Amazon Aurora
User Guide for Aurora
Table of Contents

What is Aurora? .................................................................................................................. 1
Amazon RDS shared responsibility model ........................................................................ 1
How Amazon Aurora works with Amazon RDS ................................................................. 2
Aurora DB clusters .................................................................................................................. 3
Aurora versions ........................................................................................................................ 4
  Relational databases that are available on Aurora ............................................................ 4
  Differences in version numbers between community databases and Aurora ................... 4
Amazon Aurora major versions ............................................................................................. 5
Amazon Aurora minor versions ............................................................................................. 11
Amazon Aurora patch versions ............................................................................................. 11
Learning what's new in each Amazon Aurora version ....................................................... 11
Specifying the Amazon Aurora database version for your database cluster .................... 12
Default Amazon Aurora versions ......................................................................................... 12
Automatic minor version upgrades ...................................................................................... 12
How long Amazon Aurora major versions remain available ............................................. 12
How often Amazon Aurora minor versions are released ................................................... 13
How long Amazon Aurora minor versions remain available ............................................. 13
Long-term support for selected Amazon Aurora minor versions ..................................... 13
Amazon RDS Extended Support for selected Aurora versions ......................................... 14
Manually controlling if and when your database cluster is upgraded to new versions .......... 14
Required Amazon Aurora upgrades .................................................................................... 14
Testing your DB cluster with a new Aurora version before upgrading ............................... 14
Regions and Availability Zones ........................................................................................... 16
  AWS Regions ...................................................................................................................... 16
  Availability Zones ............................................................................................................. 21
  Local time zone for DB clusters ......................................................................................... 21
Supported Aurora features by Region and engine ............................................................... 26
  Table conventions ............................................................................................................. 26
  Blue/Green Deployments ................................................................................................... 27
  Aurora cluster configurations ............................................................................................ 27
  Database activity streams in Aurora .................................................................................. 27
  Exporting cluster data to Amazon S3 ................................................................................ 31
  Exporting snapshot data to Amazon S3 ............................................................................. 32
  Aurora global databases ..................................................................................................... 32
  IAM database authentication in Aurora ............................................................................. 36
  Kerberos authentication with Aurora ................................................................................ 37
  Aurora machine learning .................................................................................................... 40
  Performance Insights with Aurora ..................................................................................... 43
  Zero-ETL integrations ........................................................................................................ 48
Amazon RDS Proxy .............................................................................................................. 49
  Secrets Manager integration .............................................................................................. 53
  Aurora Serverless v2 ......................................................................................................... 53
  Aurora Serverless v1 ......................................................................................................... 56
  Data API for Aurora Serverless v1 .................................................................................... 59
  Zero-downtime patching (ZDP) ........................................................................................ 61
Engine-native features .......................................................................................................... 61
Aurora connection management .......................................................................................... 62
  Types of Aurora endpoints ................................................................................................ 63
  Viewing endpoints .............................................................................................................. 64
  Using the cluster endpoint ................................................................................................. 65
  Using the reader endpoint ................................................................................................. 65
  Using custom endpoints ..................................................................................................... 65
  Creating a custom endpoint ............................................................................................... 68
  Viewing custom endpoints ................................................................................................. 70
Amazon Aurora User Guide for Aurora

Editing a custom endpoint ................................................................. 75
Deleting a custom endpoint .................................................................. 77
End-to-end AWS CLI example for custom endpoints .............................. 78
Using the instance endpoints ............................................................... 82
Endpoints and high availability ............................................................ 82
DB instance classes ............................................................................. 84
   DB instance class types .................................................................... 84
   Supported DB engines ..................................................................... 86
   Determining DB instance class support in AWS Regions .................. 91
   Hardware specifications ................................................................... 94
Aurora storage and reliability ............................................................. 97
   Overview of Aurora storage ........................................................... 97
   Cluster volume contents ................................................................... 97
   Aurora cluster storage configurations .......................................... 97
   How storage resizes ....................................................................... 98
   Data billing ..................................................................................... 99
   Reliability ....................................................................................... 99
Aurora security .................................................................................... 101
   Using SSL with Aurora DB clusters ............................................. 102
High availability for Amazon Aurora .................................................. 102
   High availability for Aurora data .................................................. 102
   High availability for Aurora DB instances .................................... 102
   High availability across AWS Regions with Aurora global databases ............................................................................. 103
   Fault tolerance .............................................................................. 103
   High availability with Amazon RDS Proxy .................................... 104
Replication with Aurora ....................................................................... 104
   Aurora Replicas ........................................................................... 104
   Aurora MySQL .............................................................................. 106
   Aurora PostgreSQL ......................................................................... 106
DB instance billing for Aurora ............................................................. 106
   On-Demand DB instances ............................................................ 108
   Reserved DB instances .................................................................. 109
Setting up your environment ............................................................... 119
   Sign up for an AWS account ......................................................... 119
   Create an administrative user ....................................................... 119
   Grant programmatic access ........................................................... 120
   Determine requirements ............................................................... 121
   Provide access to the DB cluster ................................................. 122
Getting started .................................................................................... 124
   Creating and connecting to an Aurora MySQL DB cluster ............ 124
      Prerequisites .............................................................................. 125
      Step 1: Create an EC2 instance .................................................. 125
      Step 2: Create an Aurora MySQL DB cluster ............................. 129
      Step 3: Connect to an Aurora MySQL DB cluster ...................... 134
      Step 4: Delete the EC2 instance and DB cluster ....................... 136
      (Optional) Connect your DB cluster to a Lambda function .......... 137
   Creating and connecting to an Aurora PostgreSQL DB cluster ......... 137
      Prerequisites .............................................................................. 138
      Step 1: Create an EC2 instance .................................................. 138
      Step 2: Create an Aurora PostgreSQL DB cluster ...................... 142
      Step 3: Connect to an Aurora PostgreSQL DB cluster ............... 147
      Step 4: Delete the EC2 instance and DB cluster ....................... 149
      (Optional) Connect your DB cluster to a Lambda function .......... 150
   Tutorial: Create a web server and an Amazon Aurora DB cluster ..... 151
      Launch an EC2 instance ............................................................. 152
      Create a DB cluster ................................................................... 157
      Install a web server .................................................................... 164
# Tutorials and sample code

Tutorials in this guide ................................................................. 173
Tutorials in other AWS guides .................................................. 173
AWS workshop and lab content portal for Amazon Aurora PostgreSQL .................................................. 174
AWS workshop and lab content portal for Amazon Aurora MySQL .................................................. 175
Tutorials and sample code in GitHub ........................................... 176
Working with AWS SDKs .............................................................. 176

# Configuring your Aurora DB cluster

Creating a DB cluster ................................................................... 178
Prerequisites .............................................................................. 179
Creating a DB cluster .................................................................. 183
Available settings ..................................................................... 190
Settings that don't apply to Aurora for DB clusters .................. 200
Settings that don't apply to Aurora DB instances ..................... 201

Creating resources with AWS CloudFormation ................. 203
Aurora and AWS CloudFormation templates ......................... 203
Learn more about AWS CloudFormation ................................. 203

Connecting to a DB cluster ......................................................... 204
Connecting to Aurora MySQL .................................................... 204
Connecting to Aurora PostgreSQL ............................................. 209
Troubleshooting connections ..................................................... 211

Working with parameter groups ................................................. 212
Overview of parameter groups .................................................. 212
Working with DB cluster parameter groups ......................... 214
Working with DB parameter groups ........................................... 226
Comparing parameter groups .................................................... 236
Specifying DB parameters ......................................................... 237

Migrating data to a DB cluster ..................................................... 241
Aurora MySQL ........................................................................ 241
Aurora PostgreSQL ................................................................. 241

Creating an ElastiCache cluster from Amazon RDS .............. 242
Overview of ElastiCache cluster creation with Aurora DB cluster settings .................................................. 242
Creating an ElastiCache cluster with settings from a new Aurora DB cluster ........................................ 243
Creating an ElastiCache cluster with settings from an existing Aurora DB cluster ................................. 245

Managing an Aurora DB cluster ............................................... 248
Stopping and starting a cluster ................................................... 249
Overview of stopping and starting a cluster ......................... 249
Limitations ............................................................................... 249
Stopping a DB cluster ............................................................... 250
While a DB cluster is stopped .................................................. 251
Starting a DB cluster ................................................................. 251

Connecting an AWS compute resource ................................. 253
Connecting an EC2 instance ..................................................... 253
Connecting a Lambda function ................................................ 260

Modifying an Aurora DB cluster ................................................. 269
Modifying the DB cluster by using the console, CLI, and API .................................................. 269
Modifying a DB instance in a DB cluster ................................. 270
Available settings ..................................................................... 272
Settings that don't apply to Aurora DB clusters .................. 291
Settings that don't apply to Aurora DB instances ................ 292

Adding Aurora Replicas ............................................................. 293
Managing performance and scaling ........................................... 297
Storage scaling ........................................................................ 297
Instance scaling ...................................................................... 301
Read scaling ............................................................................ 301
Managing connections ............................................................ 301
Managing query execution plans .............................................. 302
Cloning a volume for an Aurora DB cluster ............................................................... 303
Overview of Aurora cloning ....................................................................................... 303
Limitations of Aurora cloning .................................................................................. 304
How Aurora cloning works ....................................................................................... 304
Creating an Aurora clone ......................................................................................... 307
Cross-account cloning ............................................................................................... 316
Integrating with AWS services .................................................................................. 327
Aurora MySQL ........................................................................................................... 327
Aurora PostgreSQL .................................................................................................... 327
Using Auto Scaling with Aurora Replicas ................................................................. 328
Using machine learning with Aurora ....................................................................... 343
Maintaining an Aurora DB cluster ............................................................................. 344
Viewing pending maintenance .................................................................................. 344
Applying updates ....................................................................................................... 347
The maintenance window ......................................................................................... 348
Adjusting the maintenance window for a DB cluster .............................................. 350
Automatic minor version upgrades for Aurora DB clusters ..................................... 351
Choosing the frequency of Aurora MySQL maintenance updates ......................... 354
Working with operating system updates .................................................................. 354
Rebooting an Aurora DB cluster or instance ............................................................. 358
Rebooting a DB instance within an Aurora cluster .................................................... 358
Rebooting an Aurora cluster with read availability ................................................... 359
Rebooting an Aurora cluster without read availability .............................................. 360
Checking uptime for Aurora clusters and instances ............................................... 361
Examples of Aurora reboot operations ..................................................................... 363
Deleting Aurora clusters and instances .................................................................... 374
Deleting an Aurora DB cluster .................................................................................. 374
Deletion protection for Aurora clusters .................................................................... 379
Deleting a stopped Aurora cluster .......................................................................... 379
Deleting Aurora MySQL clusters that are read replicas ......................................... 379
The final snapshot when deleting a cluster ............................................................... 379
Deleting a DB instance from an Aurora DB cluster .................................................. 380
Tagging RDS resources ............................................................................................. 382
Overview .................................................................................................................... 382
Using tags for access control with IAM ................................................................. 383
Using tags to produce detailed billing reports ......................................................... 383
Adding, listing, and removing tags .......................................................................... 384
Using the AWS Tag Editor ...................................................................................... 386
Copying tags to DB cluster snapshots ...................................................................... 386
Tutorial: Use tags to specify which Aurora DB clusters to stop ............................. 387
Working with ARNs ................................................................................................... 390
Constructing an ARN ............................................................................................... 390
Getting an existing ARN ........................................................................................... 394
Aurora updates ......................................................................................................... 397
Identifying your Amazon Aurora version .................................................................. 397
Using Extended Support .......................................................................................... 398
Using Blue/Green Deployments for database updates .............................................. 399
Overview of Amazon RDS Blue/Green Deployments .............................................. 400
Benefits ...................................................................................................................... 400
Workflow .................................................................................................................... 401
Authorizing access ..................................................................................................... 405
Considerations .......................................................................................................... 406
Best practices ............................................................................................................ 407
Region and version availability ................................................................................. 408
Limitations ................................................................................................................ 408
Creating a blue/green deployment ............................................................................ 410
Preparing for a blue/green deployment .................................................................... 411
Exporting DB cluster snapshot data to Amazon S3 ................................................................. 471
Limitations .......................................................................................................................... 471
Overview of exporting snapshot data .................................................................................. 472
Setting up access to an S3 bucket ....................................................................................... 473
Exporting a snapshot to an S3 bucket .................................................................................. 476
Export performance in Aurora MySQL .................................................................................. 479
Monitoring snapshot exports .............................................................................................. 479
Canceling a snapshot export ............................................................................................... 480
Failure messages ................................................................................................................ 481
Troubleshooting PostgreSQL permissions errors ............................................................... 482
File naming convention ...................................................................................................... 483
Data conversion ................................................................................................................... 484
Point-in-time recovery ......................................................................................................... 490
Point-in-time recovery from a retained automated backup .................................................. 492
Point-in-time recovery using AWS Backup ......................................................................... 494
Deleting a DB cluster snapshot ............................................................................................ 499
Deleting a DB cluster snapshot ............................................................................................ 499
Tutorial: Restore a DB cluster from a snapshot ................................................................. 501
Restoring a DB cluster using the console ............................................................................ 501
Restoring a DB cluster using the AWS CLI ......................................................................... 504
Monitoring metrics in an Aurora DB cluster ...................................................................... 509
Overview of monitoring ....................................................................................................... 510
Monitoring plan .................................................................................................................... 510
Performance baseline ........................................................................................................ 510
Performance guidelines ....................................................................................................... 510
Monitoring tools ................................................................................................................ 511
Viewing cluster status and recommendations .................................................................. 514
Viewing a DB cluster ........................................................................................................... 515
Viewing DB cluster status .................................................................................................... 520
Viewing DB instance status in an Aurora cluster ............................................................... 523
Viewing Amazon Aurora recommendations ...................................................................... 527
Viewing metrics in the Amazon RDS console ................................................................... 535
Viewing combined metrics in the Amazon RDS console ..................................................... 538
Choosing the new monitoring view in the Monitoring tab ................................................ 538
Choosing the new monitoring view with Performance Insights in the navigation pane .......... 539
Choosing the legacy view with Performance Insights in the navigation pane .................... 540
Creating a custom dashboard with Performance Insights in the navigation pane ............... 541
Choosing the preconfigured dashboard with Performance Insights in the navigation pane ... 544
Monitoring Aurora with CloudWatch .................................................................................. 545
Overview of Amazon Aurora and Amazon CloudWatch ..................................................... 546
Viewing CloudWatch metrics ............................................................................................. 547
Exporting Performance Insights metrics to CloudWatch ..................................................... 552
Creating CloudWatch alarms ............................................................................................. 558
Monitoring DB load with Performance Insights ................................................................. 559
Overview of Performance Insights ...................................................................................... 559
Turning Performance Insights on and off .......................................................................... 565
Turning on the Performance Schema for Aurora MySQL .................................................... 568
Performance Insights policies ............................................................................................. 571
Analyzing metrics with the Performance Insights dashboard ............................................. 576
Retrieving metrics with the Performance Insights API ....................................................... 602
Logging Performance Insights calls using AWS CloudTrail .............................................. 619
Analyzing performance with DevOps Guru for RDS ........................................................ 622
Benefits of DevOps Guru for RDS ...................................................................................... 622
How DevOps Guru for RDS works ..................................................................................... 623
Setting up DevOps Guru for RDS ....................................................................................... 624
Monitoring threats with GuardDuty RDS Protection .......................................................... 630
Monitoring the OS with Enhanced Monitoring ................................................................. 631
Overview of Enhanced Monitoring ................................................................. 631
Setting up and enabling Enhanced Monitoring ........................................... 632
Viewing OS metrics in the RDS console ....................................................... 636
Viewing OS metrics using CloudWatch Logs ............................................... 637
Aurora metrics reference .............................................................................. 638
CloudWatch metrics for Aurora ................................................................. 638
CloudWatch dimensions for Aurora ............................................................. 654
Availability of Aurora metrics in the Amazon RDS console ......................... 654
CloudWatch metrics for Performance Insights ............................................. 657
Counter metrics for Performance Insights ................................................... 658
SQL statistics for Performance Insights ....................................................... 671
OS metrics in Enhanced Monitoring ......................................................... 675
Monitoring events, logs, and database activity streams ................................. 680
Viewing logs, events, and streams in the Amazon RDS console ................... 680
Monitoring Aurora events ........................................................................... 685
Overview of events for Aurora ................................................................. 685
Viewing Amazon RDS events ..................................................................... 687
Working with Amazon RDS event notification ......................................... 690
Creating a rule that triggers on an Amazon Aurora event ............................ 706
Amazon RDS event categories and event messages ..................................... 709
Monitoring Aurora logs ............................................................................. 722
Viewing and listing database log files ......................................................... 722
Downloading a database log file ................................................................. 723
Watching a database log file ....................................................................... 724
Publishing to CloudWatch Logs ................................................................. 726
Reading log file contents using REST ........................................................ 727
MySQL database log files ......................................................................... 729
PostgreSQL database log files .................................................................... 735
Monitoring Aurora API calls in CloudTrail ................................................ 742
CloudTrail integration with Amazon Aurora ............................................. 742
Amazon Aurora log file entries ................................................................. 742
Monitoring Aurora with Database Activity Streams ................................... 746
Overview .................................................................................................... 746
Aurora MySQL network prerequisites ......................................................... 749
Starting a database activity stream ............................................................. 750
Getting the activity stream status ............................................................... 751
Stopping a database activity stream .......................................................... 752
Monitoring activity streams ....................................................................... 753
Managing access to activity streams ......................................................... 777
Working with Aurora MySQL ..................................................................... 779
Overview of Aurora MySQL ....................................................................... 779
Amazon Aurora MySQL performance enhancements ............................... 779
Aurora MySQL and spatial data ................................................................. 780
Aurora MySQL version 3 compatible with MySQL 8.0 ............................... 781
Aurora MySQL version 2 compatible with MySQL 5.7 ............................... 811
Security with Aurora MySQL ................................................................. 813
Master user privileges with Aurora MySQL .............................................. 814
Using TLS with Aurora MySQL DB clusters ............................................. 814
Updating applications for new TLS certificates ........................................ 819
Determining whether any applications are connecting to your Aurora MySQL DB cluster using TLS ............................................................... 819
Determining whether a client requires certificate verification to connect .......... 820
Updating your application trust store ........................................................ 821
Example Java code for establishing TLS connections ............................... 821
Using Kerberos authentication for Aurora MySQL .................................... 823
Overview of Kerberos authentication for Aurora MySQL .......................... 824
Limitations ................................................................................................. 824
Setting up Kerberos authentication for Aurora MySQL ........................................... 825
Connecting to Aurora MySQL with Kerberos authentication ...................................... 832
Managing a DB cluster in a domain ............................................................................ 834
Migrating data to Aurora MySQL ............................................................................. 836
Migrating from an external MySQL database to Aurora MySQL .................................. 839
Migrating from a MySQL DB instance to Aurora MySQL .......................................... 858
Managing Aurora MySQL ......................................................................................... 875
Managing performance and scaling for Amazon Aurora MySQL ................................. 875
Backtracking a DB cluster ......................................................................................... 880
Testing Amazon Aurora MySQL using fault injection queries ................................. 894
Altering tables in Amazon Aurora using Fast DDL ................................................. 897
Displaying volume status for an Aurora DB cluster ................................................. 902
Tuning Aurora MySQL .............................................................................................. 903
Essential concepts for Aurora MySQL tuning ......................................................... 903
Tuning Aurora MySQL with wait events ............................................................... 905
Tuning Aurora MySQL with thread states ............................................................ 939
Tuning Aurora MySQL with Amazon DevOps Guru proactive insights ......................... 944
Parallel query for Aurora MySQL .............................................................................. 948
Overview of parallel query ...................................................................................... 949
Planning for a parallel query cluster .................................................................... 951
Creating a parallel query cluster ........................................................................... 952
Turning parallel query on and off ........................................................................ 955
Upgrading a parallel query cluster ....................................................................... 957
Performance tuning .............................................................................................. 958
Creating schema objects ...................................................................................... 958
Verifying parallel query usage ............................................................................. 959
Monitoring ........................................................................................................ 962
Parallel query and SQL constructs ..................................................................... 965
Advanced Auditing with Aurora MySQL ................................................................... 980
Enabling Advanced Auditing ............................................................................. 980
Viewing audit logs ............................................................................................. 982
Audit log details .................................................................................................. 982
Replication with Aurora MySQL ............................................................................. 984
Aurora Replicas .................................................................................................... 984
Replication options ............................................................................................... 985
Replication performance ...................................................................................... 985
Zero-downtime restart (ZDR) ................................................................................ 986
Configuring replication filters ............................................................................... 987
Monitoring replication ........................................................................................ 992
Using local write forwarding ............................................................................... 993
Cross-Region replication ...................................................................................... 1005
Using binary log (binlog) replication ................................................................. 1015
Using GTID-based replication .......................................................................... 1043
Integrating Aurora MySQL with AWS services ....................................................... 1047
Authorizing Aurora MySQL to access AWS services .......................................... 1047
Loading data from text files in Amazon S3 ......................................................... 1059
Saving data into text files in Amazon S3 ............................................................... 1068
Invoking a Lambda function from Aurora MySQL ............................................... 1075
Publishing Aurora MySQL logs to CloudWatch Logs ............................................ 1083
Using Aurora machine learning with Aurora MySQL .......................................... 1086
Aurora MySQL lab mode ...................................................................................... 1101
Aurora lab mode features ..................................................................................... 1101
Best practices with Amazon Aurora MySQL ........................................................ 1102
Determining which DB instance you are connected to ...................................... 1102
Best practices for Aurora MySQL performance and scaling ............................... 1103
Best practices for Aurora MySQL high availability .......................................... 1109
Recommendations for Aurora MySQL ............................................................... 1110
Managing Aurora PostgreSQL .......................................................... 1397
Scaling Aurora PostgreSQL DB instances ......................................... 1398
Maximum connections ..................................................................... 1398
Temporary storage limits ................................................................. 1399
Huge pages for Aurora PostgreSQL .................................................. 1401
Testing Amazon Aurora PostgreSQL by using fault injection queries ...... 1401
Displaying volume status for an Aurora DB cluster ......................... 1405
Specifying the RAM disk for the stats_temp_directory ...................... 1406
Managing temporary files with PostgreSQL ....................................... 1406
Tuning with wait events for Aurora PostgreSQL ............................... 1410
Essential concepts for Aurora PostgreSQL tuning .............................. 1411
Aurora PostgreSQL wait events ....................................................... 1414
Client:ClientRead ........................................................................... 1416
Client:ClientWrite ........................................................................... 1418
CPU ................................................................................................. 1420
IO:BufFileRead and IO:BufFileWrite .............................................. 1424
IO:DataFileRead ............................................................................. 1429
IO:XactSync .................................................................................. 1439
IPC:DamRecordTxAck ...................................................................... 1441
Lock:advisory .................................................................................. 1442
Lock:extend .................................................................................... 1444
Lock:Relation .................................................................................. 1445
Lock:transactionid .......................................................................... 1449
Lock:tuple ....................................................................................... 1451
LWLock:buffer_content (BufferContent) .......................................... 1454
LWLock:buffer_mapping .................................................................... 1455
LWLock:BufferIO (IPC:BufferIO) ...................................................... 1457
LWLock:lock_manager ..................................................................... 1458
LWLock:MultiXact ............................................................................ 1461
Timeout:PgSleep .............................................................................. 1463
Tuning Aurora PostgreSQL with Amazon DevOps Guru proactive insights 1463
Database has long running idle in transaction connection .................... 1464
Best practices with Aurora PostgreSQL ........................................... 1466
Avoiding slow performance, automatic restart, and failover for Aurora PostgreSQL DB instances .................................................. 1466
Diagnosing table and index bloat ...................................................... 1467
Improved memory management in Aurora PostgreSQL .................... 1469
Fast failover ...................................................................................... 1470
Fast recovery after failover .............................................................. 1478
Managing connection churn ............................................................ 1482
Tuning memory parameters for Aurora PostgreSQL ......................... 1488
Analyze resource usage with CloudWatch metrics ............................. 1494
Using logical replication for a major version upgrade ....................... 1497
Troubleshooting storage issues ......................................................... 1503
Replication with Aurora PostgreSQL .............................................. 1504
Aurora Replicas .............................................................................. 1504
Improving the availability of Aurora Replicas .................................. 1505
Monitoring replication ..................................................................... 1506
Using logical replication .................................................................. 1506
Integrating Aurora PostgreSQL with AWS services ....................... 1513
Importing data from Amazon S3 into Aurora PostgreSQL ................ 1514
Exporting PostgreSQL data to Amazon S3 ....................................... 1527
Invoking a Lambda function from Aurora PostgreSQL ..................... 1538
Publishing Aurora PostgreSQL logs to CloudWatch Logs ................. 1548
Using Aurora machine learning with Aurora PostgreSQL .......................... 1556
Managing query execution plans for Aurora PostgreSQL .......................... 1573
  Overview of Aurora PostgreSQL query plan management ...................... 1573
  Best practices for Aurora PostgreSQL query plan management ............... 1578
Understanding query plan management .............................................. 1580
Capturing Aurora PostgreSQL execution plans .................................... 1581
Using Aurora PostgreSQL managed plans ......................................... 1584
Examining Aurora PostgreSQL query plans in the dba_plans view .......... 1587
Maintaining Aurora PostgreSQL execution plans ................................ 1587
Reference ...................................................................................... 1592
Advanced features in Query Plan Management ..................................... 1606
Working with extensions and foreign data wrappers .............................. 1616
  Managing large objects more efficiently with the lo module .......... .... 1616
  Managing spatial data with PostGIS ............................................ 1618
  Managing partitions with the pg_partman extension ......................... 1625
  Scheduling maintenance with the pg_cron extension ......................... 1629
  Using pgAudit to log database activity ...................................... 1635
  Using plogicalical to synchronize data ...................................... 1643
Supported foreign data wrappers .................................................... 1653

What is Amazon Aurora?

Amazon Aurora (Aurora) is a fully managed relational database engine that's compatible with MySQL and PostgreSQL. You already know how MySQL and PostgreSQL combine the speed and reliability of high-end commercial databases with the simplicity and cost-effectiveness of open-source databases. The code, tools, and applications you use today with your existing MySQL and PostgreSQL databases can be used with Aurora. With some workloads, Aurora can deliver up to five times the throughput of MySQL and up to three times the throughput of PostgreSQL without requiring changes to most of your existing applications.

Aurora includes a high-performance storage subsystem. Its MySQL- and PostgreSQL-compatible database engines are customized to take advantage of that fast distributed storage. The underlying storage grows automatically as needed. An Aurora cluster volume can grow to a maximum size of 128 tebibytes (TiB). Aurora also automates and standardizes database clustering and replication, which are typically among the most challenging aspects of database configuration and administration.

Aurora is part of the managed database service Amazon Relational Database Service (Amazon RDS). Amazon RDS is a web service that makes it easier to set up, operate, and scale a relational database in the cloud. If you are not already familiar with Amazon RDS, see the Amazon Relational Database Service User Guide. To learn more about the variety of database options available on Amazon Web Services, see Choosing the right database for your organization on AWS.

Amazon RDS shared responsibility model

Amazon RDS is responsible for hosting the software components and infrastructure of DB instances and DB clusters. You are responsible for query tuning, which is the process of adjusting SQL queries to improve performance. Query performance is highly dependent on database design, data size, data distribution, application workload, and query patterns, which can vary greatly. Monitoring and tuning are highly individualized processes that you own for your RDS databases. You can use Amazon RDS Performance Insights and other tools to identify problematic queries.
How Amazon Aurora works with Amazon RDS

The following points illustrate how Amazon Aurora relates to the standard MySQL and PostgreSQL engines available in Amazon RDS:

- You choose Aurora MySQL or Aurora PostgreSQL as the DB engine option when setting up new database servers through Amazon RDS.
- Aurora takes advantage of the familiar Amazon Relational Database Service (Amazon RDS) features for management and administration. Aurora uses the Amazon RDS AWS Management Console interface, AWS CLI commands, and API operations to handle routine database tasks such as provisioning, patching, backup, recovery, failure detection, and repair.
- Aurora management operations typically involve entire clusters of database servers that are synchronized through replication, instead of individual database instances. The automatic clustering, replication, and storage allocation make it simple and cost-effective to set up, operate, and scale your largest MySQL and PostgreSQL deployments.
- You can bring data from Amazon RDS for MySQL and Amazon RDS for PostgreSQL into Aurora by creating and restoring snapshots, or by setting up one-way replication. You can use push-button migration tools to convert your existing RDS for MySQL and RDS for PostgreSQL applications to Aurora.

Before using Amazon Aurora, complete the steps in Setting up your environment for Amazon Aurora (p. 119), and then review the concepts and features of Aurora in Amazon Aurora DB clusters (p. 3).
Amazon Aurora DB clusters

An Amazon Aurora DB cluster consists of one or more DB instances and a cluster volume that manages the data for those DB instances. An Aurora cluster volume is a virtual database storage volume that spans multiple Availability Zones, with each Availability Zone having a copy of the DB cluster data. Two types of DB instances make up an Aurora DB cluster:

- **Primary DB instance** – Supports read and write operations, and performs all of the data modifications to the cluster volume. Each Aurora DB cluster has one primary DB instance.
- **Aurora Replica** – Connects to the same storage volume as the primary DB instance and supports only read operations. Each Aurora DB cluster can have up to 15 Aurora Replicas in addition to the primary DB instance. Maintain high availability by locating Aurora Replicas in separate Availability Zones. Aurora automatically fails over to an Aurora Replica in case the primary DB instance becomes unavailable. You can specify the failover priority for Aurora Replicas. Aurora Replicas can also offload read workloads from the primary DB instance.

The following diagram illustrates the relationship between the cluster volume, the primary DB instance, and Aurora Replicas in an Aurora DB cluster.

Note
The preceding information applies to provisioned clusters, parallel query clusters, global database clusters, Aurora Serverless clusters, and all MySQL 8.0-compatible, 5.7-compatible, and PostgreSQL-compatible clusters.

The Aurora cluster illustrates the separation of compute capacity and storage. For example, an Aurora configuration with only a single DB instance is still a cluster, because the underlying storage volume involves multiple storage nodes distributed across multiple Availability Zones (AZs).

Input/output (I/O) operations in Aurora DB clusters are counted the same way, regardless of whether they’re on a writer or reader DB instance. For more information, see Storage configurations for Amazon Aurora DB clusters (p. 97).
Amazon Aurora versions

Amazon Aurora reuses code and maintains compatibility with the underlying MySQL and PostgreSQL DB engines. However, Aurora has its own version numbers, release cycle, time line for version deprecation, and so on. The following section explains the common points and differences. This information can help you to decide such things as which version to choose and how to verify which features and fixes are available in each version. It can also help you to decide how often to upgrade and how to plan your upgrade process.

Topics

- Relational databases that are available on Aurora (p. 4)

- Manually controlling if and when your database cluster is upgraded to new versions (p. 14)
- Required Amazon Aurora upgrades (p. 14)
- Testing your DB cluster with a new Aurora version before upgrading (p. 14)

Relational databases that are available on Aurora

The following relational databases are available on Aurora:

- Amazon Aurora MySQL-Compatible Edition. For usage information, see Working with Amazon Aurora MySQL (p. 779). For a detailed list of available versions, see Database engine updates for Amazon Aurora MySQL (p. 1200).

- Amazon Aurora PostgreSQL-Compatible Edition. For usage information, see Working with Amazon Aurora PostgreSQL (p. 1229). For a detailed list of available versions, see Amazon Aurora PostgreSQL updates (p. 1780).

Differences in version numbers between community databases and Aurora

Each Amazon Aurora version is compatible with a specific community database version of either MySQL or PostgreSQL. You can find the community version of your database using the version function and the Aurora version using the aurora_version function.

Examples for Aurora MySQL and Aurora PostgreSQL are shown following.
Amazon Aurora User Guide for Aurora
Amazon Aurora major versions

mysql> select version();
+------------------+
| version()        |
+------------------+
| 5.7.12           |
+------------------+

mysql> select aurora_version(), @@aurora_version;
+------------------+------------------+
| aurora_version() | @@aurora_version |
+------------------+------------------+
| 2.08.1           | 2.08.1           |
+------------------+------------------+

postgres=> select version();
-----------------------------------------------------------------------------
PostgreSQL 11.7 on x86_64-pc-linux-gnu, compiled by gcc (GCC) 4.9.3, 64-bit
(1 row)
postgres=> select aurora_version();
aurora_version
-------------
3.2.2

For more information, see Checking Aurora MySQL versions using SQL (p. 1202) and Identifying versions of Amazon Aurora PostgreSQL (p. 1780).

Amazon Aurora major versions

Aurora versions use the `major.minor.patch` scheme. An Aurora major version refers to the MySQL or PostgreSQL community major version that Aurora is compatible with. Aurora MySQL and Aurora PostgreSQL major versions are available under standard support at least until community end of life for the corresponding community version. You can continue running a major version past its Aurora end of standard support date for a fee. For more information, see Using Amazon RDS Extended Support (p. 398) and Amazon Aurora pricing.

If Amazon extends support for an Aurora version for longer than originally stated, we plan to update this table to reflect the later date.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
**Note**
Amazon RDS Extended Support for Aurora MySQL starts on November 1, 2024, but will not be charged until December 1, 2024. Between November 1 and November 30, all Aurora MySQL version 2 DB clusters are covered under Amazon RDS Extended Support. Amazon RDS Extended Support for PostgreSQL 11 starts on March 1, 2024, but will not be charged until April 1, 2024. Between March 1 and March 31, all PostgreSQL version 11 DB instances and clusters on Aurora are covered under Amazon RDS Extended Support.

### Amazon Aurora minor versions

Aurora versions use the `major.minor.patch` scheme. An *Aurora minor version* provides incremental community and Aurora-specific improvements to the service, for example new features and fixes.

Amazon Aurora currently supports the following minor versions of MySQL.

<table>
<thead>
<tr>
<th>Aurora MySQL version</th>
<th>Aurora MySQL end of Standard Support date</th>
</tr>
</thead>
<tbody>
<tr>
<td>3.05 (Compatible with Community MySQL 8.0.32)</td>
<td>January 2025</td>
</tr>
<tr>
<td>3.04¹ (Compatible with Community MySQL 8.0.28)</td>
<td>October 2026</td>
</tr>
<tr>
<td>3.03 (Compatible with Community MySQL 8.0.26)</td>
<td>May 2024</td>
</tr>
<tr>
<td>3.02 (Compatible with Community MySQL 8.0.23)</td>
<td>January 2024</td>
</tr>
<tr>
<td>3.01 (Compatible with Community MySQL 8.0.23)</td>
<td>January 2024</td>
</tr>
<tr>
<td>2.12² (Compatible with Community MySQL 5.7.40)</td>
<td>October 2024</td>
</tr>
<tr>
<td>2.11² (Compatible with Community MySQL 5.7.12)</td>
<td>October 2024</td>
</tr>
<tr>
<td>2.07 (Compatible with Community MySQL 5.7.12)</td>
<td>April 2024</td>
</tr>
</tbody>
</table>

¹ Aurora MySQL long-term support (LTS) versions. For more information, see [Aurora MySQL long-term support (LTS) release](#).

² Amazon RDS Extended Support is only available on certain minor versions. For more information on the versions eligible for RDS Extended Support, see [Amazon Aurora major versions](#).

### Amazon Aurora patch versions

Aurora versions use the `major.minor.patch` scheme. An Aurora patch version includes important fixes added to a minor version after its initial release (for example, Aurora MySQL 2.10.0, 2.10.1, …, 2.10.3). While each new minor version provides new Aurora features, new patch versions within a specific minor version are primarily used to resolve important issues.

For more information on patching, see [Maintaining an Amazon Aurora DB cluster](#).

### Learning what's new in each Amazon Aurora version

Each new Aurora version comes with release notes that list the new features, fixes, other enhancements, and so on that apply to each version.
For Aurora MySQL release notes, see Release Notes for Aurora MySQL. For Aurora PostgreSQL release notes, see Release Notes for Aurora PostgreSQL.

Specifying the Amazon Aurora database version for your database cluster

You can specify any currently available version (major and minor) when creating a new DB cluster using the Create database operation in the AWS Management Console, the AWS CLI, or the CreateDBCluster API operation. Not every Aurora database version is available in every AWS Region.

To learn how to create Aurora clusters, see Creating an Amazon Aurora DB cluster (p. 179). To learn how to change the version of an existing Aurora cluster, see Modifying an Amazon Aurora DB cluster (p. 269).

Default Amazon Aurora versions

When a new Aurora minor version contains significant improvements compared to a previous one, it's marked as the default version for new DB clusters. Typically, we release two default versions for each major version per year.

We recommend that you keep your DB cluster upgraded to the most current default minor version, because that version contains the latest security and functionality fixes.

Automatic minor version upgrades

You can stay up to date with Aurora minor versions by turning on Auto minor version upgrade for every DB instance in the Aurora cluster. Aurora only performs the automatic upgrade if all DB instances in your cluster have this setting turned on. Auto minor version upgrades are performed to the default minor version.

We typically schedule automatic upgrades twice a year for DB clusters that have the Auto minor version upgrade setting set to Yes. These upgrades are started during the maintenance window that you specify for your cluster. For more information, see Automatic minor version upgrades for Aurora DB clusters (p. 351).

Automatic minor version upgrades are communicated in advance through an Amazon RDS DB cluster event with a category of maintenance and ID of RDS-EVENT-0156. For more information, see Amazon RDS event categories and event messages (p. 709).

How long Amazon Aurora major versions remain available

Amazon Aurora major versions remain available at least until community end of life for the corresponding community version. You can use Aurora end of standard support dates to plan your testing and upgrade cycles. These dates represent the earliest date that an upgrade to a newer version might be required. For more information on the dates, see Amazon Aurora major versions (p. 5).

Before we ask that you upgrade to a newer major version and to help you plan, we provide a reminder at least 12 months in advance. We do so to communicate the detailed upgrade process. Details include the timing of certain milestones, the impact on your DB clusters, and the actions that we recommend that you take. We always recommend that you thoroughly test your applications with new database versions before performing a major version upgrade.
After this 12-month period, an automatic upgrade to the subsequent major version might be applied to any database cluster still running the older version. If so, the upgrade is started during scheduled maintenance windows.

**How often Amazon Aurora minor versions are released**

In general, Amazon Aurora minor versions are released quarterly. The release schedule might vary to pick up additional features or fixes.

**How long Amazon Aurora minor versions remain available**

We intend to make each Amazon Aurora minor version of a particular major version available for at least 12 months. At the end of this period, Aurora might apply an auto minor version upgrade to the subsequent default minor version. Such an upgrade is started during the scheduled maintenance window for any cluster that is still running the older minor version.

We might replace a minor version of a particular major version sooner than the usual 12-month period if there are critical matters such as security issues, or if the major version has reached end of life.

Before beginning automatic upgrades of minor versions that are approaching end of life, we generally provide a reminder three months in advance. We do so to communicate the detailed upgrade process. Details include the timing of certain milestones, the impact on your DB clusters, and the actions that we recommend that you take. Notifications with less than three months notice are used when there are critical matters, such as security issues, that necessitate quicker action.

If you don’t have the **Auto minor version upgrade** setting enabled, you get a reminder but no RDS event notification. Upgrades occur within a maintenance window after the mandatory upgrade deadline has passed.

If you do have the **Auto minor version upgrade** setting enabled, you get a reminder and an Amazon RDS DB cluster event with a category of maintenance and ID of RDS-EVENT-0156. Upgrades occur during the next maintenance window.

For more information on auto minor version upgrades, see [Automatic minor version upgrades for Aurora DB clusters](#) (p. 351).

**Long-term support for selected Amazon Aurora minor versions**

For each Aurora major version, certain minor versions are designated as long-term-support (LTS) versions and made available for at least three years. That is, at least one minor version per major version is made available for longer than the typical 12 months. We generally provide a reminder six months before the end of this period. We do so to communicate the detailed upgrade process. Details include the timing of certain milestones, the impact on your DB clusters, and the actions that we recommend that you take. Notifications with less than six months notice are used when there are critical matters, such as security issues, that necessitate quicker action.

LTS minor versions include only critical fixes (through patch versions). An LTS version doesn't include new features released after its introduction. Once a year, DB clusters running on an LTS minor version are patched to the latest patch version of the LTS release. We do this patching to help ensure that you benefit from cumulative security and stability fixes. We might patch an LTS minor version more frequently if there are critical fixes, such as for security, that need to be applied.
Note

If you want to remain on an LTS minor version for the duration of its lifecycle, make sure to turn off **Auto minor version upgrade** for your DB instances. To avoid automatically upgrading your DB cluster from the LTS minor version, set **Auto minor version upgrade** to No on any DB instance in your Aurora cluster.

For the version numbers of all Aurora LTS versions, see [Aurora MySQL long-term support (LTS) releases](p. 1202) and [Aurora PostgreSQL long-term support (LTS) releases](p. 1798).

Amazon RDS Extended Support for selected Aurora versions

With Amazon RDS Extended Support, you can continue running your database on a major engine version past the Aurora end of standard support date for an additional cost. During Extended Support, Amazon RDS will supply patches for Critical and High CVEs as defined by the National Vulnerability Database (NVD) CVSS severity ratings. For more information, see [Using Amazon RDS Extended Support](p. 398).

Extended Support is only available on certain Aurora versions. For more information, see [Amazon Aurora major versions](p. 5).

Manually controlling if and when your database cluster is upgraded to new versions

Auto minor version upgrades are performed to the default minor version. We typically schedule automatic upgrades twice a year for DB clusters that have the **Auto minor version upgrade** setting set to Yes. These upgrades are started during customer-specified maintenance windows. If you want to turn off automatic minor version upgrades, set **Auto minor version upgrade** to No on any DB instance within an Aurora cluster. Aurora performs an automatic minor version upgrade only if all DB instances in your cluster have the setting turned on.

Because major version upgrades involve some compatibility risk, they don't occur automatically. You must initiate these, except in the case of a major version deprecation, as explained earlier. We always recommend that you thoroughly test your applications with new database versions before performing a major version upgrade.

For more information about upgrading a DB cluster to a new Aurora major version, see [Upgrading Amazon Aurora MySQL DB clusters](p. 1208) and [Upgrading Amazon Aurora PostgreSQL DB clusters](p. 1782).

Required Amazon Aurora upgrades

For certain critical fixes, we might perform a managed upgrade to a newer patch level within the same minor version. These required upgrades happen even if **Auto minor version upgrade** is turned off. Before doing so, we communicate the detailed upgrade process. Details include the timing of certain milestones, the impact on your DB clusters, and the actions that we recommend that you take. Such managed upgrades are performed automatically. Each such upgrade is started within the cluster maintenance window.

Testing your DB cluster with a new Aurora version before upgrading

You can test the upgrade process and how the new version works with your application and workload. Use one of the following methods:
• Clone your cluster using the Amazon Aurora fast database clone feature. Perform the upgrade and any post-upgrade testing on the new cluster.

• Restore from a cluster snapshot to create a new Aurora cluster. You can create a cluster snapshot yourself from an existing Aurora cluster. Aurora also automatically creates periodic snapshots for you for each of your clusters. You can then initiate a version upgrade for the new cluster. You can experiment on the upgraded copy of your cluster before deciding whether to upgrade your original cluster.

For more information on these ways to create new clusters for testing, see Cloning a volume for an Amazon Aurora DB cluster (p. 303) and Creating a DB cluster snapshot (p. 437).
Regions and Availability Zones

Amazon cloud computing resources are hosted in multiple locations world-wide. These locations are composed of AWS Regions and Availability Zones. Each AWS Region is a separate geographic area. Each AWS Region has multiple, isolated locations known as Availability Zones.

Note
For information about finding the Availability Zones for an AWS Region, see Describe your Availability Zones in the Amazon EC2 documentation.

Amazon operates state-of-the-art, highly-available data centers. Although rare, failures can occur that affect the availability of DB instances that are in the same location. If you host all your DB instances in one location that is affected by such a failure, none of your DB instances will be available.

It is important to remember that each AWS Region is completely independent. Any Amazon RDS activity you initiate (for example, creating database instances or listing available database instances) runs only in your current default AWS Region. The default AWS Region can be changed in the console, or by setting the `AWS_DEFAULT_REGION` environment variable. Or it can be overridden by using the `--region` parameter with the AWS Command Line Interface (AWS CLI). For more information, see Configuring the AWS Command Line Interface, specifically the sections about environment variables and command line options.

Amazon RDS supports special AWS Regions called AWS GovCloud (US). These are designed to allow US government agencies and customers to move more sensitive workloads into the cloud. The AWS GovCloud (US) Regions address the US government's specific regulatory and compliance requirements. For more information, see What is AWS GovCloud (US)?

To create or work with an Amazon RDS DB instance in a specific AWS Region, use the corresponding regional service endpoint.

Note
Aurora doesn't support Local Zones.

AWS Regions

Each AWS Region is designed to be isolated from the other AWS Regions. This design achieves the greatest possible fault tolerance and stability.
When you view your resources, you see only the resources that are tied to the AWS Region that you specified. This is because AWS Regions are isolated from each other, and we don't automatically replicate resources across AWS Regions.

**Region availability**

When you work with an Aurora DB cluster using the command line interface or API operations, make sure that you specify its regional endpoint.

**Topics**
- Aurora MySQL Region availability (p. 17)
- Aurora PostgreSQL Region availability (p. 19)

**Aurora MySQL Region availability**

The following table shows the AWS Regions where Aurora MySQL is currently available and the endpoint for each Region.

**Availability Zones**

An Availability Zone is an isolated location in a given AWS Region. Each Region has multiple Availability Zones (AZ) designed to provide high availability for the Region. An AZ is identified by the AWS Region code followed by a letter identifier (for example, us-east-1a). If you create your VPC and subnets rather than using the default VPC, you define each subnet in a specific AZ. When you create an Aurora DB cluster, Aurora creates the primary instance in one of the subnets in the VPC's DB subnet group. It thus associates that instance with a specific AZ chosen by Aurora.

Each Aurora DB cluster hosts copies of its storage in three separate AZs. Every DB instance in the cluster must be in one of these three AZs. When you create a DB instance in your cluster, Aurora automatically chooses an appropriate AZ if you don't specify an AZ.

Use the `describe-availability-zones` Amazon EC2 command as follows to describe the Availability Zones within the specified Region that are enabled for your account.

```bash
aws ec2 describe-availability-zones --region region-name
```

For example, to describe the Availability Zones within the US East (N. Virginia) Region (us-east-1) that are enabled for your account, run the following command:

```bash
aws ec2 describe-availability-zones --region us-east-1
```

To learn how to specify the AZ when you create a cluster or add instances to it, see [Configure the network for the DB cluster](p. 179).

**Local time zone for Amazon Aurora DB clusters**

By default, the time zone for an Amazon Aurora DB cluster is Universal Time Coordinated (UTC). You can set the time zone for instances in your DB cluster to the local time zone for your application instead.

To set the local time zone for a DB cluster, set the time zone parameter to one of the supported values. You set this parameter in the cluster parameter group for your DB cluster.
For Aurora MySQL, the name of this parameter is `time_zone`. For information on best practices for setting the `time_zone` parameter, see Optimizing timestamp operations (p. 1108).

For Aurora PostgreSQL, the name of this parameter is `timezone`.

When you set the time zone parameter for a DB cluster, all instances in the DB cluster change to use the new local time zone. In some cases, other Aurora DB clusters might be using the same cluster parameter group. If so, all instances in those DB clusters change to use the new local time zone also. For information on cluster-level parameters, see Amazon Aurora DB cluster and DB instance parameters (p. 215).

After you set the local time zone, all new connections to the database reflect the change. In some cases, you might have open connections to your database when you change the local time zone. If so, you don't see the local time zone update until after you close the connection and open a new connection.

If you are replicating across AWS Regions, the replication source DB cluster and the replica use different parameter groups. Parameter groups are unique to an AWS Region. To use the same local time zone for each instance, make sure to set the time zone parameter in the parameter groups for both the replication source and the replica.

When you restore a DB cluster from a DB cluster snapshot, the local time zone is set to UTC. You can update the time zone to your local time zone after the restore is complete. In some cases, you might restore a DB cluster to a point in time. If so, the local time zone for the restored DB cluster is the time zone setting from the parameter group of the restored DB cluster.

The following table lists some of the values to which you can set your local time zone. To list all of the available time zones, you can use the following SQL queries:

- Aurora MySQL: `select * from mysql.time_zone_name;`
- Aurora PostgreSQL: `select * from pg_timezone_names;`

**Note**

For some time zones, time values for certain date ranges can be reported incorrectly as noted in the table. For Australia time zones, the time zone abbreviation returned is an outdated value as noted in the table.

Supported features in Amazon Aurora by AWS Region and Aurora DB engine

Aurora MySQL- and PostgreSQL-compatible database engines support several Amazon Aurora and Amazon RDS features and options. The support varies across specific versions of each database engine, and across AWS Regions. To identify Aurora database engine version support and availability for a feature in a given AWS Region, you can use the following sections.

Some of these features are Aurora-only capabilities. For example, Aurora Serverless, Aurora global databases, and support for integration with AWS machine learning services aren't supported by Amazon RDS. Other features, such as Amazon RDS Proxy, are supported by both Amazon Aurora and Amazon RDS.

Topics

- Table conventions (p. 26)
- Blue/Green Deployments (p. 27)
- Aurora cluster storage configurations (p. 27)
- Database activity streams in Aurora (p. 27)
- Exporting cluster data to Amazon S3 (p. 31)
- Exporting snapshot data to Amazon S3 (p. 32)
- Aurora global databases (p. 32)
- IAM database authentication in Aurora (p. 36)
- Kerberos authentication with Aurora (p. 37)
- Aurora machine learning (p. 40)
- Performance Insights with Aurora (p. 43)
- Zero-ETL integrations with Amazon Redshift (p. 48)
- Amazon RDS Proxy (p. 49)
- Secrets Manager integration (p. 53)
- Aurora Serverless v2 (p. 53)
- Aurora Serverless v1 (p. 56)
- Data API for Aurora Serverless v1 (p. 59)
- Zero-downtime patching (ZDP) (p. 61)
- Engine-native features (p. 61)

Table conventions

The tables in the feature sections use the following patterns to specify version numbers and level of support:

- **Version x.y** – The specific version alone is supported.
- **Version x.y and higher** – The specified version and all higher minor versions of its major version are supported. For example, "version 10.11 and higher" means that versions 10.11, 10.11.1, and 10.12 are supported.
- **-** – The feature is not currently available for that particular Aurora feature for the given Aurora database engine, or in that specific AWS Region.
Blue/Green Deployments

A blue/green deployment copies a production database environment in a separate, synchronized staging environment. By using Amazon RDS Blue/Green Deployments, you can make changes to the database in the staging environment without affecting the production environment. For example, you can upgrade the major or minor DB engine version, change database parameters, or make schema changes in the staging environment. When you are ready, you can promote the staging environment to be the new production database environment. For more information, see Using Amazon RDS Blue/Green Deployments for database updates (p. 399).

Blue/Green Deployments with Aurora MySQL

The Blue/Green Deployments feature is available for all versions of Aurora MySQL in all available AWS Regions except Israel (Tel Aviv).

Blue/Green Deployments with Aurora PostgreSQL

The following Regions and engine versions are available for Blue/Green Deployments with Aurora PostgreSQL:

<table>
<thead>
<tr>
<th>Region</th>
<th>Aurora PostgreSQL 15</th>
<th>Aurora PostgreSQL 14</th>
<th>Aurora PostgreSQL 13</th>
<th>Aurora PostgreSQL 12</th>
<th>Aurora PostgreSQL 11</th>
</tr>
</thead>
<tbody>
<tr>
<td>All available Regions except Israel (Tel Aviv)</td>
<td>Version 15.4 and higher</td>
<td>Version 14.9 and higher</td>
<td>Version 13.12 and higher</td>
<td>Version 12.16 and higher</td>
<td>Version 11.21 and higher</td>
</tr>
</tbody>
</table>

Aurora cluster storage configurations

Amazon Aurora has two DB cluster storage configurations, Aurora I/O-Optimized and Aurora Standard. For more information, see Storage configurations for Amazon Aurora DB clusters (p. 97).

Aurora I/O-Optimized

Aurora I/O-Optimized is available in all AWS Regions for the following Amazon Aurora versions:

- Aurora MySQL version 3.03.1 and higher
- Aurora PostgreSQL versions 15.2 and higher, 14.7 and higher, and 13.10 and higher

Aurora Standard

Aurora Standard is available in all AWS Regions for all Aurora MySQL and Aurora PostgreSQL versions.

Database activity streams in Aurora

By using database activity streams in Aurora, you can monitor and set alarms for auditing activity in your Aurora database. For more information, see Monitoring Amazon Aurora with Database Activity Streams (p. 746).

Database activity streams aren't supported for the following features:

- Aurora Serverless v1
Database activity streams with Aurora MySQL

The following Regions and engine versions are available for database activity streams with Aurora MySQL.

Exporting cluster data to Amazon S3

You can export Aurora DB cluster data to an Amazon S3 bucket. After the data is exported, you can analyze the exported data directly through tools like Amazon Athena or Amazon Redshift Spectrum. For more information, see Exporting DB cluster data to Amazon S3 (p. 460).

Exporting cluster data to S3 is available in the following AWS Regions:

- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- China (Ningxia)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (London)
- Europe (Paris)
- Europe (Stockholm)
- South America (São Paulo)
- US East (N. Virginia)
- US East (Ohio)
- US West (N. California)
- US West (Oregon)

### Topics
Exporting snapshot data to Amazon S3

You can export Aurora DB cluster snapshot data to an Amazon S3 bucket. You can export manual snapshots and automated system snapshots. After the data is exported, you can analyze the exported data directly through tools like Amazon Athena or Amazon Redshift Spectrum. For more information, see Exporting DB cluster snapshot data to Amazon S3 (p. 471).

Exporting snapshots to S3 is available in all AWS Regions except the following:

- Asia Pacific (Hyderabad)
- Asia Pacific (Jakarta)
- Asia Pacific (Melbourne)
- Europe (Spain)
- Europe (Zurich)
- Israel (Tel Aviv)
- Middle East (UAE)
- AWS GovCloud (US-East)
- AWS GovCloud (US-West)

Aurora global databases

An Aurora global database is a single database that spans multiple AWS Regions, enabling low-latency global reads and disaster recovery from any Region-wide outage. It provides built-in fault tolerance for your deployment because the DB instance relies not on a single AWS Region, but upon multiple
Regions and different Availability Zones. For more information, see Using Amazon Aurora global databases (p. 1800).

</table>
IAM database authentication in Aurora

With IAM database authentication in Aurora, you can authenticate to your DB cluster using AWS Identity and Access Management (IAM) database authentication. With this authentication method, you don't need to use a password when you connect to a DB cluster. Instead, you use an authentication token. For more information, see IAM database authentication (p. 2432).

**Topics**
- IAM database authentication with Aurora MySQL (p. 36)
- IAM database authentication with Aurora PostgreSQL (p. 37)

### IAM database authentication with Aurora MySQL

IAM database authentication with Aurora MySQL is available in all Regions for the following versions:

<table>

IAM database authentication with Aurora PostgreSQL

IAM database authentication with Aurora PostgreSQL is available in all Regions for the following engine versions:

- Aurora PostgreSQL 15 – All available versions
- Aurora PostgreSQL 14 – All available versions
- Aurora PostgreSQL 13 – All available versions
- Aurora PostgreSQL 12 – All available versions
- Aurora PostgreSQL 11 – All available versions

Kerberos authentication with Aurora

By using Kerberos authentication with Aurora, you can support external authentication of database users using Kerberos and Microsoft Active Directory. Using Kerberos and Active Directory provides the benefits of single sign-on and centralized authentication of database users. Kerberos and Active Directory are available with AWS Directory Service for Microsoft Active Directory, a feature of AWS Directory Service. For more information, see Kerberos authentication (p. 2369).

Aurora machine learning

By using Amazon Aurora machine learning, you can integrate your Aurora DB cluster with Amazon Comprehend or Amazon SageMaker, depending on your needs. Amazon Comprehend and SageMaker each support different machine learning use cases. Amazon Comprehend is a natural language processing (NLP) service that's used to extract insights from documents. By using Aurora machine learning with Amazon Comprehend, you can determine the sentiment of text in your database tables. SageMaker is a full-featured machine learning service. Data scientists use Amazon SageMaker to build, train, and test machine learning models for a variety of inference tasks, such as fraud detection. By using Aurora machine learning with SageMaker, database developers can invoke the SageMaker functionality in SQL code.

Not all AWS Regions support both Amazon Comprehend and SageMaker, and only certain AWS Regions support Aurora machine learning and thus provide access to these services from an Aurora DB cluster. The integration process for Aurora machine learning also differs by database engine. For more information, see Using machine learning capabilities with Amazon Aurora (p. 343).

  • Aurora machine learning with Aurora PostgreSQL (p. 42)

Aurora machine learning with Aurora MySQL

Aurora machine learning is supported for Aurora MySQL in the AWS Regions listed in the table. In addition to having your version of Aurora MySQL available, the AWS Region must also support the service that you want to use. For a list of AWS Regions where Amazon SageMaker is available, see Amazon SageMaker endpoints and quotas in the Amazon Web Services General Reference. For a list of AWS Regions where Amazon Comprehend is available, see Amazon Comprehend endpoints and quotas in the Amazon Web Services General Reference.

Performance Insights with Aurora

Performance Insights expands on existing Amazon RDS monitoring features to illustrate and help you analyze your database performance. With the Performance Insights dashboard, you can visualize the database load on your Amazon RDS DB instance load and filter the load by waits, SQL statements, hosts, or users. For more information, see Overview of Performance Insights on Amazon Aurora (p. 559).
For the region, DB engine, and instance class support information for Performance Insights features, see Amazon Aurora DB engine, Region, and instance class support for Performance Insights features (p. 563).

Topics
- Performance Insights with Aurora MySQL (p. 44)
- Performance Insights with Aurora PostgreSQL (p. 46)
- Performance Insights with Aurora Serverless (p. 48)

Performance Insights with Aurora MySQL

Note
Engine version support is different for Performance Insights with Aurora MySQL if you have parallel query turned on. For more information on parallel query, see Working with parallel query for Amazon Aurora MySQL (p. 948).

Topics
- Performance Insights with Aurora MySQL and parallel query turned off (p. 44)

### Performance Insights with Aurora Serverless

Aurora Serverless v2 supports Performance Insights for all MySQL-compatible and PostgreSQL-compatible versions. We recommend that you set the minimum capacity to at least 2 Aurora capacity units (ACUs).

Aurora Serverless v1 doesn't support Performance Insights.

#### Zero-ETL integrations with Amazon Redshift

Amazon Aurora zero-ETL integrations with Amazon Redshift is a fully managed solution for making transactional data available in Amazon Redshift after it's written to an Aurora cluster. For more information, see *Working with zero-ETL integrations* (p. 1938).

The following Regions and engine versions are available for zero-ETL integrations with Amazon Redshift.

Amazon RDS Proxy

Amazon RDS Proxy is a fully managed, highly available database proxy that makes applications more scalable by pooling and sharing established database connections. For more information about RDS Proxy, see Using Amazon RDS Proxy for Aurora (p. 1879).

</tbody>
</table>
Secrets Manager integration

With AWS Secrets Manager, you can replace hard-coded credentials in your code, including database passwords, with an API call to Secrets Manager to retrieve the secret programmatically. For more information about Secrets Manager, see AWS Secrets Manager User Guide.

You can specify that Amazon Aurora manages the master user password in Secrets Manager for an Aurora DB cluster. Aurora generates the password, stores it in Secrets Manager, and rotates it regularly. For more information, see Password management with Amazon Aurora and AWS Secrets Manager (p. 2371).

Secrets Manager integration is available for all Aurora DB engines and all versions.

Secrets Manager integration is available in all AWS Regions except the following:
- Israel (Tel Aviv)
- AWS GovCloud (US-East)
- AWS GovCloud (US-West)

Aurora Serverless v2

Aurora Serverless v2 is an on-demand, auto-scaling feature designed to be a cost-effective approach to running intermittent or unpredictable workloads on Amazon Aurora. It automatically scales capacity up or down as needed by your applications. The scaling is faster and more granular than with Aurora Serverless v1. With Aurora Serverless v2, each cluster can contain a writer DB instance and multiple reader DB instances. You can combine Aurora Serverless v2 and traditional provisioned DB instances within the same cluster. For more information, see Using Aurora Serverless v2 (p. 1961).

Aurora Serverless v1

Aurora Serverless v1 is an on-demand, auto-scaling feature designed to be a cost-effective approach to running intermittent or unpredictable workloads on Amazon Aurora. It automatically starts up, shuts down, and scales capacity up or down, as needed by your applications, using a single DB instance in each cluster. For more information, see Using Amazon Aurora Serverless v1 (p. 2023).

Data API for Aurora Serverless v1

The Data API for Aurora Serverless provides a web-services interface to an Aurora Serverless v1 cluster. Instead of managing database connections from client applications, you can run SQL commands against an HTTPS endpoint. For more information, see Using the Data API for Aurora Serverless v1 (p. 2063).

Zero-downtime patching (ZDP)

Performing upgrades for Aurora DB clusters involves the possibility of an outage when the database is shut down and while it's being upgraded. By default, if you start the upgrade while the database is busy, you lose all the connections and transactions that the DB cluster is processing. If you wait until the database is idle to perform the upgrade, you might have to wait a long time.

The zero-downtime patching (ZDP) feature attempts, on a best-effort basis, to preserve client connections through an Aurora upgrade. If ZDP completes successfully, application sessions are preserved and the database engine restarts while the upgrade is in progress. The database engine restart can cause a drop in throughput lasting for a few seconds to approximately one minute.

For detailed information on the conditions and engine versions where ZDP is available for Aurora MySQL upgrades, see Using zero-downtime patching (p. 1211).

For detailed information on the conditions and engine versions where ZDP is available for Aurora PostgreSQL upgrades, see Minor release upgrades and zero-downtime patching (p. 1795).

Engine-native features

Aurora database engines also support additional features and functionality specifically for Aurora. Some engine-native features might have limited support or restricted privileges for a particular Aurora DB engine, version, or Region.

Topics
  • Engine-native features for Aurora MySQL (p. 62)
Engine-native features for Aurora MySQL

Following are the engine-native features for Aurora MySQL.

- Advanced Auditing (p. 980)
- Backtrack (p. 880)
- Fault injection queries (p. 894)
- In-cluster write forwarding (p. 993)
- Parallel query (p. 951)

Engine-native features for Aurora PostgreSQL

Following are the engine-native features for Aurora PostgreSQL.

- Babelfish (p. 1283)
- Fault injection queries (p. 1401)
- Query plan management (p. 1573)

Amazon Aurora connection management

Amazon Aurora typically involves a cluster of DB instances instead of a single instance. Each connection is handled by a specific DB instance. When you connect to an Aurora cluster, the host name and port that you specify point to an intermediate handler called an endpoint. Aurora uses the endpoint mechanism to abstract these connections. Thus, you don't have to hardcode all the hostnames or write your own logic for load-balancing and rerouting connections when some DB instances aren't available.

For certain Aurora tasks, different instances or groups of instances perform different roles. For example, the primary instance handles all data definition language (DDL) and data manipulation language (DML) statements. Up to 15 Aurora Replicas handle read-only query traffic.

Using endpoints, you can map each connection to the appropriate instance or group of instances based on your use case. For example, to perform DDL statements you can connect to whichever instance is the primary instance. To perform queries, you can connect to the reader endpoint, with Aurora automatically performing load-balancing among all the Aurora Replicas. For clusters with DB instances of different capacities or configurations, you can connect to custom endpoints associated with different subsets of DB instances. For diagnosis or tuning, you can connect to a specific instance endpoint to examine details about a specific DB instance.

Topics

- Types of Aurora endpoints (p. 63)
- Viewing the endpoints for an Aurora cluster (p. 64)
- Using the cluster endpoint (p. 65)
- Using the reader endpoint (p. 65)
- Using custom endpoints (p. 65)
- Creating a custom endpoint (p. 68)
- Viewing custom endpoints (p. 70)
Types of Aurora endpoints

An endpoint is represented as an Aurora-specific URL that contains a host address and a port. The following types of endpoints are available from an Aurora DB cluster.

Cluster endpoint

A cluster endpoint (or writer endpoint) for an Aurora DB cluster connects to the current primary DB instance for that DB cluster. This endpoint is the only one that can perform write operations such as DDL statements. Because of this, the cluster endpoint is the one that you connect to when you first set up a cluster or when your cluster only contains a single DB instance.

Each Aurora DB cluster has one cluster endpoint and one primary DB instance.

You use the cluster endpoint for all write operations on the DB cluster, including inserts, updates, deletes, and DDL changes. You can also use the cluster endpoint for read operations, such as queries.

The cluster endpoint provides failover support for read/write connections to the DB cluster. If the current primary DB instance of a DB cluster fails, Aurora automatically fails over to a new primary DB instance. During a failover, the DB cluster continues to serve connection requests to the cluster endpoint from the new primary DB instance, with minimal interruption of service.

The following example illustrates a cluster endpoint for an Aurora MySQL DB cluster.

mydbcluster.cluster-c7tj4example.us-east-1.rds.amazonaws.com:3306

Reader endpoint

A reader endpoint for an Aurora DB cluster provides load-balancing support for read-only connections to the DB cluster. Use the reader endpoint for read operations, such as queries. By processing those statements on the read-only Aurora Replicas, this endpoint reduces the overhead on the primary instance. It also helps the cluster to scale the capacity to handle simultaneous SELECT queries, proportional to the number of Aurora Replicas in the cluster. Each Aurora DB cluster has one reader endpoint.

If the cluster contains one or more Aurora Replicas, the reader endpoint load-balances each connection request among the Aurora Replicas. In that case, you can only perform read-only statements such as SELECT in that session. If the cluster only contains a primary instance and no Aurora Replicas, the reader endpoint connects to the primary instance. In that case, you can perform write operations through the endpoint.

The following example illustrates a reader endpoint for an Aurora MySQL DB cluster.

mydbcluster.cluster-ro-c7tj4example.us-east-1.rds.amazonaws.com:3306

Custom endpoint

A custom endpoint for an Aurora cluster represents a set of DB instances that you choose. When you connect to the endpoint, Aurora performs load balancing and chooses one of the instances in the group to handle the connection. You define which instances this endpoint refers to, and you decide what purpose the endpoint serves.
An Aurora DB cluster has no custom endpoints until you create one. You can create up to five custom endpoints for each provisioned Aurora cluster or Aurora Serverless v2 cluster. You can't use custom endpoints for Aurora Serverless v1 clusters.

The custom endpoint provides load-balanced database connections based on criteria other than the read-only or read/write capability of the DB instances. For example, you might define a custom endpoint to connect to instances that use a particular AWS instance class or a particular DB parameter group. Then you might tell particular groups of users about this custom endpoint. For example, you might direct internal users to low-capacity instances for report generation or ad hoc (one-time) querying, and direct production traffic to high-capacity instances.

Because the connection can go to any DB instance that is associated with the custom endpoint, we recommend that you make sure that all the DB instances within that group share some similar characteristic. Doing so ensures that the performance, memory capacity, and so on, are consistent for everyone who connects to that endpoint.

This feature is intended for advanced users with specialized kinds of workloads where it isn't practical to keep all the Aurora Replicas in the cluster identical. With custom endpoints, you can predict the capacity of the DB instance used for each connection. When you use custom endpoints, you typically don't use the reader endpoint for that cluster.

The following example illustrates a custom endpoint for a DB instance in an Aurora MySQL DB cluster.

myendpoint.cluster-custom-c7tj4example.us-east-1.rds.amazonaws.com:3306

**Instance endpoint**

An instance endpoint connects to a specific DB instance within an Aurora cluster. Each DB instance in a DB cluster has its own unique instance endpoint. So there is one instance endpoint for the current primary DB instance of the DB cluster, and there is one instance endpoint for each of the Aurora Replicas in the DB cluster.

The instance endpoint provides direct control over connections to the DB cluster, for scenarios where using the cluster endpoint or reader endpoint might not be appropriate. For example, your client application might require more fine-grained load balancing based on workload type. In this case, you can configure multiple clients to connect to different Aurora Replicas in a DB cluster to distribute read workloads. For an example that uses instance endpoints to improve connection speed after a failover for Aurora PostgreSQL, see Fast failover with Amazon Aurora PostgreSQL (p. 1470). For an example that uses instance endpoints to improve connection speed after a failover for Aurora MySQL, see MariaDB Connector/J failover support - case Amazon Aurora.

The following example illustrates an instance endpoint for a DB instance in an Aurora MySQL DB cluster.

mydbinstance.c7tj4example.us-east-1.rds.amazonaws.com:3306

**Viewing the endpoints for an Aurora cluster**

In the AWS Management Console, you see the cluster endpoint, the reader endpoint, and any custom endpoints in the detail page for each cluster. You see the instance endpoint in the detail page for each instance. When you connect, you must append the associated port number, following a colon, to the endpoint name shown on this detail page.

With the AWS CLI, you see the writer, reader, and any custom endpoints in the output of the describe-db-clusters command. For example, the following command shows the endpoint attributes for all clusters in your current AWS Region.
**Using the cluster endpoint**

Because each Aurora cluster has a single built-in cluster endpoint, whose name and other attributes are managed by Aurora, you can’t create, delete, or modify this kind of endpoint.

You use the cluster endpoint when you administer your cluster, perform extract, transform, load (ETL) operations, or develop and test applications. The cluster endpoint connects to the primary instance of the cluster. The primary instance is the only DB instance where you can create tables and indexes, run INSERT statements, and perform other DDL and DML operations.

The physical IP address pointed to by the cluster endpoint changes when the failover mechanism promotes a new DB instance to be the read/write primary instance for the cluster. If you use any form of connection pooling or other multiplexing, be prepared to flush or reduce the time-to-live for any cached DNS information. Doing so ensures that you don’t try to establish a read/write connection to a DB instance that became unavailable or is now read-only after a failover.

**Using the reader endpoint**

You use the reader endpoint for read-only connections for your Aurora cluster. This endpoint uses a load-balancing mechanism to help your cluster handle a query-intensive workload. The reader endpoint is the endpoint that you supply to applications that do reporting or other read-only operations on the cluster.

The reader endpoint load-balances connections to available Aurora Replicas in an Aurora DB cluster. It doesn’t load-balance individual queries. If you want to load-balance each query to distribute the read workload for a DB cluster, open a new connection to the reader endpoint for each query.

Each Aurora cluster has a single built-in reader endpoint, whose name and other attributes are managed by Aurora. You can’t create, delete, or modify this kind of endpoint.

If your cluster contains only a primary instance and no Aurora Replicas, the reader endpoint connects to the primary instance. In that case, you can perform write operations through this endpoint.

**Tip**

Through RDS Proxy, you can create additional read-only endpoints for an Aurora cluster. These endpoints perform the same kind of load-balancing as the Aurora reader endpoint. Applications can reconnect more quickly to the proxy endpoints than the Aurora reader endpoint if reader instances become unavailable. The proxy endpoints can also take advantage of other proxy features such as multiplexing. For more information, see Using reader endpoints with Aurora clusters (p. 1913).

**Using custom endpoints**

You use custom endpoints to simplify connection management when your cluster contains DB instances with different capacities and configuration settings.

Previously, you might have used the CNAMEs mechanism to set up Domain Name Service (DNS) aliases from your own domain to achieve similar results. By using custom endpoints, you can avoid updating CNAME records when your cluster grows or shrinks. Custom endpoints also mean that you can use encrypted Transport Layer Security/Secure Sockets Layer (TLS/SSL) connections.
Instead of using one DB instance for each specialized purpose and connecting to its instance endpoint, you can have multiple groups of specialized DB instances. In this case, each group has its own custom endpoint. This way, Aurora can perform load balancing among all the instances dedicated to tasks such as reporting or handling production or internal queries. The custom endpoints provide load balancing and high availability for each group of DB instances within your cluster. If one of the DB instances within a group becomes unavailable, Aurora directs subsequent custom endpoint connections to one of the other DB instances associated with the same endpoint.

Topics
- Specifying properties for custom endpoints (p. 66)
- Membership rules for custom endpoints (p. 66)
- Managing custom endpoints (p. 67)

Specifying properties for custom endpoints

The maximum length for a custom endpoint name is 63 characters. The name format is the following:

```
endpoint_name.cluster-custom-customer_DNS_identifier.AWSRegion.rds.amazonaws.com
```

You can't reuse the same custom endpoint name for more than one cluster in the same AWS Region. The customer DNS identifier is a unique identifier associated with your AWS account in a particular AWS Region.

Each custom endpoint has an associated type that determines which DB instances are eligible to be associated with that endpoint. Currently, the type can be READER, WRITER, or ANY. The following considerations apply to the custom endpoint types:

- You can't select the custom endpoint type in the AWS Management Console. All the custom endpoints you create through the AWS Management Console have a type of ANY.
- You can set and modify the custom endpoint type using the AWS CLI or Amazon RDS API.
- Only reader DB instances can be part of a READER custom endpoint.
- Both reader and writer DB instances can be part of an ANY custom endpoint. Aurora directs connections to cluster endpoints with type ANY to any associated DB instance with equal probability. The ANY type applies to clusters using any replication topology.
- If you try to create a custom endpoint with a type that isn't appropriate based on the replication configuration for a cluster, Aurora returns an error.

Membership rules for custom endpoints

When you add a DB instance to a custom endpoint or remove it from a custom endpoint, any existing connections to that DB instance remain active.

You can define a list of DB instances to include in, or exclude from, a custom endpoint. We refer to these lists as static and exclusion lists, respectively. You can use the inclusion/exclusion mechanism to further subdivide the groups of DB instances, and to make sure that the set of custom endpoints covers all the DB instances in the cluster. Each custom endpoint can contain only one of these list types.

In the AWS Management Console:

- The choice is represented by the check box Attach future instances added to this cluster. When you keep the check box clear, the custom endpoint uses a static list containing only the DB instances specified on the page. When you choose the check box, the custom endpoint uses an exclusion list.
this case, the custom endpoint represents all DB instances in the cluster (including any that you add in the future) except the ones not selected on the page.

- The console doesn't allow you to specify the endpoint type. Any custom endpoint created using the console is of type `ANY`.

Therefore, Aurora doesn't change the membership of the custom endpoint when DB instances change roles between writer and reader due to failover or promotion.

In the AWS CLI and Amazon RDS API:

- You can specify the endpoint type. Therefore, when the endpoint type is set to `READER` or `WRITER`, endpoint membership is automatically adjusted during failovers and promotions.

  For example, a custom endpoint with type `READER` includes an Aurora Replica that is then promoted to be a writer instance. The new writer instance is no longer part of the custom endpoint.

- You can add individual members to and remove them from the lists after they change their roles. Use the `modify-db-cluster-endpoint` AWS CLI command or `ModifyDBClusterEndpoint` API operation.

You can associate a DB instance with more than one custom endpoint. For example, suppose that you add a new DB instance to a cluster, or that Aurora adds a DB instance automatically through the autoscaling mechanism. In these cases, the DB instance is added to all custom endpoints for which it is eligible. Which endpoints the DB instance is added to is based on the custom endpoint type of `READER`, `WRITER`, or `ANY`, plus any static or exclusion lists defined for each endpoint. For example, if the endpoint includes a static list of DB instances, newly added Aurora Replicas aren't added to that endpoint. Conversely, if the endpoint has an exclusion list, newly added Aurora Replicas are added to the endpoint, if they aren't named in the exclusion list and their roles match the type of the custom endpoint.

If an Aurora Replica becomes unavailable, it remains associated with any custom endpoints. For example, it remains part of the custom endpoint when it is unhealthy, stopped, rebooting, and so on. However, you can't connect to it through those endpoints until it becomes available again.

### Managing custom endpoints

Because newly created Aurora clusters have no custom endpoints, you must create and manage these objects yourself. You do so using the AWS Management Console, AWS CLI, or Amazon RDS API.

**Note**

You must also create and manage custom endpoints for Aurora clusters restored from snapshots. Custom endpoints are not included in the snapshot. You create them again after restoring, and choose new endpoint names if the restored cluster is in the same region as the original one.

To work with custom endpoints from the AWS Management Console, you navigate to the details page for your Aurora cluster and use the controls under the **Custom Endpoints** section.

To work with custom endpoints from the AWS CLI, you can use these operations:

- `create-db-cluster-endpoint`
- `describe-db-cluster-endpoints`
- `modify-db-cluster-endpoint`
- `delete-db-cluster-endpoint`

To work with custom endpoints through the Amazon RDS API, you can use the following functions:
Creating a custom endpoint

Console

To create a custom endpoint with the AWS Management Console, go to the cluster detail page and choose the Create custom endpoint action in the Endpoints section. Choose a name for the custom endpoint, unique for your user ID and region. To choose a list of DB instances that remains the same even as the cluster expands, keep the check box Attach future instances added to this cluster clear. When you choose that check box, the custom endpoint dynamically adds any new instances as you add them to the cluster.
Create custom endpoint

Endpoint name

Endpoint name is case insensitive, First character must be a letter. Case

Endpoint members

Filter database
You can't select the custom endpoint type of ANY or READER in the AWS Management Console. All the custom endpoints you create through the AWS Management Console have a type of ANY.

**AWS CLI**

To create a custom endpoint with the AWS CLI, run the `create-db-cluster-endpoint` command.

The following command creates a custom endpoint attached to a specific cluster. Initially, the endpoint is associated with all the Aurora Replica instances in the cluster. A subsequent command associates it with a specific set of DB instances in the cluster.

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster-endpoint --db-cluster-endpoint-identifier custom-endpoint-doc-sample
   --endpoint-type reader
   --db-cluster-identifier cluster_id

aws rds modify-db-cluster-endpoint --db-cluster-endpoint-identifier custom-endpoint-doc-sample
   --static-members instance_name_1 instance_name_2
```

For Windows:

```bash
aws rds create-db-cluster-endpoint --db-cluster-endpoint-identifier custom-endpoint-doc-sample
   --endpoint-type reader
   --db-cluster-identifier cluster_id

aws rds modify-db-cluster-endpoint --db-cluster-endpoint-identifier custom-endpoint-doc-sample
   --static-members instance_name_1 instance_name_2
```

**RDS API**

To create a custom endpoint with the RDS API, run the `CreateDBClusterEndpoint` operation.

**Viewing custom endpoints**

**Console**

To view custom endpoints with the AWS Management Console, go to the cluster detail page for the cluster and look under the **Endpoints** section. This section contains information only about custom endpoints. The details for the built-in endpoints are listed in the main **Details** section. To see the details for a specific custom endpoint, select its name to bring up the detail page for that endpoint.

The following screenshot shows how the list of custom endpoints for an Aurora cluster is initially empty.
After you create some custom endpoints for that cluster, they are shown under the **Endpoints** section.
Clicking through to the detail page shows which DB instances the endpoint is currently associated with.
Viewing custom endpoints

Details

Endpoint name

Endpoint members

Filter endpoint members
To see the additional detail of whether new DB instances added to the cluster are automatically added to the endpoint also, open the **Edit** page for the endpoint.

**AWS CLI**

To view custom endpoints with the AWS CLI, run the `describe-db-cluster-endpoints` command.

The following command shows the custom endpoints associated with a specified cluster in a specified region. The output includes both the built-in endpoints and any custom endpoints.

For Linux, macOS, or Unix:

```bash
aws rds describe-db-cluster-endpoints --region region_name \
    --db-cluster-identifier cluster_id
```

For Windows:

```bash
aws rds describe-db-cluster-endpoints --region region_name ^ \
    --db-cluster-identifier cluster_id
```

The following shows some sample output from a `describe-db-cluster-endpoints` command. The `EndpointType` of `WRITER` or `READER` denotes the built-in read/write and read-only endpoints for the cluster. The `EndpointType` of `CUSTOM` denotes endpoints that you create and choose the associated DB instances. One of the endpoints has a non-empty `StaticMembers` field, denoting that it is associated with a precise set of DB instances. The other endpoint has a non-empty `ExcludedMembers` field, denoting that the endpoint is associated with all DB instances *other than* the ones listed under `ExcludedMembers`. This second kind of custom endpoint grows to accommodate new instances as you add them to the cluster.

```json
{
    "DBClusterEndpoints": [
        {
            "Endpoint": "custom-endpoint-demo.cluster-c7tj4example.ca-central-1.rds.amazonaws.com",
            "Status": "available",
            "DBClusterIdentifier": "custom-endpoint-demo",
            "EndpointType": "WRITER"
        },
        {
            "Endpoint": "custom-endpoint-demo.cluster-ro-c7tj4example.ca-central-1.rds.amazonaws.com",
            "Status": "available",
            "DBClusterIdentifier": "custom-endpoint-demo",
            "EndpointType": "READER"
        },
        {
            "CustomEndpointType": "ANY",
            "DBClusterEndpointIdentifier": "powers-of-2",
            "ExcludedMembers": [],
            "DBClusterIdentifier": "custom-endpoint-demo",
            "Status": "available",
            "EndpointType": "CUSTOM",
            "Endpoint": "powers-of-2.cluster-custom-c7tj4example.ca-central-1.rds.amazonaws.com",
            "StaticMembers": [
                "custom-endpoint-demo-04",
                "custom-endpoint-demo-08",
                "custom-endpoint-demo-01",
                "custom-endpoint-demo-02"
            ],
            "DBClusterEndpointResourceIdentifier": "cluster-endpoint-W7PE3TLLFNSHXQKFU6J6NV5FHU",
```
Editing a custom endpoint

You can edit the properties of a custom endpoint to change which DB instances are associated with the endpoint. You can also change an endpoint between a static list and an exclusion list. If you need more details about these endpoint properties, see Membership rules for custom endpoints (p. 66).

You can continue connecting to and using a custom endpoint while the changes from an edit action are in progress.

Console

To edit a custom endpoint with the AWS Management Console, you can select the endpoint on the cluster detail page, or bring up the detail page for the endpoint, and choose the Edit action.
Editing a custom endpoint
AWS CLI

To edit a custom endpoint with the AWS CLI, run the `modify-db-cluster-endpoint` command.

The following commands change the set of DB instances that apply to a custom endpoint and optionally switches between the behavior of a static or exclusion list. The `--static-members` and `--excluded-members` parameters take a space-separated list of DB instance identifiers.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster-endpoint --db-cluster-endpoint-identifier my-custom-endpoint
  --static-members db-instance-id-1 db-instance-id-2 db-instance-id-3
  --region region_name

aws rds modify-db-cluster-endpoint --db-cluster-endpoint-identifier my-custom-endpoint
  --excluded-members db-instance-id-4 db-instance-id-5
  --region region_name
```

For Windows:

```bash
aws rds modify-db-cluster-endpoint --db-cluster-endpoint-identifier my-custom-endpoint
  --static-members db-instance-id-1 db-instance-id-2 db-instance-id-3
  --region region_name

aws rds modify-db-cluster-endpoint --db-cluster-endpoint-identifier my-custom-endpoint
  --excluded-members db-instance-id-4 db-instance-id-5
  --region region_name
```

RDS API

To edit a custom endpoint with the RDS API, run the `ModifyDBClusterEndpoint.html` operation.

