
Enter new password for user "postgres":*****
Enter it again:*****
```

1677
ERROR: Cannot use passwords from the common password dictionary
CONTEXT: PL/pgSQL function
password_check.passcheck_hook(text, text, pgtle.password_types, timestamp with time zone, boolean) line 12 at RAISE
SQL statement "SELECT password_check.passcheck_hook($1::pg_catalog.text, $2::pg_catalog.text, $3::pgtle.password_types, $4::pg_catalog.timestamptz, $5::pg_catalog.bool)"

You can drop this TLE extension and uninstall its source files if you want. For more information, see Dropping your TLE extensions from a database (p. 1673).

Password-check hook code listing

The example code shown here defines the specification for the my_password_check_rules TLE extension. When you copy this code and paste it into your database, the code for the my_password_check_rules extension is loaded into the database, and the password_check hook is registered for use by the extension.

```
SELECT pgtle.install_extension ('my_password_check_rules', '1.0', 'Do not let users use the 10 most commonly used passwords', $pgtle$)
    CREATE SCHEMA password_check;
    REVOKE ALL ON SCHEMA password_check FROM PUBLIC;
    GRANT USAGE ON SCHEMA password_check TO PUBLIC;

    CREATE TABLE password_check.bad_passwords (plaintext) AS
VALUES
    ('123456'),
    ('password'),
    ('12345678'),
    ('qwerty'),
    ('123456789'),
    ('12345'),
    ('1234'),
    ('111111'),
    ('1234567'),
    ('dragon');
    CREATE UNIQUE INDEX ON password_check.bad_passwords (plaintext);

    CREATE FUNCTION password_check.passcheck_hook(username text, password text, password_type pgtle.password_types, valid_until timestamptz, valid_null boolean)
    RETURNS void AS $$
    DECLARE
        invalid bool := false;
    BEGIN
        IF password_type = 'PASSWORD_TYPE_MD5' THEN
            SELECT EXISTS(
                SELECT 1
                FROM password_check.bad_passwords bp
                WHERE ('md5' || md5(bp.plaintext || username)) = password
            ) INTO invalid;
            IF invalid THEN
                RAISE EXCEPTION 'Cannot use passwords from the common password dictionary';
            END IF;
        ELSIF password_type = 'PASSWORD_TYPE_PLAINTEXT' THEN
            SELECT EXISTS(
                SELECT 1
                FROM password_check.bad_passwords bp
                WHERE bp.plaintext = password
            ) INTO invalid;
            IF invalid THEN
```
Functions reference for Trusted Language Extensions for PostgreSQL

View the following reference documentation about functions available in Trusted Language Extensions for PostgreSQL. Use these functions to install, register, update, and manage your TLE extensions, that is, the PostgreSQL extensions that you develop using the Trusted Language Extensions development kit.

**Topics**
- `pgtle.available_extensions (p. 1679)`
- `pgtle.available_extension_versions (p. 1680)`
- `pgtle.extension_update_paths (p. 1681)`
- `pgtle.install_extension (p. 1681)`
- `pgtle.install_update_path (p. 1682)`
- `pgtle.register_feature (p. 1683)`
- `pgtle.register_feature_if_not_exists (p. 1683)`
- `pgtle.set_default_version (p. 1684)`
- `pgtle.uninstall_extension(name) (p. 1685)`
- `pgtle.uninstall_extension(name_version) (p. 1685)`
- `pgtle.uninstall_extension_if_exists (p. 1686)`
- `pgtle.uninstall_update_path (p. 1686)`
- `pgtle.uninstall_update_path_if_exists (p. 1687)`
- `pgtle.unregister_feature (p. 1687)`
- `pgtle.unregister_feature_if_exists (p. 1688)`

**pgtle.available_extensions**

The `pgtle.available_extensions` function is a set-returning function. It returns all available TLE extensions in the database. Each returned row contains information about a single TLE extension.

**Function prototype**

```sql
pgtle.available_extensions()
```

**Role**

None.
Arguments

None.

Output

- name – The name of the TLE extension.
- default_version – The version of the TLE extension to use when CREATE EXTENSION is called without a version specified.
- description – A more detailed description about the TLE extension.

Usage example

```sql
SELECT * FROM pgtle.available_extensions();
```

`pgtle.available_extension_versions`

The `available_extension_versions` function is a set-returning function. It returns a list of all available TLE extensions and their versions. Each row contains information about a specific version of the given TLE extension, including whether it requires a specific role.

**Function prototype**

```sql
pgtle.available_extension_versions()
```

**Role**

None.

**Arguments**

None.

**Output**

- name – The name of the TLE extension.
- version – The version of the TLE extension.
- superuser – This value is always false for your TLE extensions. The permissions needed to create the TLE extension or update it are the same as for creating other objects in the given database.
- trusted – This value is always false for a TLE extension.
- relocatable – This value is always false for a TLE extension.
- schema – Specifies the name of the schema in which the TLE extension is installed.
- requires – An array containing the names of other extensions needed by this TLE extension.
- description – A detailed description of the TLE extension.

For more information about output values, see Packaging Related Objects into an Extension > Extension Files in the PostgreSQL documentation.

**Usage example**

```sql
SELECT * FROM pgtle.available_extension_versions();
```
**pgtle.extension_update_paths**

The `extension_update_paths` function is a set-returning function. It returns a list of all the possible update paths for a TLE extension. Each row includes the available upgrades or downgrades for that TLE extension.

**Function prototype**

```
pgtle.extension_update_paths(name)
```

**Role**

None.

**Arguments**

- **name** – The name of the TLE extension from which to get upgrade paths.

**Output**

- **source** – The source version for an update.
- **target** – The target version for an update.
- **path** – The upgrade path used to update a TLE extension from `source` version to `target` version, for example, `0.1--0.2`.

**Usage example**

```
SELECT * FROM pgtle.extension_update_paths('your-TLE');
```

**pgtle.install_extension**

The `install_extension` function lets you install the artifacts that make up your TLE extension in the database, after which it can be created using the `CREATE EXTENSION` command.

**Function prototype**

```
pgtle.install_extension(name text, version text, description text, ext text, requires text[] DEFAULT NULL::text[])
```

**Role**

None.

**Arguments**

- **name** – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- **version** – The version of the TLE extension.
- **description** – A detailed description about the TLE extension. This description is displayed in the comment field in `pgtle.available_extensions()`.
- **ext** – The contents of the TLE extension. This value contains objects such as functions.
- **requires** – An optional parameter that specifies dependencies for this TLE extension. The `pg_tle` extension is automatically added as a dependency.
Many of these arguments are the same as those that are included in an extension control file for installing a PostgreSQL extension on the file system of a PostgreSQL instance. For more information, see the Extension Files in Packaging Related Objects into an Extension in the PostgreSQL documentation.

Output

This functions returns OK on success and NULL on error.

- OK – The TLE extension has been successfully installed in the database.
- NULL – The TLE extension hasn’t been successfully installed in the database.

Usage example

```
SELECT pgtle.install_extension(
  'pg_tle_test',
  '0.1',
  'My first pg_tle extension',
  $pgtle$_
CREATE FUNCTION my_test()
  RETURNS INT
  AS $$
    SELECT 42;
  $$ LANGUAGE SQL IMMUTABLE;
$pgtle$_);
```

`pgtle.install_update_path`

The install_update_path function provides an update path between two different versions of a TLE extension. This function allows users of your TLE extension to update its version by using the ALTER EXTENSION ... UPDATE syntax.

Function prototype

```
pgtle.install_update_path(name text, fromvers text, tovers text, ext text)
```

Role

`pgtle_admin`

Arguments

- `name` – The name of the TLE extension. This value is used when calling CREATE EXTENSION.
- `fromvers` – The source version of the TLE extension for the upgrade.
- `tovers` – The destination version of the TLE extension for the upgrade.
- `ext` – The contents of the update. This value contains objects such as functions.

Output

None.

Usage example

```
SELECT pgtle.install_update_path('pg_tle_test', '0.1', '0.2',
  $pgtle$_
);
CREATE OR REPLACE FUNCTION my_test()
RETURNS INT
AS $$
    SELECT 21;
$$ LANGUAGE SQL IMMUTABLE;
$pgtle$_

pgtle.register_feature

The register_feature function adds the specified internal PostgreSQL feature to the pgtle.feature_info table. PostgreSQL hooks are an example of an internal PostgreSQL feature. The Trusted Language Extensions development kit supports the use of PostgreSQL hooks. Currently, this function supports the following feature.

- passcheck – Registers the password-check hook with your procedure or function that customizes PostgreSQL’s password-check behavior.

Function prototype

pgtle.register_feature(proc regproc, feature pg_tle_feature)

Role

pgtle_admin

Arguments

- proc – The name of a stored procedure or function to use for the feature.
- feature – The name of the pg_tle feature (such as passcheck) to register with the function.

Output

None.

Usage example

SELECT pgtle.register_feature('pw_hook', 'passcheck');

pgtle.register_feature_if_not_exists

The pgtle.register_feature_if_not_exists function adds the specified PostgreSQL feature to the pgtle.feature_info table and identifies the TLE extension or other procedure or function that uses the feature. For more information about hooks and Trusted Language Extensions, see Using PostgreSQL hooks with your TLE extensions (p. 1675).

Function prototype

pgtle.register_feature_if_not_exists(proc regproc, feature pg_tle_feature)

Role

pgtle_admin

Usage example

SELECT pgtle.register_feature_if_not_exists('pw_hook', 'passcheck');
Arguments

- **proc** – The name of a stored procedure or function that contains the logic (code) to use as a feature for your TLE extension. For example, the `pw_hook` code.
- **feature** – The name of the PostgreSQL feature to register for the TLE function. Currently, the only available feature is the passcheck hook. For more information, see Password-check hook (passcheck) (p. 1689).

Output

Returns `true` after registering the feature for the specified extension. Returns `false` if the feature is already registered.

Usage example

```
SELECT pgtle.register_feature_if_not_exists('pw_hook', 'passcheck');
```

`pgtle.set_default_version`

The `set_default_version` function lets you specify a `default_version` for your TLE extension. You can use this function to define an upgrade path and designate the version as the default for your TLE extension. When database users specify your TLE extension in the `CREATE EXTENSION` and `ALTER EXTENSION ... UPDATE` commands, that version of your TLE extension is created in the database for that user.

This function returns `true` on success. If the TLE extension specified in the `name` argument doesn't exist, the function returns an error. Similarly, if the `version` of the TLE extension doesn't exist, it returns an error.

Function prototype

```
pgtle.set_default_version(name text, version text)
```

Role

`pgtle_admin`

Arguments

- **name** – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- **version** – The version of the TLE extension to set the default.

Output

- `true` – When setting default version succeeds, the function returns `true`.
- `ERROR` – Returns an error message if a TLE extension with the specified name or version doesn't exist.

Usage example

```
SELECT * FROM pgtle.set_default_version('my-extension', '1.1');
```
pgtle.uninstall_extension(name)

The uninstall_extension function removes all versions of a TLE extension from a database. This function prevents future calls of CREATE EXTENSION from installing the TLE extension. If the TLE extension doesn't exist in the database, an error is raised.

The uninstall_extension function won't drop a TLE extension that's currently active in the database. To remove a TLE extension that's currently active, you need to explicitly call DROP EXTENSION to remove it.

Function prototype

| pgtle.uninstall_extension(extname text) |

Role

pgtle_admin

Arguments

- `extname` – The name of the TLE extension to uninstall. This name is the same as the one used with CREATE EXTENSION to load the TLE extension for use in a given database.

Output

None.

Usage example

```
SELECT * FROM pgtle.uninstall_extension('pg_tle_test');
```

pgtle.uninstall_extension(name, version)

The uninstall_extension(name, version) function removes the specified version of the TLE extension from the database. This function prevents CREATE EXTENSION and ALTER EXTENSION from installing or updating a TLE extension to the specified version. This function also removes all update paths for the specified version of the TLE extension. This function won't uninstall the TLE extension if it's currently active in the database. You must explicitly call DROP EXTENSION to remove the TLE extension.

To uninstall all versions of a TLE extension, see pgtle.uninstall_extension(name) (p. 1685).

Function prototype

| pgtle.uninstall_extension(extname text, version text) |

Role

pgtle_admin

Arguments

- `extname` – The name of the TLE extension. This value is used when calling CREATE EXTENSION.
- `version` – The version of the TLE extension to uninstall from the database.
Output
None.

Usage example
```
SELECT * FROM pgtle.uninstall_extension('pg_tle_test', '0.2');
```

**pgtle.uninstall_extension_if_exists**

The `uninstall_extension_if_exists` function removes all versions of a TLE extension from a given database. If the TLE extension doesn't exist, the function returns silently (no error message is raised). If the specified extension is currently active within a database, this function doesn't drop it. You must explicitly call `DROP EXTENSION` to remove the TLE extension before using this function to uninstall its artifacts.

**Function prototype**
```
pgtle.uninstall_extension_if_exists(extname text)
```

**Role**

`pgtle_admin`

**Arguments**

- `extname` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.

**Output**

The `uninstall_extension_if_exists` function returns `true` after uninstalling the specified extension. If the specified extension doesn't exist, the function returns `false`.

- `true` – Returns `true` after uninstalling the TLE extension.
- `false` – Returns `false` when the TLE extension doesn't exist in the database.

**Usage example**
```
SELECT * FROM pgtle.uninstall_extension_if_exists('pg_tle_test');
```

**pgtle.uninstall_update_path**

The `uninstall_update_path` function removes the specific update path from a TLE extension. This prevents `ALTER EXTENSION ... UPDATE TO` from using this as an update path.

If the TLE extension is currently being used by one of the versions on this update path, it remains in the database.

If the update path specified doesn't exist, this function raises an error.

**Function prototype**
```
pgtle.uninstall_update_path(extname text, fromvers text, tovers text)
```
Role

pgtle_admin

Arguments

- extname – The name of the TLE extension. This value is used when calling CREATE EXTENSION.
- fromvers – The source version of the TLE extension used on the update path.
- tovers – The destination version of the TLE extension used on the update path.

Output

None.

Usage example

```
SELECT * FROM pgtle.uninstall_update_path('pg_tle_test', '0.1', '0.2');
```

pgtle.uninstall_update_path_if_exists

The uninstall_update_path_if_exists function is similar to uninstall_update_path in that it removes the specified update path from a TLE extension. However, if the update path doesn't exist, this function doesn't raise an error message. Instead, the function returns false.

Function prototype

```
pgtle.uninstall_update_path_if_exists(extname text, fromvers text, tovers text)
```

Role

pgtle_admin

Arguments

- extname – The name of the TLE extension. This value is used when calling CREATE EXTENSION.
- fromvers – The source version of the TLE extension used on the update path.
- tovers – The destination version of the TLE extension used on the update path.

Output

- true – The function has successfully updated the path for the TLE extension.
- false – The function wasn't able to update the path for the TLE extension.

Usage example

```
SELECT * FROM pgtle.uninstall_update_path_if_exists('pg_tle_test', '0.1', '0.2');
```

pgtle.unregister_feature

The unregister_feature function provides a way to remove functions that were registered to use pg_tle features, such as hooks. For information about registering a feature, see pgtle.register_feature (p. 1683).
Function prototype

pgtle.unregister_feature(proc regproc, feature pg_tle_features)

Role

pgtle_admin

Arguments

- proc – The name of a stored function to register with a pg_tle feature.
- feature – The name of the pg_tle feature to register with the function. For example, passcheck is a feature that can be registered for use by the trusted language extensions that you develop. For more information, see Password-check hook (passcheck) (p. 1689).

Output

None.

Usage example

SELECT * FROM pgtle.unregister_feature('pw_hook', 'passcheck');

pgtle.unregister_feature_if_exists

The unregister_feature function provides a way to remove functions that were registered to use pg_tle features, such as hooks. For more information, see Using PostgreSQL hooks with your TLE extensions (p. 1675). Returns true after successfully unregistering the feature. Returns false if the feature wasn't registered.

For information about registering pg_tle features for your TLE extensions, see pgtle.register_feature (p. 1683).

Function prototype

pgtle.unregister_feature_if_exists('proc regproc', 'feature pg_tle_features')

Role

pgtle_admin

Arguments

- proc – The name of the stored function that was registered to include a pg_tle feature.
- feature – The name of the pg_tle feature that was registered with the trusted language extension.

Output

Returns true or false, as follows.

- true – The function has successfully unregistered the feature from extension.
- false – The function wasn't able to unregister the feature from the TLE extension.
Hooks reference for Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL supports PostgreSQL hooks. A hook is an internal callback mechanism available to developers for extending PostgreSQL’s core functionality. By using hooks, developers can implement their own functions or procedures for use during various database operations, thereby modifying PostgreSQL’s behavior in some way. For example, you can use a passcheck hook to customize how PostgreSQL handles the passwords supplied when creating or changing passwords for users (roles).

View the following documentation to learn about the hooks available for your TLE extensions.

Topics
- Password-check hook (passcheck) (p. 1689)

Password-check hook (passcheck)

The passcheck hook is used to customize PostgreSQL behavior during the password-checking process for the following SQL commands and psql metacommand.

- CREATE ROLE username ... PASSWORD – For more information, see CREATE ROLE in the PostgreSQL documentation.
- ALTER ROLE username ... PASSWORD – For more information, see ALTER ROLE in the PostgreSQL documentation.
- \password username – This interactive psql metacommand securely changes the password for the specified user by hashing the password before transparently using the ALTER ROLE ... PASSWORD syntax. The metacommand is a secure wrapper for the ALTER ROLE ... PASSWORD command, thus the hook applies to the behavior of the psql metacommand.

For an example, see Password-check hook code listing (p. 1678).

Function prototype

passcheck_hook(username text, password text, password_type pgtle.password_types, valid_until timestamptz, valid_null boolean)

Arguments

A passcheck hook function takes the following arguments.

- username – The name (as text) of the role (username) that's setting a password.
- password – The plaintext or hashed password. The password entered should match the type specified in password_type.
- password_type – Specify the pgtle.password_type format of the password. This format can be one of the following options.
  - PASSWORD_TYPE_PLAINTEXT – A plaintext password.
  - PASSWORD_TYPE_MD5 – A password that's been hashed using MD5 (message digest 5) algorithm.
• PASSWORD_TYPE_SCRAM_SHA_256 – A password that's been hashed using SCRAM-SHA-256 algorithm.
• valid_until – Specify the time when the password becomes invalid. This argument is optional. If you use this argument, specify the time as a timestamptz value.
• valid_null – If this Boolean is set to true, the valid_until option is set to NULL.

Configuration

The function pgtle.enable_password_check controls whether the passcheck hook is active. The passcheck hook has three possible settings.

• off – Turns off the passcheck password-check hook. This is the default value.
• on – Turns on the passcode password-check hook so that passwords are checked against the table.
• require – Requires a password check hook to be defined.

Usage notes

To turn the passcheck hook on or off, you need to modify the custom DB parameter group for the writer instance of your Aurora PostgreSQL DB cluster.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
   --region aws-region \
   --db-parameter-group-name your-custom-parameter-group \
   --parameters "ParameterName=pgtle.enable_password_check,ParameterValue=on,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
   --region aws-region ^
   --db-parameter-group-name your-custom-parameter-group ^
   --parameters "ParameterName=pgtle.enable_password_check,ParameterValue=on,ApplyMethod=immediate"
```
Amazon Aurora PostgreSQL reference

Aurora PostgreSQL collations for EBCDIC and other mainframe migrations

Migrating mainframe applications to new platforms such as AWS ideally preserves application behavior. To preserve application behavior on a new platform exactly as it was on the mainframe requires that migrated data be collated using the same collation and sorting rules. For example, many Db2 migration solutions shift null values to u0180 (Unicode position 0180), so these collations sort u0180 first. This is one example of how collations can vary from their mainframe source and why it's necessary to choose a collation that better maps to the original EBCDIC collation.

Aurora PostgreSQL 14.3 and higher versions provide many ICU and EBCDIC collations to support such migration to AWS using the AWS Mainframe Modernization service. To learn more about this service, see What is AWS Mainframe Modernization?

In the following table, you can find Aurora PostgreSQL–provided collations. These collations follow EBCDIC rules and ensure that mainframe applications function the same on AWS as they did in the mainframe environment. The collation name includes the relevant code page, (cpnnnn), so that you can choose the appropriate collation for your mainframe source. For example, use en-US-cp037-x-icu for to achieve the collation behavior for EBCDIC data that originated from a mainframe application that used code page 037.

Collations supported in Aurora PostgreSQL

Collations are set of rules that determine how character strings stored in the database are sorted and compared. Collations play a fundamental role in the computer system and are included as part of the operating system. Collations change over time when new characters are added to languages or when ordering rules change.

Collation libraries define specific rules and algorithms for a collation. The most popular collation libraries used within PostgreSQL are GNU C (glibc) and Internationalization components for Unicode (ICU). By default, Aurora PostgreSQL uses the glibc collation that includes unicode character sort orders for multi-byte character sequences.

When you create a new Aurora PostgreSQL DB cluster, it checks the operating system for the available collation. The PostgreSQL parameters of the CREATE DATABASE command LC_COLLATE and LC_CTYPE are used to specify a collation, which stands as the default collation in that database. Alternatively, you can also use the LOCALE parameter in CREATE DATABASE to set these parameters. This determines the default collation for character strings in the database and the rules for classifying characters as letters, numbers, or symbols. You can also choose a collation to use on a column, index, or on a query.

Aurora PostgreSQL depends on the glibc library in the operating system for collation support. Aurora PostgreSQL instance is periodically updated with the latest versions of the operating system. These updates sometimes include a newer version of the glibc library. Rarely, newer versions of glibc change the sort order or collation of some characters, which can cause the data to sort differently or produce invalid index entries. If you discover sort order issues for collation during an update, you might need to rebuild the indexes.

To reduce the possible impacts of the glibc updates, Aurora PostgreSQL now includes an independent default collation library. This collation library is available in Aurora PostgreSQL 14.6, 13.9, 12.13, 11.18 and newer minor version releases. It is compatible with glibc 2.26-59.amzn2, and provides sort order stability to prevent incorrect query results.

Aurora PostgreSQL functions reference

Following, you can find a list of Aurora PostgreSQL functions that are available for your Aurora DB clusters that run the Aurora PostgreSQL-Compatible Edition DB engine. These Aurora PostgreSQL...
functions are in addition to the standard PostgreSQL functions. For more information about standard PostgreSQL functions, see PostgreSQL–Functions and Operators.

Overview

You can use the following functions for Amazon RDS DB instances running Aurora PostgreSQL:

- `aurora_db_instance_identifier` (p. 1693)
- `aurora_ccm_status` (p. 1694)
- `aurora_global_db_instance_status` (p. 1696)
- `aurora_global_db_status` (p. 1698)
- `aurora_list_builtins` (p. 1700)
- `aurora_replica_status` (p. 1701)
- `aurora_stat_backend_waits` (p. 1704)
- `aurora_stat_bgwriter` (p. 1707)
- `aurora_stat_database` (p. 1707)
- `aurora_stat_dml_activity` (p. 1709)
- `aurora_stat_get_db_commit_latency` (p. 1712)
- `aurora_stat_logical_wal_cache` (p. 1713)
- `aurora_stat_memctx_usage` (p. 1714)
- `aurora_stat_optimized_reads_cache` (p. 1716)
- `aurora_stat_reset_wal_cache` (p. 1717)
- `aurora_stat_statements` (p. 1718)
- `aurora_stat_system_waits` (p. 1719)
- `aurora_stat_wait_event` (p. 1721)
- `aurora_stat_wait_type` (p. 1722)
- `aurora_version` (p. 1723)
- `aurora_volume_logical_start_lsn` (p. 1725)
- `aurora_wait_report` (p. 1726)

`aurora_db_instance_identifier`

Reports the name of the DB instance name to which you're connected.

**Syntax**

```
aurora_db_instance_identifier()
```

**Arguments**

None

**Return type**

VARCHAR string

**Usage notes**

This function displays the name of Aurora PostgreSQL-Compatible Edition cluster's DB instance for your database client or application connection.
This function is available starting with the release of Aurora PostgreSQL versions 13.7, 12.11, 11.16, 10.21 and for all other later versions.

Examples

The following example shows results of calling the `aurora_db_instance_identifier` function.