Deleting a custom endpoint

Console

To delete a custom endpoint with the AWS Management Console, go to the cluster detail page, select the appropriate custom endpoint, and select the Delete action.

AWS CLI

To delete a custom endpoint with the AWS CLI, run the `delete-db-cluster-endpoint` command.
The following command deletes a custom endpoint. You don't need to specify the associated cluster, but you must specify the region.

For Linux, macOS, or Unix:

```bash
aws rds delete-db-cluster-endpoint --db-cluster-endpoint-identifier custom-end-point-id \ --region region_name
```

For Windows:

```bash
aws rds delete-db-cluster-endpoint --db-cluster-endpoint-identifier custom-end-point-id ^ --region region_name
```

**RDS API**

To delete a custom endpoint with the RDS API, run the **DeleteDBClusterEndpoint** operation.

**End-to-end AWS CLI example for custom endpoints**

The following tutorial uses AWS CLI examples with Unix shell syntax to show you might define a cluster with several "small" DB instances and a few "big" DB instances, and create custom endpoints to connect to each set of DB instances. To run similar commands on your own system, you should be familiar enough with the basics of working with Aurora clusters and AWS CLI usage to supply your own values for parameters such as region, subnet group, and VPC security group.

This example demonstrates the initial setup steps: creating an Aurora cluster and adding DB instances to it. This is a heterogeneous cluster, meaning not all the DB instances have the same capacity. Most instances use the AWS instance class `db.r4.4xlarge`, but the last two DB instances use `db.r4.16xlarge`. Each of these sample `create-db-instance` commands prints its output to the screen and saves a copy of the JSON in a file for later inspection.

```bash
aws rds create-db-cluster --db-cluster-identifier custom-endpoint-demo --engine aurora-mysql \ --engine-version 8.0.mysql_aurora.3.02.0 --master-username $MASTER_USER --manage-master-user-password \ --db-subnet-group-name $SUBNET_GROUP --vpc-security-group-ids $VPC_SECURITY_GROUP \ --region $REGION

for i in 01 02 03 04 05 06 07 08
do
    aws rds create-db-instance --db-instance-identifier custom-endpoint-demo-${i} \ --engine aurora --db-cluster-identifier custom-endpoint-demo --db-instance-class db.r4.4xlarge \ --region $REGION \ | tee custom-endpoint-demo-${i}.json
done

for i in 09 10
do
    aws rds create-db-instance --db-instance-identifier custom-endpoint-demo-${i} \ --engine aurora --db-cluster-identifier custom-endpoint-demo --db-instance-class db.r4.16xlarge \ --region $REGION \ | tee custom-endpoint-demo-${i}.json
done
```

The larger instances are reserved for specialized kinds of reporting queries. To make it unlikely for them to be promoted to the primary instance, the following example changes their promotion tier to the lowest priority. This example specifies the `--manage-master-user-password` option to generate the master user password and manage it in Secrets Manager. For more information, see **Password**
management with Amazon Aurora and AWS Secrets Manager (p. 2371). Alternatively, you can use the --master-password option to specify and manage the password yourself.

```bash
for i in 09 10
do
  aws rds modify-db-instance --db-instance-identifier custom-endpoint-demo-$i --region $REGION --promotion-tier 15
done
```

Suppose that you want to use the two "bigger" instances only for the most resource-intensive queries. To do this, you can first create a custom read-only endpoint. Then you can add a static list of members so that the endpoint connects only to those DB instances. Those instances are already in the lowest promotion tier, making it unlikely either of them will be promoted to the primary instance. If one of them is promoted to the primary instance, it becomes unreachable through this endpoint because we specified the READER type instead of the ANY type.

The following example demonstrates the create and modify endpoint commands, and sample JSON output showing the initial and modified state of the custom endpoint.

```bash
$ aws rds create-db-cluster-endpoint --region $REGION --db-cluster-identifier custom-endpoint-demo --db-cluster-endpoint-identifier big-instances --endpoint-type reader
{
  "EndpointType": "CUSTOM",
  "Endpoint": "big-instances.cluster-custom-c7tj4example.ca-central-1.rds.amazonaws.com",
  "DBClusterEndpointIdentifier": "big-instances",
  "DBClusterIdentifier": "custom-endpoint-demo",
  "StaticMembers": [],
  "DBClusterEndpointResourceIdentifier": "cluster-endpoint-W7PE3TLLFNSHXQKFU6J6NV5FHU",
  "ExcludedMembers": [],
  "CustomEndpointType": "READER",
  "Status": "creating",
}
```

```bash
$ aws rds modify-db-cluster-endpoint --db-cluster-endpoint-identifier big-instances --static-members custom-endpoint-demo-09 custom-endpoint-demo-10 --region $REGION
{
  "EndpointType": "CUSTOM",
  "ExcludedMembers": [],
  "DBClusterEndpointIdentifier": "big-instances",
  "DBClusterIdentifier": "custom-endpoint-demo",
  "StaticMembers": [
    "custom-endpoint-demo-10",
    "custom-endpoint-demo-09"
  ],
  "Status": "modifying",
  "Endpoint": "big-instances.cluster-custom-c7tj4example.ca-central-1.rds.amazonaws.com",
  "DBClusterIdentifier": "custom-endpoint-demo"
}
```

The default READER endpoint for the cluster can connect to either the "small" or "big" DB instances, making it impractical to predict query performance and scalability when the cluster becomes busy. To divide the workload cleanly between the sets of DB instances, you can ignore the default READER endpoint and create a second custom endpoint that connects to all other DB instances. The following example does so by creating a custom endpoint and then adding an exclusion list. Any other DB instances you add to the cluster later will be added to this endpoint automatically. The ANY type means that this endpoint is associated with eight instances in total: the primary instance and another seven
Aurora Replicas. If the example used the READER type, the custom endpoint would only be associated with the seven Aurora Replicas.

```bash
$ aws rds create-db-cluster-endpoint --region $REGION --db-cluster-identifier custom-endpoint-demo \
    --db-cluster-endpoint-identifier small-instances --endpoint-type any
{
    "Status": "creating",
    "DBClusterEndpointIdentifier": "small-instances",
    "CustomEndpointType": "ANY",
    "EndpointType": "CUSTOM",
    "Endpoint": "small-instances.cluster-custom-c7tj4example.ca-central-1.rds.amazonaws.com",
    "StaticMembers": [],
    "ExcludedMembers": [],
    "DBClusterEndpointResourceIdentifier": "cluster-endpoint-6RDDXQOC3AKKZT2PRD7ST37BMY"
}

$ aws rds modify-db-cluster-endpoint --db-cluster-endpoint-identifier small-instances \
    --excluded-members custom-endpoint-demo-09 custom-endpoint-demo-10 --region $REGION
{
    "DBClusterEndpointIdentifier": "small-instances",
    "DBClusterEndpointArn": "arn:aws:rds:ca-central-1:c7tj4example:cluster-endpoint:small-instances",
    "CustomEndpointType": "ANY",
    "Endpoint": "small-instances.cluster-custom-c7tj4example.ca-central-1.rds.amazonaws.com",
    "EndpointType": "CUSTOM",
    "ExcludedMembers": ["custom-endpoint-demo-09", "custom-endpoint-demo-10"],
    "StaticMembers": [],
    "DBClusterIdentifier": "custom-endpoint-demo",
    "Status": "modifying"
}
```

The following example checks the state of the endpoints for this cluster. The cluster still has its original cluster endpoint, with EndpointType of WRITER, which you would still use for administration, ETL, and other write operations. It still has its original READER endpoint, which you wouldn't use because each connection to it might be directed to a "small" or "big" DB instance. The custom endpoints make this behavior predictable, with connections guaranteed to use one of the "small" or "big" DB instances based on the endpoint you specify.

```bash
$ aws rds describe-db-cluster-endpoints --region $REGION
{
    "DBClusterEndpoints": [
        {
            "EndpointType": "WRITER",
            "Endpoint": "custom-endpoint-demo.cluster-c7tj4example.ca-central-1.rds.amazonaws.com",
            "Status": "available",
            "DBClusterIdentifier": "custom-endpoint-demo"
        },
        {
            "EndpointType": "READER",
            "Endpoint": "custom-endpoint-demo.cluster-ro-c7tj4example.ca-central-1.rds.amazonaws.com",
            "Status": "available",
```
The final examples demonstrate how successive database connections to the custom endpoints connect to the various DB instances in the Aurora cluster. The small-instances endpoint always connects to the db.r4.4xlarge DB instances, which are the lower-numbered hosts in this cluster.

```
$ mysql -h small-instances.cluster-custom-c7tj4example.ca-central-1.rds.amazonaws.com -u $MYUSER -p
mysql> select @aurora_server_id;
+------------------------------------------+
| @aurora_server_id | custom-endpoint-demo-02 |
| @aurora_server_id | custom-endpoint-demo-07 |
```

$ mysql -h small-instances.cluster-custom-c7tj4example.ca-central-1.rds.amazonaws.com -u $MYUSER -p
mysql> select @aurora_server_id;
+------------------------------------------+
| @aurora_server_id | custom-endpoint-demo-02 |
| @aurora_server_id | custom-endpoint-demo-07 |
```
Using the instance endpoints

Each DB instance in an Aurora cluster has its own built-in instance endpoint, whose name and other attributes are managed by Aurora. You can't create, delete, or modify this kind of endpoint. You might be familiar with instance endpoints if you use Amazon RDS. However, with Aurora you typically use the writer and reader endpoints more often than the instance endpoints.

In day-to-day Aurora operations, the main way that you use instance endpoints is to diagnose capacity or performance issues that affect one specific instance in an Aurora cluster. While connected to a specific instance, you can examine its status variables, metrics, and so on. Doing this can help you determine what's happening for that instance that's different from what's happening for other instances in the cluster.

In advanced use cases, you might configure some DB instances differently than others. In this case, use the instance endpoint to connect directly to an instance that is smaller, larger, or otherwise has different characteristics than the others. Also, set up failover priority so that this special DB instance is the last choice to take over as the primary instance. We recommend that you use custom endpoints instead of the instance endpoint in such cases. Doing so simplifies connection management and high availability as you add more DB instances to your cluster.

How Aurora endpoints work with high availability

For clusters where high availability is important, use the writer endpoint for read/write or general-purpose connections and the reader endpoint for read-only connections. The writer and reader endpoints manage DB instance failover better than instance endpoints do. Unlike the instance endpoints, the writer and reader endpoints automatically change which DB instance they connect to if a DB instance in your cluster becomes unavailable.

If the primary DB instance of a DB cluster fails, Aurora automatically fails over to a new primary DB instance. It does so by either promoting an existing Aurora Replica to a new primary DB instance or...
creating a new primary DB instance. If a failover occurs, you can use the writer endpoint to reconnect to the newly promoted or created primary DB instance, or use the reader endpoint to reconnect to one of the Aurora Replicas in the DB cluster. During a failover, the reader endpoint might direct connections to the new primary DB instance of a DB cluster for a short time after an Aurora Replica is promoted to the new primary DB instance.

If you design your own application logic to manage connections to instance endpoints, you can manually or programmatically discover the resulting set of available DB instances in the DB cluster. Use the describe-db-clusters AWS CLI command or DescribeDBClusters RDS API operation to find the DB cluster and reader endpoints, DB instances, whether DB instances are readers, and their promotion tiers. You can then confirm their instance classes after failover and connect to an appropriate instance endpoint.

For more information about failovers, see Fault tolerance for an Aurora DB cluster (p. 103).
Aurora DB instance classes

The DB instance class determines the computation and memory capacity of an Amazon Aurora DB instance. The DB instance class that you need depends on your processing power and memory requirements.

A DB instance class consists of both the DB instance class type and the size. For example, db.r6g is a memory-optimized DB instance class type powered by AWS Graviton2 processors. Within the db.r6g instance class type, db.r6g.2xlarge is a DB instance class. The size of this class is 2xlarge.

For more information about instance class pricing, see Amazon RDS pricing.

Topics

• DB instance class types (p. 84)
• Supported DB engines for DB instance classes (p. 86)
• Determining DB instance class support in AWS Regions (p. 91)
• Hardware specifications for DB instance classes for Aurora (p. 94)

DB instance class types

Amazon Aurora supports DB instance classes for the following use cases:

• Aurora Serverless v2 (p. 84)
• Memory-optimized (p. 84)
• Burstable-performance (p. 85)
• Optimized Reads (p. 86)

For more information about Amazon EC2 instance types, see Instance types in the Amazon EC2 documentation.

Aurora Serverless v2 instance class type

The following Aurora Serverless v2 type is available:

• db.serverless – A special DB instance class type used by Aurora Serverless v2. Aurora adjusts the compute, memory, and network resources dynamically as the workload changes. For usage details, see Using Aurora Serverless v2 (p. 1961).

Memory-optimized instance class type

The memory-optimized X family supports the following instance classes:

• db.x2g – Instance classes optimized for memory-intensive applications and powered by AWS Graviton2 processors. These instance classes offer low cost per GiB of memory.

You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton2 processors. To do so, complete the same steps as with any other DB instance modification.

The memory-optimized R family supports the following instance class types:

• db.r7g – Instance classes powered by AWS Graviton3 processors. These instance classes are ideal for running memory-intensive workloads.
You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton3 processors. To do so, complete the same steps as with any other DB instance modification.

- **db.r6g** – Instance classes powered by AWS Graviton2 processors. These instance classes are ideal for running memory-intensive workloads.

You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton2 processors. To do so, complete the same steps as with any other DB instance modification.

- **db.r6i** – Instance classes powered by 3rd Generation Intel Xeon Scalable processors. These instance classes are SAP-Certified and are an ideal fit for memory-intensive workloads in open-source databases such as MySQL and PostgreSQL.

- **db.r4** – These instance classes are supported only for Aurora PostgreSQL 11 and 12 versions. For all Aurora PostgreSQL DB clusters that use db.r4 DB instance classes, we recommend that you upgrade to a db.r5 or newer instance class as soon as possible.

The db.r4 instance classes aren't available for the Aurora I/O-Optimized cluster storage configuration.

- **db.r3** – Instance classes that provide memory optimization.

Amazon Aurora has started the end-of-life process for db.r3 DB instance classes using the following schedule, which includes upgrade recommendations. For all Aurora MySQL DB clusters that use db.r3 DB instance classes, we recommend that you upgrade to a db.r5 or higher DB instance class as soon as possible.

<table>
<thead>
<tr>
<th>Action or recommendation</th>
<th>Dates</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can no longer create Aurora MySQL DB clusters that use db.r3 DB instance classes.</td>
<td>Now</td>
</tr>
<tr>
<td>Amazon Aurora started automatic upgrades of Aurora MySQL DB clusters that use db.r3 DB instance classes to equivalent db.r5 or higher DB instance classes.</td>
<td>January 31, 2023</td>
</tr>
</tbody>
</table>

**Burstable-performance instance class types**

The following burstable-performance DB instance class types are available:

- **db.t4g** – General-purpose instance classes powered by Arm-based AWS Graviton2 processors. These instance classes deliver better price performance than previous burstable-performance DB instance classes for a broad set of burstable general-purpose workloads. Amazon RDS db.t4g instances are configured for Unlimited mode. This means that they can burst beyond the baseline over a 24-hour window for an additional charge.

You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton2 processors. To do so, complete the same steps as with any other DB instance modification.

- **db.t3** – Instance classes that provide a baseline performance level, with the ability to burst to full CPU usage. The db.t3 instances are configured for Unlimited mode. These instance classes provide more computing capacity than the previous db.t2 instance classes. They are powered by the AWS Nitro System, a combination of dedicated hardware and lightweight hypervisor. We recommend using these instance classes only for development and test servers, or other non-production servers.

The db.t2 instance classes aren't available for the Aurora I/O-Optimized cluster storage configuration.
Note
We recommend using the T DB instance classes only for development, test, or other nonproduction servers. For more detailed recommendations for the T instance classes, see Using T instance classes for development and testing (p. 1103).

For DB instance class hardware specifications, see Hardware specifications for DB instance classes for Aurora (p. 94).

Optimized Reads instance class type

The following Optimized Reads instance class types are available:

- **db.r6gd** – Instance classes powered by AWS Graviton2 processors. These instance classes are ideal for running memory-intensive workloads and offer local NVMe-based SSD block-level storage for applications that need high-speed, low latency local storage.

- **db.r6id** – Instance classes powered by 3rd Generation Intel Xeon Scalable processors. These instance classes are SAP-Certified and are an ideal fit for memory-intensive workloads. They offer a maximum memory of 1 TiB and up to 7.6 TB of direct-attached NVMe-based SSD storage.

Supported DB engines for DB instance classes

In the following table, you can find details about supported Amazon Aurora DB instance classes for the Aurora DB engines.

<table>
<thead>
<tr>

Determining DB instance class support in AWS Regions

To determine the DB instance classes supported by each DB engine in a specific AWS Region, you can take one of several approaches. You can use the AWS Management Console, the Amazon RDS Pricing page, or the describe-orderable-db-instance-options AWS CLI command.

**Note**
When you perform operations with the AWS Management Console, it automatically shows the supported DB instance classes for a specific DB engine, DB engine version, and AWS Region. Examples of the operations that you can perform include creating and modifying a DB instance.

**Contents**

- Using the Amazon RDS pricing page to determine DB instance class support in AWS Regions (p. 91)
- Using the AWS CLI to determine DB instance class support in AWS Regions (p. 91)
  - Listing the DB instance classes that are supported by a specific DB engine version in an AWS Region (p. 92)
  - Listing the DB engine versions that support a specific DB instance class in an AWS Region (p. 93)

**Using the Amazon RDS pricing page to determine DB instance class support in AWS Regions**

You can use the Amazon Aurora Pricing page to determine the DB instance classes supported by each DB engine in a specific AWS Region.

**To use the pricing page to determine the DB instance classes supported by each engine in a Region**

1. Go to Amazon Aurora Pricing.
2. Choose an Amazon Aurora engine in the AWS Pricing Calculator section.
3. In Choose a Region, choose an AWS Region.
4. In Cluster Configuration Option, choose a configuration option.
5. Use the section for compatible instances to view the supported DB instance classes.
6. (Optional) Choose other options in the calculator, and then choose Save and view summary or Save and add service.

**Using the AWS CLI to determine DB instance class support in AWS Regions**

You can use the AWS CLI to determine which DB instance classes are supported for specific DB engines and DB engine versions in an AWS Region.

To use the AWS CLI examples following, enter valid values for the DB engine, DB engine version, DB instance class, and AWS Region. The following table shows the valid DB engine values.
Determining DB instance class support in AWS Regions

<table>
<thead>
<tr>
<th>Engine name</th>
<th>Engine value in CLI commands</th>
<th>More information about versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.7-compatible and 8.0-compatible Aurora</td>
<td>aurora-mysql</td>
<td>Database engine updates for Amazon Aurora MySQL version 2 and Database engine updates for Amazon Aurora MySQL version 3 in the Release Notes for Aurora MySQL</td>
</tr>
<tr>
<td>Aurora PostgreSQL</td>
<td>aurora-postgresql</td>
<td>Release Notes for Aurora PostgreSQL</td>
</tr>
</tbody>
</table>

For information about AWS Region names, see [AWS Regions (p. 16)](#).

The following examples demonstrate how to determine DB instance class support in an AWS Region using the [describe-orderable-db-instance-options] AWS CLI command.

**Topics**

- Listing the DB instance classes that are supported by a specific DB engine version in an AWS Region (p. 92)
- Listing the DB engine versions that support a specific DB instance class in an AWS Region (p. 93)

### Listing the DB instance classes that are supported by a specific DB engine version in an AWS Region

To list the DB instance classes that are supported by a specific DB engine version in an AWS Region, run the following command.

For Linux, macOS, or Unix:

```bash
aws rds describe-orderable-db-instance-options --engine aurora-postgresql --engine-version 15.3 --query "OrderableDBInstanceOptions[].{DBInstanceClass:DBInstanceClass,SupportedEngineModes:SupportedEngineModes[0]}" --output table --region region
```

For Windows:

```bash
aws rds describe-orderable-db-instance-options --engine aurora-postgresql --engine-version 15.3 --query "OrderableDBInstanceOptions[].{DBInstanceClass:DBInstanceClass,SupportedEngineModes:SupportedEngineModes[0]}" --output table --region region
```

The output also shows the engine modes that are supported for each DB instance class.

For example, the following command lists the supported DB instance classes for version 13.6 of the Aurora PostgreSQL DB engine in US East (N. Virginia).

For Linux, macOS, or Unix:

```bash
aws rds describe-orderable-db-instance-options --engine aurora-postgresql --engine-version 15.3 --query "OrderableDBInstanceOptions[].{DBInstanceClass:DBInstanceClass,SupportedEngineModes:SupportedEngineModes[0]}" --output table
```
For Windows:

```
aws rds describe-orderable-db-instance-options --engine aurora-postgresql --engine-version 15.3
   --query "OrderableDBInstanceOptions[].
   {DBInstanceClass:DBInstanceClass,SupportedEngineModes:SupportedEngineModes[0]}"
   --output table
   --region us-east-1
```

Listing the DB engine versions that support a specific DB instance class in an AWS Region

To list the DB engine versions that support a specific DB instance class in an AWS Region, run the following command.

For Linux, macOS, or Unix:

```
aws rds describe-orderable-db-instance-options --engine engine --db-instance-class DB_instance_class
   --query "OrderableDBInstanceOptions[].
   {EngineVersion:EngineVersion,SupportedEngineModes:SupportedEngineModes[0]}"
   --output table
   --region region
```

For Windows:

```
aws rds describe-orderable-db-instance-options --engine engine --db-instance-class DB_instance_class
   --query "OrderableDBInstanceOptions[].
   {EngineVersion:EngineVersion,SupportedEngineModes:SupportedEngineModes[0]}"
   --output table
   --region region
```

The output also shows the engine modes that are supported for each DB engine version.

For example, the following command lists the DB engine versions of the Aurora PostgreSQL DB engine that support the db.r5.large DB instance class in US East (N. Virginia).

For Linux, macOS, or Unix:

```
aws rds describe-orderable-db-instance-options --engine aurora-postgresql --db-instance-class db.r7g.large
   --query "OrderableDBInstanceOptions[].
   {EngineVersion:EngineVersion,SupportedEngineModes:SupportedEngineModes[0]}"
   --output table
   --region us-east-1
```

For Windows:

```
aws rds describe-orderable-db-instance-options --engine aurora-postgresql --db-instance-class db.r7g.large
   --query "OrderableDBInstanceOptions[].
   {EngineVersion:EngineVersion,SupportedEngineModes:SupportedEngineModes[0]}"
   --output table
   --region us-east-1
```
Hardware specifications for DB instance classes for Aurora

The following terminology is used to describe hardware specifications for DB instance classes:

vCPU

The number of virtual central processing units (CPUs). A virtual CPU is a unit of capacity that you can use to compare DB instance classes. Instead of purchasing or leasing a particular processor to use for several months or years, you are renting capacity by the hour. Our goal is to make a consistent and specific amount of CPU capacity available, within the limits of the actual underlying hardware.

ECU

The relative measure of the integer processing power of an Amazon EC2 instance. To make it easy for developers to compare CPU capacity between different instance classes, we have defined an Amazon EC2 Compute Unit. The amount of CPU that is allocated to a particular instance is expressed in terms of these EC2 Compute Units. One ECU currently provides CPU capacity equivalent to a 1.0–1.2 GHz 2007 Opteron or 2007 Xeon processor.

Memory (GiB)

The RAM, in gibibytes, allocated to the DB instance. There is often a consistent ratio between memory and vCPU. As an example, take the db.r4 instance class, which has a memory to vCPU ratio similar to the db.r5 instance class. However, for most use cases the db.r5 instance class provides better, more consistent performance than the db.r4 instance class.

Max. EBS bandwidth (Mbps)

The maximum EBS bandwidth in megabits per second. Divide by 8 to get the expected throughput in megabytes per second.

Note

This figure refers to I/O bandwidth for local storage within the DB instance. It doesn’t apply to communication with the Aurora cluster volume.

Network bandwidth

The network speed relative to other DB instance classes.

In the following table, you can find hardware details about the Amazon RDS DB instance classes for Aurora.

For information about Aurora DB engine support for each DB instance class, see Supported DB engines for DB instance classes (p. 86).

** The r3.8xlarge DB instance class doesn't have dedicated EBS bandwidth and therefore doesn't offer EBS optimization. For this instance class, network traffic and Amazon EBS traffic share the same 10-gigabit network interface.

---

# Amazon Aurora storage and reliability

Following, you can learn about the Aurora storage subsystem. Aurora uses a distributed and shared storage architecture that is an important factor in performance, scalability, and reliability for Aurora clusters.

**Topics**

- Overview of Amazon Aurora storage (p. 97)
- What the cluster volume contains (p. 97)
- Storage configurations for Amazon Aurora DB clusters (p. 97)
- How Aurora storage automatically resizes (p. 98)
- How Aurora data storage is billed (p. 99)
- Amazon Aurora reliability (p. 99)

## Overview of Amazon Aurora storage

Aurora data is stored in the *cluster volume*, which is a single, virtual volume that uses solid state drives (SSDs). A cluster volume consists of copies of the data across three Availability Zones in a single AWS Region. Because the data is automatically replicated across Availability Zones, your data is highly durable with less possibility of data loss. This replication also ensures that your database is more available during a failover. It does so because the data copies already exist in the other Availability Zones and continue to serve data requests to the DB instances in your DB cluster. The amount of replication is independent of the number of DB instances in your cluster.

Aurora uses separate local storage for nonpersistent, temporary files. This includes files that are used for such purposes as sorting large data sets during query processing, and building indexes. For more information, see Temporary storage limits for Aurora MySQL (p. 878) and Temporary storage limits for Aurora PostgreSQL (p. 1399).

## What the cluster volume contains

The Aurora cluster volume contains all your user data, schema objects, and internal metadata such as the system tables and the binary log. For example, Aurora stores all the tables, indexes, binary large objects (BLOBs), stored procedures, and so on for an Aurora cluster in the cluster volume.

The Aurora shared storage architecture makes your data independent from the DB instances in the cluster. For example, you can add a DB instance quickly because Aurora doesn't make a new copy of the table data. Instead, the DB instance connects to the shared volume that already contains all your data. You can remove a DB instance from a cluster without removing any of the underlying data from the cluster. Only when you delete the entire cluster does Aurora remove the data.

## Storage configurations for Amazon Aurora DB clusters

Amazon Aurora has two DB cluster storage configurations:
• **Aurora I/O-Optimized** – Improved price performance and predictability for I/O-intensive applications. You pay only for the usage and storage of your DB clusters, with no additional charges for read and write I/O operations.

Aurora I/O-Optimized is the best choice when your I/O spending is 25% or more of your total Aurora database spending.

You can choose Aurora I/O-Optimized when you create or modify a DB cluster with a DB engine version that supports the Aurora I/O-Optimized cluster configuration. You can switch from Aurora I/O-Optimized to Aurora Standard at any time.

• **Aurora Standard** – Cost-effective pricing for many applications with moderate I/O usage. In addition to the usage and storage of your DB clusters, you also pay a standard rate per 1 million requests for I/O operations.

Aurora Standard is the best choice when your I/O spending is less than 25% of your total Aurora database spending.

You can switch from Aurora Standard to Aurora I/O-Optimized once every 30 days.

For information on AWS Region and version support, see [Aurora cluster storage configurations (p. 27)](#).

For more information on pricing for Amazon Aurora storage configurations, see [Amazon Aurora pricing](#).

For information on choosing the storage configuration when creating a DB cluster, see [Creating a DB cluster (p. 183)](#). For information on modifying the storage configuration for a DB cluster, see [Settings for Amazon Aurora (p. 272)](#).

### How Aurora storage automatically resizes

Aurora cluster volumes automatically grow as the amount of data in your database increases. The maximum size for an Aurora cluster volume is 128 tebibytes (TiB) or 64 TiB, depending on the DB engine version. For details about the maximum size for a specific version, see [Amazon Aurora size limits (p. 2510)](#). This automatic storage scaling is combined with a high-performance and highly distributed storage subsystem. These make Aurora a good choice for your important enterprise data when your main objectives are reliability and high availability.

To display the volume status, see [Displaying volume status for an Aurora MySQL DB cluster (p. 902)](#) or [Displaying volume status for an Aurora PostgreSQL DB cluster (p. 1405)](#). For ways to balance storage costs against other priorities, [Storage scaling (p. 297)](#) describes how to monitor the Amazon Aurora metrics `AuroraVolumeBytesLeftTotal` and `VolumeBytesUsed` in CloudWatch.

When Aurora data is removed, the space allocated for that data is freed. Examples of removing data include dropping or truncating a table. This automatic reduction in storage usage helps you to minimize storage charges.

**Note**

The storage limits and dynamic resizing behavior discussed here apply to persistent tables and other data stored in the cluster volume.

For Aurora PostgreSQL, temporary table data is stored in the local DB instance.

For Aurora MySQL version 2, temporary table data is stored by default in the cluster volume for writer instances and in local storage for reader instances. For more information, see [Storage engine for on-disk temporary tables (p. 812)](#).

For Aurora MySQL version 3, temporary table data is stored in the local DB instance or in the cluster volume. For more information, see [New temporary table behavior in Aurora MySQL version 3 (p. 783)](#).

The maximum size of temporary tables that reside in local storage is limited by the maximum local storage size of the DB instance. The local storage size depends on the instance class that
you use. For more information, see Temporary storage limits for Aurora MySQL (p. 878) and Temporary storage limits for Aurora PostgreSQL (p. 1399).

Some storage features, such as the maximum size of a cluster volume and automatic resizing when data is removed, depend on the Aurora version of your cluster. For more information, see Storage scaling (p. 297). You can also learn how to avoid storage issues and how to monitor the allocated storage and free space in your cluster.

How Aurora data storage is billed

Even though an Aurora cluster volume can grow up to 128 tebibytes (TiB), you are only charged for the space that you use in an Aurora cluster volume. In earlier Aurora versions, the cluster volume could reuse space that was freed up when you removed data, but the allocated storage space would never decrease. Now when Aurora data is removed, such as by dropping a table or database, the overall allocated space decreases by a comparable amount. Thus, you can reduce storage charges by dropping tables, indexes, databases, and so on that you no longer need.

Tip
For earlier versions without the dynamic resizing feature, resetting the storage usage for a cluster involved doing a logical dump and restoring to a new cluster. That operation can take a long time for a substantial volume of data. If you encounter this situation, consider upgrading your cluster to a version that supports dynamic volume resizing.

For information about which Aurora versions support dynamic resizing, and how to minimize storage charges by monitoring storage usage for your cluster, see Storage scaling (p. 297). For information about Aurora backup storage billing, see Understanding Amazon Aurora backup storage usage (p. 433). For pricing information about Aurora data storage, see Amazon RDS for Aurora pricing.

Amazon Aurora reliability

Aurora is designed to be reliable, durable, and fault tolerant. You can architect your Aurora DB cluster to improve availability by doing things such as adding Aurora Replicas and placing them in different Availability Zones, and also Aurora includes several automatic features that make it a reliable database solution.

Topics
- Storage auto-repair (p. 99)
- Survivable page cache (p. 99)
- Recovery from unplanned restarts (p. 100)

Storage auto-repair

Because Aurora maintains multiple copies of your data in three Availability Zones, the chance of losing data as a result of a disk failure is greatly minimized. Aurora automatically detects failures in the disk volumes that make up the cluster volume. When a segment of a disk volume fails, Aurora immediately repairs the segment. When Aurora repairs the disk segment, it uses the data in the other volumes that make up the cluster volume to ensure that the data in the repaired segment is current. As a result, Aurora avoids data loss and reduces the need to perform a point-in-time restore to recover from a disk failure.

Survivable page cache

In Aurora, each DB instance's page cache is managed in a separate process from the database, which allows the page cache to survive independently of the database. (The page cache is also called the InnoDB buffer pool on Aurora MySQL and the buffer cache on Aurora PostgreSQL.)
In the unlikely event of a database failure, the page cache remains in memory, which keeps current data pages “warm” in the page cache when the database restarts. This provides a performance gain by bypassing the need for the initial queries to execute read I/O operations to "warm up" the page cache.

For Aurora MySQL, page cache behavior when rebooting and failing over is the following:

- Versions earlier than 2.10 – When the writer DB instance reboots, the page cache on the writer instance survives, but reader DB instances lose their page caches.
- Version 2.10 and higher – You can reboot the writer instance without rebooting the reader instances.
  - If the reader instances don’t reboot when the writer instance reboots, they don’t lose their page caches.
  - If the reader instances reboot when the writer instance reboots, they do lose their page caches.
- When a reader instance reboots, the page caches on the writer and reader instances both survive.
- When the DB cluster fails over, the effect is similar to when a writer instance reboots. On the new writer instance (previously the reader instance) the page cache survives, but on the reader instance (previously the writer instance), the page cache doesn’t survive.

For Aurora PostgreSQL, you can use cluster cache management to preserve the page cache of a designated reader instance that becomes the writer instance after failover. For more information, see Fast recovery after failover with cluster cache management for Aurora PostgreSQL (p. 1478).

Recovery from unplanned restarts

Aurora is designed to recover from an unplanned restart almost instantaneously and continue to serve your application data without the binary log. Aurora recovers asynchronously on parallel threads, so that your database is open and available immediately after an unplanned restart.

For more information, see Fault tolerance for an Aurora DB cluster (p. 103) and Optimizations to reduce database restart time (p. 783).

The following are considerations for binary logging and unplanned restart recovery on Aurora MySQL:

- Enabling binary logging on Aurora directly affects the recovery time after an unplanned restart, because it forces the DB instance to perform binary log recovery.
- The type of binary logging used affects the size and efficiency of logging. For the same amount of database activity, some formats log more information than others in the binary logs. The following settings for the binlog_format parameter result in different amounts of log data:
  - ROW – The most log data
  - STATEMENT – The least log data
  - MIXED – A moderate amount of log data that usually provides the best combination of data integrity and performance

The amount of binary log data affects recovery time. If there is more data logged in the binary logs, the DB instance must process more data during recovery, which increases recovery time.

- To reduce computational overhead and improve recovery times with binary logging, you can use enhanced binlog. Enhanced binlog improves the database recovery time by up to 99%. For more information, see Setting up enhanced binlog (p. 1037).
- Aurora does not need the binary logs to replicate data within a DB cluster or to perform point-in-time restore (PITR).
- If you don't need the binary log for external replication (or an external binary log stream), we recommend that you set the binlog_format parameter to OFF to disable binary logging. Doing so reduces recovery time.
For more information about Aurora binary logging and replication, see Replication with Amazon Aurora (p. 104). For more information about the implications of different MySQL replication types, see Advantages and disadvantages of statement-based and row-based replication in the MySQL documentation.

Amazon Aurora security

Security for Amazon Aurora is managed at three levels:

• To control who can perform Amazon RDS management actions on Aurora DB clusters and DB instances, you use AWS Identity and Access Management (IAM). When you connect to AWS using IAM credentials, your AWS account must have IAM policies that grant the permissions required to perform Amazon RDS management operations. For more information, see Identity and access management for Amazon Aurora (p. 2400).

If you are using IAM to access the Amazon RDS console, you must first log on to the AWS Management Console with your user credentials, and then go to the Amazon RDS console at https://console.aws.amazon.com/rds.

• Aurora DB clusters must be created in a virtual private cloud (VPC) based on the Amazon VPC service. To control which devices and Amazon EC2 instances can open connections to the endpoint and port of the DB instance for Aurora DB clusters in a VPC, you use a VPC security group. You can make these endpoint and port connections using Transport Layer Security (TLS)/Secure Sockets Layer (SSL). In addition, firewall rules at your company can control whether devices running at your company can open connections to a DB instance. For more information on VPCs, see Amazon VPC VPCs and Amazon Aurora (p. 2478).

• To authenticate logins and permissions for an Amazon Aurora DB cluster, you can take either of the following approaches, or a combination of them.

  • You can take the same approach as with a stand-alone DB instance of MySQL or PostgreSQL.

    Techniques for authenticating logins and permissions for stand-alone DB instances of MySQL or PostgreSQL, such as using SQL commands or modifying database schema tables, also work with Aurora. For more information, see Security with Amazon Aurora MySQL (p. 813) or Security with Amazon Aurora PostgreSQL (p. 1233).

  • You can use IAM database authentication.

    With IAM database authentication, you authenticate to your Aurora DB cluster by using a user or IAM role and an authentication token. An authentication token is a unique value that is generated using the Signature Version 4 signing process. By using IAM database authentication, you can use the same credentials to control access to your AWS resources and your databases. For more information, see IAM database authentication (p. 2432).

  • You can use Kerberos authentication for Aurora PostgreSQL and Aurora MySQL.

    You can use Kerberos to authenticate users when they connect to your Aurora PostgreSQL and Aurora MySQLDB cluster. In this case, your DB cluster works with AWS Directory Service for Microsoft Active Directory to enable Kerberos authentication. AWS Directory Service for Microsoft Active Directory is also called AWS Managed Microsoft AD. Keeping all of your credentials in the same directory can save you time and effort. You have a centralized place for storing and managing credentials for multiple DB clusters. Using a directory can also improve your overall security profile. For more information, see Using Kerberos authentication with Aurora PostgreSQL (p. 1252) and Using Kerberos authentication for Aurora MySQL (p. 823).

For information about configuring security, see Security in Amazon Aurora (p. 2367).
Using SSL with Aurora DB clusters

Amazon Aurora DB clusters support Secure Sockets Layer (SSL) connections from applications using the same process and public key as Amazon RDS DB instances. For more information, see Security with Amazon Aurora MySQL (p. 813), Security with Amazon Aurora PostgreSQL (p. 1233), or Using TLS/SSL with Aurora Serverless v1 (p. 2026).

High availability for Amazon Aurora

The Amazon Aurora architecture involves separation of storage and compute. Aurora includes some high availability features that apply to the data in your DB cluster. The data remains safe even if some or all of the DB instances in the cluster become unavailable. Other high availability features apply to the DB instances. These features help to make sure that one or more DB instances are ready to handle database requests from your application.

Topics

- High availability for Aurora data (p. 102)
- High availability for Aurora DB instances (p. 102)
- High availability across AWS Regions with Aurora global databases (p. 103)
- Fault tolerance for an Aurora DB cluster (p. 103)
- High availability with Amazon RDS Proxy (p. 104)

High availability for Aurora data

Aurora stores copies of the data in a DB cluster across multiple Availability Zones in a single AWS Region. Aurora stores these copies regardless of whether the instances in the DB cluster span multiple Availability Zones. For more information on Aurora, see Managing an Amazon Aurora DB cluster (p. 248).

When data is written to the primary DB instance, Aurora synchronously replicates the data across Availability Zones to six storage nodes associated with your cluster volume. Doing so provides data redundancy, eliminates I/O freezes, and minimizes latency spikes during system backups. Running a DB instance with high availability can enhance availability during planned system maintenance, and help protect your databases against failure and Availability Zone disruption. For more information on Availability Zones, see Regions and Availability Zones (p. 16).

High availability for Aurora DB instances

After you create the primary (writer) instance, you can create up to 15 read-only Aurora Replicas. The Aurora Replicas are also known as reader instances.

During day-to-day operations, you can offload some of the work for read-intensive applications by using the reader instances to process SELECT queries. When a problem affects the primary instance, one of these reader instances takes over as the primary instance. This mechanism is known as failover. Many Aurora features apply to the failover mechanism. For example, Aurora detects database problems and activates the failover mechanism automatically when necessary. Aurora also has features that reduce the time for failover to complete. Doing so minimizes the time that the database is unavailable for writing during a failover.

To use a connection string that stays the same even when a failover promotes a new primary instance, you connect to the cluster endpoint. The cluster endpoint always represents the current primary instance in the cluster. For more information about the cluster endpoint, see Amazon Aurora connection management (p. 62).
Within each AWS Region, Availability Zones (AZs) represent locations that are distinct from each other to provide isolation in case of outages. We recommend that you distribute the primary instance and reader instances in your DB cluster across multiple Availability Zones to improve the availability of your DB cluster. That way, an issue that affects an entire Availability Zone doesn't cause an outage for your cluster.

You can set up a Multi-AZ cluster by making a simple choice when you create the cluster. The choice is simple whether you use the AWS Management Console, the AWS CLI, or the Amazon RDS API. You can also make an existing Aurora cluster into a Multi-AZ cluster by adding a new reader instance and specifying a different Availability Zone.

For high availability across multiple AWS Regions, you can set up Aurora global databases. Each Aurora global database spans multiple AWS Regions, enabling low latency global reads and disaster recovery from outages across an AWS Region. Aurora automatically handles replicating all data and updates from the primary AWS Region to each of the secondary Regions. For more information, see Using Amazon Aurora global databases (p. 1800).

Fault tolerance for an Aurora DB cluster

An Aurora DB cluster is fault tolerant by design. The cluster volume spans multiple Availability Zones (AZs) in a single AWS Region, and each Availability Zone contains a copy of the cluster volume data. This functionality means that your DB cluster can tolerate a failure of an Availability Zone without any loss of data and only a brief interruption of service.

If the primary instance in a DB cluster fails, Aurora automatically fails over to a new primary instance in one of two ways:

- By promoting an existing Aurora Replica to the new primary instance
- By creating a new primary instance

If the DB cluster has one or more Aurora Replicas, then an Aurora Replica is promoted to the primary instance during a failure event. A failure event results in a brief interruption, during which read and write operations fail with an exception. However, service is typically restored in less than 60 seconds, and often less than 30 seconds. To increase the availability of your DB cluster, we recommend that you create at least one or more Aurora Replicas in two or more different Availability Zones.

Tip
In Aurora MySQL 2.10 and higher, you can improve availability during a failover by having more than one reader DB instance in a cluster. In Aurora MySQL 2.10 and higher, Aurora restarts only the writer DB instance and the reader instance to which it fails over. Other reader instances in the cluster remain available during a failover to continue processing queries through connections to the reader endpoint. You can also improve availability during a failover by using RDS Proxy with your Aurora DB cluster. For more information, see High availability with Amazon RDS Proxy (p. 104).

You can customize the order in which your Aurora Replicas are promoted to the primary instance after a failure by assigning each replica a priority. Priorities range from 0 for the highest priority to 15 for the lowest priority. If the primary instance fails, Amazon RDS promotes the Aurora Replica with the highest priority to the new primary instance. You can modify the priority of an Aurora Replica at any time. Modifying the priority doesn't trigger a failover.

More than one Aurora Replica can share the same priority, resulting in promotion tiers. If two or more Aurora Replicas share the same priority, then Amazon RDS promotes the replica that is largest in size. If
two or more Aurora Replicas share the same priority and size, then Amazon RDS promotes an arbitrary replica in the same promotion tier.

If the DB cluster doesn't contain any Aurora Replicas, then the primary instance is recreated in the same AZ during a failure event. A failure event results in an interruption during which read and write operations fail with an exception. Service is restored when the new primary instance is created, which typically takes less than 10 minutes. Promoting an Aurora Replica to the primary instance is much faster than creating a new primary instance.

Suppose that the primary instance in your cluster is unavailable because of an outage that affects an entire AZ. In this case, the way to bring a new primary instance online depends on whether your cluster uses a Multi-AZ configuration:

- If your provisioned or Aurora Serverless v2 cluster contains any reader instances in other AZs, Aurora uses the failover mechanism to promote one of those reader instances to be the new primary instance.
- If your provisioned or Aurora Serverless v2 cluster only contains a single DB instance, or if the primary instance and all reader instances are in the same AZ, make sure to manually create one or more new DB instances in another AZ.
- If your cluster uses Aurora Serverless v1, Aurora automatically creates a new DB instance in another AZ. However, this process involves a host replacement and thus takes longer than a failover.

**Note**

Amazon Aurora also supports replication with an external MySQL database, or an RDS MySQL DB instance. For more information, see Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication) (p. 1015).

### High availability with Amazon RDS Proxy

With RDS Proxy, you can build applications that can transparently tolerate database failures without needing to write complex failure handling code. The proxy automatically routes traffic to a new database instance while preserving application connections. It also bypasses Domain Name System (DNS) caches to reduce failover times by up to 66% for Aurora Multi-AZ databases. For more information, see Using Amazon RDS Proxy for Aurora (p. 1879).

### Replication with Amazon Aurora

There are several replication options with Aurora. Each Aurora DB cluster has built-in replication between multiple DB instances in the same cluster. You can also set up replication with your Aurora cluster as the source or the target. When you replicate data into or out of an Aurora cluster, you can choose between built-in features such as Aurora global databases or the traditional replication mechanisms for the MySQL or PostgreSQL DB engines. You can choose the appropriate options based on which one provides the right combination of high availability, convenience, and performance for your needs. The following sections explain how and when to choose each technique.

**Topics**

- [Aurora Replicas](#)
- [Replication with Aurora MySQL](#)
- [Replication with Aurora PostgreSQL](#)

### Aurora Replicas

When you create a second, third, and so on DB instance in an Aurora provisioned DB cluster, Aurora automatically sets up replication from the writer DB instance to all the other DB instances. These other
DB instances are read-only and are known as Aurora Replicas. We also refer to them as reader instances when discussing the ways that you can combine writer and reader DB instances within a cluster.

Aurora Replicas have two main purposes. You can issue queries to them to scale the read operations for your application. You typically do so by connecting to the reader endpoint of the cluster. That way, Aurora can spread the load for read-only connections across as many Aurora Replicas as you have in the cluster. Aurora Replicas also help to increase availability. If the writer instance in a cluster becomes unavailable, Aurora automatically promotes one of the reader instances to take its place as the new writer.

An Aurora DB cluster can contain up to 15 Aurora Replicas. The Aurora Replicas can be distributed across the Availability Zones that a DB cluster spans within an AWS Region.

The data in your DB cluster has its own high availability and reliability features, independent of the DB instances in the cluster. If you aren't familiar with Aurora storage features, see Overview of Amazon Aurora storage (p. 97). The DB cluster volume is physically made up of multiple copies of the data for the DB cluster. The primary instance and the Aurora Replicas in the DB cluster all see the data in the cluster volume as a single logical volume.

As a result, all Aurora Replicas return the same data for query results with minimal replica lag. This lag is usually much less than 100 milliseconds after the primary instance has written an update. Replica lag varies depending on the rate of database change. That is, during periods where a large amount of write operations occur for the database, you might see an increase in replica lag.

**Note**

If an Aurora Replica loses communication with the writer DB instance for more than 60 seconds, that Aurora Replica is restarted.

Aurora Replicas work well for read scaling because they are fully dedicated to read operations on your cluster volume. Write operations are managed by the primary instance. Because the cluster volume is shared among all DB instances in your DB cluster, minimal additional work is required to replicate a copy of the data for each Aurora Replica.

To increase availability, you can use Aurora Replicas as failover targets. That is, if the primary instance fails, an Aurora Replica is promoted to the primary instance. There is a brief interruption during which read and write requests made to the primary instance fail with an exception.

Promoting an Aurora Replica by failover is much faster than recreating the primary instance. If your Aurora DB cluster doesn't include any Aurora Replicas, then your DB cluster isn't available while your DB instance is recovering from the failure.

When failover happens, some of the Aurora Replicas might be rebooted, depending on the DB engine version. For example, in Aurora MySQL 2.10 and higher, Aurora restarts only the writer DB instance and the failover target during a failover. For more information about the rebooting behavior of different Aurora DB engine versions, see Rebooting an Amazon Aurora DB cluster or Amazon Aurora DB instance (p. 358). For information about what happens to page caches when rebooting or failover, see Survivable page cache (p. 99).

For high-availability scenarios, we recommend that you create one or more Aurora Replicas. These should be of the same DB instance class as the primary instance and in different Availability Zones for your Aurora DB cluster. For more information about Aurora Replicas as failover targets, see Fault tolerance for an Aurora DB cluster (p. 103).

You can't create an encrypted Aurora Replica for an unencrypted Aurora DB cluster. You can't create an unencrypted Aurora Replica for an encrypted Aurora DB cluster.

**Tip**

You can use Aurora Replicas within an Aurora cluster as your only form of replication to keep your data highly available. You can also combine the built-in Aurora replication with the other types of replication. Doing so can help to provide an extra level of high availability and geographic distribution of your data.
Replication with Aurora MySQL

In addition to Aurora Replicas, you have the following options for replication with Aurora MySQL:

- Aurora MySQL DB clusters in different AWS Regions.
  - You can replicate data across multiple Regions by using an Aurora global database. For details, see High availability across AWS Regions with Aurora global databases (p. 103)
  - You can create an Aurora read replica of an Aurora MySQL DB cluster in a different AWS Region, by using MySQL binary log (binlog) replication. Each cluster can have up to five read replicas created this way, each in a different Region.
- Two Aurora MySQL DB clusters in the same Region, by using MySQL binary log (binlog) replication.
- An RDS for MySQL DB instance as the source of data and an Aurora MySQL DB cluster, by creating an Aurora read replica of an RDS for MySQL DB instance. Typically, you use this approach for migration to Aurora MySQL, rather than for ongoing replication.

For more information about replication with Aurora MySQL, see Replication with Amazon Aurora MySQL (p. 984).

Replication with Aurora PostgreSQL

In addition to Aurora Replicas, you have the following options for replication with Aurora PostgreSQL:

- An Aurora primary DB cluster in one Region and up to five read-only secondary DB clusters in different Regions by using an Aurora global database. Aurora PostgreSQL doesn't support cross-Region Aurora Replicas. However, you can use Aurora global database to scale your Aurora PostgreSQL DB cluster’s read capabilities to more than one AWS Region and to meet availability goals. For more information, see Using Amazon Aurora global databases (p. 1800).
- Two Aurora PostgreSQL DB clusters in the same Region, by using PostgreSQL’s logical replication feature.
- An RDS for PostgreSQL DB instance as the source of data and an Aurora PostgreSQL DB cluster, by creating an Aurora read replica of an RDS for PostgreSQL DB instance. Typically, you use this approach for migration to Aurora PostgreSQL, rather than for ongoing replication.

For more information about replication with Aurora PostgreSQL, see Replication with Amazon Aurora PostgreSQL (p. 1504).

DB instance billing for Aurora

Amazon RDS provisioned instances in an Amazon Aurora cluster are billed based on the following components:

- DB instance hours (per hour) – Based on the DB instance class of the DB instance (for example, db.t2.small or db.m4.large). Pricing is listed on a per-hour basis, but bills are calculated down to the second and show times in decimal form. RDS usage is billed in 1-second increments, with a minimum of 10 minutes. For more information, see Aurora DB instance classes (p. 84).
- Storage (per GiB per month) – Storage capacity that you have provisioned to your DB instance. If you scale your provisioned storage capacity within the month, your bill is prorated. For more information, see Amazon Aurora storage and reliability (p. 97).
- Input/output (I/O) requests (per 1 million requests) – Total number of storage I/O requests that you have made in a billing cycle, for the Aurora Standard DB cluster configuration only.
Amazon Aurora User Guide for Aurora

DB instance billing for Aurora

For more information on Amazon Aurora I/O billing, see Storage configurations for Amazon Aurora DB clusters (p. 97).

• Backup storage (per GiB per month) – Backup storage is the storage that is associated with automated database backups and any active database snapshots that you have taken. Increasing your backup retention period or taking additional database snapshots increases the backup storage consumed by your database. Per second billing doesn't apply to backup storage (metered in GB-month).

For more information, see Backing up and restoring an Amazon Aurora DB cluster (p. 426).

• Data transfer (per GB) – Data transfer in and out of your DB instance from or to the internet and other AWS Regions.

Amazon RDS provides the following purchasing options to enable you to optimize your costs based on your needs:

• **On-Demand instances** – Pay by the hour for the DB instance hours that you use. Pricing is listed on a per-hour basis, but bills are calculated down to the second and show times in decimal form. RDS usage is now billed in 1-second increments, with a minimum of 10 minutes.

• **Reserved instances** – Reserve a DB instance for a one-year or three-year term and get a significant discount compared to the on-demand DB instance pricing. With Reserved Instance usage, you can launch, delete, start, or stop multiple instances within an hour and get the Reserved Instance benefit for all of the instances.

• **Aurora Serverless v2** – Aurora Serverless v2 provides on-demand capacity where the billing unit is Aurora capacity unit (ACU) hours instead of DB instance hours. Aurora Serverless v2 capacity increases and decreases, within a range that you specify, depending on the load on your database. You can configure a cluster where all the capacity is Aurora Serverless v2. Or you can configure a combination of Aurora Serverless v2 and on-demand or reserved provisioned instances. For information about how Aurora Serverless v2 ACUs work, see How Aurora Serverless v2 works (p. 1964).

For Aurora pricing information, see the Aurora pricing page.

Topics

• On-Demand DB instances for Aurora (p. 108)
• Reserved DB instances for Aurora (p. 109)
On-Demand DB instances for Aurora

Amazon RDS on-demand DB instances are billed based on the class of the DB instance (for example, db.t3.small or db.m5.large). For Amazon RDS pricing information, see the Amazon RDS product page.

Billing starts for a DB instance as soon as the DB instance is available. Pricing is listed on a per-hour basis, but bills are calculated down to the second and show times in decimal form. Amazon RDS usage is billed in one-second increments, with a minimum of 10 minutes. In the case of billable configuration change, such as scaling compute or storage capacity, you’re charged a 10-minute minimum. Billing continues until the DB instance terminates, which occurs when you delete the DB instance or if the DB instance fails.

If you no longer want to be charged for your DB instance, you must stop or delete it to avoid being billed for additional DB instance hours. For more information about the DB instance states for which you are billed, see Viewing DB instance status in an Aurora cluster (p. 523).

Stopped DB instances

While your DB instance is stopped, you’re charged for provisioned storage, including Provisioned IOPS. You are also charged for backup storage, including storage for manual snapshots and automated backups within your specified retention window. You aren't charged for DB instance hours.

Multi-AZ DB instances

If you specify that your DB instance should be a Multi-AZ deployment, you're billed according to the Multi-AZ pricing posted on the Amazon RDS pricing page.
Reserved DB instances for Aurora

Using reserved DB instances, you can reserve a DB instance for a one- or three-year term. Reserved DB instances provide you with a significant discount compared to on-demand DB instance pricing. Reserved DB instances are not physical instances, but rather a billing discount applied to the use of certain on-demand DB instances in your account. Discounts for reserved DB instances are tied to instance type and AWS Region.

The general process for working with reserved DB instances is: First get information about available reserved DB instance offerings, then purchase a reserved DB instance offering, and finally get information about your existing reserved DB instances.

Overview of reserved DB instances

When you purchase a reserved DB instance in Amazon RDS, you purchase a commitment to getting a discounted rate, on a specific DB instance type, for the duration of the reserved DB instance. To use an Amazon RDS reserved DB instance, you create a new DB instance just like you do for an on-demand instance.

The new DB instance that you create must have the same specifications as the reserved DB instance for the following:

- AWS Region
- DB engine
- DB instance type
- Deployment model (Single-AZ or Multi-AZ)

If the specifications of the new DB instance match an existing reserved DB instance for your account, you are billed at the discounted rate offered for the reserved DB instance. Otherwise, the DB instance is billed at an on-demand rate.

You can modify a DB instance that you’re using as a reserved DB instance. If the modification is within the specifications of the reserved DB instance, part or all of the discount still applies to the modified DB instance. If the modification is outside the specifications, such as changing the instance class, the discount no longer applies. For more information, see Size-flexible reserved DB instances (p. 110).

Topics

- Offering types (p. 109)
- Aurora DB cluster configuration flexibility (p. 110)
- Size-flexible reserved DB instances (p. 110)
- Aurora reserved DB instance billing examples (p. 112)
- Deleting a reserved DB instance (p. 113)

For more information about reserved DB instances, including pricing, see Amazon RDS reserved instances.

Offering types

Reserved DB instances are available in three varieties—No Upfront, Partial Upfront, and All Upfront—that let you optimize your Amazon RDS costs based on your expected usage.

No Upfront

This option provides access to a reserved DB instance without requiring an upfront payment. Your No Upfront reserved DB instance bills a discounted hourly rate for every hour within the term,
regardless of usage, and no upfront payment is required. This option is only available as a one-year reservation.

**Partial Upfront**

This option requires a part of the reserved DB instance to be paid upfront. The remaining hours in the term are billed at a discounted hourly rate, regardless of usage. This option is the replacement for the previous Heavy Utilization option.

**All Upfront**

Full payment is made at the start of the term, with no other costs incurred for the remainder of the term regardless of the number of hours used.

If you are using consolidated billing, all the accounts in the organization are treated as one account. This means that all accounts in the organization can receive the hourly cost benefit of reserved DB instances that are purchased by any other account. For more information about consolidated billing, see [Amazon RDS reserved DB instances](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/) in the *AWS Billing and Cost Management User Guide*.

**Aurora DB cluster configuration flexibility**

You can use Aurora reserved DB instances with both DB cluster configurations:

- **Aurora I/O-Optimized** – You pay only for the usage and storage of your DB clusters, with no additional charges for read and write I/O operations.
- **Aurora Standard** – In addition to the usage and storage of your DB clusters, you also pay a standard rate per 1 million requests for I/O operations.

Aurora automatically accounts for the price difference between these configurations. Aurora I/O-Optimized consumes 30% more normalized units per hour than Aurora Standard.

For more information about Aurora cluster storage configurations, see [Storage configurations for Amazon Aurora DB clusters (p. 97)](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/). For more information about pricing for Aurora cluster storage configurations, see [Amazon Aurora pricing](https://aws.amazon.com/aurora/pricing/).

**Size-flexible reserved DB instances**

When you purchase a reserved DB instance, one thing that you specify is the instance class, for example `db.r5.large`. For more information about DB instance classes, see *Aurora DB instance classes (p. 84)*.

If you have a DB instance, and you need to scale it to larger capacity, your reserved DB instance is automatically applied to your scaled DB instance. That is, your reserved DB instances are automatically applied across all DB instance class sizes. Size-flexible reserved DB instances are available for DB instances with the same AWS Region and database engine. Size-flexible reserved DB instances can only scale in their instance class type. For example, a reserved DB instance for a `db.r5.large` can apply to a `db.r5.xlarge`, but not to a `db.r6g.large`, because `db.r5` and `db.r6g` are different instance class types.

Reserved DB instance benefits also apply for both Multi-AZ and Single-AZ configurations. Flexibility means that you can move freely between configurations within the same DB instance class type. For example, you can move from a Single-AZ deployment running on one large DB instance (four normalized units per hour) to a Multi-AZ deployment running on two small DB instances (2*2 = 4 normalized units per hour).

Size-flexible reserved DB instances are available for the following Aurora database engines:

- **Aurora MySQL**
- **Aurora PostgreSQL**
You can compare usage for different reserved DB instance sizes by using normalized units per hour. For example, one unit of usage on two db.r3.large DB instances is equivalent to eight normalized units per hour of usage on one db.r3.small. The following table shows the number of normalized units per hour for each DB instance size.

<table>
<thead>
<tr>
<th>Instance size</th>
<th>Normalized units per hour for one DB instance, Aurora Standard</th>
<th>Normalized units per hour for one DB instance, Aurora I/O-Optimized</th>
<th>Normalized units per hour for three DB instances (writer and two readers), Aurora Standard</th>
<th>Normalized units per hour for three DB instances (writer and two readers), Aurora I/O-Optimized</th>
</tr>
</thead>
<tbody>
<tr>
<td>small</td>
<td>1</td>
<td>1.3</td>
<td>3</td>
<td>3.9</td>
</tr>
<tr>
<td>medium</td>
<td>2</td>
<td>2.6</td>
<td>6</td>
<td>7.8</td>
</tr>
<tr>
<td>large</td>
<td>4</td>
<td>5.2</td>
<td>12</td>
<td>15.6</td>
</tr>
<tr>
<td>xlarge</td>
<td>8</td>
<td>10.4</td>
<td>24</td>
<td>31.2</td>
</tr>
<tr>
<td>2xlarge</td>
<td>16</td>
<td>20.8</td>
<td>48</td>
<td>62.4</td>
</tr>
<tr>
<td>4xlarge</td>
<td>32</td>
<td>41.6</td>
<td>96</td>
<td>124.8</td>
</tr>
<tr>
<td>8xlarge</td>
<td>64</td>
<td>83.2</td>
<td>192</td>
<td>249.6</td>
</tr>
<tr>
<td>12xlarge</td>
<td>96</td>
<td>124.8</td>
<td>288</td>
<td>374.4</td>
</tr>
<tr>
<td>16xlarge</td>
<td>128</td>
<td>166.4</td>
<td>384</td>
<td>499.2</td>
</tr>
<tr>
<td>24xlarge</td>
<td>192</td>
<td>249.6</td>
<td>576</td>
<td>748.8</td>
</tr>
<tr>
<td>32xlarge</td>
<td>256</td>
<td>332.8</td>
<td>768</td>
<td>998.4</td>
</tr>
</tbody>
</table>

For example, suppose that you purchase a db.t2.medium reserved DB instance, and you have two running db.t2.small DB instances in your account in the same AWS Region. In this case, the billing benefit is applied in full to both instances.

Alternatively, if you have one db.t2.large instance running in your account in the same AWS Region, the billing benefit is applied to 50 percent of the usage of the DB instance.
Note
We recommend using the T DB instance classes only for development and test servers, or other non-production servers. For more details on the T instance classes, see DB instance class types (p. 84).

Aurora reserved DB instance billing examples

The following examples illustrate the pricing for reserved DB instances for Aurora DB clusters using both the Aurora Standard and Aurora I/O-Optimized DB cluster configurations.

Example using Aurora Standard

The price for a reserved DB instance doesn't provide a discount for the costs associated with storage, backups, and I/O. The following example illustrates the total cost per month for a reserved DB instance:

- An Aurora MySQL reserved Single-AZ db.r5.large DB instance class in US East (N. Virginia) at a cost of $0.19 per hour, or $138.70 per month
- Aurora storage at a cost of $0.10 per GiB per month (assume $45.60 per month for this example)
- Aurora I/O at a cost of $0.20 per 1 million requests (assume $20 per month for this example)
- Aurora backup storage at $0.021 per GiB per month (assume $30 per month for this example)

Add all of these options ($138.70 + $45.60 + $20 + $30) with the reserved DB instance, and the total cost per month is $234.30.

If you choose to use an on-demand DB instance instead of a reserved DB instance, an Aurora MySQL Single-AZ db.r5.large DB instance class in US East (N. Virginia) costs $0.29 per hour, or $217.50 per month. So, for an on-demand DB instance, add all of these options ($217.50 + $45.60 + $20 + $30), and the total cost per month is $313.10. You save nearly $79 per month by using the reserved DB instance.

Example using an Aurora Standard DB cluster with two reader instances

To use reserved instances for Aurora DB clusters, simply purchase one reserved instance for each DB instance in the cluster.

Extending the first example, you have an Aurora MySQL DB cluster with one writer DB instance and two Aurora Replicas, for a total of three DB instances in the cluster. The two Aurora Replicas incur no extra storage or backups charges. If you purchase three db.r5.large Aurora MySQL reserved DB instances, your cost will be $234.30 (for the writer DB instance) + 2 * ($138.70 + $20 I/O per Aurora Replica), for a total of $551.70 per month.
The corresponding on-demand cost for an Aurora MySQL DB cluster with one writer DB instance and two Aurora Replicas is $313.10 + 2 * ($217.50 + $20 I/O per instance) for a total of $788.10 per month. You save $236.40 per month by using the reserved DB instances.

Example using Aurora I/O-Optimized

You can reuse your existing Aurora Standard reserved DB instances with Aurora I/O-Optimized. To fully use the benefits of your reserved instance discounts with Aurora I/O-Optimized, you can buy 30% additional reserved instances similar to your current reserved instances.

The following table shows examples of how to estimate the additional reserved instances when using Aurora I/O-Optimized. If the required reserved instances are a fraction, you can take advantage of the size flexibility available with reserved instances to get to a whole number. In these examples, "current" refers to the Aurora Standard reserved instances that you have now. Additional reserved instances are the number of Aurora Standard reserved instances that you must buy to maintain your current reserved instance discounts when using Aurora I/O-Optimized.

<table>
<thead>
<tr>
<th>DB instance class</th>
<th>Current Aurora Standard reserved instances</th>
<th>Reserved instances required for Aurora I/O-Optimized</th>
<th>Additional reserved instances needed</th>
<th>Additional reserved instances needed, using size flexibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>db.r6g.large</td>
<td>10</td>
<td>10 * 1.3 = 13</td>
<td>3 * db.r6g.large</td>
<td>3 * db.r6g.large</td>
</tr>
<tr>
<td>db.r6g.4xlarge</td>
<td>20</td>
<td>20 * 1.3 = 26</td>
<td>6 * db.r6g.4xlarge</td>
<td>6 * db.r6g.4xlarge</td>
</tr>
<tr>
<td>db.r6g.12xlarge</td>
<td>5</td>
<td>5 * 1.3 = 6.5</td>
<td>1.5 * db.r6g.12xlarge</td>
<td>One each of db.r6g.12xlarge, r6g.4xlarge, and r6g.2xlarge</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>(0.5 * db.r6g.12xlarge = 1 * db.r6g.4xlarge + 1 * db.r6g.2xlarge)</td>
</tr>
<tr>
<td>db.r6i.24xlarge</td>
<td>15</td>
<td>15 * 1.3 = 19.5</td>
<td>4.5 * db.r6i.24xlarge</td>
<td>4 * db.r6i.24xlarge + 1 * db.r6i.12xlarge</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>(0.5 * db.r6i.24xlarge = 1 * db.r6i.12xlarge)</td>
</tr>
</tbody>
</table>

Example using an Aurora I/O-Optimized DB cluster with two reader instances

You have an Aurora MySQL DB cluster with one writer DB instance and two Aurora Replicas, for a total of three DB instances in the cluster. They use the Aurora I/O-Optimized DB cluster configuration. To use reserved DB instances for this cluster, you would need to buy four reserved DB instances of the same DB instance class. Three DB instances using Aurora I/O-Optimized consume 3.9 normalized units per hour, compared to 3 normalized units per hour for three DB instances using Aurora Standard. However, you save the monthly I/O costs for each DB instance.

Note
The prices in these examples are sample prices and might not match actual prices. For Aurora pricing information, see Amazon Aurora pricing.

Deleting a reserved DB instance

The terms for a reserved DB instance involve a one-year or three-year commitment. You can't cancel a reserved DB instance. However, you can delete a DB instance that is covered by a reserved DB instance.
discount. The process for deleting a DB instance that is covered by a reserved DB instance discount is the same as for any other DB instance.

You're billed for the upfront costs regardless of whether you use the resources.

If you delete a DB instance that is covered by a reserved DB instance discount, you can launch another DB instance with compatible specifications. In this case, you continue to get the discounted rate during the reservation term (one or three years).

**Working with reserved DB instances**

You can use the AWS Management Console, the AWS CLI, and the RDS API to work with reserved DB instances.

**Console**

You can use the AWS Management Console to work with reserved DB instances as shown in the following procedures.

**To get pricing and information about available reserved DB instance offerings**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Reserved instances**.
3. Choose **Purchase Reserved DB Instance**.
4. For **Product description**, choose the DB engine and licensing type.
5. For **DB instance class**, choose the DB instance class.
6. For **Deployment Option**, choose whether you want a Single-AZ or Multi-AZ DB instance deployment.

   **Note**

   Reserved Amazon Aurora instances always have the deployment option set to **Single-AZ DB instance**. However, when you create an Aurora DB cluster, the default deployment option is **Create an Aurora Replica or Reader in a different AZ (Multi-AZ)**. You must purchase a reserved DB instance for each instance that you plan to use, including Aurora Replicas. Therefore, for Multi-AZ deployments on Aurora, you must purchase extra reserved DB instances.

7. For **Term**, choose the length of time to reserve the DB instance.
8. For **Offering type**, choose the offering type.

   After you select the offering type, you can see the pricing information.

   **Important**

   Choose **Cancel** to avoid purchasing the reserved DB instance and incurring any charges.

After you have information about the available reserved DB instance offerings, you can use the information to purchase an offering as shown in the following procedure.

**To purchase a reserved DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Reserved instances**.
3. Choose **Purchase reserved DB instance**.
4. For **Product description**, choose the DB engine and licensing type.
5. For **DB instance class**, choose the DB instance class.
6. For **Multi-AZ deployment**, choose whether you want a Single-AZ or Multi-AZ DB instance deployment.

   **Note**
   Reserved Amazon Aurora *instances* always have the deployment option set to **Single-AZ DB instance**. When you create an Amazon Aurora DB *cluster* from your reserved DB instance, the DB cluster is automatically created as Multi-AZ. Make sure to purchase a reserved DB instance for each DB instance that you plan to use, including Aurora Replicas.

7. For **Term**, choose the length of time you want the DB instance reserved.

8. For **Offering type**, choose the offering type.

   After you choose the offering type, you can see the pricing information.

9. (Optional) You can assign your own identifier to the reserved DB instances that you purchase to help you track them. For **Reserved Id**, type an identifier for your reserved DB instance.

10. Choose **Submit**.

    Your reserved DB instance is purchased, then displayed in the **Reserved instances** list.

   After you have purchased reserved DB instances, you can get information about your reserved DB instances as shown in the following procedure.

**To get information about reserved DB instances for your AWS account**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).

2. In the **Navigation** pane, choose **Reserved instances**.

   The reserved DB instances for your account appear. To see detailed information about a particular reserved DB instance, choose that instance in the list. You can then see detailed information about that instance in the detail pane at the bottom of the console.

**AWS CLI**

You can use the AWS CLI to work with reserved DB instances as shown in the following examples.

**Example of getting available reserved DB instance offerings**

To get information about available reserved DB instance offerings, call the AWS CLI command `describe-reserved-db-instances-offerings`.

```bash
aws rds describe-reserved-db-instances-offerings
```

This call returns output similar to the following:

<table>
<thead>
<tr>
<th>OFFERING</th>
<th>OfferingId</th>
<th>Class</th>
<th>Multi-AZ</th>
<th>Duration</th>
<th>Fixed</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>430c81db3-4052-4cc7-b2e3-8d372e0e706</td>
<td>db.r3.large</td>
<td>y</td>
<td>1y</td>
<td>1820.00</td>
</tr>
<tr>
<td></td>
<td>649fd0c8-cf6d-47a0-bfa6-060f8e75e95f</td>
<td>db.r3.small</td>
<td>n</td>
<td>1y</td>
<td>227.50</td>
</tr>
<tr>
<td></td>
<td>123456cd-ab1c-47a0-bfa6-1234567252f</td>
<td>db.r3.small</td>
<td>n</td>
<td>1y</td>
<td>162.00</td>
</tr>
<tr>
<td></td>
<td>0.00 USD mysql All Upfront</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>123456cd-ab1c-37a0-bfa6-1234567252d</td>
<td>db.r3.large</td>
<td>y</td>
<td>1y</td>
<td>700.00</td>
</tr>
<tr>
<td></td>
<td>0.00 USD mysql All Upfront</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
After you have information about the available reserved DB instance offerings, you can use the information to purchase an offering.

To purchase a reserved DB instance, use the AWS CLI command `purchase-reserved-db-instances-offering` with the following parameters:

- `--reserved-db-instances-offering-id` – The ID of the offering that you want to purchase. See the preceding example to get the offering ID.
- `--reserved-db-instance-id` – You can assign your own identifier to the reserved DB instances that you purchase to help track them.

**Example of purchasing a reserved DB instance**

The following example purchases the reserved DB instance offering with ID `649fd0c8-cf6d-47a0-bfa6-060f8e75e95f`, and assigns the identifier of `MyReservation`.

For Linux, macOS, or Unix:

```
aws rds purchase-reserved-db-instances-offering \
  --reserved-db-instances-offering-id 649fd0c8-cf6d-47a0-bfa6-060f8e75e95f \
  --reserved-db-instance-id MyReservation
```

For Windows:

```
aws rds purchase-reserved-db-instances-offering ^
  --reserved-db-instances-offering-id 649fd0c8-cf6d-47a0-bfa6-060f8e75e95f ^
  --reserved-db-instance-id MyReservation
```

The command returns output similar to the following:

<table>
<thead>
<tr>
<th>RESERVATION</th>
<th>ReservationId</th>
<th>Class</th>
<th>Multi-AZ</th>
<th>Start Time</th>
<th>Duration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fixed Price</td>
<td>Usage Price</td>
<td>Count</td>
<td>State</td>
<td>Description</td>
<td>Offering Type</td>
</tr>
<tr>
<td>RESERVATION</td>
<td>MyReservation</td>
<td>db.r3.small</td>
<td>y</td>
<td>2011-12-09T23:37:44.720Z</td>
<td>1y</td>
</tr>
<tr>
<td>455.00 USD</td>
<td>0.092 USD</td>
<td>1</td>
<td>payment-pending</td>
<td>mysql</td>
<td>Partial</td>
</tr>
</tbody>
</table>

After you have purchased reserved DB instances, you can get information about your reserved DB instances.

To get information about reserved DB instances for your AWS account, call the AWS CLI command `describe-reserved-db-instances`, as shown in the following example.

**Example of getting your reserved DB instances**

```
aws rds describe-reserved-db-instances
```

The command returns output similar to the following:

<table>
<thead>
<tr>
<th>RESERVATION</th>
<th>ReservationId</th>
<th>Class</th>
<th>Multi-AZ</th>

RDS API

You can use the RDS API to work with reserved DB instances:

- To get information about available reserved DB instance offerings, call the Amazon RDS API operation `DescribeReservedDBInstancesOfferings`.
- After you have information about the available reserved DB instance offerings, you can use the information to purchase an offering. Call the `PurchaseReservedDBInstancesOffering` RDS API operation with the following parameters:
  - `--reserved-db-instances-offering-id` – The ID of the offering that you want to purchase.
  - `--reserved-db-instance-id` – You can assign your own identifier to the reserved DB instances that you purchase to help track them.
- After you have purchased reserved DB instances, you can get information about your reserved DB instances. Call the `DescribeReservedDBInstances` RDS API operation.

Viewing the billing for your reserved DB instances

You can view the billing for your reserved DB instances in the Billing Dashboard in the AWS Management Console.

To view reserved DB instance billing

1. Sign in to the AWS Management Console.
2. From the account menu at the upper right, choose Billing Dashboard.
3. Choose Bill Details at the upper right of the dashboard.
4. Under AWS Service Charges, expand Relational Database Service.
5. Expand the AWS Region where your reserved DB instances are, for example US West (Oregon).

Your reserved DB instances and their hourly charges for the current month are shown under Amazon Relational Database Service for Database Engine Reserved Instances.

The reserved DB instance in this example was purchased All Upfront, so there are no hourly charges.

6. Choose the Cost Explorer (bar graph) icon next to the Reserved Instances heading.

The Cost Explorer displays the Monthly EC2 running hours costs and usage graph.

7. Clear the Usage Type Group filter to the right of the graph.
8. Choose the time period and time unit for which you want to examine usage costs.

The following example shows usage costs for on-demand and reserved DB instances for the year to date by month.
The reserved DB instance costs from January through June 2021 are monthly charges for a Partial Upfront instance, while the cost in August 2021 is a one-time charge for an All Upfront instance.

The reserved instance discount for the Partial Upfront instance expired in June 2021, but the DB instance wasn't deleted. After the expiration date, it was simply charged at the on-demand rate.
Setting up your environment for Amazon Aurora

Before you use Amazon Aurora for the first time, complete the following tasks.

Topics

- Sign up for an AWS account (p. 119)
- Create an administrative user (p. 119)
- Grant programmatic access (p. 120)
- Determine requirements (p. 121)
- Provide access to the DB cluster in the VPC by creating a security group (p. 122)

If you already have an AWS account, know your Aurora requirements, and prefer to use the defaults for IAM and VPC security groups, skip ahead to Getting started with Amazon Aurora (p. 124).

Sign up for an AWS account

If you do not have an AWS account, complete the following steps to create one.

To sign up for an AWS account

2. Follow the online instructions.

   Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

   When you sign up for an AWS account, an AWS account root user is created. The root user has access to all AWS services and resources in the account. As a security best practice, assign administrative access to an administrative user, and use only the root user to perform tasks that require root user access.

AWS sends you a confirmation email after the sign-up process is complete. At any time, you can view your current account activity and manage your account by going to https://aws.amazon.com/ and choosing My Account.

Create an administrative user

After you sign up for an AWS account, create an administrative user so that you don't use the root user for everyday tasks.

Secure your AWS account root user

1. Sign in to the AWS Management Console as the account owner by choosing Root user and entering your AWS account email address. On the next page, enter your password.

   For help signing in by using root user, see Signing in as the root user in the AWS Sign-In User Guide.

2. Turn on multi-factor authentication (MFA) for your root user.

**Create an administrative user**

- For your daily administrative tasks, grant administrative access to an administrative user in AWS IAM Identity Center.

**Sign in as the administrative user**

- To sign in with your IAM Identity Center user, use the sign-in URL that was sent to your email address when you created the IAM Identity Center user.

**Grant programmatic access**

Users need programmatic access if they want to interact with AWS outside of the AWS Management Console. The way to grant programmatic access depends on the type of user that's accessing AWS.

To grant users programmatic access, choose one of the following options.

<table>
<thead>
<tr>
<th>Which user needs programmatic access?</th>
<th>To</th>
<th>By</th>
</tr>
</thead>
</table>
| Workforce identity (Users managed in IAM Identity Center) | Use temporary credentials to sign programmatic requests to the AWS CLI, AWS SDKs, or AWS APIs. | Following the instructions for the interface that you want to use.  
  - For the AWS CLI, see [Configuring the AWS CLI to use AWS IAM Identity Center](https://docs.aws.amazon.com/cli/latest/userguide/cli-configure-profiles.html) in the AWS Command Line Interface User Guide.  
  - For AWS SDKs, tools, and AWS APIs, see [IAM Identity Center authentication](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_credentials_temp.html) in the AWS SDKs and Tools Reference Guide. |
| IAM | Use temporary credentials to sign programmatic requests to the AWS CLI, AWS SDKs, or AWS APIs. | Following the instructions in [Using temporary credentials with AWS resources](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_credentials_temp.html) in the IAM User Guide. |
| IAM | (Not recommended) Use long-term credentials to sign programmatic requests to the AWS CLI, AWS SDKs, or AWS APIs. | Following the instructions for the interface that you want to use.  
  - For the AWS CLI, see [Authenticating using IAM](https://docs.aws.amazon.com/cli/latest/userguide/cli-configure-profiles.html). |
Determine requirements

The basic building block of Aurora is the DB cluster. One or more DB instances can belong to a DB cluster. A DB cluster provides a network address called the cluster endpoint. Your applications connect to the cluster endpoint exposed by the DB cluster whenever they need to access the databases created in that DB cluster. The information you specify when you create the DB cluster controls configuration elements such as memory, database engine and version, network configuration, security, and maintenance periods.

Before you create a DB cluster and a security group, you must know your DB cluster and network needs. Here are some important things to consider:

- **Resource requirements** – What are the memory and processor requirements for your application or service? You will use these settings when you determine what DB instance class you will use when you create your DB cluster. For specifications about DB instance classes, see Aurora DB instance classes (p. 84).

- **VPC, subnet, and security group** – Your DB cluster will be in a virtual private cloud (VPC). Security group rules must be configured to connect to a DB cluster. The following list describes the rules for each VPC option:
  - **Default VPC** — If your AWS account has a default VPC in the AWS Region, that VPC is configured to support DB clusters. If you specify the default VPC when you create the DB cluster:
    - Make sure to create a VPC security group that authorizes connections from the application or service to the Aurora DB cluster. Use the Security Group option on the VPC console or the AWS CLI to create VPC security groups. For information, see Step 3: Create a VPC security group (p. 2489).
    - You must specify the default DB subnet group. If this is the first DB cluster you have created in the AWS Region, Amazon RDS will create the default DB subnet group when it creates the DB cluster.
  - **User-defined VPC** — If you want to specify a user-defined VPC when you create a DB cluster:
    - Make sure to create a VPC security group that authorizes connections from the application or service to the Aurora DB cluster. Use the Security Group option on the VPC console or the AWS CLI to create VPC security groups. For information, see Step 3: Create a VPC security group (p. 2489).
    - The VPC must meet certain requirements in order to host DB clusters, such as having at least two subnets, each in a separate availability zone. For information, see Amazon VPC VPCs and Amazon Aurora (p. 2478).
    - You must specify a DB subnet group that defines which subnets in that VPC can be used by the DB cluster. For information, see the DB Subnet Group section in Working with a DB cluster in a VPC (p. 2479).
  - **High availability**: Do you need failover support? On Aurora, a Multi-AZ deployment creates a primary instance and Aurora Replicas. You can configure the primary instance and Aurora Replicas to be in

---

<table>
<thead>
<tr>
<th>Which user needs programmatic access?</th>
<th>To</th>
<th>By</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>user credentials in the AWS Command Line Interface User Guide.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• For AWS SDKs and tools, see Authenticate using long-term credentials in the AWS SDKs and Tools Reference Guide.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• For AWS APIs, see Managing access keys for IAM users in the IAM User Guide.</td>
</tr>
</tbody>
</table>
different Availability Zones for failover support. We recommend Multi-AZ deployments for production workloads to maintain high availability. For development and test purposes, you can use a non-Multi-AZ deployment. For more information, see High availability for Amazon Aurora (p. 102).

- **IAM policies**: Does your AWS account have policies that grant the permissions needed to perform Amazon RDS operations? If you are connecting to AWS using IAM credentials, your IAM account must have IAM policies that grant the permissions required to perform Amazon RDS operations. For more information, see Identity and access management for Amazon Aurora (p. 2400).

- **Open ports**: What TCP/IP port will your database be listening on? The firewall at some companies might block connections to the default port for your database engine. If your company firewall blocks the default port, choose another port for the new DB cluster. Note that once you create a DB cluster that listens on a port you specify, you can change the port by modifying the DB cluster.

- **AWS Region**: What AWS Region do you want your database in? Having the database close in proximity to the application or web service could reduce network latency. For more information, see Regions and Availability Zones (p. 16).

Once you have the information you need to create the security group and the DB cluster, continue to the next step.

### Provide access to the DB cluster in the VPC by creating a security group

Your DB cluster will be created in a VPC. Security groups provide access to the DB cluster in the VPC. They act as a firewall for the associated DB cluster, controlling both inbound and outbound traffic at the cluster level. DB clusters are created by default with a firewall and a default security group that prevents access to the DB cluster. You must therefore add rules to a security group that enable you to connect to your DB cluster. Use the network and configuration information you determined in the previous step to create rules to allow access to your DB cluster.

For example, if you have an application that will access a database on your DB cluster in a VPC, you must add a custom TCP rule that specifies the port range and IP addresses that application will use to access the database. If you have an application on an Amazon EC2 instance, you can use the VPC security group you set up for the Amazon EC2 instance.

You can configure connectivity between an Amazon EC2 instance a DB cluster when you create the DB cluster. For more information, see Configure automatic network connectivity with an EC2 instance (p. 180).

**Tip**

You can set up network connectivity between an Amazon EC2 instance and a DB cluster automatically when you create the DB cluster. For more information, see Configure automatic network connectivity with an EC2 instance (p. 180).

For more information about creating a VPC for use with Aurora, see Tutorial: Create a VPC for use with a DB cluster (IPv4 only) (p. 2494). For information about common scenarios for accessing a DB instance, see Scenarios for accessing a DB cluster in a VPC (p. 2489).

### To create a VPC security group

   **Note**

   Make sure you are in the VPC console, not the RDS console.

2. In the top right corner of the AWS Management Console, choose the AWS Region where you want to create your VPC security group and DB cluster. In the list of Amazon VPC resources for that AWS

---

122
Region, you should see at least one VPC and several subnets. If you don't, you don't have a default VPC in that AWS Region.

3. In the navigation pane, choose Security Groups.

4. Choose Create security group.

The Create security group page appears.

5. In Basic details, enter the Security group name and Description. For VPC, choose the VPC that you want to create your DB cluster in.

6. In Inbound rules, choose Add rule.

   a. For Type, choose Custom TCP.
   b. For Port range, enter the port value to use for your DB cluster.
   c. For Source, choose a security group name or type the IP address range (CIDR value) from where you access the DB cluster. If you choose My IP, this allows access to the DB cluster from the IP address detected in your browser.

7. If you need to add more IP addresses or different port ranges, choose Add rule and enter the information for the rule.

8. (Optional) In Outbound rules, add rules for outbound traffic. By default, all outbound traffic is allowed.

9. Choose Create security group.

You can use the VPC security group you just created as the security group for your DB cluster when you create it.

   Note
   If you use a default VPC, a default subnet group spanning all of the VPC’s subnets is created for you. When you create a DB cluster, you can select the default VPC and use default for DB Subnet Group.

Once you have completed the setup requirements, you can create a DB cluster using your requirements and security group by following the instructions in Creating an Amazon Aurora DB cluster (p. 179). For information about getting started by creating a DB cluster that uses a specific DB engine, see Getting started with Amazon Aurora (p. 124).
Getting started with Amazon Aurora

In this section, you can find out how to create and connect to an Aurora DB cluster using Amazon RDS.

The following procedures are tutorials that demonstrate the basics of getting started with Aurora. Later sections introduce more advanced Aurora concepts and procedures, such as the different kinds of endpoints and how to scale Aurora clusters up and down.

**Important**
Before you can create or connect to a DB cluster, make sure to complete the tasks in Setting up your environment for Amazon Aurora (p. 119).

**Topics**
- Creating and connecting to an Aurora MySQL DB cluster (p. 124)
- Creating and connecting to an Aurora PostgreSQL DB cluster (p. 137)
- Tutorial: Create a web server and an Amazon Aurora DB cluster (p. 151)

Creating and connecting to an Aurora MySQL DB cluster

This tutorial creates an EC2 instance and an Aurora MySQL DB cluster. The tutorial shows you how to access the DB cluster from the EC2 instance using a standard MySQL client. As a best practice, this tutorial creates a private DB cluster in a virtual private cloud (VPC). In most cases, other resources in the same VPC, such as EC2 instances, can access the DB cluster, but resources outside of the VPC can't access it.

After you complete the tutorial, there is a public and private subnet in each Availability Zone in your VPC. In one Availability Zone, the EC2 instance is in the public subnet, and the DB instance is in the private subnet.

**Important**
There's no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the AWS resources that you use. You can delete these resources after you complete the tutorial if they are no longer needed.

The following diagram shows the configuration when the tutorial is complete.
This tutorial uses Easy create to create a DB cluster running Aurora MySQL with the AWS Management Console. With Easy create, you specify only the DB engine type, DB instance size, and DB cluster identifier. Easy create uses the default settings for the other configuration options. The DB cluster created by Easy create is private.

When you use Standard create instead of Easy create, you can specify more configuration options when you create a DB cluster, including ones for availability, security, backups, and maintenance. To create a public DB cluster, you must use Standard create. For information about creating DB clusters with Standard create, see the section called “Creating a DB cluster” (p. 179).

Topics

- Prerequisites (p. 125)
- Step 1: Create an EC2 instance (p. 125)
- Step 2: Create an Aurora MySQL DB cluster (p. 129)
- Step 3: Connect to an Aurora MySQL DB cluster (p. 134)
- Step 4: Delete the EC2 instance and DB cluster (p. 136)
- (Optional) Connect your DB cluster to a Lambda function (p. 137)

Prerequisites

Before you begin, complete the steps in the following sections:

- Sign up for an AWS account (p. 119)
- Create an administrative user (p. 119)

Step 1: Create an EC2 instance

Create an Amazon EC2 instance that you will use to connect to your database.

To create an EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you want to create the EC2 instance.

3. Choose **EC2 Dashboard**, and then choose **Launch instance**, as shown in the following image.

   ![Launch instance page](image)

   The **Launch an instance** page opens.

4. Choose the following settings on the **Launch an instance** page.
   a. Under **Name and tags**, for **Name**, enter **ec2-database-connect**.
   b. Under **Application and OS Images (Amazon Machine Image)**, choose **Amazon Linux**, and then choose the **Amazon Linux 2023 AMI**. Keep the default selections for the other choices.
c. Under **Instance type**, choose **t2.micro**.

d. Under **Key pair (login)**, choose a **Key pair name** to use an existing key pair. To create a new key pair for the Amazon EC2 instance, choose **Create new key pair** and then use the **Create key pair** window to create it.

For more information about creating a new key pair, see [Create a key pair](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/create-keypair.html) in the Amazon EC2 User Guide for Linux Instances.

e. For **Allow SSH traffic** in **Network settings**, choose the source of SSH connections to the EC2 instance.

You can choose **My IP** if the displayed IP address is correct for SSH connections. Otherwise, you can determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH). To determine your public IP address, in a different browser window or tab, you can use the service at [https://checkip.amazonaws.com](https://checkip.amazonaws.com). An example of an IP address is 192.0.2.1/32.

In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, make sure to determine the range of IP addresses used by client computers.

**Warning**

If you use **0.0.0.0** for SSH access, you make it possible for all IP addresses to access your public EC2 instances using SSH. This approach is acceptable for a short time in a test environment, but it’s unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your EC2 instances using SSH.
Step 1: Create an EC2 instance

f. Leave the default values for the remaining sections.

g. Review a summary of your EC2 instance configuration in the Summary panel, and when you're ready, choose Launch instance.

5. On the Launch Status page, note the identifier for your new EC2 instance, for example: i-1234567890abcdef0.
6. Choose the EC2 instance identifier to open the list of EC2 instances, and then select your EC2 instance.

7. In the Details tab, note the following values, which you need when you connect using SSH:
   a. In Instance summary, note the value for Public IPv4 DNS.

   ![Instance summary](image1)

   ![Instance details](image2)

   b. In Instance details, note the value for Key pair name.

8. Wait until the Instance state for your EC2 instance has a status of Running before continuing.

**Step 2: Create an Aurora MySQL DB cluster**

In this example, you use Easy create to create an Aurora MySQL DB cluster with a db.r6g.large DB instance class.
To create an Aurora MySQL DB cluster with Easy create

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB cluster.
3. In the navigation pane, choose Databases.
4. Choose Create database and make sure that Easy create is chosen.

5. In Configuration, choose Aurora (MySQL Compatible) for Engine type.
6. For DB instance size, choose Dev/Test.
7. For DB cluster identifier, enter database-test1.

The Create database page should look similar to the following image.
8. For **Master username**, enter a name for the master user, or keep the default name.

9. To use an automatically generated master password for the DB cluster, select **Auto generate a password**.

   To enter your master password, make sure that **Auto generate a password** is cleared, and then enter the same password in **Master password** and **Confirm password**.

10. To set up a connection with the EC2 instance you created previously, open **Set up EC2 connection - optional**.

    Select **Connect to an EC2 compute resource**. Choose the EC2 instance you created previously.
11. Open **View default settings for Easy create.**
View default settings for Easy create

Easy create sets the following configurations to their default values, some of which can be changed later. If you want to change any of these settings now, use Standard create.

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Value</th>
<th>Editable after database is created</th>
</tr>
</thead>
<tbody>
<tr>
<td>Encryption</td>
<td>Enabled</td>
<td>No</td>
</tr>
<tr>
<td>VPC</td>
<td>Default VPC (vpc-1a2b3c4d)</td>
<td>No</td>
</tr>
<tr>
<td>Option group</td>
<td>default:aurora-mysql-8:0</td>
<td>No</td>
</tr>
<tr>
<td>Subnet group</td>
<td>create-subnet-group</td>
<td>Yes</td>
</tr>
<tr>
<td>Automatic backups</td>
<td>Enabled</td>
<td>Yes</td>
</tr>
<tr>
<td>VPC security group</td>
<td>sg-1234567</td>
<td>Yes</td>
</tr>
<tr>
<td>Publicly accessible</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Database port</td>
<td>3306</td>
<td>Yes</td>
</tr>
<tr>
<td>DB cluster identifier</td>
<td>database-test1</td>
<td>Yes</td>
</tr>
<tr>
<td>DB instance identifier</td>
<td>database-1</td>
<td>Yes</td>
</tr>
<tr>
<td>DB engine version</td>
<td>8.0.mysql_aurora.3.02.0</td>
<td>Yes</td>
</tr>
<tr>
<td>DB parameter group</td>
<td>default:aurora-mysql8.0</td>
<td>Yes</td>
</tr>
<tr>
<td>DB cluster parameter group</td>
<td>default:aurora-mysql8.0</td>
<td>Yes</td>
</tr>
<tr>
<td>Performance insights</td>
<td>Enabled</td>
<td>Yes</td>
</tr>
<tr>
<td>Monitoring</td>
<td>Enabled</td>
<td>Yes</td>
</tr>
<tr>
<td>Maintenance</td>
<td>Auto minor version upgrade enabled</td>
<td>Yes</td>
</tr>
<tr>
<td>Delete protection</td>
<td>Not enabled</td>
<td>Yes</td>
</tr>
</tbody>
</table>

You can examine the default settings used with Easy create. The Editable after database is created column shows which options you can change after you create the database.

- If a setting has No in that column, and you want a different setting, you can use Standard create to create the DB cluster.
- If a setting has Yes in that column, and you want a different setting, you can either use Standard create to create the DB cluster or modify the DB cluster after you create it to change the setting.

12. Choose Create database.

To view the master username and password for the DB cluster, choose View credential details.
You can use the username and password that appears to connect to the DB cluster as the master user.

**Important**
You can't view the master user password again. If you don't record it, you might have to change it.
If you need to change the master user password after the DB cluster is available, you can modify the DB cluster to do so. For more information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster](p. 269).

13. In the **Databases** list, choose the name of the new Aurora MySQL DB cluster to show its details.

The writer instance has a status of **Creating** until the DB cluster is ready to use.

![Image showing the status of the writer instance](image)

When the status of the writer instance changes to **Available**, you can connect to the DB cluster. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new DB cluster is available.

**Step 3: Connect to an Aurora MySQL DB cluster**

You can use any standard SQL client application to connect to the DB cluster. In this example, you connect to the Aurora MySQL DB cluster using the `mysql` command line client.

**To connect to the Aurora MySQL DB cluster**

1. Find the endpoint (DNS name) and port number of the writer instance for your DB cluster.
   a. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
   b. In the upper-right corner of the Amazon RDS console, choose the AWS Region for the DB cluster.
   c. In the navigation pane, choose **Databases**.
   d. Choose the Aurora MySQL DB cluster name to display its details.
   e. On the **Connectivity & security** tab, copy the endpoint of the writer instance. Also, note the port number. You need both the endpoint and the port number to connect to the DB cluster.
2. Connect to the EC2 instance that you created earlier by following the steps in Connect to your Linux instance in the Amazon EC2 User Guide for Linux Instances.

We recommend that you connect to your EC2 instance using SSH. If the SSH client utility is installed on Windows, Linux, or Mac, you can connect to the instance using the following command format:

```
ssh -i location_of_pem_file ec2-user@ec2-instance-public-dns-name
```

For example, suppose that `ec2-database-connect-key-pair.pem` is stored in `/dir1` on Linux, and the public IPv4 DNS for your EC2 instance is `ec2-12-345-678-90.compute-1.amazonaws.com`. Then, your SSH command would look as follows:

```
ssh -i /dir1/ec2-database-connect-key-pair.pem ec2-user@ec2-12-345-678-90.compute-1.amazonaws.com
```

3. Get the latest bug fixes and security updates by updating the software on your EC2 instance. To do so, use the following command.

**Note**

The `-y` option installs the updates without asking for confirmation. To examine updates before installing, omit this option.

```
sudo dnf update -y
```

4. To install the `mysql` command line client from MariaDB on Amazon Linux 2023, run the following command:
sudo dnf install mariadb105

5. Connect to the Aurora MySQL DB cluster. For example, enter the following command. This action lets you connect to the Aurora MySQL DB cluster using the MySQL client.

Substitute the endpoint of the writer instance for endpoint, and substitute the master username that you used for admin. Provide the master password that you used when prompted for a password.

```
mysql -h endpoint -P 3306 -u admin -p
```

After you enter the password for the user, you should see output similar to the following.

```
Welcome to the MariaDB monitor. Commands end with ; or \g.
Your MySQL connection id is 217
Server version: 8.0.23 Source distribution
Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.
Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.
MySQL [(none)]>
```

For more information about connecting to an Aurora MySQL DB cluster, see Connecting to an Amazon Aurora MySQL DB cluster (p. 204). If you can't connect to your DB cluster, see Can't connect to Amazon RDS DB instance (p. 2511).

For security, it is a best practice to use encrypted connections. Only use an unencrypted MySQL connection when the client and server are in the same VPC and the network is trusted. For information about using encrypted connections, see Connecting with SSL for Aurora MySQL (p. 208).

6. Run SQL commands.

For example, the following SQL command shows the current date and time:

```
SELECT CURRENT_TIMESTAMP;
```

Step 4: Delete the EC2 instance and DB cluster

After you connect to and explore the sample EC2 instance and DB cluster that you created, delete them so you're no longer charged for them.

**To delete the EC2 instance**

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the EC2 instance, and choose Instance state, Terminate instance.
4. Choose Terminate when prompted for confirmation.

For more information about deleting an EC2 instance, see Terminate your instance in the Amazon EC2 User Guide for Linux Instances.
To delete the DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Databases and then choose the DB instance associated with the DB cluster.
3. For Actions, choose Delete.
4. Clear Create final snapshot?
5. Complete the acknowledgement and choose Delete.

After all of the DB instances associated with a DB cluster are deleted, the DB cluster is deleted automatically.

(Optional) Connect your DB cluster to a Lambda function

You can also connect your Aurora MySQL DB cluster to a Lambda serverless compute resource. Lambda functions allow you to run code without provisioning or managing infrastructure. A Lambda function also allows you to automatically respond to code execution requests at any scale, from a dozen events a day to hundreds of per second. For more information, see Automatically connecting a Lambda function and an Aurora DB cluster (p. 260).

Creating and connecting to an Aurora PostgreSQL DB cluster

This tutorial creates an EC2 instance and an Aurora PostgreSQL DB cluster. The tutorial shows you how to access the DB cluster from the EC2 instance using a standard PostgreSQL client. As a best practice, this tutorial creates a private DB cluster in a virtual private cloud (VPC). In most cases, other resources in the same VPC, such as EC2 instances, can access the DB cluster, but resources outside of the VPC can't access it.

After you complete the tutorial, there is a public and private subnet in each Availability Zone in your VPC. In one Availability Zone, the EC2 instance is in the public subnet, and the DB instance is in the private subnet.

Important
There's no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the AWS resources that you use. You can delete these resources after you complete the tutorial if they are no longer needed.

The following diagram shows the configuration when the tutorial is complete.
This tutorial uses **Easy create** to create a DB cluster running Aurora PostgreSQL with the AWS Management Console. With Easy create, you specify only the DB engine type, DB instance size, and DB cluster identifier. Easy create uses the default settings for the other configuration options. The DB cluster created by Easy create is private.

When you use **Standard create** instead of Easy create, you can specify more configuration options when you create a DB cluster, including ones for availability, security, backups, and maintenance. To create a public DB cluster, you must use Standard create. For information about creating DB clusters with Standard create, see the section called “Creating a DB cluster” (p. 179).

**Topics**

- Prerequisites (p. 138)
- Step 1: Create an EC2 instance (p. 138)
- Step 2: Create an Aurora PostgreSQL DB cluster (p. 142)
- Step 3: Connect to an Aurora PostgreSQL DB cluster (p. 147)
- Step 4: Delete the EC2 instance and DB cluster (p. 149)
- (Optional) Connect your DB cluster to a Lambda function (p. 150)

**Prerequisites**

Before you begin, complete the steps in the following sections:

- Sign up for an AWS account (p. 119)
- Create an administrative user (p. 119)

**Step 1: Create an EC2 instance**

Create an Amazon EC2 instance that you will use to connect to your database.

**To create an EC2 instance**

1. Sign in to the AWS Management Console and open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you want to create the EC2 instance.

3. Choose **EC2 Dashboard**, and then choose **Launch instance**, as shown in the following image.

![Launch instance page](image)

The **Launch an instance** page opens.

4. Choose the following settings on the **Launch an instance** page.
   a. Under **Name and tags**, for **Name**, enter `ec2-database-connect`.
   b. Under **Application and OS Images (Amazon Machine Image)**, choose **Amazon Linux**, and then choose the **Amazon Linux 2023 AMI**. Keep the default selections for the other choices.
c. Under **Instance type**, choose **t2.micro**.

d. Under **Key pair (login)**, choose a **Key pair name** to use an existing key pair. To create a new key pair for the Amazon EC2 instance, choose **Create new key pair** and then use the **Create key pair** window to create it.

For more information about creating a new key pair, see [Create a key pair](#) in the *Amazon EC2 User Guide for Linux Instances*.

e. For **Allow SSH traffic** in **Network settings**, choose the source of SSH connections to the EC2 instance.

You can choose **My IP** if the displayed IP address is correct for SSH connections. Otherwise, you can determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH). To determine your public IP address, in a different browser window or tab, you can use the service at [https://checkip.amazonaws.com](https://checkip.amazonaws.com). An example of an IP address is 192.0.2.1/32.

In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, make sure to determine the range of IP addresses used by client computers.

**Warning**

If you use 0.0.0.0/0 for SSH access, you make it possible for all IP addresses to access your public EC2 instances using SSH. This approach is acceptable for a short time in a test environment, but it’s unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your EC2 instances using SSH.
The following image shows an example of the **Network settings** section.

### Network settings

**Network**
- vpc-1a2b3c4d

**Subnet**
- No preference (Default subnet in any availability zone)

**Auto-assign public IP**
- Enable

### Firewall (security groups)

A security group is a set of firewall rules that control the traffic for your instance. Add rules to allow specific traffic to reach your instance.

- Create security group
- Select existing security group

We'll create a new security group called 'launch-wizard-1' with the following rules:

- Allow SSH traffic from
  - My IP

- Allow HTTPS traffic from the internet
  - To set up an endpoint, for example when creating a web server

- Allow HTTP traffic from the internet
  - To set up an endpoint, for example when creating a web server

f. Leave the default values for the remaining sections.

  g. Review a summary of your EC2 instance configuration in the **Summary** panel, and when you're ready, choose **Launch instance**.

5. On the **Launch Status** page, note the identifier for your new EC2 instance, for example: `i-1234567890abcdef0`. 

---

141
6. Choose the EC2 instance identifier to open the list of EC2 instances, and then select your EC2 instance.

7. In the details tab, note the following values, which you need when you connect using SSH:
   a. In Instance summary, note the value for Public IPv4 DNS.
   b. In Instance details, note the value for Key pair name.

8. Wait until the Instance state for your EC2 instance has a status of Running before continuing.

Step 2: Create an Aurora PostgreSQL DB cluster

In this example, you use Easy create to create an Aurora PostgreSQL DB cluster with a db.t4g.large DB instance class.
To create an Aurora PostgreSQL DB cluster with Easy create

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB cluster.
3. In the navigation pane, choose Databases.
4. Choose Create database, and make sure that Easy create is chosen.

5. In Configuration, choose Aurora (PostgreSQL Compatible) for Engine type.
6. For DB instance size, choose Dev/Test.
7. For DB cluster identifier, enter database-test1.

The Create database page should look similar to the following image.
8. For Master username, enter a name for the user, or keep the default name (postgres).

9. To use an automatically generated master password for the DB cluster, select Auto generate a password.

   To enter your master password, make sure Auto generate a password is cleared, and then enter the same password in Master password and Confirm password.
10. To set up a connection with the EC2 instance you created previously, open Set up EC2 connection - optional.

Select Connect to an EC2 compute resource. Choose the EC2 instance you created previously.

Set up EC2 connection - optional
You can also set up a connection to an EC2 instance after creating the database. Go to the database list page or the database details page, choose Actions, and then choose Set up to EC2 connection.

Compute resource
Choose whether to set up a connection to a compute resource for this database. Setting up a connection will automatically change connectivity settings so that the compute resource can connect to this database.

- Don’t connect to an EC2 compute resource
  - Set up a connection to a compute resource for this database. You can manually set up a connection to a compute resource later.

- Connect to an EC2 compute resource
  - Set up a connection to an EC2 compute resource for this database.

EC2 instance Info
Choose the EC2 instance to add as the compute resource for this database. A VPC security group is added to this EC2 instance. A VPC security group is also added to the database with an inbound rule that allows the EC2 instance to access the database.

11. Open View default settings for Easy create.
### View default settings for Easy create

Easy create sets the following configurations to their default values, some of which you can override. If you wish to use any of these settings now, use **Standard create**.

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Encryption</td>
<td>Enabled</td>
</tr>
<tr>
<td>VPC</td>
<td>Default VPC (vpc-1a2b3c4d)</td>
</tr>
<tr>
<td>Option group</td>
<td>default:aurora-postgresql-13</td>
</tr>
<tr>
<td>Subnet group</td>
<td>create-subnet-group</td>
</tr>
<tr>
<td>Automatic backups</td>
<td>Enabled</td>
</tr>
<tr>
<td>VPC security group</td>
<td>sg-1234567</td>
</tr>
<tr>
<td>Publicly accessible</td>
<td>No</td>
</tr>
<tr>
<td>Database port</td>
<td>5432</td>
</tr>
<tr>
<td>DB cluster identifier</td>
<td>database-test1</td>
</tr>
<tr>
<td>DB instance identifier</td>
<td>database-1</td>
</tr>
<tr>
<td>DB engine version</td>
<td>13.6</td>
</tr>
<tr>
<td>DB parameter group</td>
<td>default.aurora-postgresql13</td>
</tr>
<tr>
<td>DB cluster parameter group</td>
<td>default.aurora-postgresql13</td>
</tr>
</tbody>
</table>
You can examine the default settings used with Easy create. The Editable after database is created column shows which options you can change after you create the database.

- If a setting has No in that column, and you want a different setting, you can use Standard create to create the DB cluster.
- If a setting has Yes in that column, and you want a different setting, you can either use Standard create to create the DB cluster, or modify the DB cluster after you create it to change the setting.

12. Choose Create database.

To view the master username and password for the DB cluster, choose View credential details.

You can use the username and password that appears to connect to the DB cluster as the master user.

**Important**

You can't view the master user password again. If you don't record it, you might have to change it.

If you need to change the master user password after the DB cluster is available, you can modify the DB cluster to do so. For more information about modifying a DB cluster, see Modifying an Amazon Aurora DB cluster (p. 269).

13. In the Databases list, choose the name of the new Aurora PostgreSQL DB cluster to show its details.

The writer instance has a status of Creating until the DB cluster is ready to use.

![Screenshot of RDS console showing the Databases list with one Aurora PostgreSQL DB cluster in a status of Creating.]

When the status of the writer instance changes to Available, you can connect to the DB cluster. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new DB cluster is available.

### Step 3: Connect to an Aurora PostgreSQL DB cluster

You can use any standard PostgreSQL client application to connect to the DB cluster. In this example, you connect to the Aurora PostgreSQL DB cluster using the psql command line client.

**To connect to the Aurora PostgreSQL DB cluster**

1. Find the endpoint (DNS name) and port number of the writer instance for your DB cluster.
   a. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   b. In the upper-right corner of the Amazon RDS console, choose the AWS Region for the DB cluster.
   c. In the navigation pane, choose Databases.
   d. Choose the Aurora PostgreSQL DB cluster name to display its details.
Step 3: Connect to an Aurora PostgreSQL DB cluster

e. On the **Connectivity & security** tab, copy the endpoint of the writer instance. Also, note the port number. You need both the endpoint and the port number to connect to the DB cluster.

2. Connect to the EC2 instance that you created earlier by following the steps in **Connect to your Linux instance** in the *Amazon EC2 User Guide for Linux Instances*.

   We recommend that you connect to your EC2 instance using SSH. If the SSH client utility is installed on Windows, Linux, or Mac, you can connect to the instance using the following command format:

   ```bash
   ssh -i location_of_pem_file ec2-user@ec2-instance-public-dns-name
   ```

   For example, assume that `ec2-database-connect-key-pair.pem` is stored in `/dir1` on Linux, and the public IPv4 DNS for your EC2 instance is `ec2-12-345-678-90.compute-1.amazonaws.com`. Your SSH command would look as follows:

   ```bash
   ssh -i /dir1/ec2-database-connect-key-pair.pem ec2-user@ec2-12-345-678-90.compute-1.amazonaws.com
   ```

3. Get the latest bug fixes and security updates by updating the software on your EC2 instance. To do so, use the following command.

   **Note**
   The `--` option installs the updates without asking for confirmation. To examine updates before installing, omit this option.

   ```bash
   sudo dnf update --
   ```

4. Install the `psql` command line client from PostgreSQL on Amazon Linux 2023, using the following command:

   ```bash
   sudo dnf install postgresql15
   ```

5. Connect to the Aurora PostgreSQL DB cluster. For example, enter the following command. This action lets you connect to the Aurora PostgreSQL DB cluster using the `psql` client.
Substitute the endpoint of the writer instance for `endpoint`, substitute the database name `--dbname` that you want to connect to for `postgres`, and substitute the master username that you used for `postgres`. Provide the master password that you used when prompted for a password.

```bash
psql --host=endpoint --port=5432 --dbname=postgres --username=postgres
```

After you enter the password for the user, you should see output similar to the following.

```
psql (14.3, server 14.6)
Type "help" for help.
postgres=>
```

For more information about connecting to an Aurora PostgreSQL DB cluster, see [Connecting to an Amazon Aurora PostgreSQL DB cluster](p. 209). If you can't connect to your DB cluster, see [Can't connect to Amazon RDS DB instance](p. 2511).

For security, it is a best practice to use encrypted connections. Only use an unencrypted PostgreSQL connection when the client and server are in the same VPC and the network is trusted. For information about using encrypted connections, see [Securing Aurora PostgreSQL data with SSL/TLS](p. 1243).

6. Run SQL commands.

   For example, the following SQL command shows the current date and time:

   ```
   SELECT CURRENT_TIMESTAMP;
   ```

---

**Step 4: Delete the EC2 instance and DB cluster**

After you connect to and explore the sample EC2 instance and DB cluster that you created, delete them so you’re no longer charged for them.

**To delete the EC2 instance**

1. Sign in to the AWS Management Console and open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the EC2 instance, and choose **Instance state, Terminate instance**.
4. Choose **Terminate** when prompted for confirmation.

**To delete a DB cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Choose **Databases** and then choose the DB instance associated with the DB cluster.
3. For **Actions**, choose **Delete**.
4. Choose **Delete**.
After all of the DB instances associated with a DB cluster are deleted, the DB cluster is deleted automatically.

(Optional) Connect your DB cluster to a Lambda function

You can also connect your Aurora MySQL DB cluster to a Lambda serverless compute resource. Lambda functions allow you to run code without provisioning or managing infrastructure. A Lambda function also allows you to automatically respond to code execution requests at any scale, from a dozen events a day to hundreds of per second. For more information, see Automatically connecting a Lambda function and an Aurora DB cluster (p. 260).
Tutorial: Create a web server and an Amazon Aurora DB cluster

This tutorial shows you how to install an Apache web server with PHP and create a MariaDB, MySQL, or PostgreSQL database. The web server runs on an Amazon EC2 instance using Amazon Linux 2023, and you can choose between an Aurora MySQL or Aurora PostgreSQL DB cluster. Both the Amazon EC2 instance and the DB cluster run in a virtual private cloud (VPC) based on the Amazon VPC service.

**Important**
There’s no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the AWS resources you use. You can delete these resources after you complete the tutorial if they are no longer needed.

**Note**
This tutorial works with Amazon Linux 2023 and might not work for other versions of Linux.

In the tutorial that follows, you create an EC2 instance that uses the default VPC, subnets, and security group for your AWS account. This tutorial shows you how to create the DB cluster and automatically set up connectivity with the EC2 instance that you created. The tutorial then shows you how to install the web server on the EC2 instance. You connect your web server to your DB cluster in the VPC using the DB cluster writer endpoint.

1. **Launch an EC2 instance** (p. 152)
2. **Create an Amazon Aurora DB cluster** (p. 157)
3. **Install a web server on your EC2 instance** (p. 164)

The following diagram shows the configuration when the tutorial is complete.
Note
After you complete the tutorial, there is a public and private subnet in each Availability Zone in your VPC. This tutorial uses the default VPC for your AWS account and automatically sets up connectivity between your EC2 instance and DB cluster. If you would rather configure a new VPC for this scenario instead, complete the tasks in Tutorial: Create a VPC for use with a DB cluster (IPv4 only) (p. 2494).

Launch an EC2 instance

Create an Amazon EC2 instance in the public subnet of your VPC.

To launch an EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region where you want to create the EC2 instance.
3. Choose EC2 Dashboard, and then choose Launch instance, as shown following.
4. Choose the following settings in the **Launch an instance** page.
   
a. Under **Name and tags**, for **Name**, enter `tutorial-ec2-instance-web-server`.

b. Under **Application and OS Images (Amazon Machine Image)**, choose **Amazon Linux**, and then choose the **Amazon Linux 2023 AMI**. Keep the defaults for the other choices.
c. Under **Instance type**, choose **t2.micro**.

d. Under **Key pair (login)**, choose a **Key pair name** to use an existing key pair. To create a new key pair for the Amazon EC2 instance, choose **Create new key pair** and then use the **Create key pair** window to create it.

For more information about creating a new key pair, see [Create a key pair](#) in the *Amazon EC2 User Guide for Linux Instances*.

e. Under **Network settings**, set these values and keep the other values as their defaults:

   - For **Allow SSH traffic from**, choose the source of SSH connections to the EC2 instance.

     You can choose **My IP** if the displayed IP address is correct for SSH connections.

     Otherwise, you can determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH). To determine your public IP address, in a different browser window or tab, you can use the service at [https://checkip.amazonaws.com](https://checkip.amazonaws.com). An example of an IP address is `203.0.113.25/32`.

     In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, make sure to determine the range of IP addresses used by client computers.

     **Warning**

     If you use `0.0.0.0/0` for SSH access, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time...
in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances using SSH.

- Turn on **Allow HTTPS traffic from the internet**.
- Turn on **Allow HTTP traffic from the internet**.

f. Leave the default values for the remaining sections.
g. Review a summary of your instance configuration in the **Summary** panel, and when you're ready, choose **Launch instance**.

5. On the **Launch Status** page, note the identifier for your new EC2 instance, for example: i-1234567890abcdef0.
6. Choose the EC2 instance identifier to open the list of EC2 instances, and then select your EC2 instance.

7. In the Details tab, note the following values, which you need when you connect using SSH:
   a. In Instance summary, note the value for Public IPv4 DNS.
      
      ![Screenshot of Instance summary with Public IPv4 DNS highlighted]

   b. In Instance details, note the value for Key pair name.
      
      ![Screenshot of Instance details with Key pair name highlighted]

8. Wait until Instance state for your instance is Running before continuing.

9. Complete Create an Amazon Aurora DB cluster (p. 157).
Create an Amazon Aurora DB cluster

Create an Amazon Aurora MySQL or Aurora PostgreSQL DB cluster that maintains the data used by a web application.

Aurora MySQL

To create an Aurora MySQL DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the AWS Management Console, make sure the AWS Region is the same as the one where you created your EC2 instance.
3. In the navigation pane, choose Databases.
4. Choose Create database.
5. On the Create database page, choose Standard create.
6. For Engine options, choose Aurora (MySQL Compatible).

Keep the default values for Version and the other engine options.

7. In the Templates section, choose Dev/Test.
8. In the Settings section, set these values:
   - DB cluster identifier – Type tutorial-db-cluster.
   - Master username – Type tutorial_user.
   - Auto generate a password – Leave the option turned off.
• **Master password** – Type a password.
• **Confirm password** – Retype the password.

9. In the **Instance configuration** section, set these values:

- **Burstable classes (includes t classes)**
- **db.t3.small** or **db.t3.medium**

  **Note**
  We recommend using the T DB instance classes only for development and test servers, or other non-production servers. For more details on the T instance classes, see [DB instance class types](p. 84).
10. In the **Availability and durability** section, use the default values.
11. In the **Connectivity** section, set these values and keep the other values as their defaults:
   - For **Compute resource**, choose *Connect to an EC2 compute resource*.
   - For **EC2 instance**, choose the EC2 instance you created previously, such as *tutorial-ec2-instance-web-server**.

12. Open the **Additional configuration** section, and enter *sample* for **Initial database name**. Keep the default settings for the other options.
13. To create your Aurora MySQL DB cluster, choose *Create database*.

Your new DB cluster appears in the **Databases** list with the status *Creating*. 
14. Wait for the **Status** of your new DB cluster to show as **Available**. Then choose the DB cluster name to show its details.

15. In the **Connectivity & security** section, view the **Endpoint** and **Port** of the writer DB instance.

![Amazon Aurora User Guide for Aurora](image)

Note the endpoint and port for your writer DB instance. You use this information to connect your web server to your DB cluster.

16. Complete **Install a web server on your EC2 instance (p. 164)**.

Aurora PostgreSQL

**To create an Aurora PostgreSQL DB cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the upper-right corner of the AWS Management Console, make sure the AWS Region is the same as the one where you created your EC2 instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.
5. On the **Create database** page, choose **Standard create**.
6. For **Engine options**, choose **Aurora (PostgreSQL Compatible)**.
Keep the default values for **Version** and the other engine options.

7. In the **Templates** section, choose **Dev/Test**.

8. In the **Settings** section, set these values:
   - **DB cluster identifier** – Type `tutorial-db-cluster`.
   - **Master username** – Type `tutorial_user`.
   - **Auto generate a password** – Leave the option turned off.
   - **Master password** – Type a password.
   - **Confirm password** – Retype the password.
9. In the **Instance configuration** section, set these values:

- **Burstable classes (includes t classes)**
- **db.t3.small** or **db.t3.medium**

  **Note**
  We recommend using the T DB instance classes only for development and test servers, or other non-production servers. For more details on the T instance classes, see [DB instance class types](p. 84).

10. In the **Availability and durability** section, use the default values.
11. In the **Connectivity** section, set these values and keep the other values as their defaults:

- For **Compute resource**, choose **Connect to an EC2 compute resource**.
- For **EC2 instance**, choose the EC2 instance you created previously, such as `tutorial-ec2-instance-web-server`.

12. Open the **Additional configuration** section, and enter **sample** for **Initial database name**. Keep the default settings for the other options.

13. To create your Aurora PostgreSQL DB cluster, choose **Create database**.

Your new DB cluster appears in the **Databases** list with the status **Creating**.

14. Wait for the **Status** of your new DB cluster to show as **Available**. Then choose the DB cluster name to show its details.

15. In the **Connectivity & security** section, view the **Endpoint** and **Port** of the writer DB instance.
Note the endpoint and port for your writer DB instance. You use this information to connect your web server to your DB cluster.

16. Complete Install a web server on your EC2 instance (p. 164).

Install a web server on your EC2 instance

Install a web server on the EC2 instance you created in Launch an EC2 instance (p. 152). The web server connects to the Amazon Aurora DB cluster that you created in Create an Amazon Aurora DB cluster (p. 157).

Install an Apache web server with PHP and MariaDB

Connect to your EC2 instance and install the web server.

To connect to your EC2 instance and install the Apache web server with PHP

1. Connect to the EC2 instance that you created earlier by following the steps in Connect to your Linux instance in the Amazon EC2 User Guide for Linux Instances.

   We recommend that you connect to your EC2 instance using SSH. If the SSH client utility is installed on Windows, Linux, or Mac, you can connect to the instance using the following command format:

   
   ```
   ssh -i location_of_pem_file ec2-user@ec2-instance-public-dns-name
   ```
   
   For example, assume that ec2-database-connect-key-pair.pem is stored in /dir1 on Linux, and the public IPv4 DNS for your EC2 instance is ec2-12-345-678-90.compute-1.amazonaws.com. Your SSH command would look as follows:
2. Get the latest bug fixes and security updates by updating the software on your EC2 instance. To do this, use the following command.

   **Note**
   The `-y` option installs the updates without asking for confirmation. To examine updates before installing, omit this option.

   ```
   sudo dnf update -y
   ```

3. After the updates complete, install the Apache web server, PHP, and MariaDB or PostgreSQL software using the following commands. This command installs multiple software packages and related dependencies at the same time.

   **MariaDB & MySQL**
   ```
   sudo dnf install -y httpd php php-mysqli mariadb105
   ```

   **PostgreSQL**
   ```
   sudo dnf install -y httpd php php-pgsql postgresql15
   ```

   If you receive an error, your instance probably wasn't launched with an Amazon Linux 2023 AMI. You might be using the Amazon Linux 2 AMI instead. You can view your version of Amazon Linux using the following command.

   ```
   cat /etc/system-release
   ```

   For more information, see [Updating instance software](#).

4. Start the web server with the command shown following.

   ```
   sudo systemctl start httpd
   ```

   You can test that your web server is properly installed and started. To do this, enter the public Domain Name System (DNS) name of your EC2 instance in the address bar of a web browser, for example: `http://ec2-42-8-168-21.us-west-1.compute.amazonaws.com`. If your web server is running, then you see the Apache test page.

   If you don't see the Apache test page, check your inbound rules for the VPC security group that you created in [Tutorial: Create a VPC for use with a DB cluster (IPv4 only)](#). Make sure that your inbound rules include one allowing HTTP (port 80) access for the IP address to connect to the web server.

   **Note**
   The Apache test page appears only when there is no content in the document root directory, `/var/www/html`. After you add content to the document root directory, your content appears at the public DNS address of your EC2 instance. Before this point, it appears on the Apache test page.

5. Configure the web server to start with each system boot using the `systemctl` command.

   ```
   sudo systemctl enable httpd
   ```
To allow ec2-user to manage files in the default root directory for your Apache web server, modify the ownership and permissions of the /var/www directory. There are many ways to accomplish this task. In this tutorial, you add ec2-user to the apache group, to give the apache group ownership of the /var/www directory and assign write permissions to the group.

**To set file permissions for the Apache web server**

1. Add the ec2-user user to the apache group.

   ```bash
   sudo usermod -a -G apache ec2-user
   ```

2. Log out to refresh your permissions and include the new apache group.

   ```bash
   exit
   ```

3. Log back in again and verify that the apache group exists with the groups command.

   ```bash
   groups
   ```

   Your output looks similar to the following:

   ```bash
   ec2-user adm wheel apache systemd-journal
   ```

4. Change the group ownership of the /var/www directory and its contents to the apache group.

   ```bash
   sudo chown -R ec2-user:apache /var/www
   ```

5. Change the directory permissions of /var/www and its subdirectories to add group write permissions and set the group ID on subdirectories created in the future.

   ```bash
   sudo chmod 2775 /var/www
   find /var/www -type d -exec sudo chmod 2775 {} \;
   ```

6. Recursively change the permissions for files in the /var/www directory and its subdirectories to add group write permissions.

   ```bash
   find /var/www -type f -exec sudo chmod 0664 {} \;
   ```

Now, ec2-user (and any future members of the apache group) can add, delete, and edit files in the Apache document root. This makes it possible for you to add content, such as a static website or a PHP application.

**Note**

A web server running the HTTP protocol provides no transport security for the data that it sends or receives. When you connect to an HTTP server using a web browser, much information is visible to eavesdroppers anywhere along the network pathway. This information includes the URLs that you visit, the content of web pages that you receive, and the contents (including passwords) of any HTML forms.

The best practice for securing your web server is to install support for HTTPS (HTTP Secure). This protocol protects your data with SSL/TLS encryption. For more information, see Tutorial: Configure SSL/TLS with the Amazon Linux AMI in the Amazon EC2 User Guide.

**Connect your Apache web server to your DB cluster**

Next, you add content to your Apache web server that connects to your Amazon Aurora DB cluster.
To add content to the Apache web server that connects to your DB cluster

1. While still connected to your EC2 instance, change the directory to `/var/www` and create a new subdirectory named `inc`.

   ```
   cd /var/www
   mkdir inc
   cd inc
   ```

2. Create a new file in the `inc` directory named `dbinfo.inc`, and then edit the file by calling nano (or the editor of your choice).

   ```
   >dbinfo.inc
   nano dbinfo.inc
   ```

3. Add the following contents to the `dbinfo.inc` file. Here, `db_instance_endpoint` is DB cluster writer endpoint, without the port, for your DB cluster.

   **Note**
   We recommend placing the user name and password information in a folder that isn't part of the document root for your web server. Doing this reduces the possibility of your security information being exposed.
   
   Make sure to change `master password` to a suitable password in your application.

   ```php
   <?php
   define('DB_SERVER', 'db_cluster_writer_endpoint');
   define('DB_USERNAME', 'tutorial_user');
   define('DB_PASSWORD', 'master password');
   define('DB_DATABASE', 'sample');
   ?>
   ```

4. Save and close the `dbinfo.inc` file. If you are using nano, save and close the file by using Ctrl+S and Ctrl+X.

5. Change the directory to `/var/www/html`.

   ```
   cd /var/www/html
   ```

6. Create a new file in the `html` directory named `SamplePage.php`, and then edit the file by calling nano (or the editor of your choice).

   ```
   >SamplePage.php
   nano SamplePage.php
   ```

7. Add the following contents to the `SamplePage.php` file:

   **MariaDB & MySQL**

   ```php
   ?><?php include "./inc/dbinfo.inc"; ?>
   <html>
   <body>
   <h1>Sample page</h1>
   <?php
   /* Connect to MySQL and select the database. */
   $connection = mysqli_connect(DB_SERVER, DB_USERNAME, DB_PASSWORD);
   if (mysqli_connect_errno()) echo "Failed to connect to MySQL: " .
   mysqli_connect_error();
   ```

   ```
   <hr>
   <p>Sample page</p>
   ```
$database = mysqli_select_db($connection, DB_DATABASE);

/* Ensure that the EMPLOYEES table exists. */
VerifyEmployeesTable($connection, DB_DATABASE);

/* If input fields are populated, add a row to the EMPLOYEES table. */
$employee_name = htmlentities($_POST['NAME']);
$employee_address = htmlentities($_POST['ADDRESS']);

if (strlen($employee_name) || strlen($employee_address)) {
    AddEmployee($connection, $employee_name, $employee_address);
}

</form>

<!-- Display table data. -->
<table border="1" cellpadding="2" cellspacing="2">
<tr>
<td>ID</td>
<td>NAME</td>
<td>ADDRESS</td>
</tr>
<?php
$result = mysqli_query($connection, "SELECT * FROM EMPLOYEES");
while($query_data = mysqli_fetch_row($result)) {
    echo "<tr>",
    echo "<td>".$query_data[0].", ".</td>
    "<td>".$query_data[1].", ".</td>
    "<td>".$query_data[2].", ".</td>
    echo "</tr>";
}
?>
</table>

<!-- Clean up. -->
<?php
mysqli_free_result($result);
mysqli_close($connection);
?>
<?php

/* Add an employee to the table. */
function AddEmployee($connection, $name, $address) {
    $n = mysqli_real_escape_string($connection, $name);
    $a = mysqli_real_escape_string($connection, $address);
    $query = "INSERT INTO EMPLOYEES (NAME, ADDRESS) VALUES ('$n', '$a');";
    if(!mysqli_query($connection, $query)) echo("<p>Error adding employee data.</p>");
}

/* Check whether the table exists and, if not, create it. */
function VerifyEmployeesTable($connection, $dbName) {
    if(!TableExists("EMPLOYEES", $connection, $dbName)) {
        $query = "CREATE TABLE EMPLOYEES (ID int(11) UNSIGNED AUTO_INCREMENT PRIMARY KEY,
                                           NAME VARCHAR(45),
                                           ADDRESS VARCHAR(90))";
        if(!mysqli_query($connection, $query)) echo("<p>Error creating table.</p>");
    }
}

/* Check for the existence of a table. */
function TableExists($tableName, $connection, $dbName) {
    $t = mysqli_real_escape_string($connection, $tableName);
    $d = mysqli_real_escape_string($connection, $dbName);
    $checktable = mysqli_query($connection, "SELECT TABLE_NAME FROM information_schema.TABLES WHERE TABLE_NAME = '$t' AND TABLE_SCHEMA = '$d'");
    if(mysqli_num_rows($checktable) > 0) return true;
    return false;
}
?>

PostgreSQL

<?php include "../inc/dbinfo.inc"; ?>

<html>
<body>
<h1>Sample page</h1>
<?php

/* Connect to PostgreSQL and select the database. */
$constring = "host=\". DB_SERVER .\" dbname=\". DB_DATABASE .\" user=\". DB_USERNAME .\" password=\". DB_PASSWORD ;
$connection = pg_connect($constring);

if (!$connection){
    echo "Failed to connect to PostgreSQL";
    exit;
}
/* Ensure that the EMPLOYEES table exists. */
VerifyEmployeesTable($connection, DB_DATABASE);

/* If input fields are populated, add a row to the EMPLOYEES table. */
$employee_name = htmlentities($_POST['NAME']);
$employee_address = htmlentities($_POST['ADDRESS']);
if (strlen($employee_name) || strlen($employee_address)) {
  AddEmployee($connection, $employee_name, $employee_address);
}

<form action="<?PHP echo $_SERVER['SCRIPT_NAME'] ?>" method="POST">
  <table border="0">
    <tr>
      <td>NAME</td>
      <td>ADDRESS</td>
    </tr>
    <tr><td><input type="text" name="NAME" maxlength="45" size="30" /></td></tr>
    <tr><td><input type="text" name="ADDRESS" maxlength="90" size="60" /></td></tr>
    <tr><td><input type="submit" value="Add Data" /></td></tr>
  </table>
</form>

<!-- Display table data. -->
<table border="1" cellpadding="2" cellspacing="2">
  <tr>
    <td>ID</td>
    <td>NAME</td>
    <td>ADDRESS</td>
  </tr>
<?php
$result = pg_query($connection, "SELECT * FROM EMPLOYEES");
while($query_data = pg_fetch_row($result)) {
  echo "<tr>",
  echo "<td>".$query_data[0]. "</td>",
  echo "<td>".$query_data[1]. "</td>",
  echo "<td>".$query_data[2]. "</td>";
  echo "</tr>";
}
<?php
pg_free_result($result);
pg_close($connection);

</table>

<!-- Clean up. -->
<?php
</body>
</html>
<?php
/* Add an employee to the table. */
function AddEmployee($connection, $name, $address) {
    $n = pg_escape_string($name);
    $a = pg_escape_string($address);
    echo "Forming Query;"
    $query = "INSERT INTO EMPLOYEES (NAME, ADDRESS) VALUES ('$n', '$a');"
    if(!pg_query($connection, $query)) echo("<p>Error adding employee data.</p>";
}

/* Check whether the table exists and, if not, create it. */
function VerifyEmployeesTable($connection, $dbName) {
    if(!TableExists("EMPLOYEES", $connection, $dbName))
    {
        $query = "CREATE TABLE EMPLOYEES (ID serial PRIMARY KEY, NAME VARCHAR(45), ADDRESS VARCHAR(90))";
        if(!pg_query($connection, $query)) echo("<p>Error creating table.</p>";
    }
}
/* Check for the existence of a table. */
function TableExists($tableName, $connection, $dbName) {
    $t = strtolower(pg_escape_string($tableName)); //table name is case sensitive.
    $d = pg_escape_string($dbName); //schema is 'public' instead of 'sample' db name
    $query = "SELECT TABLE_NAME FROM information_schema.TABLES WHERE TABLE_NAME = '$t';";
    $checktable = pg_query($connection, $query);
    if (pg_num_rows($checktable) >0) return true;
return false;
}
?>

8. Save and close the SamplePage.php file.

You can use SamplePage.php to add data to your DB cluster. The data that you add is then displayed on the page. To verify that the data was inserted into the table, install MySQL client on the Amazon EC2 instance. Then connect to the DB cluster and query the table.

For information about connecting to a DB cluster, see Connecting to an Amazon Aurora DB cluster (p. 204).

To make sure that your DB cluster is as secure as possible, verify that sources outside of the VPC can't connect to your DB cluster.

After you have finished testing your web server and your database, you should delete your DB cluster and your Amazon EC2 instance.

- To delete a DB cluster, follow the instructions in Deleting Aurora DB clusters and DB instances (p. 374). You don't need to create a final snapshot.
To terminate an Amazon EC2 instance, follow the instruction in Terminate your instance in the Amazon EC2 User Guide.
Amazon Aurora tutorials and sample code

The AWS documentation includes several tutorials that guide you through common Amazon Aurora use cases. Many of these tutorials show you how to use Amazon Aurora with other AWS services. In addition, you can access sample code in GitHub.

Note
You can find more tutorials at the AWS Database Blog. For information about training, see AWS Training and Certification.

Tutorials in this guide

The following tutorials in this guide show you how to perform common tasks with Amazon Aurora:

• Tutorial: Create a VPC for use with a DB cluster (IPv4 only) (p. 2494)
  Learn how to include a DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service. In this case, the VPC shares data with a web server that is running on an Amazon EC2 instance in the same VPC.
• Tutorial: Create a VPC for use with a DB cluster (dual-stack mode) (p. 2499)
  Learn how to include a DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service. In this case, the VPC shares data with an Amazon EC2 instance in the same VPC. In this tutorial, you create the VPC for this scenario that works with a database running in dual-stack mode.
• Tutorial: Create a web server and an Amazon Aurora DB cluster (p. 151)
  Learn how to install an Apache web server with PHP and create a MySQL database. The web server runs on an Amazon EC2 instance using Amazon Linux, and the MySQL database is an Aurora MySQL DB cluster. Both the Amazon EC2 instance and the DB cluster run in an Amazon VPC.
• Tutorial: Restore an Amazon Aurora DB cluster from a DB cluster snapshot (p. 501)
  Learn how to restore a DB cluster from a DB cluster snapshot.
• Tutorial: Use tags to specify which Aurora DB clusters to stop (p. 387)
  Learn how to use tags to specify which Aurora DB clusters to stop.
• Tutorial: Log DB instance state changes using Amazon EventBridge (p. 706)
  Learn how to log a DB instance state change using Amazon EventBridge and AWS Lambda.
Tutorials in other AWS guides

The following tutorials in other AWS guides show you how to perform common tasks with Amazon Aurora:

**Note**
Some of the tutorials use Amazon RDS DB instances, but they can be adapted to use Aurora DB clusters.

- **Tutorial: Aurora Serverless** in the *AWS AppSync Developer Guide*

  Learn how to use AWS AppSync to provide a data source for running SQL commands against Aurora Serverless DB clusters with the Data API enabled. You can use AWS AppSync resolvers to run SQL statements against the Data API with GraphQL queries, mutations, and subscriptions.

- **Tutorial: Rotating a Secret for an AWS Database** in the *AWS Secrets Manager User Guide*

  Learn how to create a secret for an AWS database and configure the secret to rotate on a schedule. You trigger one rotation manually, and then confirm that the new version of the secret continues to provide access.

- **Tutorials and samples** in the *AWS Elastic Beanstalk Developer Guide*

  Learn how to deploy applications that use Amazon RDS databases with AWS Elastic Beanstalk.

- **Using Data from an Amazon RDS Database to Create an Amazon ML Datasource** in the *Amazon Machine Learning Developer Guide*

  Learn how to create an Amazon Machine Learning (Amazon ML) datasource object from data stored in a MySQL DB instance.

- **Manually Enabling Access to an Amazon RDS Instance in a VPC** in the *Amazon QuickSight User Guide*

  Learn how to enable Amazon QuickSight access to an Amazon RDS DB instance in a VPC.

AWS workshop and lab content portal for Amazon Aurora PostgreSQL

The following collection of workshops and other hands-on content helps you to gain an understanding of the Amazon Aurora PostgreSQL features and capabilities:

- **Creating an Aurora Cluster**

  Learn how to create an Amazon Aurora PostgreSQL cluster manually.

- **Creating a Cloud9 Cloud-based IDE environment to connect to your database**

  Learn how to configure Cloud9 and initialize the PostgreSQL database.

- **Fast Cloning**

  Learn how to create an Aurora fast clone.

- **Query Plan Management**

  Learn how to control execution plans for a set of statements using query plan management.

- **Cluster Cache Management**

  Learn about Cluster Cache Management feature in Aurora PostgreSQL.

- **Database Activity Streaming**
Learn how to monitor and audit your database activity with this feature.

- **Using Performance Insights**
  
  Learn how to monitor and tune your DB instance using Performance insights.

- **Performance Monitoring with RDS Tools**
  
  Learn how to use AWS and Postgres tools (Cloudwatch, Enhanced Monitoring, Slow Query Logs, Performance Insights, PostgreSQL Catalog Views) to understand performance issues and identify ways to improve performance of your database.

- **Auto Scaling Read Replicas**
  
  Learn how Aurora read replica auto scaling works in practice using a load generator script.

- **Testing Fault Tolerance**
  
  Learn how a DB cluster can tolerate a failure.

- **Aurora Global Database**

Configuring your Amazon Aurora DB cluster

This section shows how to set up your Aurora DB cluster. Before creating an Aurora DB cluster, decide on the DB instance class that will run the DB cluster. Also, decide where the DB cluster will run by choosing an AWS Region. Next, create the DB cluster. If you have data outside of Aurora, you can migrate the data into an Aurora DB cluster.

Topics

- Creating an Amazon Aurora DB cluster (p. 179)
- Creating Amazon Aurora resources with AWS CloudFormation (p. 203)
- Connecting to an Amazon Aurora DB cluster (p. 204)
- Working with parameter groups (p. 212)
- Migrating data to an Amazon Aurora DB cluster (p. 241)
- Creating an Amazon ElastiCache cluster using Aurora DB cluster settings (p. 242)
Creating an Amazon Aurora DB cluster

An Amazon Aurora DB cluster consists of a DB instance, compatible with either MySQL or PostgreSQL, and a cluster volume that holds the data for the DB cluster, copied across three Availability Zones as a single, virtual volume. By default, an Aurora DB cluster contains a primary DB instance that performs reads and writes, and, optionally, up to 15 Aurora Replicas (reader DB instances). For more information about Aurora DB clusters, see Amazon Aurora DB clusters (p. 3).

Aurora has two main types of DB cluster:

- Aurora provisioned – You choose the DB instance class for the writer and reader instances based on your expected workload. For more information, see Aurora DB instance classes (p. 84). Aurora provisioned has several options, including Aurora global databases. For more information, see Using Amazon Aurora global databases (p. 1800).

- Aurora Serverless – Aurora Serverless v1 and Aurora Serverless v2 are on-demand automatic scaling configurations for Aurora. Capacity is adjusted automatically based on application demand. You’re charged only for the resources that your DB cluster consumes. This automation is especially useful for environments with highly variable and unpredictable workloads. For more information, see Using Amazon Aurora Serverless v1 (p. 2023) and Using Aurora Serverless v2 (p. 1961).

Following, you can find out how to create an Aurora DB cluster. To get started, first see DB cluster prerequisites (p. 179).

For instructions on connecting to your Aurora DB cluster, see Connecting to an Amazon Aurora DB cluster (p. 204).

Topics
- DB cluster prerequisites (p. 179)
- Creating a DB cluster (p. 183)
- Settings for Aurora DB clusters (p. 190)
- Settings that don't apply to Amazon Aurora for DB clusters (p. 200)
- Settings that don't apply to Amazon Aurora DB instances (p. 201)

DB cluster prerequisites

Important
Before you can create an Aurora DB cluster, you must complete the tasks in Setting up your environment for Amazon Aurora (p. 119).

The following are prerequisites to complete before creating a DB cluster.

Topics
- Configure the network for the DB cluster (p. 179)
- Additional prerequisites (p. 183)

Configure the network for the DB cluster

You can create an Amazon Aurora DB cluster only in a virtual private cloud (VPC) based on the Amazon VPC service, in an AWS Region that has at least two Availability Zones. The DB subnet group that you choose for the DB cluster must cover at least two Availability Zones. This configuration ensures that your DB cluster always has at least one DB instance available for failover, in the unlikely event of an Availability Zone failure.
If you plan to set up connectivity between your new DB cluster and an EC2 instance in the same VPC, you can do so during DB cluster creation. If you plan to connect to your DB cluster from resources other than EC2 instances in the same VPC, you can configure the network connections manually.

Topics

- Configure automatic network connectivity with an EC2 instance (p. 180)
- Configure the network manually (p. 182)

Configure automatic network connectivity with an EC2 instance

When you create an Aurora DB cluster, you can use the AWS Management Console to set up connectivity between an Amazon EC2 instance and the new DB cluster. When you do so, RDS configures your VPC and network settings automatically. The DB cluster is created in the same VPC as the EC2 instance so that the EC2 instance can access the DB cluster.

The following are requirements for connecting an EC2 instance with the DB cluster:

- The EC2 instance must exist in the AWS Region before you create the DB cluster.
  
  If no EC2 instances exist in the AWS Region, the console provides a link to create one.
- Currently, the DB cluster can't be an Aurora Serverless DB cluster or part of an Aurora global database.
- The user who is creating the DB instance must have permissions to perform the following operations:
  - ec2:AssociateRouteTable
  - ec2:AuthorizeSecurityGroupEgress
  - ec2:AuthorizeSecurityGroupIngress
  - ec2:CreateRouteTable
  - ec2:CreateSubnet
  - ec2:CreateSecurityGroup
  - ec2:DescribeInstances
  - ec2:DescribeNetworkInterfaces
  - ec2:DescribeRouteTables
  - ec2:DescribeSecurityGroups
  - ec2:DescribeSubnets
  - ec2:ModifyNetworkInterfaceAttribute
  - ec2:RevokeSecurityGroupEgress

Using this option creates a private DB cluster. The DB cluster uses a DB subnet group with only private subnets to restrict access to resources within the VPC.

To connect an EC2 instance to the DB cluster, choose Connect to an EC2 compute resource in the Connectivity section on the Create database page.
When you choose **Connect to an EC2 compute resource**, RDS sets the following options automatically. You can't change these settings unless you choose not to set up connectivity with an EC2 instance by choosing **Don't connect to an EC2 compute resource**.

<table>
<thead>
<tr>
<th>Console option</th>
<th>Automatic setting</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Network type</strong></td>
<td>RDS sets network type to IPv4. Currently, dual-stack mode isn't supported when you set up a connection between an EC2 instance and the DB cluster.</td>
</tr>
<tr>
<td><strong>Virtual Private Cloud (VPC)</strong></td>
<td>RDS sets the VPC to the one associated with the EC2 instance.</td>
</tr>
<tr>
<td><strong>DB subnet group</strong></td>
<td>RDS requires a DB subnet group with a private subnet in the same Availability Zone as the EC2 instance. If a DB subnet group that meets this requirement exists, then RDS uses the existing DB subnet group. By default, this option is set to <strong>Automatic setup</strong>. When you choose <strong>Automatic setup</strong> and there is no DB subnet group that meets this requirement, the following action happens. RDS uses three available private subnets in three Availability Zones where one of the Availability Zones is the same as the EC2 instance. If a private subnet isn't available in an Availability Zone, RDS creates a private subnet in the Availability Zone. Then RDS creates the DB subnet group. When a private subnet is available, RDS uses the route table associated with the subnet and adds any subnets it creates to this route table. When no private subnet is available, RDS creates a route table without internet gateway access and adds the subnets it creates to the route table. RDS also allows you to use existing DB subnet groups. Select <strong>Choose existing</strong> if you want to use an existing DB subnet group of your choice.</td>
</tr>
<tr>
<td><strong>Public access</strong></td>
<td>RDS chooses <strong>No</strong> so that the DB cluster isn't publicly accessible. For security, it is a best practice to keep the database private and make sure it isn't accessible from the internet.</td>
</tr>
<tr>
<td><strong>VPC security group (firewall)</strong></td>
<td>RDS creates a new security group that is associated with the DB cluster. The security group is named <code>rds-ec2-n</code>, where <code>n</code> is a number. This security group is also added to the database with an inbound rule that allows the EC2 instance to access the database.</td>
</tr>
</tbody>
</table>
**Console option** | **Automatic setting**
---|---
| group includes an inbound rule with the EC2 VPC security group (firewall) as the source. This security group that is associated with the DB cluster allows the EC2 instance to access the DB cluster. RDS also creates a new security group that is associated with the EC2 instance. The security group is named **ec2-rds-n**, where *n* is a number. This security group includes an outbound rule with the VPC security group of the DB cluster as the source. This security group allows the EC2 instance to send traffic to the DB cluster. You can add another new security group by choosing **Create new** and typing the name of the new security group. You can add existing security groups by choosing **Choose existing** and selecting security groups to add. |

**Availability Zone**

When you don't create an Aurora Replica in **Availability & durability** during DB cluster creation (Single-AZ deployment), RDS chooses the Availability Zone of the EC2 instance.

When you create an Aurora Replica during DB cluster creation (Multi-AZ deployment), RDS chooses the Availability Zone of the EC2 instance for one DB instance in the DB cluster. RDS randomly chooses a different Availability Zone for the other DB instance in the DB cluster. Either the primary DB instance or the Aurora Replica is created in the same Availability Zone as the EC2 instance. There is the possibility of cross Availability Zone costs if the primary DB instance and EC2 instance are in different Availability Zones.

For more information about these settings, see [Settings for Aurora DB clusters (p. 190)](https://aws.amazon.com/rds/aurora-user-guide/). If you make any changes to these settings after the DB cluster is created, the changes might affect the connection between the EC2 instance and the DB cluster.

**Configure the network manually**

If you plan to connect to your DB cluster from resources other than EC2 instances in the same VPC, you can configure the network connections manually. If you use the AWS Management Console to create your DB cluster, you can have Amazon RDS automatically create a VPC for you. Or you can use an existing VPC or create a new VPC for your Aurora DB cluster. Whichever approach you take, your VPC must have at least one subnet in each of at least two Availability Zones for you to use it with an Amazon Aurora DB cluster.

By default, Amazon RDS creates the primary DB instance and the Aurora Replica in the Availability Zones automatically for you. To choose a specific Availability Zone, you need to change the **Availability & durability** Multi-AZ deployment setting to **Don't create an Aurora Replica**. Doing so exposes an **Availability Zone** setting that lets you choose from among the Availability Zones in your VPC. However, we strongly recommend that you keep the default setting and let Amazon RDS create a Multi-AZ deployment and choose Availability Zones for you. By doing so, your Aurora DB cluster is created with the fast failover and high availability features that are two of Aurora's key benefits.

If you don't have a default VPC or you haven't created a VPC, you can have Amazon RDS automatically create a VPC for you when you create a DB cluster using the console. Otherwise, you must do the following:
• Create a VPC with at least one subnet in each of at least two of the Availability Zones in the AWS Region where you want to deploy your DB cluster. For more information, see Working with a DB cluster in a VPC (p. 2479) and Tutorial: Create a VPC for use with a DB cluster (IPv4 only) (p. 2494).

• Specify a VPC security group that authorizes connections to your DB cluster. For more information, see Provide access to the DB cluster in the VPC by creating a security group (p. 122) and Controlling access with security groups (p. 2471).

• Specify an RDS DB subnet group that defines at least two subnets in the VPC that can be used by the DB cluster. For more information, see Working with DB subnet groups (p. 2479).

For information on VPCs, see Amazon VPC VPCs and Amazon Aurora (p. 2478). For a tutorial that configures the network for a private DB cluster, see Tutorial: Create a VPC for use with a DB cluster (IPv4 only) (p. 2494).

If you want to connect to a resource that isn't in the same VPC as the Aurora DB cluster, see the appropriate scenarios in Scenarios for accessing a DB cluster in a VPC (p. 2489).

Additional prerequisites

Before you create your DB cluster, consider the following additional prerequisites:

• If you are connecting to AWS using AWS Identity and Access Management (IAM) credentials, your AWS account must have IAM policies that grant the permissions required to perform Amazon RDS operations. For more information, see Identity and access management for Amazon Aurora (p. 2400).

If you are using IAM to access the Amazon RDS console, you must first sign on to the AWS Management Console with your user credentials. Then go to the Amazon RDS console at https://console.aws.amazon.com/rds/.

• If you want to tailor the configuration parameters for your DB cluster, you must specify a DB cluster parameter group and DB parameter group with the required parameter settings. For information about creating or modifying a DB cluster parameter group or DB parameter group, see Working with parameter groups (p. 212).

• Determine the TCP/IP port number to specify for your DB cluster. The firewalls at some companies block connections to the default ports (3306 for MySQL, 5432 for PostgreSQL) for Aurora. If your company firewall blocks the default port, choose another port for your DB cluster. All instances in a DB cluster use the same port.

Creating a DB cluster

You can create an Aurora DB cluster using the AWS Management Console, the AWS CLI, or the RDS API.

Console

You can create a DB instance running MySQL with the AWS Management Console with Easy create enabled or not enabled. With Easy create enabled, you specify only the DB engine type, DB instance size, and DB instance identifier. Easy create uses the default setting for other configuration options. With Easy create not enabled, you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

Note

For this example, Standard create is enabled, and Easy create isn't enabled. For information about creating an Aurora MySQL DB cluster with Easy create enabled, see Getting started with Amazon Aurora (p. 124).
To create an Aurora DB cluster using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you want to create the DB cluster.

   Aurora is not available in all AWS Regions. For a list of AWS Regions where Aurora is available, see Region availability (p. 17).

3. In the navigation pane, choose Databases.

4. Choose Create database.

5. For Choose a database creation method, choose Standard create.

6. For Engine type, choose one of the following:
   - Aurora (MySQL Compatible)
   - Aurora (PostgreSQL Compatible)

7. Choose the Engine version.

   For more information, see Amazon Aurora versions (p. 4). You can use the filters to choose versions that are compatible with features that you want, such as Aurora Serverless v2. For more information, see Using Aurora Serverless v2 (p. 1961).

8. In Templates, choose the template that matches your use case.

9. To enter your master password, do the following:
a. In the **Settings** section, expand **Credential Settings**.

b. Clear the **Auto generate a password** check box.

c. (Optional) Change the **Master username** value and enter the same password in **Master password** and **Confirm password**.

By default, the new DB instance uses an automatically generated password for the master user.

10. In the **Connectivity** section under **VPC security group (firewall)**, if you select **Create new**, a VPC security group is created with an inbound rule that allows your local computer's IP address to access the database.

11. For **Cluster storage configuration**, choose either **Aurora I/O-Optimized** or **Aurora Standard**. For more information, see **Storage configurations for Amazon Aurora DB clusters** (p. 97).

12. (Optional) Set up a connection to a compute resource for this DB cluster.

You can configure connectivity between an Amazon EC2 instance and the new DB cluster during DB cluster creation. For more information, see **Configure automatic network connectivity with an EC2 instance** (p. 180).

13. For the remaining sections, specify your DB cluster settings. For information about each setting, see **Settings for Aurora DB clusters** (p. 190).

14. Choose **Create database**.

If you chose to use an automatically generated password, the **View credential details** button appears on the **Databases** page.

To view the master user name and password for the DB cluster, choose **View credential details**.

To connect to the DB instance as the master user, use the user name and password that appear.

**Important**

You can't view the master user password again. If you don't record it, you might have to change it. If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see **Modifying an Amazon Aurora DB cluster** (p. 269).

15. For **Databases**, choose the name of the new Aurora DB cluster.

On the RDS console, the details for new DB cluster appear. The DB cluster and its DB instance have a status of **creating** until the DB cluster is ready to use.
Creating a DB cluster

When the state changes to available for both, you can connect to the DB cluster. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new DB cluster is available.

To view the newly created cluster, choose Databases from the navigation pane in the Amazon RDS console. Then choose the DB cluster to show the DB cluster details. For more information, see Viewing an Amazon Aurora DB cluster (p. 515).
On the Connectivity & security tab, note the port and the endpoint of the writer DB instance. Use the endpoint and port of the cluster in your JDBC and ODBC connection strings for any application that performs write or read operations.

**AWS CLI**

**Note**
Before you can create an Aurora DB cluster using the AWS CLI, you must fulfill the required prerequisites, such as creating a VPC and an RDS DB subnet group. For more information, see [DB cluster prerequisites](p. 179).

You can use the AWS CLI to create an Aurora MySQL DB cluster or an Aurora PostgreSQL DB cluster.

**To create an Aurora MySQL DB cluster using the AWS CLI**

When you create an Aurora MySQL 8.0-compatible or 5.7-compatible DB cluster or DB instance, you specify `aurora-mysql` for the `--engine` option.

Complete the following steps:
1. Identify the DB subnet group and VPC security group ID for your new DB cluster, and then call the
   `create-db-cluster` AWS CLI command to create the Aurora MySQL DB cluster.

   For example, the following command creates a new MySQL 8.0–compatible DB cluster named
   `sample-cluster`. The cluster uses the default engine version and the Aurora I/O-Optimized
   storage type.

   For Linux, macOS, or Unix:
   ```
   aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora-mysql --engine-version 8.0 --storage-type aurora-iopt1 --master-username user-name --manage-master-user-password --db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2
   ```

   For Windows:
   ```
   aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora-mysql --engine-version 8.0 --storage-type aurora-iopt1 --master-username user-name --manage-master-user-password --db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2
   ```

   The following command creates a new MySQL 5.7–compatible DB cluster named `sample-cluster`.
   The cluster uses the default engine version and the Aurora Standard storage type.

   For Linux, macOS, or Unix:
   ```
   aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora-mysql --engine-version 5.7 --storage-type aurora --master-username user-name --manage-master-user-password --db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2
   ```

   For Windows:
   ```
   aws rds create-db-cluster --db-cluster-identifier sample-cluster sample-cluster --engine aurora-mysql --engine-version 5.7 --storage-type aurora --master-username user-name --manage-master-user-password --db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2
   ```

2. If you use the console to create a DB cluster, then Amazon RDS automatically creates the primary
   instance (writer) for your DB cluster. If you use the AWS CLI to create a DB cluster, you must explicitly
   create the primary instance for your DB cluster. The primary instance is the first instance that is
   created in a DB cluster. Until you create the primary DB instance, the DB cluster endpoints remain in
   the Creating status.

   Call the `create-db-instance` AWS CLI command to create the primary instance for your DB cluster.
   Include the name of the DB cluster as the `--db-cluster-identifier` option value.

   **Note**
   You can't set the `--storage-type` option for DB instances. You can set it only for DB
   clusters.

   For example, the following command creates a new MySQL 5.7–compatible or MySQL 8.0–
   compatible DB instance named `sample-instance`.

   For Linux, macOS, or Unix:
To create an Aurora PostgreSQL DB cluster using the AWS CLI

1. Identify the DB subnet group and VPC security group ID for your new DB cluster, and then call the `create-db-cluster` AWS CLI command to create the Aurora PostgreSQL DB cluster.

   For example, the following command creates a new DB cluster named `sample-cluster`. The cluster uses the default engine version and the Aurora I/O-Optimized storage type.

   For Linux, macOS, or Unix:
   ```bash
   aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora-postgresql --storage-type aurora-iopt1 --master-username user-name --manage-master-user-password --db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2
   ```

   For Windows:
   ```bash
   aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora-postgresql --storage-type aurora-iopt1 --master-username user-name --manage-master-user-password --db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2
   ```

2. If you use the console to create a DB cluster, then Amazon RDS automatically creates the primary instance (writer) for your DB cluster. If you use the AWS CLI to create a DB cluster, you must explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster. Until you create the primary DB instance, the DB cluster endpoints remain in theCreating status.

   Call the `create-db-instance` AWS CLI command to create the primary instance for your DB cluster. Include the name of the DB cluster as the `--db-cluster-identifier` option value.

   For Linux, macOS, or Unix:
   ```bash
   aws rds create-db-instance --db-instance-identifier sample-instance --db-cluster-identifier sample-cluster --engine aurora-postgresql --db-instance-class db.r5.large
   ```

   For Windows:
   ```bash
   aws rds create-db-instance --db-instance-identifier sample-instance --db-cluster-identifier sample-cluster --engine aurora-postgresql --db-instance-class db.r5.large
   ```
These examples specify the `--manage-master-user-password` option to generate the master user password and manage it in Secrets Manager. For more information, see Password management with Amazon Aurora and AWS Secrets Manager (p. 2371). Alternatively, you can use the `--master-password` option to specify and manage the password yourself.

### RDS API

**Note**
Before you can create an Aurora DB cluster using the AWS CLI, you must fulfill the required prerequisites, such as creating a VPC and an RDS DB subnet group. For more information, see DB cluster prerequisites (p. 179).

Identify the DB subnet group and VPC security group ID for your new DB cluster, and then call the CreateDBCluster operation to create the DB cluster.

When you create an Aurora MySQL version 2 or 3 DB cluster or DB instance, specify `aurora-mysql` for the Engine parameter.

When you create an Aurora PostgreSQL DB cluster or DB instance, specify `aurora-postgresql` for the Engine parameter.

If you use the console to create a DB cluster, then Amazon RDS automatically creates the primary instance (writer) for your DB cluster. If you use the RDS API to create a DB cluster, you must explicitly create the primary instance for your DB cluster using the CreateDBInstance. The primary instance is the first instance that is created in a DB cluster. Until you create the primary DB instance, the DB cluster endpoints remain in the Creating status.

### Settings for Aurora DB clusters

The following table contains details about settings that you choose when you create an Aurora DB cluster.

**Note**
Additional settings are available if you are creating an Aurora Serverless v1 DB cluster. For information about these settings, see Creating an Aurora Serverless v1 DB cluster (p. 2040). Also, some settings aren’t available for Aurora Serverless v1 because of Aurora Serverless v1 limitations. For more information, see Limitations of Aurora Serverless v1 (p. 2024).

</tbody>
</table>
| **Initial database name** | Enter a name for your default database. If you don't provide a name for an Aurora MySQL DB cluster, Amazon RDS doesn't create a database on the DB cluster you are creating. If you don't provide a name for an Aurora PostgreSQL DB cluster, Amazon RDS creates a database named postgres. For Aurora MySQL, the default database name has these constraints:  
• It must contain 1–64 alphanumeric characters.  
• It can't be a word reserved by the database engine. For Aurora PostgreSQL, the default database name has these constraints:  
• It must contain 1–63 alphanumeric characters.  
• It must begin with a letter. Subsequent characters can be letters, underscores, or digits (0–9).  
• It can't be a word reserved by the database engine. To create additional databases, connect to the DB cluster and use the SQL command CREATE DATABASE. For more information about connecting to the DB cluster, see [Connecting to an Amazon Aurora DB cluster](p. 204). | Using the AWS CLI, run `create-db-cluster` and set the `--database-name` option.  
Using the RDS API, call `CreateDBCluster` and set the `DatabaseName` parameter. |
| **Log exports** | In the Log exports section, choose the logs that you want to start publishing to Amazon CloudWatch Logs. For more information about publishing Aurora MySQL logs to CloudWatch Logs, see [Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs](p. 1083).  
For more information about publishing Aurora PostgreSQL logs to CloudWatch Logs, see [Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs](p. 1548). | Using the AWS CLI, run `create-db-cluster` and set the `--enable-cloudwatch-logs-exports` option.  
Using the RDS API, call `CreateDBCluster` and set the `EnableCloudwatchLogsExports` parameter. |

<tr>
<td><strong>Public access</strong></td>
<td>Choose Publicly accessible to give the DB cluster a public IP address, or choose Not publicly accessible. The instances in your DB cluster can be a mix of both public and private DB instances. For more information about hiding instances from public access, see [Hiding a DB cluster in a VPC from the internet](p. 2484). To connect to a DB instance from outside of its Amazon VPC, the DB instance must be publicly accessible, access must be granted using the inbound rules of the DB instance's security group, and other requirements must be met. For more information, see [Can't connect to Amazon RDS DB instance](p. 2511). If your DB instance is isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see [Internetwork traffic privacy](p. 2399).</td>
<td>Set this value for every DB instance in your Aurora cluster. Using the AWS CLI, run <code>create-db-instance</code> and set the `--publicly-accessible</td>
</tr>
<tr>
<td><strong>RDS Proxy</strong></td>
<td>Choose Create an RDS Proxy to create a proxy for your DB cluster. Amazon RDS automatically creates an IAM role and a Secrets Manager secret for the proxy. For more information, see [Using Amazon RDS Proxy for Aurora](p. 1879).</td>
<td>Not available when creating a DB cluster.</td>
</tr>
<tr>
<td><strong>Retention period</strong></td>
<td>Choose the length of time, from 1 to 35 days, that Aurora retains backup copies of the database. Backup copies can be used for point-in-time restores (PITR) of your database down to the second.</td>
<td>Using the AWS CLI, run <code>create-db-cluster</code> and set the <code>--backup-retention-period</code> option. Using the RDS API, call <code>CreateDBCluster</code> and set the <code>BackupRetentionPeriod</code> parameter.</td>
</tr>
<tr>
<td><strong>Turn on DevOps Guru</strong></td>
<td>Choose Turn on DevOps Guru to turn on Amazon DevOps Guru for your Aurora database. For DevOps Guru for RDS to provide detailed analysis of performance anomalies, Performance Insights must be turned on. For more information, see [Setting up DevOps Guru for RDS](p. 624).</td>
<td>You can turn on DevOps Guru for RDS from within the RDS console, but not by using the RDS API or CLI. For more information about turning on DevOps Guru, see the [Amazon DevOps Guru User Guide](p. 624).</td>

Creating Amazon Aurora resources with AWS CloudFormation

Amazon Aurora is integrated with AWS CloudFormation, a service that helps you to model and set up your AWS resources so that you can spend less time creating and managing your resources and infrastructure. You create a template that describes all the AWS resources that you want (such as DB clusters and DB cluster parameter groups), and AWS CloudFormation provisions and configures those resources for you.

When you use AWS CloudFormation, you can reuse your template to set up your Aurora resources consistently and repeatedly. Describe your resources once, and then provision the same resources over and over in multiple AWS accounts and Regions.

Aurora and AWS CloudFormation templates

To provision and configure resources for Aurora and related services, you must understand AWS CloudFormation templates. Templates are formatted text files in JSON or YAML. These templates describe the resources that you want to provision in your AWS CloudFormation stacks. If you're unfamiliar with JSON or YAML, you can use AWS CloudFormation Designer to help you get started with AWS CloudFormation templates. For more information, see What is AWS CloudFormation Designer? in the AWS CloudFormation User Guide.

Aurora supports creating resources in AWS CloudFormation. For more information, including examples of JSON and YAML templates for these resources, see the RDS resource type reference in the AWS CloudFormation User Guide.

Learn more about AWS CloudFormation

To learn more about AWS CloudFormation, see the following resources:

- AWS CloudFormation
- AWS CloudFormation User Guide
- AWS CloudFormation API Reference
- AWS CloudFormation Command Line Interface User Guide
Connecting to an Amazon Aurora DB cluster

You can connect to an Aurora DB cluster using the same tools that you use to connect to a MySQL or PostgreSQL database. You specify a connection string with any script, utility, or application that connects to a MySQL or PostgreSQL DB instance. You use the same public key for Secure Sockets Layer (SSL) connections.

In the connection string, you typically use the host and port information from special endpoints associated with the DB cluster. With these endpoints, you can use the same connection parameters regardless of how many DB instances are in the cluster. You also use the host and port information from a specific DB instance in your Aurora DB cluster for specialized tasks, such as troubleshooting.

**Note**
For Aurora Serverless DB clusters, you connect to the database endpoint rather than to the DB instance. You can find the database endpoint for an Aurora Serverless DB cluster on the Connectivity & security tab of the AWS Management Console. For more information, see [Using Amazon Aurora Serverless v1](p. 2023).

Regardless of the Aurora DB engine and specific tools you use to work with the DB cluster or instance, the endpoint must be accessible. An Amazon Aurora DB cluster can be created only in a virtual private cloud (VPC) based on the Amazon VPC service. That means that you access the endpoint from either inside the VPC or outside the VPC using one of the following approaches.

- **Access the Amazon Aurora DB cluster inside the VPC** – Enable access to the Amazon Aurora DB cluster through the VPC. You do so by editing the Inbound rules on the Security group for the VPC to allow access to your specific Aurora DB cluster. To learn more, including how to configure your VPC for different Aurora DB cluster scenarios, see [Amazon Virtual Private Cloud VPCs and Amazon Aurora](p. 2023).

- **Access the Amazon Aurora DB cluster outside the VPC** – To access an Amazon Aurora DB cluster from outside the VPC, use the public endpoint address of the Amazon Aurora DB cluster. For more information, see [Troubleshooting Aurora connection failures](p. 211).

For more information, see [Troubleshooting Aurora connection failures](p. 211).

**Topics**

- Connecting to an Amazon Aurora MySQL DB cluster (p. 204)
- Connecting to an Amazon Aurora PostgreSQL DB cluster (p. 209)
- Troubleshooting Aurora connection failures (p. 211)

Connecting to an Amazon Aurora MySQL DB cluster

To authenticate to your Aurora MySQL DB cluster, you can use either MySQL user name and password authentication or AWS Identity and Access Management (IAM) database authentication. For more information on using MySQL user name and password authentication, see [Access control and account management](p. 204) in the MySQL documentation. For more information on using IAM database authentication, see [IAM database authentication](p. 2432).

When you have a connection to your Amazon Aurora DB cluster with MySQL 8.0 compatibility, you can run SQL commands that are compatible with MySQL version 8.0. The minimum compatible version is MySQL 8.0.23. For more information about MySQL 8.0 SQL syntax, see the [MySQL 8.0 reference manual](p. 204). For information about limitations that apply to Aurora MySQL version 3, see [Comparison of Aurora MySQL version 3 and MySQL 8.0 Community Edition](p. 796).

When you have a connection to your Amazon Aurora DB cluster with MySQL 5.7 compatibility, you can run SQL commands that are compatible with MySQL version 5.7. For more information about MySQL 5.7
SQL syntax, see the MySQL 5.7 reference manual. For information about limitations that apply to Aurora MySQL 5.7, see Aurora MySQL version 2 compatible with MySQL 5.7 (p. 811).

**Note**
For a helpful and detailed guide on connecting to an Amazon Aurora MySQL DB cluster, you can see the Aurora connection management handbook.

In the details view for your DB cluster, you can find the cluster endpoint, which you can use in your MySQL connection string. The endpoint is made up of the domain name and port for your DB cluster. For example, if an endpoint value is mycluster.cluster-123456789012.us-east-1.rds.amazonaws.com:3306, then you specify the following values in a MySQL connection string:

- For host or host name, specify mycluster.cluster-123456789012.us-east-1.rds.amazonaws.com
- For port, specify 3306 or the port value you used when you created the DB cluster

The cluster endpoint connects you to the primary instance for the DB cluster. You can perform both read and write operations using the cluster endpoint. Your DB cluster can also have up to 15 Aurora Replicas that support read-only access to the data in your DB cluster. The primary instance and each Aurora Replica has a unique endpoint that is independent of the cluster endpoint and allows you to connect to a specific DB instance in the cluster directly. The cluster endpoint always points to the primary instance. If the primary instance fails and is replaced, then the cluster endpoint points to the new primary instance.

To view the cluster endpoint (writer endpoint), choose **Databases** on the Amazon RDS console and choose the name of the DB cluster to show the DB cluster details.
Topics

- Connection utilities for Aurora MySQL (p. 206)
- Connecting with Aurora MySQL using the MySQL utility (p. 207)
- Connecting with the Amazon Web Services JDBC Driver for MySQL (p. 208)
- Connecting with SSL for Aurora MySQL (p. 208)

Connection utilities for Aurora MySQL

Some connection utilities you can use are the following:

- **Command line** – You can connect to an Amazon Aurora DB cluster by using tools like the MySQL command line utility. For more information on using the MySQL utility, see [mysql — the MySQL command-line client](https://dev.mysql.com/doc/mysql/en/mysql.html) in the MySQL documentation.

- **GUI** – You can use the MySQL Workbench utility to connect by using a UI interface. For more information, see the [Download MySQL workbench](https://dev.mysql.com/downloads/workbench/) page.
• **Applications** – You can use the AWS JDBC Driver for MySQL to connect your client applications to an Aurora MySQL DB cluster. For more information about the AWS JDBC Driver for MySQL and complete instructions for using it, see the [AWS JDBC Driver for MySQL GitHub repository](https://github.com/aws/aws-java-db-connector-mysql).

  **Note**
  Version 3.0.3 of the MariaDB Connector/J utility drops support for Aurora DB clusters, so we highly recommend moving to the AWS JDBC Driver for MySQL. The AWS JDBC Driver for MySQL offers improved failover speed for Aurora MySQL DB clusters.
  If you are using an Aurora Serverless v1 DB cluster, the failover benefits don’t apply, but you can disable the feature by setting the `failureDetectionEnabled` parameter to false. To review a complete list of configuration options, see the [AWS JDBC Driver for MySQL GitHub repository](https://github.com/aws/aws-java-db-connector-mysql).

### Connecting with Aurora MySQL using the MySQL utility

Use the following procedure. It assumes that you configured your DB cluster in a private subnet in your VPC. You connect using an Amazon EC2 instance that you configured according to the tutorials in Tutorial: Create a web server and an Amazon Aurora DB cluster (p. 151).

  **Note**
  This procedure doesn’t require installing the web server in the tutorial, but it does require installing MariaDB 10.5.

#### To connect to a DB cluster using the MySQL utility

1. **Log in to the EC2 instance that you’re using to connect to your DB cluster.**

   You should see output similar to the following.

   ```
   Last login: Thu Jun 23 13:32:52 2022 from xxx.xxx.xxx.xxx  
   _|__|__|__|__| Amazon Linux 2 AMI  
   [ec2-user@ip-10-0-xxx.xxx ~]$  
   ```

2. **Type the following command at the command prompt to connect to the primary DB instance of your DB cluster.**

   For the `-h` parameter, substitute the endpoint DNS name for your primary instance. For the `-u` parameter, substitute the user ID of a database user account.

   ```
   mysql -h primary-instance-endpoint.AWS_account.AWS_Region.rds.amazonaws.com -P 3306 -u database_user -p  
   ```

   For example:

   ```
   mysql -h my-aurora-cluster-instance.c1xy5example.123456789012.eu-central-1.rds.amazonaws.com -P 3306 -u admin -p  
   ```

3. **Enter the password for the database user.**

   You should see output similar to the following.

   ```
   Welcome to the MariaDB monitor. Commands end with ; or \g.  
   Your MySQL connection id is 1770  
   ```
Connecting with the Amazon Web Services JDBC Driver for MySQL

The AWS JDBC Driver for MySQL is a client driver designed for the high availability of Aurora MySQL. The driver is drop-in compatible with the MySQL Connector/J driver. To install or upgrade your connector, replace the MySQL connector .jar file (located in the application CLASSPATH) with the AWS JDBC Driver for MySQL .jar file, and update the connection URL prefix from `jdbc:mysql://` to `jdbc:mysql:aws://`.

The AWS JDBC Driver for MySQL takes full advantage of the failover capabilities of Aurora MySQL. In the event of a failover, the driver queries the cluster directly for the new topology instead of using DNS resolution. By querying the cluster directly, the driver can connect to the new primary faster in a reliable and predictable manner. This approach helps avoid potential delays caused by DNS resolution.

The AWS JDBC Driver for MySQL supports IAM database authentication. For more information, see AWS IAM Database Authentication in the AWS JDBC Driver for MySQL GitHub repository. For more information about IAM database authentication, see IAM database authentication (p. 2432).

For more information about the AWS JDBC Driver for MySQL and complete instructions for using it, see the AWS JDBC Driver for MySQL GitHub repository.

Connecting with SSL for Aurora MySQL

You can use SSL encryption on connections to an Aurora MySQL DB instance. For information, see Using TLS with Aurora MySQL DB clusters (p. 814).

To connect using SSL, use the MySQL utility as described in the following procedure. If you are using IAM database authentication, you must use an SSL connection. For information, see IAM database authentication (p. 2432).

**Note**
To connect to the cluster endpoint using SSL, your client connection utility must support Subject Alternative Names (SAN). If your client connection utility doesn't support SAN, you can connect directly to the instances in your Aurora DB cluster. For more information on Aurora endpoints, see Amazon Aurora connection management (p. 62).

To connect to a DB cluster with SSL using the MySQL utility

1. Download the public key for the Amazon RDS signing certificate.

   For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 2385).

2. Type the following command at a command prompt to connect to the primary instance of a DB cluster with SSL using the MySQL utility. For the `-h` parameter, substitute the endpoint DNS name for your primary instance. For the `-u` parameter, substitute the user ID of a database user account. For the `--ssl-ca` parameter, substitute the SSL certificate file name as appropriate. Type the master user password when prompted.
You should see output similar to the following.

Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 350
Server version: 8.0.26-log MySQL Community Server (GPL)
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql>

For general instructions on constructing RDS for MySQL connection strings and finding the public key for SSL connections, see Connecting to a DB instance running the MySQL database engine.

Connecting to an Amazon Aurora PostgreSQL DB cluster

You can connect to a DB instance in your Amazon Aurora PostgreSQL DB cluster using the same tools that you use to connect to a PostgreSQL database. As part of this, you use the same public key for Secure Sockets Layer (SSL) connections. You can use the endpoint and port information from the primary instance or Aurora Replicas in your Aurora PostgreSQL DB cluster in the connection string of any script, utility, or application that connects to a PostgreSQL DB instance. In the connection string, specify the DNS address from the primary instance or Aurora Replica endpoint as the host parameter. Specify the port number from the endpoint as the port parameter.

When you have a connection to a DB instance in your Amazon Aurora PostgreSQL DB cluster, you can run any SQL command that is compatible with PostgreSQL.

In the details view for your Aurora PostgreSQL DB cluster you can find the cluster endpoint name, status, type, and port number. You use the endpoint and port number in your PostgreSQL connection string. For example, if an endpoint value is mycluster.cluster-123456789012.us-east-1.rds.amazonaws.com, then you specify the following values in a PostgreSQL connection string:

- For host or host name, specify mycluster.cluster-123456789012.us-east-1.rds.amazonaws.com
- For port, specify 5432 or the port value you used when you created the DB cluster

The cluster endpoint connects you to the primary instance for the DB cluster. You can perform both read and write operations using the cluster endpoint. Your DB cluster can also have up to 15 Aurora Replicas that support read-only access to the data in your DB cluster. Each DB instance in the Aurora cluster (that is, the primary instance and each Aurora Replica) has a unique endpoint that is independent of the cluster endpoint. This unique endpoint allows you to connect to a specific DB instance in the cluster directly. The cluster endpoint always points to the primary instance. If the primary instance fails and is replaced, the cluster endpoint points to the new primary instance.

To view the cluster endpoint (writer endpoint), choose Databases on the Amazon RDS console and choose the name of the DB cluster to show the DB cluster details.
Connection utilities for Aurora PostgreSQL

Some connection utilities you can use are the following:

- **Command line** – You can connect to Aurora PostgreSQL DB clusters by using tools like psql, the PostgreSQL interactive terminal. For more information on using the PostgreSQL interactive terminal, see `psql` in the PostgreSQL documentation.

- **GUI** – You can use the pgAdmin utility to connect to Aurora PostgreSQL DB clusters by using a UI interface. For more information, see the Download page from the pgAdmin website.

- **Applications** – You can use the AWS JDBC Driver for PostgreSQL to connect your applications to your Aurora PostgreSQL DB clusters. For more information, see the Connecting with the AWS JDBC Driver for PostgreSQL (p. 210).

Connecting with the AWS JDBC Driver for PostgreSQL

The AWS JDBC Driver for PostgreSQL is a client wrapper designed to help you take full advantage of the high availability features of Aurora PostgreSQL. For more information about the AWS JDBC Driver
for PostgreSQL and complete instructions for using it, see the AWS JDBC Driver for PostgreSQL GitHub repository.

The AWS JDBC Driver for PostgreSQL extends the community pgJDBC driver. It has been designed to take full advantage of the cluster-aware failover capabilities of Aurora PostgreSQL. In the event of a failover, the AWS JDBC Driver for PostgreSQL queries the cluster directly for the new topology instead of using DNS resolution. By querying the cluster directly, the AWS JDBC Driver for PostgreSQL is able to connect to the new primary faster in a reliable and predictable manner, avoiding potential delays caused by DNS resolution.

The AWS JDBC Driver for PostgreSQL supports AWS Identity and Access Management (IAM) database authentication and AWS Secrets Manager. For more information on using these authentication mechanisms with the driver, see AWS IAM Authentication Plugin and AWS Secrets Manager Plugin in the AWS JDBC Driver for PostgreSQL GitHub repository.

For more information about IAM database authentication, see IAM database authentication (p. 2432). For more information about Secrets Manager, see the AWS Secrets Manager User Guide.

**Troubleshooting Aurora connection failures**

Common causes of connection failures to a new Aurora DB cluster include the following:

- **Security group in the VPC doesn't allow access** – Your VPC needs to allow connections from your device or from an Amazon EC2 instance by proper configuration of the security group in the VPC. To resolve, modify your VPC's Security group Inbound rules to allow connections. For an example, see Tutorial: Create a VPC for use with a DB cluster (IPv4 only) (p. 2494).
- **Port blocked by firewall rules** – Check the value of the port configured for your Aurora DB cluster. If a firewall rule blocks that port, you can re-create the instance using a different port.
- **Incomplete or incorrect IAM configuration** – If you created your Aurora DB instance to use IAM-based authentication, make sure that it's properly configured. For more information, see IAM database authentication (p. 2432).

For more information about troubleshooting Aurora DB connection issues, see Can't connect to Amazon RDS DB instance (p. 2511).
Working with parameter groups

*Database parameters* specify how the database is configured. For example, database parameters can specify the amount of resources, such as memory, to allocate to a database.

You manage your database configuration by associating your DB instances and Aurora DB clusters with parameter groups. Aurora defines parameter groups with default settings. You can also define your own parameter groups with customized settings.

**Topics**
- Overview of parameter groups (p. 212)
- Working with DB cluster parameter groups (p. 214)
- Working with DB parameter groups (p. 226)
- Comparing parameter groups (p. 236)
- Specifying DB parameters (p. 237)

**Overview of parameter groups**

A *DB cluster parameter group* acts as a container for engine configuration values that apply to every DB instance in an Aurora DB cluster. For example, the Aurora shared storage model requires that every DB instance in an Aurora cluster use the same setting for parameters such as `innodb_file_per_table`. Thus, parameters that affect the physical storage layout are part of the cluster parameter group. The DB cluster parameter group also includes default values for all instance-level parameters.

A *DB parameter group* acts as a container for engine configuration values that are applied to one or more DB instances. DB parameter groups apply to DB instances in both Amazon RDS and Aurora. These configuration settings apply to properties that can vary among the DB instances within an Aurora cluster, such as the sizes for memory buffers.

**Topics**
- Default and custom parameter groups (p. 212)
- Static and dynamic DB cluster parameters (p. 213)
- Static and dynamic DB instance parameters (p. 213)
- Character set parameters (p. 214)
- Supported parameters and parameter values (p. 214)

**Default and custom parameter groups**

If you create a DB instance without specifying a DB parameter group, the DB instance uses a default DB parameter group. Likewise, if you create an Aurora DB cluster without specifying a DB cluster parameter group, the DB cluster uses a default DB cluster parameter group. Each default parameter group contains database engine defaults and Amazon RDS system defaults based on the engine, compute class, and allocated storage of the instance.

You can't modify the parameter settings of a default parameter group. Instead, you can do the following:

1. Create a new parameter group.
2. Change the settings of your desired parameters. Not all DB engine parameters in a parameter group are eligible to be modified.
3. Modify your DB instance or DB cluster to use the custom parameter group. For information about modifying a DB cluster or DB instance, see Modifying an Amazon Aurora DB cluster (p. 269).
Note
If you have modified your DB instance to use a custom parameter group, and you start the DB instance, RDS automatically reboots the DB instance as part of the startup process.

If you update parameters within a DB parameter group, the changes apply to all DB instances that are associated with that parameter group. Likewise, if you update parameters within an Aurora DB cluster parameter group, the changes apply to all Aurora DB clusters that are associated with that DB cluster parameter group.

If you don't want to create a parameter group from scratch, you can copy an existing parameter group with the AWS CLI `copy-db-parameter-group` command or `copy-db-cluster-parameter-group` command. You might find that copying a parameter group is useful in some cases. For example, you might want to include most of an existing parameter group's custom parameters and values in a new parameter group.

Static and dynamic DB cluster parameters

DB cluster parameters are either static or dynamic. They differ in the following ways:

- When you change a static parameter and save the DB cluster parameter group, the parameter change takes effect after you manually reboot the DB instances in each associated DB cluster. When you use the AWS Management Console to change static DB cluster parameter values, it always uses `pending-reboot` for the `ApplyMethod`.

- When you change a dynamic parameter, by default the parameter change takes effect immediately, without requiring a reboot. When you use the console, it always uses `immediate` for the `ApplyMethod`. To defer the parameter change until after you reboot the DB instances in an associated DB cluster, use the AWS CLI or RDS API. Set the `ApplyMethod` to `pending-reboot` for the parameter change.

For more information about using the AWS CLI to change a parameter value, see `modify-db-cluster-parameter-group`. For more information about using the RDS API to change a parameter value, see `ModifyDBClusterParameterGroup`.

If you change the DB cluster parameter group associated with a DB cluster, reboot the DB instances in the DB cluster. The reboot applies the changes to all DB instances in the DB cluster. To determine whether the DB instances of a DB cluster must be rebooted to apply changes, run the following AWS CLI command.