```
=> SELECT aurora_db_instance_identifier();
arora_db_instance_identifier
-------------------------------
test-my-instance-name
```

You can join the results of this function with the `aurora_replica_status` function to obtain details about the DB instance for your connection. The `aurora_replica_status` function alone doesn't provide show you which DB instance you're using. The following example shows you how.

```
=> SELECT *
    FROM aurora_replica_status() rt,
    aurora_db_instance_identifier() di
    WHERE rt.server_id = di;
- [ RECORD 1 ]-----------------------------------------------
  server_id                          | test-my-instance-name
  session_id                         | MASTER_SESSION_ID
  durable_lsn                         | 88492069
  highest_lsn_rcvd                   |
  current_read_lsn                   |
  cur_replay_latency_in_usec         |
  active_txns                        |
  is_current                         | t
  last_transport_error               | 0
  last_error_timestamp               | 2022-06-03 11:18:25+00
  feedback_xmin                      |
  feedback_epoch                     |
  replica_lag_in_msec                |
  log_stream_speed_in_kib_per_second | 0
  log_buffer_sequence_number         | 0
  oldest_read_view_trx_id            |
  oldest_read_view_lsn               |
  pending_read_ios                   | 819
```

**aurora_ccm_status**

Displays the status of cluster cache manager.

**Syntax**

```
aurora_ccm_status()
```

**Arguments**

None.

**Return type**

SETOF record with the following columns:

- **buffers_sent_last_minute** – The number of buffers sent to the designated reader in the past minute.
• **buffers_found_last_minute** – The number of frequently accessed buffers identified during the past minute.
• **buffers_sent_last_scan** – The number of buffers sent to the designated reader during the last complete scan of the buffer cache.
• **buffers_found_last_scan** – The number of frequently accessed buffers sent during the last complete scan of the buffer cache. Buffers that are already cached on the designated reader aren’t sent.
• **buffers_sent_current_scan** – The number of buffers sent during the current scan.
• **buffers_found_current_scan** – The number of frequently accessed buffers that were identified in the current scan.
• **current_scan_progress** – The number of buffers visited so far during the current scan.

**Usage notes**

You can use this function to check and monitor the cluster cache management (CCM) feature. This function works only if CCM is active on your Aurora PostgreSQL DB cluster. To use this function you connect to the Write DB instance on your Aurora PostgreSQL DB cluster.

You turn on CCM for an Aurora PostgreSQL DB cluster by setting the `apg_ccm_enabled` to 1 in the cluster’s custom DB cluster parameter group. To learn how, see [Configuring cluster cache management](p. 1478).

Cluster cache management is active on an Aurora PostgreSQL DB cluster when the cluster has an Aurora Reader instance configured as follows:

• The Aurora Reader instance uses same DB instance class type and size as the cluster’s Writer instance.
• The Aurora Reader instance is configured as Tier-0 for the cluster. If the cluster has more than one Reader, this is its only Tier-0 Reader.

Setting more than one Reader to Tier-0 disables CCM. When CCM is disabled, calling this function returns the following error message:

```
ERROR: Cluster Cache Manager is disabled
```

You can also the PostgreSQL `pg_buffercache` extension to analyze the buffer cache. For more information, see `pg_buffercache` in the PostgreSQL documentation.

For more information, see [Introduction to Aurora PostgreSQL cluster cache management](p. 1478).

**Examples**

The following example shows the results of calling the `aurora_ccm_status` function. This first example shows CCM statistics.

```
=> SELECT * FROM aurora_ccm_status();
 buffers_sent_last_minute | buffers_found_last_minute | buffers_sent_last_scan | buffers_found_last_scan | buffers_sent_current_scan | buffers_found_current_scan | current_scan_progress
----------------------------+---------------------------+------------------------+---------------------------+-----------------------------+-----------------------------+-----------------
 2242000                   | 2242003                   | 17920442               | 17923410                 | 14098000                    | 14100964                    | 1695
```
For more complete detail, you can use expanded display, as shown following:

```
\x
Expanded display is on.
SELECT * FROM aurora_ccm_status();
[ RECORD 1 ]-----------------------+--------
buffers_sent_last_minute           | 2242000
buffers_found_last_minute          | 2242003
buffers_sent_last_scan             | 17920442
buffers_found_last_scan            | 17923410
buffers_sent_current_scan          | 14098000
buffers_found_current_scan         | 14100964
current_scan_progress              | 15877443
```

This example shows how to check warm rate and warm percentage.

```
=> SELECT buffers_sent_last_minute * 8/60 AS warm_rate_kbps,
   100 * (1.0-buffers_sent_last_scan/buffers_found_last_scan) AS warm_percent
FROM aurora_ccm_status();
+----------------+--------------
| warm_rate_kbps | warm_percent |
+----------------+--------------
|    16523        |      100.0   |
```

**aurora_global_db_instance_status**

Displays the status of all Aurora instances, including replicas in an Aurora global DB cluster.

**Syntax**

```
aurora_global_db_instance_status()
```

**Arguments**

None

**Return type**

SETOF record with the following columns:

- **server_id** – The identifier of the DB instance.
- **session_id** – A unique identifier for the current session. A value of MASTER_SESSION_ID identifies the Writer (primary) DB instance.
- **aws_region** – The AWS Region in which this global DB instance runs. For a list of Regions, see Region availability (p. 17).
- **durable_lsn** – The log sequence number (LSN) made durable in storage. A log sequence number (LSN) is a unique sequential number that identifies a record in the database transaction log. LSNs are ordered such that a larger LSN represents a later transaction.
- **highest_lsn_rcvd** – The highest LSN received by the DB instance from the writer DB instance.
- **feedback_epoch** – The epoch that the DB instance uses when it generates hot standby information. A hot standby is a DB instance that supports connections and queries while the primary DB is in recovery or standby mode. The hot standby information includes the epoch (point in time) and other details about the DB instance that’s being used as a hot standby. For more information, see Hot Standby in the PostgreSQL documentation.
- **feedback_xmin** – The minimum (oldest) active transaction ID used by the DB instance.
• **oldest_read_view_lsn** – The oldest LSN used by the DB instance to read from storage.
• **visibility_lag_in_msec** – How far this DB instance is lagging behind the writer DB instance in milliseconds.

### Usage notes

This function shows replication statistics for an Aurora DB cluster. For each Aurora PostgreSQL DB instance in the cluster, the function shows a row of data that includes any cross-Region replicas in a global database configuration.

You can run this function from any instance in an Aurora PostgreSQL DB cluster or an Aurora PostgreSQL global database. The function returns details about lag for all replica instances.

To learn more about monitoring lag using this function (`aurora_global_db_instance_status`) or by using `aurora_global_db_status`, see Monitoring Aurora PostgreSQL-based global databases (p. 1873).

For more information about Aurora global databases, see Overview of Amazon Aurora global databases (p. 1800).

To get started with Aurora global databases, see Getting started with Amazon Aurora global databases (p. 1804) or see Amazon Aurora FAQs.

### Examples

This example shows cross-Region instance stats.

```sql
=> SELECT * FROM aurora_global_db_instance_status();
```

| server_id                  | session_id               | aws_region | durable_lsn | highest_lsn_rcvd | feedback_epoch | feedback_xmin | oldest_read_view_lsn | visibility_lag_in_msec |
|---------------------------|--------------------------|------------|-------------|------------------|----------------|---------------------|------------------------|
| db-119-001-instance-01    | MASTER_SESSION_ID        | eu-west-1  | 2534560273  | [NULL]           | 0              | 19669196           | [NULL]                 |

aurora_global_db_status
Displays information about various aspects of Aurora global database lag, specifically, lag of the underlying Aurora storage (so called durability lag) and lag between the recovery point objective (RPO).
Syntax

aurora_global_db_status()

Arguments

None.

Return type

SETOF record with the following columns:

- `aws_region` – The AWS Region that this DB cluster is in. For a complete listing of AWS Regions by engine, see Regions and Availability Zones (p. 16).
- `highest_lsn_written` – The highest log sequence number (LSN) that currently exists on this DB cluster. A log sequence number (LSN) is a unique sequential number that identifies a record in the database transaction log. LSNs are ordered such that a larger LSN represents a later transaction.
- `durability_lag_in_msec` – The difference in the timestamp values between the `highest_lsn_written` on a secondary DB cluster and the `highest_lsn_written` on the primary DB cluster. A value of -1 identifies the primary DB cluster of the Aurora global database.
- `rpo_lag_in_msec` – The recovery point objective (RPO) lag. The RPO lag is the time it takes for the most recent user transaction COMMIT to be stored on a secondary DB cluster after it's been stored on the primary DB cluster of the Aurora global database. A value of -1 denotes the primary DB cluster (and thus, lag isn't relevant).
- `last_lag_calculation_time` – The timestamp that specifies when values were last calculated for `durability_lag_in_msec` and `rpo_lag_in_msec`. A time value such as 1970-01-01 00:00:00+00 means this is the primary DB cluster.
- `feedback_epoch` – The epoch that the secondary DB cluster uses when it generates hot standby information. A hot standby is a DB instance that supports connections and queries while the primary DB is in recovery or standby mode. The hot standby information includes the epoch (point in time) and other details about the DB instance that's being used as a hot standby. For more information, see Hot Standby in the PostgreSQL documentation.
- `feedback_xmin` – The minimum (oldest) active transaction ID used by a secondary DB cluster.

Usage notes

This function shows replication statistics for an Aurora global database. It shows one row for each DB cluster in the Aurora global database, that is, how much data might be lost if there were an outage. As with lag, RPO is measured in time.

Examples

This example shows how to display cross-region storage statistics.
=> SELECT CASE
    WHEN '-1' = durability_lag_in_msec THEN 'Primary'
    ELSE 'Secondary'
END AS global_role,
* FROM aurora_global_db_status();

| global_role | aws_region | highest_lsn_written | durability_lag_in_msec | rpo_lag_in_msec | last_lag_calculation_time  | feedback_epoch | feedback_xmin |
|-------------|------------|---------------------|------------------------|-----------------|----------------------------|----------------+--------------|
| Primary     | eu-west-1  | 131031557            | -1                     | -1              | 1970-01-01 00:00:00+00    | 0              | 0            |
| Secondary   | eu-west-2  | 131031554            | 410                    | 0               | 2021-06-01 18:59:36.124+00 | 0              | 12640        |
| Secondary   | eu-west-3  | 131031554            | 410                    | 0               | 2021-06-01 18:59:36.124+00 | 0              | 12640        |

aurora_list_builtins

Lists all available Aurora PostgreSQL built-in functions, along with brief descriptions and function details.

Syntax

aurora_list_builtins()

Arguments

None

Return type

SETOF record

Examples

The following example shows results from calling the aurora_list_builtins function.

=> SELECT *
FROM aurora_list_builtins();

<table>
<thead>
<tr>
<th>Name</th>
<th>Result data type</th>
<th>Argument data types</th>
<th>Description</th>
</tr>
</thead>
</table>
| aurora_version                      | text             | func | stable | safe | invoker | Amazon Aurora PostgreSQL-Compatible Edition version string
| aurora_stat_wait_type               | SETOF record     | OUT type_id smallint, OUT type_name text | Lists all supported wait types
| aurora_stat_wait_event              | SETOF record     | OUT type_id smallint, OUT event_id integer, OUT event_na. | Lists all supported wait events

1700
**aurora_list_builtins**

Lists all Aurora built-in functions.

**aurora_stat_file**

Lists all files present in Aurora storage.

**aurora_stat_get_db_commit_latency**

Per DB commit latency in microsecs.

---

**aurora_replica_status**

Displays the status of all Aurora PostgreSQL reader nodes.

**Syntax**

```sql
aurora_replica_status()
```

**Arguments**

None

**Return type**

SETOF record with the following columns:

- `server_id` – The DB instance ID (identifier).
- `session_id` – A unique identifier for the current session, returned for primary instance and reader instances as follows:
  - For the primary instance, `session_id` is always `MASTER_SESSION_ID`.
  - For reader instances, `session_id` is always the UUID (universally unique identifier) of the reader instance.
- `durable_lsn` – The log sequence number (LSN) that's been saved in storage.
  - For the primary volume, the primary volume durable LSN (VDL) that's currently in effect.
  - For any secondary volumes, the VDL of the primary up to which the secondary has successfully been applied.

**Note**

A log sequence number (LSN) is a unique sequential number that identifies a record in the database transaction log. LSNs are ordered such that a larger LSN represents a transaction that's occurred later in the sequence.

- `highest_lsn_rcvd` – The highest (most recent) LSN received by the DB instance from the writer DB instance.
• `current_read_lsn` – The LSN of the most recent snapshot that's been applied to all readers.
• `cur_replay_latency_in_usec` – The number of microseconds that it's expected to take to replay the log on the secondary.
• `active_txns` – The number of currently active transactions.
• `is_current` – Not used.
• `last_transport_error` – Last replication error code.
• `last_error_timestamp` – Timestamp of last replication error.
• `last_update_timestamp` – Timestamp of last update to replica status. From Aurora PostgreSQL 13.9, the last_update_timestamp value for the DB instance that you are connected to is set to NULL.
• `feedback_xmin` – The hot standby feedback_xmin of the replica. The minimum (oldest) active transaction ID used by the DB instance.
• `feedback_epoch` – The epoch the DB instance uses when it generates hot standby information.
• `replica_lag_in_msec` – Time that reader instance lags behind writer writer instance, in milliseconds.
• `log_stream_speed_in_kib_per_second` – The log stream throughput in kilobytes per second.
• `log_buffer_sequence_number` – The log buffer sequence number.
• `oldest_read_view_trx_id` – Not used.
• `oldest_read_view_lsn` – The oldest LSN used by the DB instance to read from storage.
• `pending_read_ios` – The outstanding page reads that are still pending on replica.
• `read_ios` – The total number of page reads on replica.
• `iops` – Not used.
• `cpu` – CPU usage by the replica process. Note that this isn't CPU usage by the instance but rather the process. For information about CPU usage by the instance, see Instance-level metrics for Amazon Aurora (p. 643).

**Usage notes**

The `aurora_replica_status` function returns values from an Aurora PostgreSQL DB cluster's replica status manager. You can use this function to obtain information about the status of replication on your Aurora PostgreSQL DB cluster, including metrics for all DB instances in your Aurora DB cluster. For example, you can do the following:

• **Get information about the type of instance (writer, reader) in the Aurora PostgreSQL DB cluster** – You can obtain this information by checking the values of the following columns:
  • `server_id` – Contains the name of the instance that you specified when you created the instance. In some cases, such as for the primary (writer) instance, the name is typically created for you by appending `-instance-1` to the name that you create for your Aurora PostgreSQL DB cluster.
  • `session_id` – The session_id field indicates whether the instance is a reader or a writer. For a writer instance, session_id is always set to "MASTER_SESSION_ID". For a reader instance, session_id is set to the UUID of the specific reader.

• **Diagnose common replication issues, such as replica lag** – Replica lag is the time in milliseconds that the page cache of a reader instance is behind that of the writer instance. This lag occurs because Aurora clusters use asynchronous replication, as described in Replication with Amazon Aurora (p. 104). It's shown in the `replica_lag_in_msec` column in the results returned by this function. Lag can also occur when a query is cancelled due to conflicts with recovery on a standby server. You can check `pg_stat_database_conflicts()` to verify that such a conflict is causing the replica lag (or not). For more information, see The Statistics Collector in the PostgreSQL documentation. To learn more about high availability and replication, see Amazon Aurora FAQs.
Amazon CloudWatch stores `replica_lag_in_msec` results over time, as the `AuroraReplicaLag` metric. For information about using CloudWatch metrics for Aurora, see Monitoring Amazon Aurora metrics with Amazon CloudWatch (p. 545).

To learn more about troubleshooting Aurora read replicas and restarts, see Why did my Amazon Aurora read replica fall behind and restart? in the AWS Support Center.

**Examples**

The following example shows how to get the replication status of all instances in an Aurora PostgreSQL DB cluster:

```sql
=> SELECT * FROM aurora_replica_status();
```

The following example shows the writer instance in the `docs-lab-apg-main` Aurora PostgreSQL DB cluster:

```sql
=> SELECT server_id,
    CASE
        WHEN 'MASTER_SESSION_ID' = session_id THEN 'writer'
        ELSE 'reader'
    END AS instance_role
FROM aurora_replica_status()
WHERE session_id = 'MASTER_SESSION_ID';
```

```
server_id | instance_role
----------+---------------
        db-119-001-instance-01 | writer
```

The following example lists all reader instances in a cluster:

```sql
=> SELECT server_id,
    CASE
        WHEN 'MASTER_SESSION_ID' = session_id THEN 'writer'
        ELSE 'reader'
    END AS instance_role
FROM aurora_replica_status()
WHERE session_id <> 'MASTER_SESSION_ID';
```

```
server_id       | instance_role       |
------------------------+---------------------|
      db-119-001-instance-02 | reader              |
      db-119-001-instance-03 | reader              |
      db-119-001-instance-04 | reader              |
      db-119-001-instance-05 | reader              |
(4 rows)
```

The following example lists all instances, how far each instance is lagging behind the writer, and how long since the last update:

```sql
=> SELECT server_id,
    CASE
        WHEN 'MASTER_SESSION_ID' = session_id THEN 'writer'
        ELSE 'reader'
    END AS instance_role,
    replica_lag_in_msec AS replica_lag_ms,
    round(extract (epoch FROM (SELECT age(clock_timestamp(), last_update_timestamp))) * 1000) AS last_update_age_ms
FROM aurora_replica_status();
```

```
server_id       | instance_role | replica_lag_ms | last_update_age_ms|
------------------------+---------------+------------------|------------------|
        db-119-001-instance-01 | writer        | 1703             | 1703              |
```

1703
ORDER BY replica_lag_in_msec NULLS FIRST;

<table>
<thead>
<tr>
<th>server_id</th>
<th>instance_role</th>
<th>replica_lag_ms</th>

(a3 rows)

aurora_stat_backend_waits

Displays statistics for wait activity for a specific backend process.

Syntax

aurora_stat_backend_waits(pid)

Arguments

pid – The ID for the backend process. You can obtain process IDs by using the pg_stat_activity view.

Return type

SETOF record with the following columns:

- type_id – A number that denotes the type of wait event, such as 1 for a lightweight lock (LWLock), 3 for a lock, or 6 for a client session, to name some examples. These values become meaningful when you join the results of this function with columns from aurora_stat_wait_type function, as shown in the Examples (p. 1704).
- event_id – An identifying number for the wait event. Join this value with the columns from aurora_stat_wait_event to obtain meaningful event names.
- waits – A count of the number of waits accumulated for the specified process ID.
- wait_time – Wait time in milliseconds.

Usage notes

You can use this function to analyze specific backend (session) wait events that occurred since a connection opened. To get more meaningful information about wait event names and types, you can combine this function aurora_stat_wait_type and aurora_stat_wait_event, by using JOIN as shown in the examples.

Examples

This example shows all waits, types, and event names for a backend process ID 3027.

```sql
=> SELECT type_name, event_name, waits, wait_time
FROM aurora_stat_backend_waits(3027)
NATURAL JOIN aurora_stat_wait_type()
NATURAL JOIN aurora_stat_wait_event();
```

<table>

</table>
aurora_stat_bgwriter

`aurora_stat_bgwriter` is a statistics view showing information about Optimized Reads cache writes.

**Syntax**

```sql
aurora_stat_bgwriter()
```

**Arguments**

None

**Return type**

SETOF record with all `pg_stat_bgwriter` columns and the following additional columns. For more information on `pg_stat_bgwriter` columns, see [pg_stat_bgwriter](#).

You can reset stats for this function using `pg_stat_reset_shared("bgwriter")`.

- `orcache_blks_written` – Total number of optimized reads cache data blocks written.
- `orcache_blk_write_time` – If `track_io_timing` is enabled, it tracks the total time spent writing optimized reads cache data file blocks, in milliseconds. For more information, see [track_io_timing](#).

**Usage notes**

This function is available in the following Aurora PostgreSQL versions:

- 15.4 and higher 15 versions
- 14.9 and higher 14 versions

**Examples**

```sql
=> select * from aurora_stat_bgwriter();
-[
  RECORD 1 ]-----------------+-----------
orcache_blks_written          | 246522
orcache_blk_write_time        | 339276.404
```

aurora_stat_database

It carries all columns of `pg_stat_database` and adds new columns in the end.

**Syntax**

```sql
aurora_stat_database()
```
aurora_stat_database()

Arguments
None

Return type
SETOF record with all pg_stat_database columns and the following additional columns. For more information on pg_stat_database columns, see pg_stat_database.

- **storage_blks_read** – Total number of shared blocks read from aurora storage in this database.
- **orcache_blks_hit** – Total number of optimized reads cache hits in this database.
- **local_blks_read** – Total number of local blocks read in this database.
- **storage_blk_read_time** – If track_io_timing is enabled, it tracks the total time spent reading data file blocks from aurora storage, in milliseconds, otherwise the value is zero. For more information, see track_io_timing.
- **local_blk_read_time** – If track_io_timing is enabled, it tracks the total time spent reading local data file blocks, in milliseconds, otherwise the value is zero. For more information, see track_io_timing.
- **orcache_blk_read_time** – If track_io_timing is enabled, it tracks the total time spent reading data file blocks from optimized reads cache, in milliseconds, otherwise the value is zero. For more information, see track_io_timing.

Note
The value of blks_read is the sum of storage_blks_read, orcache_blks_hit, and local_blks_read.
The value of blk_read_time is the sum of storage_blk_read_time, orcache_blk_read_time, and local_blk_read_time.

Usage notes
This function is available in the following Aurora PostgreSQL versions:

- 15.4 and higher 15 versions
- 14.9 and higher 14 versions

Examples
The following example shows how it carries all the pg_stat_database columns and appends 6 new columns in the end:

```sql
=> select * from aurora_stat_database() where datid=14717;
- [ RECORD 1 ]---------------------------------------------
  datid     | 14717
  datname   | postgres
  numbackends | 1
  xact_commit | 223
  xact_rollback | 4
  blks_read | 1059
  blks_hit  | 11456
  tup_returned | 27746
  tup_fetched | 5220
  tup_inserted | 165
  tup_updated | 42
```

1708
**aurora_stat_dml_activity**

Reports cumulative activity for each type of data manipulation language (DML) operation on a database in an Aurora PostgreSQL cluster.

**Syntax**

```
aurora_stat_dml_activity(database_oid)
```

**Arguments**

*database_oid*

The object ID (OID) of the database in the Aurora PostgreSQL cluster.

**Return type**

SETOF record

**Usage notes**

The `aurora_stat_dml_activity` function is only available with Aurora PostgreSQL release 3.1 compatible with PostgreSQL engine 11.6 and later.

Use this function on Aurora PostgreSQL clusters with a large number of databases to identify which databases have more or slower DML activity, or both.

The `aurora_stat_dml_activity` function returns the number of times the operations ran and the cumulative latency in microseconds for SELECT, INSERT, UPDATE, and DELETE operations. The report includes only successful DML operations.

You can reset this statistic by using the PostgreSQL statistics access function `pg_stat_reset`. You can check the last time this statistic was reset by using the `pg_stat_get_db_stat_reset_time` function.
For more information about PostgreSQL statistics access functions, see The Statistics Collector in the PostgreSQL documentation.

Examples

The following example shows how to report DML activity statistics for the connected database.