```
aws rds describe-db-clusters --db-cluster-identifier db_cluster_identifier
```

Check the `DBClusterParameterGroupStatus` value for the primary DB instance in the output. If the value is `pending-reboot`, then reboot the DB instances of the DB cluster.

Static and dynamic DB instance parameters

DB instance parameters are either static or dynamic. They differ as follows:

- When you change a static parameter and save the DB parameter group, the parameter change takes effect after you manually reboot the associated DB instances. For static parameters, the console always uses `pending-reboot` for the `ApplyMethod`.

- When you change a dynamic parameter, by default the parameter change takes effect immediately, without requiring a reboot. When you use the AWS Management Console to change DB instance parameter values, it always uses `immediate` for the `ApplyMethod` for dynamic parameters. To defer the parameter change until after you reboot an associated DB instance, use the AWS CLI or RDS API. Set the `ApplyMethod` to `pending-reboot` for the parameter change.
For more information about using the AWS CLI to change a parameter value, see modify-db-parameter-group. For more information about using the RDS API to change a parameter value, see ModifyDBParameterGroup.

When you associate a new DB parameter group with a DB instance, RDS applies the modified static and dynamic parameters only after the DB instance is rebooted. However, if you modify dynamic parameters in the DB parameter group after you associate it with the DB instance, these changes are applied immediately without a reboot. For more information about changing the DB parameter group, see Modifying an Amazon Aurora DB cluster (p. 269).

If a DB instance isn’t using the latest changes to its associated DB parameter group, the console shows a status of pending-reboot for the DB parameter group. This status doesn’t result in an automatic reboot during the next maintenance window. To apply the latest parameter changes to that DB instance, manually reboot the DB instance.

### Character set parameters

Before you create a DB cluster, set any parameters that relate to the character set or collation of your database in your parameter group. Also do so before you create a database in it. In this way, you ensure that the default database and new databases use the character set and collation values that you specify. If you change character set or collation parameters, the parameter changes aren’t applied to existing databases.

For some DB engines, you can change character set or collation values for an existing database using the ALTER DATABASE command, for example:

```
ALTER DATABASE database_name CHARACTER SET character_set_name COLLATE collation;
```

For more information about changing the character set or collation values for a database, check the documentation for your DB engine.

### Supported parameters and parameter values

To determine the supported parameters for your DB engine, view the parameters in the DB parameter group and DB cluster parameter group used by the DB instance or DB cluster. For more information, see Viewing parameter values for a DB parameter group (p. 235) and Viewing parameter values for a DB cluster parameter group (p. 224).

In many cases, you can specify integer and Boolean parameter values using expressions, formulas, and functions. Functions can include a mathematical log expression. However, not all parameters support expressions, formulas, and functions for parameter values. For more information, see Specifying DB parameters (p. 237).

For an Aurora global database, you can specify different configuration settings for the individual Aurora clusters. Make sure that the settings are similar enough to produce consistent behavior if you promote a secondary cluster to be the primary cluster. For example, use the same settings for time zones and character sets across all the clusters of an Aurora global database.

Improperly setting parameters in a parameter group can have unintended adverse effects, including degraded performance and system instability. Always be cautious when modifying database parameters, and back up your data before modifying a parameter group. Try parameter group setting changes on a test DB instance or DB cluster before applying those parameter group changes to a production DB instance or DB cluster.

### Working with DB cluster parameter groups

Amazon Aurora DB clusters use DB cluster parameter groups. The following sections describe configuring and managing DB cluster parameter groups.
Aurora uses a two-level system of configuration settings:

- Parameters in a **DB cluster parameter group** apply to every DB instance in a DB cluster. Your data is stored in the Aurora shared storage subsystem. Because of this, all parameters related to physical layout of table data must be the same for all DB instances in an Aurora cluster. Likewise, because Aurora DB instances are connected by replication, all the parameters for replication settings must be identical throughout an Aurora cluster.

- Parameters in a **DB parameter group** apply to a single DB instance in an Aurora DB cluster. These parameters are related to aspects such as memory usage that you can vary across DB instances in the same Aurora cluster. For example, a cluster often contains DB instances with different AWS instance classes.

Every Aurora cluster is associated with a DB cluster parameter group. This parameter group assigns default values for every configuration value for the corresponding DB engine. The cluster parameter group includes defaults for both the cluster-level and instance-level parameters. Each DB instance within a provisioned or Aurora Serverless v2 cluster inherits the settings from that DB cluster parameter group.

Each DB instance is also associated with a DB parameter group. The values in the DB parameter group can override default values from the cluster parameter group. For example, if one instance in a cluster experienced issues, you might assign a custom DB parameter group to that instance. The custom parameter group might have specific settings for parameters related to debugging or performance tuning.

Aurora assigns default parameter groups when you create a cluster or a new DB instance, based on the specified database engine and version. You can specify custom parameter groups instead. You create those parameter groups yourself, and you can edit the parameter values. You can specify these custom parameter groups at creation time. You can also modify a DB cluster or instance later to use a custom parameter group.

For provisioned and Aurora Serverless v2 instances, any configuration values that you modify in the DB cluster parameter group override default values in the DB parameter group. If you edit the corresponding values in the DB parameter group, those values override the settings from the DB cluster parameter group.

Any DB parameter settings that you modify take precedence over the DB cluster parameter group values, even if you change the configuration parameters back to their default values. You can see which parameters are overridden by using the `describe-db-parameters` AWS CLI command or the `DescribeDBParameters` RDS API operation. The `Source` field contains the value `user` if you modified that parameter. To reset one or more parameters so that the value from the DB cluster parameter group takes precedence, use the `reset-db-parameter-group` AWS CLI command or the `ResetDBParameterGroup` RDS API operation.
The DB cluster and DB instance parameters available to you in Aurora vary depending on database engine compatibility.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL</td>
<td>See [Aurora MySQL configuration parameters](p. 1115).</td>
</tr>
<tr>
<td></td>
<td>For Aurora Serverless clusters, see additional details in [Working with parameter groups for Aurora Serverless v2](p. 2014) and [Parameter groups for Aurora Serverless v1](p. 2034).</td>
</tr>
<tr>
<td>Aurora PostgreSQL</td>
<td>See [Amazon Aurora PostgreSQL parameters](p. 1728).</td>
</tr>
<tr>
<td></td>
<td>For Aurora Serverless clusters, see additional details in [Working with parameter groups for Aurora Serverless v2](p. 2014) and [Parameter groups for Aurora Serverless v1](p. 2034).</td>
</tr>
</tbody>
</table>

**Note**
Aurora Serverless v1 clusters have only DB cluster parameter groups, not DB parameter groups.
For Aurora Serverless v2 clusters, you make all your changes to custom parameters in the DB cluster parameter group.
Aurora Serverless v2 uses both DB cluster parameter groups and DB parameter groups. With Aurora Serverless v2, you can modify almost all of the configuration parameters. Aurora Serverless v2 overrides the settings of some capacity-related configuration parameters so that your workload isn't interrupted when Aurora Serverless v2 instances scale down.
To learn more about Aurora Serverless configuration settings and which settings you can modify, see [Working with parameter groups for Aurora Serverless v2](p. 2014) and [Parameter groups for Aurora Serverless v1](p. 2034).

**Creating a DB cluster parameter group**

You can create a new DB cluster parameter group using the AWS Management Console, the AWS CLI, or the RDS API.

After you create a DB cluster parameter group, wait at least 5 minutes before creating a DB cluster that uses that DB cluster parameter group. Doing this allows Amazon RDS to fully create the parameter group before it is used by the new DB cluster. You can use the Parameter groups page in the Amazon RDS console or the describe-db-cluster-parameters command to verify that your DB cluster parameter group is created.

The following limitations apply to the DB cluster parameter group name:

- The name must be 1 to 255 letters, numbers, or hyphens.
  
  Default parameter group names can include a period, such as default.aurora-mysql5.7. However, custom parameter group names can't include a period.
- The first character must be a letter.
- The name can't end with a hyphen or contain two consecutive hyphens.

**Console**

**To create a DB cluster parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Parameter groups.
3. Choose **Create parameter group**.
   The **Create parameter group** window appears.
4. In the **Parameter group family** list, select a DB parameter group family
5. In the **Type** list, select **DB Cluster Parameter Group**.
6. In the **Group name** box, enter the name of the new DB cluster parameter group.
7. In the **Description** box, enter a description for the new DB cluster parameter group.
8. Choose **Create**.

**AWS CLI**

To create a DB cluster parameter group, use the AWS CLI `create-db-cluster-parameter-group` command.

The following example creates a DB cluster parameter group named `mydbclusterparametergroup` for Aurora MySQL version 5.7 with a description of "My new cluster parameter group."

Include the following required parameters:

- `--db-cluster-parameter-group-name`
- `--db-parameter-group-family`
- `--description`

To list all of the available parameter group families, use the following command:

```
aws rds describe-db-engine-versions --query "DBEngineVersions[].DBParameterGroupFamily"
```

**Note**
The output contains duplicates.

**Example**

For Linux, macOS, or Unix:

```
aws rds create-db-cluster-parameter-group \
    --db-cluster-parameter-group-name mydbclusterparametergroup \
    --db-parameter-group-family aurora-mysql5.7 \
    --description "My new cluster parameter group"
```

For Windows:

```
aws rds create-db-cluster-parameter-group ^
    --db-cluster-parameter-group-name mydbclusterparametergroup ^
    --db-parameter-group-family aurora-mysql5.7 ^
    --description "My new cluster parameter group"
```

This command produces output similar to the following:

```
{
    "DBClusterParameterGroup": {
        "DBClusterParameterGroupName": "mydbclusterparametergroup",
        "DBParameterGroupFamily": "aurora-mysql5.7",
        "Description": "My new cluster parameter group",
        "DBClusterParameterGroupArn": "arn:aws:rds:us-east-1:123456789012:cluster-pg:mydbclusterparametergroup"
    }
}
```
RDS API

To create a DB cluster parameter group, use the RDS API CreateDBClusterParameterGroup action. Include the following required parameters:

- DBClusterParameterGroupName
- DBParameterGroupFamily
- Description

Associating a DB cluster parameter group with a DB cluster

You can create your own DB cluster parameter groups with customized settings. You can associate a DB cluster parameter group with a DB cluster using the AWS Management Console, the AWS CLI, or the RDS API. You can do so when you create or modify a DB cluster.

For information about creating a DB cluster parameter group, see Creating a DB cluster parameter group (p. 216). For information about creating a DB cluster, see Creating an Amazon Aurora DB cluster (p. 179). For information about modifying a DB cluster, see Modifying an Amazon Aurora DB cluster (p. 269).

Note
After you change the DB cluster parameter group associated with a DB cluster, reboot the primary DB instance in the cluster to apply the changes to all of the DB instances in the cluster. To determine whether the primary DB instance of a DB cluster must be rebooted to apply changes, run the following AWS CLI command:

```bash
aws rds describe-db-clusters --db-cluster-identifier db_cluster_identifier
```

Check the DBClusterParameterGroupStatus value for the primary DB instance in the output. If the value is pending-reboot, then reboot the primary DB instance of the DB cluster.

Console

To associate a DB cluster parameter group with a DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then select the DB cluster that you want to modify.
4. Change the DB cluster parameter group setting.
5. Choose Continue and check the summary of modifications.

The change is applied immediately regardless of the Scheduling of modifications setting.
6. On the confirmation page, review your changes. If they are correct, choose Modify cluster to save your changes.

Alternatively, choose Back to edit your changes, or choose Cancel to cancel your changes.

AWS CLI

To associate a DB cluster parameter group with a DB cluster, use the AWS CLI modify-db-cluster command with the following options:

- --db-cluster-name
• **--db-cluster-parameter-group-name**

The following example associates the `mydbclpg` DB parameter group with the `mydbcluster` DB cluster.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster
   --db-cluster-identifier mydbcluster
   --db-cluster-parameter-group-name mydbclpg
```

For Windows:

```bash
aws rds modify-db-cluster ^
   --db-cluster-identifier mydbcluster ^
   --db-cluster-parameter-group-name mydbclpg
```

**RDS API**

To associate a DB cluster parameter group with a DB cluster, use the RDS API `ModifyDBCluster` operation with the following parameters:

- `DBClusterIdentifier`
- `DBClusterParameterGroupName`

**Modifying parameters in a DB cluster parameter group**

You can modify parameter values in a customer-created DB cluster parameter group. You can't change the parameter values in a default DB cluster parameter group. Changes to parameters in a customer-created DB cluster parameter group are applied to all DB clusters that are associated with the DB cluster parameter group.

**Console**

**To modify a DB cluster parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the parameter group that you want to modify.
4. For **Parameter group actions**, choose **Edit**.
5. Change the values of the parameters you want to modify. You can scroll through the parameters using the arrow keys at the top right of the dialog box.
   
   You can't change values in a default parameter group.
6. Choose **Save changes**.
7. Reboot the primary DB instance in the cluster to apply the changes to all of the DB instances in the cluster.

**AWS CLI**

To modify a DB cluster parameter group, use the AWS CLI `modify-db-cluster-parameter-group` command with the following required parameters:
The following example modifies the `server_audit_logging` and `server_audit_logs_upload` values in the DB cluster parameter group named `mydbclusterparametergroup`.

**Example**

For Linux, macOS, or Unix:

```bash/aws rds modify-db-cluster-parameter-group \
--db-cluster-parameter-group-name mydbclusterparametergroup \
--parameters "ParameterName=server_audit_logging,ParameterValue=1,ApplyMethod=immediate" \
"ParameterName=server_audit_logs_upload,ParameterValue=1,ApplyMethod=immediate"
```

For Windows:

```bash
/aws rds modify-db-cluster-parameter-group ^
--db-cluster-parameter-group-name mydbclusterparametergroup ^
--parameters "ParameterName=server_audit_logging,ParameterValue=1,ApplyMethod=immediate" ^
"ParameterName=server_audit_logs_upload,ParameterValue=1,ApplyMethod=immediate"
```

The command produces output like the following:

```
DBCLUSTERPARAMETERGROUP mydbclusterparametergroup
```

**RDS API**

To modify a DB cluster parameter group, use the RDS API `ModifyDBClusterParameterGroup` command with the following required parameters:

- DBClusterParameterGroupName
- Parameters

**Resetting parameters in a DB cluster parameter group**

You can reset parameters to their default values in a customer-created DB cluster parameter group. Changes to parameters in a customer-created DB cluster parameter group are applied to all DB clusters that are associated with the DB cluster parameter group.

**Note**

In a default DB cluster parameter group, parameters are always set to their default values.

**Console**

**To reset parameters in a DB cluster parameter group to their default values**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the parameter group.
4. For **Parameter group actions**, choose **Edit**.
5. Choose the parameters that you want to reset to their default values. You can scroll through the parameters using the arrow keys at the top right of the dialog box.

You can't reset values in a default parameter group.

6. Choose **Reset** and then confirm by choosing **Reset parameters**.

7. Reboot the primary DB instance in the DB cluster to apply the changes to all of the DB instances in the DB cluster.

**AWS CLI**

To reset parameters in a DB cluster parameter group to their default values, use the AWS CLI `reset-db-cluster-parameter-group` command with the following required option: `--db-cluster-parameter-group-name`.

To reset all of the parameters in the DB cluster parameter group, specify the `--reset-all-parameters` option. To reset specific parameters, specify the `--parameters` option.

The following example resets all of the parameters in the DB parameter group named `mydbparametergroup` to their default values.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds reset-db-cluster-parameter-group
   --db-cluster-parameter-group-name mydbparametergroup
   --reset-all-parameters
```

For Windows:

```bash
aws rds reset-db-cluster-parameter-group ^
   --db-cluster-parameter-group-name mydbparametergroup ^
   --reset-all-parameters
```

The following example resets the `server_audit_logging` and `server_audit_logs_upload` to their default values in the DB cluster parameter group named `mydbclusterparametergroup`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds reset-db-cluster-parameter-group
   --db-cluster-parameter-group-name mydbclusterparametergroup
   --parameters "ParameterName=server_audit_logging,ApplyMethod=immediate"
   "ParameterName=server_audit_logs_upload,ApplyMethod=immediate"
```

For Windows:

```bash
aws rds reset-db-cluster-parameter-group ^
   --db-cluster-parameter-group-name mydbclusterparametergroup ^
   --parameters
   "ParameterName=server_audit_logging,ParameterValue=1,ApplyMethod=immediate" ^
   "ParameterName=server_audit_logs_upload,ParameterValue=1,ApplyMethod=immediate"
```

The command produces output like the following:

```
DBClusterParameterGroupName  mydbclusterparametergroup
```
RDS API

To reset parameters in a DB cluster parameter group to their default values, use the RDS API `ResetDBClusterParameterGroup` command with the following required parameter: `DBClusterParameterGroupName`.

To reset all of the parameters in the DB cluster parameter group, set the `ResetAllParameters` parameter to `true`. To reset specific parameters, specify the `Parameters` parameter.

**Copying a DB cluster parameter group**

You can copy custom DB cluster parameter groups that you create. Copying a parameter group is a convenient solution when you have already created a DB cluster parameter group and you want to include most of the custom parameters and values from that group in a new DB cluster parameter group. You can copy a DB cluster parameter group by using the AWS CLI `copy-db-cluster-parameter-group` command or the RDS API `CopyDBClusterParameterGroup` operation.

After you copy a DB cluster parameter group, wait at least 5 minutes before creating a DB cluster that uses that DB cluster parameter group. Doing this allows Amazon RDS to fully copy the parameter group before it is used by the new DB cluster. You can use the Parameter groups page in the Amazon RDS console or the `describe-db-cluster-parameters` command to verify that your DB cluster parameter group is created.

**Note**
- You can't copy a default parameter group. However, you can create a new parameter group that is based on a default parameter group.
- You can't copy a DB cluster parameter group to a different AWS account or AWS Region.

**Console**

**To copy a DB cluster parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Parameter groups.
3. In the list, choose the custom parameter group that you want to copy.
4. For Parameter group actions, choose Copy.
5. In New DB parameter group identifier, enter a name for the new parameter group.
6. In Description, enter a description for the new parameter group.
7. Choose Copy.

**AWS CLI**

To copy a DB cluster parameter group, use the AWS CLI `copy-db-cluster-parameter-group` command with the following required parameters:

- `--source-db-cluster-parameter-group-identifier`
- `--target-db-cluster-parameter-group-identifier`
- `--target-db-cluster-parameter-group-description`

The following example creates a new DB cluster parameter group named `mygroup2` that is a copy of the DB cluster parameter group `mygroup1`.

**Example**

For Linux, macOS, or Unix:
aws rds copy-db-cluster-parameter-group \
  --source-db-cluster-parameter-group-identifier mygroup1 \
  --target-db-cluster-parameter-group-identifier mygroup2 \
  --target-db-cluster-parameter-group-description "DB parameter group 2"

For Windows:

aws rds copy-db-cluster-parameter-group ^
  --source-db-cluster-parameter-group-identifier mygroup1 ^
  --target-db-cluster-parameter-group-identifier mygroup2 ^
  --target-db-cluster-parameter-group-description "DB parameter group 2"

**RDS API**

To copy a DB cluster parameter group, use the RDS API [CopyDBClusterParameterGroup](https://docs.aws.amazon.com/cli/latest/reference/rds/copy-db-cluster-parameter-group.html) operation with the following required parameters:

- SourceDBClusterParameterGroupIdentifier
- TargetDBClusterParameterGroupIdentifier
- TargetDBClusterParameterGroupDescription

**Listing DB cluster parameter groups**

You can list the DB cluster parameter groups you've created for your AWS account.

**Note**

Default parameter groups are automatically created from a default parameter template when you create a DB cluster for a particular DB engine and version. These default parameter groups contain preferred parameter settings and can't be modified. When you create a custom parameter group, you can modify parameter settings.

**Console**

**To list all DB cluster parameter groups for an AWS account**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Parameter groups**. The DB cluster parameter groups appear in the list with **DB cluster parameter group** for **Type**.

**AWS CLI**

To list all DB cluster parameter groups for an AWS account, use the AWS CLI `describe-db-cluster-parameter-groups` command.

**Example**

The following example lists all available DB cluster parameter groups for an AWS account.

```
aws rds describe-db-cluster-parameter-groups
```

The following example describes the `mydbclusterparametergroup` parameter group.

For Linux, macOS, or Unix:

```
aws rds describe-db-cluster-parameter-groups \
```

---

223
For Windows:

```
aws rds describe-db-cluster-parameter-groups
  --db-cluster-parameter-group-name mydbclusterparametergroup
```

The command returns a response like the following:

```
{
  "DBClusterParameterGroups": [
    {
      "DBClusterParameterGroupName": "mydbclusterparametergroup",
      "DBParameterGroupFamily": "aurora-mysql5.7",
      "Description": "My new cluster parameter group",
      "DBClusterParameterGroupArn": "arn:aws:rds:us-east-1:123456789012:cluster-pg:mydbclusterparametergroup"
    }
  ]
}
```

RDS API

To list all DB cluster parameter groups for an AWS account, use the RDS API `DescribeDBClusterParameterGroups` action.

**Viewing parameter values for a DB cluster parameter group**

You can get a list of all parameters in a DB cluster parameter group and their values.

**Console**

**To view the parameter values for a DB cluster parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
   The DB cluster parameter groups appear in the list with DB cluster parameter group for Type.
3. Choose the name of the DB cluster parameter group to see its list of parameters.

**AWS CLI**

To view the parameter values for a DB cluster parameter group, use the AWS CLI `describe-db-cluster-parameters` command with the following required parameter.

- `--db-cluster-parameter-group-name`

**Example**

The following example lists the parameters and parameter values for a DB cluster parameter group named `mydbclusterparametergroup`, in JSON format.

The command returns a response like the following:

```
aws rds describe-db-cluster-parameters
  --db-cluster-parameter-group-name mydbclusterparametergroup
```
[{
  "Parameters": [
    {
      "ParameterName": "allow-suspicious-udfs",
      "Description": "Controls whether user-defined functions that have only an xxx symbol for the main function can be loaded",
      "Source": "engine-default",
      "ApplyType": "static",
      "DataType": "boolean",
      "ApplyMethod": "pending-reboot",
      "IsModifiable": false,
      "SupportedEngineModes": ["provisioned"
    }
  ]
  {
    "ParameterName": "aurora_binlog_read_buffer_size",
    "ParameterValue": "5242880",
    "Description": "Read buffer size used by master dump thread when the switch aurora_binlog_use_large_read_buffer is ON.",
    "Source": "engine-default",
    "ApplyType": "dynamic",
    "DataType": "integer",
    "AllowedValues": "8192-536870912",
    "IsModifiable": true,
    "ApplyMethod": "pending-reboot",
    "SupportedEngineModes": ["provisioned"
  ]
}, ...

RDS API

To view the parameter values for a DB cluster parameter group, use the RDS API `DescribeDBClusterParameters` command with the following required parameter.

- `DBClusterParameterGroupName`

In some cases, the allowed values for a parameter aren’t shown. These are always parameters where the source is the database engine default.

To view the values of these parameters, you can run the following SQL statements:

- **MySQL**:

  -- Show the value of a particular parameter
  mysql$ SHOW VARIABLES LIKE '%parameter_name%';

  -- Show the values of all parameters
  mysql$ SHOW VARIABLES;

- **PostgreSQL**:

  -- Show the value of a particular parameter
  postgresql=> SHOW parameter_name;

  -- Show the values of all parameters
  postgresql=> SHOW ALL;
Working with DB parameter groups

DB instances use DB parameter groups. The following sections describe configuring and managing DB instance parameter groups.

Topics
- Creating a DB parameter group (p. 226)
- Associating a DB parameter group with a DB instance (p. 227)
- Modifying parameters in a DB parameter group (p. 229)
- Resetting parameters in a DB parameter group to their default values (p. 231)
- Copying a DB parameter group (p. 233)
- Listing DB parameter groups (p. 234)
- Viewing parameter values for a DB parameter group (p. 235)

Creating a DB parameter group

You can create a new DB parameter group using the AWS Management Console, the AWS CLI, or the RDS API.

The following limitations apply to the DB parameter group name:
- The name must be 1 to 255 letters, numbers, or hyphens.
- The first character must be a letter.
- The name can't end with a hyphen or contain two consecutive hyphens.
- Default parameter group names can include a period, such as default.mysql8.0. However, custom parameter group names can't include a period.

Console

To create a DB parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose Create parameter group.
   - The Create parameter group window appears.
4. In the Parameter group family list, select a DB parameter group family.
5. In the Type list, select DB Parameter Group.
6. In the Group name box, enter the name of the new DB parameter group.
7. In the Description box, enter a description for the new DB parameter group.
8. Choose Create.

AWS CLI

To create a DB parameter group, use the AWS CLI create-db-parameter-group command. The following example creates a DB parameter group named mydbparametergroup for MySQL version 8.0 with a description of "My new parameter group."

Include the following required parameters:
• `--db-parameter-group-name`
• `--db-parameter-group-family`
• `--description`

To list all of the available parameter group families, use the following command:

```
aws rds describe-db-engine-versions --query "DBEngineVersions[].DBParameterGroupFamily"
```

**Note**
The output contains duplicates.

**Example**

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
    --db-parameter-group-name mydbparametergroup \
    --db-parameter-group-family aurora-mysql5.7 \
    --description "My new parameter group"
```

For Windows:

```
aws rds create-db-parameter-group ^
    --db-parameter-group-name mydbparametergroup ^
    --db-parameter-group-family aurora-mysql5.7 ^
    --description "My new parameter group"
```

This command produces output similar to the following:

```
DBPARAMETERGROUP mydbparametergroup aurora-mysql5.7 My new parameter group
```

**RDS API**

To create a DB parameter group, use the RDS API [CreateDBParameterGroup](p. 226) operation.

Include the following required parameters:

• `DBParameterGroupName`
• `DBParameterGroupFamily`
• `Description`

**Associating a DB parameter group with a DB instance**

You can create your own DB parameter groups with customized settings. You can associate a DB parameter group with a DB instance using the AWS Management Console, the AWS CLI, or the RDS API. You can do so when you create or modify a DB instance.

For information about creating a DB parameter group, see [Creating a DB parameter group](p. 226). For information about modifying a DB instance, see [Modifying a DB instance in a DB cluster](p. 270).

**Note**
When you associate a new DB parameter group with a DB instance, the modified static and dynamic parameters are applied only after the DB instance is rebooted. However, if you modify dynamic parameters in the DB parameter group after you associate it with the DB instance, these changes are applied immediately without a reboot.
Console

To associate a DB parameter group with a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance that you want to modify.
4. Change the DB parameter group setting.
5. Choose Continue and check the summary of modifications.
6. (Optional) Choose Apply immediately to apply the changes immediately. Choosing this option can cause an outage in some cases.
7. On the confirmation page, review your changes. If they are correct, choose Modify DB instance to save your changes.
   Or choose Back to edit your changes or Cancel to cancel your changes.

AWS CLI

To associate a DB parameter group with a DB instance, use the AWS CLI modify-db-instance command with the following options:

- --db-instance-identifier
- --db-parameter-group-name

The following example associates the mydbpg DB parameter group with the database-1 DB instance. The changes are applied immediately by using --apply-immediately. Use --no-apply-immediately to apply the changes during the next maintenance window.

Example

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
   --db-instance-identifier database-1 \
   --db-parameter-group-name mydbpg \
   --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
   --db-instance-identifier database-1 ^
   --db-parameter-group-name mydbpg ^
   --apply-immediately
```

RDS API

To associate a DB parameter group with a DB instance, use the RDS API ModifyDBInstance operation with the following parameters:

- DBInstanceName
- DBParameterGroupName
Modifying parameters in a DB parameter group

You can modify parameter values in a customer-created DB parameter group; you can't change the parameter values in a default DB parameter group. Changes to parameters in a customer-created DB parameter group are applied to all DB instances that are associated with the DB parameter group.

Changes to some parameters are applied to the DB instance immediately without a reboot. Changes to other parameters are applied only after the DB instance is rebooted. The RDS console shows the status of the DB parameter group associated with a DB instance on the **Configuration** tab. For example, suppose that the DB instance isn't using the latest changes to its associated DB parameter group. If so, the RDS console shows the DB parameter group with a status of **pending-reboot**. To apply the latest parameter changes to that DB instance, manually reboot the DB instance.

**Console**

**To modify a DB parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Parameter groups.
3. In the list, choose the parameter group that you want to modify.
4. For Parameter group actions, choose Edit.
5. Change the values of the parameters that you want to modify. You can scroll through the parameters using the arrow keys at the top right of the dialog box.
   You can't change values in a default parameter group.
6. Choose Save changes.

AWS CLI

To modify a DB parameter group, use the AWS CLI `modify-db-parameter-group` command with the following required options:

- `--db-parameter-group-name`
- `--parameters`

The following example modifies the `max_connections` and `max_allowed_packet` values in the DB parameter group named `mydbparametergroup`.

Example

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group \
  --db-parameter-group-name mydbparametergroup \
  --parameters "ParameterName=max_connections,ParameterValue=250,ApplyMethod=immediate" \
  "ParameterName=max_allowed_packet,ParameterValue=1024,ApplyMethod=immediate"
```

For Windows:

```bash
aws rds modify-db-parameter-group ^
  --db-parameter-group-name mydbparametergroup ^
  --parameters "ParameterName=max_connections,ParameterValue=250,ApplyMethod=immediate" ^
  "ParameterName=max_allowed_packet,ParameterValue=1024,ApplyMethod=immediate"
```

The command produces output like the following:

```
DBPARAMETERGROUP mydbparametergroup
```

RDS API

To modify a DB parameter group, use the RDS API `ModifyDBParameterGroup` operation with the following required parameters:

- `DBParameterGroupName`
- `Parameters`
Resetting parameters in a DB parameter group to their default values

You can reset parameter values in a customer-created DB parameter group to their default values. Changes to parameters in a customer-created DB parameter group are applied to all DB instances that are associated with the DB parameter group.

When you use the console, you can reset specific parameters to their default values. However, you can't easily reset all of the parameters in the DB parameter group at once. When you use the AWS CLI or RDS API, you can reset specific parameters to their default values. You can also reset all of the parameters in the DB parameter group at once.

Changes to some parameters are applied to the DB instance immediately without a reboot. Changes to other parameters are applied only after the DB instance is rebooted. The RDS console shows the status of the DB parameter group associated with a DB instance on the Configuration tab. For example, suppose that the DB instance isn't using the latest changes to its associated DB parameter group. If so, the RDS console shows the DB parameter group with a status of pending-reboot. To apply the latest parameter changes to that DB instance, manually reboot the DB instance.
Note
In a default DB parameter group, parameters are always set to their default values.

Console

To reset parameters in a DB parameter group to their default values
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. In the list, choose the parameter group.
4. For Parameter group actions, choose Edit.
5. Choose the parameters that you want to reset to their default values. You can scroll through the parameters using the arrow keys at the top right of the dialog box.
   You can't reset values in a default parameter group.
6. Choose Reset and then confirm by choosing Reset parameters.

AWS CLI

To reset some or all of the parameters in a DB parameter group, use the AWS CLI reset-db-parameter-group command with the following required option: --db-parameter-group-name.

To reset all of the parameters in the DB parameter group, specify the --reset-all-parameters option. To reset specific parameters, specify the --parameters option.

The following example resets all of the parameters in the DB parameter group named mydbparametergroup to their default values.

Example

For Linux, macOS, or Unix:

```
aws rds reset-db-parameter-group \\
   --db-parameter-group-name mydbparametergroup \\
   --reset-all-parameters
```

For Windows:

```
aws rds reset-db-parameter-group ^
   --db-parameter-group-name mydbparametergroup ^
   --reset-all-parameters
```

The following example resets the max_connections and max_allowed_packet options to their default values in the DB parameter group named mydbparametergroup.

Example

For Linux, macOS, or Unix:

```
aws rds reset-db-parameter-group \\
   --db-parameter-group-name mydbparametergroup \\
   --parameters "ParameterName=max_connections,ApplyMethod=immediate"
```
"ParameterName=max_allowed_packet,ApplyMethod=immediate"

For Windows:

```bash
aws rds reset-db-parameter-group
   --db-parameter-group-name mydbparametergroup
   --parameters "ParameterName=max_connections,ApplyMethod=immediate" ^
   "ParameterName=max_allowed_packet,ApplyMethod=immediate"
```

The command produces output like the following:

<table>
<thead>
<tr>
<th>ParameterGroupName</th>
<th>mydbparametergroup</th>
</tr>
</thead>
</table>

**RDS API**

To reset parameters in a DB parameter group to their default values, use the RDS API `ResetDBParameterGroup` command with the following required parameter: `DBParameterGroupName`.

To reset all of the parameters in the DB parameter group, set the `ResetAllParameters` parameter to `true`. To reset specific parameters, specify the `Parameters` parameter.

**Copying a DB parameter group**

You can copy custom DB parameter groups that you create. Copying a parameter group can be a convenient solution. An example is when you have created a DB parameter group and want to include most of its custom parameters and values in a new DB parameter group. You can copy a DB parameter group by using the AWS Management Console. You can also use the AWS CLI `copy-db-parameter-group` command or the RDS API `CopyDBParameterGroup` operation.

After you copy a DB parameter group, wait at least 5 minutes before creating your first DB instance that uses that DB parameter group as the default parameter group. Doing this allows Amazon RDS to fully complete the copy action before the parameter group is used. This is especially important for parameters that are critical when creating the default database for a DB instance. An example is the character set for the default database defined by the `character_set_database` parameter. Use the `ParameterGroups` option of the Amazon RDS console or the `describe-db-parameters` command to verify that your DB parameter group is created.

**Note**

You can't copy a default parameter group. However, you can create a new parameter group that is based on a default parameter group.

You can't copy a DB parameter group to a different AWS account or AWS Region.

**Console**

**To copy a DB parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose `Parameter groups`.
3. In the list, choose the custom parameter group that you want to copy.
4. For `Parameter group actions`, choose `Copy`.
5. In `New DB parameter group identifier`, enter a name for the new parameter group.
6. In `Description`, enter a description for the new parameter group.
7. Choose `Copy`. 
AWS CLI

To copy a DB parameter group, use the AWS CLI `copy-db-parameter-group` command with the following required options:

- `--source-db-parameter-group-identifier`
- `--target-db-parameter-group-identifier`
- `--target-db-parameter-group-description`

The following example creates a new DB parameter group named `mygroup2` that is a copy of the DB parameter group `mygroup1`.

**Example**

For Linux, macOS, or Unix:

```
aws rds copy-db-parameter-group \
  --source-db-parameter-group-identifier mygroup1 \
  --target-db-parameter-group-identifier mygroup2 \
  --target-db-parameter-group-description "DB parameter group 2"
```

For Windows:

```
aws rds copy-db-parameter-group ^
  --source-db-parameter-group-identifier mygroup1 ^
  --target-db-parameter-group-identifier mygroup2 ^
  --target-db-parameter-group-description "DB parameter group 2"
```

RDS API

To copy a DB parameter group, use the RDS API `CopyDBParameterGroup` operation with the following required parameters:

- `SourceDBParameterGroupIdentifier`
- `TargetDBParameterGroupIdentifier`
- `TargetDBParameterGroupDescription`

Listing DB parameter groups

You can list the DB parameter groups you've created for your AWS account.

**Note**

Default parameter groups are automatically created from a default parameter template when you create a DB instance for a particular DB engine and version. These default parameter groups contain preferred parameter settings and can't be modified. When you create a custom parameter group, you can modify parameter settings.

Console

To list all DB parameter groups for an AWS account

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
The DB parameter groups appear in a list.

**AWS CLI**

To list all DB parameter groups for an AWS account, use the AWS CLI `describe-db-parameter-groups` command.

**Example**

The following example lists all available DB parameter groups for an AWS account.

```bash
aws rds describe-db-parameter-groups
```

The command returns a response like the following:

```
DBPARAMETERGROUP  default.mysql8.0     mysql8.0  Default parameter group for MySQL8.0
DBPARAMETERGROUP  mydbparametergroup   mysql8.0  My new parameter group
```

The following example describes the `mydbparamgroup1` parameter group.

For Linux, macOS, or Unix:

```bash
aws rds describe-db-parameter-groups \
   --db-parameter-group-name mydbparamgroup1
```

For Windows:

```bash
aws rds describe-db-parameter-groups ^
   --db-parameter-group-name mydbparamgroup1
```

The command returns a response like the following:

```
DBPARAMETERGROUP  mydbparametergroup1  mysql8.0  My new parameter group
```

**RDS API**

To list all DB parameter groups for an AWS account, use the RDS API `DescribeDBParameterGroups` operation.

**Viewing parameter values for a DB parameter group**

You can get a list of all parameters in a DB parameter group and their values.

**Console**

**To view the parameter values for a DB parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Parameter groups**.
   The DB parameter groups appear in a list.
3. Choose the name of the parameter group to see its list of parameters.

**AWS CLI**

To view the parameter values for a DB parameter group, use the AWS CLI `describe-db-parameters` command with the following required parameter.

- `--db-parameter-group-name`

**Example**

The following example lists the parameters and parameter values for a DB parameter group named `mydbparametergroup`.

```
aws rds describe-db-parameters --db-parameter-group-name mydbparametergroup
```

The command returns a response like the following:

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Parameter Value</th>
<th>Source</th>
<th>Data Type</th>
<th>Apply Type</th>
<th>Is Modifiable</th>
</tr>
</thead>
<tbody>
<tr>
<td>allow-suspicious-udfs</td>
<td></td>
<td>engine-default</td>
<td>boolean</td>
<td>static</td>
<td>false</td>
</tr>
<tr>
<td>auto_increment_increment</td>
<td></td>
<td>engine-default</td>
<td>integer</td>
<td>dynamic</td>
<td>true</td>
</tr>
<tr>
<td>auto_increment_offset</td>
<td></td>
<td>engine-default</td>
<td>integer</td>
<td>dynamic</td>
<td>true</td>
</tr>
<tr>
<td>binlog_cache_size</td>
<td>32768</td>
<td>system</td>
<td>integer</td>
<td>dynamic</td>
<td>true</td>
</tr>
<tr>
<td>socket</td>
<td>/tmp/mysql.sock</td>
<td>system</td>
<td>string</td>
<td>static</td>
<td>false</td>
</tr>
</tbody>
</table>

**RDS API**

To view the parameter values for a DB parameter group, use the RDS API `DescribeDBParameters` command with the following required parameter.

- `DBParameterGroupName`

**Comparing parameter groups**

You can use the AWS Management Console to view the differences between two parameter groups.

The specified parameter groups must both be DB parameter groups, or they both must be DB cluster parameter groups. This is true even when the DB engine and version are the same. For example, you can't compare an `aurora-mysql8.0` (Aurora MySQL version 3) DB parameter group and an `aurora-mysql8.0` DB cluster parameter group.

You can compare Aurora MySQL and RDS for MySQL DB parameter groups, even for different versions, but you can't compare Aurora PostgreSQL and RDS for PostgreSQL DB parameter groups.

**To compare two parameter groups**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the two parameter groups that you want to compare.
Specifying DB parameters

DB parameter types include the following:

- Integer
- Boolean
- String
- Long
- Double
- Timestamp
- Object of other defined data types
- Array of values of type integer, Boolean, string, long, double, timestamp, or object

You can also specify integer and Boolean parameters using expressions, formulas, and functions.

Contents

- DB parameter formulas (p. 237)
  - DB parameter formula variables (p. 237)
  - DB parameter formula operators (p. 238)
- DB parameter functions (p. 238)
- DB parameter log expressions (p. 239)
- DB parameter value examples (p. 239)

DB parameter formulas

A DB parameter formula is an expression that resolves to an integer value or a Boolean value. You enclose the expression in braces: {}. You can use a formula for either a DB parameter value or as an argument to a DB parameter function.

Syntax

```
{FormulaVariable}
{FormulaVariable*Integer}
{FormulaVariable*Integer/Integer}
{FormulaVariable/Integer}
```

DB parameter formula variables

Each formula variable returns an integer or a Boolean value. The names of the variables are case-sensitive.

AllocatedStorage

Returns an integer representing the size, in bytes, of the data volume.
### DBInstanceClassMemory

Returns an integer for the number of bytes of memory available to the database process. This number is internally calculated by starting with the total amount of memory for the DB instance class. From this, the calculation subtracts memory reserved for the operating system and the RDS processes that manage the instance. Therefore, the number is always somewhat lower than the memory figures shown in the instance class tables in [Aurora DB instance classes](p. 84). The exact value depends on a combination of factors. These include instance class, DB engine, and whether it applies to an RDS instance or an instance that's part of an Aurora cluster.

### EndPointPort

Returns an integer representing the port used when connecting to the DB instance.

### TrueIfReplica

Returns 1 if the DB instance is a read replica and 0 if it is not. This is the default value for the `read_only` parameter in Aurora MySQL.

### DB parameter formula operators

DB parameter formulas support two operators: division and multiplication.

#### Division operator: /

Divides the dividend by the divisor, returning an integer quotient. Decimals in the quotient are truncated, not rounded.

**Syntax**

```
dividend / divisor
```

The dividend and divisor arguments must be integer expressions.

#### Multiplication operator: *

Multiplies the expressions, returning the product of the expressions. Decimals in the expressions are truncated, not rounded.

**Syntax**

```
expression * expression
```

Both expressions must be integers.

### DB parameter functions

You specify the arguments of DB parameter functions as either integers or formulas. Each function must have at least one argument. Specify multiple arguments as a comma-separated list. The list can't have any empty members, such as `argument1,argument3`. Function names are case-insensitive.

#### IF

Returns an argument.

**Syntax**

```
IF(argument1, argument2, argument3)
```
Returns the second argument if the first argument evaluates to true. Returns the third argument otherwise.

**GREATEST**

Returns the largest value from a list of integers or parameter formulas.

**Syntax**

\[
\text{GREATEST}(\text{argument1}, \text{argument2}, \ldots, \text{argumentn})
\]

Returns an integer.

**LEAST**

Returns the smallest value from a list of integers or parameter formulas.

**Syntax**

\[
\text{LEAST}(\text{argument1}, \text{argument2}, \ldots, \text{argumentn})
\]

Returns an integer.

**SUM**

Adds the values of the specified integers or parameter formulas.

**Syntax**

\[
\text{SUM}(\text{argument1}, \text{argument2}, \ldots, \text{argumentn})
\]

Returns an integer.

### DB parameter log expressions

You can set an integer DB parameter value to a log expression. You enclose the expression in braces: `{}`. For example:

\[
\{\log(DBInstanceClassMemory/8187281418)\times1000\}
\]

The \(\log\) function represents log base 2. This example also uses the `DBInstanceClassMemory` formula variable. See [DB parameter formula variables (p. 237)](https://aws.amazon.com/).

### DB parameter value examples

These examples show using formulas, functions, and expressions for the values of DB parameters.

**Note**

DB Parameter functions are currently supported only in the console and aren't supported in the AWS CLI.

**Warning**

Improperly setting parameters in a DB parameter group can have unintended adverse effects. These might include degraded performance and system instability. Use caution when modifying database parameters and back up your data before modifying your DB parameter group. Try out parameter group changes on a test DB instance, created using point-in-time-restores, before applying those parameter group changes to your production DB instances.
Example using the DB parameter function LEAST

You can specify the LEAST function in an Aurora MySQL table_definition_cache parameter value. Use it to set the number of table definitions that can be stored in the definition cache to the lesser of `DBInstanceClassMemory/393040` or 20,000.

```
LEAST({DBInstanceClassMemory/393040}, 20000)
```
Migrating data to an Amazon Aurora DB cluster

You have several options for migrating data from your existing database to an Amazon Aurora DB cluster, depending on database engine compatibility. Your migration options also depend on the database that you are migrating from and the size of the data that you are migrating.

Migrating data to an Amazon Aurora MySQL DB cluster

You can migrate data from one of the following sources to an Amazon Aurora MySQL DB cluster.

- An RDS for MySQL DB instance
- A MySQL database external to Amazon RDS
- A database that is not MySQL-compatible

For more information, see Migrating data to an Amazon Aurora MySQL DB cluster (p. 836).

Migrating data to an Amazon Aurora PostgreSQL DB cluster

You can migrate data from one of the following sources to an Amazon Aurora PostgreSQL DB cluster.

- An Amazon RDS PostgreSQL DB instance
- A database that is not PostgreSQL-compatible

For more information, see Migrating data to Amazon Aurora with PostgreSQL compatibility (p. 1265).
Creating an Amazon ElastiCache cluster using
Aurora DB cluster settings

ElastiCache is a fully managed, in-memory caching service that provides microsecond read and write
latencies that support flexible, real-time use cases. ElastiCache can help you accelerate application and
database performance. You can use ElastiCache as a primary data store for use cases that don't require
data durability, such as gaming leaderboards, streaming, and data analytics. ElastiCache helps remove
the complexity associated with deploying and managing a distributed computing environment. For more
information, see Common ElastiCache Use Cases and How ElastiCache Can Help for Memcached and
Common ElastiCache Use Cases and How ElastiCache Can Help for Redis. You can use the Amazon RDS
console for creating ElastiCache clusters.

Amazon ElastiCache works with both the Redis and Memcached engines. If you're unsure which engine
you want to use, see Comparing Memcached and Redis. For more information about Amazon ElastiCache,
see the Amazon ElastiCache User Guide.

Topics
• Overview of ElastiCache cluster creation with Aurora DB cluster settings (p. 242)
• Creating an ElastiCache cluster with settings from a new Aurora DB cluster (p. 243)
• Creating an ElastiCache cluster with settings from an existing Aurora DB cluster (p. 245)

Overview of ElastiCache cluster creation with Aurora
DB cluster settings

You can create an ElastiCache cluster from Amazon RDS using the same configuration settings as a newly
created or existing Aurora DB cluster.

Some use-cases to associate an ElastiCache cluster with your DB cluster:

• You can save costs and improve your performance by using ElastiCache with RDS versus running on
  RDS alone.
• You can use the ElastiCache cluster as a primary data store for applications that don't require data
durability. Your applications that use Redis or Memcached can use ElastiCache with almost no
modification.

When you create an ElastCache cluster from RDS, the ElastiCache cluster inherits the following settings
from the associated Aurora DB cluster:

• ElastiCache connectivity settings
• ElastiCache security settings

You can also set the cluster configuration settings according to your requirements.

Setting up ElastiCache in your applications

Your applications must be set up to utilize ElastiCache clusters. You can also optimize and improve
cluster performance by setting up your applications to use caching strategies depending on your
requirements.

• To access your ElastiCache cluster and get started, see Getting started with Amazon ElastiCache for
  Redis and Getting started with Amazon ElastiCache for Memcached.
Creating an ElastiCache cluster with settings from a new Aurora DB cluster

After creating a new Aurora DB cluster in the RDS console, you can create add-ons for your Aurora DB cluster from the Suggested add-ons window.

In the Suggested add-ons window, you can create an ElastiCache cluster from RDS with the same settings as your newly created Aurora DB cluster.

Create an ElastiCache cluster with settings from a new DB cluster

1. To create a DB cluster, follow the instructions in Creating an Amazon Aurora DB cluster (p. 179).

2. After creating a new Aurora DB cluster, the console displays the Suggested add-ons window. Select Create an ElastiCache cluster from RDS using your DB settings.

   In the ElastiCache configuration section, the Source DB identifier displays which DB cluster the ElastiCache cluster inherits settings from.

3. Choose whether you want to create a Redis or Memcached cluster. For more information, see Comparing Memcached and Redis.

   If you choose Redis cluster, then choose whether you want to keep the cluster mode Enabled or Disabled. For more information, see Replication: Redis (Cluster Mode Disabled) vs. Redis (Cluster Mode Enabled).

   ![ElastiCache cluster configuration](Image)

4. Enter values for Name, Description, and Engine version.
Creating an ElastiCache cluster with settings from a new Aurora DB cluster

For **Engine version**, the recommended default value is the latest engine version. You can also choose an **Engine version** for the ElastiCache cluster that best meets your requirements.

5. Choose the node type in the **Node type** option. For more information, see [Managing nodes](#).

If you choose to create a Redis cluster with the **Cluster mode** set to **Enabled**, then enter the number of shards (partitions/node groups) in the **Number of shards** option.

Enter the number of replicas of each shard in **Number of replicas**.

**Note**
The selected node type, the number of shards, and the number of replicas all affect your cluster performance and resource costs. Be sure these settings match your database needs. For pricing information, see [Amazon ElastiCache pricing](#).

6. Confirm the ElastiCache connectivity settings.

RDS automatically fills the **Port** and the **Network type**. ElastiCache creates an equivalent **Subnet group** from the source database. To customize these settings, select [Customize your connectivity settings](#).

7. Confirm the ElastiCache security settings.

ElastiCache provides the default values for **Encryption at rest**, **Encryption key**, **Encryption in transit**, **Access control**, and **Security groups**. To customize these settings, select [Customize your security settings](#).
8. Verify the default and inherited settings of your ElastiCache cluster. Some settings can't be changed after creation.

**Note**
RDS might adjust the backup window of your ElastiCache cluster to meet the minimum window requirement of 60 minutes. The backup window of your source database remains the same.

9. When you're ready, choose **Create ElastiCache cluster**.

The console displays a confirmation banner for the ElastiCache cluster creation. Follow the link in the banner to the ElastiCache console to view the cluster details. The ElastiCache console displays the newly created ElastiCache cluster.

### Creating an ElastiCache cluster with settings from an existing Aurora DB cluster

You can create an ElastiCache cluster for your existing Aurora DB clusters from the **Actions** dropdown menu in the console.

**Create an ElastiCache cluster with settings from an existing DB cluster**

1. In the **Databases** page, select the required DB cluster.
2. In the **Actions** dropdown menu, choose **Create ElastiCache cluster** to create an ElastiCache cluster in RDS that has the same settings as your existing Aurora DB cluster.

   In the **ElastiCache configuration section**, the **Source DB identifier** shows which DB cluster the ElastiCache cluster inherits settings from.
3. Choose whether you want to create a Redis or Memcached cluster. For more information, see **Comparing Memcached and Redis**.

   If you choose **Redis cluster**, then choose whether you want to keep the cluster mode **Enabled** or **Disabled**. For more information, see **Replication: Redis (Cluster Mode Disabled) vs. Redis (Cluster Mode Enabled)**.

---

**ElastiCache cluster configuration**

<table>
<thead>
<tr>
<th>Source DB identifier</th>
<th>Info</th>
</tr>
</thead>
<tbody>
<tr>
<td>database-1</td>
<td></td>
</tr>
</tbody>
</table>

**Cluster type**
- **Redis cluster**
- **Memcached cluster**

**Cluster mode**
- **Enabled**
  - Cluster mode enables replication across multiple shards for enhanced scalability and availability.

- **Disabled**
  - The Redis cluster will have a single shard (node group) with one primary node and up to 5 read replicas.

- **Turning on cluster mode supports partitioning your data across up to 500 node groups and improves performance of Redis clusters. Some commands are unavailable in this mode. Learn more**
4. Enter values for **Name**, **Description**, and **Engine version**.

   For **Engine version**, the recommended default value is the latest engine version. You can also choose an **Engine version** for the ElastiCache cluster that best meets your requirements.

5. Choose the node type in the **Node type** option. For more information, see [Managing nodes](#).

   If you choose to create a Redis cluster with the **Cluster mode** set to **Enabled**, then enter the number of shards (partitions/node groups) in the **Number of shards** option.

   Enter the number of replicas of each shard in **Number of replicas**.

   **Note**

   The selected node type, the number of shards, and the number of replicas all affect your cluster performance and resource costs. Be sure these settings match your database needs.

   For pricing information, see [Amazon ElastiCache pricing](#).

6. Confirm the ElastiCache connectivity settings.

   RDS automatically fills the **Port** and the **Network type**. ElastiCache creates an equivalent **Subnet group** from the source database. To customize these settings, select **Customize your connectivity settings**.

   **ElastiCache connectivity settings**

   You can configure your connectivity settings by using inherited and default values or define your own.

   **ElastiCache default connectivity settings**

   Use the following default values.

   - **Port**: 6379
   - **Network type**: IPv4
   - **Subnet group**: sg-

   **Customize your connectivity settings**

   Edit the default values according to your requirements.

   **Note**

   We will create a subnet group using the same subnets associated to the source RDS database database-1. You can use the newly created subnet group or change the subnet group in the ElastiCache connectivity settings. You can't change this setting after the cluster is created. [Learn more](#).

7. Confirm the ElastiCache security settings.

   ElastiCache provides the default values for **Encryption at rest**, **Encryption key**, **Encryption in transit**, **Access control**, and **Security groups**. To customize these settings, select **Customize your security settings**.
8. Verify the default and inherited settings of your ElastiCache cluster. Some settings can't be changed after creation.

**Note**
RDS might adjust the backup window of your ElastiCache cluster to meet the minimum window requirement of 60 minutes. The backup window of your source database remains the same.

9. When you're ready, choose **Create ElastiCache cluster**.

The console displays a confirmation banner for the ElastiCache cluster creation. Follow the link in the banner to the ElastiCache console to view the cluster details. The ElastiCache console displays the newly created ElastiCache cluster.
Managing an Amazon Aurora DB cluster

This section shows how to manage and maintain your Aurora DB cluster. Aurora involves clusters of database servers that are connected in a replication topology. Thus, managing Aurora often involves deploying changes to multiple servers and making sure that all Aurora Replicas are keeping up with the master server. Because Aurora transparently scales the underlying storage as your data grows, managing Aurora requires relatively little management of disk storage. Likewise, because Aurora automatically performs continuous backups, an Aurora cluster does not require extensive planning or downtime for performing backups.

Stopping and starting a cluster

Stopping and starting Amazon Aurora clusters helps you manage costs for development and test environments. You can temporarily stop all the DB instances in your cluster, instead of setting up and tearing down all the DB instances each time that you use the cluster.

Topics

- Overview of stopping and starting an Aurora DB cluster (p. 249)
- Limitations for stopping and starting Aurora DB clusters (p. 249)

- Possible operations while an Aurora DB cluster is stopped (p. 251)
- Starting an Aurora DB cluster (p. 251)

Overview of stopping and starting an Aurora DB cluster

During periods where you don't need an Aurora cluster, you can stop all instances in that cluster at once. You can start the cluster again anytime you need to use it. Starting and stopping simplifies the setup and teardown processes for clusters used for development, testing, or similar activities that don't require continuous availability. You can perform all the AWS Management Console procedures involved with only a single action, regardless of how many instances are in the cluster.

While your DB cluster is stopped, you are charged only for cluster storage, manual snapshots, and automated backup storage within your specified retention window. You aren't charged for any DB instance hours.

Important
You can stop a DB cluster for up to seven days. If you don't manually start your DB cluster after seven days, your DB cluster is automatically started so that it doesn’t fall behind any required maintenance updates.

To minimize charges for a lightly loaded Aurora cluster, you can stop the cluster instead of deleting all of its Aurora Replicas. For clusters with more than one or two instances, frequently deleting and recreating the DB instances is only practical using the AWS CLI or Amazon RDS API. Such a sequence of operations can also be difficult to perform in the right order, for example to delete all Aurora Replicas before deleting the primary instance to avoid activating the failover mechanism.

Don't use starting and stopping if you need to keep your DB cluster running but it has more capacity than you need. If your cluster is too costly or not very busy, delete one or more DB instances or change all your DB instances to a small instance class. You can't stop an individual Aurora DB instance.

Limitations for stopping and starting Aurora DB clusters

Some Aurora clusters can't be stopped and started:

- You can't stop and start a cluster that's part of an Aurora global database (p. 1800).
- You can't stop and start a cluster that has a cross-Region read replica.
- For a cluster that uses the Aurora parallel query (p. 948) feature, the minimum Aurora MySQL version is 2.09.0.
• You can't stop and start an Aurora Serverless v1 cluster (p. 2023). With Aurora Serverless v2 (p. 1961), you can stop and start the cluster.

If an existing cluster can't be stopped and started, the Stop action isn't available from the Actions menu on the Databases page or the details page.

**Stopping an Aurora DB cluster**

To use an Aurora DB cluster or perform administration, you always begin with a running Aurora DB cluster, then stop the cluster, and then start the cluster again. While your cluster is stopped, you are charged for cluster storage, manual snapshots, and automated backup storage within your specified retention window, but not for DB instance hours.

The stop operation stops the Aurora Replica instances first, then the primary instance, to avoid activating the failover mechanism.

You can't stop a DB cluster that acts as the replication target for data from another DB cluster, or acts as the replication master and transmits data to another cluster.

You can't stop certain special kinds of clusters. Currently, you can't stop a cluster that's part of an Aurora global database.

**Console**

**To stop an Aurora cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose a cluster. You can perform the stop operation from this page, or navigate to the details page for the DB cluster that you want to stop.
3. For Actions, choose Stop temporarily.

   If a DB cluster can't be stopped and started, the Stop temporarily action isn't available from the Actions menu on the Databases page or the details page. For the kinds of clusters that you can't start and stop, see Limitations for stopping and starting Aurora DB clusters (p. 249).

4. In the Stop DB cluster temporarily window, select the acknowledgement that the DB cluster will restart automatically after 7 days.
5. Choose Stop temporarily to stop the DB cluster, or choose Cancel to cancel the operation.

**AWS CLI**

To stop a DB instance by using the AWS CLI, call the stop-db-cluster command with the following parameters:

• --db-cluster-identifier – the name of the Aurora cluster.

**Example**

```
aws rds stop-db-cluster --db-cluster-identifier mydbcluster
```

**RDS API**

To stop a DB instance by using the Amazon RDS API, call the StopDBCluster operation with the following parameter:
Possible operations while an Aurora DB cluster is stopped

While an Aurora cluster is stopped, you can do a point-in-time restore to any point within your specified automated backup retention window. For details about doing a point-in-time restore, see Restoring data (p. 432).

You can't modify the configuration of an Aurora DB cluster, or any of its DB instances, while the cluster is stopped. You also can't add or remove DB instances from the cluster, or delete the cluster if it still has any associated DB instances. You must start the cluster before performing any such administrative actions.

Stopping a DB cluster removes pending actions, except for the DB cluster parameter group or for the DB parameter groups of the DB cluster instances.

Aurora applies any scheduled maintenance to your stopped cluster after it's started again. Remember that after seven days, Aurora automatically starts any stopped clusters so that they don't fall too far behind in their maintenance status.

Aurora also doesn't perform any automated backups, because the underlying data can't change while the cluster is stopped. Aurora doesn't extend the backup retention period while the cluster is stopped.

Starting an Aurora DB cluster

You always start an Aurora DB cluster beginning with an Aurora cluster that is already in the stopped state. When you start the cluster, all its DB instances become available again. The cluster keeps its configuration settings such as endpoints, parameter groups, and VPC security groups.

Restarting a DB cluster usually takes several minutes.

Console

To start an Aurora cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose a cluster. You can perform the start operation from this page, or navigate to the details page for the DB cluster that you want to start.
3. For Actions, choose Start.

AWS CLI

To start a DB cluster by using the AWS CLI, call the start-db-cluster command with the following parameters:

- --db-cluster-identifier – the name of the Aurora cluster. This name is either a specific cluster identifier you chose when creating the cluster, or the DB instance identifier you chose with -cluster appended to the end.

Example

```
aws rds start-db-cluster --db-cluster-identifier mydbcluster
```
RDS API

To start an Aurora DB cluster by using the Amazon RDS API, call the `StartDBCluster` operation with the following parameter:

- `DBCluster` – the name of the Aurora cluster. This name is either a specific cluster identifier you chose when creating the cluster, or the DB instance identifier you chose with `-cluster` appended to the end.
Automatically connecting an AWS compute resource and an Aurora DB cluster

You can automatically connect an Aurora DB cluster and AWS compute resources such as Amazon Elastic Compute Cloud (Amazon EC2) instances and AWS Lambda functions.

Topics

- Automatically connecting an EC2 instance and an Aurora DB cluster (p. 253)
- Automatically connecting a Lambda function and an Aurora DB cluster (p. 260)

Automatically connecting an EC2 instance and an Aurora DB cluster

You can use the Amazon RDS console to simplify setting up a connection between an Amazon Elastic Compute Cloud (Amazon EC2) instance and an Aurora DB cluster. Often, your DB cluster is in a private subnet and your EC2 instance is in a public subnet within a VPC. You can use a SQL client on your EC2 instance to connect to your DB cluster. The EC2 instance can also run web servers or applications that access your private DB cluster.

If you want to connect to an EC2 instance that isn't in the same VPC as the Aurora DB cluster, see the scenarios in Scenarios for accessing a DB cluster in a VPC (p. 2489).

Topics

- Overview of automatic connectivity with an EC2 instance (p. 254)
- Automatically connecting an EC2 instance and an Aurora DB cluster (p. 256)
- Viewing connected compute resources (p. 258)
Overview of automatic connectivity with an EC2 instance

When you set up a connection between an EC2 instance and an Aurora DB cluster, Amazon RDS automatically configures the VPC security group for your EC2 instance and for your DB cluster.

The following are requirements for connecting an EC2 instance with an Aurora DB cluster:

- The EC2 instance must exist in the same VPC as the DB cluster.
  - If no EC2 instances exist in the same VPC, then the console provides a link to create one.
- Currently, the DB cluster can’t be an Aurora Serverless DB cluster or part of an Aurora global database.
- The user who sets up connectivity must have permissions to perform the following Amazon EC2 operations:
  - ec2:AuthorizeSecurityGroupEgress
  - ec2:AuthorizeSecurityGroupIngress
  - ec2:CreateSecurityGroup
  - ec2:DescribeInstances
  - ec2:DescribeNetworkInterfaces
  - ec2:DescribeSecurityGroups
  - ec2:ModifyNetworkInterfaceAttribute
  - ec2:RevokeSecurityGroupEgress

If the DB instance and EC2 instance are in different Availability Zones, your account may incur cross-Availability Zone costs.

When you set up a connection to an EC2 instance, Amazon RDS acts according to the current configuration of the security groups associated with the DB cluster and EC2 instance, as described in the following table.

<table>
<thead>
<tr>
<th>Current RDS security group configuration</th>
<th>Current EC2 security group configuration</th>
<th>RDS action</th>
</tr>
</thead>
<tbody>
<tr>
<td>There are one or more security groups associated with the DB cluster with a name that matches the pattern rds-ec2-n (where n is a number). A security group that matches the pattern hasn’t been modified. This security group has only one inbound rule with the VPC security group of the EC2 instance as the source.</td>
<td>There are one or more security groups associated with the EC2 instance with a name that matches the pattern rds-ec2-n (where n is a number). A security group that matches the pattern hasn’t been modified. This security group has only one outbound rule with the VPC security group of the DB cluster as the source.</td>
<td>RDS takes no action. A connection was already configured automatically between the EC2 instance and DB cluster. Because a connection already exists between the EC2 instance and the RDS database, the security groups aren’t modified.</td>
</tr>
<tr>
<td>Either of the following conditions apply:</td>
<td>Either of the following conditions apply:</td>
<td>RDS action: create new security groups</td>
</tr>
<tr>
<td>• There is no security group associated with the DB cluster with a name that matches the pattern rds-ec2-n.</td>
<td>• There is no security group associated with the EC2 instance with a name that matches the pattern ec2-rds-n.</td>
<td></td>
</tr>
<tr>
<td>• There are one or more security groups associated with the</td>
<td>• There are one or more security groups associated with the</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Current RDS security group configuration</td>
<td>Current EC2 security group configuration</td>
<td>RDS action</td>
</tr>
<tr>
<td>----------------------------------------</td>
<td>----------------------------------------</td>
<td>------------</td>
</tr>
<tr>
<td>DB cluster with a name that matches the pattern <code>rds-ec2-n</code>. However, Amazon RDS can't use any of these security groups for the connection with the EC2 instance. Amazon RDS can't use a security group that doesn't have one inbound rule with the VPC security group of the EC2 instance as the source. Amazon RDS also can't use a security group that has been modified. Examples of modifications include adding a rule or changing the port of an existing rule.</td>
<td>EC2 instance with a name that matches the pattern <code>ec2-rds-n</code>. However, Amazon RDS can't use any of these security groups for the connection with the DB cluster. Amazon RDS can't use a security group that doesn't have one outbound rule with the VPC security group of the DB cluster as the source. Amazon RDS also can't use a security group that has been modified.</td>
<td>RDS action: create new security groups</td>
</tr>
<tr>
<td>There are one or more security groups associated with the DB cluster with a name that matches the pattern <code>rds-ec2-n</code>. A security group that matches the pattern hasn't been modified. This security group has only one inbound rule with the VPC security group of the EC2 instance as the source.</td>
<td>There are one or more security groups associated with the EC2 instance with a name that matches the pattern <code>ec2-rds-n</code>. However, Amazon RDS can't use any of these security groups for the connection with the DB cluster. Amazon RDS can't use a security group that doesn't have one outbound rule with the VPC security group of the DB cluster as the source. Amazon RDS also can't use a security group that has been modified.</td>
<td>RDS action: create new security groups</td>
</tr>
<tr>
<td>There are one or more security groups associated with the DB cluster with a name that matches the pattern <code>rds-ec2-n</code>. A security group that matches the pattern hasn't been modified. This security group has only one inbound rule with the VPC security group of the EC2 instance as the source.</td>
<td>A valid EC2 security group for the connection exists, but it is not associated with the EC2 instance. This security group has a name that matches the pattern <code>rds-ec2-n</code>. It hasn't been modified. It has only one outbound rule with the VPC security group of the DB cluster as the source.</td>
<td>RDS action: associate EC2 security group</td>
</tr>
</tbody>
</table>
Either of the following conditions apply:

- There is no security group associated with the DB cluster with a name that matches the pattern `rds-ec2-n`.
- There are one or more security groups associated with the DB cluster with a name that matches the pattern `rds-ec2-n`. However, Amazon RDS can't use any of these security groups for the connection with the EC2 instance. Amazon RDS can't use a security group that doesn't have one inbound rule with the VPC security group of the EC2 instance as the source. Amazon RDS also can't use security group that has been modified.

There are one or more security groups associated with the EC2 instance with a name that matches the pattern `rds-ec2-n`. A security group that matches the pattern hasn't been modified. This security group has only one outbound rule with the VPC security group of the DB cluster as the source.

Amazon RDS takes the following actions:

- Creates a new security group that matches the pattern `rds-ec2-n`. This security group has an inbound rule with the VPC security group of the EC2 instance as the source. This security group is associated with the DB cluster and allows the EC2 instance to access the DB cluster.
- Creates a new security group that matches the pattern `ec2-rds-n`. This security group has an outbound rule with the VPC security group of the DB cluster as the source. This security group is associated with the EC2 instance and allows the EC2 instance to send traffic to the DB cluster.

Amazon RDS associates the valid, existing EC2 security group with the EC2 instance. This security group allows the EC2 instance to send traffic to the DB cluster.

Automatically connecting an EC2 instance and an Aurora DB cluster

Before setting up a connection between an EC2 instance and an Aurora DB cluster, make sure you meet the requirements described in Overview of automatic connectivity with an EC2 instance (p. 254).

If you make changes to security groups after you configure connectivity, the changes might affect the connection between the EC2 instance and the Aurora DB cluster.

Note
You can only set up a connection between an EC2 instance and an Aurora DB cluster automatically by using the AWS Management Console. You can't set up a connection automatically with the AWS CLI or RDS API.
To connect an EC2 instance and an Aurora DB cluster automatically

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB cluster.
3. From Actions, choose Set up EC2 connection.

   The Set up EC2 connection page appears.

4. On the Set up EC2 connection page, choose the EC2 instance.

   If no EC2 instances exist in the same VPC, choose Create EC2 instance to create one. In this case, make sure the new EC2 instance is in the same VPC as the DB cluster.

5. Choose Continue.

   The Review and confirm page appears.
6. On the **Review and confirm** page, review the changes that RDS will make to set up connectivity with the EC2 instance.

   If the changes are correct, choose **Confirm and set up**.

   If the changes aren't correct, choose **Previous** or **Cancel**.

### Viewing connected compute resources

You can use the AWS Management Console to view the compute resources that are connected to an Aurora DB cluster. The resources shown include compute resource connections that were set up automatically. You can set up connectivity with compute resources automatically in the following ways:

- You can select the compute resource when you create the database.

For more information, see [Creating an Amazon Aurora DB cluster](p. 179).
• You can set up connectivity between an existing database and a compute resource.

For more information, see **Automatically connecting an EC2 instance and an Aurora DB cluster** (p. 256).

The listed compute resources don’t include ones that were connected to the database manually. For example, you can allow a compute resource to access a database manually by adding a rule to the VPC security group associated with the database.

For a compute resource to be listed, the following conditions must apply:

• The name of the security group associated with the compute resource matches the pattern `ec2-rds-n` (where `n` is a number).
• The security group associated with the compute resource has an outbound rule with the port range set to the port that the DB cluster uses.
• The security group associated with the compute resource has an outbound rule with the source set to a security group associated with the DB cluster.
• The name of the security group associated with the DB cluster matches the pattern `rds-ec2-n` (where `n` is a number).
• The security group associated with the DB cluster has an inbound rule with the port range set to the port that the DB cluster uses.
• The security group associated with the DB cluster has an inbound rule with the source set to a security group associated with the compute resource.

**To view compute resources connected to an Aurora DB cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**, and then choose the name of the DB cluster.
3. On the **Connectivity & security** tab, view the compute resources in the **Connected compute resources**.

![Connected compute resources](image)

**Connecting to a DB instance that is running a specific DB engine**

For information about connecting to a DB instance that is running a specific DB engine, follow the instructions for your DB engine:

• **Connecting to an Amazon Aurora MySQL DB cluster** (p. 204)
• **Connecting to an Amazon Aurora PostgreSQL DB cluster** (p. 209)
Automatically connecting a Lambda function and an Aurora DB cluster

You can use the Amazon RDS console to simplify setting up a connection between a Lambda function and an Aurora DB cluster. Often, your DB cluster is in a private subnet within a VPC. The Lambda function can be used by applications to access your private DB cluster.

The following image shows a direct connection between your DB cluster and your Lambda function.

You can set up the connection between your Lambda function and your DB cluster through RDS Proxy to improve your database performance and resiliency. Often, Lambda functions make frequent, short database connections that benefit from connection pooling that RDS Proxy offers. You can take advantage of any AWS Identity and Access Management (IAM) authentication that you already have for Lambda functions, instead of managing database credentials in your Lambda application code. For more information, see Using Amazon RDS Proxy for Aurora (p. 1879).

When you use the console to connect with an existing proxy, Amazon RDS updates the proxy security group to allow connections from your DB cluster and Lambda function.

You can also create a new proxy from the same console page. When you create a proxy in the console, to access the DB cluster, you must input your database credentials or select an AWS Secrets Manager secret.
Overview of automatic connectivity with a Lambda function

The following are requirements for connecting a Lambda function with an Aurora DB cluster:

- The Lambda function must exist in the same VPC as the DB cluster.
- Currently, the DB cluster can’t be an Aurora Serverless DB cluster or part of an Aurora global database.
- The user who sets up connectivity must have permissions to perform the following Amazon RDS, Amazon EC2, Lambda, Secrets Manager, and IAM operations:
  - Amazon RDS
    - rds:CreateDBProxies
    - rds:DescribeDBClusters
    - rds:DescribeDBProxies
    - rds:ModifyDBCluster
    - rds:ModifyDBProxy
    - rds:RegisterProxyTargets
  - Amazon EC2
    - ec2:AuthorizeSecurityGroupEgress
    - ec2:AuthorizeSecurityGroupIngress
    - ec2:CreateSecurityGroup
    - ec2:DeleteSecurityGroup
- ec2:DescribeSecurityGroups
- ec2:RevokeSecurityGroupEgress
- ec2:RevokeSecurityGroupIngress
- Lambda
  - lambda:CreateFunctions
  - lambda:ListFunctions
  - lambda:UpdateFunctionConfiguration
- Secrets Manager
  - secretsmanager:CreateSecret
  - secretsmanager:DescribeSecret
- IAM
  - iam:AttachPolicy
  - iam:CreateRole
  - iam:CreatePolicy
- AWS KMS
  - kms:describeKey

**Note**

If the DB cluster and Lambda function are in different Availability Zones, your account might incur cross-Availability Zone costs.

When you set up a connection between a Lambda function and an Aurora DB cluster, Amazon RDS configures the VPC security group for your function and for your DB cluster. If you use RDS Proxy, then Amazon RDS also configures the VPC security group for the proxy. Amazon RDS acts according to the current configuration of the security groups associated with the DB cluster, Lambda function, and proxy, as described in the following table.

<table>
<thead>
<tr>
<th>Current RDS security group configuration</th>
<th>Current Lambda security group configuration</th>
<th>Current proxy security group configuration</th>
<th>RDS action</th>
</tr>
</thead>
<tbody>
<tr>
<td>There are one or more security groups associated with the DB cluster with a name that matches the pattern rds-lambda-(n) or if a proxy is already connected to your DB cluster, RDS checks if the TargetHealth of an associated proxy is AVAILABLE. A security group that matches the pattern hasn't been modified. This security group has only one inbound rule with the VPC security group of the Lambda function or proxy as the source.</td>
<td>There are one or more security groups associated with the Lambda function with a name that matches the pattern lambda-rds-(n) or lambda-rdsproxy-(n) (where (n) is a number). A security group that matches the pattern hasn't been modified. This security group has only one outbound rule with either the VPC security group of the DB cluster or the proxy as the destination.</td>
<td>There are one or more security groups associated with the proxy with a name that matches the pattern rdsproxy-lambda-(n) (where (n) is a number). A security group that matches the pattern hasn't been modified. This security group has inbound and outbound rules with the VPC security groups of the Lambda function and the DB cluster.</td>
<td>Amazon RDS takes no action. A connection was already configured automatically between the Lambda function, the proxy (optional), and DB cluster. Because a connection already exists between the function, proxy, and the database, the security groups aren't modified.</td>
</tr>
</tbody>
</table>
Either of the following conditions apply:

- There is no security group associated with the DB cluster with a name that matches the pattern `rds-lambda-n` or if the TargetHealth of an associated proxy is AVAILABLE.
- There are one or more security groups associated with the DB cluster with a name that matches the pattern `rds-lambda-n` or if the TargetHealth of an associated proxy is AVAILABLE. However, none of these security groups can be used for the connection with the Lambda function.

Amazon RDS can't use a security group that doesn't have one inbound rule with the VPC security group of the Lambda function or proxy as the source. Amazon RDS also can't use a security group that has been modified. Examples of modifications include adding a rule or changing the port of an existing rule.

Amazon Aurora User Guide for Aurora
Connecting a Lambda function
### Connecting a Lambda function

Either of the following conditions apply:

- There is no security group associated with the DB cluster with a name that matches the pattern `rds-lambda-\(n\)` or if the TargetHealth of an associated proxy is AVAILABLE.
- There are one or more security groups associated with the DB cluster with a name that matches the pattern `rds-lambda-\(n\)` or if the TargetHealth of an associated proxy is AVAILABLE. However, Amazon RDS can't use any of these security groups for the connection with the Lambda function or proxy.

Amazon RDS can't use a security group that doesn't have one inbound rule with the VPC security group of the Lambda function or proxy. Amazon RDS also can't use a security group that has been modified.

Either of the following conditions apply:

- There is no security group associated with the Lambda function with a name that matches the pattern `lambda-rds-\(n\)` or `lambda-rdsproxy-\(n\).
- There are one or more security groups associated with the Lambda function with a name that matches the pattern `lambda-rds-\(n\)` or `lambda-rdsproxy-\(n\). However, Amazon RDS can't use any of these security groups for the connection with the DB cluster.

Amazon RDS can't use a security group that doesn't have one outbound rule with the VPC security group of the DB cluster or proxy as the source. Amazon RDS also can't use a security group that has been modified.

Either of the following conditions apply:

- There is no security group associated with the proxy with a name that matches the pattern `rdsproxy-lambda-\(n\).` Amazon RDS can't use a security group that doesn't have inbound and outbound rules with the VPC security group of the DB cluster and the Lambda function. Amazon RDS also can't use a security group that has been modified.

### RDS action: create new security groups

Amazon RDS takes the following actions:

- Creates a new security group that matches the pattern `rds-lambda-\(n\)` or `rds-rdsproxy-\(n\)` (if you choose to use RDS Proxy). This security group has an inbound rule with the VPC security group of the Lambda function or proxy as the source. This security group is associated with the DB cluster and allows the function or proxy to access the DB cluster.
- Creates a new security group that matches the pattern `lambda-rds-\(n\)` or `lambda-rdsproxy-\(n\).` This security group has an outbound rule with the VPC security group of the DB cluster or proxy as the destination. This security group is associated with the Lambda function and allows the function to send traffic to the DB cluster or send traffic through a proxy.
- Creates a new security group that matches the pattern `rdsproxy-lambda-\(n\).` This security group has inbound and outbound rules with the VPC security group of the DB cluster and the Lambda function.
RDS action: associate Lambda security group

Amazon RDS associates the valid, existing Lambda security group with the Lambda function. This security group allows the function to send traffic to the DB cluster or send traffic through a proxy.

Automatically connecting a Lambda function and an Aurora DB cluster

You can use the Amazon RDS console to automatically connect a Lambda function to your DB cluster. This simplifies the process of setting up a connection between these resources.

You can also use RDS Proxy to include a proxy in your connection. Lambda functions make frequent short database connections that benefit from the connection pooling that RDS Proxy offers. You can also use any IAM authentication that you've already set up for your Lambda function, instead of managing database credentials in your Lambda application code.

You can connect an existing DB cluster to new and existing Lambda functions using the Set up Lambda connection page. The setup process automatically sets up the required security groups for you.

Before setting up a connection between a Lambda function and a DB cluster, make sure that:

- Your Lambda function and DB cluster are in the same VPC.
- You have the right permissions for your user account. For more information about the requirements, see Overview of automatic connectivity with a Lambda function (p. 261).

If you change security groups after you configure connectivity, the changes might affect the connection between the Lambda function and the DB cluster.

Note
You can automatically set up a connection between a DB cluster and a Lambda function only in the AWS Management Console. To connect a Lambda function, all instances in the DB cluster must be in the Available state.

To automatically connect a Lambda function and a DB cluster

After you confirm the setup, Amazon RDS begins the process of connecting your Lambda function, RDS Proxy (if you used a proxy), and DB cluster. The console shows the Connection details dialog box, which lists the security group changes that allow connections between your resources.

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB cluster that you want to connect to a Lambda function.
3. For Actions, choose Set up Lambda connection.
4. On the Set up Lambda connection page, under Select Lambda function, do either of the following:
   - If you have an existing Lambda function in the same VPC as your DB cluster, choose Choose existing function, and then choose the function.
   - If you don't have a Lambda function in the same VPC, choose Create new function, and then enter a Function name. The default runtime is set to Nodejs.18. You can modify the settings for your new Lambda function in the Lambda console after you complete the connection setup.
5. (Optional) Under RDS Proxy, select Connect using RDS Proxy, and then do any of the following:
   - If you have an existing proxy that you want to use, choose Choose existing proxy, and then choose the proxy.
If you don't have a proxy, and you want Amazon RDS to automatically create one for you, choose Create new proxy. Then, for Database credentials, do either of the following:

a. Choose Database username and password, and then enter the Username and Password for your DB cluster.

b. Choose Secrets Manager secret. Then, for Select secret, choose an AWS Secrets Manager secret. If you don't have a Secrets Manager secret, choose Create new Secrets Manager secret to create a new secret. After you create the secret, for Select secret, choose the new secret.

After you create the new proxy, choose Choose existing proxy, and then choose the proxy. Note that it might take some time for your proxy to be available for connection.

6. (Optional) Expand Connection summary and verify the highlighted updates for your resources.

7. Choose Set up.

**Viewing connected compute resources**

You can use the AWS Management Console to view the Lambda functions that are connected to your DB cluster. The resources shown include compute resource connections that Amazon RDS set up automatically.

The listed compute resources don't include those that are manually connected to the DB cluster. For example, you can allow a compute resource to access your DB cluster manually by adding a rule to your VPC security group associated with the database.

For the console to list a Lambda function, the following conditions must apply:

- The name of the security group associated with the compute resource matches the pattern lambda-rds-n or lambda-rdsproxy-n (where n is a number).
- The security group associated with the compute resource has an outbound rule with the port range set to the port of the DB cluster or an associated proxy. The destination for the outbound rule must be set to a security group associated with the DB cluster or an associated proxy.
- If the configuration includes a proxy, the name of the security group attached to the proxy associated with your database matches the pattern rdsproxy-lambda-n (where n is a number).
- The security group associated with the function has an outbound rule with the port set to the port that the DB cluster or associated proxy uses. The destination must be set to a security group associated with the DB cluster or associated proxy.

**To view compute resources automatically connected to an DB cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB cluster.
3. On the Connectivity & security tab, view the compute resources under Connected compute resources.
Modifying an Amazon Aurora DB cluster

You can change the settings of a DB cluster to accomplish tasks such as changing its backup retention period or its database port. You can also modify DB instances in a DB cluster to accomplish tasks such as changing its DB instance class or enabling Performance Insights for it. This topic guides you through modifying an Aurora DB cluster and its DB instances, and describes the settings for each.

We recommend that you test any changes on a test DB cluster or DB instance before modifying a production DB cluster or DB instance, so that you fully understand the impact of each change. This is especially important when upgrading database versions.

Modifying the DB cluster by using the console, CLI, and API

You can modify a DB cluster using the AWS Management Console, the AWS CLI, or the RDS API.

**Note**

Most modifications can be applied immediately or during the next scheduled maintenance window. Some modifications, such as turning on deletion protection, are applied immediately—regardless of when you choose to apply them.

Changing the master password in the AWS Management Console is always applied immediately. However, when using the AWS CLI or RDS API, you can choose whether to apply this change immediately or during the next scheduled maintenance window.

If you're using SSL endpoints and change the DB cluster identifier, stop and restart the DB cluster to update the SSL endpoints. For more information, see Stopping and starting an Amazon Aurora DB cluster (p. 249).

**Console**

**To modify a DB cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then select the DB cluster that you want to modify.
4. Change any of the settings that you want. For information about each setting, see Settings for Amazon Aurora (p. 272).

   **Note**

   In the AWS Management Console, some instance level changes only apply to the current DB instance, while others apply to the entire DB cluster. For information about whether a setting applies to the DB instance or the DB cluster, see the scope for the setting in Settings for Amazon Aurora (p. 272). To change a setting that modifies the entire DB cluster at the instance level in the AWS Management Console, follow the instructions in Modifying a DB instance in a DB cluster (p. 270).

5. When all the changes are as you want them, choose Continue and check the summary of modifications.
6. To apply the changes immediately, select Apply immediately.
7. On the confirmation page, review your changes. If they are correct, choose Modify cluster to save your changes.

   Alternatively, choose Back to edit your changes, or choose Cancel to cancel your changes.
AWS CLI

To modify a DB cluster using the AWS CLI, call the `modify-db-cluster` command. Specify the DB cluster identifier, and the values for the settings that you want to modify. For information about each setting, see [Settings for Amazon Aurora](p. 272).

**Note**

Some settings only apply to DB instances. To change those settings, follow the instructions in [Modifying a DB instance in a DB cluster](p. 270).

**Example**

The following command modifies `mydbcluster` by setting the backup retention period to 1 week (7 days).

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
    --db-cluster-identifier mydbcluster \
    --backup-retention-period 7
```

For Windows:

```
aws rds modify-db-cluster ^
    --db-cluster-identifier mydbcluster ^
    --backup-retention-period 7
```

RDS API

To modify a DB cluster using the Amazon RDS API, call the `ModifyDBCluster` operation. Specify the DB cluster identifier, and the values for the settings that you want to modify. For information about each parameter, see [Settings for Amazon Aurora](p. 272).

**Note**

Some settings only apply to DB instances. To change those settings, follow the instructions in [Modifying a DB instance in a DB cluster](p. 270).

Modifying a DB instance in a DB cluster

You can modify a DB instance in a DB cluster using the AWS Management Console, the AWS CLI, or the RDS API.

When you modify a DB instance, you can apply the changes immediately. To apply changes immediately, you select the **Apply Immediately** option in the AWS Management Console, you use the `--apply-immediately` parameter when calling the AWS CLI, or you set the `ApplyImmediately` parameter to `true` when using the Amazon RDS API.

If you don’t choose to apply changes immediately, the changes are deferred until the next maintenance window. During the next maintenance window, any of these deferred changes are applied. If you choose to apply changes immediately, your new changes and any previously deferred changes are applied.

**Important**

If any of the deferred modifications require downtime, choosing **Apply immediately** can cause unexpected downtime for the DB instance. There is no downtime for the other DB instances in the DB cluster.

Modifications that you defer aren’t listed in the output of the `describe-pending-maintenance-actions` CLI command. Maintenance actions only include system upgrades that you schedule for the next maintenance window.
Console

To modify a DB instance in a DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then select the DB instance that you want to modify.
3. For Actions, choose Modify. The Modify DB instance page appears.
4. Change any of the settings that you want. For information about each setting, see Settings for Amazon Aurora (p. 272).

   Note
   Some settings apply to the entire DB cluster and must be changed at the cluster level. To change those settings, follow the instructions in Modifying the DB cluster by using the console, CLI, and API (p. 269).

   In the AWS Management Console, some instance level changes only apply to the current DB instance, while others apply to the entire DB cluster. For information about whether a setting applies to the DB instance or the DB cluster, see the scope for the setting in Settings for Amazon Aurora (p. 272).

5. When all the changes are as you want them, choose Continue and check the summary of modifications.
6. To apply the changes immediately, select Apply immediately.
7. On the confirmation page, review your changes. If they are correct, choose Modify DB instance to save your changes.

   Alternatively, choose Back to edit your changes, or choose Cancel to cancel your changes.

AWS CLI

To modify a DB instance in a DB cluster by using the AWS CLI, call the modify-db-instance command. Specify the DB instance identifier, and the values for the settings that you want to modify. For information about each parameter, see Settings for Amazon Aurora (p. 272).

   Note
   Some settings apply to the entire DB cluster. To change those settings, follow the instructions in Modifying the DB cluster by using the console, CLI, and API (p. 269).

Example

The following code modifies mydbinstance by setting the DB instance class to db.r4.xlarge. The changes are applied during the next maintenance window by using --no-apply-immediately. Use --apply-immediately to apply the changes immediately.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \ 
  --db-instance-identifier mydbinstance \ 
  --db-instance-class db.r4.xlarge \ 
  --no-apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --db-instance-class db.r4.xlarge ^
  --no-apply-immediately
```
RDS API

To modify a MySQL instance by using the Amazon RDS API, call the `ModifyDBInstance` operation. Specify the DB instance identifier, and the values for the settings that you want to modify. For information about each parameter, see `Settings for Amazon Aurora` (p. 272).

**Note**

Some settings apply to the entire DB cluster. To change those settings, follow the instructions in `Modifying the DB cluster by using the console, CLI, and API` (p. 269).

**Settings for Amazon Aurora**

The following table contains details about which settings you can modify, the methods for modifying the setting, and the scope of the setting. The scope determines whether the setting applies to the entire DB cluster or if it can be set only for specific DB instances.

**Note**

Additional settings are available if you are modifying an Aurora Serverless v1 or Aurora Serverless v2 DB cluster. For information about these settings, see `Modifying an Aurora Serverless v1 DB cluster` (p. 2051) and `Managing Aurora Serverless v2` (p. 1987).

Some settings aren't available for Aurora Serverless v1 and Aurora Serverless v2 because of their limitations. For more information, see `Limitations of Aurora Serverless v1` (p. 2024) and `Requirements for Aurora Serverless v2` (p. 1969).

To connect to a DB instance from outside of its Amazon VPC, the DB instance must be publicly accessible, access must be granted using the inbound rules of the DB instance's security group, and other requirements must be met. For more information, see [Can't connect to Amazon RDS DB instance](p. 2511).

If your DB instance isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see [Internetwork traffic privacy](p. 2399).

Adding Aurora Replicas to a DB cluster

An Aurora DB cluster with replication has one primary DB instance and up to 15 Aurora Replicas. The primary DB instance supports read and write operations, and performs all data modifications to the cluster volume. Aurora Replicas connect to the same storage volume as the primary DB instance, but support read operations only. You use Aurora Replicas to offload read workloads from the primary DB instance. For more information, see Aurora Replicas (p. 104).

Amazon Aurora Replicas have the following limitations:

- You can't create an Aurora Replica for an Aurora Serverless v1 DB cluster. Aurora Serverless v1 has a single DB instance that scales up and down automatically to support all database read and write operations.

  However, you can add reader instances to Aurora Serverless v2 DB clusters. For more information, see Adding an Aurora Serverless v2 reader (p. 1995).

We recommend that you distribute the primary instance and Aurora Replicas of your Aurora DB cluster over multiple Availability Zones to improve the availability of your DB cluster. For more information, see Region availability (p. 17).

To remove an Aurora Replica from an Aurora DB cluster, delete the Aurora Replica by following the instructions in Deleting a DB instance from an Aurora DB cluster (p. 380).

Note

Amazon Aurora also supports replication with an external database, such as an RDS DB instance. The RDS DB instance must be in the same AWS Region as Amazon Aurora. For more information, see Replication with Amazon Aurora (p. 104).

You can add Aurora Replicas to a DB cluster using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To add an Aurora replica to a DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then select the DB cluster where you want to add the new DB instance.
3. Make sure that both the cluster and the primary instance are in the Available state. If the DB cluster or the primary instance are in a transitional state such as Creating, you can't add a replica.

   If the cluster doesn't have a primary instance, create one using the create-db-instance AWS CLI command. This situation can arise if you used the CLI to restore a DB cluster snapshot and then view the cluster in the AWS Management Console.
4. For Actions, choose Add reader.

   The Add reader page appears.
5. On the Add reader page, specify options for your Aurora Replica. The following table shows settings for an Aurora Replica.

<table>
<thead>
<tr>
<th>For this option</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability zone</td>
<td>Determine if you want to specify a particular Availability Zone. The list includes only those Availability Zones</td>
</tr>
<tr>
<td>For this option</td>
<td>Do this</td>
</tr>
<tr>
<td>---------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>that are mapped to the DB subnet group that you chose when you created the DB cluster. For more information about Availability Zones, see [Regions and Availability Zones](p. 16).</td>
</tr>
<tr>
<td>Publicly accessible</td>
<td>Select Yes to give the Aurora Replica a public IP address; otherwise, select No. For more information about hiding Aurora Replicas from public access, see [Hiding a DB cluster in a VPC from the internet](p. 2484).</td>
</tr>
<tr>
<td>Encryption</td>
<td>Select Enable encryption to enable encryption at rest for this Aurora Replica. For more information, see [Encrypting Amazon Aurora resources](p. 2381).</td>
</tr>
<tr>
<td>DB instance class</td>
<td>Select a DB instance class that defines the processing and memory requirements for the Aurora Replica. For more information about DB instance class options, see [Aurora DB instance classes](p. 84).</td>
</tr>
<tr>
<td>Aurora replica source</td>
<td>Select the identifier of the primary instance to create an Aurora Replica for.</td>
</tr>
<tr>
<td>DB instance identifier</td>
<td>Enter a name for the instance that is unique for your account in the AWS Region you selected. You might choose to add some intelligence to the name such as including the AWS Region and DB engine you selected, for example <code>aurora-read-instance1</code>.</td>
</tr>
<tr>
<td>Priority</td>
<td>Choose a failover priority for the instance. If you don't select a value, the default is <code>tier-1</code>. This priority determines the order in which Aurora Replicas are promoted when recovering from a primary instance failure. For more information, see [Fault tolerance for an Aurora DB cluster](p. 103).</td>
</tr>
<tr>
<td>Database port</td>
<td>The port for an Aurora Replica is the same as the port for the DB cluster.</td>
</tr>
<tr>
<td>DB parameter group</td>
<td>Select a parameter group. Aurora has a default parameter group you can use, or you can create your own parameter group. For more information about parameter groups, see [Working with parameter groups](p. 212).</td>
</tr>
<tr>
<td>Performance Insights</td>
<td>The <strong>Turn on Performance Insights</strong> check box is selected by default. The value isn't inherited from the writer instance. For more information, see [Monitoring DB load with Performance Insights on Amazon Aurora](p. 559).</td>
</tr>
<tr>
<td>Enhanced monitoring</td>
<td>Choose <strong>Enable enhanced monitoring</strong> to enable gathering metrics in real time for the operating system that your DB cluster runs on. For more information, see [Monitoring OS metrics with Enhanced Monitoring](p. 631).</td>
</tr>
</tbody>
</table>
### For this option | Do this
--- | ---
**Monitoring Role** | Only available if Enhanced Monitoring is set to Enable enhanced monitoring. Choose the IAM role that you created to permit Amazon RDS to communicate with Amazon CloudWatch Logs for you, or choose Default to have RDS create a role for you named rds-monitoring-role. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 631).

**Granularity** | Only available if Enhanced Monitoring is set to Enable enhanced monitoring. Set the interval, in seconds, between when metrics are collected for your DB cluster.

**Auto minor version upgrade** | Select Enable auto minor version upgrade if you want to enable your Aurora DB cluster to receive minor DB Engine version upgrades automatically when they become available.

The Auto minor version upgrade setting applies to both Aurora PostgreSQL and Aurora MySQL DB clusters. For Aurora MySQL 2.x clusters, this setting upgrades the clusters to a maximum version of 2.07.2.

For more information about engine updates for Aurora PostgreSQL, see Amazon Aurora PostgreSQL updates (p. 1780).

For more information about engine updates for Aurora MySQL, see Database engine updates for Amazon Aurora MySQL (p. 1200).

6. Choose Add reader to create the Aurora Replica.

**AWS CLI**

To create an Aurora Replica in your DB cluster, run the create-db-instance AWS CLI command. Include the name of the DB cluster as the --db-cluster-identifier option. You can optionally specify an Availability Zone for the Aurora Replica using the --availability-zone parameter, as shown in the following examples.

For example, the following command creates a new MySQL 5.7–compatible Aurora Replica named sample-instance-us-west-2a.

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance --db-instance-identifier sample-instance-us-west-2a \
  --db-cluster-identifier sample-cluster --engine aurora-mysql --db-instance-class db.r5.large \
  --availability-zone us-west-2a
```

For Windows:

```bash
aws rds create-db-instance --db-instance-identifier sample-instance-us-west-2a ^
  --db-cluster-identifier sample-cluster --engine aurora-mysql --db-instance-class db.r5.large ^
  --availability-zone us-west-2a
```
The following command creates a new MySQL 5.7–compatible Aurora Replica named sample-instance-us-west-2a.

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance --db-instance-identifier sample-instance-us-west-2a --db-cluster-identifier sample-cluster --engine aurora-mysql --db-instance-class db.r5.large --availability-zone us-west-2a
```

For Windows:

```bash
aws rds create-db-instance --db-instance-identifier sample-instance-us-west-2a --db-cluster-identifier sample-cluster --engine aurora --db-instance-class db.r5.large --availability-zone us-west-2a
```

The following command creates a new PostgreSQL-compatible Aurora Replica named sample-instance-us-west-2a.

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance --db-instance-identifier sample-instance-us-west-2a --db-cluster-identifier sample-cluster --engine aurora-postgresql --db-instance-class db.r5.large --availability-zone us-west-2a
```

For Windows:

```bash
aws rds create-db-instance --db-instance-identifier sample-instance-us-west-2a --db-cluster-identifier sample-cluster --engine aurora-postgresql --db-instance-class db.r5.large --availability-zone us-west-2a
```

**RDS API**

To create an Aurora Replica in your DB cluster, call the `CreateDBInstance` operation. Include the name of the DB cluster as the `DBClusterIdentifier` parameter. You can optionally specify an Availability Zone for the Aurora Replica using the `AvailabilityZone` parameter.
Managing performance and scaling for Aurora DB clusters

You can use the following options to manage performance and scaling for Aurora DB clusters and DB instances:

Topics
• Storage scaling (p. 297)
• Instance scaling (p. 301)
• Read scaling (p. 301)
• Managing connections (p. 301)
• Managing query execution plans (p. 302)

Storage scaling

Aurora storage automatically scales with the data in your cluster volume. As your data grows, your cluster volume storage expands up to a maximum of 128 tebibytes (TiB) or 64 TiB. The maximum size depends on the DB engine version. To learn what kinds of data are included in the cluster volume, see Amazon Aurora storage and reliability (p. 97). For details about the maximum size for a specific version, see Amazon Aurora size limits (p. 2510).

The size of your cluster volume is evaluated on an hourly basis to determine your storage costs. For pricing information, see the Aurora pricing page.

Even though an Aurora cluster volume can scale up in size to many tebibytes, you are only charged for the space that you use in the volume. The mechanism for determining billed storage space depends on the version of your Aurora cluster.

• When Aurora data is removed from the cluster volume, the overall billed space decreases by a comparable amount. This dynamic resizing behavior happens when underlying tablespaces are dropped or reorganized to require less space. Thus, you can reduce storage charges by dropping tables and databases that you no longer need. Dynamic resizing applies to certain Aurora versions. The following are the Aurora versions where the cluster volume dynamically resizes as you remove data:

<table>
<thead>
<tr>
<th>Aurora MySQL</th>
<th>Version 3 (compatible with MySQL 8.0): all supported versions</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Version 2 (compatible with MySQL 5.7): 2.09 and higher</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Aurora PostgreSQL</th>
<th>All 14 and 13 versions</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Version 12.4 and higher</td>
</tr>
<tr>
<td></td>
<td>Version 11.8 and higher</td>
</tr>
<tr>
<td></td>
<td>Version 10.13 and higher</td>
</tr>
</tbody>
</table>

• In Aurora versions lower than those in the preceding list, the cluster volume can reuse space that was freed up when you removed data, but the volume itself never decreases in size.

• This feature is being deployed in phases to the AWS Regions where Aurora is available. Depending on the Region where your cluster is, this feature might not be available yet.

Dynamic resizing applies to operations that physically remove or resize tablespaces within the cluster volume. Thus, it applies to SQL statements such as DROP TABLE, DROP DATABASE, TRUNCATE TABLE,
and ALTER TABLE ... DROP PARTITION. It doesn’t apply to deleting rows using the DELETE statement. If you delete a large number of rows from a table, you can run the Aurora MySQL OPTIMIZE TABLE statement or use the Aurora PostgreSQL pg_repack extension afterward to reorganize the table and dynamically resize the cluster volume.

**Note**

For Aurora MySQL, the innodb_file_per_table parameter affects how table storage is organized. When tables are part of the system tablespace, dropping the table doesn’t reduce the size of the system tablespace. Thus, make sure to set innodb_file_per_table to 1 for Aurora MySQL DB clusters to take full advantage of dynamic resizing.

For Aurora MySQL version 2.10 and higher, the InnoDB temporary tablespace is dropped and recreated on restart. This releases the space occupied by the temporary tablespace to the system, and then the cluster volume resizes. To take full advantage of the dynamic resizing feature, we recommend that you upgrade your DB cluster to Aurora MySQL version 2.10 or higher.

The dynamic resizing feature reclaims space from dropped tablespaces over time, not immediately, when tables in those tablespaces are dropped. Space in the system tablespace isn’t reclaimed because the system tablespace is never removed. Unreclaimed free space in a tablespace is reused when an operation needs space in that tablespace. The dynamic resizing feature can reclaim storage space only when the cluster is in an available state.

You can check how much storage space a cluster is using by monitoring the VolumeBytesUsed metric in CloudWatch. For more information on storage billing, see How Aurora data storage is billed (p. 99).

- In the AWS Management Console, you can see this figure in a chart by viewing the Monitoring tab on the details page for the cluster.
- With the AWS CLI, you can run a command similar to the following Linux example. Substitute your own values for the start and end times and the name of the cluster.

```bash
aws cloudwatch get-metric-statistics --metric-name "VolumeBytesUsed" \\
    --start-time "$(date -d '6 hours ago')" --end-time "$(date -d 'now')" --period 60 \\
    --namespace "AWS/RDS" \\
    --statistics Average Maximum Minimum \\
    --dimensions Name=DBClusterIdentifier,Value=my_cluster_identifier
```

That command produces output similar to the following.

```json
{
    "Label": "VolumeBytesUsed",
    "Datapoints": [
        {
            "Timestamp": "2020-08-04T21:25:00+00:00",
            "Average": 182871982080.0,
            "Minimum": 182871982080.0,
            "Maximum": 182871982080.0,
            "Unit": "Bytes"
        }
    ]
}
```

The following examples show how you might track storage usage for an Aurora cluster over time using AWS CLI commands on a Linux system. The --start-time and --end-time parameters define the overall time interval as one day. The --period parameter requests the measurements at one hour intervals. It doesn’t make sense to choose a --period value that’s small, because the metrics are collected at intervals, not continuously. Also, Aurora storage operations sometimes continue for some time in the background after the relevant SQL statement finishes.
The first example returns output in the default JSON format. The data points are returned in arbitrary order, not sorted by timestamp. You might import this JSON data into a charting tool to do sorting and visualization.

```
$ aws cloudwatch get-metric-statistics --metric-name "VolumeBytesUsed" \\
  --start-time "$(date -d '1 day ago')" --end-time "$(date -d 'now')" --period 3600 \\
  --namespace "AWS/RDS" --statistics Maximum --dimensions \\
  Name=DBClusterIdentifier,Value=my_cluster_id \\
  { 
    "Label": "VolumeBytesUsed", 
    "Datapoints": [ 
      { 
        "Timestamp": "2020-08-04T19:40:00+00:00", 
        "Maximum": 182872522752.0, 
        "Unit": "Bytes"
      }, 
      { 
        "Timestamp": "2020-08-05T00:40:00+00:00", 
        "Maximum": 198573719552.0, 
        "Unit": "Bytes"
      }, 
      { 
        "Timestamp": "2020-08-05T05:40:00+00:00", 
        "Maximum": 206827454464.0, 
        "Unit": "Bytes"
      }, 
      { 
        "Timestamp": "2020-08-04T17:40:00+00:00", 
        "Maximum": 182872522752.0, 
        "Unit": "Bytes"
      }
    ]
  },
  ...
```

This example returns the same data as the previous one. The --output parameter represents the data in compact plain text format. The `aws cloudwatch` command pipes its output to the `sort` command. The `-k` parameter of the `sort` command sorts the output by the third field, which is the timestamp in Universal Coordinated Time (UTC) format.

```
$ aws cloudwatch get-metric-statistics --metric-name "VolumeBytesUsed" \\
  --start-time "$(date -d '1 day ago')" --end-time "$(date -d 'now')" --period 3600 \\
  --namespace "AWS/RDS" --statistics Maximum --dimensions \\
  Name=DBClusterIdentifier,Value=my_cluster_id \\
  --output text | sort -k 3
```

```text

```
The sorted output shows how much storage was used at the start and end of the monitoring period. You can also find the points during that period when Aurora allocated more storage for the cluster. The following example uses Linux commands to reformat the starting and ending `VolumeBytesUsed` values as gigabytes (GB) and as gibibytes (GiB). Gigabytes represent units measured in powers of 10 and are commonly used in discussions of storage for rotational hard drives. Gibibytes represent units measured in powers of 2. Aurora storage measurements and limits are typically stated in the power-of-2 units, such as gibibytes and tebibytes.

```
$ GiB=$((1024*1024*1024))
$ GB=$((1000*1000*1000))
$ echo "Start: $((182872522752/$GiB)) GiB, End: $((206833664000/$GiB)) GiB"
Start: 170 GiB, End: 192 GiB
$ echo "Start: $((182872522752/$GB)) GB, End: $((206833664000/$GB)) GB"
Start: 182 GB, End: 206 GB
```

The `VolumeBytesUsed` metric tells you how much storage in the cluster is incurring charges. Thus, it's best to minimize this number when practical. However, this metric doesn't include some storage that Aurora uses internally in the cluster and doesn't charge for. If your cluster is approaching the storage limit and might run out of space, it's more helpful to monitor the `AuroraVolumeBytesLeftTotal` metric and try to maximize that number. The following example runs a similar calculation as the previous one, but for `AuroraVolumeBytesLeftTotal` instead of `VolumeBytesUsed`.

```
$ aws cloudwatch get-metric-statistics --metric-name "AuroraVolumeBytesLeftTotal" --start-time "$(date -d '1 hour ago')" --end-time "$(date -d 'now')" --period 3600 --namespace "AWS/RDS" --statistics Maximum --dimensions Name=DBClusterIdentifier,Value=my_old_cluster_id --output text | sort -k 3
AuroraVolumeBytesLeftTotal
DATAPOINTS      140530528288768.0       2023-02-23T19:25:00+00:00       Count
$ TiB=$((1024*1024*1024*1024))
$ TB=$((1000*1000*1000*1000))
$ echo "$((69797067915264 / $TB)) TB remaining for this cluster"
69 TB remaining for this cluster
$ echo "$((69797067915264 / $TiB)) TiB remaining for this cluster"
63 TiB remaining for this cluster
```

For a cluster running Aurora MySQL version 2.09 or higher, or Aurora PostgreSQL, the free size reported by `VolumeBytesUsed` increases when data is added and decreases when data is removed. The following example shows how. This report shows the maximum and minimum storage size for a cluster at 15-minute intervals as tables with temporary data are created and dropped. The report lists the maximum value before the minimum value. Thus, to understand how storage usage changed within the 15-minute interval, interpret the numbers from right to left.

```
$ aws cloudwatch get-metric-statistics --metric-name "VolumeBytesUsed" --start-time "$(date -d '4 hours ago')" --end-time "$(date -d 'now')" --period 1800 --namespace "AWS/RDS" --statistics Maximum Minimum --dimensions Name=DBClusterIdentifier,Value=my_new_cluster_id --output text | sort -k 4
VolumeBytesUsed
DATAPOINTS 14545305600.0 14545305600.0 2020-08-05T20:49:00+00:00 Bytes
DATAPOINTS 14545305600.0 14545305600.0 2020-08-05T21:19:00+00:00 Bytes
DATAPOINTS 2202217668.0 14545305600.0 2020-08-05T21:49:00+00:00 Bytes
DATAPOINTS 2202217668.0 2202217668.0 2020-08-05T22:19:00+00:00 Bytes
DATAPOINTS 2202217668.0 2202217668.0 2020-08-05T22:49:00+00:00 Bytes
```
The following example shows how with a cluster running Aurora MySQL version 2.09 or higher, or Aurora PostgreSQL, the free size reported by `AuroraVolumeBytesLeftTotal` reflects the 128-TiB size limit.

```bash
$ aws cloudwatch get-metric-statistics --region us-east-1 --metric-name "AuroraVolumeBytesLeftTotal" --start-time "$(date -d '4 hours ago')" --end-time "$(date -d 'now')" --period 1800 --namespace AWS/RDS --statistics Minimum --dimensions Name=DBClusterIdentifier,Value=pq-57 --output text | sort -k 3
AuroraVolumeBytesLeftTotal
```

```bash
$ TiB=$((1024*1024*1024*1024))
$ TB=$((1000*1000*1000*1000))
$ echo "$((140515818864640 / $TB)) TB remaining for this cluster"
140 TB remaining for this cluster
$ echo "$((140515818864640 / $TiB)) TiB remaining for this cluster"
127 TiB remaining for this cluster
```

### Instance scaling

You can scale your Aurora DB cluster as needed by modifying the DB instance class for each DB instance in the DB cluster. Aurora supports several DB instance classes optimized for Aurora, depending on database engine compatibility.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instance scaling</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Aurora MySQL</td>
<td>See <a href="#p.875">Scaling Aurora MySQL DB instances</a></td>
</tr>
<tr>
<td>Amazon Aurora PostgreSQL</td>
<td>See <a href="#p.1398">Scaling Aurora PostgreSQL DB instances</a></td>
</tr>
</tbody>
</table>

### Read scaling

You can achieve read scaling for your Aurora DB cluster by creating up to 15 Aurora Replicas in a DB cluster. Each Aurora Replica returns the same data from the cluster volume with minimal replica lag—usually considerably less than 100 milliseconds after the primary instance has written an update. As your read traffic increases, you can create additional Aurora Replicas and connect to them directly to distribute the read load for your DB cluster. Aurora Replicas don't have to be of the same DB instance class as the primary instance.

For information about adding Aurora Replicas to a DB cluster, see [Adding Aurora Replicas to a DB cluster](#p.293).

### Managing connections

The maximum number of connections allowed to an Aurora DB instance is determined by the `max_connections` parameter in the instance-level parameter group for the DB instance. The default
value of that parameter varies depends on the DB instance class used for the DB instance and database engine compatibility.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>max_connections default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Aurora MySQL</td>
<td>See Maximum connections to an Aurora MySQL DB instance (p. 875)</td>
</tr>
<tr>
<td>Amazon Aurora PostgreSQL</td>
<td>See Maximum connections to an Aurora PostgreSQL DB instance (p. 1398)</td>
</tr>
</tbody>
</table>

**Tip**
If your applications frequently open and close connections, or keep a large number of long-lived connections open, we recommend that you use Amazon RDS Proxy. RDS Proxy is a fully managed, highly available database proxy that uses connection pooling to share database connections securely and efficiently. To learn more about RDS Proxy, see Using Amazon RDS Proxy for Aurora (p. 1879).

**Managing query execution plans**
If you use query plan management for Aurora PostgreSQL, you gain control over which plans the optimizer runs. For more information, see Managing query execution plans for Aurora PostgreSQL (p. 1573).
Cloning a volume for an Amazon Aurora DB cluster

By using Aurora cloning, you can create a new cluster that initially shares the same data pages as the original, but is a separate and independent volume. The process is designed to be fast and cost-effective. The new cluster with its associated data volume is known as a clone. Creating a clone is faster and more space-efficient than physically copying the data using other techniques, such as restoring a snapshot.

Aurora supports many different types of cloning:

- You can create an Aurora provisioned clone from a provisioned Aurora DB cluster.
- You can create an Aurora Serverless v1 clone from an Aurora Serverless v1 DB cluster.
- You can also create Aurora Serverless v1 clones from Aurora provisioned DB clusters, and you can create provisioned clones from Aurora Serverless v1 DB clusters.
- Clusters with Aurora Serverless v2 instances follow the same rules as provisioned clusters.

When you create a clone using a different deployment configuration than the source, the clone is created using the latest minor version of the source's Aurora DB engine.

A cloned Aurora Serverless DB cluster has the same behavior and limitations as any Aurora Serverless v1 DB cluster. For more information, see Using Amazon Aurora Serverless v1 (p. 2023).

When you create clones from your Aurora DB clusters, the clones are created in your AWS account—the same account that owns the source Aurora DB cluster. However, you can also share provisioned Aurora DB clusters and clones with other AWS accounts. For more information, see Cross-account cloning with AWS RAM and Amazon Aurora (p. 316).

Cross-account cloning currently doesn't support cloning Aurora Serverless v1 DB clusters. For more information, see Limitations of cross-account cloning (p. 316).

Topics

- Overview of Aurora cloning (p. 303)
- Limitations of Aurora cloning (p. 304)
- How Aurora cloning works (p. 304)
- Creating an Amazon Aurora clone (p. 307)
- Cross-account cloning with AWS RAM and Amazon Aurora (p. 316)

Overview of Aurora cloning

Aurora uses a copy-on-write protocol to create a clone. This mechanism uses minimal additional space to create an initial clone. When the clone is first created, Aurora keeps a single copy of the data that is used by the source Aurora DB cluster and the new (cloned) Aurora DB cluster. Additional storage is allocated only when changes are made to data (on the Aurora storage volume) by the source Aurora DB cluster or the Aurora DB cluster clone. To learn more about the copy-on-write protocol, see How Aurora cloning works (p. 304).

Aurora cloning is especially useful for quickly setting up test environments using your production data, without risking data corruption. You can use clones for many types of applications, such as the following:

- Experiment with potential changes (schema changes and parameter group changes, for example) to assess all impacts.
- Run workload-intensive operations, such as exporting data or running analytical queries on the clone.
- Create a copy of your production DB cluster for development, testing, or other purposes.
You can create more than one clone from the same Aurora DB cluster. You can also create multiple clones from another clone.

After creating an Aurora clone, you can configure the Aurora DB instances differently from the source Aurora DB cluster. For example, you might not need a clone for development purposes to meet the same high availability requirements as the source production Aurora DB cluster. In this case, you can configure the clone with a single Aurora DB instance rather than the multiple DB instances used by the Aurora DB cluster.

When you finish using the clone for your testing, development, or other purposes, you can delete it.

Limitations of Aurora cloning

Aurora cloning currently has the following limitations:

- You can create as many clones as you want, up to the maximum number of DB clusters allowed in the AWS Region.

  You can create the clones using the copy-on-write protocol or the full-copy protocol. The full-copy protocol acts like a point-in-time recovery.

- You can't create a clone in a different AWS Region from the source Aurora DB cluster.

- You can't create an Aurora Serverless v1 clone from a nonencrypted, provisioned Aurora DB cluster.

- You can't create a clone from an Aurora DB cluster without the parallel query feature to a cluster that uses parallel query. To bring data into a cluster that uses parallel query, create a snapshot of the original cluster and restore it to the cluster that's using the parallel query feature.

- You can't create a clone from an Aurora DB cluster that has no DB instances. You can only clone Aurora DB clusters that have at least one DB instance.

- You can create a clone in a different virtual private cloud (VPC) than that of the Aurora DB cluster. If you do, the subnets of the VPCs must map to the same Availability Zones.

How Aurora cloning works

Aurora cloning works at the storage layer of an Aurora DB cluster. It uses a *copy-on-write* protocol that's both fast and space-efficient in terms of the underlying durable media supporting the Aurora storage volume. You can learn more about Aurora cluster volumes in the [Overview of Amazon Aurora storage](p. 97).

Topics

- Understanding the copy-on-write protocol (p. 304)
- Deleting a source cluster volume (p. 307)

Understanding the copy-on-write protocol

An Aurora DB cluster stores data in pages in the underlying Aurora storage volume.

For example, in the following diagram you can find an Aurora DB cluster (A) that has four data pages, 1, 2, 3, and 4. Imagine that a clone, B, is created from the Aurora DB cluster. When the clone is created, no data is copied. Rather, the clone points to the same set of pages as the source Aurora DB cluster.
When the clone is created, no additional storage is usually needed. The copy-on-write protocol uses the same segment on the physical storage media as the source segment. Additional storage is required only if the capacity of the source segment isn't sufficient for the entire clone segment. If that's the case, the source segment is copied to another physical device.

In the following diagrams, you can find an example of the copy-on-write protocol in action using the same cluster A and its clone, B, as shown preceding. Let's say that you make a change to your Aurora DB cluster (A) that results in a change to data held on page 1. Instead of writing to the original page 1, Aurora creates a new page 1[A]. The Aurora DB cluster volume for cluster (A) now points to page 1[A], 2, 3, and 4, while the clone (B) still references the original pages.
On the clone, a change is made to page 4 on the storage volume. Instead of writing to the original page 4, Aurora creates a new page, 4[B]. The clone now points to pages 1, 2, 3, and to page 4[B], while the cluster (A) continues pointing to 1[A], 2, 3, and 4.
As more changes occur over time in both the source Aurora DB cluster volume and the clone, more storage is needed to capture and store the changes.

**Deleting a source cluster volume**

When you delete a source cluster volume that has one or more clones associated with it, the clones aren't affected. The clones continue to point to the pages that were previously owned by the source cluster volume.

**Creating an Amazon Aurora clone**

You can create a clone in the same AWS account as the source Aurora DB cluster. To do so, you can use the AWS Management Console or the AWS CLI and the procedures following.

To allow another AWS account to create a clone or to share a clone with another AWS account, use the procedures in [Cross-account cloning with AWS RAM and Amazon Aurora](p. 316).

By using Aurora cloning, you can do the following types of cloning operations:

- Create a provisioned Aurora DB cluster clone from a provisioned Aurora DB cluster.
- Create an Aurora Serverless v1 cluster clone from an Aurora Serverless v1 DB cluster.
- Create an Aurora Serverless v1 DB cluster clone from a provisioned Aurora DB cluster.
- Create an Aurora provisioned DB cluster clone from an Aurora Serverless v1 DB cluster.

Aurora Serverless v1 DB clusters are always encrypted. When you clone an Aurora Serverless v1 DB cluster into a provisioned Aurora DB cluster, the provisioned Aurora DB cluster is encrypted. You can
choose the encryption key, but you can’t disable the encryption. To clone from a provisioned Aurora DB cluster to an Aurora Serverless v1 cluster, you need an encrypted provisioned Aurora DB cluster.

**Console**

The following procedure describes how to clone an Aurora DB cluster using the AWS Management Console.

Creating a clone using the AWS Management Console results in an Aurora DB cluster with one Aurora DB instance.

These instructions apply for DB clusters owned by the same AWS account that is creating the clone. If the DB cluster is owned by a different AWS account, see [Cross-account cloning with AWS RAM and Amazon Aurora](p. 316) instead.

**To create a clone of a DB cluster owned by your AWS account using the AWS Management Console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Databases.
3. Choose your Aurora DB cluster from the list, and for Actions, choose Create clone.

![Create clone page](image)

The Create clone page opens, where you can configure Settings, Connectivity, and other options for the Aurora DB cluster clone.

4. In the Settings section, do the following:
   a. For DB instance identifier, enter the name that you want to give to your cloned Aurora DB cluster.
b. For **Capacity type**, choose **Provisioned** or **Serverless** as needed for your use case.

You can choose **Serverless** only if the source Aurora DB cluster is an Aurora Serverless v1 DB cluster or is a provisioned Aurora DB cluster that is encrypted.

c. For **Cluster storage configuration**, choose either **Aurora I/O-Optimized** or **Aurora Standard**. For more information, see *Storage configurations for Amazon Aurora DB clusters (p. 97).*

d. Choose the DB instance size or DB cluster capacity:

- If you choose **Provisioned** for **Capacity type**, you see a **DB instance size** configuration card.
You can accept the provided setting, or you can use a different DB instance class for your clone.

- If you choose **Serverless** for **Capacity type**, you see a **Capacity settings** configuration card.

![Capacity settings](image)

You can accept the provided settings, or you can change them for your use case.

- For **Additional configuration**, choose settings as you usually do for your Aurora DB clusters.

Additional settings include your choice for the database name and whether you want to use many optional features. These features include backup, Enhanced Monitoring, exporting logs to Amazon CloudWatch, deletion protection, and so on.

Some of the choices displayed depend on the type of clone that you are creating. For example, Aurora Serverless doesn't support Amazon RDS Performance Insights, so that option isn't shown in this case.

Encryption is a standard option available in **Additional configuration**. Aurora Serverless DB clusters are always encrypted. You can create an Aurora Serverless clone only from an Aurora Serverless DB cluster or an encrypted provisioned Aurora DB cluster. However, you can choose a different key for the Aurora Serverless clone than that used for the encrypted provisioned cluster.

![Encryption](image)

When you create an Aurora Serverless clone from an Aurora Serverless DB cluster, you can choose a different key for the clone.
f. Finish entering all settings for your Aurora DB cluster clone. To learn more about Aurora DB cluster and instance settings, see Creating an Amazon Aurora DB cluster (p. 179).

5. Choose **Create clone** to launch the Aurora clone of your chosen Aurora DB cluster.

When the clone is created, it's listed with your other Aurora DB clusters in the console **Databases** section and displays its current state. Your clone is ready to use when its state is **Available**.

**AWS CLI**

Using the AWS CLI for cloning your Aurora DB cluster involves a couple of steps.

The `restore-db-cluster-to-point-in-time` AWS CLI command that you use results in an empty Aurora DB cluster with 0 Aurora DB instances. That is, the command restores only the Aurora DB cluster, not the DB instances for that cluster. You do that separately after the clone is available. The two steps in the process are as follows:

1. Create the clone by using the `restore-db-cluster-to-point-in-time` CLI command. The parameters that you use with this command control the capacity type and other details of the empty Aurora DB cluster (clone) being created.
2. Create the Aurora DB instance for the clone by using the `create-db-instance` CLI command to recreate the Aurora DB instance in the restored Aurora DB cluster.

The commands following assume that the AWS CLI is set up with your AWS Region as the default. This approach saves you from passing the `--region` name in each of the commands. For more information, see Configuring the AWS CLI. You can also specify the `--region` in each of the CLI commands that follow.

Topics
- Creating the clone (p. 311)
- Checking the status and getting clone details (p. 314)
- Creating the Aurora DB instance for your clone (p. 314)
- Parameters to use for cloning (p. 315)

**Creating the clone**

The specific parameters that you pass to the `restore-db-cluster-to-point-in-time` CLI command vary. What you pass depends on the engine-mode type of the source DB cluster—Serverless or Provisioned—and the type of clone that you want to create.

Use the following procedure to create an Aurora Serverless clone from an Aurora Serverless DB cluster, or to create a provisioned Aurora clone from a provisioned Aurora DB cluster.
To create a clone of the same engine mode as the source Aurora DB cluster

- Use the `restore-db-cluster-to-point-in-time` CLI command and specify values for the following parameters:
  - `--db-cluster-identifier` – Choose a meaningful name for your clone. You name the clone when you use the `restore-db-cluster-to-point-in-time` CLI command. You then pass the name of the clone in the `create-db-instance` CLI command.
  - `--restore-type` – Use copy-on-write to create a clone of the source DB cluster. Without this parameter, the `restore-db-cluster-to-point-in-time` restores the Aurora DB cluster rather than creating a clone.
  - `--source-db-cluster-identifier` – Use the name of the source Aurora DB cluster that you want to clone.
  - `--use-latest-restorable-time` – This value points to the latest restorable volume data for the clone.

The following example creates a clone named `my-clone` from a cluster named `my-source-cluster`.

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-to-point-in-time
   --source-db-cluster-identifier my-source-cluster
   --db-cluster-identifier my-clone
   --restore-type copy-on-write
   --use-latest-restorable-time
```

For Windows:

```
aws rds restore-db-cluster-to-point-in-time ^
   --source-db-cluster-identifier my-source-cluster ^
   --db-cluster-identifier my-clone ^
   --restore-type copy-on-write ^
   --use-latest-restorable-time
```

The command returns the JSON object containing details of the clone. Check to make sure that your cloned DB cluster is available before trying to create the DB instance for your clone. For more information, see [Checking the status and getting clone details (p. 314)](#).

To create a clone with a different engine mode than the source Aurora DB cluster

- Use the `restore-db-cluster-to-point-in-time` CLI command and specify values for the following parameters:
  - `--db-cluster-identifier` – Choose a meaningful name for your clone. You name the clone when you use the `restore-db-cluster-to-point-in-time` CLI command. You then pass the name of the clone in the `create-db-instance` CLI command.
  - `--engine-mode` – Use this parameter only to create clones that are of a different type than the source Aurora DB cluster. Choose the value to pass with `--engine-mode` as follows:
    - Use `provisioned` to create a provisioned Aurora DB cluster clone from an Aurora Serverless DB cluster.
    - Use `serverless` to create an Aurora Serverless DB cluster clone from a provisioned Aurora DB cluster. When you specify `serverless` engine mode, you can also choose `--scaling-configuration`.
  - `--restore-type` – Use copy-on-write to create a clone of the source DB cluster. Without this parameter, the `restore-db-cluster-to-point-in-time` restores the Aurora DB cluster rather than creating a clone.
Amazon Aurora User Guide for Aurora
Creating an Aurora clone

- **--scaling-configuration** – (Optional) Use only with **--engine-mode serverless** to configure the minimum and maximum capacity for the clone. If you don’t use this parameter, Aurora creates the clone using a minimum capacity of 1. It uses a maximum capacity that matches the capacity of the source provisioned Aurora DB cluster.
- **--source-db-cluster-identifier** – Use the name of the source Aurora DB cluster that you want to clone.
- **--use-latest-restorable-time** – This value points to the latest restorable volume data for the clone.

The following example creates an Aurora Serverless clone (**my-clone**) from a provisioned Aurora DB cluster named **my-source-cluster**. The provisioned Aurora DB cluster is encrypted.

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-to-point-in-time \\
  --source-db-cluster-identifier my-source-cluster \\
  --db-cluster-identifier my-clone \\
  --engine-mode serverless \\
  --scaling-configuration MinCapacity=8, MaxCapacity=64 \\
  --restore-type copy-on-write \\
  --use-latest-restorable-time
```

For Windows:

```
aws rds restore-db-cluster-to-point-in-time ^
  --source-db-cluster-identifier my-source-cluster ^
  --db-cluster-identifier my-clone ^
  --engine-mode serverless ^
  --scaling-configuration MinCapacity=8, MaxCapacity=64 ^
  --restore-type copy-on-write ^
  --use-latest-restorable-time
```

These commands return the JSON object containing details of the clone that you need to create the DB instance. You can’t do that until the status of the clone (the empty Aurora DB cluster) has the status **Available**.

**Note**
The **restore-db-cluster-to-point-in-time** AWS CLI command only restores the DB cluster, not the DB instances for that DB cluster. You must invoke the **create-db-instance** command to create DB instances for the restored DB cluster, specifying the identifier of the restored DB cluster in **--db-cluster-identifier**. You can create DB instances only after the **restore-db-cluster-to-point-in-time** command has completed and the DB cluster is available.

For example, suppose you have a cluster named **tpch100g** that you want to clone. The following Linux example creates a cloned cluster named **tpch100g-clone** and a primary instance named **tpch100g-clone-instance** for the new cluster. You don’t need to supply some parameters, such as **--master-username** **reinvent** and **--master-user-password**. Aurora automatically determines those from the original cluster. You do need to specify the DB engine to use. Thus, the example tests the new cluster to determine the right value to use for the **--engine** parameter.

```
$ aws rds restore-db-cluster-to-point-in-time \\
  --source-db-cluster-identifier tpch100g \\
  --db-cluster-identifier tpch100g-clone \\
  --restore-type copy-on-write \\
  --use-latest-restorable-time
```

```
$ aws rds describe-db-clusters \\
  --db-cluster-identifier tpch100g-clone
```
Creating an Aurora clone

---query '[].[Engine]' 
--output text
aurora

$ aws rds create-db-instance 
--db-instance-identifier tpch100g-clone-instance 
--db-cluster-identifier tpch100g-clone 
--db-instance-class db.r5.4xlarge 
--engine aurora

Checking the status and getting clone details

You can use the following command to check the status of your newly created empty DB cluster.

$ aws rds describe-db-clusters --db-cluster-identifier my-clone --query '[].[Status]' --output text

Or you can obtain the status and the other values that you need to create the DB instance for your clone (p. 314) by using the following AWS CLI query.

For Linux, macOS, or Unix:

aws rds describe-db-clusters --db-cluster-identifier my-clone 
--query '[].

For Windows:

aws rds describe-db-clusters --db-cluster-identifier my-clone 
--query "[].

This query returns output similar to the following.

[
  {
    "Status": "available",
    "Engine": "aurora-mysql",
    "EngineVersion": "5.7.mysql_aurora.2.09.1",
    "EngineMode": "provisioned"
  }
]

Creating the Aurora DB instance for your clone

Use the create-db-instance CLI command to create the DB instance for your clone.

The --db-instance-class parameter is used for provisioned Aurora DB clusters only.

For Linux, macOS, or Unix:

aws rds create-db-instance 
--db-instance-identifier my-new-db 
--db-cluster-identifier my-clone 
--db-instance-class db.r5.4xlarge 
--engine aurora-mysql

For Windows:

aws rds create-db-instance
For an Aurora Serverless clone created from an Aurora Serverless DB cluster, you specify only a few parameters. The DB instance inherits the --engine-mode, --master-username, and --master-user-password properties from the source DB cluster. You can change the --scaling-configuration.

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance \
  --db-instance-identifier my-new-db \
  --db-cluster-identifier my-clone \
  --engine aurora-postgresql
```

For Windows:

```bash
aws rds create-db-instance ^
  --db-instance-identifier my-new-db ^
  --db-cluster-identifier my-clone ^
  --engine aurora-postgresql
```

### Parameters to use for cloning

The following table summarizes the various parameters used with `restore-db-cluster-to-point-in-time` to clone Aurora DB clusters.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--source-db-cluster-identifier</td>
<td>Use the name of the source Aurora DB cluster that you want to clone.</td>
</tr>
<tr>
<td>--db-cluster-identifier</td>
<td>Choose a meaningful name for your clone. You name your clone with the <code>restore-db-cluster-to-point-in-time</code> command. Then you pass this name to the <code>create-db-instance</code> command.</td>
</tr>
<tr>
<td>--engine-mode</td>
<td>Use this parameter to create clones that are of a different type than the source Aurora DB cluster. Choose the value to pass with <code>--engine-mode</code> as follows:</td>
</tr>
<tr>
<td></td>
<td>• Use <code>provisioned</code> to create a provisioned Aurora DB cluster clone from an Aurora Serverless DB cluster.</td>
</tr>
<tr>
<td></td>
<td>• Use <code>serverless</code> to create an Aurora Serverless DB cluster clone from a provisioned Aurora DB cluster. When you specify serverless engine mode, you can also choose <code>--scaling-configuration</code></td>
</tr>
<tr>
<td>--restore-type</td>
<td>Specify copy-on-write as the <code>--restore-type</code> to create a clone of the source DB cluster rather than restoring the source Aurora DB cluster.</td>
</tr>
<tr>
<td>--scaling-configuration</td>
<td>Use this parameter with <code>--engine-mode serverless</code> to configure the minimum and maximum capacity for the clone. If you don't use this parameter, Aurora creates the Aurora Serverless clone using a minimum capacity of 1 and a maximum capacity of 16.</td>
</tr>
<tr>
<td>--use-latest-restorable-time</td>
<td>This value points to the latest restorable volume data for the clone.</td>
</tr>
</tbody>
</table>
Cross-account cloning with AWS RAM and Amazon Aurora

By using AWS Resource Access Manager (AWS RAM) with Amazon Aurora, you can share Aurora DB clusters and clones that belong to your AWS account with another AWS account or organization. Such cross-account cloning is much faster than creating and restoring a database snapshot. You can create a clone of one of your Aurora DB clusters and share the clone. Or you can share your Aurora DB cluster with another AWS account and let the account holder create the clone. The approach that you choose depends on your use case.

For example, you might need to regularly share a clone of your financial database with your organization’s internal auditing team. In this case, your auditing team has its own AWS account for the applications that it uses. You can give the auditing team’s AWS account the permission to access your Aurora DB cluster and clone it as needed.

On the other hand, if an outside vendor audits your financial data you might prefer to create the clone yourself. You then give the outside vendor access to the clone only.

You can also use cross-account cloning to support many of the same use cases for cloning within the same AWS account, such as development and testing. For example, your organization might use different AWS accounts for production, development, testing, and so on. For more information, see Overview of Aurora cloning (p. 303).

Thus, you might want to share a clone with another AWS account or allow another AWS account to create clones of your Aurora DB clusters. In either case, start by using AWS RAM to create a share object. For complete information about sharing AWS resources between AWS accounts, see the AWS RAM User Guide.

Creating a cross-account clone requires actions from the AWS account that owns the original cluster, and the AWS account that creates the clone. First, the original cluster owner modifies the cluster to allow one or more other accounts to clone it. If any of the accounts is in a different AWS organization, AWS generates a sharing invitation. The other account must accept the invitation before proceeding. Then each authorized account can clone the cluster. Throughout this process, the cluster is identified by its unique Amazon Resource Name (ARN).

As with cloning within the same AWS account, additional storage space is used only if changes are made to the data by the source or the clone. Charges for storage are then applied at that time. If the source cluster is deleted, storage costs are distributed equally among remaining cloned clusters.

Topics

- Limitations of cross-account cloning (p. 316)
- Allowing other AWS accounts to clone your cluster (p. 317)
- Cloning a cluster that is owned by another AWS account (p. 319)

Limitations of cross-account cloning

Aurora cross-account cloning has the following limitations:

- You can’t clone an Aurora Serverless v1 cluster across AWS accounts.
- You can’t view or accept invitations to shared resources with the AWS Management Console. Use the AWS CLI, the Amazon RDS API, or the AWS RAM console to view and accept invitations to shared resources.
- You can create only one new clone from a clone that’s been shared with your AWS account.
• You can't share resources (clones or Aurora DB clusters) that have been shared with your AWS account.
• You can create a maximum of 15 cross-account clones from any single Aurora DB cluster.
• Each of the 15 cross-account clones must be owned by a different AWS account. That is, you can only create one cross-account clone of a cluster within any AWS account.
• After you clone a cluster, the original cluster and its clone are considered to be the same for purposes of enforcing limits on cross-account clones. You can't create cross-account clones of both the original cluster and the cloned cluster within the same AWS account. The total number of cross-account clones for the original cluster and any of its clones can't exceed 15.
• You can't share an Aurora DB cluster with other AWS accounts unless the cluster is in an ACTIVE state.
• You can't rename an Aurora DB cluster that's been shared with other AWS accounts.
• You can't create a cross-account clone of a cluster that is encrypted with the default RDS key.
• You can't create nonencrypted clones in one AWS account from encrypted Aurora DB clusters that have been shared by another AWS account. The cluster owner must grant permission to access the source cluster's AWS KMS key. However, you can use a different key when you create the clone.

Allowing other AWS accounts to clone your cluster

To allow other AWS accounts to clone a cluster that you own, use AWS RAM to set the sharing permission. Doing so also sends an invitation to each of the other accounts that's in a different AWS organization.

For the procedures to share resources owned by you in the AWS RAM console, see Sharing resources owned by you in the AWS RAM User Guide.

Topics
• Granting permission to other AWS accounts to clone your cluster (p. 317)
• Checking if a cluster that you own is shared with other AWS accounts (p. 319)

Granting permission to other AWS accounts to clone your cluster

If the cluster that you're sharing is encrypted, you also share the AWS KMS key for the cluster. You can allow AWS Identity and Access Management (IAM) users or roles in one AWS account to use a KMS key in a different account.

To do this, you first add the external account (root user) to the KMS key's key policy through AWS KMS. You don't add the individual users or roles to the key policy, only the external account that owns them. You can only share a KMS key that you create, not the default RDS service key. For information about access control for KMS keys, see Authentication and access control for AWS KMS.

Console

To grant permission to clone your cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB cluster that you want to share to see its Details page, and choose the Connectivity & security tab.
4. In the Share DB cluster with other AWS accounts section, enter the numeric account ID for the AWS account that you want to allow to clone this cluster. For account IDs in the same organization, you can begin typing in the box and then choose from the menu.
Important
In some cases, you might want an account that is not in the same AWS organization as your account to clone a cluster. In these cases, for security reasons the console doesn't report who owns that account ID or whether the account exists. Be careful entering account numbers that are not in the same AWS organization as your AWS account. Immediately verify that you shared with the intended account.

5. On the confirmation page, verify that the account ID that you specified is correct. Enter share in the confirmation box to confirm.

On the Details page, an entry appears that shows the specified AWS account ID under Accounts that this DB cluster is shared with. The Status column initially shows a status of Pending.

6. Contact the owner of the other AWS account, or sign in to that account if you own both of them. Instruct the owner of the other account to accept the sharing invitation and clone the DB cluster, as described following.

AWS CLI

To grant permission to clone your cluster

1. Gather the information for the required parameters. You need the ARN for your cluster and the numeric ID for the other AWS account.

2. Run the AWS RAM CLI command create-resource-share.

For Linux, macOS, or Unix:

```
aws ram create-resource-share --name descriptive_name \   
--region region \   
--resource-arns cluster_arn \   
--principals other_account_ids
```

For Windows:

```
aws ram create-resource-share --name descriptive_name ^ 
--region region ^ 
--resource-arns cluster_arn ^ 
--principals other_account_ids
```

To include multiple account IDs for the --principals parameter, separate IDs from each other with spaces. To specify whether the permitted account IDs can be outside your AWS organization, include the --allow-external-principals or --no-allow-external-principals parameter for create-resource-share.

AWS RAM API

To grant permission to clone your cluster

1. Gather the information for the required parameters. You need the ARN for your cluster and the numeric ID for the other AWS account.

2. Call the AWS RAM API operation CreateResourceShare, and specify the following values:

   • Specify the account ID for one or more AWS accounts as the principals parameter.
   • Specify the ARN for one or more Aurora DB clusters as the resourceArns parameter.
   • Specify whether the permitted account IDs can be outside your AWS organization by including a Boolean value for the allowExternalPrincipals parameter.
Recreating a cluster that uses the default RDS key

If the encrypted cluster that you plan to share uses the default RDS key, make sure to recreate the cluster. To do this, create a manual snapshot of your DB cluster, use an AWS KMS key, and then restore the cluster to a new cluster. Then share the new cluster. To perform this process, take the following steps.

To recreate an encrypted cluster that uses the default RDS key

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Snapshots from the navigation pane.
3. Choose your snapshot.
4. For Actions, choose Copy Snapshot, and then choose Enable encryption.
5. For AWS KMS key, choose the new encryption key that you want to use.
6. Restore the copied snapshot. To do so, follow the procedure in Restoring from a DB cluster snapshot (p. 439). The new DB instance uses your new encryption key.
7. (Optional) Delete the old DB cluster if you no longer need it. To do so, follow the procedure in Deleting a DB cluster snapshot (p. 499). Before you do, confirm that your new cluster has all necessary data and that your application can access it successfully.

Checking if a cluster that you own is shared with other AWS accounts

You can check if other users have permission to share a cluster. Doing so can help you understand whether the cluster is approaching the limit for the maximum number of cross-account clones.

For the procedures to share resources using the AWS RAM console, see Sharing resources owned by you in the AWS RAM User Guide.

AWS CLI

To find out if a cluster that you own is shared with other AWS accounts

- Call the AWS RAM CLI command list-principals, using your account ID as the resource owner and the ARN of your cluster as the resource ARN. You can see all shares with the following command. The results indicate which AWS accounts are allowed to clone the cluster.

```
aws ram list-principals \
   --resource-arns your_cluster_arn \
   --principals your aws id
```

AWS RAM API

To find out if a cluster that you own is shared with other AWS accounts

- Call the AWS RAM API operation ListPrincipals. Use your account ID as the resource owner and the ARN of your cluster as the resource ARN.

Cloning a cluster that is owned by another AWS account

To clone a cluster that's owned by another AWS account, use AWS RAM to get permission to make the clone. After you have the required permission, use the standard procedure for cloning an Aurora cluster.

You can also check whether a cluster that you own is a clone of a cluster owned by a different AWS account.
For the procedures to work with resources owned by others in the AWS RAM console, see Accessing resources shared with you in the AWS RAM User Guide.

Topics
- Viewing invitations to clone clusters that are owned by other AWS accounts (p. 320)
- Accepting invitations to share clusters owned by other AWS accounts (p. 320)
- Cloning an Aurora cluster that is owned by another AWS account (p. 321)
- Checking if a DB cluster is a cross-account clone (p. 324)

Viewing invitations to clone clusters that are owned by other AWS accounts

To work with invitations to clone clusters owned by AWS accounts in other AWS organizations, use the AWS CLI, the AWS RAM console, or the AWS RAM API. Currently, you can't perform this procedure using the Amazon RDS console.

For the procedures to work with invitations in the AWS RAM console, see Accessing resources shared with you in the AWS RAM User Guide.

AWS CLI

To see invitations to clone clusters that are owned by other AWS accounts

1. Run the AWS RAM CLI command get-resource-share-invitations.

   ```bash
   aws ram get-resource-share-invitations --region region_name
   ```

   The results from the preceding command show all invitations to clone clusters, including any that you already accepted or rejected.

2. (Optional) Filter the list so you see only the invitations that require action from you. To do so, add the parameter --query 'resourceShareInvitations[?status==`PENDING`]'.

AWS RAM API

To see invitations to clone clusters that are owned by other AWS accounts

1. Call the AWS RAM API operation GetResourceShareInvitations. This operation returns all such invitations, including any that you already accepted or rejected.

2. (Optional) Find only the invitations that require action from you by checking the resourceShareAssociations return field for a status value of PENDING.

Accepting invitations to share clusters owned by other AWS accounts

You can accept invitations to share clusters owned by other AWS accounts that are in different AWS organizations. To work with these invitations, use the AWS CLI, the AWS RAM and RDS APIs, or the AWS RAM console. Currently, you can't perform this procedure using the RDS console.

For the procedures to work with invitations in the AWS RAM console, see Accessing resources shared with you in the AWS RAM User Guide.

AWS CLI

To accept an invitation to share a cluster from another AWS account

1. Find the invitation ARN by running the AWS RAM CLI command get-resource-share-invitations, as shown preceding.
2. Accept the invitation by calling the AWS RAM CLI command `accept-resource-share-invitation`, as shown following.

For Linux, macOS, or Unix:

```shell
aws ram accept-resource-share-invitation
   --resource-share-invitation-arn invitation_arn
   --region region
```

For Windows:

```shell
aws ram accept-resource-share-invitation
   --resource-share-invitation-arn invitation_arn
   --region region
```

### AWS RAM and RDS API

**To accept invitations to share somebody's cluster**

1. Find the invitation ARN by calling the AWS RAM API operation `GetResourceShareInvitations`, as shown preceding.
2. Pass that ARN as the `resourceShareInvitationArn` parameter to the RDS API operation `AcceptResourceShareInvitation`.

### Cloning an Aurora cluster that is owned by another AWS account

After you accept the invitation from the AWS account that owns the DB cluster, as shown preceding, you can clone the cluster.

**Console**

**To clone an Aurora cluster that is owned by another AWS account**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
   
   At the top of the database list, you should see one or more items with a **Role** value of **Shared from account** `#account_id`. For security reasons, you can only see limited information about the original clusters. The properties that you can see are the ones such as database engine and version that must be the same in your cloned cluster.
3. Choose the cluster that you intend to clone.
4. For **Actions**, choose **Create clone**.
5. Follow the procedure in **Console (p. 308)** to finish setting up the cloned cluster.
6. As needed, enable encryption for the cloned cluster. If the cluster that you are cloning is encrypted, you must enable encryption for the cloned cluster. The AWS account that shared the cluster with you must also share the KMS key that was used to encrypt the cluster. You can use the same KMS key to encrypt the clone, or your own KMS key. You can't create a cross-account clone for a cluster that is encrypted with the default KMS key.

The account that owns the encryption key must grant permission to use the key to the destination account by using a key policy. This process is similar to how encrypted snapshots are shared, by using a key policy that grants permission to the destination account to use the key.
AWS CLI

To clone an Aurora cluster owned by another AWS account

1. Accept the invitation from the AWS account that owns the DB cluster, as shown preceding.
2. Clone the cluster by specifying the full ARN of the source cluster in the `source-db-cluster-identifier` parameter of the RDS CLI command `restore-db-cluster-to-point-in-time`, as shown following.

If the ARN passed as the `source-db-cluster-identifier` hasn't been shared, the same error is returned as if the specified cluster doesn't exist.

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-to-point-in-time \
  --source-db-cluster-identifier=arn:aws:rds:arn_details \
  --db-cluster-identifier=new_cluster_id \
  --restore-type=copy-on-write \
  --use-latest-restorable-time
```

For Windows:

```
aws rds restore-db-cluster-to-point-in-time ^
  --source-db-cluster-identifier=arn:aws:rds:arn_details ^
  --db-cluster-identifier=new_cluster_id ^
  --restore-type=copy-on-write ^
  --use-latest-restorable-time
```

3. If the cluster that you are cloning is encrypted, encrypt your cloned cluster by including a `kms-key-id` parameter. This `kms-key-id` value can be the same one used to encrypt the original DB cluster, or your own KMS key. Your account must have permission to use that encryption key.

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-to-point-in-time \
  --source-db-cluster-identifier=arn:aws:rds:arn_details \
  --db-cluster-identifier=new_cluster_id \
  --restore-type=copy-on-write \
  --use-latest-restorable-time \
  --kms-key-id=arn:aws:kms:arn_details
```

For Windows:

```
aws rds restore-db-cluster-to-point-in-time ^
  --source-db-cluster-identifier=arn:aws:rds:arn_details ^
  --db-cluster-identifier=new_cluster_id ^
  --restore-type=copy-on-write ^
  --use-latest-restorable-time ^
  --kms-key-id=arn:aws:kms:arn_details
```

The account that owns the encryption key must grant permission to use the key to the destination account by using a key policy. This process is similar to how encrypted snapshots are shared, by using a key policy that grants permission to the destination account to use the key. An example of a key policy follows.

```
{
  "Id": "key-policy-1",
  "Version": "2012-10-17",
```
"Statement": [
  {
    "Sid": "Allow use of the key",
    "Effect": "Allow",
    "Principal": {"AWS": [
      "arn:aws:iam::account_id:user/KeyUser",
      "arn:aws:iam::account_id:root"
    ]},
    "Action": [
      "kms:CreateGrant",
      "kms:Encrypt",
      "kms:Decrypt",
      "kms:ReEncrypt*",
      "kms:GenerateDataKey*",
      "kms:DescribeKey"
    ],
    "Resource": "*"
  },
  {
    "Sid": "Allow attachment of persistent resources",
    "Effect": "Allow",
    "Principal": {"AWS": [
      "arn:aws:iam::account_id:user/KeyUser",
      "arn:aws:iam::account_id:root"
    ]},
    "Action": [
      "kms:CreateGrant",
      "kms:ListGrants",
      "kms:RevokeGrant"
    ],
    "Resource": "*",
    "Condition": {"Bool": {"kms:GrantIsForAWSResource": true}}
  }
]

Note
The `restore-db-cluster-to-point-in-time` AWS CLI command restores only the DB cluster, not the DB instances for that DB cluster. To create DB instances for the restored DB cluster, invoke the `create-db-instance` command. Specify the identifier of the restored DB cluster in `--db-cluster-identifier`. You can create DB instances only after the `restore-db-cluster-to-point-in-time` command has completed and the DB cluster is available.

RDS API

To clone an Aurora cluster owned by another AWS account

1. Accept the invitation from the AWS account that owns the DB cluster, as shown preceding.
2. Clone the cluster by specifying the full ARN of the source cluster in the `SourceDBClusterIdentifier` parameter of the RDS API operation `RestoreDBClusterToPointInTime`.
3. If the ARN passed as the `SourceDBClusterIdentifier` hasn't been shared, then the same error is returned as if the specified cluster doesn't exist.
4. If the cluster that you are cloning is encrypted, include a `KmsKeyId` parameter to encrypt your cloned cluster. This `kms-key-id` value can be the same one used to encrypt the original DB cluster, or your own KMS key. Your account must have permission to use that encryption key.
When you clone a volume, the destination account must have permission to use the encryption key used to encrypt the source cluster. Aurora encrypts the new cloned cluster with the encryption key specified in `KmsKeyId`.

The account that owns the encryption key must grant permission to use the key to the destination account by using a key policy. This process is similar to how encrypted snapshots are shared, by using a key policy that grants permission to the destination account to use the key. An example of a key policy follows.