```
-- Define the oid variable from connected database by using \gset
=> SELECT oid,
   datname
 FROM pg_database
 WHERE datname=(select current_database()) \gset
=> SELECT *
   FROM aurora_stat_dml_activity(:oid);
```

```
(SELECT oid, datname, aurora_stat_dml_activity(oid)
 FROM pg_database;
```

```
| oid  |    datname     |                    aurora_stat_dml_activity |
|------|----------------+--------------------------------------|
| 14006| template0      | (,,,,,,,)                            |
| 16384| rdsadmin       | (2346623,1211703821,4297518,817184554,0,0,0,0) |
| 1    | template1      | (,,,,,,,)                            |
| 14007| postgres       | (178961,66716329,171065,28876649,519538,1454579206167,1,53027) |
| 16401| mydb           | (200246,64302436,200036,10710185,600000,83659417514,0,0) |
```

The following example shows DML activity statistics for all databases in the Aurora PostgreSQL cluster. This cluster has two databases, postgres and mydb. The comma-separated list corresponds with the select_count, select_latency_microsecs, insert_count, insert_latency_microsecs, update_count, update_latency_microsecs, delete_count, and delete_latency_microsecs fields.

Aurora PostgreSQL creates and uses a system database named rdsadmin to support administrative operations such as backups, restores, health checks, replication, and so on. These DML operations have no impact on your Aurora PostgreSQL cluster.

```
=> SELECT oid,
   datname,
   aurora_stat_dml_activity(oid)
 FROM pg_database;
```

```
(SELECT oid, datname, aurora_stat_dml_activity(oid)
 FROM pg_database);
```

```
  |    datname     |                    aurora_stat_dml_activity |
  |----------------+--------------------------------------|
  | template0      | (,,,,,,,)                            |
  | rdsadmin       | (2346623,1211703821,4297518,817184554,0,0,0,0) |
  | template1      | (,,,,,,,)                            |
  | postgres       | (178961,66716329,171065,28876649,519538,1454579206167,1,53027) |
  | mydb           | (200246,64302436,200036,10710185,600000,83659417514,0,0) |
```

The following example shows DML activity statistics for all databases, organized in columns for better readability.

```
SELECT db.datname,
```

```
  | datname     | aurora_stat_dml_activity |
  |----------------+--------------------------------------|
  | template0      | (,,,,,,,)                            |
  | rdsadmin       | (2346623,1211703821,4297518,817184554,0,0,0,0) |
  | template1      | (,,,,,,,)                            |
  | postgres       | (178961,66716329,171065,28876649,519538,1454579206167,1,53027) |
  | mydb           | (200246,64302436,200036,10710185,600000,83659417514,0,0) |
```

1710
The following example shows the average cumulative latency (cumulative latency divided by count) for each DML operation for the database with the OID 16401.

```sql
>> SELECT select_count,
    select_latency_microsecs,
    select_latency_microsecs/NUL"(select_count,0) select_latency_per_exec,
    insert_count,
    insert_latency_microsecs,
    insert_latency_microsecs/NUL"(insert_count,0) insert_latency_per_exec,
    update_count,
    update_latency_microsecs,
    update_latency_microsecs/NUL"(update_count,0) update_latency_per_exec,
    delete_count,
    delete_latency_microsecs,
    delete_latency_microsecs/NUL"(delete_count,0) delete_latency_per_exec
FROM aurora_stat_dml_activity(16401);
```

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

1711
aurora_stat_get_db_commit_latency

Gets the cumulative commit latency in microseconds for Aurora PostgreSQL databases. Commit latency is measured as the time between when a client submits a commit request and when it receives the commit acknowledgement.

Syntax

aurora_stat_get_db_commit_latency(database_oid)

Arguments

database_oid

The object ID (OID) of the Aurora PostgreSQL database.

Return type

SETOF record

Usage notes

Amazon CloudWatch uses this function to calculate the average commit latency. For more information about Amazon CloudWatch metrics and how to troubleshoot high commit latency, see Viewing metrics in the Amazon RDS console (p. 535) and Making better decisions about Amazon RDS with Amazon CloudWatch metrics.

You can reset this statistic by using the PostgreSQL statistics access function pg_stat_reset. You can check the last time this statistic was reset by using the pg_stat_get_db_stat_reset_time function. For more information about PostgreSQL statistics access functions, see The Statistics Collector in the PostgreSQL documentation.

Examples

The following example gets the cumulative commit latency for each database in the pg_database cluster.

```sql
=> SELECT oid, datname, aurora_stat_get_db_commit_latency(oid)
FROM pg_database;

<table>
<thead>
<tr>
<th>oid</th>
<th>datname</th>
<th>aurora_stat_get_db_commit_latency</th>
</tr>
</thead>
<tbody>
<tr>
<td>14006</td>
<td>template0</td>
<td>0</td>
</tr>
<tr>
<td>16384</td>
<td>rdsadmin</td>
<td>654387789</td>
</tr>
<tr>
<td>1</td>
<td>template1</td>
<td>0</td>
</tr>
<tr>
<td>16401</td>
<td>mydb</td>
<td>229556</td>
</tr>
<tr>
<td>69768</td>
<td>postgres</td>
<td>22011</td>
</tr>
</tbody>
</table>
```

The following example gets the cumulative commit latency for the currently connected database. Before calling the aurora_stat_get_db_commit_latency function, the example first uses \gset to define a variable for the oid argument and sets its value from the connected database.

```sql
-- Get the oid value from the connected database before calling
aurora_stat_get_db_commit_latency
```
The following example gets the cumulative commit latency for the `mydb` database in the `pg_database` cluster. Then, it resets this statistic by using the `pg_stat_reset` function and shows the results. Finally, it uses the `pg_stat_get_db_stat_reset_time` function to check the last time this statistic was reset.

```sql
=> SELECT oid,
    datname,
    aurora_stat_get_db_commit_latency(oid)
FROM pg_database
WHERE datname = 'mydb';
```

<table>
<thead>
<tr>
<th>oid</th>
<th>datname</th>
<th>aurora_stat_get_db_commit_latency</th>
</tr>
</thead>
<tbody>
<tr>
<td>16427</td>
<td>mydb</td>
<td>3320370</td>
</tr>
</tbody>
</table>

```sql
=> SELECT pg_stat_reset();
```

```sql
=> SELECT oid,
    datname,
    aurora_stat_get_db_commit_latency(oid)
FROM pg_database
WHERE datname = 'mydb';
```

<table>
<thead>
<tr>
<th>oid</th>
<th>datname</th>
<th>aurora_stat_get_db_commit_latency</th>
</tr>
</thead>
<tbody>
<tr>
<td>16427</td>
<td>mydb</td>
<td></td>
</tr>
</tbody>
</table>

```sql
=> SELECT * FROM pg_stat_get_db_stat_reset_time(16427);  
```

<table>
<thead>
<tr>
<th>pg_stat_get_db_stat_reset_time</th>
</tr>
</thead>
<tbody>
<tr>
<td>2021-04-29 21:36:15.707399+00</td>
</tr>
</tbody>
</table>

---

**aurora_stat_logical_wal_cache**

Shows logical write-ahead log (WAL) cache usage per slot.

**Syntax**

```sql
SELECT * FROM aurora_stat_logical_wal_cache()
```

**Arguments**

None
Return type

SETOF record with the following columns:

- **name** – The name of the replication slot.
- **active_pid** – ID of the walsender process.
- **cache_hit** – The total number of wal cache hits since last reset.
- **cache_miss** – The total number of wal cache misses since last reset.
- **blks_read** – The total number of wal cache read requests.
- **hit_rate** – The WAL cache hit rate (cache_hit / blks_read).
- **last_reset_timestamp** – Last time that the counter was reset.

Usage notes

This function is available for the following versions.

- Aurora PostgreSQL 14.7
- Aurora PostgreSQL version 13.8 and higher
- Aurora PostgreSQL version 12.12 and higher
- Aurora PostgreSQL version 11.17 and higher

Examples

The following example shows two replication slots with only one active. `aurora_stat_logical_wal_cache` function.

```sql
=> SELECT *
    FROM aurora_stat_logical_wal_cache();
```

```
name    | active_pid | cache_hit | cache_miss | blks_read | hit_rate | last_reset_timestamp
------ |------------|-----------|------------|-----------|----------|--------------------------
test_slot1 |      79183 |        24 |          0 |        24 | 100.00%  | 2022-08-05 17:39:56.830635+00
test_slot2 |            |         1 |          0 |         1 | 100.00%  | 2022-08-05 17:34:04.036795+00
(2 rows)
```

`aurora_stat_memctx_usage`

Reports the memory context usage for each PostgreSQL process.

Syntax

```sql
aurora_stat_memctx_usage()
```

Arguments

None

Return type

SETOF record with the following columns:
• *pid* – The ID of the process.
• *name* – The name of the memory context.
• *allocated* – The number of bytes obtained from the underlying memory subsystem by the memory context.
• *used* – The number of bytes committed to clients of the memory context.
• *instances* – The count of currently existing contexts of this type.

**Usage notes**

This function displays the memory context usage for each PostgreSQL process. Some processes are labeled anonymous. The processes aren’t exposed because they contain restricted keywords.

This function is available starting with the following Aurora PostgreSQL versions:

- 15.3 and higher 15 versions
- 14.8 and higher 14 versions
- 13.11 and higher 13 versions
- 12.15 and higher 12 versions
- 11.20 and higher 11 versions

**Examples**

The following example shows the results of calling the `aurora_stat_memctx_usage` function.

```sql
=> SELECT * 
    FROM aurora_stat_memctx_usage();
```

<table>

</tbody>
</table>
```

aurora_stat_optimized_reads_cache

This function shows tiered cache stats.

Syntax

```
aurora_stat_optimized_reads_cache()
```

Arguments

None

Return type

SETOF record with the following columns:

- `total_size` – Total optimized reads cache size.
- `used_size` – Used page size in optimized reads cache.

Usage notes

This function is available in the following Aurora PostgreSQL versions:

- 15.4 and higher 15 versions
- 14.9 and higher 14 versions

Examples

The following example shows the output on a r6gd.8xlarge instance:

```
=> select pg_size_pretty(total_size) as total_size, pg_size_pretty(used_size) as used_size from aurora_stat_optimized_reads_cache();
```

1716
### total_size | used_size

---

| 1054 GB | 975 GB |

---

#### aurora_stat_reset_wal_cache

Resets the counter for logical wal cache.

**Syntax**

To reset a specific slot

```sql
SELECT * FROM aurora_stat_reset_wal_cache('slot_name')
```

To reset all slots

```sql
SELECT * FROM aurora_stat_reset_wal_cache(NULL)
```

**Arguments**

NULL or slot_name

**Return type**

Status message, text string

- Reset the logical wal cache counter – Success message. This text is returned when the function succeeds.
- Replication slot not found. Please try again. – Failure message. This text is returned when the function doesn't succeed.

**Usage notes**

This function is available for the following versions.

- Aurora PostgreSQL 14.5 and higher
- Aurora PostgreSQL version 13.8 and higher
- Aurora PostgreSQL version 12.12 and higher
- Aurora PostgreSQL version 11.17 and higher

**Examples**

The following example uses the `aurora_stat_reset_wal_cache` function to reset a slot named `test_results`, and then tries to reset a slot that doesn't exist.

```sql
=> SELECT *
    FROM aurora_stat_reset_wal_cache('test_slot');
```

```
aurora_stat_reset_wal_cache
-----------------------------
Reset the logical wal cache counter.
(1 row)
```

```sql
=> SELECT *
    FROM aurora_stat_reset_wal_cache('slot-not-exist');
```
aurora_stat_statements

Displays all pg_stat_statements columns and adds more columns in the end.

Syntax

```sql
aurora_stat_statements(showtext boolean)
```

Arguments

`showtext boolean`

Return type

SETOF record with all pg_stat_statements columns and the following additional columns. For more information on pg_stat_statements columns, see pg_stat_statements.

You can reset stats for this function using pg_stat_statements_reset().

- `storage_blks_read` – Total number of shared blocks read from aurora storage by this statement.
- `orcache_blks_hit` – Total number of optimized reads cache hits by this statement.
- `storage_blk_read_time` – If track_io_timing is enabled, it tracks the total time the statement spent reading data file blocks from aurora storage, in milliseconds, otherwise the value is zero. For more information, see track_io_timing.
- `local_blk_read_time` – If track_io_timing is enabled, it tracks the total time the statement spent reading local data file blocks, in milliseconds, otherwise the value is zero. For more information, see track_io_timing.
- `orcache_blk_read_time` – If track_io_timing is enabled, it tracks the total time the statement spent reading data file blocks from optimized reads cache, in milliseconds, otherwise the value is zero. For more information, see track_io_timing.

Usage notes

you must create pg_stat_statements extension first, to receive correct data from this virtual function.

This function is available in the following Aurora PostgreSQL versions:

- 15.4 and higher 15 versions
- 14.9 and higher 14 versions

Examples

The following example shows how it carries all the pg_stat_statements columns and append 5 new columns in the end:

```sql
=> select * from aurora_stat_statements(true) where queryid=-7342090857217643794;
-|-- [ RECORD 1 ]-+------------------------------------------
```
aurora_stat_system_waits

Reports wait event information for the Aurora PostgreSQL DB instance.

Syntax

```
aurora_stat_system_waits()
```

Arguments

None

Return type

SETOF record

Usage notes

This function returns the cumulative number of waits and cumulative wait time for each wait event generated by the DB instance that you're currently connected to.
The returned recordset includes the following fields:

- **type_id** – The ID of the type of wait event.
- **event_id** – The ID of the wait event.
- **waits** – The number of times the wait event occurred.
- **wait_time** – The total amount of time in microseconds spent waiting for this event.

Statistics returned by this function are reset when a DB instance restarts.

**Examples**

The following example shows results from calling the `aurora_stat_system_waits` function.

```sql
=> SELECT *
    FROM aurora_stat_system_waits();
```

<table>
<thead>
<tr>
<th>type_id</th>
<th>event_id</th>
<th>waits</th>
<th>wait_time</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>16777219</td>

</tbody>
</table>

The following example shows how you can use this function together with `aurora_stat_wait_event` and `aurora_stat_wait_type` to produce more readable results.

```sql
=> SELECT type_name,
       event_name,
       waits,
       wait_time
FROM aurora_stat_system_waits()
    NATURAL JOIN aurora_stat_wait_event()
    NATURAL JOIN aurora_stat_wait_type();
```

<table>

</tbody>
</table>
Lists all supported wait events for Aurora PostgreSQL. For information about Aurora PostgreSQL wait events, see Amazon Aurora PostgreSQL wait events (p. 1762).

Syntax

```
aurora_stat_wait_event()
```

Arguments

None

Return type

SETOF record with the following columns:

- `type_id` – The ID of the type of wait event.
- `event_id` – The ID of the wait event.
- `type_name` – Wait type name
- `event_name` – Wait event name

Usage notes

To see event names with event types instead of IDs, use this function together with other functions such as `aurora_stat_wait_type` and `aurora_stat_system_waits`. Wait event names returned by this function are the same as those returned by the `aurora_wait_report` function.

Examples

The following example shows results from calling the `aurora_stat_wait_event` function.

```
=> SELECT *
    FROM aurora_stat_wait_event();

<table>
<thead>
<tr>
<th>type_id</th>
<th>event_id</th>
<th>event_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>16777216</td>
<td><a href="">unassigned:0</a></td>

</tbody>
</table>

`aurora_stat_wait_type`

Lists all supported wait types for Aurora PostgreSQL.

**Syntax**

```
aurora_stat_wait_type()
```

**Arguments**

None

**Return type**

SETOF record with the following columns:

- `type_id` – The ID of the type of wait event.
• type_name – Wait type name.

Usage notes

To see wait event names with wait event types instead of IDs, use this function together with other functions such as `aurora_stat_wait_event` and `aurora_stat_system_waits`. Wait type names returned by this function are the same as those returned by the `aurora_wait_report` function.

Examples

The following example shows results from calling the `aurora_stat_wait_type` function.

```sql
=> SELECT *
    FROM aurora_stat_wait_type();

<table>
<thead>
<tr>
<th>type_id</th>
<th>type_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>LWLock</td>
</tr>
<tr>
<td>3</td>
<td>Lock</td>
</tr>
<tr>
<td>4</td>
<td>BufferPin</td>
</tr>
<tr>
<td>5</td>

<td>IO</td>
</tr>
<tr>
<td>11</td>
<td>LSN</td>
</tr>
</tbody>
</table>
```

**aurora_version**

Returns the string value of the Amazon Aurora PostgreSQL-Compatible Edition version number.

Syntax

```sql
aurora_version()
```

Arguments

None

Return type

CHAR or VARCHAR string

Usage notes

This function displays the version of the Amazon Aurora PostgreSQL-Compatible Edition database engine. The version number is returned as a string formatted as `major.minor.patch`. For more information about Aurora PostgreSQL version numbers, see `Aurora version number` (p. 1780).

You can choose when to apply minor version upgrades by setting the maintenance window for your Aurora PostgreSQL DB cluster. To learn how, see `Maintaining an Amazon Aurora DB cluster` (p. 344).

Starting with the release of Aurora PostgreSQL versions 13.3, 12.8, 11.13, 10.18, and for all other later versions, Aurora version numbers follow PostgreSQL version numbers. For more information about all Aurora PostgreSQL releases, see `Amazon Aurora PostgreSQL updates` in the `Release Notes for Aurora PostgreSQL`.
Examples

The following example shows the results of calling the `aurora_version` function on an Aurora PostgreSQL DB cluster running PostgreSQL 12.7, Aurora PostgreSQL release 4.2 and then running the same function on a cluster running Aurora PostgreSQL version 13.3.

```
=> SELECT * FROM aurora_version();
aurora_version
----------------
4.2.2

SELECT * FROM aurora_version();
aurora_version
----------------
13.3.0
```

This example shows how to use the function with various options to get more detail about the Aurora PostgreSQL version. This example has an Aurora version number that's distinct from the PostgreSQL version number.

```
=> SHOW SERVER_VERSION;
server_version
----------------
12.7
(1 row)

=> SELECT * FROM aurora_version();
aurora_version
----------------
4.2.2
(1 row)

=> SELECT current_setting('server_version') AS "PostgreSQL Compatibility";
PostgreSQL Compatibility
---------------------------
12.7
(1 row)

=> SELECT version() AS "PostgreSQL Compatibility Full String";
PostgreSQL Compatibility Full String
-------------------------------------------------------------------------------------------------------------
PostgreSQL 12.7 on aarch64-unknown-linux-gnu, compiled by aarch64-unknown-linux-gnu-gcc (GCC) 7.4.0, 64-bit
(1 row)

=> SELECT 'Aurora: ' || aurora_version() || ' Compatible with PostgreSQL: ' || current_setting('server_version') AS "Instance Version";
Instance Version
-----------------------------------------------
Aurora: 4.2.2 Compatible with PostgreSQL: 12.7
(1 row)
```

This next example uses the function with the same options in the previous example. This example doesn't have an Aurora version number that's distinct from the PostgreSQL version number.