```json
{
    "Id": "key-policy-1",
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Allow use of the key",
            "Effect": "Allow",
            "Principal": {"AWS": [
                "arn:aws:iam::account_id:user/KeyUser",
                "arn:aws:iam::account_id:root"
            ]},
            "Action": [
                "kms:CreateGrant",
                "kms:Encrypt",
                "kms:Decrypt",
                "kms:ReEncrypt*",
                "kms:GenerateDataKey*",
                "kms:DescribeKey"
            ],
            "Resource": "*"
        },
        {
            "Sid": "Allow attachment of persistent resources",
            "Effect": "Allow",
            "Principal": {"AWS": [
                "arn:aws:iam::account_id:user/KeyUser",
                "arn:aws:iam::account_id:root"
            ]},
            "Action": [
                "kms:CreateGrant",
                "kms:ListGrants",
                "kms:RevokeGrant"
            ],
            "Resource": "*",
            "Condition": {"Bool": {"kms:GrantIsForAWSResource": true}}
        }
    ]
}
```

**Note**
The `RestoreDBClusterToPointInTime` RDS API operation restores only the DB cluster, not the DB instances for that DB cluster. To create DB instances for the restored DB cluster, invoke the `CreateDBInstance` RDS API operation. Specify the identifier of the restored DB cluster in `DBClusterIdentifier`. You can create DB instances only after the `RestoreDBClusterToPointInTime` operation has completed and the DB cluster is available.

**Checking if a DB cluster is a cross-account clone**

The `DBClusters` object identifies whether each cluster is a cross-account clone. You can see the clusters that you have permission to clone by using the `include-shared` option when you run the RDS CLI.
command `describe-db-clusters`. However, you can't see most of the configuration details for such clusters.

**AWS CLI**

To check if a DB cluster is a cross-account clone

- Call the RDS CLI command `describe-db-clusters`.

The following example shows how actual or potential cross-account clone DB clusters appear in `describe-db-clusters` output. For existing clusters owned by your AWS account, the `CrossAccountClone` field indicates whether the cluster is a clone of a DB cluster that is owned by another AWS account.

In some cases, an entry might have a different AWS account number than yours in the `DBClusterArn` field. In this case, that entry represents a cluster that is owned by a different AWS account and that you can clone. Such entries have few fields other than `DBClusterArn`. When creating the cloned cluster, specify the same `StorageEncrypted`, `Engine`, and `EngineVersion` values as in the original cluster.

```bash
$aws rds describe-db-clusters --include-shared --region us-east-1
{
    "DBClusters": [
        {
            "EarliestRestorableTime": "2023-02-01T21:17:54.106Z",
            "Engine": "aurora-mysql",
            "EngineVersion": "8.0.mysql_aurora.3.02.0",
            "CrossAccountClone": false,
            ...
        },
        {
            "EarliestRestorableTime": "2023-02-09T16:01:07.398Z",
            "Engine": "aurora-mysql",
            "EngineVersion": "8.0.mysql_aurora.3.02.0",
            "CrossAccountClone": true,
            ...
        },
        {
            "StorageEncrypted": false,
            "Engine": "aurora-mysql",
            "EngineVersion": "8.0.mysql_aurora.3.02.0"
        }
    ]
}
```

**RDS API**

To check if a DB cluster is a cross-account clone

- Call the RDS API operation `DescribeDBClusters`.

For existing clusters owned by your AWS account, the `CrossAccountClone` field indicates whether the cluster is a clone of a DB cluster owned by another AWS account. Entries with a different AWS account number in the `DBClusterArn` field represent clusters that you can clone and that are owned by other AWS accounts. These entries have few fields other than `DBClusterArn`. When creating the cloned cluster, specify the same `StorageEncrypted`, `Engine`, and `EngineVersion` values as in the original cluster.

The following example shows a return value that demonstrates both actual and potential cloned clusters.
Integrating Aurora with other AWS services

Integrate Amazon Aurora with other AWS services so that you can extend your Aurora DB cluster to use additional capabilities in the AWS Cloud.

Topics

- Integrating AWS services with Amazon Aurora MySQL (p. 327)
- Integrating AWS services with Amazon Aurora PostgreSQL (p. 327)
- Using Amazon Aurora Auto Scaling with Aurora Replicas (p. 328)
- Using machine learning capabilities with Amazon Aurora (p. 343)

Integrating AWS services with Amazon Aurora MySQL

Amazon Aurora MySQL integrates with other AWS services so that you can extend your Aurora MySQL DB cluster to use additional capabilities in the AWS Cloud. Your Aurora MySQL DB cluster can use AWS services to do the following:

- Synchronously or asynchronously invoke an AWS Lambda function using the native functions `lambda_sync` or `lambda_async`. Or, asynchronously invoke an AWS Lambda function using the `mysql.lambda_async` procedure.
- Load data from text or XML files stored in an Amazon S3 bucket into your DB cluster using the `LOAD DATA FROM S3` or `LOAD XML FROM S3` command.
- Save data to text files stored in an Amazon S3 bucket from your DB cluster using the `SELECT INTO OUTFILE S3` command.
- Automatically add or remove Aurora Replicas with Application Auto Scaling. For more information, see Using Amazon Aurora Auto Scaling with Aurora Replicas (p. 328).

For more information about integrating Aurora MySQL with other AWS services, see Integrating Amazon Aurora MySQL with other AWS services (p. 1047).

Integrating AWS services with Amazon Aurora PostgreSQL

Amazon Aurora PostgreSQL integrates with other AWS services so that you can extend your Aurora PostgreSQL DB cluster to use additional capabilities in the AWS Cloud. Your Aurora PostgreSQL DB cluster can use AWS services to do the following:

- Quickly collect, view, and assess performance on your relational database workloads with Performance Insights.
- Automatically add or remove Aurora Replicas with Aurora Auto Scaling. For more information, see Using Amazon Aurora Auto Scaling with Aurora Replicas (p. 328).

For more information about integrating Aurora PostgreSQL with other AWS services, see Integrating Amazon Aurora PostgreSQL with other AWS services (p. 1513).
Using Amazon Aurora Auto Scaling with Aurora Replicas

To meet your connectivity and workload requirements, Aurora Auto Scaling dynamically adjusts the number of Aurora Replicas (reader DB instances) provisioned for an Aurora DB cluster. Aurora Auto Scaling is available for both Aurora MySQL and Aurora PostgreSQL. Aurora Auto Scaling enables your Aurora DB cluster to handle sudden increases in connectivity or workload. When the connectivity or workload decreases, Aurora Auto Scaling removes unnecessary Aurora Replicas so that you don’t pay for unused provisioned DB instances.

You define and apply a scaling policy to an Aurora DB cluster. The scaling policy defines the minimum and maximum number of Aurora Replicas that Aurora Auto Scaling can manage. Based on the policy, Aurora Auto Scaling adjusts the number of Aurora Replicas up or down in response to actual workloads, determined by using Amazon CloudWatch metrics and target values.

You can use the AWS Management Console to apply a scaling policy based on a predefined metric. Alternatively, you can use either the AWS CLI or Aurora Auto Scaling API to apply a scaling policy based on a predefined or custom metric.

Topics
- Before you begin (p. 328)
- Aurora Auto Scaling policies (p. 329)
- Adding a scaling policy to an Aurora DB cluster (p. 330)
- Editing a scaling policy (p. 339)
- Deleting a scaling policy (p. 341)
- DB instance IDs and tagging (p. 342)
- Aurora Auto Scaling and Performance Insights (p. 343)

Before you begin

Before you can use Aurora Auto Scaling with an Aurora DB cluster, you must first create an Aurora DB cluster with a primary (writer) DB instance. For more information about creating an Aurora DB cluster, see Creating an Amazon Aurora DB cluster (p. 179).

Aurora Auto Scaling only scales a DB cluster if the DB cluster is in the available state.

When Aurora Auto Scaling adds a new Aurora Replica, the new Aurora Replica is the same DB instance class as the one used by the primary instance. For more information about DB instance classes, see Aurora DB instance classes (p. 84). Also, the promotion tier for new Aurora Replicas is set to the last priority, which is 15 by default. This means that during a failover, a replica with a better priority, such as one created manually, would be promoted first. For more information, see Fault tolerance for an Aurora DB cluster (p. 103).

Aurora Auto Scaling only removes Aurora Replicas that it created.

To benefit from Aurora Auto Scaling, your applications must support connections to new Aurora Replicas. To do so, we recommend using the Aurora reader endpoint. For Aurora MySQL you can use a driver such as the AWS JDBC Driver for MySQL. For more information, see Connecting to an Amazon Aurora DB cluster (p. 204).

Note
- Aurora global databases currently don’t support Aurora Auto Scaling for secondary DB clusters.
Aurora Auto Scaling policies

Aurora Auto Scaling uses a scaling policy to adjust the number of Aurora Replicas in an Aurora DB cluster. Aurora Auto Scaling has the following components:

- A service-linked role
- A target metric
- Minimum and maximum capacity
- A cooldown period

Topics

- Service linked role (p. 329)
- Target metric (p. 329)
- Minimum and maximum capacity (p. 329)
- Cooldown period (p. 329)
- Enable or disable scale-in activities (p. 330)

Service linked role

Aurora Auto Scaling uses the AWSServiceRoleForApplicationAutoScaling_RDSCluster service-linked role. For more information, see Service-linked roles for Application Auto Scaling in the Application Auto Scaling User Guide.

Target metric

In this type of policy, a predefined or custom metric and a target value for the metric is specified in a target-tracking scaling policy configuration. Aurora Auto Scaling creates and manages CloudWatch alarms that trigger the scaling policy and calculates the scaling adjustment based on the metric and target value. The scaling policy adds or removes Aurora Replicas as required to keep the metric at, or close to, the specified target value. In addition to keeping the metric close to the target value, a target-tracking scaling policy also adjusts to fluctuations in the metric due to a changing workload. Such a policy also minimizes rapid fluctuations in the number of available Aurora Replicas for your DB cluster.

For example, take a scaling policy that uses the predefined average CPU utilization metric. Such a policy can keep CPU utilization at, or close to, a specified percentage of utilization, such as 40 percent.

Note

For each Aurora DB cluster, you can create only one Auto Scaling policy for each target metric.

Minimum and maximum capacity

You can specify the maximum number of Aurora Replicas to be managed by Application Auto Scaling. This value must be set to 0–15, and must be equal to or greater than the value specified for the minimum number of Aurora Replicas.

You can also specify the minimum number of Aurora Replicas to be managed by Application Auto Scaling. This value must be set to 0–15, and must be equal to or less than the value specified for the maximum number of Aurora Replicas.

Note

The minimum and maximum capacity are set for an Aurora DB cluster. The specified values apply to all of the policies associated with that Aurora DB cluster.

Cooldown period

You can tune the responsiveness of a target-tracking scaling policy by adding cooldown periods that affect scaling your Aurora DB cluster in and out. A cooldown period blocks subsequent scale-in or scale-
out requests until the period expires. These blocks slow the deletions of Aurora Replicas in your Aurora DB cluster for scale-in requests, and the creation of Aurora Replicas for scale-out requests.

You can specify the following cooldown periods:

- A scale-in activity reduces the number of Aurora Replicas in your Aurora DB cluster. A scale-in cooldown period specifies the amount of time, in seconds, after a scale-in activity completes before another scale-in activity can start.

- A scale-out activity increases the number of Aurora Replicas in your Aurora DB cluster. A scale-out cooldown period specifies the amount of time, in seconds, after a scale-out activity completes before another scale-out activity can start.

  **Note**  
  A scale-out cooldown period is ignored if a subsequent scale-out request is for a larger number of Aurora Replicas than the first request.

If you don’t set the scale-in or scale-out cooldown period, the default for each is 300 seconds.

### Enable or disable scale-in activities

You can enable or disable scale-in activities for a policy. Enabling scale-in activities allows the scaling policy to delete Aurora Replicas. When scale-in activities are enabled, the scale-in cooldown period in the scaling policy applies to scale-in activities. Disabling scale-in activities prevents the scaling policy from deleting Aurora Replicas.

  **Note**  
  Scale-out activities are always enabled so that the scaling policy can create Aurora Replicas as needed.

### Adding a scaling policy to an Aurora DB cluster

You can add a scaling policy using the AWS Management Console, the AWS CLI, or the Application Auto Scaling API.

  **Note**  
  For an example that adds a scaling policy using AWS CloudFormation, see [Declaring a scaling policy for an Aurora DB cluster](#) in the [AWS CloudFormation User Guide](#).

#### Console

You can add a scaling policy to an Aurora DB cluster by using the AWS Management Console.

**To add an auto scaling policy to an Aurora DB cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the Aurora DB cluster that you want to add a policy for.
4. Choose the **Logs & events** tab.
5. In the **Auto scaling policies** section, choose **Add**.

   The **Add Auto Scaling policy** dialog box appears.
6. For **Policy Name**, type the policy name.
7. For the target metric, choose one of the following:

   - **Average CPU utilization of Aurora Replicas** to create a policy based on the average CPU utilization.
8. For the target value, type one of the following:
   
   - **Average connections of Aurora Replicas** to create a policy based on the average number of connections to Aurora Replicas.
   
   9. (Optional) Expand **Additional Configuration** to create a scale-in or scale-out cooldown period.

10. For **Minimum capacity**, type the minimum number of Aurora Replicas that the Aurora Auto Scaling policy is required to maintain.

11. For **Maximum capacity**, type the maximum number of Aurora Replicas the Aurora Auto Scaling policy is required to maintain.

12. Choose **Add policy**.

The following dialog box creates an Auto Scaling policy based an average CPU utilization of 40 percent. The policy specifies a minimum of 5 Aurora Replicas and a maximum of 15 Aurora Replicas.
The following dialog box creates an auto scaling policy based an average number of connections of 100. The policy specifies a minimum of two Aurora Replicas and a maximum of eight Aurora Replicas.
You can apply a scaling policy based on either a predefined or custom metric. To do so, you can use the AWS CLI or the Application Auto Scaling API. The first step is to register your Aurora DB cluster with Application Auto Scaling.

Registering an Aurora DB cluster

Before you can use Aurora Auto Scaling with an Aurora DB cluster, you register your Aurora DB cluster with Application Auto Scaling. You do so to define the scaling dimension and limits to be applied to that cluster. Application Auto Scaling dynamically scales the Aurora DB cluster along the

AWS CLI or Application Auto Scaling API

You can apply a scaling policy based on either a predefined or custom metric. To do so, you can use the AWS CLI or the Application Auto Scaling API. The first step is to register your Aurora DB cluster with Application Auto Scaling.

Registering an Aurora DB cluster

Before you can use Aurora Auto Scaling with an Aurora DB cluster, you register your Aurora DB cluster with Application Auto Scaling. You do so to define the scaling dimension and limits to be applied to that cluster. Application Auto Scaling dynamically scales the Aurora DB cluster along the
rds:cluster:ReadReplicaCount scalable dimension, which represents the number of Aurora Replicas.

To register your Aurora DB cluster, you can use either the AWS CLI or the Application Auto Scaling API.

**AWS CLI**

To register your Aurora DB cluster, use the `register-scalable-target` AWS CLI command with the following parameters:

- `--service-namespace` – Set this value to `rds`.
- `--resource-id` – The resource identifier for the Aurora DB cluster. For this parameter, the resource type is `cluster` and the unique identifier is the name of the Aurora DB cluster, for example `cluster:myscalablecluster`.
- `--scalable-dimension` – Set this value to `rds:cluster:ReadReplicaCount`.
- `--min-capacity` – The minimum number of reader DB instances to be managed by Application Auto Scaling. For information about the relationship between `--min-capacity`, `--max-capacity`, and the number of DB instances in your cluster, see Minimum and maximum capacity (p. 329).
- `--max-capacity` – The maximum number of reader DB instances to be managed by Application Auto Scaling. For information about the relationship between `--min-capacity`, `--max-capacity`, and the number of DB instances in your cluster, see Minimum and maximum capacity (p. 329).

**Example**

In the following example, you register an Aurora DB cluster named `myscalablecluster`. The registration indicates that the DB cluster should be dynamically scaled to have from one to eight Aurora Replicas.

For Linux, macOS, or Unix:

```
aws application-autoscaling register-scalable-target \
   --service-namespace rds \ 
   --resource-id cluster:myscalablecluster \ 
   --scalable-dimension rds:cluster:ReadReplicaCount \ 
   --min-capacity 1 \ 
   --max-capacity 8 \
```

For Windows:

```
aws application-autoscaling register-scalable-target ^
   --service-namespace rds ^ 
   --resource-id cluster:myscalablecluster ^ 
   --scalable-dimension rds:cluster:ReadReplicaCount ^ 
   --min-capacity 1 ^ 
   --max-capacity 8 ^
```

**Application Auto Scaling API**

To register your Aurora DB cluster with Application Auto Scaling, use the `RegisterScalableTarget` Application Auto Scaling API operation with the following parameters:

- `ServiceNamespace` – Set this value to `rds`.
- `ResourceID` – The resource identifier for the Aurora DB cluster. For this parameter, the resource type is `cluster` and the unique identifier is the name of the Aurora DB cluster, for example `cluster:myscalablecluster`. 
• **ScalableDimension** – Set this value to `rds:cluster:ReadReplicaCount`.

• **MinCapacity** – The minimum number of reader DB instances to be managed by Application Auto Scaling. For information about the relationship between MinCapacity, MaxCapacity, and the number of DB instances in your cluster, see [Minimum and maximum capacity (p. 329)](https://aws.amazon.com/autoscaling/userguide/)

• **MaxCapacity** – The maximum number of reader DB instances to be managed by Application Auto Scaling. For information about the relationship between MinCapacity, MaxCapacity, and the number of DB instances in your cluster, see [Minimum and maximum capacity (p. 329)](https://aws.amazon.com/autoscaling/userguide/)

**Example**

In the following example, you register an Aurora DB cluster named `myscalablecluster` with the Application Auto Scaling API. This registration indicates that the DB cluster should be dynamically scaled to have from one to eight Aurora Replicas.

```
POST / HTTP/1.1

{
   "ServiceNamespace": "rds",
   "ResourceId": "cluster:myscalablecluster",
   "ScalableDimension": "rds:cluster:ReadReplicaCount",
   "MinCapacity": 1,
   "MaxCapacity": 8
}
```

**Defining a scaling policy for an Aurora DB cluster**

A target-tracking scaling policy configuration is represented by a JSON block that the metrics and target values are defined in. You can save a scaling policy configuration as a JSON block in a text file. You use that text file when invoking the AWS CLI or the Application Auto Scaling API. For more information about policy configuration syntax, see [TargetTrackingScalingPolicyConfiguration](https://aws.amazon.com/autoscaling/userguide/) in the [Application Auto Scaling API Reference](https://aws.amazon.com/autoscaling/userguide/).

The following options are available for defining a target-tracking scaling policy configuration.

**Topics**

- [Using a predefined metric (p. 335)](https://aws.amazon.com/autoscaling/userguide/)
- [Using a custom metric (p. 336)](https://aws.amazon.com/autoscaling/userguide/)
- [Using cooldown periods (p. 336)](https://aws.amazon.com/autoscaling/userguide/)
- [Disabling scale-in activity (p. 337)](https://aws.amazon.com/autoscaling/userguide/)

**Using a predefined metric**

By using predefined metrics, you can quickly define a target-tracking scaling policy for an Aurora DB cluster that works well with both target tracking and dynamic scaling in Aurora Auto Scaling.

Currently, Aurora supports the following predefined metrics in Aurora Auto Scaling:

- **RDSReaderAverageCPUUtilization** – The average value of the CPUUtilization metric in CloudWatch across all Aurora Replicas in the Aurora DB cluster.
• **RDSReaderAverageDatabaseConnections** – The average value of the DatabaseConnections metric in CloudWatch across all Aurora Replicas in the Aurora DB cluster.

For more information about the CPUUtilization and DatabaseConnections metrics, see [Amazon CloudWatch metrics for Amazon Aurora](p. 638).

To use a predefined metric in your scaling policy, you create a target tracking configuration for your scaling policy. This configuration must include a PredefinedMetricSpecification for the predefined metric and a TargetValue for the target value of that metric.

**Example**

The following example describes a typical policy configuration for target-tracking scaling for an Aurora DB cluster. In this configuration, the RDSReaderAverageCPUUtilization predefined metric is used to adjust the Aurora DB cluster based on an average CPU utilization of 40 percent across all Aurora Replicas.

```json
{
    "TargetValue": 40.0,
    "PredefinedMetricSpecification":
    {
        "PredefinedMetricType": "RDSReaderAverageCPUUtilization"
    }
}
```

Using a custom metric

By using custom metrics, you can define a target-tracking scaling policy that meets your custom requirements. You can define a custom metric based on any Aurora metric that changes in proportion to scaling.

Not all Aurora metrics work for target tracking. The metric must be a valid utilization metric and describe how busy an instance is. The value of the metric must increase or decrease in proportion to the number of Aurora Replicas in the Aurora DB cluster. This proportional increase or decrease is necessary to use the metric data to proportionally scale out or in the number of Aurora Replicas.

**Example**

The following example describes a target-tracking configuration for a scaling policy. In this configuration, a custom metric adjusts an Aurora DB cluster based on an average CPU utilization of 50 percent across all Aurora Replicas in an Aurora DB cluster named `my-db-cluster`.

```json
{
    "TargetValue": 50,
    "CustomizedMetricSpecification":
    {
        "MetricName": "CPUUtilization",
        "Namespace": "AWS/RDS",
        "Dimensions": [
            {"Name": "DBClusterIdentifier","Value": "my-db-cluster"},
            {"Name": "Role","Value": "READER"}
        ],
        "Statistic": "Average",
        "Unit": "Percent"
    }
}
```

Using cooldown periods

You can specify a value, in seconds, for `ScaleOutCooldown` to add a cooldown period for scaling out your Aurora DB cluster. Similarly, you can add a value, in seconds, for `ScaleInCooldown` to add a
cooldown period for scaling in your Aurora DB cluster. For more information about ScaleInCooldown and ScaleOutCooldown, see TargetTrackingScalingPolicyConfiguration in the Application Auto Scaling API Reference.

Example

The following example describes a target-tracking configuration for a scaling policy. In this configuration, the RDSReaderAverageCPUUtilization predefined metric is used to adjust an Aurora DB cluster based on an average CPU utilization of 40 percent across all Aurora Replicas in that Aurora DB cluster. The configuration provides a scale-in cooldown period of 10 minutes and a scale-out cooldown period of 5 minutes.

```
{
  "TargetValue": 40.0,
  "PredefinedMetricSpecification":
  {
    "PredefinedMetricType": "RDSReaderAverageCPUUtilization"
  },
  "ScaleInCooldown": 600,
  "ScaleOutCooldown": 300
}
```

Disabling scale-in activity

You can prevent the target-tracking scaling policy configuration from scaling in your Aurora DB cluster by disabling scale-in activity. Disabling scale-in activity prevents the scaling policy from deleting Aurora Replicas, while still allowing the scaling policy to create them as needed.

You can specify a Boolean value for DisableScaleIn to enable or disable scale in activity for your Aurora DB cluster. For more information about DisableScaleIn, see TargetTrackingScalingPolicyConfiguration in the Application Auto Scaling API Reference.

Example

The following example describes a target-tracking configuration for a scaling policy. In this configuration, the RDSReaderAverageCPUUtilization predefined metric adjusts an Aurora DB cluster based on an average CPU utilization of 40 percent across all Aurora Replicas in that Aurora DB cluster. The configuration disables scale-in activity for the scaling policy.

```
{
  "TargetValue": 40.0,
  "PredefinedMetricSpecification":
  {
    "PredefinedMetricType": "RDSReaderAverageCPUUtilization"
  },
  "DisableScaleIn": true
}
```

Applying a scaling policy to an Aurora DB cluster

After registering your Aurora DB cluster with Application Auto Scaling and defining a scaling policy, you apply the scaling policy to the registered Aurora DB cluster. To apply a scaling policy to an Aurora DB cluster, you can use the AWS CLI or the Application Auto Scaling API.

AWS CLI

To apply a scaling policy to your Aurora DB cluster, use the put-scaling-policy AWS CLI command with the following parameters:
• --policy-name – The name of the scaling policy.
• --policy-type – Set this value to TargetTrackingScaling.
• --resource-id – The resource identifier for the Aurora DB cluster. For this parameter, the resource type is cluster and the unique identifier is the name of the Aurora DB cluster, for example cluster:myscalablecluster.
• --service-namespace – Set this value to rds.
• --scalable-dimension – Set this value to rds:cluster:ReadReplicaCount.
• --target-tracking-scaling-policy-configuration – The target-tracking scaling policy configuration to use for the Aurora DB cluster.

Example

In the following example, you apply a target-tracking scaling policy named myscalablepolicy to an Aurora DB cluster named myscalablecluster with Application Auto Scaling. To do so, you use a policy configuration saved in a file named config.json.

For Linux, macOS, or Unix:

```
aws application-autoscaling put-scaling-policy
  --policy-name myscalablepolicy
  --policy-type TargetTrackingScaling
  --resource-id cluster:myescalablecluster
  --service-namespace rds
  --scalable-dimension rds:cluster:ReadReplicaCount
  --target-tracking-scaling-policy-configuration file://config.json
```

For Windows:

```
aws application-autoscaling put-scaling-policy
  --policy-name myscalablepolicy
  --policy-type TargetTrackingScaling
  --resource-id cluster:myescalablecluster
  --service-namespace rds
  --scalable-dimension rds:cluster:ReadReplicaCount
  --target-tracking-scaling-policy-configuration file://config.json
```

Application Auto Scaling API

To apply a scaling policy to your Aurora DB cluster with the Application Auto Scaling API, use the PutScalingPolicy Application Auto Scaling API operation with the following parameters:

• PolicyName – The name of the scaling policy.
• ServiceNamespace – Set this value to rds.
• ResourceID – The resource identifier for the Aurora DB cluster. For this parameter, the resource type is cluster and the unique identifier is the name of the Aurora DB cluster, for example cluster:myescalablecluster.
• ScalableDimension – Set this value to rds:cluster:ReadReplicaCount.
• PolicyType – Set this value to TargetTrackingScaling.
• TargetTrackingScalingPolicyConfiguration – The target-tracking scaling policy configuration to use for the Aurora DB cluster.
Example

In the following example, you apply a target-tracking scaling policy named `myscalablepolicy` to an Aurora DB cluster named `myscalablecluster` with Application Auto Scaling. You use a policy configuration based on the `RDSReaderAverageCPUUtilization` predefined metric.

```
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
Content-Length: 219
X-Amz-Target: AnyScaleFrontendService.PutScalingPolicy
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
    "PolicyName": "myscalablepolicy",
    "ServiceNamespace": "rds",
    "ResourceId": "cluster:myscalablecluster",
    "ScalableDimension": "rds:cluster:ReadReplicaCount",
    "PolicyType": "TargetTrackingScaling",
    "TargetTrackingScalingPolicyConfiguration": {
        "TargetValue": 40.0,
        "PredefinedMetricSpecification": {
            "PredefinedMetricType": "RDSReaderAverageCPUUtilization"
        }
    }
}
```

Editing a scaling policy

You can edit a scaling policy using the AWS Management Console, the AWS CLI, or the Application Auto Scaling API.

**Console**

You can edit a scaling policy by using the AWS Management Console.

**To edit an auto scaling policy for an Aurora DB cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the Aurora DB cluster whose auto scaling policy you want to edit.
4. Choose the Logs & events tab.
5. In the Auto scaling policies section, choose the auto scaling policy, and then choose Edit.
6. Make changes to the policy.
7. Choose Save.

The following is a sample Edit Auto Scaling policy dialog box.
You can use the AWS CLI or the Application Auto Scaling API to edit a scaling policy in the same way that you apply a scaling policy:

- When using the AWS CLI, specify the name of the policy you want to edit in the `--policy-name` parameter. Specify new values for the parameters you want to change.
• When using the Application Auto Scaling API, specify the name of the policy you want to edit in the PolicyName parameter. Specify new values for the parameters you want to change.

For more information, see Applying a scaling policy to an Aurora DB cluster (p. 337).

Deleting a scaling policy

You can delete a scaling policy using the AWS Management Console, the AWS CLI, or the Application Auto Scaling API.

Console

You can delete a scaling policy by using the AWS Management Console.

To delete an auto scaling policy for an Aurora DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the Aurora DB cluster whose auto scaling policy you want to delete.
4. Choose the Logs & events tab.
5. In the Auto scaling policies section, choose the auto scaling policy, and then choose Delete.

AWS CLI

To delete a scaling policy from your Aurora DB cluster, use the delete-scaling-policy AWS CLI command with the following parameters:

• --policy-name – The name of the scaling policy.
• --resource-id – The resource identifier for the Aurora DB cluster. For this parameter, the resource type is cluster and the unique identifier is the name of the Aurora DB cluster, for example cluster:myscalablecluster.
• --service-namespace – Set this value to rds.
• --scalable-dimension – Set this value to rds:cluster:Read Replica Count.

Example

In the following example, you delete a target-tracking scaling policy named myscalablepolicy from an Aurora DB cluster named myscalablecluster.

For Linux, macOS, or Unix:

```bash
aws application-autoscaling delete-scaling-policy \
  --policy-name myscalablepolicy \
  --resource-id cluster:myscalablecluster \
  --service-namespace rds \
  --scalable-dimension rds:cluster:Read Replica Count \
```

For Windows:

```bash
aws application-autoscaling delete-scaling-policy ^
```
Application Auto Scaling API

To delete a scaling policy from your Aurora DB cluster, use the `DeleteScalingPolicy` the Application Auto Scaling API operation with the following parameters:

- **PolicyName** – The name of the scaling policy.
- **ServiceNamespace** – Set this value to `rds`.
- **ResourceId** – The resource identifier for the Aurora DB cluster. For this parameter, the resource type is `cluster` and the unique identifier is the name of the Aurora DB cluster, for example `cluster:mynewcluster`.
- **ScalableDimension** – Set this value to `rds:cluster:ReadReplicaCount`.

Example

In the following example, you delete a target-tracking scaling policy named `myscalablepolicy` from an Aurora DB cluster named `myscalablecluster` with the Application Auto Scaling API.

```
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
Content-Length: 219
X-Amz-Target: AnyScaleFrontendService.DeleteScalingPolicy
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS
{
    "PolicyName": "myscalablepolicy",
    "ServiceNamespace": "rds",
    "ResourceId": "cluster:mynewcluster",
    "ScalableDimension": "rds:cluster:ReadReplicaCount"
}
```

DB instance IDs and tagging

When a replica is added by Aurora Auto Scaling, its DB instance ID is prefixed by `application-autoscaling-`, for example, `application-autoscaling-61aabbcc-4e2f-4c65-b620-ab7421abc123`.

The following tag is automatically added to the DB instance. You can view it on the Tags tab of the DB instance detail page.

<table>
<thead>
<tr>
<th>Tag</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>application-autoscaling:resourceId</td>
<td>cluster:mynewcluster-cluster</td>
</tr>
</tbody>
</table>

For more information on Amazon RDS resource tags, see [Tagging Amazon RDS resources](p. 382).
Aurora Auto Scaling and Performance Insights

You can use Performance Insights to monitor replicas that have been added by Aurora Auto Scaling, the same as with any Aurora reader DB instance.

You can't turn on Performance Insights for an Aurora DB cluster. You can manually turn on Performance Insights for each DB instance in the DB cluster.

When you turn on Performance Insights for the writer DB instance in your Aurora DB cluster, Performance Insights isn't turned on automatically for reader DB instances. You have to turn on Performance Insights manually for the existing reader DB instances and new replicas added by Aurora Auto Scaling.

For more information on using Performance Insights to monitor Aurora DB clusters, see Monitoring DB load with Performance Insights on Amazon Aurora (p. 559).

Using machine learning capabilities with Amazon Aurora

Following, you can learn how to use AWS machine learning services with your Aurora database applications. By using Amazon Aurora machine learning, you can integrate your Aurora DB cluster with Amazon Comprehend or Amazon SageMaker or both, depending on your needs. Amazon Comprehend and Amazon SageMaker each support specific machine learning use cases, as follows.

- **Amazon Comprehend** – Amazon Comprehend is a managed natural language processing (NLP) service that's used to extract insights from documents. With Amazon Comprehend, you can deduce sentiment based on the content of documents, by analyzing entities, key phrases, language, and other features. To learn more, see [What is Amazon Comprehend?](https://docs.aws.amazon.com/comprehend/latest/dg/what-is.html) in the Amazon Comprehend Developer Guide. For a list of AWS Regions where Amazon Comprehend is available, see Amazon Comprehend endpoints and quotas in the Amazon Web Services General Reference.

- **Amazon SageMaker** – Amazon SageMaker is a fully managed machine learning service. Data scientists and developers use Amazon SageMaker to build, train, and test machine learning models for a variety of inference tasks, such as fraud detection and product recommendation. When a machine learning model is ready for use in production, it can be deployed to the Amazon SageMaker hosted environment. For more information, see [What Is Amazon SageMaker?](https://docs.aws.amazon.com/sagemaker/latest/dg/what-is-sagemaker.html) in the Amazon SageMaker Developer Guide. For a list of AWS Regions where Amazon SageMaker is available, see Amazon SageMaker endpoints and quotas in the Amazon Web Services General Reference.

To integrate Aurora machine learning with your Aurora DB cluster, the Amazon Comprehend and the Amazon SageMaker components must be set up and ready for use. The data scientists on your team work with SageMaker to get the models ready for use. The database developers on your team can focus on using the Amazon Comprehend or the SageMaker services through the familiar SQL database interface after Aurora machine learning is integrated with your Aurora DB cluster. For more information about Amazon Aurora machine learning, see Amazon Aurora ML.

Aurora machine learning is supported in certain AWS Regions and for specific versions of Aurora MySQL and Aurora PostgreSQL only. Before trying to set up Aurora machine learning, check availability in your AWS Region for your Aurora MySQL or Aurora PostgreSQL version. For details, see [Aurora machine learning](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-ml.html).

**Topics**

- Using Amazon Aurora machine learning with Aurora MySQL (p. 1086)
- Using Amazon Aurora machine learning with Aurora PostgreSQL (p. 1556)
Maintaining an Amazon Aurora DB cluster

Periodically, Amazon RDS performs maintenance on Amazon RDS resources. Maintenance most often involves updates to the following resources in your DB cluster:

- Underlying hardware
- Underlying operating system (OS)
- Database engine version

Updates to the operating system most often occur for security issues. You should do them as soon as possible.

Some maintenance items require that Amazon RDS take your DB cluster offline for a short time. Maintenance items that require a resource to be offline include required operating system or database patching. Required patching is automatically scheduled only for patches that are related to security and instance reliability. Such patching occurs infrequently, typically once every few months. It seldom requires more than a fraction of your maintenance window.

Deferred DB cluster and instance modifications that you have chosen not to apply immediately are also applied during the maintenance window. For example, you might choose to change DB instance classes or cluster or DB parameter groups during the maintenance window. Such modifications that you specify using the pending reboot setting don’t show up in the Pending maintenance list. For information about modifying a DB cluster, see Modifying an Amazon Aurora DB cluster (p. 269).

Topics

- Viewing pending maintenance (p. 344)
- Applying updates for a DB cluster (p. 347)
- The Amazon RDS maintenance window (p. 348)
- Adjusting the preferred DB cluster maintenance window (p. 350)
- Automatic minor version upgrades for Aurora DB clusters (p. 351)
- Choosing the frequency of Aurora MySQL maintenance updates (p. 354)
- Working with operating system updates (p. 354)

Viewing pending maintenance

View whether a maintenance update is available for your DB cluster by using the RDS console, the AWS CLI, or the RDS API. If an update is available, it is indicated in the Maintenance column for the DB cluster on the Amazon RDS console, as shown following.
If no maintenance update is available for a DB cluster, the column value is **none** for it.

If a maintenance update is available for a DB cluster, the following column values are possible:

- **required** – The maintenance action will be applied to the resource and can't be deferred indefinitely.
- **available** – The maintenance action is available, but it will not be applied to the resource automatically. You can apply it manually.
- **next window** – The maintenance action will be applied to the resource during the next maintenance window.
- **in progress** – The maintenance action is in the process of being applied to the resource.

If an update is available, you can take one of the actions:

- If the maintenance value is **next window**, defer the maintenance items by choosing **Defer upgrade** from Actions. You can't defer a maintenance action if it has already started.
- Apply the maintenance items immediately.
- Schedule the maintenance items to start during your next maintenance window.
- Take no action.

To take an action, choose the DB cluster to show its details, then choose **Maintenance & backups**. The pending maintenance items appear.
The maintenance window determines when pending operations start, but doesn't limit the total run time of these operations. Maintenance operations aren't guaranteed to finish before the maintenance window ends, and can continue beyond the specified end time. For more information, see The Amazon RDS maintenance window (p. 348).

For information about updates to Amazon Aurora engines and instructions for upgrading and patching them, see Database engine updates for Amazon Aurora MySQL (p. 1200) and Amazon Aurora PostgreSQL updates (p. 1780).

You can also view whether a maintenance update is available for your DB cluster by running the describe-pending-maintenance-actions AWS CLI command.
Applying updates for a DB cluster

With Amazon RDS, you can choose when to apply maintenance operations. You can decide when Amazon RDS applies updates by using the RDS console, AWS Command Line Interface (AWS CLI), or RDS API.

**Note**
For RDS for SQL Server, an update to the underlying operating system can be applied by stopping and starting your DB instance, or by scaling your DB instance class up and then down again.

**Console**

**To manage an update for a DB cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Databases.
3. Choose the DB cluster that has a required update.
4. For Actions, choose one of the following:
   - Upgrade now
   - Upgrade at next window

**Note**
If you choose Upgrade at next window and later want to delay the update, you can choose Defer upgrade. You can't defer a maintenance action if it has already started. To cancel a maintenance action, modify the DB instance and disable Auto minor version upgrade.

**AWS CLI**

To apply a pending update to a DB cluster, use the `apply-pending-maintenance-action` AWS CLI command.

**Example**

For Linux, macOS, or Unix:

```
aws rds apply-pending-maintenance-action \   
  --apply-action system-update \   
  --opt-in-type immediate
```

For Windows:

```
aws rds apply-pending-maintenance-action ^
  --apply-action system-update ^
  --opt-in-type immediate
```

**Note**
To defer a maintenance action, specify `undo-opt-in` for --opt-in-type. You can't specify `undo-opt-in` for --opt-in-type if the maintenance action has already started. To cancel a maintenance action, run the `modify-db-instance` AWS CLI command and specify `--no-auto-minor-version-upgrade`. 
To return a list of resources that have at least one pending update, use the `describe-pending-maintenance-actions` AWS CLI command.

**Example**

For Linux, macOS, or Unix:

```
aws rds describe-pending-maintenance-actions
```

For Windows:

```
aws rds describe-pending-maintenance-actions
```

You can also return a list of resources for a DB cluster by specifying the `--filters` parameter of the `describe-pending-maintenance-actions` AWS CLI command. The format for the `--filters` command is `Name=filter-name,Value=resource-id,...`.

The following are the accepted values for the `Name` parameter of a filter:

- `db-instance-id` – Accepts a list of DB instance identifiers or Amazon Resource Names (ARNs). The returned list only includes pending maintenance actions for the DB instances identified by these identifiers or ARNs.
- `db-cluster-id` – Accepts a list of DB cluster identifiers or ARNs for Amazon Aurora. The returned list only includes pending maintenance actions for the DB clusters identified by these identifiers or ARNs.

For example, the following example returns the pending maintenance actions for the `sample-cluster1` and `sample-cluster2` DB clusters.

**Example**

For Linux, macOS, or Unix:

```
aws rds describe-pending-maintenance-actions
  --filters Name=db-cluster-id,Values=sample-cluster1,sample-cluster2
```

For Windows:

```
aws rds describe-pending-maintenance-actions
  --filters Name=db-cluster-id,Values=sample-cluster1,sample-cluster2
```

**RDS API**

To apply an update to a DB cluster, call the Amazon RDS API `ApplyPendingMaintenanceAction` operation.

To return a list of resources that have at least one pending update, call the Amazon RDS API `DescribePendingMaintenanceActions` operation.

**The Amazon RDS maintenance window**

Every DB cluster has a weekly maintenance window during which any system changes are applied. Think of the maintenance window as an opportunity to control when modifications and software patching occur. If a maintenance event is scheduled for a given week, it is initiated during the 30-minute maintenance window you identify. Most maintenance events also complete during the 30-minute maintenance window, although larger maintenance events may take more than 30 minutes to complete.
The 30-minute maintenance window is selected at random from an 8-hour block of time per region. If you don't specify a maintenance window when you create the DB cluster, RDS assigns a 30-minute maintenance window on a randomly selected day of the week.

RDS consumes some of the resources on your DB cluster while maintenance is being applied. You might observe a minimal effect on performance. For a DB instance, on rare occasions, a Multi-AZ failover might be required for a maintenance update to complete.

Following, you can find the time blocks for each region from which default maintenance windows are assigned.

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>
<th>Time Block</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2</td>

</table>
Adjusting the preferred DB cluster maintenance window

The Aurora DB cluster maintenance window should fall at the time of lowest usage and thus might need modification from time to time. Your DB cluster is unavailable during this time only if the updates that are being applied require an outage. The outage is for the minimum amount of time required to make the necessary updates.

**Console**

**To adjust the preferred DB cluster maintenance window**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Databases.
3. Choose the DB cluster for which you want to change the maintenance window.
4. Choose Modify.
5. In the Maintenance section, update the maintenance window.
6. Choose Continue.

   On the confirmation page, review your changes.
7. To apply the changes to the maintenance window immediately, choose Immediately in the Schedule of modifications section.
8. Choose Modify cluster to save your changes.

   Alternatively, choose Back to edit your changes, or choose Cancel to cancel your changes.

**AWS CLI**

To adjust the preferred DB cluster maintenance window, use the AWS CLI `modify-db-cluster` command with the following parameters:
Automatic minor version upgrades for Aurora DB clusters

The Auto minor version upgrade setting specifies whether Aurora automatically applies upgrades to your DB cluster. These upgrades include new minor versions containing additional features and patches containing bug fixes.

This setting is turned on by default. For each new DB cluster, choose the appropriate value for this setting. This value is based on its importance, expected lifetime, and the amount of verification testing that you do after each upgrade.

For instructions on turning the Auto minor version upgrade setting on or off, see the following:

- Enabling automatic minor version upgrades for an Aurora DB cluster (p. 352)
- Enabling automatic minor version upgrades for individual DB instances in an Aurora DB cluster (p. 353)

Important

We strongly recommend that for new and existing DB clusters, you apply this setting to the DB cluster and not to the DB instances in the cluster individually. If any DB instance in your cluster has this setting turned off, the DB cluster isn't automatically upgraded.

The following table shows how the Auto minor version upgrade setting works when applied at the cluster and instance levels.
## Automatic minor version upgrades for Aurora DB clusters

### Table: Action and Cluster setting

<table>
<thead>
<tr>
<th>Action</th>
<th>Cluster setting</th>
<th>Instance settings</th>
<th>Cluster upgraded automatically?</th>
</tr>
</thead>
<tbody>
<tr>
<td>You set it to True on the DB cluster.</td>
<td>True</td>
<td>True for all new and existing instances</td>
<td>Yes</td>
</tr>
<tr>
<td>You set it to False on the DB cluster.</td>
<td>False</td>
<td>False for all new and existing instances</td>
<td>No</td>
</tr>
<tr>
<td>It was set previously to True on the DB cluster.</td>
<td>Changes to False</td>
<td>False for one or more instances</td>
<td>No</td>
</tr>
<tr>
<td>You set it to False on at least one DB instance.</td>
<td>False</td>
<td>True for one or more instances, but not all instances</td>
<td>No</td>
</tr>
<tr>
<td>It was set previously to False on the DB cluster.</td>
<td>False</td>
<td>True for all instances</td>
<td>Yes</td>
</tr>
<tr>
<td>You set it to True on at least one DB instance, but not all instances.</td>
<td>Changes to True</td>
<td>True for all instances</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Automatic minor version upgrades are communicated in advance through an Amazon RDS DB cluster event with a category of `maintenance` and ID of `RDS-EVENT-0156`. For more information, see [Amazon RDS event categories and event messages](p. 709).

Automatic upgrades occur during the maintenance window. If the individual DB instances in the DB cluster have different maintenance windows from the cluster maintenance window, then the cluster maintenance window takes precedence.

For more information about engine updates for Aurora PostgreSQL, see [Amazon Aurora PostgreSQL updates](p. 1780).

For more information about the **Auto minor version upgrade** setting for Aurora MySQL, see [Enabling automatic upgrades between minor Aurora MySQL versions](p. 1210). For general information about engine updates for Aurora MySQL, see [Database engine updates for Amazon Aurora MySQL](p. 1200).

### Enabling automatic minor version upgrades for an Aurora DB cluster

Follow the general procedure in [Modifying the DB cluster by using the console, CLI, and API](p. 269).

#### Console

On the **Modify DB cluster** page, in the **Maintenance** section, select the **Enable auto minor version upgrade** check box.

#### AWS CLI

Call the `modify-db-cluster` AWS CLI command. Specify the name of your DB cluster for the `--db-cluster-identifier` option and `true` for the `--auto-minor-version-upgrade` option.
Optionally, specify the --apply-immediately option to immediately enable this setting for your DB cluster.

RDS API

Call the ModifyDBCluster API operation and specify the name of your DB cluster for the DBClusterIdentifier parameter and true for the AutoMinorVersionUpgrade parameter. Optionally, set the ApplyImmediately parameter to true to immediately enable this setting for your DB cluster.

Enabling automatic minor version upgrades for individual DB instances in an Aurora DB cluster

Follow the general procedure in Modifying a DB instance in a DB cluster (p. 270).

Console

On the Modify DB instance page, in the Maintenance section, select the Enable auto minor version upgrade check box.

AWS CLI

Call the modify-db-instance AWS CLI command. Specify the name of your DB instance for the --db-instance-identifier option and true for the --auto-minor-version-upgrade option. Optionally, specify the --apply-immediately option to immediately enable this setting for your DB instance. Run a separate modify-db-instance command for each DB instance in the cluster.

RDS API

Call the ModifyDBInstance API operation and specify the name of your DB cluster for the DBInstanceIdentifier parameter and true for the AutoMinorVersionUpgrade parameter. Optionally, set the ApplyImmediately parameter to true to immediately enable this setting for your DB instance. Call a separate ModifyDBInstance operation for each DB instance in the cluster.

You can use a CLI command such as the following to check the status of the AutoMinorVersionUpgrade setting for all of the DB instances in your Aurora MySQL clusters.

```
aws rds describe-db-instances \
  --query '.*[].{DBClusterIdentifier:DBClusterIdentifier,DBInstanceIdentifier:DBInstanceIdentifier,AutoMinorVersionUpgrade:AutoMinorVersionUpgrade}'
```

That command produces output similar to the following:

```
[ 
  { 
    "DBInstanceIdentifier": "db-writer-instance", 
    "DBClusterIdentifier": "my-db-cluster-57", 
    "AutoMinorVersionUpgrade": true 
  }, 
  { 
    "DBInstanceIdentifier": "db-reader-instance1", 
    "DBClusterIdentifier": "my-db-cluster-57", 
    "AutoMinorVersionUpgrade": false 
  }, 
  { 
    "DBInstanceIdentifier": "db-writer-instance2", 
    "DBClusterIdentifier": "my-db-cluster-80", 
    "AutoMinorVersionUpgrade": true 
  }, 
]```
In this example, **Enable auto minor version upgrade** is turned off for the DB cluster `my-db-cluster-57`, because it's turned off for one of the DB instances in the cluster.

### Choosing the frequency of Aurora MySQL maintenance updates

You can control whether Aurora MySQL upgrades happen frequently or rarely for each DB cluster. The best choice depends on your usage of Aurora MySQL and the priorities for your applications that run on Aurora. For information about the Aurora MySQL long-term stability (LTS) releases that require less frequent upgrades, see *Aurora MySQL long-term support (LTS) releases* (p. 1202).

You might choose to upgrade an Aurora MySQL cluster rarely if some or all of the following conditions apply:

- Your testing cycle for your application takes a long time for each update to the Aurora MySQL database engine.
- You have many DB clusters or many applications all running on the same Aurora MySQL version. You prefer to upgrade all of your DB clusters and associated applications at the same time.
- You use both Aurora MySQL and RDS for MySQL. You prefer to keep the Aurora MySQL clusters and RDS for MySQL DB instances compatible with the same level of MySQL.
- Your Aurora MySQL application is in production or is otherwise business-critical. You can’t afford downtime for upgrades outside of rare occurrences for critical patches.
- Your Aurora MySQL application isn't limited by performance issues or feature gaps that are addressed in subsequent Aurora MySQL versions.

If the preceding factors apply to your situation, you can limit the number of forced upgrades for an Aurora MySQL DB cluster. You do so by choosing a specific Aurora MySQL version known as the "Long-Term Support" (LTS) version when you create or upgrade that DB cluster. Doing so minimizes the number of upgrade cycles, testing cycles, and upgrade-related outages for that DB cluster.

You might choose to upgrade an Aurora MySQL cluster frequently if some or all of the following conditions apply:

- The testing cycle for your application is straightforward and brief.
- Your application is still in the development stage.
- Your database environment uses a variety of Aurora MySQL versions, or Aurora MySQL and RDS for MySQL versions. Each Aurora MySQL cluster has its own upgrade cycle.
- You are waiting for specific performance or feature improvements before you increase your usage of Aurora MySQL.

If the preceding factors apply to your situation, you can enable Aurora to apply important upgrades more frequently. To do so, upgrade an Aurora MySQL DB cluster to a more recent Aurora MySQL version than the LTS version. Doing so makes the latest performance enhancements, bug fixes, and features available to you more quickly.

### Working with operating system updates

DB instances in Aurora MySQL and Aurora PostgreSQL DB clusters occasionally require operating system updates. Amazon RDS upgrades the operating system to a newer version to improve database performance and customers' overall security posture. Typically, the updates take about 10 minutes. Operating system updates don't change the DB engine version or DB instance class of a DB instance.
We recommend that you update the reader DB instances in a DB cluster first, then the writer DB instance. We don't recommend updating reader and writer instances at the same time, because you might incur downtime in the event of a failover.

There are two types of operating system updates, differentiated by the description visible in the pending maintenance action on the DB instance:

- **Operating system distribution upgrade** – Used to migrate to the latest supported major version of Amazon Linux. Its description in the pending maintenance action is New Operating System upgrade is available.

- **Operating system patch** – Used to apply various security fixes and sometimes to improve database performance. Its description in the pending maintenance action is New Operating System patch is available.

Operating system updates can be either optional or mandatory:

- **An optional update** can be applied at any time. While these updates are optional, we recommend that you apply them periodically to keep your RDS fleet up to date. RDS does not apply these updates automatically.

  To be notified when a new, optional operating system patch becomes available, you can subscribe to RDS-EVENT-0230 (p. 718) in the security patching event category. For information about subscribing to RDS events, see Subscribing to Amazon RDS event notification (p. 696).

  **Note**
  
  RDS-EVENT-0230 doesn't apply to operating system distribution upgrades.

  **Note**
  
  If you received RDS-EVENT-0230 for an RDS for SQL Server DB instance, the OS update can't be applied via the apply-pending-maintenance action. For more information, see Applying updates for a DB cluster (p. 347).

- **A mandatory update** is required, and we send a notification before the mandatory update. The notification might contain a due date. Plan to schedule your update before this due date. After the specified due date, Amazon RDS automatically upgrades the operating system for your DB instance to the latest version during one of your assigned maintenance windows.

Operating system distribution upgrades are mandatory.

  **Note**
  
  Staying current on all optional and mandatory updates might be required to meet various compliance obligations. We recommend that you apply all updates made available by RDS routinely during your maintenance windows.

You can use the AWS Management Console or the AWS CLI to get information about the type of operating system upgrade.

**Console**

**To get update information using the AWS Management Console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**, and then select the DB instance.
3. Choose **Maintenance**.
4. In the **Pending maintenance** section, find the operating system update, and check the **Description** value.
In the AWS Management Console, an operating system distribution upgrade has its **Description** set to **New Operating System upgrade is available**, as shown in the following image. This upgrade is mandatory.

![Operating System Distribution Upgrade](image1)

An operating system patch has its **Description** set to **New Operating System patch is available**, as shown in the following image.

![Operating System Patch](image2)

**AWS CLI**

To get update information from the AWS CLI, use the `describe-pending-maintenance-actions` command.

```bash
aws rds describe-pending-maintenance-actions
```

The following output shows an operating system distribution upgrade.

```json
{
    "PendingMaintenanceActionDetails": [
        {
            "Action": "system-update",
            "Description": "New Operating System upgrade is available"
        }
    ]
}
```

The following output shows an operating system patch.

```json
{
```
Availability of operating system updates

Operating system updates are specific to DB engine version and DB instance class. Therefore, DB instances receive or require updates at different times. When an operating system update is available for your DB instance based on its engine version and instance class, the update appears in the console. It can also be viewed by running AWS CLI `describe-pending-maintenance-actions` command or by calling the RDS `DescribePendingMaintenanceActions` API operation. If an update is available for your instance, you can update your operating system by following the instructions in Applying updates for a DB cluster (p. 347).
Rebooting an Amazon Aurora DB cluster or Amazon Aurora DB instance

You might need to reboot your DB cluster or some instances within the cluster, usually for maintenance reasons. For example, suppose that you modify the parameters within a parameter group or associate a different parameter group with your cluster. In these cases, you must reboot the cluster for the changes to take effect. Similarly, you might reboot one or more reader DB instances within the cluster. You can arrange the reboot operations for individual instances to minimize downtime for the entire cluster.

The time required to reboot each DB instance in your cluster depends on the database activity at the time of reboot. It also depends on the recovery process of your specific DB engine. If it's practical, reduce database activity on that particular instance before starting the reboot process. Doing so can reduce the time needed to restart the database.

You can only reboot each DB instance in your cluster when it's in the available state. A DB instance can be unavailable for several reasons. These include the cluster being stopped state, a modification being applied to the instance, and a maintenance-window action such as a version upgrade.

Rebooting a DB instance restarts the database engine process. Rebooting a DB instance results in a momentary outage, during which the DB instance status is set to `rebooting`.

**Note**

If a DB instance isn't using the latest changes to its associated DB parameter group, the AWS Management Console shows the DB parameter group with a status of `pending-reboot`. The `pending-reboot` parameter groups status doesn't result in an automatic reboot during the next maintenance window. To apply the latest parameter changes to that DB instance, manually reboot the DB instance. For more information about parameter groups, see [Working with parameter groups](p. 212).

**Topics**

- Rebooting a DB instance within an Aurora cluster (p. 358)
- Rebooting an Aurora cluster with read availability (p. 359)
- Rebooting an Aurora cluster without read availability (p. 360)
- Checking uptime for Aurora clusters and instances (p. 361)
- Examples of Aurora reboot operations (p. 363)

Rebooting a DB instance within an Aurora cluster

This procedure is the most important operation that you take when performing reboots with Aurora. Many of the maintenance procedures involve rebooting one or more Aurora DB instances in a particular order.

**Console**

**To reboot a DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Databases, and then choose the DB instance that you want to reboot.
3. For Actions, choose Reboot.

   The Reboot DB Instance page appears.
4. Choose Reboot to reboot your DB instance.
Rebooting an Aurora cluster with read availability

AWS CLI

To reboot a DB instance by using the AWS CLI, call the `reboot-db-instance` command.

**Example**

For Linux, macOS, or Unix:

```
aws rds reboot-db-instance --db-instance-identifier mydbinstance
```

For Windows:

```
aws rds reboot-db-instance ^
   --db-instance-identifier mydbinstance
```

RDS API

To reboot a DB instance by using the Amazon RDS API, call the `RebootDBInstance` operation.

Rebooting an Aurora cluster with read availability

With the read availability feature, you can reboot the writer instance of your Aurora cluster without rebooting the reader instances in the cluster. Doing so can help maintain high availability of the cluster for read operations while you reboot the writer instance. You can reboot the reader instances later, on a schedule that's convenient for you. For example, for a production cluster, you might reboot the reader instances one at a time, starting only after the reboot of the primary instance is finished. For each DB instance that you reboot, follow the procedure in Rebooting a DB instance within an Aurora cluster (p. 358).

The read availability feature is available in Aurora MySQL 2.10 and higher.

For Aurora PostgreSQL this feature is available by default in the following versions:

- 15.2 and higher 15 versions
- 14.7 and higher 14 versions
- 13.10 and higher 13 versions
- 12.14 and higher 12 versions

For more information on the read availability feature in Aurora PostgreSQL, see Improving the read availability of Aurora Replicas (p. 1505).

Prior to this feature, rebooting the primary instance caused a reboot for each reader instance at the same time. If your Aurora cluster is running an older version, use the reboot procedure in Rebooting an Aurora cluster without read availability (p. 360) instead.

**Important**

The change to reboot behavior in Aurora cluster with read availability feature is different for Aurora global databases. If you reboot the writer instance for the primary cluster in an Aurora global database, the reader instances in the primary cluster remain available. However, the DB instances in any secondary clusters reboot at the same time.

You frequently reboot the cluster after making changes to cluster parameter groups. You make parameter changes by following the procedures in Working with parameter groups (p. 212). Suppose
that you reboot the writer DB instance in an Aurora cluster to apply changes to cluster parameters. Some or all of the reader DB instances might continue using the old parameter settings. However, the different parameter settings don't affect the data integrity of the cluster. Any cluster parameters that affect the organization of data files are only used by the writer DB instance.

For example, in an Aurora MySQL cluster, you can update cluster parameters such as `binlog_format` and `innodb_purge_threads` on the writer instance before the reader instances. Only the writer instance is writing binary logs and purging undo records. For parameters that change how queries interpret SQL statements or query output, you might need to take care to reboot the reader instances immediately. You do this to avoid unexpected application behavior during queries. For example, suppose that you change the `lower_case_table_names` parameter and reboot the writer instance. In this case, the reader instances might not be able to access a newly created table until they are all rebooted.

For a list of all the Aurora MySQL cluster parameters, see [Cluster-level parameters](p. 1116).

For a list of all the Aurora PostgreSQL cluster parameters, see [Aurora PostgreSQL cluster-level parameters](p. 1731).

**Tip**

Aurora MySQL might still reboot some of the reader instances along with the writer instance if your cluster is processing a workload with high throughput.

The reduction in the number of reboots applies during failover operations also. Aurora MySQL only restarts the writer DB instance and the failover target during a failover. Other reader DB instances in the cluster remain available to continue processing queries through connections to the reader endpoint. Thus, you can improve availability during a failover by having more than one reader DB instance in a cluster.

**Rebooting an Aurora cluster without read availability**

Without the read availability feature, you reboot an entire Aurora DB cluster by rebooting the writer DB instance of that cluster. To do so, follow the procedure in [Rebooting a DB instance within an Aurora cluster](p. 358).

Rebooting the writer DB instance also initiates a reboot for each reader DB instance in the cluster. That way, any cluster-wide parameter changes are applied to all DB instances at the same time. However, the reboot of all DB instances causes a brief outage for the cluster. The reader DB instances remain unavailable until the writer DB instance finishes rebooting and becomes available.

This reboot behavior applies to all DB clusters created in Aurora MySQL version 2.09 and lower.

For Aurora PostgreSQL this behavior applies to the following versions:

- 14.6 and lower 14 versions
- 13.9 and lower 13 versions
- 12.13 and lower 12 versions
- All PostgreSQL 11 versions

In the RDS console, the writer DB instance has the value **Writer** under the **Role** column on the **Databases** page. In the RDS CLI, the output of the `describe-db-clusters` command includes a section **DBClusterMembers**. The **DBClusterMembers** element representing the writer DB instance has a value of true for the **IsClusterWriter** field.

**Important**

With the read availability feature, the reboot behavior is different in Aurora MySQL and Aurora PostgreSQL: the reader DB instances typically remain available while you reboot the writer instance. Then you can reboot the reader instances at a convenient time. You can reboot the reader instances on a staggered schedule if you want some reader instances to always be available. For more information, see [Rebooting an Aurora cluster with read availability](p. 359).
Checking uptime for Aurora clusters and instances

You can check and monitor the length of time since the last reboot for each DB instance in your Aurora cluster. The Amazon CloudWatch metric `EngineUptime` reports the number of seconds since the last time a DB instance was started. You can examine this metric at a point in time to find out the uptime for the DB instance. You can also monitor this metric over time to detect when the instance is rebooted.

You can also examine the `EngineUptime` metric at the cluster level. The `Minimum` and `Maximum` dimensions report the smallest and largest uptime values for all DB instances in the cluster. To check the most recent time when any reader instance in a cluster was rebooted, or restarted for another reason, monitor the cluster-level metric using the `Minimum` dimension. To check which instance in the cluster has gone the longest without a reboot, monitor the cluster-level metric using the `Maximum` dimension. For example, you might want to confirm that all DB instances in the cluster were rebooted after a configuration change.

Tip
For long-term monitoring, we recommend monitoring the `EngineUptime` metric for individual instances instead of at the cluster level. The cluster-level `EngineUptime` metric is set to zero when a new DB instance is added to the cluster. Such cluster changes can happen as part of maintenance and scaling operations such as those performed by Auto Scaling.

The following CLI examples show how to examine the `EngineUptime` metric for the writer and reader instances in a cluster. The examples use a cluster named `tpch100g`. This cluster has a writer DB instance `instance-1234`. It also has two reader DB instances, `instance-7448` and `instance-6305`.

First, the `reboot-db-instance` command reboots one of the reader instances. The `wait` command waits until the instance is finished rebooting.

```bash
$ aws rds reboot-db-instance --db-instance-identifier instance-6305
{
  "DBInstance": {
    "DBInstanceIdentifier": "instance-6305",
    "DBInstanceStatus": "rebooting",
  ...
$ aws rds wait db-instance-available --db-instance-id instance-6305
```

The CloudWatch `get-metric-statistics` command examines the `EngineUptime` metric over the last five minutes at one-minute intervals. The uptime for the instance-6305 instance is reset to zero and begins counting upwards again. This AWS CLI example for Linux uses `$( )` variable substitution to insert the appropriate timestamps into the CLI commands. It also uses the Linux `sort` command to order the output by the time the metric was collected. That timestamp value is the third field in each line of output.

```bash
$ aws cloudwatch get-metric-statistics --metric-name "EngineUptime" \
--start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" \
--period 60 --namespace "AWS/RDS" --statistics Maximum \
--dimensions Name=DBInstanceIdentifier,Value=instance-6305 --output text \
| sort -k 3
```

The minimum uptime for the cluster is reset to zero because one of the instances in the cluster was rebooted. The maximum uptime for the cluster isn't reset because at least one of the DB instances in the cluster remained available.
Checking uptime for Aurora clusters and instances

$ aws cloudwatch get-metric-statistics --metric-name "EngineUptime" \
--start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" \
--period 60 --namespace "AWS/RDS" --statistics Minimum \
--dimensions Name=DBClusterIdentifier,Value=tpch100g --output text \
| sort -k 3

<table>
<thead>
<tr>
<th>EngineUptime</th>
<th>DATAPOINTS</th>
<th>Start Time</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>63099.0</td>
<td>2021-03-16T12:00+00:00 Seconds</td>
</tr>
<tr>
<td></td>
<td>63159.0</td>
<td>2021-03-16T13:00+00:00 Seconds</td>
</tr>
<tr>
<td></td>
<td>63219.0</td>
<td>2021-03-16T14:00+00:00 Seconds</td>
</tr>
<tr>
<td></td>
<td>63279.0</td>
<td>2021-03-16T15:00+00:00 Seconds</td>
</tr>
<tr>
<td></td>
<td>51.0</td>
<td>2021-03-16T16:00+00:00 Seconds</td>
</tr>
</tbody>
</table>

$ aws cloudwatch get-metric-statistics --metric-name "EngineUptime" \
--start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" \
--period 60 --namespace "AWS/RDS" --statistics Maximum \
--dimensions Name=DBClusterIdentifier,Value=tpch100g --output text \
| sort -k 3

<table>
<thead>
<tr>
<th>EngineUptime</th>
<th>DATAPOINTS</th>
<th>Start Time</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>63389.0</td>
<td>2021-03-16T12:00+00:00 Seconds</td>
</tr>
<tr>
<td></td>
<td>63449.0</td>
<td>2021-03-16T13:00+00:00 Seconds</td>
</tr>
<tr>
<td></td>
<td>63509.0</td>
<td>2021-03-16T14:00+00:00 Seconds</td>
</tr>
<tr>
<td></td>
<td>63569.0</td>
<td>2021-03-16T15:00+00:00 Seconds</td>
</tr>
<tr>
<td></td>
<td>63629.0</td>
<td>2021-03-16T16:00+00:00 Seconds</td>
</tr>
</tbody>
</table>

Then another `reboot-db-instance` command reboots the writer instance of the cluster. Another `wait` command pauses until the writer instance is finished rebooting.

$ aws rds reboot-db-instance --db-instance-identifier instance-1234
{
  "DBInstanceIdentifier": "instance-1234",
  "DBInstanceStatus": "rebooting",
  ...
}

$ aws rds wait db-instance-available --db-instance-id instance-1234

Now the `EngineUptime` metric for the writer instance shows that the instance `instance-1234` was rebooted recently. The reader instance `instance-6305` was also rebooted automatically along with the writer instance. This cluster is running Aurora MySQL 2.09, which doesn't keep the reader instances running as the writer instance reboots.

$ aws cloudwatch get-metric-statistics --metric-name "EngineUptime" \
--start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" \
--period 60 --namespace "AWS/RDS" --statistics Maximum \
--dimensions Name=DBInstanceIdentifier,Value=instance-1234 --output text \
| sort -k 3

<table>
<thead>
<tr>
<th>EngineUptime</th>
<th>DATAPOINTS</th>
<th>Start Time</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>6469.0</td>
<td>2021-03-16T22:00+00:00 Seconds</td>
</tr>
<tr>
<td></td>
<td>63089.0</td>
<td>2021-03-16T23:00+00:00 Seconds</td>
</tr>
<tr>
<td></td>
<td>63069.0</td>
<td>2021-03-16T24:00+00:00 Seconds</td>
</tr>
<tr>
<td></td>
<td>41.0</td>
<td>2021-03-16T25:00+00:00 Seconds</td>
</tr>
<tr>
<td></td>
<td>101.0</td>
<td>2021-03-16T26:00+00:00 Seconds</td>
</tr>
</tbody>
</table>

$ aws cloudwatch get-metric-statistics --metric-name "EngineUptime" \
--start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" \
--period 60 --namespace "AWS/RDS" --statistics Maximum \
--dimensions Name=DBInstanceIdentifier,Value=instance-6305 --output text \
| sort -k 3

<table>
<thead>
<tr>
<th>EngineUptime</th>
<th>DATAPOINTS</th>
<th>Start Time</th>

362
Examples of Aurora reboot operations

The following Aurora MySQL examples show different combinations of reboot operations for reader and writer DB instances in an Aurora DB cluster. After each reboot, SQL queries demonstrate the uptime for the instances in the cluster.

Topics

- **Finding the writer and reader instances for an Aurora cluster** (p. 363)
- **Rebooting a single reader instance** (p. 363)
- **Rebooting the writer instance** (p. 364)
- **Rebooting the writer and readers independently** (p. 365)
- **Applying a cluster parameter change to an Aurora MySQL version 2.10 cluster** (p. 368)

Finding the writer and reader instances for an Aurora cluster

In an Aurora MySQL cluster with multiple DB instances, it's important to know which one is the writer and which ones are the readers. The writer and reader instances also can switch roles when a failover operation happens. Thus, it's best to perform a check like the following before doing any operation that requires a writer or reader instance. In this case, the False values for IsClusterWriter identify the reader instances, instance-6305 and instance-7448. The True value identifies the writer instance, instance-1234.

```
$ aws rds describe-db-clusters --db-cluster-id tpch100g
--query '*[.["Cluster",DBClusterIdentifier,DBClusterMembers[*].["Instance",DBInstanceIdentifier,IsClusterWriter]]" --output text
Cluster:     tpch100g
Instance:    instance-6305    False
Instance:    instance-7448    False
Instance:    instance-1234    True
```

Before we start the examples of rebooting, the writer instance has an uptime of approximately one week. The SQL query in this example shows a MySQL-specific way to check the uptime. You might use this technique in a database application. For another technique that uses the AWS CLI and works for both Aurora engines, see [Checking uptime for Aurora clusters and instances](p. 361).

```
$ mysql -h instance-7448.a12345.us-east-1.rds.amazonaws.com -P 3306 -u my-user -p ...
mysql> select date_sub(now(), interval variable_value second) "Last Startup",
       -> time_format(sec_to_time(variable_value),'%Hh %im') as "Uptime"
       -> from performance_schema.global_status
       -> where variable_name='Uptime';
+-----------------------------+---------+
| Last Startup               | Uptime  |
| 2021-03-08 17:49:06.000000 | 174h 42m|
```

Rebooting a single reader instance

This example reboots one of the reader DB instances. Perhaps this instance was overloaded by a huge query or many concurrent connections. Or perhaps it fell behind the writer instance because of a network issue. After starting the reboot operation, the example uses a `wait` command to pause until the instance becomes available. By that point, the instance has an uptime of a few minutes.
Rebooting the reader instance didn't affect the uptime of the writer instance. It still has an uptime of about one week.

Rebooting the writer instance

This example reboots the writer instance. This cluster is running Aurora MySQL version 2.09. Because the Aurora MySQL version is lower than 2.10, rebooting the writer instance also reboots any reader instances in the cluster.

A wait command pauses until the reboot is finished. Now the uptime for that instance is reset to zero. It's possible that a reboot operation might take substantially different times for writer and reader DB instances. The writer and reader DB instances perform different kinds of cleanup operations depending on their roles.

Rebooting the reader instance

Rebooting the writer instance
### Examples of Aurora reboot operations

<table>
<thead>
<tr>
<th>Last Startup</th>
<th>Uptime</th>
</tr>
</thead>
<tbody>
<tr>
<td>2021-03-16 00:40:27.000000</td>
<td>00h 00m</td>
</tr>
</tbody>
</table>

After the reboot for the writer DB instance, both of the reader DB instances also have their uptime reset. Rebooting the writer instance caused the reader instances to reboot also. This behavior applies to Aurora PostgreSQL clusters and to Aurora MySQL clusters before version 2.10.

```
$ mysql -h instance-7448.a12345.us-east-1.rds.amazonaws.com -P 3306 -u my-user -p
...
mysql> select date_sub(now(), interval variable_value second) "Last Startup",
   -> time_format(sec_to_time(variable_value),'%Hh %im') as "Uptime"
   -> from performance_schema.global_status where variable_name='Uptime';
+----------------------------+---------|
| Last Startup               | Uptime  |
| 2021-03-16 00:40:35.000000 | 00h 00m |
```

```
$ mysql -h instance-6305.a12345.us-east-1.rds.amazonaws.com -P 3306 -u my-user -p
...
mysql> select date_sub(now(), interval variable_value second) "Last Startup",
   -> time_format(sec_to_time(variable_value),'%Hh %im') as "Uptime"
   -> from performance_schema.global_status where variable_name='Uptime';
+----------------------------+---------|
| Last Startup               | Uptime  |
| 2021-03-16 00:40:33.000000 | 00h 01m |
```

### Rebooting the writer and readers independently

These next examples show a cluster that runs Aurora MySQL version 2.10. In this Aurora MySQL version and higher, you can reboot the writer instance without causing reboots for all the reader instances. That way, your query-intensive applications don't experience any outage when you reboot the writer instance. You can reboot the reader instances later. You might do those reboots at a time of low query traffic. You might also reboot the reader instances one at a time. That way, at least one reader instance is always available for the query traffic of your application.

The following example uses a cluster named cluster-2393, running Aurora MySQL version 5.7.mysqlaurora.2.10.0. This cluster has a writer instance named instance-9404 and three reader instances named instance-6772, instance-2470, and instance-5138.

```
$ aws rds describe-db-clusters --db-cluster-id cluster-2393
  --query '[][].['Cluster:',DBClusterIdentifier,DClusterMembers[*].['Instance:',DBInstanceIdentifier,IsClusterWriter]]'
  --output text
Cluster:   cluster-2393
Instance:  instance-5138 False
Instance:  instance-6772 False
Instance:  instance-9404 True
```

Checking the uptime value of each database instance through the `mysql` command shows that each one has roughly the same uptime. For example, here is the uptime for instance-5138.

```
mysql> SHOW GLOBAL STATUS LIKE 'uptime';
+--------------------------+
| uptime                   |
| 2021-03-16 00:40:27.000000 | 00h 00m |
+--------------------------+
```
On choosing CloudWatch, we can get the corresponding uptime information without actually logging into the instances. That way, an administrator can monitor the database but can’t view or change any table data. In this case, we specify a time period spanning five minutes, and check the uptime value every minute. The increasing uptime values demonstrate that the instances weren’t restarted during that period.

```
$ aws cloudwatch get-metric-statistics --metric-name "EngineUptime" \
    --start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" --period 60 \
    --namespace "AWS/RDS" --statistics Minimum --dimensions \
    Name=DBInstanceIdentifier,Value=instance-9404 \
    --output text | sort -k 3
```

```
EngineUptime
DATAPoints 4648.0 2021-03-17T23:42:00+00:00 Seconds
DATAPoints 4708.0 2021-03-17T23:43:00+00:00 Seconds
DATAPoints 4768.0 2021-03-17T23:44:00+00:00 Seconds
DATAPoints 4828.0 2021-03-17T23:45:00+00:00 Seconds
DATAPoints 4888.0 2021-03-17T23:46:00+00:00 Seconds
```

```
$ aws cloudwatch get-metric-statistics --metric-name "EngineUptime" \
    --start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" --period 60 \
    --namespace "AWS/RDS" --statistics Minimum --dimensions \
    Name=DBInstanceIdentifier,Value=instance-6772 \
    --output text | sort -k 3
```

```
EngineUptime

DATAPoints 4555.0 2021-03-17T23:46:00+00:00 Seconds
```

Now we reboot one of the reader instances, instance-5138. We wait for the instance to become available again after the reboot. Now monitoring the uptime over a five-minute period shows that the uptime was reset to zero during that time. The most recent uptime value was measured five seconds after the reboot finished.

```
$ aws rds reboot-db-instance --db-instance-identifier instance-5138
{
    "DBInstanceIdentifier": "instance-5138",
    "DBInstanceStatus": "rebooting"
}
$ aws rds wait db-instance-available --db-instance-id instance-5138
```

```
$ aws cloudwatch get-metric-statistics --metric-name "EngineUptime" \
    --start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" --period 60 \
    --namespace "AWS/RDS" --statistics Minimum --dimensions \
    Name=DBInstanceIdentifier,Value=instance-5138 \
    --output text | sort -k 3
```

```
EngineUptime
DATAPoints 4500.0 2021-03-17T23:46:00+00:00 Seconds

DATAPoints 4680.0 2021-03-17T23:49:00+00:00 Seconds
DATAPoints  5.0 2021-03-17T23:50:00+00:00 Seconds
```

Next, we perform a reboot for the writer instance, instance-9404. We compare the uptime values for the writer instance and one of the reader instances. By doing so, we can see that rebooting the writer

---

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Uptime</td>
<td>3866</td>
</tr>
<tr>
<td>---------------</td>
<td>-------</td>
</tr>
</tbody>
</table>
Examples of Aurora reboot operations

didn't cause a reboot for the readers. In versions before Aurora MySQL 2.10, the uptime values for all the readers would be reset at the same time as the writer.

```bash
$ aws rds reboot-db-instance --db-instance-identifier instance-9404
{
  "DBInstanceIdentifier": "instance-9404",
  "DBInstanceStatus": "rebooting"
}

$ aws rds wait db-instance-available --db-instance-id instance-9404

$ aws cloudwatch get-metric-statistics --metric-name "EngineUptime" --start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" --period 60 --namespace "AWS/RDS" --statistics Minimum --dimensions Name=DBInstanceIdentifier,Value=instance-9404 --output text | sort -k 3

<table>
<thead>
<tr>
<th>EngineUptime</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>371.0</td>
<td>2021-03-17T23:57:00+00:00 Seconds</td>
<td></td>
</tr>
<tr>
<td>431.0</td>
<td>2021-03-17T23:58:00+00:00 Seconds</td>
<td></td>
</tr>
<tr>
<td>491.0</td>
<td>2021-03-17T23:59:00+00:00 Seconds</td>
<td></td>
</tr>
<tr>
<td>551.0</td>
<td>2021-03-18T00:00:00+00:00 Seconds</td>
<td></td>
</tr>
</tbody>
</table>

$ aws cloudwatch get-metric-statistics --metric-name "EngineUptime" --start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" --period 60 --namespace "AWS/RDS" --statistics Minimum --dimensions Name=DBInstanceIdentifier,Value=instance-6772 --output text | sort -k 3

<table>
<thead>
<tr>
<th>EngineUptime</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>37.0</td>
<td>2021-03-18T00:01:00+00:00 Seconds</td>
<td></td>
</tr>
</tbody>
</table>

To make sure that all the reader instances have all the same changes to configuration parameters as the writer instance, reboot all the reader instances after the writer. This example reboots all the readers and then waits until all of them are available before proceeding.

```bash
$ aws rds reboot-db-instance --db-instance-identifier instance-6772
{
  "DBInstanceIdentifier": "instance-6772",
  "DBInstanceStatus": "rebooting"
}

$ aws rds reboot-db-instance --db-instance-identifier instance-2470
{
  "DBInstanceIdentifier": "instance-2470",
  "DBInstanceStatus": "rebooting"
}

$ aws rds reboot-db-instance --db-instance-identifier instance-5138
{
  "DBInstanceIdentifier": "instance-5138",
  "DBInstanceStatus": "rebooting"
}

$ aws rds wait db-instance-available --db-instance-id instance-6772
$ aws rds wait db-instance-available --db-instance-id instance-2470
$ aws rds wait db-instance-available --db-instance-id instance-5138

Now we can see that the writer DB instance has the highest uptime. This instance's uptime value increased steadily throughout the monitoring period. The reader DB instances were all rebooted after

367
the reader. We can see the point within the monitoring period when each reader was rebooted and its uptime was reset to zero.

```
$ aws cloudwatch get-metric-statistics --metric-name "EngineUptime" \
    --start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" --period 60 \ 
    --namespace "AWS/RDS" --statistics Minimum --dimensions
    Name=DBInstanceIdentifier,Value=instance-9404 \
    --output text | sort -k 3
```

```

Applying a cluster parameter change to an Aurora MySQL version 2.10 cluster

The following example demonstrates how to apply a parameter change to all DB instances in your Aurora MySQL 2.10 cluster. With this Aurora MySQL version, you reboot the writer instance and all the reader instances independently.

The example uses the MySQL configuration parameter lower_case_table_names for illustration. When this parameter setting is different between the writer and reader DB instances, a query might not be able to access a table declared with an uppercase or mixed-case name. Or if two table names differ only in terms of uppercase and lowercase letters, a query might access the wrong table.

This example shows how to determine the writer and reader instances in the cluster by examining the IsClusterWriter attribute of each instance. The cluster is named cluster-2393. The cluster has a writer instance named instance-9404. The reader instances in the cluster are named instance-5138 and instance-2470.

```
$ aws rds describe-db-clusters --db-cluster-id cluster-2393 \
    --query '[].[DBClusterIdentifier, DBClusterMembers[*].
    [DBInstanceIdentifier,IsClusterWriter]]' \
    --output text
cluster-2393
```

```
cluster-2393
```

```
```

368
Examples of Aurora reboot operations

To demonstrate the effects of changing the lower_case_table_names parameter, we set up two DB cluster parameter groups. The lower_case_table_names=0 parameter group has this parameter set to 0. The lower_case_table_names=1 parameter group has this parameter group set to 1.

```
$ aws rds create-db-cluster-parameter-group --description 'lower-case-table-names-0' --db-parameter-group-family aurora-mysql5.7 --db-cluster-parameter-group-name lower-case-table-names-0
{
    "DBClusterParameterGroup": {
        "DBClusterParameterGroupName": "lower-case-table-names-0",
        "DBParameterGroupFamily": "aurora-mysql5.7",
        "Description": "lower-case-table-names-0"
    }
}

$ aws rds create-db-cluster-parameter-group --description 'lower-case-table-names-1' --db-parameter-group-family aurora-mysql5.7 --db-cluster-parameter-group-name lower-case-table-names-1
{
    "DBClusterParameterGroup": {
        "DBClusterParameterGroupName": "lower-case-table-names-1",
        "DBParameterGroupFamily": "aurora-mysql5.7",
        "Description": "lower-case-table-names-1"
    }
}

$ aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name lower-case-table-names-0 --parameters ParameterName=lower_case_table_names,ParameterValue=0,ApplyMethod=pending-reboot
{
    "DBClusterParameterGroupName": "lower-case-table-names-0"
}

$ aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name lower-case-table-names-1 --parameters ParameterName=lower_case_table_names,ParameterValue=1,ApplyMethod=pending-reboot
{
    "DBClusterParameterGroupName": "lower-case-table-names-1"
}
```

The default value of lower_case_table_names is 0. With this parameter setting, the table foo is distinct from the table F00. This example verifies that the parameter is still at its default setting. Then the example creates three tables that differ only in uppercase and lowercase letters in their names.

```
mysql> create database lctn;
Query OK, 1 row affected (0.07 sec)

mysql> use lctn;
Database changed
mysql> select @@lower_case_table_names;
+--------------------------+
<table>
<thead>
<tr>
<th>@@lower_case_table_names</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
+--------------------------+
mysql> create table foo (s varchar(128));
```
Examples of Aurora reboot operations

```
mysql> insert into foo values ('Lowercase table name foo');
mysql> create table Foo (s varchar(128));
mysql> insert into Foo values ('Mixed-case table name Foo');
mysql> create table FOO (s varchar(128));
mysql> insert into FOO values ('Uppercase table name FOO');
mysql> select * from foo;
+--------------------------+
| s                        |
| +--------------------------+
| Lowercase table name foo |
+--------------------------+
mysql> select * from Foo;
+---------------------------+
| s                         |
| +---------------------------+
| Mixed-case table name Foo |
+---------------------------+
mysql> select * from FOO;
+--------------------------+
| s                        |
+--------------------------+
| Uppercase table name FOO |
+--------------------------+
```

Next, we associate the DB parameter group with the cluster to set the `lower_case_table_names` parameter to 1. This change only takes effect after each DB instance is rebooted.

```
$ aws rds modify-db-cluster --db-cluster-identifier cluster-2393 --db-cluster-parameter-group-name lower-case-table-names-1
{
  "DBClusterIdentifier": "cluster-2393",
  "DBClusterParameterGroup": "lower-case-table-names-1",
  "Engine": "aurora-mysql",
  "EngineVersion": "5.7.mysql_aurora.2.10.0"
}
```

The first reboot we do is for the writer DB instance. Then we wait for the instance to become available again. At that point, we connect to the writer endpoint and verify that the writer instance has the changed parameter value. The `SHOW TABLES` command confirms that the database contains the three different tables. However, queries that refer to tables named `foo`, `Foo`, or `FOO` all access the table whose name is all-lowercase, `foo`.

```
# Rebooting the writer instance
$ aws rds reboot-db-instance --db-instance-identifier instance-9404
$ aws rds wait db-instance-available --db-instance-id instance-9404
```

Now, queries using the cluster endpoint show the effects of the parameter change. Whether the table name in the query is uppercase, lowercase, or mixed case, the SQL statement accesses the table whose name is all lowercase.