```
=> SHOW SERVER_VERSION;
server_version
----------------
1724
```
aurora_volume_logical_start_lsn

Returns the log sequence number (LSN) used for identifying the beginning of a record in the logical write-ahead log (WAL) stream of the Aurora cluster volume.

Syntax

```
aurora_volume_logical_start_lsn()
```

Arguments

None

Return type

pg_lsn

Usage notes

This function identifies the beginning of the record in the logical WAL stream for a given Aurora cluster volume. You can use this function while performing major version upgrade using logical replication and Aurora fast cloning to determine the LSN at which a snapshot or database clone is taken. You can then use logical replication to continuously stream the newer data recorded after the LSN and synchronize the changes from publisher to subscriber.

For more information on using logical replication for a major version upgrade, see [Using logical replication to perform a major version upgrade for Aurora PostgreSQL](p. 1497).

This function is available on the following versions of Aurora PostgreSQL:

- 15.2 and higher 15 versions
- 14.3 and higher 14 versions
- 13.6 and higher 13 versions
12.10 and higher 12 versions
11.15 and higher 11 versions
10.20 and higher 10 versions

**Examples**

You can obtain the log sequence number (LSN) using the following query:

```sql
postgres=> SELECT aurora_volume_logical_start_lsn();
aurora_volume_logical_start_lsn
---------------------
0/402E2F0
(1 row)
```

**aurora_wait_report**

This function shows wait event activity over a period of time.

**Syntax**

```sql
aurora_wait_report([time])
```

**Arguments**

`time (optional)`

The time in seconds. Default is 10 seconds.

**Return type**

SETOF record with the following columns:

- `type_name` – Wait type name
- `event_name` – Wait event name
- `wait` – Number of waits
- `wait_time` – Wait time in milliseconds
- `ms_per_wait` – Average milliseconds by the number of an wait
- `waits_per_xact` – Average waits by the number of one transaction
- `ms_per_xact` – Average milliseconds by the number of transactions

**Usage notes**

This function is available as of Aurora PostgreSQL release 1.1 compatible with PostgreSQL 9.6.6 and higher versions.

To use this function, you need to first create the Aurora PostgreSQL `aurora_stat_utils` extension, as follows:

```sql
=> CREATE extension aurora_stat_utils;
```
CREATE EXTENSION

For more information about available Aurora PostgreSQL extension versions, see Extension versions for Amazon Aurora PostgreSQL in Release Notes for Aurora PostgreSQL.

This function calculates the instance-level wait events by comparing two snapshots of statistics data from aurora_stat_system_waits() function and pg_stat_database PostgreSQL Statistics Views.

For more information about aurora_stat_system_waits() and pg_stat_database, see The Statistics Collector in the PostgreSQL documentation.

When run, this function takes an initial snapshot, waits the number of seconds specified, and then takes a second snapshot. The function compares the two snapshots and returns the difference. This difference represents the instance's activity for that time interval.

On the writer instance, the function also displays the number of committed transactions and TPS (transactions per second). This function returns information at the instance level and includes all databases on the instance.

Examples

This example shows how to create aurora_stat_utils extension to be able to use aurora_log_report function.

=> CREATE extension aurora_stat_utils;
CREATE EXTENSION

This example shows how to check wait report for 10 seconds.

=> SELECT *
FROM aurora_wait_report();
NOTICE: committed 34 transactions in 10 seconds (tps 3)
type_name | event_name     | waits | wait_time | ms_per_wait | waits_per_xact | ms_per_xact
-----------+---------------+-------+-----------+-------------+----------------+-------------
+-----------+---------------+-------+-----------+-------------+----------------+-------------
Client     | ClientRead    | 26    | 30003.00  | 1153.961    | 0.76           | 882.441

Activity   |BgWriterHibernate| 1    | 10048.15  | 10048.153   | 0.03           | 295.534     
Activity   | AutoVacuumMain| 18    | 9941.66   | 552.314     | 0.53           | 292.402     
Activity   | BgWriterMain  | 1     | 201.09    | 201.085     | 0.03           | 5.914       
IO         | XactSync      | 15    | 25.34     | 1.690       | 0.44           | 0.765       
IO         | RelationMapRead| 12   | 0.54      | 0.045       | 0.35           | 0.016       
IO         | WALWrite      | 84    | 0.21      | 0.002       | 2.47           | 0.006       
IO         | DataFileExtend| 1     | 0.02      | 0.018       | 0.03           | 0.001       

This example shows how to check wait report for 60 seconds.

=> SELECT *

1727
You manage your Amazon Aurora DB cluster in the same way that you manage Amazon RDS DB instances, by using parameters in a DB parameter group. However, Amazon Aurora differs from Amazon RDS in that an Aurora DB cluster has multiple DB instances. Some of the parameters that you use to manage your Amazon Aurora DB cluster apply to the entire cluster, while other parameters apply only to a given DB instance in the DB cluster, as follows:

- **DB cluster parameter group** – A DB cluster parameter group contains the set of engine configuration parameters that apply throughout the Aurora DB cluster. For example, cluster cache management is a feature of an Aurora DB cluster that's controlled by the `pg_ccm_enabled` parameter which is part of the DB cluster parameter group. The DB cluster parameter group also contains default settings for the DB parameter group for the DB instances that make up the cluster.

- **DB parameter group** – A DB parameter group is the set of engine configuration values that apply to a specific DB instance of that engine type. The DB parameter groups for the PostgreSQL DB engine are

```sql

Amazon Aurora PostgreSQL parameters

You manage your Amazon Aurora DB cluster in the same way that you manage Amazon RDS DB instances, by using parameters in a DB parameter group. However, Amazon Aurora differs from Amazon RDS in that an Aurora DB cluster has multiple DB instances. Some of the parameters that you use to manage your Amazon Aurora DB cluster apply to the entire cluster, while other parameters apply only to a given DB instance in the DB cluster, as follows:

- **DB cluster parameter group** – A DB cluster parameter group contains the set of engine configuration parameters that apply throughout the Aurora DB cluster. For example, cluster cache management is a feature of an Aurora DB cluster that's controlled by the `apg_ccm_enabled` parameter which is part of the DB cluster parameter group. The DB cluster parameter group also contains default settings for the DB parameter group for the DB instances that make up the cluster.

- **DB parameter group** – A DB parameter group is the set of engine configuration values that apply to a specific DB instance of that engine type. The DB parameter groups for the PostgreSQL DB engine are
used by an RDS for PostgreSQL DB instance and Aurora PostgreSQL DB cluster. These configuration settings apply to properties that can vary among the DB instances within an Aurora cluster, such as the sizes for memory buffers.

You manage cluster-level parameters in DB cluster parameter groups. You manage instance-level parameters in DB parameter groups. You can manage parameters using the Amazon RDS console, the AWS CLI, or the Amazon RDS API. There are separate commands for managing cluster-level parameters and instance-level parameters.

- To manage cluster-level parameters in a DB cluster parameter group, use the `modify-db-cluster-parameter-group` AWS CLI command.
- To manage instance-level parameters in a DB parameter group for a DB instance in a DB cluster, use the `modify-db-parameter-group` AWS CLI command.

To learn more about the AWS CLI, see [Using the AWS CLI](https://docs.aws.amazon.com/cli/latest/userguide/) in the AWS Command Line Interface User Guide. For more information about parameter groups, see [Working with parameter groups](https://docs.aws.amazon.com/ru-ru/rds/latest/userguide/RDS-Parameters.html) (p. 212).

### Viewing Aurora PostgreSQL DB cluster and DB parameters

You can view all available default parameter groups for RDS for PostgreSQL DB instances and for Aurora PostgreSQL DB clusters in the AWS Management Console. The default parameter groups for all DB engines and DB cluster types and versions are listed for each AWS Region. Any custom parameter groups are also listed.

Rather than viewing in the AWS Management Console, you can also list parameters contained in DB cluster parameter groups and DB parameter groups by using the AWS CLI or the Amazon RDS API. For example, to list parameters in a DB cluster parameter group you use the `describe-db-cluster-parameters` AWS CLI command as shown following:

```bash
aws rds describe-db-cluster-parameters --db-cluster-parameter-group-name default.aurora-postgresql12
```

The command returns detailed JSON descriptions of each parameter. To reduce the amount of information returned, you can specify what you want by using the `--query` option. For example, you can get the parameter name, its description, and allowed values for the default Aurora PostgreSQL 12 DB cluster parameter group as follows:

For Linux, macOS, or Unix:

```bash
aws rds describe-db-cluster-parameters --db-cluster-parameter-group-name default.aurora-postgresql12 \   --query 'Parameters[].
   {[ParameterName:ParameterName,Description:Description,ApplyType:ApplyType,AllowedValues:AllowedValues]}
```

For Windows:

```bash
aws rds describe-db-cluster-parameters --db-cluster-parameter-group-name default.aurora-postgresql12 ^   --query "Parameters[].
   {[ParameterName:ParameterName,Description:Description,ApplyType:ApplyType,AllowedValues:AllowedValues]}
```

An Aurora DB cluster parameter group includes the DB instance parameter group and default values for a given Aurora DB engine. You can get the list of DB parameters from the same default Aurora PostgreSQL default parameter group by using the `describe-db-parameters` AWS CLI command as shown following.
For Linux, macOS, or Unix:

```bash
aws rds describe-db-parameters --db-parameter-group-name default.aurora-postgresql12 \
--query 'Parameters[].
[[ParameterName:ParameterName,Description:Description,ApplyType:ApplyType,AllowedValues:AllowedValues]]'
```

For Windows:

```bash
aws rds describe-db-parameters --db-parameter-group-name default.aurora-postgresql12 ^
--query "Parameters[].
[[ParameterName:ParameterName,Description:Description,ApplyType:ApplyType,AllowedValues:AllowedValues]]"
```

The preceding commands return lists of parameters from the DB cluster or DB parameter group with
descriptions and other details specified in the query. Following is an example response.

```
[
  [
    "ParameterName": "apg_enable_batch_mode_function_execution",
    "ApplyType": "dynamic",
    "Description": "Enables batch-mode functions to process sets of rows at a
    time.",
    "AllowedValues": "0,1"
  ],
  [
    "ParameterName": "apg_enable_correlated_any_transform",
    "ApplyType": "dynamic",
    "Description": "Enables the planner to transform correlated ANY Sublink (IN/NOT IN
    subquery) to JOIN when possible.",
    "AllowedValues": "0,1"
  ],
  ...
]
```

Following are tables containing values for the default DB cluster parameter and DB parameter for Aurora
PostgreSQL version 14.
Aurora PostgreSQL cluster-level parameters

You can view the cluster-level parameters available for a specific Aurora PostgreSQL version using the AWS Management console, the AWS CLI, or the Amazon RDS API. For information about viewing the parameters in an Aurora PostgreSQL DB cluster parameter groups in the RDS console, see Viewing parameter values for a DB cluster parameter group (p. 224).

Some cluster-level parameters aren't available in all versions and some are being deprecated. For information about viewing the parameters of a specific Aurora PostgreSQL version, see Viewing Aurora PostgreSQL DB cluster and DB parameters (p. 1729).

For example, the following table lists the parameters available in the default DB cluster parameter group for Aurora PostgreSQL version 14. If you create an Aurora PostgreSQL DB cluster without specifying your own custom DB parameter group, your DB cluster is created using the default Aurora DB cluster parameter group for the version chosen, such as default.aurora-postgresql14, default.aurora-postgresql13, and so on.

For a listing of the DB instance parameters for this same default DB cluster parameter group, see Aurora PostgreSQL instance-level parameters (p. 1750).

<tr>
<td><code>pg_bigm.gin_key_limit</code></td>
<td>It specifies the maximum number of 2-grams of the search keyword to be used for full text search.</td>
<td>0</td>
</tr>
<tr>
<td><code>pg_bigm.last_update</code></td>
<td>It reports the last updated date of the pg_bigm module.</td>
<td>2013.11.22</td>
</tr>
<tr>
<td><code>pg_bigm.similarity_limit</code></td>
<td>It specifies the minimum threshold used by the similarity search.</td>
<td>0.3</td>
</tr>
<tr>
<td><code>pg_hint_plan.debug_print</code></td>
<td>Logs results of hint parsing.</td>
<td>–</td>
</tr>
<tr>
<td><code>pg_hint_plan.enable_hint</code></td>
<td>Force planner to use plans specified in the hint comment preceding to the query.</td>
<td>–</td>
</tr>
<tr>
<td><code>pg_hint_plan.enable_hint_table</code></td>
<td>Force planner to not get hint by using table lookups.</td>
<td>–</td>
</tr>
<tr>
<td><code>pg_hint_plan.message_level</code></td>
<td>Message level of debug messages.</td>
<td>–</td>
</tr>
<tr>
<td><code>pg_hint_plan.parse_messages</code></td>
<td>Message level of parse errors.</td>
<td>–</td>
</tr>
<tr>
<td><code>pglogical.batch_inserts</code></td>
<td>Batch inserts if possible</td>
<td>–</td>
</tr>
<tr>
<td><code>pglogical.conflict_log_level</code></td>
<td>Sets log level used for logging resolved conflicts.</td>
<td>–</td>
</tr>
<tr>
<td><code>pglogical.conflict_resolution</code></td>
<td>Sets method used for conflict resolution for resolvable conflicts.</td>
<td>–</td>
</tr>
<tr>
<td><code>pglogical.extra_connection_options</code></td>
<td>Connection options to add to all peer node connections</td>
<td>–</td>
</tr>
<tr>
<td><code>pglogical.synchronous_commit</code></td>
<td>pglogical specific synchronous commit value</td>
<td>–</td>
</tr>
<tr>
<td><code>pglogical.use_spi</code></td>
<td>Use SPI instead of low-level API for applying changes</td>
<td>–</td>
</tr>
<tr>
<td><code>pg_prewarm.autoprewarm</code></td>
<td>Starts the autoprewarm worker.</td>
<td>–</td>
</tr>
<tr>
<td><code>pg_prewarm.autoprewarm_interval</code></td>
<td>Interval between dumps of shared buffers</td>
<td>–</td>
</tr>
<tr>
<td><code>pg_similarity.block_is_normalized</code></td>
<td>The result value is normalized or not.</td>
<td>–</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>--------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>

<tr>
<td>pg_similarity.block_threshold</td>
<td>Sets the threshold used by the Block similarity function.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.block_tokenizer</td>
<td>Sets the tokenizer for Block similarity function.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.cosine_is_normalized</td>
<td>Sets if the result value is normalized or not.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.cosine_threshold</td>
<td>Sets the threshold used by the Cosine similarity function.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.cosine_tokenizer</td>
<td>Sets the tokenizer for Cosine similarity function.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.dice_is_normalized</td>
<td>Sets if the result value is normalized or not.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.dice_threshold</td>
<td>Sets the threshold used by the Dice similarity measure.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.dice_tokenizer</td>
<td>Sets the tokenizer for Dice similarity measure.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.euclidean_is_normalized</td>
<td>Sets if the result value is normalized or not.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.euclidean_threshold</td>
<td>Sets the threshold used by the Euclidean similarity measure.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.euclidean_tokenizer</td>
<td>Sets the tokenizer for Euclidean similarity measure.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.hamming_is_normalized</td>
<td>Sets if the result value is normalized or not.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.hamming_threshold</td>
<td>Sets the threshold used by the Block similarity metric.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.jaccard_is_normalized</td>
<td>Sets if the result value is normalized or not.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.jaccard_threshold</td>
<td>Sets the threshold used by the Jaccard similarity measure.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.jaccard_tokenizer</td>
<td>Sets the tokenizer for Jaccard similarity measure.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.jaro_is_normalized</td>
<td>Sets if the result value is normalized or not.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.jaro_threshold</td>
<td>Sets the threshold used by the Jaro similarity measure.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.jarowinkler_is_normalized</td>
<td>Sets if the result value is normalized or not.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.jarowinkler_threshold</td>
<td>Sets the threshold used by the Jarowinkler similarity measure.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.levenshtein_is_normalized</td>
<td>Sets if the result value is normalized or not.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.levenshtein_threshold</td>
<td>Sets the threshold used by the Levenshtein similarity measure.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.matching_is_normalized</td>
<td>Sets if the result value is normalized or not.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.matching_threshold</td>
<td>Sets the threshold used by the Matching Coefficient similarity measure.</td>
<td>–</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>--------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>pg_similarity.matching_tokenizer</td>
<td>Sets the tokenizer for Matching Coefficient similarity measure.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.mongeelkan_is_normalized</td>
<td>Sets if the result value is normalized or not.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.mongeelkan_threshold</td>
<td>Sets the threshold used by the Monge-Elkan similarity measure.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.mongeelkan_tokenizer</td>
<td>Sets the tokenizer for Monge-Elkan similarity measure.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.nw_gap_penalty</td>
<td>Sets the gap penalty used by the Needleman-Wunsch similarity measure.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.nw_is_normalized</td>
<td>Sets if the result value is normalized or not.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.nw_threshold</td>
<td>Sets the threshold used by the Needleman-Wunsch similarity measure.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.overlap_is_normalized</td>
<td>Sets if the result value is normalized or not.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.overlap_threshold</td>
<td>Sets the threshold used by the Overlap Coefficient similarity measure.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.overlap_tokenizer</td>
<td>Sets the tokenizer for Overlap Coefficientsimilarity measure.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.qgram_is_normalized</td>
<td>Sets if the result value is normalized or not.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.qgram_threshold</td>
<td>Sets the threshold used by the Q-Gram similarity measure.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.qgram_tokenizer</td>
<td>Sets the tokenizer for Q-Gram measure.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.swg_is_normalized</td>
<td>Sets if the result value is normalized or not.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.swg_threshold</td>
<td>Sets the threshold used by the Smith-Waterman-Gotoh similarity measure.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.sw_is_normalized</td>
<td>Sets if the result value is normalized or not.</td>
<td>–</td>
</tr>
<tr>
<td>pg_similarity.sw_threshold</td>
<td>Sets the threshold used by the Smith-Waterman similarity measure.</td>
<td>–</td>
</tr>
<tr>
<td>pg_stat_statements.max</td>
<td>Sets the maximum number of statements tracked by pg_stat_statements.</td>
<td>–</td>
</tr>
<tr>
<td>pg_stat_statements.save</td>
<td>Save pg_stat_statements statistics across server shutdowns.</td>
<td>–</td>
</tr>
<tr>
<td>pg_stat_statements.track</td>
<td>Selects which statements are tracked by pg_stat_statements.</td>
<td>–</td>
</tr>
<tr>
<td>pg_stat_statements.track_planning</td>
<td>Selects whether planning duration is tracked by pg_stat_statements.</td>
<td>–</td>
</tr>
<tr>
<td>pg_stat_statements.track_utility</td>
<td>Selects whether utility commands are tracked by pg_stat_statements.</td>
<td>–</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>--------------------------------</td>
</tr>
<tr>
<td>plan_cache_mode</td>
<td>Controls the planner selection of custom or generic plan.</td>
<td>–</td>
</tr>
<tr>
<td>port</td>
<td>Sets the TCP port the server listens on.</td>
<td>EndPointPort</td>
</tr>
<tr>
<td>postgres.gdal_enabled_drivers</td>
<td>Enable or disable GDAL drivers used with PostGIS in Postgres 9.3.5 and above.</td>
<td>ENABLE_ALL</td>
</tr>
<tr>
<td>quote_all_identifiers</td>
<td>When generating SQL fragments, quote all identifiers.</td>
<td>–</td>
</tr>
<tr>
<td>random_page_cost</td>
<td>Sets the planners estimate of the cost of a nonsequentially fetched disk page.</td>
<td>–</td>
</tr>
<tr>
<td>rdkit.dice_threshold</td>
<td>Lower threshold of Dice similarity. Molecules with similarity lower than threshold are not similar by # operation.</td>
<td>–</td>
</tr>
<tr>
<td>rdkit.do_chiral_sss</td>
<td>Should stereochemistry be taken into account in substructure matching. If false, no stereochemistry information is used in substructure matches.</td>
<td>–</td>
</tr>

## Aurora PostgreSQL parameters

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>rds.force_ssl</code></td>
<td>Force SSL connections.</td>
<td>0</td>
</tr>
<tr>
<td><code>rds.global_db_rpo</code></td>
<td>(s) Recovery point objective threshold, in seconds, that blocks user commits when it is violated. Important This parameter is meant for Aurora PostgreSQL-based global databases. For a non-global database, leave it at the default value. For more information about using this parameter, see the section called “Managing RPOs for Aurora PostgreSQL-based global databases” (p. 1865).</td>
<td>–</td>
</tr>
<tr>
<td><code>rds.logical_replication</code></td>
<td>Enables logical decoding.</td>
<td>0</td>
</tr>
<tr>
<td><code>rds.logically_replicate_unlogged_tables</code></td>
<td>Unlogged tables are logically replicated.</td>
<td>1</td>
</tr>
<tr>
<td><code>rds.log_retention_period</code></td>
<td>Amazon RDS will delete PostgreSQL log that are older than N minutes.</td>
<td>4320</td>
</tr>
<tr>
<td><code>rds.pg_stat_ramdisk_size</code></td>
<td>Size of the stats ramdisk in MB. A nonzero value will setup the ramdisk. This parameter is only available in Aurora PostgreSQL 14 and lower versions.</td>
<td>0</td>
</tr>
<tr>
<td><code>rds.rds_superuser_reserved_connections</code></td>
<td>Number of connection slots reserved for rds superusers.</td>
<td>2</td>
</tr>
<tr>
<td><code>rds.restrict_password_commands</code></td>
<td>Restricts password-related commands to members of rds_password.</td>
<td>–</td>
</tr>
<tr>
<td><code>rds.superuser_variables</code></td>
<td>List of superuser-only variables for which we elevate rds_superuser modification statements.</td>
<td>session_replication_role</td>
</tr>
<tr>
<td><code>recovery_init_sync_method</code></td>
<td>Sets the method for synchronizing the data directory before crash recovery.</td>
<td>syncfs</td>
</tr>
<tr>
<td><code>remove_temp_files_after_crash</code></td>
<td>Remove temporary files after backend crash.</td>
<td>0</td>
</tr>
<tr>
<td><code>restart_after_crash</code></td>
<td>Reinitialize server after backend crash.</td>
<td>–</td>
</tr>
<tr>
<td><code>row_security</code></td>
<td>Enable row security.</td>
<td>–</td>
</tr>
<tr>
<td><code>search_path</code></td>
<td>Sets the schema search order for names that are not schema-qualified.</td>
<td>–</td>
</tr>
<tr>
<td><code>seq_page_cost</code></td>
<td>Sets the planners estimate of the cost of a sequentially fetched disk page.</td>
<td>–</td>
</tr>
<tr>
<td><code>session_replication_role</code></td>
<td>Sets the sessions behavior for triggers and rewrite rules.</td>
<td>–</td>
</tr>
<tr>
<td><code>shared_buffers</code></td>
<td>(8kB) Sets the number of shared memory buffers used by the server.</td>
<td>SUM(DBInstanceClassMemory/12038,-50003)</td>
</tr>
<tr>
<td><code>shared_preload_libraries</code></td>
<td>Lists shared libraries to preload into server.</td>
<td>pg_stat_statements</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------</td>
</tr>
<tr>
<td>ssl</td>
<td>Enables SSL connections.</td>
<td>1</td>
</tr>
<tr>
<td>ssl_ca_file</td>
<td>Location of the SSL server authority file.</td>
<td>/rdsdbdata/rds-metadata/ca-cert.pem</td>
</tr>
<tr>
<td>ssl_cert_file</td>
<td>Location of the SSL server certificate file.</td>
<td>/rdsdbdata/rds-metadata/server-cert.pem</td>
</tr>
<tr>
<td>ssl_ciphers</td>
<td>Sets the list of allowed TLS ciphers to be used on secure connections.</td>
<td>–</td>
</tr>
<tr>
<td>ssl_crl_dir</td>
<td>Location of the SSL certificate revocation list directory.</td>
<td>/rdsdbdata/rds-metadata/ssl_crl_dir/</td>
</tr>
<tr>
<td>ssl_key_file</td>
<td>Location of the SSL server private key file</td>
<td>/rdsdbdata/rds-metadata/server-key.pem</td>

<tr>
<td>tcp_keepalives_idle</td>
<td>(s) Time between issuing TCP keepalives.</td>
<td>–</td>
</tr>
<tr>
<td>tcp_keepalives_interval</td>
<td>(s) Time between TCP keepalive retransmits.</td>
<td>–</td>
</tr>
<tr>
<td>temp_buffers</td>
<td>(8kB) Sets the maximum number of temporary buffers used by each session.</td>
<td>–</td>
</tr>
<tr>
<td>temp_file_limit</td>
<td>Constrains the total amount disk space in kilobytes that a given PostgreSQL process can use for temporary files, excluding space used for explicit temporary tables</td>
<td>-1</td>
</tr>
<tr>
<td>temp_tablespaces</td>
<td>Sets the tablespace(s) to use for temporary tables and sort files.</td>
<td>–</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>timezone</td>
<td>Sets the time zone for displaying and interpreting time stamps.</td>
<td>UTC</td>
</tr>
<tr>
<td>track_activities</td>
<td>Collects information about executing commands.</td>
<td>–</td>
</tr>
<tr>
<td>track_activity_query_size</td>
<td>Sets the size reserved for pg_stat_activity.current_query, in bytes.</td>
<td>4096</td>
</tr>
<tr>
<td>track_commit_timestamp</td>
<td>Collects transaction commit time.</td>
<td>–</td>
</tr>
<tr>
<td>track_counts</td>
<td>Collects statistics on database activity.</td>
<td>–</td>
</tr>
<tr>
<td>track_functions</td>
<td>Collects function-level statistics on database activity.</td>
<td>pl</td>
</tr>
<tr>
<td>track_io_timing</td>
<td>Collects timing statistics on database IO activity.</td>
<td>1</td>
</tr>
<tr>
<td>track_wal_io_timing</td>
<td>Collects timing statistics for WAL I/O activity.</td>
<td>–</td>
</tr>
<tr>
<td>transform_null_equals</td>
<td>Treats expr=NULL as expr IS NULL.</td>
<td>–</td>
</tr>
<tr>
<td>update_process_title</td>
<td>Updates the process title to show the active SQL command.</td>
<td>–</td>
</tr>
<tr>
<td>vacuum_cost_delay</td>
<td>(ms) Vacuum cost delay in milliseconds.</td>
<td>–</td>
</tr>
<tr>
<td>vacuum_cost_limit</td>
<td>Vacuum cost amount available before napping.</td>
<td>–</td>
</tr>
<tr>
<td>vacuum_cost_page_dirty</td>

Aurora PostgreSQL instance-level parameters

You can view the instance-level parameters available for a specific Aurora PostgreSQL version using the AWS Management console, the AWS CLI, or the Amazon RDS API. For information about viewing the parameters in an Aurora PostgreSQL DB parameter groups in the RDS console, see Viewing parameter values for a DB parameter group (p. 235).

Some instance-level parameters aren't available in all versions and some are being deprecated. For information about viewing the parameters of a specific Aurora PostgreSQL version, see Viewing Aurora PostgreSQL DB cluster and DB parameters (p. 1729).

For example, the following table lists the parameters that apply to a specific DB instance in an Aurora PostgreSQL DB cluster. This list was generated by running the describe-db-parameters AWS CLI command with default.aurora-postgresql14 for the --db-parameter-group-name value.

For a listing of the DB cluster parameters for this same default DB parameter group, see Aurora PostgreSQL cluster-level parameters (p. 1731).

<tr>
<td>stats_temp_directory</td>
<td>Writes temporary statistics files to the specified directory.</td>
<td>/rdsdbdata/db/pg_stat_tmp</td>
</tr>
<tr>
<td>superuser_reserved_connections</td>
<td>Sets the number of connection slots reserved for superusers.</td>
<td>3</td>
</tr>
<tr>
<td>synchronize_seqscans</td>
<td>Enable synchronized sequential scans.</td>
<td>–</td>
</tr>
<tr>
<td>tcp_keepalives_count</td>
<td>Maximum number of TCP keepalive retransmits.</td>
<td>–</td>
</tr>
<tr>
<td>tcp_keepalives_idle</td>
<td>(s Time between issuing TCP keepalives.</td>
<td>–</td>
</tr>
<tr>
<td>tcp_keepalives_interval</td>
<td>(s Time between TCP keepalive retransmits.</td>
<td>–</td>
</tr>
<tr>
<td>temp_buffers</td>
<td>(8kB Sets the maximum number of temporary buffers used by each session.</td>
<td>–</td>
</tr>
<tr>
<td>temp_file_limit</td>
<td>Constrains the total amount disk space in kilobytes that a given PostgreSQL process can use for temporary files, excluding space used for explicit temporary tables</td>
<td>1</td>
</tr>
<tr>
<td>temp_tablespaces</td>
<td>Sets the tablespace(s to use for temporary tables and sort files.</td>
<td>–</td>
</tr>
<tr>
<td>track_activities</td>
<td>Collects information about executing commands.</td>
<td>–</td>
</tr>
<tr>
<td>track_activity_query_size</td>
<td>Sets the size reserved for pg_stat_activity.current_query, in bytes.</td>
<td>4096</td>
</tr>
<tr>
<td>track_counts</td>
<td>Collects statistics on database activity.</td>
<td>–</td>
</tr>
<tr>
<td>track_functions</td>
<td>Collects function-level statistics on database activity.</td>
<td>pl</td>
</tr>
<tr>
<td>track_io_timing</td>
<td>Collects timing statistics on database IO activity.</td>
<td>1</td>
</tr>
<tr>
<td>transform_--equals</td>
<td>Treats expr=-- as expr IS --.</td>
<td>–</td>
</tr>
<tr>
<td>update_process_title</td>
<td>Updates the process title to show the active SQL command.</td>
<td>–</td>
</tr>
</tbody>
</table>
### Amazon Aurora PostgreSQL wait events

The following are common wait events for Aurora PostgreSQL. To learn more about wait events and tuning your Aurora PostgreSQL DB cluster, see [Tuning with wait events for Aurora PostgreSQL](#).

**Activity:ArchiverMain**

The archiver process is waiting for activity.

**Activity:AutoVacuumMain**

The autovacuum launcher process is waiting for activity.

**Activity:BgWriterHibernate**

The background writer process is hibernating while waiting for activity.

**Activity:BgWriterMain**

The background writer process is waiting for activity.

**Activity:CheckpointerMain**

The checkpointer process is waiting for activity.

**Activity:LogicalApplyMain**

The logical replication apply process is waiting for activity.

**Activity:LogicalLauncherMain**

The logical replication launcher process is waiting for activity.

**Activity:PgStatMain**

The statistics collector process is waiting for activity.

**Activity:RecoveryWalAll**

A process is waiting for the write-ahead log (WAL) from a stream at recovery.

**Activity:RecoveryWalStream**

The startup process is waiting for the write-ahead log (WAL) to arrive during streaming recovery.

**Activity:SysLoggerMain**

The syslogger process is waiting for activity.

**Activity:WalReceiverMain**

The write-ahead log (WAL) receiver process is waiting for activity.

---

### Amazon Aurora PostgreSQL wait events

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>wal_receiver_status_interval</td>
<td>Sets the maximum interval between WAL receiver status reports to the primary.</td>
<td>–</td>
</tr>
<tr>
<td>work_mem</td>
<td>(kB Sets the maximum memory to be used for query workspaces.</td>
<td>–</td>
</tr>
<tr>
<td>xmlbinary</td>
<td>Sets how binary values are to be encoded in XML.</td>
<td>–</td>
</tr>
<tr>
<td>xmloption</td>
<td>Sets whether XML data in implicit parsing and serialization operations is to be considered as documents or content fragments.</td>
<td>–</td>
</tr>
</tbody>
</table>
Activity:WalSenderMain

The write-ahead log (WAL) sender process is waiting for activity.

Activity:WalWriterMain

The write-ahead log (WAL) writer process is waiting for activity.

BufferPin:BufferPin

A process is waiting to acquire an exclusive pin on a buffer.

Client:GSSOpenServer

A process is waiting to read data from the client while establishing a Generic Security Service Application Program Interface (GSSAPI) session.

Client:ClientRead

A backend process is waiting to receive data from a PostgreSQL client. For more information, see Client:ClientRead (p. 1416).

Client:ClientWrite

A backend process is waiting to send more data to a PostgreSQL client. For more information, see Client:ClientWrite (p. 1418).

Client:LibPQWalReceiverConnect

A process is waiting in the write-ahead log (WAL) receiver to establish connection to remote server.

Client:LibPQWalReceiverReceive

A process is waiting in the write-ahead log (WAL) receiver to receive data from remote server.

Client:SSLOpenServer

A process is waiting for Secure Sockets Layer (SSL) while attempting connection.

Client:WalReceiverWaitStart

A process is waiting for startup process to send initial data for streaming replication.

Client:WalSenderWaitForWAL

A process is waiting for the write-ahead log (WAL) to be flushed in the WAL sender process.

Client:WalSenderWriteData

A process is waiting for any activity when processing replies from the write-ahead log (WAL) receiver in the WAL sender process.

CPU

A backend process is active in or is waiting for CPU. For more information, see CPU (p. 1420).

Extension:extension

A backend process is waiting for a condition defined by an extension or module.

IO:AuroraOptimizedReadsCacheRead

A process is waiting for a read from Optimized Reads tiered cache because the page isn't available in shared memory.

IO:AuroraOptimizedReadsCacheSegmentTruncate

A process is waiting for an Optimized Reads tiered cache segment file to be truncated.

IO:AuroraOptimizedReadsCacheWrite

The background writer process is waiting to write in Optimized Reads tiered cache.
IO:AuroraStorageLogAllocate

A session is allocating metadata and preparing for a transaction log write.

IO:BufFileRead

When operations require more memory than the amount defined by working memory parameters, the engine creates temporary files on disk. This wait event occurs when operations read from the temporary files. For more information, see IO:BufFileRead and IO:BufFileWrite (p. 1424).

IO:BufFileWrite

When operations require more memory than the amount defined by working memory parameters, the engine creates temporary files on disk. This wait event occurs when operations write to the temporary files. For more information, see IO:BufFileRead and IO:BufFileWrite (p. 1424).

IO:ControlFileRead

A process is waiting for a read from the pg_control file.

IO:ControlFileSync

A process is waiting for the pg_control file to reach durable storage.

IO:ControlFileSyncUpdate

A process is waiting for an update to the pg_control file to reach durable storage.

IO:ControlFileWrite

A process is waiting for a write to the pg_control file.

IO:ControlFileWriteUpdate

A process is waiting for a write to update the pg_control file.

IO:CopyFileRead

A process is waiting for a read during a file copy operation.

IO:CopyFileWrite

A process is waiting for a write during a file copy operation.

IO:DataFileExtend

A process is waiting for a relation data file to be extended.

IO:DataFileFlush

A process is waiting for a relation data file to reach durable storage.

IO:DataFileImmediateSync

A process is waiting for an immediate synchronization of a relation data file to durable storage.

IO:DataFilePrefetch

A process is waiting for an asynchronous prefetch from a relation data file.

IO:DataFileSync

A process is waiting for changes to a relation data file to reach durable storage.

IO:DataFileRead

A backend process tried to find a page in the shared buffers, didn't find it, and so read it from storage. For more information, see IO:DataFileRead (p. 1429).

IO:DataFileTruncate

A process is waiting for a relation data file to be truncated.
IO:DataFileWrite
    A process is waiting for a write to a relation data file.

IO:DSMFillZeroWrite
    A process is waiting to write zero bytes to a dynamic shared memory backing file.

IO:LockFileAddToDataDirRead
    A process is waiting for a read while adding a line to the data directory lock file.

IO:LockFileAddToDataDirSync
    A process is waiting for data to reach durable storage while adding a line to the data directory lock file.

IO:LockFileAddToDataDirWrite
    A process is waiting for a write while adding a line to the data directory lock file.

IO:LockFileCreateRead
    A process is waiting to read while creating the data directory lock file.

IO:LockFileCreateSync
    A process is waiting for data to reach durable storage while creating the data directory lock file.

IO:LockFileCreateWrite
    A process is waiting for a write while creating the data directory lock file.

IO:LockFileReCheckDataDirRead
    A process is waiting for a read during recheck of the data directory lock file.

IO:LogicalRewriteCheckpointSync
    A process is waiting for logical rewrite mappings to reach durable storage during a checkpoint.

IO:LogicalRewriteMappingSync
    A process is waiting for mapping data to reach durable storage during a logical rewrite.

IO:LogicalRewriteMappingWrite
    A process is waiting for a write of mapping data during a logical rewrite.

IO:LogicalRewriteSync
    A process is waiting for logical rewrite mappings to reach durable storage.

IO:LogicalRewriteTruncate
    A process is waiting for the truncation of mapping data during a logical rewrite.

IO:LogicalRewriteWrite
    A process is waiting for a write of logical rewrite mappings.

IO:RelationMapRead
    A process is waiting for a read of the relation map file.

IO:RelationMapSync
    A process is waiting for the relation map file to reach durable storage.

IO:RelationMapWrite
    A process is waiting for a write to the relation map file.
IO:ReorderBufferRead
A process is waiting for a read during reorder buffer management.

IO:ReorderBufferWrite
A process is waiting for a write during reorder buffer management.

IO:ReorderLogicalMappingRead
A process is waiting for a read of a logical mapping during reorder buffer management.

IO:ReplicationSlotRead
A process is waiting for a read from a replication slot control file.

IO:ReplicationSlotRestoreSync
A process is waiting for a replication slot control file to reach durable storage while restoring it to memory.

IO:ReplicationSlotSync
A process is waiting for a replication slot control file to reach durable storage.

IO:ReplicationSlotWrite
A process is waiting for a write to a replication slot control file.

IO:SLRUFlushSync
A process is waiting for simple least-recently used (SLRU) data to reach durable storage during a checkpoint or database shutdown.

IO:SLRURead
A process is waiting for a read of a simple least-recently used (SLRU) page.

IO:SLRUSync
A process is waiting for simple least-recently used (SLRU) data to reach durable storage following a page write.

IO:SLRUWrite
A process is waiting for a write of a simple least-recently used (SLRU) page.

IO:SnapbuildRead
A process is waiting for a read of a serialized historical catalog snapshot.

IO:SnapbuildSync
A process is waiting for a serialized historical catalog snapshot to reach durable storage.

IO:SnapbuildWrite
A process is waiting for a write of a serialized historical catalog snapshot.

IO:TimelineHistoryFileSync
A process is waiting for a timeline history file received through streaming replication to reach durable storage.

IO:TimelineHistoryFileWrite
A process is waiting for a write of a timeline history file received through streaming replication.

IO:TimelineHistoryRead
A process is waiting for a read of a timeline history file.
IO:TimelineHistorySync
A process is waiting for a newly created timeline history file to reach durable storage.

IO:TimelineHistoryWrite
A process is waiting for a write of a newly created timeline history file.

IO:TwoPhaseFileRead
A process is waiting for a read of a two phase state file.

IO:TwoPhaseFileSync
A process is waiting for a two phase state file to reach durable storage.

IO:TwoPhaseFileWrite
A process is waiting for a write of a two phase state file.

IO:WALBootstrapSync
A process is waiting for the write-ahead log (WAL) to reach durable storage during bootstrapping.

IO:WALBootstrapWrite
A process is waiting for a write of a write-ahead log (WAL) page during bootstrapping.

IO:WALCopyRead
A process is waiting for a read when creating a new write-ahead log (WAL) segment by copying an existing one.

IO:WALCopySync
A process is waiting for a new write-ahead log (WAL) segment created by copying an existing one to reach durable storage.

IO:WALCopyWrite
A process is waiting for a write when creating a new write-ahead log (WAL) segment by copying an existing one.

IO:WALInitSync
A process is waiting for a newly initialized write-ahead log (WAL) file to reach durable storage.

IO:WALInitWrite
A process is waiting for a write while initializing a new write-ahead log (WAL) file.

IO:WALRead
A process is waiting for a read from a write-ahead log (WAL) file.

IO:WALSenderTimelineHistoryRead
A process is waiting for a read from a timeline history file during a WAL sender timeline command.

IO:WALSync
A process is waiting for a write-ahead log (WAL) file to reach durable storage.

IO:WALSyncMethodAssign
A process is waiting for data to reach durable storage while assigning a new write-ahead log (WAL) sync method.

IO:WALWrite
A process is waiting for a write to a write-ahead log (WAL) file.
IO:XactSync

A backend process is waiting for the Aurora storage subsystem to acknowledge the commit of a regular transaction, or the commit or rollback of a prepared transaction. For more information, see IO:XactSync (p. 1439).

IPC:BackupWaitWalArchive

A process is waiting for write-ahead log (WAL) files required for a backup to be successfully archived.

IPC:BgWorkerShutdown

A process is waiting for a background worker to shut down.

IPC:BgWorkerStartup

A process is waiting for a background worker to start.

IPC:BtreePage

A process is waiting for the page number needed to continue a parallel B-tree scan to become available.

IPC:CheckpointDone

A process is waiting for a checkpoint to complete.

IPC:CheckpointStart

A process is waiting for a checkpoint to start.

IPC:ClogGroupUpdate

A process is waiting for the group leader to update the transaction status at a transaction's end.

IPC:DamRecordTxAck

A backend process has generated a database activity streams event and is waiting for the event to become durable. For more information, see IPC:DamRecordTxAck (p. 1441).

IPC:ExecuteGather

A process is waiting for activity from a child process while executing a Gather plan node.

IPC:Hash/Batch/Allocating

A process is waiting for an elected parallel hash participant to allocate a hash table.

IPC:Hash/Batch/Electing

A process is electing a parallel hash participant to allocate a hash table.

IPC:Hash/Batch/Loading

A process is waiting for other parallel hash participants to finish loading a hash table.

IPC:Hash/Build/Allocating

A process is waiting for an elected parallel hash participant to allocate the initial hash table.

IPC:Hash/Build/Electing

A process is electing a parallel hash participant to allocate the initial hash table.

IPC:Hash/Build/HashingInner

A process is waiting for other parallel hash participants to finish hashing the inner relation.

IPC:Hash/Build/HashingOuter

A process is waiting for other parallel hash participants to finish partitioning the outer relation.
IPC:Hash/GrowBatches/Allocating
A process is waiting for an elected parallel hash participant to allocate more batches.

IPC:Hash/GrowBatches/Deciding
A process is electing a parallel hash participant to decide on future batch growth.

IPC:Hash/GrowBatches/Electing
A process is electing a parallel hash participant to allocate more batches.

IPC:Hash/GrowBatches/Finishing
A process is waiting for an elected parallel hash participant to decide on future batch growth.

IPC:Hash/GrowBatches/Repartitioning
A process is waiting for other parallel hash participants to finishing repartitioning.

IPC:Hash/GrowBuckets/Allocating
A process is waiting for an elected parallel hash participant to finish allocating more buckets.

IPC:Hash/GrowBuckets/Electing
A process is electing a parallel hash participant to allocate more buckets.

IPC:Hash/GrowBuckets/Reinserting
A process is waiting for other parallel hash participants to finish inserting tuples into new buckets.

IPC:HashBatchAllocate
A process is waiting for an elected parallel hash participant to allocate a hash table.

IPC:HashBatchElect
A process is waiting to elect a parallel hash participant to allocate a hash table.

IPC:HashBatchLoad
A process is waiting for other parallel hash participants to finish loading a hash table.

IPC:HashBuildAllocate
A process is waiting for an elected parallel hash participant to allocate the initial hash table.

IPC:HashBuildElect
A process is waiting to elect a parallel hash participant to allocate the initial hash table.

IPC:HashBuildHashInner
A process is waiting for other parallel hash participants to finish hashing the inner relation.

IPC:HashBuildHashOuter
A process is waiting for other parallel hash participants to finish partitioning the outer relation.

IPC:HashGrowBatchesAllocate
A process is waiting for an elected parallel hash participant to allocate more batches.

IPC:HashGrowBatchesDecide
A process is waiting to elect a parallel hash participant to decide on future batch growth.

IPC:HashGrowBatchesElect
A process is waiting to elect a parallel hash participant to allocate more batches.

IPC:HashGrowBatchesFinish
A process is waiting for an elected parallel hash participant to decide on future batch growth.
**IPC:HashGrowBatchesRepartition**
A process is waiting for other parallel hash participants to finish repartitioning.

**IPC:HashGrowBucketsAllocate**
A process is waiting for an elected parallel hash participant to finish allocating more buckets.

**IPC:HashGrowBucketsElect**
A process is waiting to elect a parallel hash participant to allocate more buckets.

**IPC:HashGrowBucketsReinsert**
A process is waiting for other parallel hash participants to finish inserting tuples into new buckets.

**IPC:LogicalSyncData**
A process is waiting for a logical replication remote server to send data for initial tables synchronization.

**IPC:LogicalSyncStateChange**
A process is waiting for a logical replication remote server to change state.

**IPC:MessageQueueInternal**
A process is waiting for another process to be attached to a shared message queue.

**IPC:MessageQueuePutMessage**
A process is waiting to write a protocol message to a shared message queue.

**IPC:MessageQueueReceive**
A process is waiting to receive bytes from a shared message queue.

**IPC:MessageQueueSend**
A process is waiting to send bytes to a shared message queue.

**IPC:ParallelBitmapScan**
A process is waiting for a parallel bitmap scan to become initialized.

**IPC:ParallelCreateIndexScan**
A process is waiting for parallel CREATE INDEX workers to finish a heap scan.

**IPC:ParallelFinish**
A process is waiting for parallel workers to finish computing.

**IPC:ProcArrayGroupUpdate**
A process is waiting for the group leader to clear the transaction ID at the end of a parallel operation.

**IPC:ProcSignalBarrier**
A process is waiting for a barrier event to be processed by all backends.

**IPC:Promote**
A process is waiting for standby promotion.

**IPC:RecoveryConflictSnapshot**
A process is waiting for recovery conflict resolution for a vacuum cleanup.

**IPC:RecoveryConflictTablespace**
A process is waiting for recovery conflict resolution for dropping a tablespace.
**IPC:RecoveryPause**
A process is waiting for recovery to be resumed.

**IPC:ReplicationOriginDrop**
A process is waiting for a replication origin to become inactive so it can be dropped.

**IPC:ReplicationSlotDrop**
A process is waiting for a replication slot to become inactive so it can be dropped.

**IPC:SafeSnapshot**
A process is waiting to obtain a valid snapshot for a READ ONLY DEFERRABLE transaction.

**IPC:SyncRep**
A process is waiting for confirmation from a remote server during synchronous replication.

**IPC:XactGroupUpdate**
A process is waiting for the group leader to update the transaction status at the end of a parallel operation.

**Lock:advisory**
A backend process requested an advisory lock and is waiting for it. For more information, see [Lock:advisory](p. 1442).

**Lock:extend**
A backend process is waiting for a lock to be released so that it can extend a relation. This lock is needed because only one backend process can extend a relation at a time. For more information, see [Lock:extend](p. 1444).

**Lock:frozenid**
A process is waiting to update pg_database.datfrozenxid and pg_database.datminxid.

**Lock:object**
A process is waiting to get a lock on a nonrelation database object.

**Lock:page**
A process is waiting to get a lock on a page of a relation.

**Lock:Relation**
A backend process is waiting to acquire a lock on a relation that is locked by another transaction. For more information, see [Lock:Relation](p. 1445).

**Lock:spectoken**
A process is waiting to get a speculative insertion lock.

**Lock:speculative token**
A process is waiting to acquire a speculative insertion lock.

**Lock:transactionid**
A transaction is waiting for a row-level lock. For more information, see [Lock:transactionid](p. 1449).

**Lock:tuple**
A backend process is waiting to acquire a lock on a tuple while another backend process holds a conflicting lock on the same tuple. For more information, see [Lock:tuple](p. 1451).