```
mysql> select @@lower_case_table_names;
+--------------------------+
| @@lower_case_table_names |
| +--------------------------+
| 1                        |
+--------------------------+
```
Examples of Aurora reboot operations

The next example shows the same queries as the previous one. In this case, the queries use the reader endpoint and run on one of the reader DB instances. Those instances haven't been rebooted yet. Thus, they still have the original setting for the `lower_case_table_names` parameter. That means that queries can access each of the `foo`, `Foo`, and `FOO` tables.

```
mysql> select @@lower_case_table_names;
+--------------------------+
| @@lower_case_table_names |
+--------------------------+
|                        0 |
+--------------------------+
mysql> use lctn;
mysql> select * from foo;
+--------------------------+
| s                        |
+--------------------------+
| Lowercase table name foo |
+--------------------------+
mysql> select * from Foo;
+---------------------------+
| s                         |
+---------------------------+
| Mixed-case table name Foo |
+---------------------------+
mysql> select * from FOO;
+--------------------------+
| s                        |
+--------------------------+
```

371
Next, we reboot one of the reader instances and wait for it to become available again.

$ aws rds reboot-db-instance --db-instance-identifier instance-2470

```json
{
  "DBInstanceIdentifier": "instance-2470",
  "DBInstanceStatus": "rebooting"
}
```

$ aws rds wait db-instance-available --db-instance-id instance-2470

While connected to the instance endpoint for instance-2470, a query shows that the new parameter is in effect.

```
mysql> select @@lower_case_table_names;
+--------------------------+--------------------------+
|@@lower_case_table_names |
+--------------------------+--------------------------+
|                        1 |
+--------------------------+--------------------------+
```

At this point, the two reader instances in the cluster are running with different lower_case_table_names settings. Thus, any connection to the reader endpoint of the cluster uses a value for this setting that's unpredictable. It's important to immediately reboot the other reader instance so that they both have consistent settings.

$ aws rds reboot-db-instance --db-instance-identifier instance-5138

```json
{
  "DBInstanceIdentifier": "instance-5138",
  "DBInstanceStatus": "rebooting"
}
```

$ aws rds wait db-instance-available --db-instance-id instance-5138

The following example confirms that all the reader instances have the same setting for the lower_case_table_names parameter. The commands check the lower_case_table_names setting value on each reader instance. Then the same command using the reader endpoint demonstrates that each connection to the reader endpoint uses one of the reader instances, but which one isn't predictable.

# Check lower_case_table_names setting on each reader instance.

```
$ mysql -h instance-5138.a12345.us-east-1.rds.amazonaws.com \
   -u my-user -p -e 'select @@aurora_server_id, @@lower_case_table_names' \
   +-------------------------------+-------------------------------+
   |@@aurora_server_id |@@lower_case_table_names |
   +-------------------------------+-------------------------------+
   | instance-5138              | 1                           |
   +-------------------------------+-------------------------------+
$ mysql -h instance-2470.a12345.us-east-1.rds.amazonaws.com \
   -u my-user -p -e 'select @@aurora_server_id, @@lower_case_table_names' \
   +-------------------------------+-------------------------------+
   |@@aurora_server_id |@@lower_case_table_names |
   +-------------------------------+-------------------------------+
   | instance-2470              | 1                           |
   +-------------------------------+-------------------------------+
```

# Check lower_case_table_names setting on the reader endpoint of the cluster.

```
$ mysql -h cluster-2393.cluster-ro-a12345.us-east-1.rds.amazonaws.com \
```
Examples of Aurora reboot operations

- **-u my-user -p -e 'select @@aurora_server_id, @@lower_case_table_names'

+--------------------------+--------------------------+
| @@aurora_server_id       | @@lower_case_table_names |
+--------------------------+--------------------------+
| instance-5138            |                        1 |
+--------------------------+--------------------------+

# Run query on writer instance

$ mysql -h cluster-2393.cluster-a12345.us-east-1.rds.amazonaws.com \
   -u my-user -p -e 'select @@aurora_server_id, @@lower_case_table_names'

+--------------------------+--------------------------+
| @@aurora_server_id       | @@lower_case_table_names |
+--------------------------+--------------------------+
| instance-9404            |                        1 |
+--------------------------+--------------------------+

With the parameter change applied everywhere, we can see the effect of setting `lower_case_table_names=1`. Whether the table is referred to as foo, Foo, or FOO the query converts the name to `foo` and accesses the same table in each case.

mysql> use lctn;

mysql> select * from foo;
+--------------------------+
| s                        |
| Lowercase table name foo |
+--------------------------+

mysql> select * from Foo;
+--------------------------+
| s                        |
| Lowercase table name foo |
+--------------------------+

mysql> select * from FOO;
+--------------------------+
| s                        |
| Lowercase table name foo |
+--------------------------+

373
Deleting Aurora DB clusters and DB instances

You can delete an Aurora DB cluster when you no longer need it. Deleting the cluster removes the cluster volume containing all your data. Before deleting the cluster, you can save a snapshot of your data. You can restore the snapshot later to create a new cluster containing the same data.

You can also delete DB instances from a cluster while preserving the cluster itself and the data that it contains. Deleting DB instances can help you reduce your charges if the cluster isn’t busy, or you don’t need the computation capacity of multiple DB instances.

Topics
- Deleting an Aurora DB cluster (p. 374)
- Deletion protection for Aurora clusters (p. 379)
- Deleting a stopped Aurora cluster (p. 379)
- Deleting Aurora MySQL clusters that are read replicas (p. 379)
- The final snapshot when deleting a cluster (p. 380)
- Deleting a DB instance from an Aurora DB cluster (p. 380)

Deleting an Aurora DB cluster

Aurora doesn’t provide a single-step method to delete a DB cluster. This design choice is intended to prevent you from accidentally losing data or taking your application offline. Aurora applications are typically mission-critical and require high availability. Thus, Aurora makes it easy to scale the capacity of the cluster up and down by adding and removing DB instances. Removing the DB cluster itself requires you to make a separate deletion.

Use the following general procedure to remove all the DB instances from a cluster and then delete the cluster itself.

1. Delete any reader instances in the cluster. Use the procedure in Deleting a DB instance from an Aurora DB cluster (p. 380).

   If the cluster has any reader instances, deleting one of the instances only reduces the computation capacity of the cluster. Deleting the reader instances first ensures that the cluster remains available throughout the procedure and doesn’t perform unnecessary failover operations.

2. Delete the writer instance from the cluster. Again, use the procedure in Deleting a DB instance from an Aurora DB cluster (p. 380).

   When you delete the DB instances, the cluster and its associated cluster volume remain even after you delete all the DB instances.

3. Delete the DB cluster.
   - AWS Management Console – Choose the cluster, then choose Delete from the Actions menu. You can choose the following options to preserve the data from the cluster in case you need it later:
     - Create a final snapshot of the cluster volume. The default setting is to create a final snapshot.
     - Retain automated backups. The default setting is not to retain automated backups.

       Note
       Automated backups for Aurora Serverless v1 DB clusters aren’t retained.

   Aurora also requires you to confirm that you intend to delete the cluster.
   - CLI and API – Call the delete-db-cluster CLI command or DeleteDBCluster API operation. You can choose the following options to preserve the data from the cluster in case you need it later:
     - Create a final snapshot of the cluster volume.
Retain automated backups.

**Note**
Automated backups for Aurora Serverless v1 DB clusters aren't retained.

**Topics**
- Deleting an empty Aurora cluster (p. 375)
- Deleting an Aurora cluster with a single DB instance (p. 376)
- Deleting an Aurora cluster with multiple DB instances (p. 377)

### Deleting an empty Aurora cluster

You can delete an empty DB cluster using the AWS Management Console, AWS CLI, or Amazon RDS API.

**Tip**
You can keep a cluster with no DB instances to preserve your data without incurring CPU charges for the cluster. You can quickly start using the cluster again by creating one or more new DB instances for the cluster. You can perform Aurora-specific administrative operations on the cluster while it doesn't have any associated DB instances. You just can't access the data or perform any operations that require connecting to a DB instance.

**Console**

**To delete a DB cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB cluster that you want to delete.
3. For **Actions**, choose **Delete**.
4. To create a final DB snapshot for the DB cluster, choose **Create final snapshot?**. This is the default setting.
5. If you chose to create a final snapshot, enter the **Final snapshot name**.
6. To retain automated backups, choose **Retain automated backups**. This is not the default setting.
7. Enter **delete me** in the box.
8. Choose **Delete**.

**CLI**

To delete an empty Aurora DB cluster by using the AWS CLI, call the `delete-db-cluster` command.

Suppose that the empty cluster `deleteme-zero-instances` was only used for development and testing and doesn't contain any important data. In that case, you don't need to preserve a snapshot of the cluster volume when you delete the cluster. The following example demonstrates that a cluster doesn't contain any DB instances, and then deletes the empty cluster without creating a final snapshot or retaining automated backups.

```
$ aws rds describe-db-clusters --db-cluster-identifier deleteme-zero-instances --output text \
   --query '[].["Cluster:",DBClusterIdentifier,DBClusterMembers[*]."Instance:",DBInstanceIdentifier,IsClusterWriter]]
Cluster: deleteme-zero-instances
$ aws rds delete-db-cluster --db-cluster-identifier deleteme-zero-instances \
```
Deleting an Aurora DB cluster

```json

--skip-final-snapshot \
--delete-automated-backups
{
  "DBClusterIdentifier": "deleteme-zero-instances",
  "Status": "available",
  "Engine": "aurora-mysql"
}
```

RDS API

To delete an empty Aurora DB cluster by using the Amazon RDS API, call the `DeleteDBCluster` operation.

Deleting an Aurora cluster with a single DB instance

You can delete the last DB instance, even if the DB cluster has deletion protection enabled. In this case, the DB cluster itself still exists and your data is preserved. You can access the data again by attaching a new DB instance to the cluster.

The following example shows how the `delete-db-cluster` command doesn't work when the cluster still has any associated DB instances. This cluster has a single writer DB instance. When we examine the DB instances in the cluster, we check the `IsClusterWriter` attribute of each one. The cluster could have zero or one writer DB instance. A value of `true` signifies a writer DB instance. A value of `false` signifies a reader DB instance. The cluster could have zero, one, or many reader DB instances. In this case, we delete the writer DB instance using the `delete-db-instance` command. As soon as the DB instance goes into deleting state, we can delete the cluster also. For this example also, suppose that the cluster doesn't contain any data worth preserving. Therefore, we don't create a snapshot of the cluster volume or retain automated backups.

```bash
$ aws rds delete-db-cluster --db-cluster-identifier deleteme-writer-only --skip-final-snapshot
An error occurred (InvalidDBClusterStateFault) when calling the DeleteDBCluster operation: Cluster cannot be deleted, it still contains DB instances in non-deleting state.

$ aws rds describe-db-clusters --db-cluster-identifier deleteme-writer-only \
--query '[*].[DBClusterIdentifier,Status,DBClusterMembers[*].DBInstanceIdentifier,IsClusterWriter]]' 
[ 
  ["deleteme-writer-only", "available", 
  ["instance-2130", true 
  ] 
  ]
]

$ aws rds delete-db-instance --db-instance-identifier instance-2130
{
  "DBInstanceIdentifier": "instance-2130",
  "DBInstanceStatus": "deleting",
  "Engine": "aurora-mysql"
}

$ aws rds delete-db-cluster --db-cluster-identifier deleteme-writer-only \
--skip-final-snapshot \
--delete-automated-backups
{
  "DBClusterIdentifier": "deleteme-writer-only",
  "Status": "available",
}
```
Deleting an Aurora DB cluster

If your cluster contains multiple DB instances, typically there is a single writer instance and one or more reader instances. The reader instances help with high availability, by being on standby to take over if the writer instance encounters a problem. You can also use reader instances to scale the cluster up to handle a read-intensive workload without adding overhead to the writer instance.

To delete a cluster with multiple reader DB instances, you delete the reader instances first and then the writer instance. Deleting the writer instance leaves the cluster and its data in place. You delete the cluster through a separate action.

- For the procedure to delete an Aurora DB instance, see Deleting a DB instance from an Aurora DB cluster (p. 380).
- For the procedure to delete the writer DB instance in an Aurora cluster, see Deleting an Aurora cluster with a single DB instance (p. 376).
- For the procedure to delete an empty Aurora cluster, see Deleting an empty Aurora cluster (p. 375).

This CLI example shows how to delete a cluster containing both a writer DB instance and a single reader DB instance. The describe-db-clusters output shows that instance-7384 is the writer instance and instance-1039 is the reader instance. The example deletes the reader instance first, because deleting the writer instance while a reader instance still existed would cause a failover operation. It doesn't make sense to promote the reader instance to a writer if you plan to delete that instance also. Again, suppose that these db.t2.small instances are only used for development and testing, and so the delete operation skips the final snapshot and doesn't retain automated backups.

```bash
$ aws rds delete-db-cluster --db-cluster-identifier deleteme-writer-and-reader --skip-final-snapshot
An error occurred (InvalidDBClusterStateFault) when calling the DeleteDBCluster operation: Cluster cannot be deleted, it still contains DB instances in non-deleting state.

$ aws rds describe-db-clusters --db-cluster-identifier deleteme-writer-and-reader --output text
  --query '[].["Cluster":DBClusterIdentifier,DBC ClusterMembers[*].
  ["Instance":DBInstanceIdentifier,IsClusterWriter]]
Cluster: deleteme-writer-and-reader
Instance: instance-1039 False
Instance: instance-7384 True

$ aws rds delete-db-instance --db-instance-identifier instance-1039
{
  "DBInstanceIdentifier": "instance-1039",
  "DBInstanceStatus": "deleting",
  "Engine": "aurora-mysql"
}

$ aws rds delete-db-instance --db-instance-identifier instance-7384
{
  "DBInstanceIdentifier": "instance-7384",
  "DBInstanceStatus": "deleting",
  "Engine": "aurora-mysql"
}

$ aws rds delete-db-cluster --db-cluster-identifier deleteme-writer-and-reader \
  --skip-final-snapshot \ 
  --delete-automated-backups
```

The following example shows how to delete a DB cluster containing a writer DB instance and multiple reader DB instances. It uses concise output from the describe-db-clusters command to get a report of the writer and reader instances. Again, we delete all reader DB instances before deleting the writer DB instance. It doesn't matter what order we delete the reader DB instances in.

Suppose that this cluster with several DB instances does contain data worth preserving. Thus, the delete-db-cluster command in this example includes the --no-skip-final-snapshot and --final-db-snapshot-identifier parameters to specify the details of the snapshot to create. It also includes the --no-delete-automated-backups parameter to retain automated backups.

```bash
$ aws rds describe-db-clusters --db-cluster-identifier deleteme-multiple-readers --output text --query '[].["Cluster":DBClusterIdentifier,DBClusterMembers[*]."Instance":DBInstanceIdentifier,IsClusterWriter]
Cluster: deleteme-multiple-readers
Instance: instance-1010 False
Instance: instance-5410 False
Instance: instance-9948 False
Instance: instance-8451 True
$ aws rds delete-db-instance --db-instance-identifier instance-1010
{
  "DBInstanceIdentifier": "instance-1010",
  "DBInstanceStatus": "deleting",
  "Engine": "aurora-mysql"
}
$ aws rds delete-db-instance --db-instance-identifier instance-5410
{
  "DBInstanceIdentifier": "instance-5410",
  "DBInstanceStatus": "deleting",
  "Engine": "aurora-mysql"
}
$ aws rds delete-db-instance --db-instance-identifier instance-9948
{
  "DBInstanceIdentifier": "instance-9948",
  "DBInstanceStatus": "deleting",
  "Engine": "aurora-mysql"
}
$ aws rds delete-db-instance --db-instance-identifier instance-8451
{
  "DBInstanceIdentifier": "instance-8451",
  "DBInstanceStatus": "deleting",
  "Engine": "aurora-mysql"
}
$ aws rds delete-db-cluster --db-cluster-identifier deleteme-multiple-readers \
--no-delete-automated-backups \
--no-skip-final-snapshot \
--final-db-snapshot-identifier deleteme-multiple-readers-final-snapshot
{
  "DBClusterIdentifier": "deleteme-multiple-readers",
  "Status": "available",
  "Engine": "aurora-mysql"
}
```
The following example shows how to confirm that Aurora created the requested snapshot. You can request details for the specific snapshot by specifying its identifier `deleteme-multiple-readers-final-snapshot`. You can also get a report of all snapshots for the cluster that was deleted by specifying the cluster identifier `deleteme-multiple-readers`. Both of those commands return information about the same snapshot.

```bash
$ aws rds describe-db-cluster-snapshots --db-cluster-snapshot-identifier deleteme-multiple-readers-final-snapshot
{
  "DBClusterSnapshots": [
    {
      "AvailabilityZones": [],
      "DBClusterSnapshotIdentifier": "deleteme-multiple-readers-final-snapshot",
      "DBClusterIdentifier": "deleteme-multiple-readers",
      "SnapshotCreateTime": "11T01:40:07.354000+00:00",
      "Engine": "aurora-mysql",
      ...
    }
  ]
}
```

```bash
$ aws rds describe-db-cluster-snapshots --db-cluster-identifier deleteme-multiple-readers
{
  "DBClusterSnapshots": [
    {
      "AvailabilityZones": [],
      "DBClusterSnapshotIdentifier": "deleteme-multiple-readers-final-snapshot",
      "DBClusterIdentifier": "deleteme-multiple-readers",
      "SnapshotCreateTime": "11T01:40:07.354000+00:00",
      "Engine": "aurora-mysql",
      ...
    }
  ]
}
```

**Deletion protection for Aurora clusters**

You can't delete clusters that have deletion protection enabled. You can delete DB instances within the cluster, but not the cluster itself. That way, the cluster volume containing all your data is safe from accidental deletion. Aurora enforces deletion protection for a DB cluster whether you try to delete the cluster using the console, the AWS CLI, or the RDS API.

Deletion protection is enabled by default when you create a production DB cluster using the AWS Management Console. However, deletion protection is disabled by default if you create a cluster using the AWS CLI or API. Enabling or disabling deletion protection doesn't cause an outage. To be able to delete the cluster, modify the cluster and disable deletion protection. For more information about turning deletion protection on and off, see [Modifying the DB cluster by using the console, CLI, and API](p. 269).

**Tip**

Even if all the DB instances are deleted, you can access the data by creating a new DB instance in the cluster.

**Deleting a stopped Aurora cluster**

You can't delete a cluster if it's in the stopped state. In this case, start the cluster before deleting it. For more information, see [Starting an Aurora DB cluster](p. 251).

**Deleting Aurora MySQL clusters that are read replicas**

For Aurora MySQL, you can't delete a DB instance in a DB cluster if both of the following conditions are true:

- The DB cluster is a read replica of another Aurora DB cluster.
• The DB instance is the only instance in the DB cluster.

To delete a DB instance in this case, first promote the DB cluster so that it's no longer a read replica. After the promotion completes, you can delete the final DB instance in the DB cluster. For more information, see Replicating Amazon Aurora MySQL DB clusters across AWS Regions (p. 1005).

The final snapshot when deleting a cluster

Throughout this section, the examples show how you can choose whether to take a final snapshot when you delete an Aurora cluster. If you choose to take a final snapshot but the name you specify matches an existing snapshot, the operation stops with an error. In this case, examine the snapshot details to confirm if it represents your current detail or if it is an older snapshot. If the existing snapshot doesn't have the latest data that you want to preserve, rename the snapshot and try again, or specify a different name for the final snapshot parameter.

Deleting a DB instance from an Aurora DB cluster

You can delete a DB instance from an Aurora DB cluster as part of the process of deleting the entire cluster. If your cluster contains a certain number of DB instances, then deleting the cluster requires deleting each of those DB instances. You can also delete one or more reader instances from a cluster while leaving the cluster running. You might do so to reduce compute capacity and associated charges if your cluster isn’t busy.

To delete a DB instance, you specify the name of the instance.

You can delete a DB instance using the AWS Management Console, the AWS CLI, or the RDS API.

Note
When an Aurora Replica is deleted, its instance endpoint is removed immediately, and the Aurora Replica is removed from the reader endpoint. If there are statements running on the Aurora Replica that is being deleted, there is a three-minute grace period. Existing statements can finish during the grace period. When the grace period ends, the Aurora Replica is shut down and deleted.

For Aurora DB clusters, deleting a DB instance doesn't necessarily delete the entire cluster. You can delete a DB instance in an Aurora cluster to reduce compute capacity and associated charges when the cluster isn't busy. For information about the special circumstances for Aurora clusters that have one DB instance or zero DB instances, see Deleting an Aurora cluster with a single DB instance (p. 376) and Deleting an empty Aurora cluster (p. 375).

Note
You can't delete a DB cluster when deletion protection is enabled for it. For more information, see Deletion protection for Aurora clusters (p. 379). You can disable deletion protection by modifying the DB cluster. For more information, see Modifying an Amazon Aurora DB cluster (p. 269).

Console

To delete a DB instance in a DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance that you want to delete.
3. For Actions, choose Delete.
4. Enter delete me in the box.
5. Choose Delete.
AWS CLI

To delete a DB instance by using the AWS CLI, call the `delete-db-instance` command and specify the `--db-instance-identifier` value.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds delete-db-instance \
  --db-instance-identifier mydbinstance
```

For Windows:

```bash
aws rds delete-db-instance ^
  --db-instance-identifier mydbinstance
```

RDS API

To delete a DB instance by using the Amazon RDS API, call the `DeleteDBInstance` operation and specify the `DBInstanceIdentifier` parameter.

**Note**

When the status for a DB instance is `deleting`, its CA certificate value doesn't appear in the RDS console or in output for AWS CLI commands or RDS API operations. For more information about CA certificates, see [*Using SSL/TLS to encrypt a connection to a DB cluster*](#).
Tagging Amazon RDS resources

You can use Amazon RDS tags to add metadata to your Amazon RDS resources. You can use the tags to add your own notations about database instances, snapshots, Aurora clusters, and so on. Doing so can help you to document your Amazon RDS resources. You can also use the tags with automated maintenance procedures.

In particular, you can use these tags with IAM policies. You can use them to manage access to RDS resources and to control what actions can be applied to the RDS resources. You can also use these tags to track costs by grouping expenses for similarly tagged resources.

You can tag the following Amazon RDS resources:

- DB instances
- DB clusters
- Read replicas
- DB snapshots
- DB cluster snapshots
- Reserved DB instances
- Event subscriptions
- DB option groups
- DB parameter groups
- DB cluster parameter groups
- DB subnet groups
- RDS Proxies
- RDS Proxy endpoints
- Blue/green deployments
- Zero-ETL integrations (preview)

**Note**
Currently, you can't tag RDS Proxies and RDS Proxy endpoints by using the AWS Management Console.

Topics
- Overview of Amazon RDS resource tags (p. 382)

- Using tags to produce detailed billing reports (p. 383)
- Adding, listing, and removing tags (p. 384)
- Using the AWS Tag Editor (p. 386)
- Copying tags to DB cluster snapshots (p. 386)
- Tutorial: Use tags to specify which Aurora DB clusters to stop (p. 387)

Overview of Amazon RDS resource tags

An Amazon RDS tag is a name-value pair that you define and associate with an Amazon RDS resource. The name is referred to as the key. Supplying a value for the key is optional. You can use tags to assign arbitrary information to an Amazon RDS resource. You can use a tag key, for example, to define a category, and the tag value might be an item in that category. For example, you might define a tag key of "project" and a tag value of "Salix". In this case, these indicate that the Amazon RDS resource is
assigned to the Salix project. You can also use tags to designate Amazon RDS resources as being used for test or production by using a key such as environment=test or environment=production. We recommend that you use a consistent set of tag keys to make it easier to track metadata associated with Amazon RDS resources.

In addition, you can use conditions in your IAM policies to control access to AWS resources based on the tags on that resource. You can do this by using the global aws:ResourceTag/tag-key condition key. For more information, see Controlling access to AWS resources in the AWS Identity and Access Management User Guide.

Each Amazon RDS resource has a tag set, which contains all the tags that are assigned to that Amazon RDS resource. A tag set can contain as many as 50 tags, or it can be empty. If you add a tag to an RDS resource with the same key as an existing resource tag, the new value overwrites the old.

AWS doesn’t apply any semantic meaning to your tags; tags are interpreted strictly as character strings. RDS can set tags on a DB instance or other RDS resources. Tag setting depends on the options that you use when you create the resource. For example, Amazon RDS might add a tag indicating that a DB instance is for production or for testing.

- The tag key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with aws: or rds:. The string can contain only the set of Unicode letters, digits, white space, '-', ',', ';', '/', '=', '+', '-', '@' (Java regex: "^[\p{L}\p{Z}\p{N}_.:/=+\-@]*$").

- The tag value is an optional string value of the tag. The string value can be from 1 to 256 Unicode characters in length. The string can contain only the set of Unicode letters, digits, white space, '-', ',', ';', '/', '=', '+', '-', '@' (Java regex: "^[\p{L}\p{Z}\p{N}_.:/=+\-@]*$").

Values do not have to be unique in a tag set and can be null. For example, you can have a key-value pair in a tag set of project=Trinity and cost-center=Trinity.

You can use the AWS Management Console, the AWS CLI, or the Amazon RDS API to add, list, and delete tags on Amazon RDS resources. When using the CLI or API, make sure to provide the Amazon Resource Name (ARN) for the RDS resource to work with. For more information about constructing an ARN, see Constructing an ARN for Amazon RDS (p. 390).

Tags are cached for authorization purposes. Because of this, additions and updates to tags on Amazon RDS resources can take several minutes before they are available.

Using tags for access control with IAM

You can use tags with IAM policies to manage access to Amazon RDS resources. You can also use tags to control what actions can be applied to the Amazon RDS resources.

For information on managing access to tagged resources with IAM policies, see Identity and access management for Amazon Aurora (p. 2400).

Using tags to produce detailed billing reports

You can also use tags to track costs by grouping expenses for similarly tagged resources.

Use tags to organize your AWS bill to reflect your own cost structure. To do this, sign up to get your AWS account bill with tag key values included. Then, to see the cost of combined resources, organize your billing information according to resources with the same tag key values. For example, you can tag several resources with a specific application name, and then organize your billing information to see the total cost of that application across several services. For more information, see Using Cost Allocation Tags in the AWS Billing User Guide.
Adding, listing, and removing tags

The following procedures show how to perform typical tagging operations on resources related to DB instances and Aurora DB clusters.

Console

The process to tag an Amazon RDS resource is similar for all resources. The following procedure shows how to tag an Amazon RDS DB instance.

To add a tag to a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
   
   **Note**
   To filter the list of DB instances in the Databases pane, enter a text string for Filter databases. Only DB instances that contain the string appear.
3. Choose the name of the DB instance that you want to tag to show its details.
4. In the details section, scroll down to the Tags section.
5. Choose Add. The Add tags window appears.

   ![Add tags window](image)

   Add tags to your RDS resources to organize and track your Amazon RDS costs. Learn more

6. Enter a value for Tag key and Value.
7. To add another tag, you can choose Add another Tag and enter a value for its Tag key and Value.

   Repeat this step as many times as necessary.
8. Choose Add.

To delete a tag from a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

   **Note**
   You can add a tag to a snapshot, however, your bill will not reflect this grouping.
2. In the navigation pane, choose **Databases**.

   **Note**
   To filter the list of DB instances in the **Databases** pane, enter a text string in the **Filter databases** box. Only DB instances that contain the string appear.

3. Choose the name of the DB instance to show its details.
4. In the details section, scroll down to the **Tags** section.
5. Choose the tag you want to delete.

6. Choose **Delete**, and then choose **Delete** in the **Delete tags** window.

### AWS CLI

You can add, list, or remove tags for a DB instance using the AWS CLI.

- To add one or more tags to an Amazon RDS resource, use the AWS CLI command `add-tags-to-resource`.
- To list the tags on an Amazon RDS resource, use the AWS CLI command `list-tags-for-resource`.
- To remove one or more tags from an Amazon RDS resource, use the AWS CLI command `remove-tags-from-resource`.

To learn more about how to construct the required ARN, see [Constructing an ARN for Amazon RDS](p. 390).

### RDS API

You can add, list, or remove tags for a DB instance using the Amazon RDS API.

- To add a tag to an Amazon RDS resource, use the `AddTagsToResource` operation.
- To list tags that are assigned to an Amazon RDS resource, use the `ListTagsForResource`.
- To remove tags from an Amazon RDS resource, use the `RemoveTagsFromResource` operation.

To learn more about how to construct the required ARN, see [Constructing an ARN for Amazon RDS](p. 390).

When working with XML using the Amazon RDS API, tags use the following schema:

```xml
<Tagging>
  <TagSet>
    <Tag>
      <Key>Project</Key>
      <Value>Trinity</Value>
    </Tag>
    <Tag>
      <Key>workload-type</Key>
      <Value>other</Value>
    </Tag>
  </TagSet>
</Tagging>
```
<Key>User</Key>
<Value>Jones</Value>
</Tag>
</TagSet>
</Tagging>

The following table provides a list of the allowed XML tags and their characteristics. Values for Key and Value are case-dependent. For example, project=Trinity and PROJECT=Trinity are two distinct tags.

<table>
<thead>
<tr>
<th>Tagging element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TagSet</td>
<td>A tag set is a container for all tags assigned to an Amazon RDS resource. There can be only one tag set per resource. You work with a TagSet only through the Amazon RDS API.</td>
</tr>
<tr>
<td>Tag</td>
<td>A tag is a user-defined key-value pair. There can be from 1 to 50 tags in a tag set.</td>
</tr>
<tr>
<td>Key</td>
<td>A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with aws: or rds:. The string can only contain only the set of Unicode letters, digits, white space, ', ',', /, =, +, - (Java regex: &quot;^[[\p{L}\p{Z}\p{N}_.:/=+-]*$&quot;). Keys must be unique to a tag set. For example, you cannot have a key-pair in a tag set with the key the same but with different values, such as project/Trinity and project/Xanadu.</td>
</tr>
<tr>
<td>Value</td>
<td>A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with aws: or rds:. The string can only contain only the set of Unicode letters, digits, white space, ', ',', /, =, +, - (Java regex: &quot;^[[\p{L}\p{Z}\p{N}_.:/=+-]*$&quot;. Values do not have to be unique in a tag set and can be null. For example, you can have a key-value pair in a tag set of project/Trinity and cost-center/Trinity.</td>
</tr>
</tbody>
</table>

Using the AWS Tag Editor

You can browse and edit the tags on your RDS resources in the AWS Management Console by using the AWS Tag editor. For more information, see Tag Editor in the AWS Resource Groups User Guide.

Copying tags to DB cluster snapshots

When you create or restore a DB cluster, you can specify that the tags from the DB cluster are copied to snapshots of the DB cluster. Copying tags ensures that the metadata for the DB snapshots matches that of the source DB cluster. It also ensures any access policies for the DB snapshot also match those of the source DB cluster. Tags are not copied by default.

You can specify that tags are copied to DB snapshots for the following actions:

- Creating a DB cluster.
- Restoring a DB cluster.
- Creating a read replica.
- Copying a DB cluster snapshot.
Note
In some cases, you might include a value for the --tag-key parameter of the create-db-snapshot AWS CLI command. Or you might supply at least one tag to the CreateDBSnapshot API operation. In these cases, RDS doesn’t copy tags from the source DB instance to the new DB snapshot. This functionality applies even if the source DB instance has the --copy-tags-to-snapshot (CopyTagsToSnapshot) option turned on.

If you take this approach, you can create a copy of a DB instance from a DB snapshot. This approach avoids adding tags that don’t apply to the new DB instance. You create your DB snapshot using the AWS CLI create-db-snapshot command (or the CreateDBSnapshot RDS API operation). After you create your DB snapshot, you can add tags as described later in this topic.

Tutorial: Use tags to specify which Aurora DB clusters to stop

Suppose that you’re creating a number of Aurora DB clusters in a development or test environment. You need to keep all of these clusters for several days. Some of the clusters run tests overnight. Other clusters can be stopped overnight and started again the next day. The following example shows how to assign a tag to those clusters that are suitable to stop overnight. Then the example shows how a script can detect which clusters have that tag and then stop those clusters. In this example, the value portion of the key-value pair doesn’t matter. The presence of the stoppable tag signifies that the cluster has this user-defined property.

To specify which Aurora DB clusters to stop

1. Determine the ARN of a cluster that you want to designate as stoppable.

   The commands and APIs for tagging work with ARNs. That way, they can work seamlessly across AWS Regions, AWS accounts, and different types of resources that might have identical short names. You can specify the ARN instead of the cluster ID in CLI commands that operate on clusters. Substitute the name of your own cluster for dev-test-cluster. In subsequent commands that use ARN parameters, substitute the ARN of your own cluster. The ARN includes your own AWS account ID and the name of the AWS Region where your cluster is located.

   ```
   $ aws rds describe-db-clusters --db-cluster-identifier dev-test-cluster
   ```

2. Add the tag stoppable to this cluster.

   You choose the name for this tag. This approach means that you can avoid devising a naming convention that encodes all relevant information in names. In such a convention, you might encode information in the DB instance name or names of other resources. Because this example treats the tag as an attribute that is either present or absent, it omits the Value= part of the --tags parameter.

   ```
   $ aws rds add-tags-to-resource
   --tags Key=startable
   ```

3. Confirm that the tag is present in the cluster.

   These commands retrieve the tag information for the cluster in JSON format and in plain tab-separated text.

   ```
   $ aws rds list-tags-for-resource
   ```
Tutorial: Use tags to specify which Aurora DB clusters to stop

```
{
    "TagList": [
        {
            "Key": "stoppable",
            "Value": ""
        }
    ]
}
```

$ aws rds list-tags-for-resource --resource-name arn:aws:rds:us-east-1:123456789:cluster:dev-test-cluster --output text

```
TAGLIST stoppable
```

4. To stop all the clusters that are designated as stoppable, prepare a list of all your clusters. Loop through the list and check if each cluster is tagged with the relevant attribute.

This Linux example uses shell scripting to save the list of cluster ARNs to a temporary file and then perform CLI commands for each cluster.

```
$ aws rds describe-db-clusters --query "*[].[DBClusterArn]" --output text >/tmp/cluster_arns.lst
$ for arn in $(cat /tmp/cluster_arns.lst)
do
    match="$(aws rds list-tags-for-resource --resource-name $arn --output text | grep 'TAGLIST\stoppable\')"
    if [[ ! -z "$match" ]]
    then
        echo "Cluster $arn is tagged as stoppable. Stopping it now."
        # Note that you can specify the full ARN value as the parameter instead of the short ID 'dev-test-cluster'.
        aws rds stop-db-cluster --db-cluster-identifier $arn
    fi
done
```

```
{
    "DBCluster": {
        "AllocatedStorage": 1,
        "AvailabilityZones": [
            "us-east-1e",
            "us-east-1c",
            "us-east-1d"
        ],
        "BackupRetentionPeriod": 1,
        "DBClusterIdentifier": "dev-test-cluster",
        ...
    }
}
```

You can run a script like this at the end of each day to make sure that nonessential clusters are stopped. You might also schedule a job using a utility such as cron to perform such a check each night. For example, you might do this in case some clusters were left running by mistake. Here, you might fine-tune the command that prepares the list of clusters to check.

The following command produces a list of your clusters, but only the ones in available state. The script can ignore clusters that are already stopped, because they will have different status values such as stopped or stopping.

```
$ aws rds describe-db-clusters --query "*[].{DBClusterArn:DBClusterArn,Status:Status}|?[Status == 'available']|[]" 
```

388
| arn:aws:rds:us-east-1:123456789:cluster:dev-test-cluster |
| arn:aws:rds:us-east-1:123456789:cluster:pg2-cluster |

**Tip**

You can use assigning tags and finding clusters that have those tags to reduce costs in other ways. For example, take the scenario with Aurora DB clusters used for development and testing. Here, you might designate some clusters to be deleted at the end of each day, or to have only their reader DB instances deleted. Or you might designate some to have their DB instances changed to small DB instance classes during times of expected low usage.
Working with Amazon Resource Names (ARNs) in Amazon RDS

Resources created in Amazon Web Services are each uniquely identified with an Amazon Resource Name (ARN). For certain Amazon RDS operations, you must uniquely identify an Amazon RDS resource by specifying its ARN. For example, when you create an RDS DB instance read replica, you must supply the ARN for the source DB instance.

Constructing an ARN for Amazon RDS

Resources created in Amazon Web Services are each uniquely identified with an Amazon Resource Name (ARN). You can construct an ARN for an Amazon RDS resource using the following syntax.

```
ar:n:aws:rds:<region>:<account number>:<resource type>:<name>
```

<table>

|                         | For example: arn:aws:rds:us-east-2:123456789012:cluster-snapshot:my-
|                         | aurora-cluster-snap                                                        |
| DB subnet group         | arn:aws:rds:<region>:<account>:subgrp:<name>                               |
|                         | For example: arn:aws:rds:us-east-2:123456789012:subgrp:my-subnet-10        |

### Getting an existing ARN

You can get the ARN of an RDS resource by using the AWS Management Console, AWS Command Line Interface (AWS CLI), or RDS API.

**Console**

To get an ARN from the AWS Management Console, navigate to the resource you want an ARN for, and view the details for that resource.

For example, you can get the ARN for a DB cluster from the Configuration tab of the DB cluster details.

**AWS CLI**

To get an ARN from the AWS CLI for a particular RDS resource, you use the describe command for that resource. The following table shows each AWS CLI command, and the ARN property used with the command to get an ARN.

<table>
<thead>
<tr>
<th>AWS CLI command</th>
<th>ARN property</th>
</tr>
</thead>
<tbody>
<tr>
<td>describe-event-subscriptions</td>
<td>EventSubscriptionArn</td>
</tr>
<tr>
<td>describe-certificates</td>
<td>CertificateArn</td>
</tr>
<tr>
<td>describe-db-parameter-groups</td>
<td>DBParameterGroupArn</td>
</tr>
<tr>
<td>describe-db-cluster-parameter-groups</td>
<td>DBClusterParameterGroupArn</td>
</tr>
<tr>
<td>describe-db-instances</td>
<td>DBInstanceArn</td>
</tr>
<tr>
<td>describe-db-security-groups</td>
<td>DBSecurityGroupArn</td>
</tr>
</tbody>
</table>
For example, the following AWS CLI command gets the ARN for a DB instance.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds describe-db-instances \
--db-instance-identifier DBInstanceIdentifier \
--region us-west-2 \
--query "[*].{DBInstanceIdentifier:DBInstanceIdentifier,DBInstanceArn:DBInstanceArn}"
```

For Windows:

```bash
aws rds describe-db-instances ^
--db-instance-identifier DBInstanceIdentifier ^
--region us-west-2 ^
--query "[*].{DBInstanceIdentifier:DBInstanceIdentifier,DBInstanceArn:DBInstanceArn}"
```

The output of that command is like the following:

```json
[
  {
    "DBInstanceIdentifier": "instance_id"
  }
]
```

**RDS API**

To get an ARN for a particular RDS resource, you can call the following RDS API operations and use the ARN properties shown following.

<table>
<thead>
<tr>
<th>RDS API operation</th>
<th>ARN property</th>
</tr>
</thead>
<tbody>
<tr>
<td>DescribeEventSubscriptions</td>
<td>EventSubscriptionArn</td>
</tr>
<tr>
<td>DescribeCertificates</td>
<td>CertificateArn</td>
</tr>
<tr>
<td>DescribeDBParameterGroups</td>
<td>DBParameterGroupArn</td>
</tr>
<tr>
<td>DescribeDBClusterParameterGroups</td>
<td>DBClusterParameterGroupArn</td>
</tr>
<tr>
<td>RDS API operation</td>
<td>ARN property</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-------------------------</td>
</tr>
<tr>
<td>DescribeDBInstances</td>
<td>DBInstanceArn</td>
</tr>
<tr>
<td>DescribeDBSecurityGroups</td>
<td>DBSecurityGroupArn</td>
</tr>
<tr>
<td>DescribeDBSnapshots</td>
<td>DBSnapshotArn</td>
</tr>
<tr>
<td>DescribeEvents</td>
<td>SourceArn</td>
</tr>
<tr>
<td>DescribeReservedDBInstances</td>
<td>ReservedDBInstanceArn</td>
</tr>
<tr>
<td>DescribeDBSubnetGroups</td>
<td>DBSubnetGroupArn</td>
</tr>
<tr>
<td>DescribeDBClusters</td>
<td>DBClusterArn</td>
</tr>
<tr>
<td>DescribeDBClusterSnapshots</td>
<td>DBClusterSnapshotArn</td>
</tr>
</tbody>
</table>
Amazon Aurora updates

Amazon Aurora releases updates regularly. Updates are applied to Amazon Aurora DB clusters during system maintenance windows. The timing when updates are applied depends on the region and maintenance window setting for the DB cluster, and also the type of update. Updates require a database restart, so you typically experience 20–30 seconds of downtime. After this downtime, you can resume using your DB cluster or clusters. You can view or change your maintenance window settings from the AWS Management Console.

**Note**

The time required to reboot your DB instance depends on the crash recovery process, database activity at the time of reboot, and the behavior of your specific DB engine. To improve the reboot time, we recommend that you reduce database activity as much as possible during the reboot process. Reducing database activity reduces rollback activity for in-transit transactions.

For information on operating system updates for Amazon Aurora, see Working with operating system updates (p. 354).

Some updates are specific to a database engine supported by Aurora. For more information about database engine updates, see the following table.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Updates</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Aurora MySQL</td>
<td>See Database engine updates for Amazon Aurora MySQL (p. 1200)</td>
</tr>
<tr>
<td>Amazon Aurora PostgreSQL</td>
<td>See Amazon Aurora PostgreSQL updates (p. 1780)</td>
</tr>
</tbody>
</table>

**Identifying your Amazon Aurora version**

Amazon Aurora includes certain features that are general to Aurora and available to all Aurora DB clusters. Aurora includes other features that are specific to a particular database engine that Aurora supports. These features are available only to those Aurora DB clusters that use that database engine, such as Aurora PostgreSQL.

An Aurora DB instance provides two version numbers, the Aurora version number and the Aurora database engine version number. Aurora version numbers use the following format.

```
<major version>.<minor version>.<patch version>
```

To get the Aurora version number from an Aurora DB instance using a particular database engine, use one of the following queries.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Queries</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Aurora MySQL</td>
<td>SELECT AURORA_VERSION();</td>
</tr>
<tr>
<td></td>
<td>SHOW @@aurora_version;</td>
</tr>
<tr>
<td>Amazon Aurora PostgreSQL</td>
<td>SELECT AURORA_VERSION();</td>
</tr>
</tbody>
</table>
Using Amazon RDS Extended Support

After a major engine version of your database reaches the Aurora end of standard support date, Amazon RDS automatically upgrades your databases to the next supported major engine version. With Amazon RDS Extended Support, you can continue running your database on a major engine version past the Aurora end of standard support date for an additional cost.

This paid feature gives you more time to upgrade to a supported major engine version. During Extended Support, Amazon RDS will supply patches for Critical and High CVEs as defined by the National Vulnerability Database (NVD) CVSS severity ratings. For more information, see Vulnerability Metrics. You can also create new databases with major engine versions that have reached the Aurora end of standard support date. When you create these databases, Amazon RDS automatically enables Amazon RDS Extended Support.

For example, the Aurora end of standard support date for Aurora MySQL version 2 is October 31, 2024. However, you aren't ready to manually upgrade to Aurora MySQL version 3 before that date or for Amazon RDS to automatically upgrade your DB cluster to Aurora MySQL version 3 after that date. If you enable Extended Support for those DB instances before October 31, 2024, you can continue to run Aurora MySQL version 2, and starting on December 1, 2024, Amazon RDS will automatically charge you for Extended Support.

This additional charge for Extended Support ends as soon as you upgrade to a supported major engine version or you delete the database that was running a major version past the Aurora end of standard support date. For more information, see Amazon Aurora pricing.

Note
Extended Support is only available on certain minor versions. For more information, see Amazon Aurora minor versions (p. 11).
Extended Support is only available on Aurora Serverless v2. It is not available on Aurora Serverless v1.

Extended Support is available for up to 3 years past the Aurora end of standard support date for a major engine version. After 3 years, if you haven't upgraded your major engine version to a supported version, then Amazon RDS will automatically upgrade your major engine version. We recommend that you upgrade to a supported major engine version as soon as possible.

Extended Support is available for Aurora MySQL versions 2 and 3, and for Aurora PostgreSQL version 11 and higher. For more information, see Amazon Aurora major versions (p. 5).

Note
You must enable Extended Support for a particular version before the Aurora end of standard support date for that version.
Extended Support will be available through the AWS Management Console or the Amazon RDS API in December 2023.
Using Amazon RDS Blue/Green Deployments for database updates

A blue/green deployment copies a production database environment to a separate, synchronized staging environment. By using Amazon RDS Blue/Green Deployments, you can make changes to the database in the staging environment without affecting the production environment. For example, you can upgrade the major or minor DB engine version, change database parameters, or make schema changes in the staging environment. When you are ready, you can promote the staging environment to be the new production database environment, with downtime typically under one minute.

Note
Currently, Blue/Green Deployments are supported only for Aurora MySQL and Aurora PostgreSQL. For Amazon RDS engine availability, see Using Amazon RDS Blue/Green Deployments for database updates in the Amazon RDS User Guide.

Topics
- Overview of Amazon RDS Blue/Green Deployments for Aurora (p. 400)
- Creating a blue/green deployment (p. 410)
- Viewing a blue/green deployment (p. 414)
- Switching a blue/green deployment (p. 418)
- Deleting a blue/green deployment (p. 423)
Overview of Amazon RDS Blue/Green Deployments for Aurora

By using Amazon RDS Blue/Green Deployments, you can make and test database changes before implementing them in a production environment. A blue/green deployment creates a staging environment that copies the production environment. In a blue/green deployment, the blue environment is the current production environment. The green environment is the staging environment. The staging environment stays in sync with the current production environment using logical replication.

You can make changes to the Aurora DB cluster in the green environment without affecting production workloads. For example, you can upgrade the major or minor DB engine version or change database parameters in the staging environment. You can thoroughly test changes in the green environment. When ready, you can switch over the environments to promote the green environment to be the new production environment. The switchover typically takes under a minute with no data loss and no need for application changes.

Because the green environment is a copy of the topology of the production environment, the DB cluster and all of its DB instances are copied in the deployment. The green environment also includes the features used by the DB cluster, such as DB cluster snapshots, Performance Insights, Enhanced Monitoring, and Aurora Serverless v2.

Note
Currently, Blue/Green Deployments are supported only for Aurora MySQL and Aurora PostgreSQL. For Amazon RDS engine availability, see Using Amazon RDS Blue/Green Deployments for database updates in the Amazon RDS User Guide.

Topics
• Benefits of using Amazon RDS Blue/Green Deployments (p. 400)
• Workflow of a blue/green deployment (p. 401)
• Authorizing access to blue/green deployment operations (p. 405)
• Considerations for blue/green deployments (p. 406)
• Best practices for blue/green deployments (p. 407)
• Region and version availability (p. 408)
• Limitations for blue/green deployments (p. 408)

Benefits of using Amazon RDS Blue/Green Deployments

By using Amazon RDS Blue/Green Deployments, you can stay current on security patches, improve database performance, and adopt newer database features with short, predictable downtime. Blue/green deployments reduce the risks and downtime for database updates, such as major or minor engine version upgrades.

Blue/green deployments provide the following benefits:

• Easily create a production-ready staging environment.
• Automatically replicate database changes from the production environment to the staging environment.
• Test database changes in a safe staging environment without affecting the production environment.
• Stay current with database patches and system updates.
• Implement and test newer database features.
• Switch over your staging environment to be the new production environment without changes to your application.
• Safely switch over through the use of built-in switchover guardrails.
• Eliminate data loss during switchover.
• Switch over quickly, typically under a minute depending on your workload.

Workflow of a blue/green deployment

Complete the following major steps when you use a blue/green deployment for Aurora DB cluster updates.

1. Identify a production DB cluster that requires updates.

The following image shows an example of a production DB cluster.

![Production environment (blue)](image)

2. Create the blue/green deployment. For instructions, see Creating a blue/green deployment (p. 410).

The following image shows an example of a blue/green deployment of the production environment from step 1. While creating the blue/green deployment, RDS copies the complete topology and configuration of the Aurora DB cluster to create the green environment. The names of the copied DB cluster and DB instances are appended with -green-random-characters. The staging environment in the image contains the DB cluster (auroradb-green-abc123). It also contains the three DB instances in the DB cluster (auroradb-instance1-green-abc123, auroradb-instance2-green-abc123, and auroradb-instance3-green-abc123).
When you create the blue/green deployment, you can specify a higher DB engine version and a different DB cluster parameter group for the DB cluster in the green environment. You can also specify a different DB parameter group for the DB instances in the DB cluster.

RDS also configures replication from the primary DB instance in the blue environment to the primary DB instance in the green environment.
Important
After you create the blue/green deployment, the DB cluster in the green environment allows write operations by default. We recommend that you make the DB cluster read-only.

3. Make changes to the staging environment.

For example, you might make schema changes to your database or change the DB instance class used by one or more DB instances in the green environment.

For information about modifying a DB cluster, see Modifying an Amazon Aurora DB cluster (p. 269).

4. Test your staging environment.

During testing, we recommend that you keep your databases in the green environment read only. We recommend that you enable write operations on the green environment with caution because they can result in replication conflicts. They can also result in unintended data in the production databases after switchover.

5. When ready, switch over to promote the staging environment to be the new production environment. For instructions, see Switching a blue/green deployment (p. 418).

The switchover results in downtime. The downtime is usually under one minute, but it can be longer depending on your workload.

The following image shows the DB clusters after the switchover.
After the switchover, the Aurora DB cluster in the green environment becomes the new production DB cluster. The names and endpoints in the current production environment are assigned to the newly promoted production environment, requiring no changes to your application. As a result, your production traffic now flows to the new production environment. The DB cluster and DB instances in the blue environment are renamed by appending `-old$n` to the current name, where $n$ is a number. For example, assume the name of the DB instance in the blue environment is `auroradb-instance-1`. After switchover, the DB instance name might be `auroradb-instance-1-old1`.

In the example in the image, the following changes occur during switchover:
• The green environment DB cluster `auroradb-green-abc123` becomes the production DB cluster named `auroradb`.
• The green environment DB instance named `auroradb-instance1-green-abc123` becomes the production DB instance `auroradb-instance1`.
• The green environment DB instance named `auroradb-instance2-green-abc123` becomes the production DB instance `auroradb-instance2`.
• The green environment DB instance named `auroradb-instance3-green-abc123` becomes the production DB instance `auroradb-instance3`.
• The blue environment DB cluster named `auroradb` becomes `auroradb-old1`.
• The blue environment DB instance named `auroradb-instance1` becomes `auroradb-instance1-old1`.
• The blue environment DB instance named `auroradb-instance2` becomes `auroradb-instance2-old1`.
• The blue environment DB instance named `auroradb-instance3` becomes `auroradb-instance3-old1`.

6. If you no longer need a blue/green deployment, you can delete it. For instructions, see Deleting a blue/green deployment (p. 423).

After switchover, the previous production environment isn't deleted so that you can use it for regression testing, if necessary.

**Authorizing access to blue/green deployment operations**

Users must have the required permissions to perform operations related to blue/green deployments. You can create IAM policies that grant users and roles permission to perform specific API operations on the specified resources they need. You can then attach those policies to the IAM permission sets or roles that require those permissions. For more information, see Identity and access management for Amazon Aurora (p. 2400).

The user who creates a blue/green deployment must have permissions to perform the following RDS operations:

- `rds:AddTagsToResource`
- `rds:CreateDBCluster`
- `rds:CreateDBInstance`
- `rds:CreateDBClusterEndpoint`

The user who switches over a blue/green deployment must have permissions to perform the following RDS operations:

- `rds:ModifyDBCluster`
- `rds:PromoteReadReplicaDBCluster`

The user who deletes a blue/green deployment must have permissions to perform the following RDS operations:

- `rds:DeleteDBCluster`
- `rds:DeleteDBInstance`
- `rds:DeleteDBClusterEndpoint`
Considerations for blue/green deployments

Amazon RDS tracks resources in blue/green deployments with the DbiResourceId and DbClusterResourceId of each resource. This resource ID is an AWS Region-unique, immutable identifier for the resource.

The resource ID is separate from the DB cluster ID:

![Database configuration table]

The name (cluster ID) of a resource changes when you switch over a blue/green deployment, but each resource keeps the same resource ID. For example, a DB cluster identifier might have been mycluster in the blue environment. After switchover, the same DB cluster might be renamed to mycluster-old1. However, the resource ID of the DB cluster doesn’t change during switchover. So, when the green resources are promoted to be the new production resources, their resource IDs don’t match the blue resource IDs that were previously in production.

After switching over a blue/green deployment, consider updating the resource IDs to those of the newly promoted production resources for integrated features and services that you used with the production resources. Specifically, consider the following updates:

- If you perform filtering using the RDS API and resource IDs, adjust the resource IDs used in filtering after switchover.
- If you use CloudTrail for auditing resources, adjust the consumers of the CloudTrail to track the new resource IDs after switchover. For more information, see Monitoring Amazon Aurora API calls in AWS CloudTrail (p. 742).
- If you use Database Activity Streams for resources in the blue environment, adjust your application to monitor database events for the new stream after switchover. For more information, see Database activity streams in Aurora (p. 27).
- If you use the Performance Insights API, adjust the resource IDs in calls to the API after switchover. For more information, see Monitoring DB load with Performance Insights on Amazon Aurora (p. 559).

You can monitor a database with the same name after switchover, but it doesn’t contain the data from before the switchover.

- If you use resource IDs in IAM policies, make sure you add the resource IDs of the newly promoted resources when necessary. For more information, see Identity and access management for Amazon Aurora (p. 2400).
- If you authenticate to your DB cluster using IAM database authentication (p. 2432), make sure that the IAM policy used for database access has both the blue and the green databases listed under the Resource element of the policy. This is required in order to connect to the green database after switchover. For more information, see the section called “Creating and using an IAM policy for IAM database access” (p. 2436).
- If you want to restore a manual DB cluster snapshot for a DB cluster that was part of a blue/green deployment, make sure you restore the correct DB cluster snapshot by examining the time when the snapshot was taken. For more information, see Restoring from a DB cluster snapshot (p. 439).
Amazon Aurora creates the green environment by cloning the underlying Aurora storage volume in the blue environment. The green cluster volume only stores incremental changes made to the green environment. If you delete the DB cluster in the blue environment, the size of the underlying Aurora storage volume in the green environment grows to the full size. For more information, see the section called “Cloning a volume for an Aurora DB cluster” (p. 303).

When you add a DB instance to the DB cluster in the green environment of a blue/green deployment, the new DB instance won't replace a DB instance in the blue environment when you switch over. However, the new DB instance is retained in the DB cluster and becomes a DB instance in the new production environment.

When you delete a DB instance in the DB cluster in the green environment of a blue/green deployment, you can't create a new DB instance to replace it in the blue/green deployment.

If you create a new DB instance with the same name and ARN as the deleted DB instance, it has a different DbiResourceId, so it isn't part of the green environment.

The following behavior results if you delete a DB instance in the DB cluster in the green environment:

- If the DB instance in the blue environment with the same name exists, it won’t be switched over to the DB instance in the green environment. This DB instance won’t be renamed by appending -old to the DB instance name.
- Any application that points to the DB instance in the blue environment continues to use the same DB instance after switchover.

Best practices for blue/green deployments

The following are best practices for blue/green deployments:

General best practices

- Thoroughly test the Aurora DB cluster in the green environment before switching over.
- Keep your databases in the green environment read only. We recommend that you enable write operations on the green environment with caution because they can result in replication conflicts. They can also result in unintended data in the production databases after switchover.
- When using a blue/green deployment to implement schema changes, make only replication-compatible changes.

  For example, you can add new columns at the end of a table, create indexes, or drop indexes without disrupting replication from the blue deployment to the green deployment. However, schema changes, such as renaming columns or renaming tables, break replication to the green deployment.

  For more information about replication-compatible changes, see Replication with Differing Table Definitions on Source and Replica in the MySQL documentation and Restrictions in the PostgreSQL logical replication documentation.

- Use the cluster endpoint, reader endpoint, or custom endpoint for all connections in both environments. Don't use instance endpoints or custom endpoints with static or exclusion lists.
- When you switch over a blue/green deployment, follow the switchover best practices. For more information, see the section called “Switchover best practices” (p. 420).

Aurora PostgreSQL best practices

- Monitor the Aurora PostgreSQL logical replication write-through cache and make adjustments to the cache buffer if necessary. For more information, see the section called "Monitoring the logical replication write-through cache" (p. 1509).
If your database is running PostgreSQL version 13 or higher, and if it has sufficient freeable memory, increase the value of the `logical_decoding_work_mem` DB parameter in the blue environment. Doing so allows for less decoding on disk and instead uses memory. You can monitor freeable memory with the `FreeableMemory` CloudWatch metric. For more information, see the section called “CloudWatch metrics for Aurora” (p. 638).

- Update all of your PostgreSQL extensions to the latest version before you create a blue/green deployment. For more information, see the section called “Upgrading PostgreSQL extensions” (p. 1798).

- If you’re using the `aws_s3` extension, make sure to give the green DB cluster access to Amazon S3 through an IAM role after the green environment is created. This allows the import and export commands to continue functioning after switchover. For instructions, see the section called “Setting up access to an Amazon S3 bucket” (p. 1530).

### Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability with Amazon RDS Blue/Green Deployments, see Blue/Green Deployments (p. 27).

### Limitations for blue/green deployments

The following limitations apply to blue/green deployments.

#### Topics

- General limitations for blue/green deployments (p. 408)
- Limitations for changes in blue/green deployments (p. 409)
- PostgreSQL logical replication limitations for blue/green deployments (p. 409)

#### General limitations for blue/green deployments

The following general limitations apply to blue/green deployments:

- Aurora MySQL versions 2.08 and 2.09 aren’t supported as upgrade source or target versions.
- For Aurora MySQL, the source DB cluster can’t contain any databases named `tmp`. Databases with this name will not be copied to the green environment.
- For Aurora PostgreSQL, unlogged tables aren’t replicated to the green environment unless the `rds.logically_replicate_unlogged_tables` parameter is set to 1 on the blue DB cluster. We recommend that you don’t modify this parameter value after you create a blue/green deployment to avoid possible replication errors on unlogged tables.
- During switchover, the blue and green environments can’t have zero-ETL integrations with Amazon Redshift. You must delete the integration first and switch over, then recreate the integration.
- The Event Scheduler (`event_scheduler` parameter) must be disabled on the green environment when you create a blue/green deployment. This prevents events from being generated in the green environment and causing inconsistencies.
- Blue/green deployments aren’t supported for the following features:
  - Amazon RDS Proxy
  - Cross-Region read replicas
  - Aurora Serverless v1 DB clusters
  - DB clusters that are part of an Aurora global database
  - Babelfish for Aurora PostgreSQL
  - AWS CloudFormation
The following limitations apply to PostgreSQL extensions:

- The `pg_partman` extension must be disabled on the blue environment when you create a blue/green deployment. The extension performs DDL operations such as `CREATE TABLE`, which break logical replication from the blue environment to the green environment.

- The `pg_cron` extension must remain disabled on all green databases after the blue/green deployment is created. The extension has background workers that run as superuser and bypass the read-only setting of the green environment, which might cause replication conflicts.

- The `apg_plan_mgmt` extension must have the `apg_plan_mgmt.capture_plan_baselines` parameter set to off on all green databases to avoid primary key conflicts if an identical plan is captured in the blue environment. For more information, see the section called “Overview of Aurora PostgreSQL query plan management” (p. 1573).

- If you want to capture execution plans in Aurora Replicas, you must provide the blue DB cluster endpoint when calling the `apg_plan_mgmt.create_replica_plan_capture` function. This ensures that plan captures continue to work after switchover. For more information, see the section called “Capturing Aurora PostgreSQL execution plans in Replicas” (p. 1606).

- If the blue DB cluster is configured as the foreign server of a foreign data wrapper (FDW) extension, you must use the cluster endpoint name instead of IP addresses. This allows the configuration to remain functional after switchover.

- The `pglogical` and `pg_active` extensions must be disabled on the blue environment when you create a blue/green deployment. In addition, the blue database can't be a logical subscriber of an external instance.

Limitations for changes in blue/green deployments

The following are limitations for changes in a blue/green deployment:

- You can't change an unencrypted DB cluster into an encrypted DB cluster.

- You can't change an encrypted DB cluster into an unencrypted DB cluster.

- You can't change a blue environment DB cluster to a higher engine version than its corresponding green environment DB cluster.

- The resources in the blue environment and green environment must be in the same AWS account.

- During switchover, the blue DB cluster can't be the source or target of external replication.

- If the blue environment contains any Aurora Auto Scaling policies, these policies aren't copied over to the green environment. You must manually re-add the policies to the green environment.

PostgreSQL logical replication limitations for blue/green deployments

Blue/green deployments use logical replication to keep the staging environment in sync with the production environment. PostgreSQL has certain restrictions related to logical replication, which translate to limitations when creating blue/green deployments for Aurora PostgreSQL DB clusters.

The following table describes logical replication limitations that apply to blue/green deployments for Aurora PostgreSQL.

<table>
<thead>
<tr>
<th>Limitation</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data definition language (DDL)</td>
<td>If Aurora detects a DDL change in the blue environment, your green databases enter a state of <strong>Replication degraded</strong>.</td>
</tr>
<tr>
<td>Limitation</td>
<td>Explanation</td>
</tr>
<tr>
<td>------------</td>
<td>-------------</td>
</tr>
<tr>
<td>statements, such as CREATE TABLE and CREATE SCHEMA, aren't replicated from the blue environment to the green environment.</td>
<td>You receive an event notifying you that DDL changes in the blue environment can't be replicated to the green environment. You must delete the blue/green deployment and all green databases, then recreate it. Otherwise, you won't be able to switch over the blue/green deployment.</td>
</tr>
<tr>
<td>NEXTVAL operations on sequence objects aren't synchronized between the blue environment and the green environment.</td>
<td>During switchover, Aurora increments sequence values in the green environment to match those in the blue environment. If you have thousands of sequences, this can delay switchover.</td>
</tr>
<tr>
<td>Creation or modification of large objects in the blue environment aren't replicated to the green environment.</td>
<td>If Aurora detects the creation or modification of large objects in the blue environment that are stored in the pg_largeobject system table, your green databases enter a state of Replication degraded. Aurora generates an event notifying you that large object changes in the blue environment can't be replicated to the green environment. You must delete the blue/green deployment and all green databases, then recreate it. Otherwise, you won't be able to switch over the blue/green deployment.</td>
</tr>
<tr>
<td>Materialized views aren't automatically refreshed on the green environment.</td>
<td>Refreshing materialized views in the blue environment doesn't refresh them in the green environment. After switchover, you can schedule a refresh of materialized views.</td>
</tr>
<tr>
<td>UPDATE and DELETE operations aren't permitted on tables that don't have a primary key.</td>
<td>Before you create a blue/green deployment, make sure that all tables in the DB cluster have a primary key.</td>
</tr>
</tbody>
</table>

For more information, see Restrictions in the PostgreSQL logical replication documentation.

Creating a blue/green deployment

When you create a blue/green deployment, you specify the DB cluster to copy in the deployment. The DB cluster you choose is the production DB cluster, and it becomes the DB cluster in the blue environment. RDS copies the blue environment's topology to a staging area, along with its configured features. The DB cluster is copied to the green environment, and RDS configures replication from the DB cluster in the blue environment to the DB cluster in the green environment. RDS also copies all of the DB instances in the DB cluster.

Topics
- Preparing for a blue/green deployment (p. 411)
- Specifying changes when creating a blue/green deployment (p. 412)
- Creating a blue/green deployment (p. 412)
Preparing for a blue/green deployment

There are certain steps you must take before you create a blue/green deployment, depending on the engine that your Aurora DB cluster is running.

Topics
- Preparing an Aurora MySQL cluster for a blue/green deployment (p. 411)
- Preparing an Aurora PostgreSQL cluster for a blue/green deployment (p. 411)

Preparing an Aurora MySQL cluster for a blue/green deployment

Before you create a blue/green deployment for an Aurora MySQL DB cluster, the cluster must be associated with a custom DB cluster parameter group with binary logging [binlog_format](p. 732) turned on. Binary logging is required for replication from the blue environment to the green environment. While any binlog format works, we recommend ROW to reduce the risk of replication inconsistencies. For information about creating a custom DB cluster parameter group and setting parameters, see [the section called “Working with DB cluster parameter groups”](p. 214).

**Note**

Enabling binary logging increases the number of write disk I/O operations to the DB cluster. You can monitor IOPS usage with the VolumeWriteIOPs CloudWatch metric.

You can modify the DB cluster to associate it with a custom DB cluster parameter group. For more information, see [the section called “Modifying an Aurora DB cluster”](p. 269).

If you change the binlog_format parameter setting or any other parameter settings for a DB cluster, check the **DB cluster parameter group** setting on the cluster’s **Configuration** tab. If the status is Pending reboot, reboot the DB cluster. Blue/Green Deployments require that the writer instance be in sync with the DB cluster parameter group, otherwise creation fails. For more information, see [Rebooting a DB instance within an Aurora cluster](p. 358).

Preparing an Aurora PostgreSQL cluster for a blue/green deployment

Before you create a blue/green deployment for an Aurora PostgreSQL DB cluster, make sure to do the following:

- Associate the cluster with a custom DB cluster parameter group that has logical replication (rds.logical_replication) enabled. Logical replication is required for replication from the blue environment to the green environment. For instructions to enable logical replication, see [the section called “Setting up logical replication”](p. 1507).

  After you enable logical replication, make sure to reboot the DB cluster so that your changes take effect. Blue/green deployments require that the writer instance be in sync with the DB cluster parameter group, otherwise creation fails. For more information, see [Rebooting a DB instance within an Aurora cluster](p. 358).

- Make sure that your DB cluster is running a version of Aurora PostgreSQL that’s compatible with Blue/Green Deployments. For a list of compatible versions, see [the section called “Blue/Green Deployments with Aurora PostgreSQL”](p. 27).

- Confirm that the DB cluster isn’t the source or target of external replication. For more information, see [the section called “General limitations”](p. 408).

- Make sure that all tables in the DB cluster have a primary key. PostgreSQL logical replication doesn't allow UPDATE or DELETE operations on tables that don't have a primary key.
Specifying changes when creating a blue/green deployment

You can make the following changes to the DB cluster in the green environment when you create the blue/green deployment.

You can make other modifications to the DB cluster and its DB instances in the green environment after it is deployed. For example, you might make schema changes to your database.

For information about modifying a DB cluster, see Modifying an Amazon Aurora DB cluster (p. 269).

Specify a higher engine version

You can specify a higher engine version if you want to test a DB engine upgrade. Upon switchover, the database is upgraded to the major or minor DB engine version that you specify.

Specify a different DB parameter group

Specify a DB cluster parameter group that is different from the one used by the DB cluster. You can test how parameter changes affect the DB cluster in the green environment or specify a parameter group for a new major DB engine version in the case of an upgrade.

If you specify a different DB cluster parameter group, the specified parameter group is associated with the DB cluster in the green environment. If you don't specify a different DB cluster parameter group, the DB cluster in the green environment is associated with the same parameter group as the blue DB cluster.

Creating a blue/green deployment

You can create a blue/green deployment using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To create a blue/green deployment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB cluster that you want to copy to a green environment.
3. For Actions, choose Create Blue/Green Deployment.

   If you choose an Aurora PostgreSQL DB cluster, review and acknowledge the logical replication limitations. For more information, see the section called “PostgreSQL logical replication limitations” (p. 409).

   The Create Blue/Green Deployment page appears.
4. On the **Create Blue/Green Deployment** page, review the blue database identifiers. Make sure they match the DB instances that you expect in the blue environment. If they don't, choose **Cancel**.

5. For **Blue/Green Deployment identifier**, enter a name for your blue/green deployment.

6. (Optional) For **Blue/Green Deployment settings**, specify the settings for the green environment:
   - Choose a DB engine version if you want to test a DB engine version upgrade.
   - Choose a DB cluster parameter group to associate with the DB cluster in the green environment.
   - Choose a DB parameter group to associate with the DB instances in the green environment.

   You can make other modifications to the databases in the green environment after it is deployed.

7. Choose **Create Blue/Green Deployment**.

**AWS CLI**

To create a blue/green deployment by using the AWS CLI, use the `create-blue-green-deployment` command with the following options:
• `--blue-green-deployment-name` – Specify the name of the blue/green deployment.
• `--source` – Specify the ARN of the DB cluster that you want to copy.
• `--target-engine-version` – Specify an engine version if you want to test a DB engine version upgrade in the green environment. This option upgrades the DB cluster in the green environment to the specified DB engine version.

If not specified, the DB cluster in the green environment is created with the same engine version as DB cluster in the blue environment.
• `--target-db-cluster-parameter-group-name` – Specify a DB cluster parameter group to associate with the DB cluster in the green environment.
• `--target-db-parameter-group-name` – Specify a DB parameter group to associate with the DB instances in the green environment.

Example Create a blue/green deployment

For Linux, macOS, or Unix:

```
aws rds create-blue-green-deployment \
  --blue-green-deployment-name aurora-blue-green-deployment \
  --source arn:aws:rds:us-east-2:123456789012:cluster:auroradb \
  --target-engine-version 8.0 \
  --target-db-cluster-parameter-group mydbclusterparametergroup
```

For Windows:

```
aws rds create-blue-green-deployment ^
  --blue-green-deployment-name aurora-blue-green-deployment ^
  --target-engine-version 8.0 ^
  --target-db-cluster-parameter-group mydbclusterparametergroup
```

RDS API

To create a blue/green deployment by using the Amazon RDS API, use the `CreateBlueGreenDeployment` operation with the following parameters:

• `BlueGreenDeploymentName` – Specify the name of the blue/green deployment.
• `Source` – Specify the ARN of the DB cluster that you want to copy to the green environment.
• `TargetEngineVersion` – Specify an engine version if you want to test a DB engine version upgrade in the green environment. This option upgrades the DB cluster in the green environment to the specified DB engine version.

If not specified, the DB cluster in the green environment is created with the same engine version as DB cluster in the blue environment.
• `TargetDBClusterParameterGroupName` – Specify a DB cluster parameter group to associate with the DB cluster in the green environment.
• `TargetDBParameterGroupName` – Specify a DB parameter group to associate with the DB instances in the green environment.

Viewing a blue/green deployment

You can view the details about a blue/green deployment using the AWS Management Console, the AWS CLI, or the RDS API.
You can also view and subscribe to events for information about a blue/green deployment. For more information, see Blue/green deployment events (p. 720).

**Console**

**To view the details about a blue/green deployment**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then find the blue/green deployment in the list.

3. Choose the name of blue/green deployment that you want to view to display its details.

Each tab has a section for the blue deployment and a section for the green deployment. The section for the blue deployment shows the details about the DB cluster in the blue environment. The section for the green deployment shows the details about the DB cluster in the green environment. You can examine the details in both environments to see differences between them. For example, on the Configuration tab, the DB engine version might be different in the blue environment and in the green environment if you are upgrading the DB engine version in the green environment. Make sure the values for the the DB cluster in both environments are the expected values.

The following image shows an example of the Connectivity & security tab.
The Connectivity & security tab also includes a section called Replication, which shows the current state of logical replication and replica lag between the blue and green environments. If the replication state is Replicating, the blue/green deployment is replicating successfully.

For Aurora PostgreSQL blue/green deployments, the replication state can change to Replication degraded if you make unsupported DDL or large object changes in the blue environment. For more information, see the section called “PostgreSQL logical replication limitations” (p. 409).

The following image shows an example of the Configuration tab.
AWS CLI

To view the details about a blue/green deployment by using the AWS CLI, use the `describe-blue-green-deployments` command.
Example View the details about a blue/green deployment by filtering on its name

When you use the `describe-blue-green-deployments` command, you can filter on the `--blue-green-deployment-name`. The following example shows the details for a blue/green deployment named `my-blue-green-deployment`.

```
aws rds describe-blue-green-deployments --filters Name=blue-green-deployment-name,Values=my-blue-green-deployment
```

Example View the details about a blue/green deployment by specifying its identifier

When you use the `describe-blue-green-deployments` command, you can specify the `--blue-green-deployment-identifier`. The following example shows the details for a blue/green deployment with the identifier `bgd-1234567890abcdef`.