**Lock:userlock**
A process is waiting to get a user lock.
**Lock:virtualxid**
A process is waiting to get a virtual transaction ID lock.

**LWLock:AddinShmemInit**
A process is waiting to manage an extension's space allocation in shared memory.

**LWLock:AddinShmemInitLock**
A process is waiting to manage space allocation in shared memory.

**LWLock:async**
A process is waiting for I/O on an async (notify) buffer.

**LWLock:AsyncCtlLock**
A process is waiting to read or update a shared notification state.

**LWLock:AsyncQueueLock**
A process is waiting to read or update notification messages.

**LWLock:AuroraOptimizedReadsCacheMapping**
A process is waiting to associate a data block with a page in the Optimized Reads tiered cache.

**LWLock:AutoFile**
A process is waiting to update the `postgresql.auto.conf` file.

**LWLock:AutoFileLock**
A process is waiting to update the `postgresql.auto.conf` file.

**LWLock:Autovacuum**
A process is waiting to read or update the current state of autovacuum workers.

**LWLock:AutovacuumLock**
An autovacuum worker or launcher is waiting to update or read the current state of autovacuum workers.

**LWLock:AutovacuumSchedule**
A process is waiting to ensure that a table selected for autovacuum still needs vacuuming.

**LWLock:AutovacuumScheduleLock**
A process is waiting to ensure that the table it has selected for a vacuum still needs vacuuming.

**LWLock:BackendRandomLock**
A process is waiting to generate a random number.

**LWLock:BackgroundWorker**
A process is waiting to read or update background worker state.

**LWLock:BackgroundWorkerLock**
A process is waiting to read or update the background worker state.

**LWLock:BtreeVacuum**
A process is waiting to read or update vacuum-related information for a B-tree index.

**LWLock:BtreeVacuumLock**
A process is waiting to read or update vacuum-related information for a B-tree index.
LWLock:buffer_content

A backend process is waiting to acquire a lightweight lock on the contents of a shared memory buffer. For more information, see LWLock:buffer_content (BufferContent) (p. 1454).

LWLock:buffer_mapping

A backend process is waiting to associate a data block with a buffer in the shared buffer pool. For more information, see LWLock:buffer_mapping (p. 1455).

LWLock:BufferIO

A backend process wants to read a page into shared memory. The process is waiting for other processes to finish their I/O for the page. For more information, see LWLock:BufferIO (IPC:BufferIO) (p. 1457).

LWLock:Checkpoint

A process is waiting to begin a checkpoint.

LWLock:CheckpointLock

A process is waiting to perform checkpoint.

LWLock:CheckpointerComm

A process is waiting to manage fsync requests.

LWLock:CheckpointerCommLock

A process is waiting to manage fsync requests.

LWLock:clog

A process is waiting for I/O on a clog (transaction status) buffer.

LWLock:CLogControlLock

A process is waiting to read or update transaction status.

LWLock:CLogTruncationLock

A process is waiting to run txid_status or update the oldest transaction ID available to it.

LWLock:commit_timestamp

A process is waiting for I/O on a commit timestamp buffer.

LWLock:CommitTs

A process is waiting to read or update the last value set for a transaction commit timestamp.

LWLock:CommitTsBuffer

A process is waiting for I/O on a simple least-recently used (SLRU) buffer for a commit timestamp.

LWLock:CommitTsControlLock

A process is waiting to read or update transaction commit timestamps.

LWLock:CommitTsLock

A process is waiting to read or update the last value set for the transaction timestamp.

LWLock:CommitTsSLRU

A process is waiting to access the simple least-recently used (SLRU) cache for a commit timestamp.

LWLock:ControlFile

A process is waiting to read or update the pg_control file or create a new write-ahead log (WAL) file.
**LWLock:ControlFileLock**

A process is waiting to read or update the control file or creation of a new write-ahead log (WAL) file.

**LWLock:DynamicSharedMemoryControl**

A process is waiting to read or update dynamic shared memory allocation information.

**LWLock:DynamicSharedMemoryControlLock**

A process is waiting to read or update the dynamic shared memory state.

**LWLock:lock_manager**

A backend process is waiting to add or examine locks for backend processes. Or it's waiting to join or exit a locking group that is used by parallel query. For more information, see [LWLock:lock_manager (p. 1458)](#).

**LWLock:LockFastPath**

A process is waiting to read or update a process's fast-path lock information.

**LWLock:LogicalRepWorker**

A process is waiting to read or update the state of logical replication workers.

**LWLock:LogicalRepWorkerLock**

A process is waiting for an action on a logical replication worker to finish.

**LWLock:multixact_member**

A process is waiting for I/O on a multixact_member buffer.

**LWLock:multixact_offset**

A process is waiting for I/O on a multixact offset buffer.

**LWLock:MultiXactGen**

A process is waiting to read or update shared multixact state.

**LWLock:MultiXactGenLock**

A process is waiting to read or update a shared multixact state.

**LWLock:MultiXactMemberBuffer**

A process is waiting for I/O on a simple least-recently used (SLRU) buffer for a multixact member. For more information, see [LWLock:MultiXact (p. 1461)](#).

**LWLock:MultiXactMemberControlLock**

A process is waiting to read or update multixact member mappings.

**LWLock:MultiXactMemberSLRU**

A process is waiting to access the simple least-recently used (SLRU) cache for a multixact member. For more information, see [LWLock:MultiXact (p. 1461)](#).

**LWLock:MultiXactOffsetBuffer**

A process is waiting for I/O on a simple least-recently used (SLRU) buffer for a multixact offset. For more information, see [LWLock:MultiXact (p. 1461)](#).

**LWLock:MultiXactOffsetControlLock**

A process is waiting to read or update multixact offset mappings.

**LWLock:MultiXactOffsetSLRU**

A process is waiting to access the simple least-recently used (SLRU) cache for a multixact offset. For more information, see [LWLock:MultiXact (p. 1461)](#).
LWLock:MultiXactTruncation
A process is waiting to read or truncate multixact information.

LWLock:MultiXactTruncationLock
A process is waiting to read or truncate multixact information.

LWLock:NotifyBuffer
A process is waiting for I/O on the simple least-recently used (SLRU) buffer for a NOTIFY message.

LWLock:NotifyQueue
A process is waiting to read or update NOTIFY messages.

LWLock:NotifyQueueTail
A process is waiting to update a limit on NOTIFY message storage.

LWLock:NotifyQueueTailLock
A process is waiting to update limit on notification message storage.

LWLock:NotifySLRU
A process is waiting to access the simple least-recently used (SLRU) cache for a NOTIFY message.

LWLock:OidGen
A process is waiting to allocate a new object ID (OID).

LWLock:OidGenLock
A process is waiting to allocate or assign an object ID (OID).

LWLock:oldserxid
A process is waiting for I/O on an oldserxid buffer.

LWLock:OldSerXidLock
A process is waiting to read or record conflicting serializable transactions.

LWLock:OldSnapshotTimeMap
A process is waiting to read or update old snapshot control information.

LWLock:OldSnapshotTimeMapLock
A process is waiting to read or update old snapshot control information.

LWLock:parallel_append
A process is waiting to choose the next subplan during parallel append plan execution.

LWLock:parallel_hash_join
A process is waiting to allocate or exchange a chunk of memory or update counters during a parallel hash plan execution.

LWLock:parallel_query_dsa
A process is waiting for a lock on dynamic shared memory allocation for a parallel query.

LWLock:ParallelAppend
A process is waiting to choose the next subplan during parallel append plan execution.

LWLock:ParallelHashJoin
A process is waiting to synchronize workers during plan execution for a parallel hash join.
**Lwlock:ParallelQueryDSA**

A process is waiting for dynamic shared memory allocation for a parallel query.

**Lwlock:PerSessionDSA**

A process is waiting for dynamic shared memory allocation for a parallel query.

**Lwlock:PerSessionRecordType**

A process is waiting to access a parallel query's information about composite types.

**Lwlock:PerSessionRecordTypmod**

A process is waiting to access a parallel query's information about type modifiers that identify anonymous record types.

**Lwlock:PerXactPredicateList**

A process is waiting to access the list of predicate locks held by the current serializable transaction during a parallel query.

**Lwlock:Predicate_lock_manager**

A process is waiting to add or examine predicate lock information.

**Lwlock:PredicateLockManager**

A process is waiting to access predicate lock information used by serializable transactions.

**Lwlock:proc**

A process is waiting to read or update the fast-path lock information.

**LWLock:ProcArray**

A process is waiting to access the shared per-process data structures (typically, to get a snapshot or report a session's transaction ID).

**LWLock:ProcArrayLock**

A process is waiting to get a snapshot or clearing a transaction Id at a transaction's end.

**LWLock:RelationMapping**

A process is waiting to read or update a `pg_filenode.map` file (used to track the file-node assignments of certain system catalogs).

**LWLock:RelationMappingLock**

A process is waiting to update the relation map file used to store catalog-to-file-node mapping.

**LWLock:RelCacheInit**

A process is waiting to read or update a `pg_internal.init` file (a relation cache initialization file).

**LWLock:RelCacheInitLock**

A process is waiting to read or write a relation cache initialization file.

**LWLock:replication_origin**

A process is waiting to read or update the replication progress.

**LWLock:replication_slot_io**

A process is waiting for I/O on a replication slot.

**LWLock:ReplicationOrigin**

A process is waiting to create, drop, or use a replication origin.
LWLock:ReplicationOriginLock

A process is waiting to set up, drop, or use a replication origin.

LWLock:ReplicationOriginState

A process is waiting to read or update the progress of one replication origin.

LWLock:ReplicationSlotAllocation

A process is waiting to allocate or free a replication slot.

LWLock:ReplicationSlotAllocationLock

A process is waiting to allocate or free a replication slot.

LWLock:ReplicationSlotControl

A process is waiting to read or update a replication slot state.

LWLock:ReplicationSlotControlLock

A process is waiting to read or update the replication slot state.

LWLock:ReplicationSlotIO

A process is waiting for I/O on a replication slot.

LWLock:SerializableBuffer

A process is waiting for I/O on a simple least-recently used (SLRU) buffer for a serializable transaction conflict.

LWLock:SerializableFinishedList

A process is waiting to access the list of finished serializable transactions.

LWLock:SerializableFinishedListLock

A process is waiting to access the list of finished serializable transactions.

LWLock:SerializablePredicateList

A process is waiting to access the list of predicate locks held by serializable transactions.

LWLock:SerializablePredicateLockListLock

A process is waiting to perform an operation on a list of locks held by serializable transactions.

LWLock:SerializableXactHash

A process is waiting to read or update information about serializable transactions.

LWLock:SerializableXactHashLock

A process is waiting to retrieve or store information about serializable transactions.

LWLock:SerialSLRU

A process is waiting to access the simple least-recently used (SLRU) cache for a serializable transaction conflict.

LWLock:SharedTidBitmap

A process is waiting to access a shared tuple identifier (TID) bitmap during a parallel bitmap index scan.

LWLock:SharedTupleStore

A process is waiting to access a shared tuple store during a parallel query.

LWLock:ShmemIndex

A process is waiting to find or allocate space in shared memory.
LWLock:ShmemIndexLock
A process is waiting to find or allocate space in shared memory.

LWLock:SInvalRead
A process is waiting to retrieve messages from the shared catalog invalidation queue.

LWLock:SInvalReadLock
A process is waiting to retrieve or remove messages from a shared invalidation queue.

LWLock:SInvalWrite
A process is waiting to add a message to the shared catalog invalidation queue.

LWLock:SInvalWriteLock
A process is waiting to add a message in a shared invalidation queue.

LWLock:subtrans
A process is waiting for I/O on a subtransaction buffer.

LWLock:SubtransBuffer
A process is waiting for I/O on a simple least-recently used (SLRU) buffer for a subtransaction.

LWLock:SubtransControlLock
A process is waiting to read or update subtransaction information.

LWLock:SubtransSLRU
A process is waiting to access the simple least-recently used (SLRU) cache for a subtransaction.

LWLock:SyncRep
A process is waiting to read or update information about the state of synchronous replication.

LWLock:SyncRepLock
A process is waiting to read or update information about synchronous replicas.

LWLock:SyncScan
A process is waiting to select the starting location of a synchronized table scan.

LWLock:SyncScanLock
A process is waiting to get the start location of a scan on a table for synchronized scans.

LWLock:TablespaceCreate
A process is waiting to create or drop a tablespace.

LWLock:TablespaceCreateLock
A process is waiting to create or drop the tablespace.

LWLock:tbm
A process is waiting for a shared iterator lock on a tree bitmap (TBM).

LWLock:TwoPhaseState
A process is waiting to read or update the state of prepared transactions.

LWLock:TwoPhaseStateLock
A process is waiting to read or update the state of prepared transactions.

LWLock:wal_insert
A process is waiting to insert the write-ahead log (WAL) into a memory buffer.
LWLock: WALBufMapping
A process is waiting to replace a page in write-ahead log (WAL) buffers.

LWLock: WALBufMappingLock
A process is waiting to replace a page in write-ahead log (WAL) buffers.

LWLock: WALInsert
A process is waiting to insert write-ahead log (WAL) data into a memory buffer.

LWLock: WALWrite
A process is waiting for write-ahead log (WAL) buffers to be written to disk.

LWLock: WALWriteLock
A process is waiting for write-ahead log (WAL) buffers to be written to disk.

LWLock: WrapLimitsVacuum
A process is waiting to update limits on transaction ID and multixact consumption.

LWLock: WrapLimitsVacuumLock
A process is waiting to update limits on transaction ID and multixact consumption.

LWLock: XactBuffer
A process is waiting for I/O on a simple least-recently used (SLRU) buffer for a transaction status.

LWLock: XactSLRU
A process is waiting to access the simple least-recently used (SLRU) cache for a transaction status.

LWLock: XactTruncation
A process is waiting to run pg_xact_status or update the oldest transaction ID available to it.

LWLock: XidGen
A process is waiting to allocate a new transaction ID.

LWLock: XidGenLock
A process is waiting to allocate or assign a transaction ID.

Timeout: BaseBackupThrottle
A process is waiting during base backup when throttling activity.

Timeout: PgSleep
A backend process has called the pg_sleep function and is waiting for the sleep timeout to expire. For more information, see Timeout: PgSleep (p. 1463).

Timeout: RecoveryApplyDelay
A process is waiting to apply write-ahead log (WAL) during recovery because of a delay setting.

Timeout: RecoveryRetrieveRetryInterval
A process is waiting during recovery when write-ahead log (WAL) data is not available from any source (pg_wal, archive, or stream).

Timeout: VacuumDelay
A process is waiting in a cost-based vacuum delay point.

For a complete list of PostgreSQL wait events, see The Statistics Collector > Wait Event tables in the PostgreSQL documentation.
Amazon Aurora PostgreSQL updates

Following, you can find information about Amazon Aurora PostgreSQL engine version releases and updates. You can also find information about how to upgrade your Aurora PostgreSQL engine. For more information about Aurora releases in general, see Amazon Aurora versions (p. 4).

Tip
You can minimize the downtime required for a DB cluster upgrade by using a blue/green deployment. For more information, see Using Blue/Green Deployments for database updates (p. 399).

Topics
- Identifying versions of Amazon Aurora PostgreSQL (p. 1780)
- Amazon Aurora PostgreSQL releases and engine versions (p. 1781)
- Extension versions for Amazon Aurora PostgreSQL (p. 1782)
- Upgrading Amazon Aurora PostgreSQL DB clusters (p. 1782)
- Aurora PostgreSQL long-term support (LTS) releases (p. 1798)

Identifying versions of Amazon Aurora PostgreSQL

Amazon Aurora includes certain features that are general to Aurora and available to all Aurora DB clusters. Aurora includes other features that are specific to a particular database engine that Aurora supports. These features are available only to those Aurora DB clusters that use that database engine, such as Aurora PostgreSQL.

An Aurora database release typically has two version numbers, the database engine version number and the Aurora version number. If an Aurora PostgreSQL release has an Aurora version number, it’s included after the engine version number in the Amazon Aurora PostgreSQL releases and engine versions (p. 1781) listing.

Aurora version number

Aurora version numbers use the major.minor.patch naming scheme. An Aurora patch version includes important bug fixes added to a minor version after its release. To learn more about Amazon Aurora major, minor, and patch releases, see Amazon Aurora major versions (p. 5), Amazon Aurora minor versions (p. 11), and Amazon Aurora patch versions (p. 11).

You can find out the Aurora version number of your Aurora PostgreSQL DB instance with the following SQL query:

```
postgres=> SELECT aurora_version();
```

Starting with the release of PostgreSQL versions 13.3, 12.8, 11.13, 10.18, and for all other later versions, Aurora version numbers align more closely to the PostgreSQL engine version. For example, querying an Aurora PostgreSQL 13.3 DB cluster returns the following:

```
aurora_version
----------------
13.3.1
(1 row)
```

Prior releases, such as Aurora PostgreSQL 10.14 DB cluster, return version numbers similar to the following:
### PostgreSQL engine version numbers

Starting with PostgreSQL 10, PostgreSQL database engine versions use a *major.minor* numbering scheme for all releases. Some examples include PostgreSQL 10.18, PostgreSQL 12.7, and PostgreSQL 13.3.

Releases prior to PostgreSQL 10 used a *major.major.minor* numbering scheme in which the first two digits make up the major version number and a third digit denotes a minor version. For example, PostgreSQL 9.6 was a major version, with minor versions 9.6.21 or 9.6.22 indicated by the third digit.

**Note**
The PostgreSQL engine version 9.6 is no longer supported. To upgrade, see [Upgrading Amazon Aurora PostgreSQL DB clusters](#). For version policies and release timelines, see [How long Amazon Aurora major versions remain available](#).

You can find out the PostgreSQL database engine version number with the following SQL query:

```sql
postgres=> SELECT version();
```

For an Aurora PostgreSQL 13.3 DB cluster, the results are as follows:

<table>
<thead>
<tr>
<th>version</th>
</tr>
</thead>
<tbody>
<tr>
<td>PostgreSQL 13.3 on x86_64-pc-linux-gnu, compiled by x86_64-pc-linux-gnu-gcc (GCC) 7.4.0, 64-bit</td>
</tr>
</tbody>
</table>

### Amazon Aurora PostgreSQL releases and engine versions

Amazon Aurora PostgreSQL-Compatible Edition releases are updated regularly. Updates are applied to Aurora PostgreSQL DB clusters during system maintenance windows. When updates are applied depends on the type of update, the AWS Region, and maintenance window setting for the DB cluster. Many of the listed releases include both a PostgreSQL version number and an Amazon Aurora version number. However, starting with the release of PostgreSQL versions 13.3, 12.8, 11.13, 10.18, and for all other later versions, Aurora version numbers aren't used. To identify the version numbers of your Aurora PostgreSQL database, see [Identifying versions of Amazon Aurora PostgreSQL](#).

For information about extensions and modules, see [Extension versions for Amazon Aurora PostgreSQL](#).

**Note**
For information about Amazon Aurora version policies and release timelines, see [How long Amazon Aurora major versions remain available](#).

For information about support for Amazon Aurora see [Amazon RDS FAQs](#).

To determine which Aurora PostgreSQL DB engine versions are available in an AWS Region, use the `describe-db-engine-versions` AWS CLI command. For example:

```bash
aws rds describe-db-engine-versions --engine aurora-postgresql --query '***[].[EngineVersion]' --output text --region aws-region
```
For a list of AWS Regions, see Aurora PostgreSQL Region availability (p. 19).

For details about the PostgreSQL versions that are available on Aurora PostgreSQL, see the Release Notes for Aurora PostgreSQL.

Extension versions for Amazon Aurora PostgreSQL

You can install and configure various PostgreSQL extensions for use with Aurora PostgreSQL DB clusters. For example, you can use the PostgreSQL pg_partman extension to automate the creation and maintenance of table partitions. To learn more about this and other extensions available for Aurora PostgreSQL, see Working with extensions and foreign data wrappers (p. 1616).

For details about the PostgreSQL extensions that are supported on Aurora PostgreSQL, see Extension versions for Amazon Aurora PostgreSQL in Release Notes for Aurora PostgreSQL.

Upgrading Amazon Aurora PostgreSQL DB clusters

Amazon Aurora makes new versions of the PostgreSQL database engine available in AWS Regions only after extensive testing. You can upgrade your Aurora PostgreSQL DB clusters to the new version when it’s available in your Region.

Depending on the version of Aurora PostgreSQL that your DB cluster is currently running, an upgrade to the new release is either a minor upgrade or a major upgrade. For example, upgrading an Aurora PostgreSQL 11.15 DB cluster to Aurora PostgreSQL 13.6 is a major version upgrade. Upgrading an Aurora PostgreSQL 13.3 DB cluster to Aurora PostgreSQL 13.7 is a minor version upgrade. In the following topics, you can find information about how to perform both types of upgrades.

Contents

- Overview of the Aurora PostgreSQL upgrade processes (p. 1782)
- Getting a list of available versions in your AWS Region (p. 1784)
- How to perform a major version upgrade (p. 1786)
  - Testing an upgrade of your production DB cluster to a new major version (p. 1786)
  - Upgrading the Aurora PostgreSQL engine to a new major version (p. 1790)
    - Major upgrades for global databases (p. 1792)
- How to perform minor version upgrades and apply patches (p. 1794)
  - Minor release upgrades and zero-downtime patching (p. 1795)
  - Upgrading the Aurora PostgreSQL engine to a new minor version (p. 1796)
- Upgrading PostgreSQL extensions (p. 1798)
- Alternative blue/green upgrade technique (p. 1798)

Overview of the Aurora PostgreSQL upgrade processes

The differences between major and minor version upgrades are as follows:

Minor version upgrades and patches

Minor version upgrades and patches include only those changes that are backward-compatible with existing applications. Minor version upgrades and patches become available to you only after Aurora PostgreSQL tests and approves them.

Minor version upgrades can be applied for you automatically by Aurora. When you create a new Aurora PostgreSQL DB cluster, the Enable minor version upgrade option is preselected. Unless you turn off this option, minor version upgrades are applied automatically during your scheduled
maintenance window. For more information about the automatic minor version upgrade (AmVU) option and how to modify your Aurora DB cluster to use it, see Automatic minor version upgrades for Aurora DB clusters (p. 351).

If the automatic minor version upgrade option isn't set for your Aurora PostgreSQL DB cluster, your Aurora PostgreSQL isn't automatically upgraded to the new minor version. Instead, when a new minor version is released in your AWS Region and your Aurora PostgreSQL DB cluster is running an older minor version, Aurora prompts you to upgrade. It does so by adding a recommendation to the maintenance tasks for your cluster.

Patches aren't considered an upgrade, and they aren't applied automatically. Aurora PostgreSQL prompts you to apply any patches by adding a recommendation to maintenance tasks for your Aurora PostgreSQL DB cluster. For more information, see How to perform minor version upgrades and apply patches (p. 1794).

Note
Patches that resolve security or other critical issues are also added as maintenance tasks. However, these patches are required. Make sure to apply security patches to your Aurora PostgreSQL DB cluster when they become available in your pending maintenance tasks.

The upgrade process involves the possibility of brief outages as each instance in the cluster is upgraded to the new version. However, after Aurora PostgreSQL versions 14.3.3, 13.7.3, 12.11.3, 11.16.3, 10.21.3 and other higher releases of these minor versions and newer major versions, the upgrade process uses the zero-downtime patching (ZDP) feature. This feature minimizes outages, and in most cases completely eliminates them. For more information, see Minor release upgrades and zero-downtime patching (p. 1795).

Note
ZDP isn't supported in the following cases:
- When Aurora PostgreSQL DB clusters are configured as Aurora Serverless v1.
- During the upgrade of reader instances in Aurora global database.
- During OS patches and OS upgrades.

Major version upgrades

Unlike for minor version upgrades and patches, Aurora PostgreSQL doesn't have an automatic major version upgrade option. New major PostgreSQL versions might contain database changes that aren't backward-compatible with existing applications. The new functionality can cause your existing applications to stop working correctly.

To prevent any issues, we strongly recommend that you follow the process outlined in Testing an upgrade of your production DB cluster to a new major version (p. 1786) before upgrading the DB instances in your Aurora PostgreSQL DB clusters. First ensure that your applications can run on the new version by following that procedure. Then you can manually upgrade your Aurora PostgreSQL DB cluster to the new version.

The upgrade process involves the possibility of brief outages as each instance in the cluster is upgraded to the new version. The preliminary planning process also takes time. We recommend that you always perform upgrade tasks during your cluster's maintenance window or when operations are minimal. For more information, see How to perform a major version upgrade (p. 1786).

Note
Both minor version upgrades and major version upgrades might involve brief outages. For that reason, we recommend strongly that you perform or schedule upgrades during your maintenance window or during other periods of low utilization.

Aurora PostgreSQL DB clusters occasionally require operating system updates. These updates might include a newer version of glibc library. During such updates, we recommend you to follow the guidelines as described in Collations supported in Aurora PostgreSQL (p. 1692).
Getting a list of available versions in your AWS Region

You can get a list of all engine versions available as upgrade targets for your Aurora PostgreSQL DB cluster by querying your AWS Region using the `describe-db-engine-versions` AWS CLI command, as follows.

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions \
  --engine aurora-postgresql \
  --engine-version version-number \
  --query 'DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}' \
  --output text
```

For Windows:

```bash
aws rds describe-db-engine-versions ^
  --engine aurora-postgresql ^
  --engine-version version-number ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" ^
  --output text
```

For example, to identify the valid upgrade targets for an Aurora PostgreSQL version 12.10 DB cluster, run the following AWS CLI command:

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions \
  --engine aurora-postgresql \
  --engine-version 12.10 \
  --query 'DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}' \
  --output text
```

For Windows:

```bash
aws rds describe-db-engine-versions ^
  --engine aurora-postgresql ^
  --engine-version 12.10 ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" ^
  --output text
```

In this table, you can find both major and minor version upgrade targets that are available for various Aurora PostgreSQL DB versions.

<table>

</tr>
</tbody>
</table>

For any version that you’re considering, always check the availability of your cluster’s DB instance class. For example, db.1.14 isn’t supported for Aurora PostgreSQL 13. If your Aurora PostgreSQL DB cluster
Currently uses a db.r4 instance class, you need to move to db.r5 before trying to upgrade. For more information about DB instance classes, including which ones are Graviton2-based and which ones are Intel-based, see Aurora DB instance classes (p. 84).

**How to perform a major version upgrade**

Major version upgrades might contain database changes that are not backward-compatible with previous versions of the database. New functionality in a new version can cause your existing applications to stop working correctly. To avoid issues, Amazon Aurora doesn't apply major version upgrades automatically. Rather, we recommend that you carefully plan for a major version upgrade by following these steps:

1. Choose the major version that you want from the list of available targets from those listed for your version in the table. You can get a precise list of versions available in your AWS Region for your current version by using the AWS CLI. For details, see Getting a list of available versions in your AWS Region (p. 1784).

2. Verify that your applications work as expected on a trial deployment of the new version. For information about the complete process, see Testing an upgrade of your production DB cluster to a new major version (p. 1786).

3. After verifying that your applications work as expected on the trial deployment, you can upgrade your cluster. For details, see Upgrading the Aurora PostgreSQL engine to a new major version (p. 1790).

**Note**

You can perform a major version upgrade from Babelfish for Aurora PostgreSQL 13-based versions starting from 13.6 to Aurora PostgreSQL 14-based versions starting from 14.6. Babelfish for Aurora PostgreSQL 13.4 and 13.5 don't support major version upgrade.

You can get a list of engine versions available as major version upgrade targets for your Aurora PostgreSQL DB cluster by querying your AWS Region using the describe-db-engine-versions AWS CLI command, as follows.

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions
   --engine aurora-postgresql
   --engine-version version-number
   --query "DBEngineVersions[].ValidUpgradeTarget[?IsMajorVersionUpgrade == `true`].
   (EngineVersion:EngineVersion)"
   --output text
```

For Windows:

```bash
aws rds describe-db-engine-versions ^
   --engine aurora-postgresql ^
   --engine-version version-number ^
   --query "DBEngineVersions[].ValidUpgradeTarget[?IsMajorVersionUpgrade == `true`].
   (EngineVersion:EngineVersion)" ^
   --output text
```

In some cases, the version that you want to upgrade to isn't a target for your current version. In such cases, use the information in the versions table to perform minor version upgrades until your cluster is at a version that has your chosen target in its row of targets.

**Testing an upgrade of your production DB cluster to a new major version**

Each new major version includes enhancements to the query optimizer that are designed to improve performance. However, your workload might include queries that result in a worse performing plan in
the new version. That's why we recommend that you test and review performance before upgrading in
production. You can manage query plan stability across versions by using the Query Plan Management
(QPM) extension, as detailed in Ensuring plan stability after a major version upgrade (p. 1579).

Before upgrading your production Aurora PostgreSQL DB clusters to a new major version, we strongly
recommend that you test the upgrade to verify that all your applications work correctly:

1. Have a version-compatible parameter group ready.

If you are using a custom DB instance or DB cluster parameter group, you can choose from two
options:
   a. Specify the default DB instance, DB cluster parameter group, or both for the new DB engine
      version.
   b. Create your own custom parameter group for the new DB engine version.

If you associate a new DB instance or DB cluster parameter group as a part of the upgrade request,
make sure to reboot the database after the upgrade completes to apply the parameters. If a DB
instance needs to be rebooted to apply the parameter group changes, the instance's parameter group
status shows pending-reboot. You can view an instance's parameter group status in the console or
by using a CLI command such as describe-db-instances or describe-db-clusters.

2. Check for unsupported usage:
   - Commit or roll back all open prepared transactions before attempting an upgrade. You can use the
     following query to verify that there are no open prepared transactions on your instance.

   ```sql
   SELECT count(*) FROM pg_catalog.pg_prepared_xacts;
   ```

   - Remove all uses of the reg* data types before attempting an upgrade. Except for regtype and
     regclass, you can't upgrade the reg* data types. The pg_upgrade utility (used by Amazon Aurora
doing the upgrade) can't persist this data type. To learn more about this utility, see pg_upgrade in
the PostgreSQL documentation.

   To verify that there are no uses of unsupported reg* data types, use the following query for each
database.

   ```sql
   SELECT count(*) FROM pg_catalog.pg_class c, pg_catalog.pg_namespace n,
   pg_catalog.pg_attribute a
   WHERE c.oid = a.attrelid
   AND NOT a.attisdropped
   AND a.atttypid IN ('pg_catalog.regproc':pg_catalog.regtype,
   'pg_catalog.regprocedure':pg_catalog.regtype,
   'pg_catalog.regoper':pg_catalog.regtype,
   'pg_catalog.regoperator':pg_catalog.regtype,
   'pg_catalog.regconfig':pg_catalog.regtype,
   'pg_catalog.regdictionary':pg_catalog.regtype)
   AND c.relnamespace = n.oid
   AND n.nspname NOT IN ('pg_catalog', 'information_schema');
   ```

   - If you are upgrading an Aurora PostgreSQL version 10.18 or higher DB cluster that has the
   pgRouting extension installed, drop the extension before upgrading to version 12.4 or higher.

   If you are upgrading an Aurora PostgreSQL 10.x version that has the extension pg_repack version
1.4.3 installed, drop the extension before upgrading to any higher version.

3. Check for template1 and template0 databases.

For a successful upgrade, template 1 and template 0 databases must exist and should be listed as a
template. To check on this, use the following command:

```sql
SELECT datname, datistemplate FROM pg_database;
```
<table>
<thead>
<tr>
<th>datname</th>
<th>datistemplate</th>
</tr>
</thead>
<tbody>
<tr>
<td>template0</td>
<td>t</td>
</tr>
<tr>
<td>rdsadmin</td>
<td>f</td>
</tr>
<tr>
<td>template1</td>
<td>t</td>
</tr>
<tr>
<td>postgres</td>
<td>f</td>
</tr>
</tbody>
</table>

In the command output, the `datistemplate` value for template1 and template0 databases should be `t`.

4. Drop logical replication slots.

The upgrade process can't proceed if the Aurora PostgreSQL DB cluster is using any logical replication slots. Logical replication slots are typically used for short-term data migration tasks, such as migrating data using AWS DMS or for replicating tables from the database to data lakes, BI tools, or other targets. Before upgrading, make sure that you know the purpose of any logical replication slots that exist, and confirm that it's okay to delete them. You can check for logical replication slots using the following query:

```sql
SELECT * FROM pg_replication_slots;
```

If logical replication slots are still being used, you shouldn't delete them, and you can't proceed with the upgrade. However, if the logical replication slots aren't needed, you can delete them using the following SQL:

```sql
SELECT pg_drop_replication_slot(slot_name);
```

Logical replication scenarios that use the `pglogical` extension also need to have slots dropped from the publisher node for a successful major version upgrade on that node. However, you can restart the replication process from the subscriber node after the upgrade. For more information, see Reestablishing logical replication after a major upgrade (p. 1649).

5. Perform a backup.

   The upgrade process creates a DB cluster snapshot of your DB cluster during upgrading. If you also want to do a manual backup before the upgrade process, see Creating a DB cluster snapshot (p. 437) for more information.

6. Upgrade certain extensions to the latest available version before performing the major version upgrade. The extensions to update include the following:
   - `pgRouting`
   - `postgis_raster`
   - `postgis_tiger_geocoder`
   - `postgis_topology`
   - `address_standardizer`
   - `address_standardizer_data_us`

   Run the following command for each extension that's currently installed.

   ```sql
   ALTER EXTENSION PostgreSQL-extension UPDATE TO 'new-version';
   ```

   For more information, see Upgrading PostgreSQL extensions (p. 1798). To learn more about upgrading PostGIS, see Step 6: Upgrade the PostGIS extension (p. 1622).

7. If you're upgrading to version 11.x, drop the extensions that it doesn't support before performing the major version upgrade. The extensions to drop include:
8. Drop unknown data types, depending on your target version.

PostgreSQL version 10 doesn't support the unknown data type. If a version 9.6 database uses the unknown data type, an upgrade to version 10 shows an error message such as the following:

```
Database instance is in a state that cannot be upgraded: PreUpgrade checks failed:
The instance could not be upgraded because the 'unknown' data type is used in user
tables.
Please remove all usages of the 'unknown' data type and try again.
```

To find the unknown data type in your database so that you can remove such columns or change them to supported data types, use the following SQL code for each database.

```
SELECT n.nspname, c.relname, a.attname
 FROM pg_catalog.pg_class c,
    pg_catalog.pg_namespace n,
    pg_catalog.pg_attribute a
 WHERE c.oid = a.attrelid AND NOT a.attisdropped AND
 a.atttypid = 'pg_catalog.unknown'::pg_catalog.regtype AND
 c.relkind IN ('r', 'm', 'c') AND
 c.relnamespace = n.oid AND
 n.nspname !~ '^pg_temp_' AND
 n.nspname !~ '^pg_toast_temp_' AND n.nspname NOT IN ('pg_catalog',
   'information_schema');
```

We highly recommend testing a major version upgrade on a duplicate of your production database before trying the upgrade on your production database. You can monitor the execution plans on the duplicate test instance for any possible execution plan regressions and to evaluate its performance. To create a duplicate test instance, you can either restore your database from a recent snapshot or clone your database. For more information, see Restoring from a snapshot (p. 440) or Cloning a volume for an Amazon Aurora DB cluster (p. 303).

For more information, see Upgrading the Aurora PostgreSQL engine to a new major version (p. 1790).

10. Upgrade your production instance.

When your dry-run major version upgrade is successful, you should be able to upgrade your production database with confidence. For more information, see Upgrading the Aurora PostgreSQL engine to a new major version (p. 1790).

**Note**

During the upgrade process, Aurora PostgreSQL takes a DB cluster snapshot if the cluster's backup retention period is greater than 0. You can't do a point-in-time restore of your cluster during this process. Later, you can perform a point-in-time restore to times before the upgrade began and after the automatic snapshot of your instance has completed. However, you can't perform a point-in-time restore to a previous minor version.

For information about an upgrade in progress, you can use Amazon RDS to view two logs that the pg_upgrade utility produces. These are pg_upgrade_internal.log and pg_upgrade_server.log. Amazon Aurora appends a timestamp to the file name for these logs. You can view these logs as you can any other log. For more information, see Monitoring Amazon Aurora log files (p. 722).

11. Upgrade PostgreSQL extensions. The PostgreSQL upgrade process doesn't upgrade any PostgreSQL extensions. For more information, see Upgrading PostgreSQL extensions (p. 1798).
After you complete a major version upgrade, we recommend the following:

- Run the ANALYZE operation to refresh the pg_statistic table. You should do this for every database on all your PostgreSQL DB instances. Optimizer statistics aren't transferred during a major version upgrade, so you need to regenerate all statistics to avoid performance issues. Run the command without any parameters to generate statistics for all regular tables in the current database, as follows:

  ```sql
  ANALYZE VERBOSE;
  ```

  The VERBOSE flag is optional, but using it shows you the progress. For more information, see `ANALYZE` in the PostgreSQL documentation.

  **Note**
  Run ANALYZE on your system after the upgrade to avoid performance issues.

- If you upgraded to PostgreSQL version 10, run REINDEX on any hash indexes you have. Hash indexes were changed in version 10 and must be rebuilt. To locate invalid hash indexes, run the following SQL for each database that contains hash indexes.

  ```sql
  SELECT idx.indrelid::regclass AS table_name,
          idx.indexrelid::regclass AS index_name
  FROM pg_catalog.pg_index idx
  JOIN pg_catalog.pg_class cls ON cls.oid = idx.indexrelid
  JOIN pg_catalog.pg_am am ON am.oid = cls.relam
  WHERE am.amname = 'hash'
    AND NOT idx.indisvalid;
  ```

- We recommend that you test your application on the upgraded database with a similar workload to verify that everything works as expected. After the upgrade is verified, you can delete this test instance.

### Upgrading the Aurora PostgreSQL engine to a new major version

When you initiate the upgrade process to a new major version, Aurora PostgreSQL takes a snapshot of the Aurora DB cluster before it makes any changes to your cluster. This snapshot is created for major version upgrades only, not minor version upgrades. When the upgrade process completes, you can find this snapshot among the manual snapshots listed under **Snapshots** in the RDS console. The snapshot name includes `preupgrade` as its prefix, the name of your Aurora PostgreSQL DB cluster, the source version, the target version, and the date and timestamp, as shown in the following example.

```text
preupgrade-docs-lab-apg-global-db-12-8-to-13-6-2022-05-19-00-19
```

After the upgrade completes, you can use the snapshot that Aurora created and stored in your manual snapshot list to restore the DB cluster to its previous version, if necessary.

**Tip**
In general, snapshots provide many ways to restore your Aurora DB cluster to various points in time. To learn more, see [Restoring from a DB cluster snapshot](p. 439) and [Restoring a DB cluster to a specified time](p. 490). However, Aurora PostgreSQL doesn't support using a snapshot to restore to a previous minor version.

During the major version upgrade process, Aurora allocates a volume and clones the source Aurora PostgreSQL DB cluster. If the upgrade fails for any reason, Aurora PostgreSQL uses the clone to roll back the upgrade. After more than 15 clones of a source volume are allocated, subsequent clones become full copies and take longer. This can cause the upgrade process also to take longer. If Aurora PostgreSQL rolls back the upgrade, be aware of the following:
• You might see billing entries and metrics for both the original volume and the cloned volume allocated during the upgrade. Aurora PostgreSQL cleans up the extra volume after the cluster backup retention window is beyond the time of the upgrade.
• The next cross-Region snapshot copy from this cluster will be a full copy instead of an incremental copy.

To safely upgrade the DB instances that make up your cluster, Aurora PostgreSQL uses the pg_upgrade utility. After the writer upgrade completes, each reader instance experiences a brief outage while it's upgraded to the new major version. To learn more about this PostgreSQL utility, see `pg_upgrade` in the PostgreSQL documentation.

You can upgrade your Aurora PostgreSQL DB cluster to a new version by using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To upgrade the engine version of a DB cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB cluster that you want to upgrade.
4. For Engine version, choose the new version.
5. Choose Continue and check the summary of modifications.
6. To apply the changes immediately, choose Apply immediately. Choosing this option can cause an outage in some cases. For more information, see Modifying an Amazon Aurora DB cluster (p. 269).
7. On the confirmation page, review your changes. If they are correct, choose Modify Cluster to save your changes.

    Or choose Back to edit your changes or Cancel to cancel your changes.

**AWS CLI**

To upgrade the engine version of a DB cluster, use the `modify-db-cluster` AWS CLI command. Specify the following parameters:

- `--db-cluster-identifier` – The name of the DB cluster.
- `--engine-version` – The version number of the database engine to upgrade to. For information about valid engine versions, use the AWS CLI `describe-db-engine-versions` command.
- `--allow-major-version-upgrade` – A required flag when the `--engine-version` parameter is a different major version than the DB cluster's current major version.
- `--no-apply-immediately` – Apply changes during the next maintenance window. To apply changes immediately, use `--apply-immediately`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster \
  --db-cluster-identifier mydbcluster \
  --engine-version new_version \
  --allow-major-version-upgrade \
  --no-apply-immediately
```
For Windows:

```bash
aws rds modify-db-cluster
--db-cluster-identifier mydbcluster
--engine-version new_version
--allow-major-version-upgrade
--no-apply-immediately
```

**RDS API**

To upgrade the engine version of a DB cluster, use the [ModifyDBCluster](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/任务.修改数据库引擎版本.html) operation. Specify the following parameters:

- **DBClusterIdentifier** – The name of the DB cluster, for example `mydbcluster`.
- **EngineVersion** – The version number of the database engine to upgrade to. For information about valid engine versions, use the [DescribeDBEngineVersions](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/任务.显示数据库引擎版本.html) operation.
- **AllowMajorVersionUpgrade** – A required flag when the `EngineVersion` parameter is a different major version than the DB cluster's current major version.
- **ApplyImmediately** – Whether to apply changes immediately or during the next maintenance window. To apply changes immediately, set the value to `true`. To apply changes during the next maintenance window, set the value to `false`.

**Major upgrades for global databases**

For an Aurora global database cluster, the upgrade process upgrades all DB clusters that make up your Aurora global database at the same time. It does so to ensure that each runs the same Aurora PostgreSQL version. It also ensures that any changes to system tables, data file formats, and so on, are automatically replicated to all secondary clusters.

To upgrade a global database cluster to a new major version of Aurora PostgreSQL, we recommend that you test your applications on the upgraded version, as detailed in [Testing an upgrade of your production DB cluster to a new major version](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/任务.测试数据库升级.html) (p. 1786). Be sure to prepare your DB cluster parameter group and DB parameter group settings for each AWS Region in your Aurora global database before the upgrade as detailed in [step 1.](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/任务.测试数据库升级.html) of [Testing an upgrade of your production DB cluster to a new major version](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/任务.测试数据库升级.html) (p. 1786).

If your Aurora PostgreSQL global database cluster has a recovery point objective (RPO) set for its `rds.global_db_rpo` parameter, make sure to reset the parameter before upgrading. The major version upgrade process doesn't work if the RPO is turned on. By default, this parameter is turned off. For more information about Aurora PostgreSQL global databases and RPO, see [Managing RPOs for Aurora PostgreSQL–based global databases](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/任务.管理RPOs.html) (p. 1865).

If you verify that your applications can run as expected on the trial deployment of the new version, you can start the upgrade process. To do so, see [Upgrading the Aurora PostgreSQL engine to a new major version](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/任务.升级数据库版本.html) (p. 1790). Be sure to choose the top-level item from the Databases list in the RDS console, **Global database**, as shown in the following image.
As with any modification, you can confirm that you want the process to proceed when prompted.

Rather than using the console, you can start the upgrade process by using the AWS CLI or the RDS API. As with the console, you operate on the Aurora global database cluster rather than any of its constituents, as follows:
- Use the `modify-global-cluster` AWS CLI command to start the upgrade for your Aurora global database by using the AWS CLI.
- Use the `ModifyGlobalCluster` API to start the upgrade.

### How to perform minor version upgrades and apply patches

Minor version upgrades and patches become available in AWS Regions only after rigorous testing. Before releasing upgrades and patches, Aurora PostgreSQL tests to ensure that known security issues, bugs, and other issues that emerge after the release of the minor community version don't disrupt overall Aurora PostgreSQL fleet stability.

As Aurora PostgreSQL makes new minor versions available, the instances that make up your Aurora PostgreSQL DB cluster can be automatically upgraded during your specified maintenance window. For this to happen, your Aurora PostgreSQL DB cluster must have the **Enable auto minor version upgrade** option turned on. All DB instances that make up your Aurora PostgreSQL DB cluster must have the automatic minor version upgrade (AmVU) option turned on so that the minor upgrade to be applied throughout the cluster.

**Tip**

Make sure that the **Enable auto minor version upgrade** option is turned on for all PostgreSQL DB instances that make up your Aurora PostgreSQL DB cluster. This option must be turned on for every instance in the DB cluster to work. For information on how to set **Auto minor version upgrade**, and how the setting works when applied at the cluster and instance levels, see [Automatic minor version upgrades for Aurora DB clusters (p. 351)](#).

You can check the value of the **Enable auto minor version upgrade** option for all your Aurora PostgreSQL DB clusters by using the `describe-db-instances` AWS CLI command with the following query.

```bash
aws rds describe-db-instances \
  --query '{DBClusterIdentifier:DBClusterIdentifier,DBInstanceIdentifier:DBInstanceIdentifier,AutoMinorVersionUpgrade:AutoMinorVersionUpgrade}[]'.
```

This query returns a list of all Aurora DB clusters and their instances with a `true` or `false` value for the status of the AutoMinorVersionUpgrade setting. The command as shown assumes that you have your AWS CLI configured to target your default AWS Region.

For more information about the AmVU option and how to modify your Aurora DB cluster to use it, see [Automatic minor version upgrades for Aurora DB clusters (p. 351)](#).

You can upgrade your Aurora PostgreSQL DB clusters to new minor versions either by responding to maintenance tasks, or by modifying the cluster to use the new version.

You can identify any available upgrades or patches for your Aurora PostgreSQL DB clusters by using the RDS console and opening the **Recommendations** menu. There, you can find a list of various maintenance issues such as **Old minor versions**. Depending on your production environment, you can choose to **Schedule** the upgrade or take immediate action, by choosing **Apply now**, as shown following.
To learn more about how to maintain an Aurora DB cluster, including how to manually apply patches and minor version upgrades, see [Maintaining an Amazon Aurora DB cluster (p. 344)](#).

## Minor release upgrades and zero-downtime patching

Upgrading an Aurora PostgreSQL DB cluster involves the possibility of an outage. During the upgrade process, the database is shut down as it's being upgraded. If you start the upgrade while the database is busy, you lose all connections and transactions that the DB cluster is processing. If you wait until the database is idle to perform the upgrade, you might have to wait a long time.

The zero-downtime patching (ZDP) feature improves the upgrading process. With ZDP, both minor version upgrades and patches can be applied with minimal impact to your Aurora PostgreSQL DB cluster. ZDP is used when applying patches or newer minor version upgrades to Aurora PostgreSQL versions and other higher releases of these minor versions and newer major versions. That is, upgrading to new minor versions from any of these releases onward uses ZDP.

The following table shows the Aurora PostgreSQL versions and DB instance classes where ZDP is available:

<table>
<thead>
<tr>
<th>Version</th>
<th>db.r* instance classes</th>
<th>db.t* instance classes</th>
<th>db.x* instance classes</th>
<th>db.serverless instance class</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.21.0 and higher 10.21 versions</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>N/A</td>
</tr>
<tr>
<td>11.16.0 and higher 11.16 versions</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>N/A</td>
</tr>
<tr>
<td>11.17 and higher versions</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>N/A</td>

**Note**

ZDP isn't supported for Aurora PostgreSQL DB clusters that are configured as Aurora Serverless v1, or Aurora global databases. ZDP isn't supported during OS patches and OS upgrades.

ZDP works by preserving current client connections to your Aurora PostgreSQL DB cluster throughout the Aurora PostgreSQL upgrade process. However, in the following cases, connections will be dropped for ZDP to complete:

- Long running query or transactions are in progress.
- Data definition language (DDL) statements are running.
- Temporary tables or table locks are in use.
- All sessions are listening on notification channels.
- A cursor in 'WITH HOLD' status is in use.
- TLSv1.3 or TLSv1.1 connections are in use.

During the upgrade process using ZDP, the database engine looks for a quiet point to pause all new transactions. This action safeguards the database during patches and upgrades. To make sure that your applications run smoothly with paused transactions, we recommend integrating retry logic into your code. This approach ensures that the system can manage any brief downtime without failing and can retry the new transactions after the upgrade.

When ZDP completes successfully, application sessions are maintained except for those with dropped connections, and the database engine restarts while the upgrade is still in progress. Although the database engine restart can cause a temporary drop in throughput, this typically lasts only for a few seconds or at most, approximately one minute.

In some cases, zero-downtime patching (ZDP) might not succeed. For example, parameter changes that are in a pending state on your Aurora PostgreSQL DB cluster or its instances interfere with ZDP.

You can find metrics and events for ZDP operations in the Events page in the console. The events include the start of the ZDP upgrade and completion of the upgrade. In this event you can find how long the process took, and the numbers of preserved and dropped connections that occurred during the restart. You can find details in your database error log.

**Upgrading the Aurora PostgreSQL engine to a new minor version**

You can upgrade your Aurora PostgreSQL DB cluster to a new minor version by using the console, the AWS CLI, or the RDS API. Before performing the upgrade, we recommend that you follow the same best
practice that we recommend for major version upgrades. As with new major versions, new minor versions can also have optimizer improvements, such as fixes, that can cause query plan regressions. To ensure plan stability, we recommend that you use the Query Plan Management (QPM) extension as detailed in Ensuring plan stability after a major version upgrade (p. 1579).

Console

**To upgrade the engine version of your Aurora PostgreSQL DB cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB cluster that you want to upgrade.
4. For Engine version, choose the new version.
5. Choose Continue and check the summary of modifications.
6. To apply the changes immediately, choose Apply immediately. Choosing this option can cause an outage in some cases. For more information, see Modifying an Amazon Aurora DB cluster (p. 269).
7. On the confirmation page, review your changes. If they are correct, choose Modify Cluster to save your changes.
   Or choose Back to edit your changes or Cancel to cancel your changes.

AWS CLI

To upgrade the engine version of a DB cluster, use the `modify-db-cluster` AWS CLI command with the following parameters:

- `--db-cluster-identifier` – The name of your Aurora PostgreSQL DB cluster.
- `--engine-version` – The version number of the database engine to upgrade to. For information about valid engine versions, use the AWS CLI `describe-db-engine-versions` command.
- `--no-apply-immediately` – Apply changes during the next maintenance window. To apply changes immediately, use `--apply-immediately` instead.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster \\
   --db-cluster-identifier mydbcluster \\
   --engine-version new_version \\
   --no-apply-immediately
```

For Windows:

```bash
aws rds modify-db-cluster ^
   --db-cluster-identifier mydbcluster ^
   --engine-version new_version ^
   --no-apply-immediately
```

RDS API

To upgrade the engine version of a DB cluster, use the `ModifyDBCluster` operation. Specify the following parameters:

- `DBClusterIdentifier` – The name of the DB cluster, for example `mydbcluster`. 
• **EngineVersion** – The version number of the database engine to upgrade to. For information about valid engine versions, use the [DescribeDBEngineVersions](https://docs.aws.amazon.com/aurora/latest/userguide/Aurora-LTS-Engine.html) operation.

• **ApplyImmediately** – Whether to apply changes immediately or during the next maintenance window. To apply changes immediately, set the value to `true`. To apply changes during the next maintenance window, set the value to `false`.

## Upgrading PostgreSQL extensions

Upgrading your Aurora PostgreSQL DB cluster to a new major or minor version doesn't upgrade the PostgreSQL extensions at the same time. For most extensions, you upgrade the extension after the major or minor version upgrade completes. However, in some cases, you upgrade the extension before you upgrade the Aurora PostgreSQL DB engine. For more information, see the [list of extensions to update](https://docs.aws.amazon.com/aurora/latest/userguide/Aurora-LTS-Extensions.html) in Testing an upgrade of your production DB cluster to a new major version (p. 1786).

Installing PostgreSQL extensions requires `rds_superuser` privileges. Typically, an `rds_superuser` delegates permissions over specific extensions to relevant users (roles), to facilitate the management of a given extension. That means that the task of upgrading all the extensions in your Aurora PostgreSQL DB cluster might involve many different users (roles). Keep this in mind especially if you want to automate the upgrade process by using scripts. For more information about PostgreSQL privileges and roles, see Security with Amazon Aurora PostgreSQL (p. 1233).

**Note**

For information about updating the PostGIS extension, see Managing spatial data with the PostGIS extension (p. 1618) (Step 6: Upgrade the PostGIS extension (p. 1622)).

To update the `pg_repack` extension, drop the extension and then create the new version in the upgraded DB instance. For more information, see pg_repack installation in the pg_repack documentation.

To update an extension after an engine upgrade, use the `ALTER EXTENSION UPDATE` command.

```
ALTER EXTENSION extension_name UPDATE TO 'new_version';
```

To list your currently installed extensions, use the PostgreSQL `pg_extension` catalog in the following command.

```
SELECT * FROM pg_extension;
```

To view a list of the specific extension versions that are available for your installation, use the PostgreSQL `pg_available_extension_versions` view in the following command.

```
SELECT * FROM pg_available_extension_versions;
```

## Alternative blue/green upgrade technique

In some situations, your top priority is to perform an immediate switchover from the old cluster to an upgraded one. In such situations, you can use a multistep process that runs the old and new clusters side-by-side. Here, you replicate data from the old cluster to the new one until you are ready for the new cluster to take over. For details, see Using Blue/Green Deployments for database updates (p. 399).

## Aurora PostgreSQL long-term support (LTS) releases

Each new Aurora PostgreSQL version remains available for a certain amount of time for you to use when you create or upgrade a DB cluster. After this period, you must upgrade any clusters that use
that version. You can manually upgrade your cluster before the support period ends, or Aurora can automatically upgrade it for you when its Aurora PostgreSQL version is no longer supported.

Aurora designates certain Aurora PostgreSQL versions as long-term support (LTS) releases. Database clusters that use LTS releases can stay on the same version longer and undergo fewer upgrade cycles than clusters that use non-LTS releases. LTS minor versions include only bug fixes (through patch versions); an LTS version doesn't include new features released after its introduction.

Once a year, DB clusters running on an LTS minor version are patched to the latest patch version of the LTS release. We do this patching to help ensure that you benefit from cumulative security and stability fixes. We might patch an LTS minor version more frequently if there are critical fixes, such as for security, that need to be applied.

**Note**
To remain on an LTS minor version for the duration of its lifecycle, make sure to turn off Auto minor version upgrade for your DB instances. To avoid automatically upgrading your DB cluster from the LTS minor version, set Auto minor version upgrade to No on all DB instances in your Aurora cluster.

We recommend that you upgrade to the latest release, instead of using the LTS release, for most of your Aurora PostgreSQL clusters. Doing so takes advantage of Aurora as a managed service and gives you access to the latest features and bug fixes. LTS releases are intended for clusters with the following characteristics:

- You can't afford downtime on your Aurora PostgreSQL application for upgrades outside of rare occurrences for critical patches.
- The testing cycle for the cluster and associated applications takes a long time for each update to the Aurora PostgreSQL database engine.
- The database version for your Aurora PostgreSQL cluster has all the DB engine features and bug fixes that your application needs.

The current LTS releases for Aurora PostgreSQL are as follows:

- PostgreSQL 14.6. It was released on January 20, 2023. For more information, see [PostgreSQL 14.6](https://aws.amazon.com/about-aws/documents/release-notes-for-aurora-postgresql/) in the Release Notes for Aurora PostgreSQL.
- PostgreSQL 13.9. It was released on January 20, 2023. For more information, see [PostgreSQL 13.9](https://aws.amazon.com/about-aws/documents/release-notes-for-aurora-postgresql/) in the Release Notes for Aurora PostgreSQL.
- PostgreSQL 12.9. It was released on February 25, 2022. For more information, see [PostgreSQL 12.9](https://aws.amazon.com/about-aws/documents/release-notes-for-aurora-postgresql/) in the Release Notes for Aurora PostgreSQL.
- PostgreSQL 11.9 (Aurora PostgreSQL release 3.4). It was released on December 11, 2020. For more information about this version, see [PostgreSQL 11.9, Aurora PostgreSQL release 3.4](https://aws.amazon.com/about-aws/documents/release-notes-for-aurora-postgresql/) in the Release Notes for Aurora PostgreSQL.

For information about how to identify Aurora and database engine versions, see [Identifying versions of Amazon Aurora PostgreSQL](https://docs.aws.amazon.com/aurora/latest/userguide/Aurora-PostgreSQL-Identifying-Versions.html).
Using Amazon Aurora global databases

Amazon Aurora global databases span multiple AWS Regions, enabling low latency global reads and providing fast recovery from the rare outage that might affect an entire AWS Region. An Aurora global database has a primary DB cluster in one Region, and up to five secondary DB clusters in different Regions.

Topics

• Overview of Amazon Aurora global databases (p. 1800)
• Advantages of Amazon Aurora global databases (p. 1801)
• Region and version availability (p. 1802)

• Getting started with Amazon Aurora global databases (p. 1804)
• Managing an Amazon Aurora global database (p. 1824)
• Connecting to an Amazon Aurora global database (p. 1830)
• Using write forwarding in an Amazon Aurora global database (p. 1831)
• Using switchover or failover in an Amazon Aurora global database (p. 1854)
• Monitoring an Amazon Aurora global database (p. 1869)
• Using Amazon Aurora global databases with other AWS services (p. 1875)
• Upgrading an Amazon Aurora global database (p. 1876)

Overview of Amazon Aurora global databases

By using an Amazon Aurora global database, you can run your globally distributed applications using a single Aurora database that spans multiple AWS Regions.

An Aurora global database consists of one primary AWS Region where your data is written, and up to five read-only secondary AWS Regions. You issue write operations directly to the primary DB cluster in the primary AWS Region. Aurora replicates data to the secondary AWS Regions using dedicated infrastructure, with latency typically under a second.

In the following diagram, you can find an example Aurora global database that spans two AWS Regions.
Advantages of Amazon Aurora global databases

You can scale up each secondary cluster independently, by adding one or more Aurora Replicas (read-only Aurora DB instances) to serve read-only workloads.

Only the primary cluster performs write operations. Clients that perform write operations connect to the DB cluster endpoint of the primary DB cluster. As shown in the diagram, Aurora global database uses the cluster storage volume and not the database engine for replication. To learn more, see Overview of Amazon Aurora storage (p. 97).

Aurora global databases are designed for applications with a worldwide footprint. The read-only secondary DB clusters (AWS Regions) allow you to support read operations closer to application users. By using the write forwarding feature, you can also configure an Aurora global database so that secondary clusters send data to the primary. For more information, see Using write forwarding in an Amazon Aurora global database (p. 1831).

An Aurora global database supports two different operations for changing the Region of your primary DB cluster, depending on the scenario: global database switchover and global database failover.

- For planned operational procedures such as Regional rotation, use global database switchover (previously called “managed planned failover”). With this feature, you can relocate the primary cluster of a healthy Aurora global database to one of its secondary Regions with no data loss. To learn more, see Performing switchovers for Amazon Aurora global databases (p. 1861).
- To recover your Aurora global database after an outage in the primary Region, use global database failover. With this feature, you fail over your primary DB cluster to another Region (cross-Region failover). To learn more, see Performing managed failovers for Aurora global databases (p. 1855).

Advantages of Amazon Aurora global databases

By using Aurora global databases, you can get the following advantages:

- **Global reads with local latency** – If you have offices around the world, you can use an Aurora global database to keep your main sources of information updated in the primary AWS Region. Offices in your other Regions can access the information in their own Region, with local latency.

- **Scalable secondary Aurora DB clusters** – You can scale your secondary clusters by adding more read-only instances (Aurora Replicas) to a secondary AWS Region. The secondary cluster is read-only, so it can support up to 16 read-only Aurora Replica instances rather than the usual limit of 15 for a single Aurora cluster.

- **Fast replication from primary to secondary Aurora DB clusters** – The replication performed by an Aurora global database has little performance impact on the primary DB cluster. The resources of the DB instances are fully devoted to serve application read and write workloads.
• **Recovery from Region-wide outages** – The secondary clusters allow you to make an Aurora global database available in a new primary AWS Region more quickly (lower RTO) and with less data loss (lower RPO) than traditional replication solutions.

### Region and version availability

Feature availability and support vary across specific versions of each Aurora database engine, and across AWS Regions. For more information on version and Region availability with Aurora and global databases, see [Aurora global databases](#) (p. 32).

### Limitations of Amazon Aurora global databases

The following limitations currently apply to Aurora global databases:

- Aurora global databases are available in certain AWS Regions and for specific Aurora MySQL and Aurora PostgreSQL versions only. For more information, see [Aurora global databases](#) (p. 32).
- Aurora global databases have specific configuration requirements for supported Aurora DB instance classes, maximum number of AWS Regions, and so on. For more information, see [Configuration requirements of an Amazon Aurora global database](#) (p. 1804).
- Aurora global database switchovers require one of the following Aurora database engines:
  - Aurora MySQL with MySQL 8.0 compatibility, version 3.01.0 and higher
  - Aurora MySQL with MySQL 5.7 compatibility, version 2.09.1 and higher
  - Aurora PostgreSQL versions 13.3 and higher, 12.4 and higher, and 11.9 and higher
- You can only perform a managed cross-Region switchovers or failovers on an Aurora global database if the primary and secondary DB clusters have the same major, minor, and patch level engine versions. However, the patch levels can be different if the minor engine versions are one of the following.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Minor engine versions</th>
</tr>
</thead>
</table>
| Aurora PostgreSQL | • Version 14.5 or higher minor version  
                      • Version 13.8 or higher minor version  
                      • Version 12.12 or higher minor version  
                      • Version 11.17 or higher minor version |

For more information, see [Patch level compatibility for managed cross-Region switchovers and failovers](#) (p. 1877).

- Aurora global databases currently don't support the following Aurora features:
  - Aurora Serverless v1
  - Backtracking in Aurora
- For limitations with using the RDS Proxy feature with global databases, see [Limitations for RDS Proxy with global databases](#) (p. 1936).
- Automatic minor version upgrade doesn't apply to Aurora MySQL and Aurora PostgreSQL clusters that are part of an Aurora global database. Note that you can specify this setting for a DB instance that is part of a global database cluster, but the setting has no effect.
- Aurora global databases currently don't support Aurora Auto Scaling for secondary DB clusters.
- You can start database activity streams on Aurora global databases running the following Aurora MySQL and Aurora PostgreSQL versions only.
Limitations of Aurora global databases

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Primary AWS Region</th>
<th>Secondary AWS Regions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL 5.7</td>
<td>version 2.08 and higher</td>
<td>version 2.08 and higher</td>
</tr>
<tr>
<td>Aurora PostgreSQL</td>
<td>version 13.3 and higher</td>
<td>version 13.3 and higher</td>
</tr>
<tr>
<td></td>
<td>version 12.4 and higher</td>
<td>version 12.4 and higher</td>
</tr>
<tr>
<td></td>
<td>version 11.7 and higher</td>
<td>version 11.9 and higher</td>
</tr>
<tr>
<td></td>
<td>version 10.11 and higher</td>
<td>version 10.14 and higher</td>
</tr>
</tbody>
</table>

For information about database activity streams, see Monitoring Amazon Aurora with Database Activity Streams (p. 746).

• The following limitations currently apply to upgrading Aurora global databases:
  • You can't apply a custom parameter group to the global database cluster while you're performing a major version upgrade of that Aurora global database. You create your custom parameter groups in each Region of the global cluster and you apply them manually to the Regional clusters after the upgrade.
  • With an Aurora global database based on Aurora MySQL, you can't perform an in-place upgrade from Aurora MySQL version 2 to version 3 if the lower_case_table_names parameter is turned on. For more information on the methods that you can use, see Major version upgrades (p. 1876).
  • With an Aurora global database based on Aurora PostgreSQL, you can't perform a major version upgrade of the Aurora DB engine if the recovery point objective (RPO) feature is turned on. For information about the RPO feature, see Managing RPOs for Aurora PostgreSQL–based global databases (p. 1865).
  • With an Aurora global database based on Aurora MySQL, you can't perform a minor version upgrade from version 3.01 or 3.02 to 3.03 or higher by using the standard process. For details about the process to use, see Upgrading Aurora MySQL by modifying the engine version (p. 1209).

For information about upgrading an Aurora global database, see Upgrading an Amazon Aurora global database (p. 1876).

• You can't stop or start the Aurora DB clusters in your Aurora global database individually. To learn more, see Stopping and starting an Amazon Aurora DB cluster (p. 249).

• Aurora Replicas attached to the secondary Aurora DB cluster can restart under certain circumstances. If the primary AWS Region's writer DB instance restarts or fails over, Aurora Replicas in secondary Regions also restart. The secondary cluster is then unavailable until all replicas are back in sync with the primary DB cluster's writer instance. The behavior of the primary cluster when rebooting or failing over is the same as for a singular, nonglobal DB cluster. For more information, see Replication with Amazon Aurora (p. 104).

Be sure that you understand the impacts to your Aurora global database before making changes to your primary DB cluster. To learn more, see Recovering an Amazon Aurora global database from an unplanned outage (p. 1855).

• Aurora global databases currently don't support the inaccessible-encryption-credentials-recoverable status when Amazon Aurora loses access to the AWS KMS key for the DB cluster. In these cases, the encrypted DB cluster goes directly into the terminal inaccessible-encryption-credentials state. For more information about these states, see Viewing DB cluster status (p. 520).

• Aurora PostgreSQL–based DB clusters running in an Aurora global database have the following limitations:
  • Cluster cache management isn't supported for Aurora PostgreSQL DB clusters that are part of Aurora global databases.
• If the primary DB cluster of your Aurora global database is based on a replica of an Amazon RDS PostgreSQL instance, you can't create a secondary cluster. Don't attempt to create a secondary from that cluster using the AWS Management Console, the AWS CLI, or the CreateDBCluster API operation. Attempts to do so time out, and the secondary cluster isn't created.

We recommend that you create secondary DB clusters for your Aurora global databases by using the same version of the Aurora DB engine as the primary. For more information, see Creating an Amazon Aurora global database (p. 1805).

Getting started with Amazon Aurora global databases

To get started with Aurora global databases, first decide which Aurora DB engine you want to use and in which AWS Regions. Only specific versions of the Aurora MySQL and Aurora PostgreSQL database engines in certain AWS Regions support Aurora global databases. For the complete list, see Aurora global databases (p. 32).

You can create an Aurora global database in one of the following ways:

• **Create a new Aurora global database with new Aurora DB clusters and Aurora DB instances** – You can do this by following the steps in Creating an Amazon Aurora global database (p. 1805). After you create the primary Aurora DB cluster, you then add the secondary AWS Region by following the steps in Adding an AWS Region to an Amazon Aurora global database (p. 1817).

• **Use an existing Aurora DB cluster that supports the Aurora global database feature and add an AWS Region to it** – You can do this only if your existing Aurora DB cluster uses a DB engine version that supports the Aurora global mode or is global-compatible. For some DB engine versions, this mode is explicit, but for others, it's not.

Check whether you can choose Add region for Action on the AWS Management Console when your Aurora DB cluster is selected. If you can, you can use that Aurora DB cluster for your Aurora global cluster. For more information, see Adding an AWS Region to an Amazon Aurora global database (p. 1817).

Before creating an Aurora global database, we recommend that you understand all configuration requirements.

**Topics**

- Configuration requirements of an Amazon Aurora global database (p. 1804)
- Creating an Amazon Aurora global database (p. 1805)
- Adding an AWS Region to an Amazon Aurora global database (p. 1817)
- Creating a headless Aurora DB cluster in a secondary Region (p. 1821)
- Using a snapshot for your Amazon Aurora global database (p. 1823)

**Configuration requirements of an Amazon Aurora global database**

An Aurora global database spans at least two AWS Regions. The primary AWS Region supports an Aurora DB cluster that has one writer Aurora DB instance. A secondary AWS Region runs a read-only Aurora
Creating an Aurora global database