```
aws rds describe-blue-green-deployments --blue-green-deployment-identifier bgd-1234567890abcdef
```

RDS API

To view the details about a blue/green deployment by using the Amazon RDS API, use the `DescribeBlueGreenDeployments` operation and specify the `BlueGreenDeploymentIdentifier`.

Switching a blue/green deployment

A `switchover` promotes the DB cluster, including its DB instances, in the green environment to be the production DB cluster. Before you switch over, production traffic is routed to the cluster in the blue environment. After you switch over, production traffic is routed to the DB cluster in the green environment.

Topics

- Switchover timeout (p. 418)
- Switchover guardrails (p. 418)
- Switchover actions (p. 419)
- Switchover best practices (p. 420)
- Verifying CloudWatch metrics before switchover (p. 420)
- Switching over a blue/green deployment (p. 421)
- After switchover (p. 423)

Switchover timeout

You can specify a switchover timeout period between 30 seconds and 3,600 seconds (one hour). If the switchover takes longer than the specified duration, then any changes are rolled back and no changes are made to either environment. The default timeout period is 300 seconds (five minutes).

Switchover guardrails

When you start a switchover, Amazon RDS runs some basic checks to test the readiness of the blue and green environments for switchover. These checks are known as `switchover guardrails`. These switchover guardrails prevent a switchover if the environments aren't ready for it. Therefore, they avoid longer than expected downtime and prevent the loss of data between the blue and green environments that might result if the switchover started.
Amazon RDS runs the following guardrail checks on the green environment:

- **Replication health** – Checks if green DB cluster replication status is healthy. The green DB cluster is a replica of the blue DB cluster.
- **Replication lag** – Checks if the replica lag of the green DB cluster is within allowable limits for switchover. The allowable limits are based on the specified timeout period. Replica lag indicates how far the green DB cluster is lagging behind its blue DB cluster. For more information, see the section called “Diagnosing and resolving lag between read replicas” (p. 2516) for Aurora MySQL and the section called “Monitoring replication” (p. 1506) for Aurora PostgreSQL.
- **Active writes** – Makes sure there are no active writes on the green DB cluster.

Amazon RDS runs the following guardrail checks on the blue environment:

- **External replication** – Makes sure the blue DB cluster isn't the target of external replication to prevent writes on the blue DB cluster during switchover.
- **Long-running active writes** – Makes sure there are no long-running active writes on the blue DB cluster because they can increase replica lag.
- **Long-running DDL statements** – Makes sure there are no long-running DDL statements on the blue DB cluster because they can increase replica lag.
- **Unsupported PostgreSQL changes** – For Aurora PostgreSQL DB clusters, makes sure that no DDL changes and no additions or modifications of large objects have been performed on the blue environment. For more information, see the section called “PostgreSQL logical replication limitations” (p. 409).

If Amazon RDS detects unsupported PostgreSQL changes, it changes the replication state to Replication degraded and notifies you that switchover is not available for the blue/green deployment. To proceed with switchover, we recommend that you delete and recreate the blue/green deployment and all green databases. To do so, choose Actions, Delete with green databases.

## Switchover actions

When you switch over a blue/green deployment, RDS performs the following actions:

1. Runs guardrail checks to verify if the blue and green environments are ready for switchover.
2. Stops new write operations on the DB cluster in both environments.
3. Drops connections to the DB instances in both environments and doesn't allow new connections.
4. Waits for replication to catch up in the green environment so that the green environment is in sync with the blue environment.
5. Renames the DB cluster and DB instances in the both environments.

RDS renames the DB cluster and DB instances in the green environment to match the corresponding DB cluster and DB instances in the blue environment. For example, assume the name of a DB instance in the blue environment is mydb. Also assume the name of the corresponding DB instance in the green environment is mydb-green-abc123. During switchover, the name of the DB instance in the green environment is changed to mydb.

RDS renames the DB cluster and DB instances in the blue environment by appending -oldn to the current name, where n is a number. For example, assume the name of a DB instance in the blue environment is mydb. After switchover, the DB instance name might be mydb-old1.

RDS also renames the endpoints in the green environment to match the corresponding endpoints in the blue environment so that application changes aren't required.

6. Allows connections to databases in both environments.
7. Allows write operations on the DB cluster in the new production environment.

After switchover, the previous production DB cluster only allows read operations until the writer instance is rebooted.

You can monitor the status of a switchover using Amazon EventBridge. For more information, see the section called “Blue/green deployment events” (p. 720).

If you have tags configured in the blue environment, these tags are moved to the new production environment during switchover. The previous production environment also retains these tags. For more information about tags, see Tagging Amazon RDS resources (p. 382).

If the switchover starts and then stops before finishing for any reason, then any changes are rolled back, and no changes are made to either environment.

**Switchover best practices**

Before you switch over, we strongly recommend that you adhere to best practices by completing the following tasks:

- Thoroughly test the resources in the green environment. Make sure they function properly and efficiently.
- Monitor relevant Amazon CloudWatch metrics. For more information, see the section called “Verifying CloudWatch metrics before switchover” (p. 420).
- Identify the best time for the switchover.

During the switchover, writes are cut off from databases in both environments. Identify a time when traffic is lowest on your production environment. Long-running transactions, such as active DDLs, can increase your switchover time, resulting in longer downtime for your production workloads.

If there's a large number of connections on your DB cluster and DB instances, consider manually reducing them to the minimum amount necessary for your application before you switch over the blue/green deployment. One way to achieve this is to create a script that monitors the status of the blue/green deployment and starts cleaning up connections when it detects that the status has changed to SWITCHOVER_IN_PROGRESS.

- Make sure the DB cluster and DB instances in both environments are in Available state.
- Make sure the DB cluster in the green environment is healthy and replicating.
- Make sure that your network and client configurations don't increase the DNS cache Time-To-Live (TTL) beyond five seconds, which is the default for Aurora DNS zones. Otherwise, applications will continue to send write traffic to the blue environment after switchover.
- For Aurora PostgreSQL DB clusters, review the logical replication limitations and take any required actions prior to switchover. For more information, see the section called “PostgreSQL logical replication limitations” (p. 409).

**Note**
During a switchover, you can't modify any DB cluster included in the switchover.

**Verifying CloudWatch metrics before switchover**

Before you switch over a blue/green deployment, we recommend that you check the values of the following metrics within Amazon CloudWatch.
• **AuroraBinlogReplicaLag** (for Aurora MySQL) or **AuroraReplicaLag** (for Aurora PostgreSQL) – Use this metric to identify the current replication lag on the green environment. To reduce downtime, make sure that this value is close to zero before you switch over.

• **DatabaseConnections** – Use this metric to estimate the level of activity on the blue/green deployment, and make sure that the value is at an acceptable level for your deployment before you switch over. If Performance Insights is turned on, **DBLoad** is a more accurate metric.

• **ActiveTransactions** – If **innodb_monitor_enable** is set to **all** in the DB parameter group for any of your DB instances, use this metric to see if there's a high number of active transactions that might block switchover.

For more information about these metrics, see the section called "CloudWatch metrics for Aurora" (p. 638).

### Switching over a blue/green deployment

You can switch over a blue/green deployment using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To switch over a blue/green deployment**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**, and then choose the blue/green deployment that you want to switch over.
3. For **Actions**, choose **Switch over**.

   The **Switch over** page appears.
4. On the Switch over page, review the switchover summary. Make sure the resources in both environments match what you expect. If they don't, choose Cancel.

5. For Timeout settings, enter the time limit for switchover.

6. If your cluster is running Aurora PostgreSQL, review and acknowledge the pre-switchover recommendations. For more information, see the section called "PostgreSQL logical replication limitations" (p. 409).

7. Choose Switch over.

AWS CLI

To switch over a blue/green deployment by using the AWS CLI, use the switchover-blue-green-deployment command with the following options:

- --blue-green-deployment-identifier – Specify the identifier of the blue/green deployment.
- --switchover-timeout – Specify the time limit for the switchover, in seconds. The default is 300.

Example Switch over a blue/green deployment

For Linux, macOS, or Unix:

```
aws rds switchover-blue-green-deployment \
  --blue-green-deployment-identifier bgd-1234567890abcdef \
```
After switchover

--switchover-timeout 600

For Windows:

```
aws rds switchover-blue-green-deployment ^
   --blue-green-deployment-identifier bgd-1234567890abcdef ^
   --switchover-timeout 600
```

RDS API

To switch over a blue/green deployment by using the Amazon RDS API, use the `SwitchoverBlueGreenDeployment` operation with the following parameters:

- **BlueGreenDeploymentIdentifier** – Specify the identifier of the blue/green deployment.
- **SwitchoverTimeout** – Specify the time limit for the switchover, in seconds. The default is 300.

After switchover

After a switchover, the DB cluster and DB instances in the previous blue environment are retained. Standard costs apply to these resources. Replication and binary logging between the blue and green environments stops.

RDS renames the DB cluster and DB instances in the blue environment by appending `-oldn` to the current resource name, where `n` is a number. The DB cluster is read-only until its writer instance is rebooted.

Deleting a blue/green deployment

You can delete a blue/green deployment before or after you switch it over.

When you delete a blue/green deployment before switching it over, Amazon RDS optionally deletes the DB cluster in the green environment:

- If you choose to delete the DB cluster in the green environment (`--delete-target`), it must have deletion protection turned off.
- If you don't delete the DB cluster in the green environment (`--no-delete-target`), the cluster is retained, but it's no longer part of a blue/green deployment. Replication continues between the environments.

The option to delete the green databases isn't available in the console after switchover (p. 418). When you delete blue/green deployments using the AWS CLI, you can't specify the `--delete-target` option if the deployment `status` is `SWITCHOVER_COMPLETED`.

**Important**

Deleting a blue/green deployment doesn't affect the blue environment.

You can delete a blue/green deployment using the AWS Management Console, the AWS CLI, or the RDS API.

Console

**To delete a blue/green deployment**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Databases, and then choose the blue/green deployment that you want to delete.

3. For Actions, choose Delete.

The Delete Blue/Green Deployment? window appears.

![Delete Blue/Green Deployment? window]

To delete the green databases, select Delete the green databases in this Blue/Green Deployment.

4. Enter delete me in the box.

5. Choose Delete.

**AWS CLI**

To delete a blue/green deployment by using the AWS CLI, use the `delete-blue-green-deployment` command with the following options:

- `--blue-green-deployment-identifier` – The identifier of the blue/green deployment to be deleted.
- `--delete-target` – Specifies that the DB cluster in the green environment is deleted. You can't specify this option if the blue/green deployment has a status of SWITCHOVER_COMPLETED.
- `--no-delete-target` – Specifies that the DB cluster in the green environment is retained.

**Example Delete a blue/green deployment and the DB cluster in the green environment**

For Linux, macOS, or Unix:

```
aws rds delete-blue-green-deployment \
   --blue-green-deployment-identifier bgd-1234567890abcdef \
   --delete-target
```

For Windows:
Deleting a blue/green deployment

Example Delete a blue/green deployment but retain the DB cluster in the green environment

For Linux, macOS, or Unix:

```bash
aws rds delete-blue-green-deployment
   --blue-green-deployment-identifier bgd-1234567890abcdef
   --no-delete-target
```

For Windows:

```bash
aws rds delete-blue-green-deployment
   --blue-green-deployment-identifier bgd-1234567890abcdef
   --no-delete-target
```

RDS API

To delete a blue/green deployment by using the Amazon RDS API, use the `DeleteBlueGreenDeployment` operation with the following parameters:

- `BlueGreenDeploymentIdentifier` – The identifier of the blue/green deployment to be deleted.
- `DeleteTarget` – Specify `TRUE` to delete the DB cluster in the green environment or `FALSE` to retain it. Cannot be `TRUE` if the blue/green deployment has a status of `SWITCHOVER_COMPLETED`. 

Back up and restore Amazon Aurora DB clusters

These topics provide information about backing up and restoring Amazon Aurora DB clusters.

Tip
The Aurora high availability features and automatic backup capabilities help keep your data safe without requiring extensive setup from you. Before you implement a backup strategy, learn about the ways that Aurora maintains multiple copies of your data and helps you to access them across multiple DB instances and AWS Regions. For details, see [High availability for Amazon Aurora](p. 102).

Topics
- Overview of backing up and restoring an Aurora DB cluster (p. 427)
- Understanding Amazon Aurora backup storage usage (p. 433)
- Creating a DB cluster snapshot (p. 437)
- Restoring from a DB cluster snapshot (p. 439)
- Copying a DB cluster snapshot (p. 442)
- Sharing a DB cluster snapshot (p. 452)
- Exporting DB cluster data to Amazon S3 (p. 460)
- Exporting DB cluster snapshot data to Amazon S3 (p. 471)

Overview of backing up and restoring an Aurora DB cluster

The following topics describe Aurora backups and how to restore your Aurora DB cluster.

Contents
- Backups (p. 427)
  - Using AWS Backup (p. 427)
- Backup window (p. 428)
- Retaining automated backups (p. 429)
  - Retention period (p. 430)
  - Viewing retained backups (p. 430)
  - Retention costs (p. 430)
  - Limitations (p. 430)
  - Deleting retained automated backups (p. 431)
- Restoring data (p. 432)
- Database cloning for Aurora (p. 432)
- Backtrack (p. 432)

Backups

Aurora backs up your cluster volume automatically and retains restore data for the length of the backup retention period. Aurora automated backups are continuous and incremental, so you can quickly restore to any point within the backup retention period. No performance impact or interruption of database service occurs as backup data is being written. You can specify a backup retention period from 1–35 days when you create or modify a DB cluster. Aurora automated backups are stored in Amazon S3.

If you want to retain data beyond the backup retention period, you can take a snapshot of the data in your cluster volume. Aurora DB cluster snapshots don't expire. You can create a new DB cluster from the snapshot. For more information, see Creating a DB cluster snapshot (p. 437).

Note

- For Amazon Aurora DB clusters, the default backup retention period is one day regardless of how the DB cluster is created.
- You can't disable automated backups on Aurora. The backup retention period for Aurora is managed by the DB cluster.

Your costs for backup storage depend upon the amount of Aurora backup and snapshot data you keep and how long you keep it. For information about the storage associated with Aurora backups and snapshots, see Understanding Amazon Aurora backup storage usage (p. 433). For pricing information about Aurora backup storage, see Amazon RDS for Aurora pricing. After the Aurora cluster associated with a snapshot is deleted, storing that snapshot incurs the standard backup storage charges for Aurora.

Using AWS Backup

You can use AWS Backup to manage backups of Amazon Aurora DB clusters.

Snapshots managed by AWS Backup are considered manual DB cluster snapshots, but don't count toward the DB cluster snapshot quota for Aurora. Snapshots that were created with AWS Backup have names
with `awsbackup:job-AWS-Backup-job-number`. For more information about AWS Backup, see the
AWS Backup Developer Guide.

You can also use AWS Backup to manage automated backups of Amazon Aurora DB clusters. If your
DB cluster is associated with a backup plan in AWS Backup, you can use that backup plan for point-in-
time recovery. Automated (continuous) backups that are managed by AWS Backup have names with
`continuous:cluster-AWS-Backup-job-number`. For more information, see Restoring a DB cluster
to a specified time using AWS Backup (p. 494).

### Backup window

Automated backups occur daily during the preferred backup window. If the backup requires more time
than allotted to the backup window, the backup continues after the window ends, until it finishes. The
backup window can't overlap with the weekly maintenance window for the DB cluster.

Aurora automated backups are continuous and incremental, but the backup window is used to create a
daily system backup that is preserved within the backup retention period. You can copy the backup to
preserve it outside of the retention period.

**Note**

When you create a DB cluster using the AWS Management Console, you can’t specify a backup
window. However, you can specify a backup window when you create a DB cluster using the AWS
CLI or RDS API.

If you don’t specify a preferred backup window when you create the DB cluster, Aurora assigns a default
30-minute backup window. This window is selected at random from an 8-hour block of time for each
AWS Region. The following table lists the time blocks for each AWS Region from which the default
backup windows are assigned.

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>
<th>Time Block</th>
</tr>

</tbody>
</table>
Retaining automated backups

When you delete a provisioned or Aurora Serverless v2 DB cluster, you can retain automated backups. This allows you to restore a DB cluster to a specific point in time within the backup retention period, even after the cluster is deleted.

Retained automated backups contain system snapshots and transaction logs from a DB cluster. They also include DB cluster properties, such as DB instance class, which are required to restore it to an active cluster.

You can restore or remove retained automated backups using the AWS Management Console, RDS API, and AWS CLI.

Note

You can't retain automated backups for Aurora Serverless v1 DB clusters.

</tbody>
</table>
Retention period

The system snapshots and transaction logs in a retained automated backup expire the same way that they expire for the source DB cluster. The settings for the retention period of the source cluster also apply to the automated backups. Because no new snapshots or logs are created for this cluster, the retained automated backups eventually expire completely. After the retention period is over, you continue to retain manual DB cluster snapshots, but all of the automated backups expire.

You can remove retained automated backups using the console, AWS CLI or RDS API. For more information, see Deleting retained automated backups (p. 431).

Unlike a retained automated backup, a final snapshot doesn't expire. We strongly suggest that you take a final snapshot even if you retain automated backups, because the retained automated backups eventually expire.

Viewing retained backups

To view your retained automated backups in the RDS console, choose Automated backups in the navigation pane, then choose Retained. To view individual snapshots associated with a retained automated backup, choose Snapshots in the navigation pane. Alternatively, you can describe individual snapshots associated with a retained automated backup. From there, you can restore a DB instance directly from one of those snapshots.

To describe your retained automated backups using the AWS CLI, use the following command:

```
aws rds describe-db-cluster-automated-backups --db-cluster-resource-id DB_cluster_resource_ID
```

To describe your retained automated backups using the RDS API, call the DescribeDBClusterAutomatedBackups action with the DbClusterResourceId parameter.

Retention costs

There is no additional charge for backup storage of up to 100% of your total Aurora database storage for each Aurora DB cluster. There is also no additional charge up to one day when you retain automated backups after deleting a DB cluster. Backups that you retain for more than one day are charged.

There is no additional charge for transaction logs or instance metadata. All other pricing rules for backups apply to restorable clusters. For more information, see the Amazon Aurora pricing page.

Limitations

The following limitations apply to retained automated backups:

- The maximum number of retained automated backups in one AWS Region is 40. It's not included in the quota for DB clusters. You can have up to 40 running DB clusters, 40 running DB instances, and 40 retained automated backups for DB clusters at the same time.

For more information, see Quotas in Amazon Aurora (p. 2506).
Retained automated backups don't contain information about parameters or option groups.
• You can restore a deleted cluster to a point in time that is within the retention period at the time of deletion.
• You can't modify a retained automated backup because it consists of system backups, transaction logs, and the DB cluster properties that existed at the time that you deleted the source cluster.

Deleting retained automated backups
You can delete retained automated backups when they are no longer needed.

Console

To delete a retained automated backup
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Automated backups**.
3. Choose the **Retained** tab.
4. Choose the retained automated backup that you want to delete.
5. For **Actions**, choose **Delete**.
6. On the confirmation page, enter **delete me** and choose **Delete**.

AWS CLI
You can delete a retained automated backup by using the AWS CLI command **delete-db-cluster-automated-backup** with the following option:

• **--db-cluster-resource-id** – The resource identifier for the source DB cluster.
You can find the resource identifier for the source DB cluster of a retained automated backup by running the AWS CLI command **describe-db-cluster-automated-backups**.

Example
This example deletes the retained automated backup for the source DB cluster that has the resource ID **cluster-123ABCEXAMPLE**.

For Linux, macOS, or Unix:

```bash
aws rds delete-db-cluster-automated-backup \  
   --db-cluster-resource-id cluster-123ABCEXAMPLE
```

For Windows:

```bash
aws rds delete-db-cluster-automated-backup ^
```
Restoring data

You can recover your data by creating a new Aurora DB cluster from the backup data that Aurora retains, from a DB cluster snapshot that you have saved, or from a retained automated backup. You can quickly restore a new copy of a DB cluster created from backup data to any point in time during your backup retention period. Because Aurora backups are continuous and incremental during the backup retention period, you don't need to take frequent snapshots of your data to improve restore times.

The latest restorable time for a DB cluster is the most recent point to which you can restore your DB cluster. This is typically within 5 minutes of the current time for an active DB cluster, or 5 minutes of the cluster deletion time for a retained automated backup.

The earliest restorable time specifies how far back within the backup retention period that you can restore your cluster volume.

To determine the latest or earliest restorable time for a DB cluster, look for the Latest restorable time or Earliest restorable time values on the RDS console. For information about viewing these values, see Viewing retained backups (p. 430).

You can determine when the restore of a DB cluster is complete by checking the Latest restorable time and Earliest restorable time values. These values return NULL until the restore operation is complete. You can't request a backup or restore operation if either Latest restorable time or Earliest restorable time returns NULL.

For information about restoring a DB cluster to a specified time, see Restoring a DB cluster to a specified time (p. 490).

Database cloning for Aurora

You can also use database cloning to clone the databases of your Aurora DB cluster to a new DB cluster, instead of restoring a DB cluster snapshot. The clone databases use only minimal additional space when first created. Data is copied only as data changes, either on the source databases or on the clone databases. You can make multiple clones from the same DB cluster, or create additional clones even from other clones. For more information, see Cloning a volume for an Amazon Aurora DB cluster (p. 303).

Backtrack

Aurora MySQL now supports "rewinding" a DB cluster to a specific time, without restoring data from a backup. For more information, see Backtracking an Aurora DB cluster (p. 880).
Understanding Amazon Aurora backup storage usage

Amazon Aurora maintains two types of backup: automated (continuous) backups and snapshots.

Automated backup storage

The automated (continuous) backup for a cluster incrementally stores all database changes within a specified retention period to be able to restore to any point in time within that retention period. Retention periods can range from 1–35 days. Automated backups are incremental and charged based on the amount of storage that's required to restore to any time within the retention period.

Aurora also provides a free amount of backup usage. This free amount of usage is equal to the latest cluster volume size (as represented by the `VolumeBytesUsed` Amazon CloudWatch metric). This amount is subtracted from the calculated automated backup usage. There is also no charge for an automated backup whose retention period is just 1 day.

For example, your automated backup has a retention period of 7 days, and you want to restore your cluster to its state from four days ago. Aurora uses the incremental data stored in the automated backup to re-create the state of the cluster at that exact time four days ago.

The automated backup stores all the required information to be able to restore the cluster at any point in time in the retention window. That means that it stores all changes during the retention window, including writes of new information or deletion of existing information. For databases where many changes occur, the size of the automated backup grows over time. After a database stops experiencing changes, you can expect the size of the automated backup to decrease, as the previously stored changes exit the retention window.

The total billed usage for the automated backup never exceeds the cumulative cluster volume size over the retention period. For example, if your retention period is 7 days, and your cluster volume was 100 GB every day, then the billed automated backup usage never exceeds 700 GB (100 GB * 7).

Snapshot storage

DB cluster snapshots are always full backups whose size is that of the cluster volume at the time the snapshot is taken. Snapshots, either taken manually by the user or automatically by an AWS Backups plan, are treated as manual snapshots. Aurora provides unlimited free storage for all snapshots that lie within the automated backup retention period. After a manual snapshot is outside the retention period, it's billed per GB-month. Any automated system snapshot is never charged unless copied and retained past the retention period.

For general information about Aurora backups, see Backups (p. 427). For pricing information about Aurora backup storage, see the Amazon Aurora pricing page.

Amazon CloudWatch metrics for Aurora backup storage

You can monitor your Aurora clusters and create reports using Amazon CloudWatch metrics through the CloudWatch console. You can use the following CloudWatch metrics to review and monitor the amount of storage used by your Aurora backups. These metrics are computed independently for each Aurora DB cluster.

- `BackupRetentionPeriodStorageUsed` – Represents the amount of backup storage used, in bytes, for storing automated backups at the current time.
Calculating backup storage usage

The usage for an automated backup is calculated by looking at all of the incremental records that must be stored, to be able to restore to any point in time within the retention period of the backup.

For example, you have an automated backup with retention period of 7 days. Your cluster volume size just before the retention period was 100 GB, so that's the least amount that Aurora needs to store. Then you have the following activity for the next 7 days, where the incremental record size is the amount of storage needed to store the change records coming from your database's writes and updates.

<table>
<thead>
<tr>
<th>Day</th>
<th>Incremental record size (GB)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>10</td>
</tr>
<tr>
<td>2</td>
<td>15</td>
</tr>
<tr>
<td>3</td>
<td>25</td>
</tr>
<tr>
<td>4</td>
<td>20</td>
</tr>
<tr>
<td>5</td>
<td>10</td>
</tr>
<tr>
<td>6</td>
<td>25</td>
</tr>
</tbody>
</table>
This data means that the calculated automated backup usage for your backup is the following:

\[
100 \text{ GB (volume size before retention period)} + 135 \text{ GB (size of incremental records)} = 235 \text{ GB total backup usage}
\]

The billed usage then subtracts the free tier of usage. Assume that the latest size of your volume is 200 GB:

\[
235 \text{ GB total backup usage} - 200 \text{ GB (latest volume size)} = 35 \text{ GB billed backup usage}
\]

**FAQs**

**When am I billed for snapshots?**

You're billed for manual snapshots that are outside (older than) the retention period of the automated backup.

**What's a manual snapshot?**

A manual snapshot is a snapshot to which one of the following conditions applies:

- Manually requested by you
- Taken by an automated backup service such as AWS Backup
- Copied from an automated system snapshot to preserve it outside the retention period

**What happens to my manual snapshots if I delete my DB cluster?**

Manual snapshots don't expire until you delete them.

When you delete your DB cluster, the manual snapshots that you previously took continue to exist. If these snapshots previously weren't being billed because they were within the automated backup retention period, now they're not covered anymore and all start to be billed at their full size for their usage.

**How can I reduce my backup storage costs?**

There are a few ways to reduce backup usage related costs:

- Delete manual snapshots that lie outside your automated backup's retention period. This includes the snapshots you've taken, as well as the snapshots that your AWS Backup plan might have taken. Make sure to check your AWS Backup plan to make sure it isn't keeping snapshots outside the retention period that you don't expect.
- Evaluate your writes and updates to your database to see if you can reduce the number of changes you're making. Because our automated backup stores all incremental changes within the retention period, reducing the number of updates that you're making also reduces your automated backup charges.
- Evaluate whether reducing your automated backup's retention period would make sense. Reducing the retention period means that the backup stores fewer days of incremental data, which could reduce the overall backup cost. However, reducing this retention period could also cause some snapshots to start being billed because they're now outside the retention period. Make sure to check all the extra snapshot costs that you might incur before deciding whether this is the right course of action for you.
How is backup storage billed?

Backup storage is billed by the GB-month.

This means that the backup storage usage is charged as the weighted average of the usage over the given month. Here are a few examples for a 30-day month:

- Billed backup usage is 100 GB for all 30 days of the month. Your charge is the following:

\[
\frac{100 \text{ GB} \times 30}{30} = 100 \text{ GB-month}
\]

- Billed backup usage is 100 GB for the first 15 days of the month, then 0 GB for the last 15. Your charge is the following:

\[
\frac{100 \text{ GB} \times 15 + 0 \text{ GB} \times 15}{30} = 50 \text{ GB-month}
\]

- Billed backup usage is 50 GB for the first 10 days of the month, 100 GB for the next 10 days, then 150 GB for the final 10. Your charge is the following:

\[
\frac{50 \text{ GB} \times 10 + 100 \text{ GB} \times 10 + 150 \text{ GB} \times 10}{30} = 100 \text{ GB-month}
\]

How does the backtrack setting for my DB cluster affect backup storage usage?

The backtrack setting for an Aurora DB cluster doesn't affect the volume of backup data for that cluster. Amazon bills the storage for backtracking data separately. For pricing information about Aurora backtracking, see the Amazon Aurora pricing page.

How do storage costs apply to shared snapshots?

If you share a snapshot with another user, you're still the owner of that snapshot. The storage costs apply to the snapshot owner. If you delete a shared snapshot that you own, nobody can access it.

To keep access to a shared snapshot owned by someone else, you can copy that snapshot. Doing so makes you the owner of the new snapshot. Any storage costs for the copied snapshot apply to your account.

For more information on sharing snapshots, see Sharing a DB cluster snapshot (p. 452). For more information on copying snapshots, see Copying a DB cluster snapshot (p. 442).
Creating a DB cluster snapshot

Amazon RDS creates a storage volume snapshot of your DB cluster, backing up the entire DB cluster and not just individual databases. When you create a DB cluster snapshot, you need to identify which DB cluster you are going to back up, and then give your DB cluster snapshot a name so you can restore from it later. The amount of time it takes to create a DB cluster snapshot varies with the size of your databases. Because the snapshot includes the entire storage volume, the size of files, such as temporary files, also affects the amount of time it takes to create the snapshot.

**Note**
Your DB cluster must be in the available state to take a DB cluster snapshot.

Unlike automated backups, manual snapshots aren't subject to the backup retention period. Snapshots don't expire.

For very long-term backups, we recommend exporting snapshot data to Amazon S3. If the major version of your DB engine is no longer supported, you can't restore to that version from a snapshot. For more information, see [Exporting DB cluster snapshot data to Amazon S3](p. 471).

You can create a DB cluster snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To create a DB cluster snapshot**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. In the list of DB instances, choose a writer instance for the DB cluster.
4. Choose **Actions**, and then choose **Take snapshot**.

   The **Take DB Snapshot** window appears.

5. Enter the name of the DB cluster snapshot in the **Snapshot name** box.

6. Choose **Take Snapshot**.
**AWS CLI**

When you create a DB cluster snapshot using the AWS CLI, you need to identify which DB cluster you are going to back up, and then give your DB cluster snapshot a name so you can restore from it later. You can do this by using the AWS CLI `create-db-cluster-snapshot` command with the following parameters:

- `--db-cluster-identifier`
- `--db-cluster-snapshot-identifier`

In this example, you create a DB cluster snapshot named *mydbclustersnapshot* for a DB cluster called *mydbcluster*.

**Example**

For Linux, macOS, or Unix:

```
aws rds create-db-cluster-snapshot \
  --db-cluster-identifier mydbcluster \
  --db-cluster-snapshot-identifier mydbclustersnapshot
```

For Windows:

```
aws rds create-db-cluster-snapshot ^
  --db-cluster-identifier mydbcluster ^
  --db-cluster-snapshot-identifier mydbclustersnapshot
```

**RDS API**

When you create a DB cluster snapshot using the Amazon RDS API, you need to identify which DB cluster you are going to back up, and then give your DB cluster snapshot a name so you can restore from it later. You can do this by using the Amazon RDS API `CreateDBClusterSnapshot` command with the following parameters:

- `DBClusterIdentifier`
- `DBClusterSnapshotIdentifier`

**Determining whether the DB cluster snapshot is available**

You can check that the DB cluster snapshot is available by looking under *Snapshots* on the *Maintenance & backups* tab on the detail page for the cluster in the AWS Management Console, by using the `describe-db-cluster-snapshots` CLI command, or by using the `DescribeDBClusterSnapshots` API action.

You can also use the `wait db-cluster-snapshot-available` CLI command to poll the API every 30 seconds until the snapshot is available.
Restoring from a DB cluster snapshot

Amazon RDS creates a storage volume snapshot of your DB cluster, backing up the entire DB cluster and not just individual databases. You can create a new DB cluster by restoring from a DB snapshot. You provide the name of the DB cluster snapshot to restore from, and then provide a name for the new DB cluster that is created from the restore. You can't restore from a DB cluster snapshot to an existing DB cluster; a new DB cluster is created when you restore.

You can use the restored DB cluster as soon as its status is available.

You can use AWS CloudFormation to restore a DB cluster from a DB cluster snapshot. For more information, see `AWS::RDS::DBCluster` in the AWS CloudFormation User Guide.

Note
Sharing a manual DB cluster snapshot, whether encrypted or unencrypted, enables authorized AWS accounts to directly restore a DB cluster from the snapshot instead of taking a copy of it and restoring from that. For more information, see Sharing a DB cluster snapshot (p. 452).

Parameter group considerations

We recommend that you retain the DB parameter group and DB cluster parameter group for any DB cluster snapshots you create, so that you can associate your restored DB cluster with the correct parameter groups.

The default DB parameter group and DB cluster parameter group are associated with the restored cluster, unless you choose different ones. No custom parameter settings are available in the default parameter groups.

You can specify the parameter groups when you restore the DB cluster.

For more information about DB parameter groups and DB cluster parameter groups, see Working with parameter groups (p. 212).

Security group considerations

When you restore a DB cluster, the default virtual private cloud (VPC), DB subnet group, and VPC security group are associated with the restored instance, unless you choose different ones.

- If you're using the Amazon RDS console, you can specify a custom VPC security group to associate with the cluster or create a new VPC security group.
- If you're using the AWS CLI, you can specify a custom VPC security group to associate with the cluster by including the `--vpc-security-group-ids` option in the `restore-db-cluster-from-snapshot` command.
- If you're using the Amazon RDS API, you can include the `VpcSecurityGroupIds.VpcSecurityGroupId.N` parameter in the `RestoreDBClusterFromSnapshot` action.

As soon as the restore is complete and your new DB cluster is available, you can also change the VPC settings by modifying the DB cluster. For more information, see Modifying an Amazon Aurora DB cluster (p. 269).

Amazon Aurora considerations

With Aurora, you restore a DB cluster snapshot to a DB cluster.
With both Aurora MySQL and Aurora PostgreSQL, you can also restore a DB cluster snapshot to an Aurora Serverless DB cluster. For more information, see Restoring an Aurora Serverless v1 DB cluster (p. 2047).

With Aurora MySQL, you can restore a DB cluster snapshot from a cluster without parallel query to a cluster with parallel query. Because parallel query is typically used with very large tables, the snapshot mechanism is the fastest way to ingest large volumes of data to an Aurora MySQL parallel query-enabled cluster. For more information, see Working with parallel query for Amazon Aurora MySQL (p. 948).

## Restoring from a snapshot

You can restore a DB cluster from a DB cluster snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

### Console

**To restore a DB cluster from a DB cluster snapshot**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Snapshots.
3. Choose the DB cluster snapshot that you want to restore from.
4. For Actions, choose Restore snapshot.
   
   The Restore snapshot page displays.
5. Choose the DB engine version to which you want to restore the DB cluster.
   
   By default, the snapshot is restored to the same DB engine version as the source DB cluster, if that version is available.
6. For DB instance identifier, enter the name for your restored DB cluster.
7. Specify other settings, such as the DB cluster storage configuration.
   
   For information about each setting, see Settings for Aurora DB clusters (p. 190).
8. Choose Restore DB cluster.

### AWS CLI

To restore a DB cluster from a DB cluster snapshot, use the AWS CLI command `restore-db-cluster-from-snapshot`.

In this example, you restore from a previously created DB cluster snapshot named mydbclustersnapshot. You restore to a new DB cluster named mynewdbcluster.

You can specify other settings, such as the DB engine version. If you don't specify an engine version, the DB cluster is restored to the default engine version.

For information about each setting, see Settings for Aurora DB clusters (p. 190).

**Example**

For Linux, macOS, or Unix:

```bash
aws rds restore-db-cluster-from-snapshot 
   --db-cluster-identifier mynewdbcluster 
   --snapshot-identifier mydbclustersnapshot
```
Restoring from a snapshot

--engine aurora-mysql|aurora-postgresql

For Windows:

```bash
aws rds restore-db-cluster-from-snapshot ^
  --db-cluster-identifier mynewdbcluster ^
  --snapshot-identifier mydbclustersnapshot ^
  --engine aurora-mysql|aurora-postgresql
```

After the DB cluster has been restored, you must add the DB cluster to the security group used by the DB cluster used to create the DB cluster snapshot if you want the same functionality as that of the previous DB cluster.

**Important**
If you use the console to restore a DB cluster, then Amazon RDS automatically creates the primary DB instance (writer) for your DB cluster. If you use the AWS CLI to restore a DB cluster, you must explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster. If you don't create the primary DB instance, the DB cluster endpoints remain in the creating status.

Call the **create-db-instance** AWS CLI command to create the primary instance for your DB cluster. Include the name of the DB cluster as the **--db-cluster-identifier** option value.

**RDS API**

To restore a DB cluster from a DB cluster snapshot, call the RDS API operation **RestoreDBClusterFromSnapshot** with the following parameters:

- **DBClusterIdentifier**
- **SnapshotIdentifier**

**Important**
If you use the console to restore a DB cluster, then Amazon RDS automatically creates the primary DB instance (writer) for your DB cluster. If you use the RDS API to restore a DB cluster, you must explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster. If you don't create the primary DB instance, the DB cluster endpoints remain in the creating status.

Call the RDS API operation **CreateDBInstance** to create the primary instance for your DB cluster. Include the name of the DB cluster as the **DBClusterIdentifier** parameter value.
Copying a DB cluster snapshot

With Amazon Aurora, you can copy automated backups or manual DB cluster snapshots. After you copy a snapshot, the copy is a manual snapshot. You can make multiple copies of an automated backup or manual snapshot, but each copy must have a unique identifier.

You can copy a snapshot within the same AWS Region, you can copy a snapshot across AWS Regions, and you can copy shared snapshots.

You can't copy a DB cluster snapshot across Regions and accounts in a single step. Perform one step for each of these copy actions. As an alternative to copying, you can also share manual snapshots with other AWS accounts. For more information, see Sharing a DB cluster snapshot (p. 452).

Note
Amazon bills you based upon the amount of Amazon Aurora backup and snapshot data you keep and the period of time that you keep it. For information about the storage associated with Aurora backups and snapshots, see Understanding Amazon Aurora backup storage usage (p. 433). For pricing information about Aurora storage, see Amazon RDS for Aurora pricing.

Limitations
The following are some limitations when you copy snapshots:

- You can't copy a snapshot to or from the following AWS Regions:
  - China (Beijing)
  - China (Ningxia)
- You can copy a snapshot between AWS GovCloud (US-East) and AWS GovCloud (US-West). However, you can't copy a snapshot between these AWS GovCloud (US) Regions and commercial AWS Regions.
- If you delete a source snapshot before the target snapshot becomes available, the snapshot copy might fail. Verify that the target snapshot has a status of AVAILABLE before you delete a source snapshot.
- You can have up to five snapshot copy requests in progress to a single destination Region per account.
- When you request multiple snapshot copies for the same source DB instance, they're queued internally. The copies requested later won't start until the previous snapshot copies are completed. For more information, see Why is my EC2 AMI or EBS snapshot creation slow? in the AWS Knowledge Center.
- Depending on the AWS Regions involved and the amount of data to be copied, a cross-Region snapshot copy can take hours to complete. In some cases, there might be a large number of cross-Region snapshot copy requests from a given source Region. In such cases, Amazon RDS might put new cross-Region copy requests from that source Region into a queue until some in-progress copies complete. No progress information is displayed about copy requests while they are in the queue. Progress information is displayed when the copy starts.

Snapshot retention
Amazon RDS deletes automated backups in several situations:

- At the end of their retention period.
- When you disable automated backups for a DB cluster.
- When you delete a DB cluster.
If you want to keep an automated backup for a longer period, copy it to create a manual snapshot, which is retained until you delete it. Amazon RDS storage costs might apply to manual snapshots if they exceed your default storage space.

For more information about backup storage costs, see Amazon RDS pricing.

Copying shared snapshots

You can copy snapshots shared to you by other AWS accounts. In some cases, you might copy an encrypted snapshot that has been shared from another AWS account. In these cases, you must have access to the AWS KMS key that was used to encrypt the snapshot.

You can only copy a shared DB cluster snapshot, whether encrypted or not, in the same AWS Region. For more information, see Sharing encrypted snapshots (p. 453).

Handling encryption

You can copy a snapshot that has been encrypted using a KMS key. If you copy an encrypted snapshot, the copy of the snapshot must also be encrypted. If you copy an encrypted snapshot within the same AWS Region, you can encrypt the copy with the same KMS key as the original snapshot. Or you can specify a different KMS key.

If you copy an encrypted snapshot across Regions, you must specify a KMS key valid in the destination AWS Region. It can be a Region-specific KMS key, or a multi-Region key. For more information on multi-Region KMS keys, see Using multi-Region keys in AWS KMS.

The source snapshot remains encrypted throughout the copy process. For more information, see Limitations of Amazon Aurora encrypted DB clusters (p. 2383).

Note
For Amazon Aurora DB cluster snapshots, you can't encrypt an unencrypted DB cluster snapshot when you copy the snapshot.

Incremental snapshot copying

Aurora doesn't support incremental snapshot copying. Aurora DB cluster snapshot copies are always full copies. A full snapshot copy contains all of the data and metadata required to restore the DB cluster.

Cross-Region snapshot copying

You can copy DB cluster snapshots across AWS Regions. However, there are certain constraints and considerations for cross-Region snapshot copying.

Depending on the AWS Regions involved and the amount of data to be copied, a cross-Region snapshot copy can take hours to complete.

In some cases, there might be a large number of cross-Region snapshot copy requests from a given source AWS Region. In such cases, Amazon RDS might put new cross-Region copy requests from that source AWS Region into a queue until some in-progress copies complete. No progress information is displayed about copy requests while they are in the queue. Progress information is displayed when the copying starts.

Parameter group considerations

When you copy a snapshot across Regions, the copy doesn't include the parameter group used by the original DB cluster. When you restore a snapshot to create a new DB cluster, that DB cluster gets
the default parameter group for the AWS Region it is created in. To give the new DB cluster the same parameters as the original, do the following:

1. In the destination AWS Region, create a DB cluster parameter group with the same settings as the original DB cluster. If one already exists in the new AWS Region, you can use that one.
2. After you restore the snapshot in the destination AWS Region, modify the new DB cluster and add the new or existing parameter group from the previous step.

### Copying a DB cluster snapshot

Use the procedures in this topic to copy a DB cluster snapshot. If your source database engine is Aurora, then your snapshot is a DB cluster snapshot.

For each AWS account, you can copy up to five DB cluster snapshots at a time from one AWS Region to another. Copying both encrypted and unencrypted DB cluster snapshots is supported. If you copy a DB cluster snapshot to another AWS Region, you create a manual DB cluster snapshot that is retained in that AWS Region. Copying a DB cluster snapshot out of the source AWS Region incurs Amazon RDS data transfer charges.

For more information about data transfer pricing, see [Amazon RDS pricing](#).

After the DB cluster snapshot copy has been created in the new AWS Region, the DB cluster snapshot copy behaves the same as all other DB cluster snapshots in that AWS Region.

### Console

This procedure works for copying encrypted or unencrypted DB cluster snapshots, in the same AWS Region or across Regions.

To cancel a copy operation once it is in progress, delete the target DB cluster snapshot while that DB cluster snapshot is in **copying** status.

### To copy a DB cluster snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Snapshots.
3. Select the check box for the DB cluster snapshot you want to copy.
4. For Actions, choose Copy snapshot. The Copy snapshot page appears.
5. (Optional) To copy the DB cluster snapshot to a different AWS Region, choose that AWS Region for Destination Region.

6. Type the name of the DB cluster snapshot copy in New DB Snapshot Identifier.

7. To copy tags and values from the snapshot to the copy of the snapshot, choose Copy Tags.

8. Choose Copy Snapshot.

Copying an unencrypted DB cluster snapshot by using the AWS CLI or Amazon RDS API

Use the procedures in the following sections to copy an unencrypted DB cluster snapshot by using the AWS CLI or Amazon RDS API.

To cancel a copy operation once it is in progress, delete the target DB cluster snapshot identified by --target-db-cluster-snapshot-identifier or TargetDBClusterSnapshotIdentifier while that DB cluster snapshot is in copying status.
AWS CLI

To copy a DB cluster snapshot, use the AWS CLI `copy-db-cluster-snapshot` command. If you are copying the snapshot to another AWS Region, run the command in the AWS Region to which the snapshot will be copied.

The following options are used to copy an unencrypted DB cluster snapshot:

- `--source-db-cluster-snapshot-identifier` – The identifier for the DB cluster snapshot to be copied. If you are copying the snapshot to another AWS Region, this identifier must be in the ARN format for the source AWS Region.
- `--target-db-cluster-snapshot-identifier` – The identifier for the new copy of the DB cluster snapshot.

The following code creates a copy of DB cluster snapshot `arn:aws:rds:us-east-1:123456789012:cluster-snapshot:aurora-cluster1-snapshot-20130805` named `myclustersnapshotcopy` in the AWS Region in which the command is run. When the copy is made, all tags on the original snapshot are copied to the snapshot copy.

Example

For Linux, macOS, or Unix:

```
aws rds copy-db-cluster-snapshot
  --target-db-cluster-snapshot-identifier myclustersnapshotcopy
  --copy-tags
```

For Windows:

```
aws rds copy-db-cluster-snapshot ^
  --target-db-cluster-snapshot-identifier myclustersnapshotcopy ^
  --copy-tags
```

RDS API

To copy a DB cluster snapshot, use the Amazon RDS API `CopyDBClusterSnapshot` operation. If you are copying the snapshot to another AWS Region, perform the action in the AWS Region to which the snapshot will be copied.

The following parameters are used to copy an unencrypted DB cluster snapshot:

- `SourceDBClusterSnapshotIdentifier` – The identifier for the DB cluster snapshot to be copied. If you are copying the snapshot to another AWS Region, this identifier must be in the ARN format for the source AWS Region.
- `TargetDBClusterSnapshotIdentifier` – The identifier for the new copy of the DB cluster snapshot.

The following code creates a copy of a snapshot `arn:aws:rds:us-east-1:123456789012:cluster-snapshot:aurora-cluster1-snapshot-20130805` named `myclustersnapshotcopy` in the US West (N. California) Region. When the copy is made, all tags on the original snapshot are copied to the snapshot copy.
Copying an encrypted DB cluster snapshot by using the AWS CLI or Amazon RDS API

Use the procedures in the following sections to copy an encrypted DB cluster snapshot by using the AWS CLI or Amazon RDS API.

To cancel a copy operation once it is in progress, delete the target DB cluster snapshot identified by --target-db-cluster-snapshot-identifier or TargetDBClusterSnapshotIdentifier while that DB cluster snapshot is in copying status.

AWS CLI

To copy a DB cluster snapshot, use the AWS CLI copy-db-cluster-snapshot command. If you are copying the snapshot to another AWS Region, run the command in the AWS Region to which the snapshot will be copied.

The following options are used to copy an encrypted DB cluster snapshot:

- --source-db-cluster-snapshot-identifier – The identifier for the encrypted DB cluster snapshot to be copied. If you are copying the snapshot to another AWS Region, this identifier must be in the ARN format for the source AWS Region.
- --target-db-cluster-snapshot-identifier – The identifier for the new copy of the encrypted DB cluster snapshot.
- --kms-key-id – The KMS key identifier for the key to use to encrypt the copy of the DB cluster snapshot.

You can optionally use this option if the DB cluster snapshot is encrypted, you copy the snapshot in the same AWS Region, and you want to specify a new KMS key to encrypt the copy. Otherwise, the copy of the DB cluster snapshot is encrypted with the same KMS key as the source DB cluster snapshot.

You must use this option if the DB cluster snapshot is encrypted and you are copying the snapshot to another AWS Region. In that case, you must specify a KMS key for the destination AWS Region.

The following code example copies the encrypted DB cluster snapshot from the US West (Oregon) Region to the US East (N. Virginia) Region. The command is called in the US East (N. Virginia) Region.

Example

For Linux, macOS, or Unix:

```
aws rds copy-db-cluster-snapshot \
```
Copying a DB cluster snapshot

```
--target-db-cluster-snapshot-identifier myclustersnapshotcopy \
--kms-key-id my-us-east-1-key
```

For Windows:
```
aws rds copy-db-cluster-snapshot ^
--target-db-cluster-snapshot-identifier myclustersnapshotcopy ^
--kms-key-id my-us-east-1-key
```

The --source-region parameter is required when you're copying an encrypted DB cluster snapshot between the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions. For --source-region, specify the AWS Region of the source DB instance. The AWS Region specified in source-db-cluster-snapshot-identifier must match the AWS Region specified for --source-region.

If --source-region isn't specified, specify a --pre-signed-url value. A presigned URL is a URL that contains a Signature Version 4 signed request for the copy-db-cluster-snapshot command that's called in the source AWS Region. To learn more about the pre-signed-url option, see copy-db-cluster-snapshot in the AWS CLI Command Reference.

RDS API

To copy a DB cluster snapshot, use the Amazon RDS API CopyDBClusterSnapshot operation. If you are copying the snapshot to another AWS Region, perform the action in the AWS Region to which the snapshot will be copied.

The following parameters are used to copy an encrypted DB cluster snapshot:

- **SourceDBClusterSnapshotIdentifier** – The identifier for the encrypted DB cluster snapshot to be copied. If you are copying the snapshot to another AWS Region, this identifier must be in the ARN format for the source AWS Region.
- **TargetDBClusterSnapshotIdentifier** – The identifier for the new copy of the encrypted DB cluster snapshot.
- **KmsKeyId** – The KMS key identifier for the key to use to encrypt the copy of the DB cluster snapshot.

You can optionally use this parameter if the DB cluster snapshot is encrypted, you copy the snapshot in the same AWS Region, and you specify a new KMS key to use to encrypt the copy. Otherwise, the copy of the DB cluster snapshot is encrypted with the same KMS key as the source DB cluster snapshot.

You must use this parameter if the DB cluster snapshot is encrypted and you are copying the snapshot to another AWS Region. In that case, you must specify a KMS key for the destination AWS Region.

- **PreSignedUrl** – If you are copying the snapshot to another AWS Region, you must specify the PreSignedUrl parameter. The PreSignedUrl value must be a URL that contains a Signature Version 4 signed request for the CopyDBClusterSnapshot action to be called in the source AWS Region where the DB cluster snapshot is copied from. To learn more about using a presigned URL, see CopyDBClusterSnapshot.

The following code example copies the encrypted DB cluster snapshot from the US West (Oregon) Region to the US East (N. Virginia) Region. The action is called in the US East (N. Virginia) Region.

**Example**

https://rds.us-east-1.amazonaws.com/
The `PreSignedUrl` parameter is required when you are copying an encrypted DB cluster snapshot between the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions. The `PreSignedUrl` value must be a URL that contains a Signature Version 4 signed request for the `CopyDBClusterSnapshot` operation to be called in the source AWS Region where the DB cluster snapshot is copied from. To learn more about using a presigned URL, see `CopyDBClusterSnapshot` in the Amazon RDS API Reference.

To automatically rather than manually generate a presigned URL, use the AWS CLI `copy-db-cluster-snapshot` command with the `--source-region` option instead.

### Copying a DB cluster snapshot across accounts

You can enable other AWS accounts to copy DB cluster snapshots that you specify by using the Amazon RDS API `ModifyDBClusterSnapshotAttribute` and `CopyDBClusterSnapshot` actions. You can only copy DB cluster snapshots across accounts in the same AWS Region. The cross-account copying process works as follows, where Account A is making the snapshot available to copy, and Account B is copying it.

1. Using Account A, call `ModifyDBClusterSnapshotAttribute`, specifying `restore` for the `AttributeName` parameter, and the ID for Account B for the `ValuesToAdd` parameter.
2. (If the snapshot is encrypted) Using Account A, update the key policy for the KMS key, first adding the ARN of Account B as a Principal, and then allow the `kms:CreateGrant` action.
3. (If the snapshot is encrypted) Using Account B, choose or create a user and attach an IAM policy to that user that allows it to copy an encrypted DB cluster snapshot using your KMS key.
4. Using Account B, call `CopyDBClusterSnapshot` and use the `SourceDBClusterSnapshotIdentifier` parameter to specify the ARN of the DB cluster snapshot to be copied, which must include the ID for Account A.
To list all of the AWS accounts permitted to restore a DB cluster snapshot, use the DescribeDBSnapshotAttributes or DescribeDBClusterSnapshotAttributes API operation.

To remove sharing permission for an AWS account, use the ModifyDBSnapshotAttribute or ModifyDBClusterSnapshotAttribute action with AttributeName set to restore and the ID of the account to remove in the ValuesToRemove parameter.

### Copying an unencrypted DB cluster snapshot to another account

Use the following procedure to copy an unencrypted DB cluster snapshot to another account in the same AWS Region.

1. In the source account for the DB cluster snapshot, call ModifyDBClusterSnapshotAttribute, specifying restore for the AttributeName parameter, and the ID for the target account for the ValuesToAdd parameter.

   Running the following example using the account 987654321 permits two AWS account identifiers, 123451234512 and 123456789012, to restore the DB cluster snapshot named manual-snapshot1.

   ```
   https://rds.us-west-2.amazonaws.com/?Action=ModifyDBClusterSnapshotAttribute
   &AttributeName=restore
   &DBClusterSnapshotIdentifier=manual-snapshot1
   &SignatureMethod=HmacSHA256&SignatureVersion=4
   &ValuesToAdd.member.1=123451234512
   &ValuesToAdd.member.2=123456789012
   &Version=2014-10-31
   &X-Amz-Algorithm=AWS4-HMAC-SHA256
   &X-Amz-Credential=AKIADQKE4SARGYLE/20150922/us-west-2/rds/aws4_request
   &X-Amz-Date=20150922T220515Z
   &X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
   &X-Amz-Signature=ef38f1ce3dab4e1dbf113d8d2a256c67d17ece1999fffd56be85714ed36ddbb3
   ```

2. In the target account, call CopyDBClusterSnapshot and use the SourceDBClusterSnapshotIdentifier parameter to specify the ARN of the DB cluster snapshot to be copied, which must include the ID for the source account.

   Running the following example using the account 123451234512 copies the DB cluster snapshot aurora-cluster1-snapshot-20130805 from account 987654321 and creates a DB cluster snapshot named dbclustersnapshot1.

   ```
   https://rds.us-west-2.amazonaws.com/?Action=CopyDBClusterSnapshot
   &CopyTags=true
   &SignatureMethod=HmacSHA256
   &SignatureVersion=4
   &TargetDBClusterSnapshotIdentifier=dbclustersnapshot1
   &Version=2013-09-09
   &X-Amz-Algorithm=AWS4-HMAC-SHA256
   &X-Amz-Credential=AKIADQKE4SARGYLE/20150922/us-west-2/rds/aws4_request
   &X-Amz-Date=20140429T175351Z
   &X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
   &X-Amz-Signature=9164337efa99caf850e874a1cb7ef62f3cea29d0b448b9e0e7c53b288dffd3d2
Copying an encrypted DB cluster snapshot to another account

Use the following procedure to copy an encrypted DB cluster snapshot to another account in the same AWS Region.

1. In the source account for the DB cluster snapshot, call `ModifyDBClusterSnapshotAttribute`, specifying `restore` for the `AttributeName` parameter, and the ID for the target account for the `ValuesToAdd` parameter.

Running the following example using the account 987654321 permits two AWS account identifiers, 123451234512 and 123456789012, to restore the DB cluster snapshot named `manual-snapshot1`.

```
https://rds.us-west-2.amazonaws.com/
?Action=ModifyDBClusterSnapshotAttribute
&AttributeName=restore
&DBClusterSnapshotIdentifier=manual-snapshot1
&SignatureMethod=HmacSHA256&SignatureVersion=4
&ValuesToAdd.member.1=123451234512
&ValuesToAdd.member.2=123456789012
&Version=2014-10-31
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20150922/us-west-2/rds/aws4_request
&X-Amz-Date=20150922T220515Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=ef38f1ce3dad4eb1bdf113d8d2a265c67d17ece1999fdd56e85714ed36ddbb3
```

2. In the source account for the DB cluster snapshot, update the key policy for the KMS key, first adding the ARN of the target account as a `Principal`, and then allow the `kms:CreateGrant` action. For more information, see [Allowing access to an AWS KMS key](p. 453).

3. In the target account, choose or create a user and attach an IAM policy to that user that allows it to copy an encrypted DB cluster snapshot using your KMS key. For more information, see [Creating an IAM policy to enable copying of the encrypted snapshot](p. 454).

4. In the target account, call `CopyDBClusterSnapshot` and use the `SourceDBClusterSnapshotIdentifier` parameter to specify the ARN of the DB cluster snapshot to be copied, which must include the ID for the source account.

Running the following example using the account 123451234512 copies the DB cluster snapshot `aurora-cluster1-snapshot-20130805` from account 987654321 and creates a DB cluster snapshot named `dbclustersnapshot1`.

```
https://rds.us-west-2.amazonaws.com/
?Action=CopyDBClusterSnapshot
&CopyTags=true
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&TargetDBClusterSnapshotIdentifier=dbclustersnapshot1
&Version=2013-09-09

```
Sharing a DB cluster snapshot

Using Amazon RDS, you can share a manual DB cluster snapshot in the following ways:

- Sharing a manual DB cluster snapshot, whether encrypted or unencrypted, enables authorized AWS accounts to copy the snapshot.
- Sharing a manual DB cluster snapshot, whether encrypted or unencrypted, enables authorized AWS accounts to directly restore a DB cluster from the snapshot instead of taking a copy of it and restoring from that.

**Note**
To share an automated DB cluster snapshot, create a manual DB cluster snapshot by copying the automated snapshot, and then share that copy. This process also applies to AWS Backup–generated resources.

For more information on copying a snapshot, see [Copying a DB cluster snapshot](#). For more information on restoring a DB instance from a DB cluster snapshot, see [Restoring from a DB cluster snapshot](#).

For more information on restoring a DB cluster from a DB cluster snapshot, see [Overview of backing up and restoring an Aurora DB cluster](#).

You can share a manual snapshot with up to 20 other AWS accounts.

The following limitation applies when sharing manual snapshots with other AWS accounts:

- When you restore a DB cluster from a shared snapshot using the AWS Command Line Interface (AWS CLI) or Amazon RDS API, you must specify the Amazon Resource Name (ARN) of the shared snapshot as the snapshot identifier.

**Sharing public snapshots**

You can also share an unencrypted manual snapshot as public, which makes the snapshot available to all AWS accounts. Make sure when sharing a snapshot as public that none of your private information is included in the public snapshot.

When a snapshot is shared publicly, it gives all AWS accounts permission both to copy the snapshot and to create DB clusters from it.

You aren't billed for the backup storage of public snapshots owned by other accounts. You're billed only for snapshots that you own.

If you copy a public snapshot, you own the copy. You're billed for the backup storage of your snapshot copy. If you create a DB cluster from a public snapshot, you're billed for that DB cluster. For Amazon Aurora pricing information, see the [Aurora pricing page](#).

You can delete only the public snapshots that you own. To delete a shared or public snapshot, make sure to log into the AWS account that owns the snapshot.

**Viewing public snapshots owned by other AWS accounts**

You can view public snapshots owned by other accounts in a particular AWS Region on the Public tab of the Snapshots page in the Amazon RDS console. Your snapshots (those owned by your account) don't appear on this tab.
To view public snapshots

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Choose the Public tab.

The public snapshots appear. You can see which account owns a public snapshot in the Owner column.

Note
You might have to modify the page preferences, by selecting the gear icon at the upper right of the Public snapshots list, to see this column.

Viewing your own public snapshots

You can use the following AWS CLI command (Unix only) to view the public snapshots owned by your AWS account in a particular AWS Region.

```
aws rds describe-db-cluster-snapshots --snapshot-type public --include-public | grep account_number
```

The output returned is similar to the following example if you have public snapshots.

```
```

Sharing encrypted snapshots

You can share DB cluster snapshots that have been encrypted “at rest” using the AES-256 encryption algorithm, as described in Encrypting Amazon Aurora resources (p. 2381). To do this, take the following steps:

1. Share the AWS KMS key that was used to encrypt the snapshot with any accounts that you want to be able to access the snapshot.

   You can share KMS keys with another AWS account by adding the other account to the KMS key policy. For details on creating a key policy, see Key policies in the AWS KMS Developer Guide. For an example of creating a key policy, see Allowing access to an AWS KMS key (p. 453) later in this topic.

2. Use the AWS Management Console, AWS CLI, or Amazon RDS API to share the encrypted snapshot with the other accounts.

These restrictions apply to sharing encrypted snapshots:

- You can't share encrypted snapshots as public.
- You can't share a snapshot that has been encrypted using the default KMS key of the AWS account that shared the snapshot.

Allowing access to an AWS KMS key

For another AWS account to copy an encrypted DB cluster snapshot shared from your account, the account that you share your snapshot with must have access to the AWS KMS key that encrypted the snapshot.
Sharing encrypted snapshots

To allow another AWS account access to a KMS key, update the key policy for the KMS key. You update it with the Amazon Resource Name (ARN) of the AWS account that you are sharing to as Principal in the KMS key policy. Then you allow the kms:CreateGrant action.

After you have given an AWS account access to your KMS key, to copy your encrypted snapshot that AWS account must create an AWS Identity and Access Management (IAM) role or user if it doesn't already have one. In addition, that AWS account must also attach an IAM policy to that IAM role or permission set that allows the role or user to copy an encrypted DB cluster snapshot using your KMS key. The account must be a user and cannot be a root AWS account identity due to AWS KMS security restrictions.

In the following key policy example, user 111122223333 is the owner of the KMS key, and user 444455556666 is the account that the key is being shared with. This updated key policy gives the AWS account access to the KMS key by including the ARN for the root AWS account identity for user 444455556666 as a Principal for the policy, and by allowing the kms:CreateGrant action.

```json
{
  "Id": "key-policy-1",
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Allow use of the key",
      "Effect": "Allow",
      "Principal": {"AWS": [
        "arn:aws:iam::111122223333:user/KeyUser",
        "arn:aws:iam::444455556666:root"
      ]},
      "Action": [
        "kms:CreateGrant",
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncrypt*",
        "kms:GenerateDataKey*",
        "kms:DescribeKey"
      ],
      "Resource": "*"
    },
    {
      "Sid": "Allow attachment of persistent resources",
      "Effect": "Allow",
      "Principal": {"AWS": [
        "arn:aws:iam::111122223333:user/KeyUser",
        "arn:aws:iam::444455556666:root"
      ]},
      "Action": [
        "kms:CreateGrant",
        "kms:ListGrants",
        "kms:RevokeGrant"
      ],
      "Resource": "*",
      "Condition": {"Bool": {"kms:GrantIsForAWSResource": true}}
    }
  ]
}
```

Creating an IAM policy to enable copying of the encrypted snapshot

Once the external AWS account has access to your KMS key, the owner of that AWS account can create a policy that allows a user created for that account to copy an encrypted snapshot encrypted with that KMS key.
The following example shows a policy that can be attached to a user for AWS account 444455556666 that enables the user to copy a shared snapshot from AWS account 111122223333 that has been encrypted with the KMS key c989c1dd-a3f2-4a5d-8d96-e793d082ab26 in the us-west-2 region.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "AllowUseOfTheKey",
         "Effect": "Allow",
         "Action": [
            "kms:Encrypt",
            "kms:Decrypt",
            "kms:ReEncrypt*",
            "kms:GenerateDataKey*",
            "kms:DescribeKey",
            "kms:CreateGrant",
            "kms:RetireGrant"
         ],
         "Resource": ["arn:aws:kms:us-west-2:111122223333:key/c989c1dd-a3f2-4a5d-8d96-e793d082ab26"]
      },
      {
         "Sid": "AllowAttachmentOfPersistentResources",
         "Effect": "Allow",
         "Action": [
            "kms:CreateGrant",
            "kms:ListGrants",
            "kms:RevokeGrant"
         ],
         "Resource": ["arn:aws:kms:us-west-2:111122223333:key/c989c1dd-a3f2-4a5d-8d96-e793d082ab26"],
         "Condition": {
            "Bool": {
               "kms:GrantIsForAWSResource": true
            }
         }
      }
   ]
}
```

For details on updating a key policy, see Key policies in the AWS KMS Developer Guide.

**Sharing a snapshot**

You can share a DB cluster snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

Using the Amazon RDS console, you can share a manual DB cluster snapshot with up to 20 AWS accounts. You can also use the console to stop sharing a manual snapshot with one or more accounts.

**To share a manual DB cluster snapshot by using the Amazon RDS console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Select the manual snapshot that you want to share.
4. For Actions, choose Share snapshot.
5. Choose one of the following options for **DB snapshot visibility**.
   - If the source is unencrypted, choose **Public** to permit all AWS accounts to restore a DB cluster from your manual DB cluster snapshot, or choose **Private** to permit only AWS accounts that you specify to restore a DB cluster from your manual DB cluster snapshot.

   **Warning**
   If you set **DB snapshot visibility** to **Public**, all AWS accounts can restore a DB cluster from your manual DB cluster snapshot and have access to your data. Do not share any manual DB cluster snapshots that contain private information as **Public**.

   - If the source is encrypted, **DB snapshot visibility** is set as **Private** because encrypted snapshots can’t be shared as public.

6. For **AWS Account ID**, type the AWS account identifier for an account that you want to permit to restore a DB cluster from your manual snapshot, and then choose **Add**. Repeat to include additional AWS account identifiers, up to 20 AWS accounts.

   If you make an error when adding an AWS account identifier to the list of permitted accounts, you can delete it from the list by choosing **Delete** at the right of the incorrect AWS account identifier.

7. After you have added identifiers for all of the AWS accounts that you want to permit to restore the manual snapshot, choose **Save** to save your changes.

### To stop sharing a manual DB cluster snapshot with an AWS account

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Snapshots**.
3. Select the manual snapshot that you want to stop sharing.
4. Choose **Actions**, and then choose **Share snapshot**.
5. To remove permission for an AWS account, choose **Delete** for the AWS account identifier for that account from the list of authorized accounts.

![Snapshot permissions](image)

6. Choose **Save** to save your changes.

**AWS CLI**

To share a DB cluster snapshot, use the `aws rds modify-db-cluster-snapshot-attribute` command. Use the `--values-to-add` parameter to add a list of the IDs for the AWS accounts that are authorized to restore the manual snapshot.

**Example of sharing a snapshot with a single account**

The following example enables AWS account identifier `123456789012` to restore the DB cluster snapshot named `cluster-3-snapshot`.

For Linux, macOS, or Unix:

```sh
aws rds modify-db-cluster-snapshot-attribute \\
--db-cluster-snapshot-identifier cluster-3-snapshot \\
--attribute-name restore \\
--values-to-add 123456789012
```

For Windows:

```sh
aws rds modify-db-cluster-snapshot-attribute ^
--db-cluster-snapshot-identifier cluster-3-snapshot ^
--attribute-name restore ^
--values-to-add 123456789012
```
Sharing a snapshot

Example of sharing a snapshot with multiple accounts

The following example enables two AWS account identifiers, 111122223333 and 444455556666, to restore the DB cluster snapshot named manual-cluster-snapshot1.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-snapshot-attribute
  --db-cluster-snapshot-identifier manual-cluster-snapshot1
  --attribute-name restore
  --values-to-add "111122223333","444455556666"
```

For Windows:

```
aws rds modify-db-cluster-snapshot-attribute
  --db-cluster-snapshot-identifier manual-cluster-snapshot1
  --attribute-name restore
  --values-to-add "["111122223333","444455556666"]"
```

Note

When using the Windows command prompt, you must escape double quotes (") in JSON code by prefixing them with a backslash (\).

To remove an AWS account identifier from the list, use the --values-to-remove parameter.

Example of stopping snapshot sharing

The following example prevents AWS account ID 444455556666 from restoring the snapshot.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-snapshot-attribute
  --db-cluster-snapshot-identifier manual-cluster-snapshot1
  --attribute-name restore
  --values-to-remove 444455556666
```

For Windows:

```
aws rds modify-db-cluster-snapshot-attribute
  --db-cluster-snapshot-identifier manual-cluster-snapshot1
  --attribute-name restore
  --values-to-remove 444455556666
```

To list the AWS accounts enabled to restore a snapshot, use the `describe-db-cluster-snapshot-attributes` AWS CLI command.

RDS API

You can also share a manual DB cluster snapshot with other AWS accounts by using the Amazon RDS API. To do so, call the `ModifyDBClusterSnapshotAttribute` operation. Specify `restore` for `AttributeName`, and use the `ValuesToAdd` parameter to add a list of the IDs for the AWS accounts that are authorized to restore the manual snapshot.

To make a manual snapshot public and restorable by all AWS accounts, use the `all` value. However, take care not to add the `all` value for any manual snapshots that contain private information that you don't want to be available to all AWS accounts. Also, don't specify `all` for encrypted snapshots, because making such snapshots public isn't supported.
To remove sharing permission for an AWS account, use the `ModifyDBClusterSnapshotAttribute` operation with `AttributeName` set to `restore` and the `ValuesToRemove` parameter. To mark a manual snapshot as private, remove the value `all` from the values list for the `restore` attribute.

To list all of the AWS accounts permitted to restore a snapshot, use the `DescribeDBClusterSnapshotAttributes` API operation.
Exporting DB cluster data to Amazon S3

You can export data from a live Amazon Aurora DB cluster to an Amazon S3 bucket. The export process runs in the background and doesn't affect the performance of your active DB cluster.

By default, all data in the DB cluster is exported. However, you can choose to export specific sets of databases, schemas, or tables.

Amazon Aurora clones the DB cluster, extracts data from the clone, and stores the data in an Amazon S3 bucket. The data is stored in an Apache Parquet format that is compressed and consistent. Individual Parquet files are usually 1–10 MB in size.

The faster performance that you can get with exporting snapshot data for Aurora MySQL version 2 and version 3 doesn't apply to exporting DB cluster data. For more information, see Exporting DB cluster snapshot data to Amazon S3 (p. 471).

You're charged for exporting the entire DB cluster, whether you export all or partial data. For more information, see the Amazon Aurora pricing page.

After the data is exported, you can analyze the exported data directly through tools like Amazon Athena or Amazon Redshift Spectrum. For more information on using Athena to read Parquet data, see Parquet SerDe in the Amazon Athena User Guide. For more information on using Redshift Spectrum to read Parquet data, see COPY from columnar data formats in the Amazon Redshift Database Developer Guide.

Feature availability and support varies across specific versions of each database engine and across AWS Regions. For more information on version and Region availability of exporting DB cluster data to S3, see Exporting cluster data to Amazon S3 (p. 31).

Topics
- Limitations (p. 460)
- Overview of exporting DB cluster data (p. 461)
- Setting up access to an Amazon S3 bucket (p. 462)
- Exporting DB cluster data to an Amazon S3 bucket (p. 464)
- Monitoring DB cluster export tasks (p. 466)
- Canceling a DB cluster export task (p. 468)
- Failure messages for Amazon S3 export tasks (p. 469)
- Troubleshooting PostgreSQL permissions errors (p. 470)
- File naming convention (p. 470)
- Data conversion and storage format (p. 470)

Limitations

Exporting DB cluster data to Amazon S3 has the following limitations:

- You can't run multiple export tasks for the same DB cluster simultaneously. This applies to both full and partial exports.
- Aurora Serverless v1 DB clusters don't support exports to S3.
- Aurora MySQL and Aurora PostgreSQL support exports to S3 only for the provisioned engine mode.
- DB clusters can have at most 15 clones. Because of this limit, if your cluster already has 15 clones, the export task copies the DB cluster instead of cloning it. Copying causes the export task to take longer. For more information on cloning, see Cloning a volume for an Amazon Aurora DB cluster (p. 303).
The following characters in the S3 file path are converted to underscores (_) during export:

```
\ " (space)
```

- If a database, schema, or table has characters in its name other than the following, partial export isn't supported. However, you can export the entire DB cluster.
  - Latin letters (A–Z)
  - Digits (0–9)
  - Dollar symbol ($)
  - Underscore (_)
- Spaces ( ) and certain characters aren't supported in database table column names. Tables with the following characters in column names are skipped during export:

```
, ; { } ( ) \n \t = (space)
```
- Tables with slashes (/) in their names are skipped during export.
- Aurora PostgreSQL temporary and unlogged tables are skipped during export.
- If the data contains a large object, such as a BLOB or CLOB, that is close to or greater than 500 MB, then the export fails.
- If a table contains a large row that is close to or greater than 2 GB, then the table is skipped during export.
- We strongly recommend that you use a unique name for each export task. If you don't use a unique task name, you might receive the following error message:

```
ExportTaskAlreadyExistsFault: An error occurred (ExportTaskAlreadyExists) when calling the StartExportTask operation: The export task with the ID xxxxxx already exists.
```
- Because some tables might be skipped, we recommend that you verify row and table counts in the data after export.

### Overview of exporting DB cluster data

You use the following process to export DB cluster data to an Amazon S3 bucket. For more details, see the following sections.

1. Identify the DB cluster whose data you want to export.
2. Set up access to the Amazon S3 bucket.

   A bucket is a container for Amazon S3 objects or files. To provide the information to access a bucket, take the following steps:

   a. Identify the S3 bucket where the DB cluster data is to be exported. The S3 bucket must be in the same AWS Region as the DB cluster. For more information, see Identifying the Amazon S3 bucket for export (p. 462).
   b. Create an AWS Identity and Access Management (IAM) role that grants the DB cluster export task access to the S3 bucket. For more information, see Providing access to an Amazon S3 bucket using an IAM role (p. 462).
3. Create a symmetric encryption AWS KMS key for the server-side encryption. The KMS key is used by the cluster export task to set up AWS KMS server-side encryption when writing the export data to S3. The KMS key policy must include both the kms:Encrypt and kms:Decrypt permissions. For more information on using KMS keys in Amazon Aurora, see AWS KMS key management (p. 2384).

   If you have a deny statement in your KMS key policy, make sure to explicitly exclude the AWS service principal export.rds.amazonaws.com.
You can use a KMS key within your AWS account, or you can use a cross-account KMS key. For more information, see Using a cross-account AWS KMS key (p. 475).

4. Export the DB cluster to Amazon S3 using the console or the start-export-task CLI command. For more information, see Exporting DB cluster data to an Amazon S3 bucket (p. 464).

5. To access your exported data in the Amazon S3 bucket, see Uploading, downloading, and managing objects in the Amazon Simple Storage Service User Guide.

### Setting up access to an Amazon S3 bucket

You identify the Amazon S3 bucket, then you give the DB cluster export task permission to access it.

**Topics**
- Identifying the Amazon S3 bucket for export (p. 462)
- Providing access to an Amazon S3 bucket using an IAM role (p. 462)
- Using a cross-account Amazon S3 bucket (p. 464)

### Identifying the Amazon S3 bucket for export

Identify the Amazon S3 bucket to export the DB cluster data to. Use an existing S3 bucket or create a new S3 bucket.

**Note**
The S3 bucket must be in the same AWS Region as the DB cluster.

For more information about working with Amazon S3 buckets, see the following in the Amazon Simple Storage Service User Guide:

- How do I view the properties for an S3 bucket?
- How do I enable default encryption for an Amazon S3 bucket?
- How do I create an S3 bucket?

### Providing access to an Amazon S3 bucket using an IAM role

Before you export DB cluster data to Amazon S3, give the export tasks write-access permission to the Amazon S3 bucket.

To grant this permission, create an IAM policy that provides access to the bucket, then create an IAM role and attach the policy to the role. Later, you can assign the IAM role to your DB cluster export task.

**Important**
If you plan to use the AWS Management Console to export your DB cluster, you can choose to create the IAM policy and the role automatically when you export the DB cluster. For instructions, see Exporting DB cluster data to an Amazon S3 bucket (p. 464).

**To give tasks access to Amazon S3**

1. Create an IAM policy. This policy provides the bucket and object permissions that allow your DB cluster export task to access Amazon S3.

   In the policy, include the following required actions to allow the transfer of files from Amazon Aurora to an S3 bucket:

   - s3:PutObject*
   - s3:GetObject*
• s3:ListBucket
• s3:DeleteObject*
• s3:GetBucketLocation

In the policy, include the following resources to identify the S3 bucket and objects in the bucket. The following list of resources shows the Amazon Resource Name (ARN) format for accessing Amazon S3.

• arn:aws:s3:::your-s3-bucket
• arn:aws:s3:::your-s3-bucket/*

For more information about creating an IAM policy for Amazon Aurora, see Creating and using an IAM policy for IAM database access (p. 2436). See also Tutorial: Create and attach your first customer managed policy in the IAM User Guide.

The following AWS CLI command creates an IAM policy named ExportPolicy with these options. It grants access to a bucket named your-s3-bucket.

Note
After you create the policy, note the ARN of the policy. You need the ARN for a subsequent step when you attach the policy to an IAM role.

```
aws iam create-policy --policy-name ExportPolicy --policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ExportPolicy",
            "Effect": "Allow",
            "Action": [
                "s3:PutObject*",
                "s3:ListBucket",
                "s3:GetObject*",
                "s3:DeleteObject*",
                "s3:GetBucketLocation"
            ],
            "Resource": [
                "arn:aws:s3:::your-s3-bucket",
                "arn:aws:s3:::your-s3-bucket/*"
            ]
        }
    ]
}',
```

2. Create an IAM role, so that Aurora can assume this IAM role on your behalf to access your Amazon S3 buckets. For more information, see Creating a role to delegate permissions to an IAM user in the IAM User Guide.

The following example shows using the AWS CLI command to create a role named rds-s3-export-role.

```
aws iam create-role --role-name rds-s3-export-role --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "export.rds.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}',
```
3. Attach the IAM policy that you created to the IAM role that you created.

The following AWS CLI command attaches the policy created earlier to the role named rds-s3-export-role. Replace `your-policy-arn` with the policy ARN that you noted in an earlier step.

```bash
aws iam attach-role-policy --policy-arn your-policy-arn --role-name rds-s3-export-role
```

### Using a cross-account Amazon S3 bucket

You can use S3 buckets across AWS accounts. For more information, see [Using a cross-account Amazon S3 bucket](p. 475).

### Exporting DB cluster data to an Amazon S3 bucket

You can have up to five concurrent DB cluster export tasks in progress per AWS account.

**Note**

Exporting DB cluster data can take a while depending on your database type and size. The export task first clones and scales the entire database before extracting the data to Amazon S3. The task's progress during this phase displays as **Starting**. When the task switches to exporting data to S3, progress displays as **In progress**. The time it takes for the export to complete depends on the data stored in the database. For example, tables with well-distributed numeric primary key or index columns export the fastest. Tables that don't contain a column suitable for partitioning and tables with only one index on a string-based column take longer because the export uses a slower single-threaded process.

You can export DB cluster data to Amazon S3 using the AWS Management Console, the AWS CLI, or the RDS API.

If you use a Lambda function to export the DB cluster data, add the `kms:DescribeKey` action to the Lambda function policy. For more information, see [AWS Lambda permissions](https://docs.aws.amazon.com/lambda/latest/dg/permissions-essential.html).

#### Console

The **Export to Amazon S3** console option appears only for DB clusters that can be exported to Amazon S3. A DB cluster might not be available for export because of the following reasons:

- The DB engine isn't supported for S3 export.
- The DB cluster version isn't supported for S3 export.
- S3 export isn't supported in the AWS Region where the DB cluster was created.

**To export DB cluster data**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the DB cluster whose data you want to export.
4. For **Actions**, choose **Export to Amazon S3**.

   The **Export to Amazon S3** window appears.
5. For **Export identifier**, enter a name to identify the export task. This value is also used for the name of the file created in the S3 bucket.

6. Choose the data to be exported:
   - Choose **All** to export all data in the DB cluster.
   - Choose **Partial** to export specific parts of the DB cluster. To identify which parts of the cluster to export, enter one or more databases, schemas, or tables for **Identifiers**, separated by spaces.

   Use the following format:

   \[
   \text{database}[	ext{.schema}][\text{.table}] \text{database2}[	ext{.schema2}][\text{.table2}] \ldots \text{databases}[	ext{.schema}][\text{.tablen}]
   \]

   For example:

   mydatabase  mydatabase2.myschema1  mydatabase2.myschema2.mytable1  mydatabase2.myschema2.mytable2

7. For **S3 bucket**, choose the bucket to export to.
   
   To assign the exported data to a folder path in the S3 bucket, enter the optional path for **S3 prefix**.

8. For **IAM role**, either choose a role that grants you write access to your chosen S3 bucket, or create a new role.

   - If you created a role by following the steps in [Providing access to an Amazon S3 bucket using an IAM role](p. 462), choose that role.
   - If you didn't create a role that grants you write access to your chosen S3 bucket, then choose **Create a new role** to create the role automatically. Next, enter a name for the role in **IAM role name**.

9. For **KMS key**, enter the ARN for the key to use for encrypting the exported data.

10. Choose **Export to Amazon S3**.

**AWS CLI**

To export DB cluster data to Amazon S3 using the AWS CLI, use the `start-export-task` command with the following required options:

- `--export-task-identifier`
- `--source-arn` – the Amazon Resource Name (ARN) of the DB cluster
- `--s3-bucket-name`
- `--iam-role-arn`
- `--kms-key-id`

In the following examples, the export task is named `my-cluster-export`, which exports the data to an S3 bucket named `my-export-bucket`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds start-export-task \  
--export-task-identifier my-cluster-export \  
```
Monitoring DB cluster exports

To provide a folder path in the S3 bucket for the DB cluster export, include the `--s3-prefix` option in the `start-export-task` command.

**RDS API**

To export DB cluster data to Amazon S3 using the Amazon RDS API, use the `StartExportTask` operation with the following required parameters:

- `ExportTaskIdentifier`
- `SourceArn` – the ARN of the DB cluster
- `S3BucketName`
- `IamRoleArn`
- `KmsKeyId`

**Monitoring DB cluster export tasks**

You can monitor DB cluster exports using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To monitor DB cluster exports**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Exports in Amazon S3**.

   DB cluster exports are indicated in the **Source type** column. Export status is displayed in the **Status** column.
3. To view detailed information about a specific DB cluster export, choose the export task.

**AWS CLI**

To monitor DB cluster export tasks using the AWS CLI, use the `describe-export-tasks` command.

The following example shows how to display current information about all of your DB cluster exports.

**Example**

```bash
aws rds describe-export-tasks
{
  "ExportTasks": [
    {
      "Status": "CANCELED",
      "TaskEndTime": "2022-11-01T17:36:46.961Z",
      "S3Prefix": "something",
      "S3Bucket": "examplebucket",
      "PercentProgress": 0,
      "KmsKeyId": "arn:aws:kms:us-west-2:123456789012:key/K7MDENG/bPxRfiCYEXAMPLEKEY",
      "ExportTaskIdentifier": "anewtest",
      "IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
      "TotalExtractedDataInGB": 0,
    },
    {
      "Status": "COMPLETE",
      "TaskStartTime": "2022-10-31T20:58:06.998Z",
      "WarningMessage": "{\"skippedTables\":[],\"skippedObjectives\":[]},{\"general\": [{\"reason\":\"FAILED_TO_EXTRACT_TABLES_LIST_FOR_DATABASE\"}}]",
      "S3Prefix": "",
      "S3Bucket": "examplebucket1",
      "PercentProgress": 100,
      "KmsKeyId": "arn:aws:kms:us-west-2:123456789012:key/2Zp9UtK/h3yCo8nvbEXAMPLEKEY",
      "ExportTaskIdentifier": "thursday-events-test",
      "IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
      "TotalExtractedDataInGB": 263,
    },
    {
      "Status": "FAILED",
      "TaskEndTime": "2022-10-31T02:12:36.409Z",
      "FailureCause": "The S3 bucket examplebucket2 isn't located in the current AWS Region. Please, review your S3 bucket name and retry the export.",
      "S3Prefix": "",
      "S3Bucket": "examplebucket2",
      "PercentProgress": 0,
      "KmsKeyId": "arn:aws:kms:us-west-2:123456789012:key/2Zp9UtK/h3yCo8nvbEXAMPLEKEY",
      "ExportTaskIdentifier": "wednesday-afternoon-test",
      "IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
      "TotalExtractedDataInGB": 0,
    }
  ]
}
```
Canceling a DB cluster export

To display information about a specific export task, include the `--export-task-identifier` option with the `describe-export-tasks` command. To filter the output, include the `--Filters` option. For more options, see the `describe-export-tasks` command.

**RDS API**

To display information about DB cluster exports using the Amazon RDS API, use the `DescribeExportTasks` operation.

To track completion of the export workflow or to initiate another workflow, you can subscribe to Amazon Simple Notification Service topics. For more information on Amazon SNS, see *Working with Amazon RDS event notification (p. 690).*

## Canceling a DB cluster export task

You can cancel a DB cluster export task using the AWS Management Console, the AWS CLI, or the RDS API.

**Note**

Canceling an export task doesn't remove any data that was exported to Amazon S3. For information about how to delete the data using the console, see *How do I delete objects from an S3 bucket?* To delete the data using the CLI, use the `delete-object` command.

### Console

**To cancel a DB cluster export task**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose *Exports in Amazon S3.*

   DB cluster exports are indicated in the *Source type* column. Export status is displayed in the *Status* column.
3. Choose the export task that you want to cancel.
4. Choose *Cancel.*
5. Choose *Cancel export task* on the confirmation page.

### AWS CLI

To cancel an export task using the AWS CLI, use the `cancel-export-task` command. The command requires the `--export-task-identifier` option.

**Example**

```bash
aws rds cancel-export-task --export-task-identifier my-export
{
    "Status": "CANCELING",
    "S3Prefix": "",
    "S3Bucket": "examplebucket",
    "PercentProgress": 0,
    "KmsKeyId": "arn:aws:kms:us-west-2:123456789012:key/K7MDENG/bPxRfICyEXAMPLEKEY",
    "ExportTaskIdentifier": "my-export",
    "IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
    "TotalExtractedDataInGB": 0,
    "SourceArn": "arn:aws:rds:us-west-2:123456789012:cluster:export-example-1"
}
```
RDS API

To cancel an export task using the Amazon RDS API, use the `CancelExportTask` operation with the `ExportTaskIdentifier` parameter.

Failure messages for Amazon S3 export tasks

The following table describes the messages that are returned when Amazon S3 export tasks fail.

<table>
<thead>
<tr>
<th>Failure message</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Failed to find or access the source DB cluster: [cluster name]</td>
<td>The source DB cluster can't be cloned.</td>
</tr>
<tr>
<td>An unknown internal error occurred.</td>
<td>The task has failed because of an unknown error, exception, or failure.</td>
</tr>
<tr>
<td>An unknown internal error occurred writing the export task's metadata to the S3 bucket [bucket name].</td>
<td>The task has failed because of an unknown error, exception, or failure.</td>
</tr>
<tr>
<td>The RDS export failed to write the export task's metadata because it can't assume the IAM role [role ARN].</td>
<td>The export task assumes your IAM role to validate whether it is allowed to write metadata to your S3 bucket. If the task can't assume your IAM role, it fails.</td>
</tr>
</tbody>
</table>
| The RDS export failed to write the export task's metadata to the S3 bucket [bucket name] using the IAM role [role ARN] with the KMS key [key ID]. Error code: [error code] | One or more permissions are missing, so the export task can't access the S3 bucket. This failure message is raised when receiving one of the following error codes:  
  • AWSSecurityTokenServiceException with the error code AccessDenied  
  • AmazonS3Exception with the error code NoSuchBucket, AccessDenied, KMS.KMSInvalidStateException, 403 Forbidden, or KMS.DisabledException  
  These error codes indicate that settings are misconfigured for the IAM role, S3 bucket, or KMS key. |
<p>| The IAM role [role ARN] isn't authorized to call [S3 action] on the S3 bucket [bucket name]. Review your permissions and retry the export. | The IAM policy is misconfigured. Permission for the specific S3 action on the S3 bucket is missing, which causes the export task to fail. |
| KMS key check failed. Check the credentials on your KMS key and try again.      | The KMS key credential check failed.                                                                                                       |
| S3 credential check failed. Check the permissions on your S3 bucket and IAM policy. | The S3 credential check failed.                                                                                                             |
| The S3 bucket [bucket name] isn't valid. Either it isn't located in the current AWS Region or it doesn't exist. Review your S3 bucket name and retry the export. | The S3 bucket is invalid.                                                                                                                  |</p>
<table>
<thead>
<tr>
<th>Failure message</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>The S3 bucket [bucket name] isn't located in the current AWS Region. Review</td>
<td>The S3 bucket is in the wrong AWS Region.</td>
</tr>
<tr>
<td>your S3 bucket name and retry the export.</td>
<td></td>
</tr>
</tbody>
</table>

**Troubleshooting PostgreSQL permissions errors**

When exporting PostgreSQL databases to Amazon S3, you might see a PERMISSIONS_D0_NOT_EXIST error stating that certain tables were skipped. This error usually occurs when the superuser, which you specified when creating the DB cluster, doesn't have permissions to access those tables.

To fix this error, run the following command:

```
GRANT ALL PRIVILEGES ON ALL TABLES IN SCHEMA schema_name TO superuser_name
```

For more information on superuser privileges, see [Master user account privileges (p. 2474)](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-access-control.html).

**File naming convention**

Exported data for specific tables is stored in the format `base_prefix/files`, where the base prefix is the following:

```
export_identifier/database_name/schema_name.table_name/
```

For example:

```
export-1234567890123-459/rdststcluster/mycluster.DataInsert_7ADB5D19965123A2/
```

Output files use the following naming convention, where `partition_index` is alphanumeric:

```
partition_index/part-00000-random_uid.format-based_extension
```

For example:

```
1/part-00000-c5a881bb-58ff-4ee6-1111-b41ecff340a3-c000.gz.parquet
a/part-00000-d7a881cc-88cc-5ab7-2222-c41ecab340a4-c000.gz.parquet
```

The file naming convention is subject to change. Therefore, when reading target tables, we recommend that you read everything inside the base prefix for the table.

**Data conversion and storage format**

When you export a DB cluster to an Amazon S3 bucket, Amazon Aurora converts data to, exports data in, and stores data in the Parquet format. For more information, see [Data conversion when exporting to an Amazon S3 bucket (p. 484)](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-export.html).
Exporting DB cluster snapshot data to Amazon S3

You can export DB cluster snapshot data to an Amazon S3 bucket. The export process runs in the background and doesn't affect the performance of your active DB cluster.

When you export a DB cluster snapshot, Amazon Aurora extracts data from the snapshot and stores it in an Amazon S3 bucket. You can export manual snapshots and automated system snapshots. By default, all data in the snapshot is exported. However, you can choose to export specific sets of databases, schemas, or tables.

The data is stored in an Apache Parquet format that is compressed and consistent. Individual Parquet files are usually 1–10 MB in size.

After the data is exported, you can analyze the exported data directly through tools like Amazon Athena or Amazon Redshift Spectrum. For more information on using Athena to read Parquet data, see Parquet SerDe in the Amazon Athena User Guide. For more information on using Redshift Spectrum to read Parquet data, see COPY from columnar data formats in the Amazon Redshift Database Developer Guide.

Feature availability and support varies across specific versions of each database engine and across AWS Regions. For more information on version and Region availability of exporting DB cluster snapshot data to S3, see Exporting snapshot data to Amazon S3 (p. 32).

Topics

- Limitations (p. 471)
- Overview of exporting snapshot data (p. 472)
- Setting up access to an Amazon S3 bucket (p. 473)
- Exporting a snapshot to an Amazon S3 bucket (p. 476)
- Export performance in Aurora MySQL (p. 479)
- Monitoring snapshot exports (p. 479)
- Canceling a snapshot export task (p. 480)
- Failure messages for Amazon S3 export tasks (p. 481)
- Troubleshooting PostgreSQL permissions errors (p. 482)
- File naming convention (p. 483)
- Data conversion when exporting to an Amazon S3 bucket (p. 484)

Limitations

Exporting DB snapshot data to Amazon S3 has the following limitations:

- You can't run multiple export tasks for the same DB cluster snapshot simultaneously. This applies to both full and partial exports.
- The following characters in the S3 file path are converted to underscores (_) during export:

  \ ` " (space)

- If a database, schema, or table has characters in its name other than the following, partial export isn't supported. However, you can export the entire DB snapshot.
  - Latin letters (A–Z)
  - Digits (0–9)
  - Dollar symbol ($)
  - Underscore (_)
• Spaces ( ) and certain characters aren't supported in database table column names. Tables with the following characters in column names are skipped during export:

, ; { } ( ) \n \t = (space)

• Tables with slashes (/) in their names are skipped during export.
• Aurora PostgreSQL temporary and unlogged tables are skipped during export.
• If the data contains a large object, such as a BLOB or CLOB, that is close to or greater than 500 MB, then the export fails.
• If a table contains a large row that is close to or greater than 2 GB, then the table is skipped during export.
• We strongly recommend that you use a unique name for each export task. If you don't use a unique task name, you might receive the following error message:

ExportTaskAlreadyExistsFault: An error occurred (ExportTaskAlreadyExists) when calling the StartExportTask operation: The export task with the ID xxxxx already exists.

• You can delete a snapshot while you're exporting its data to S3, but you're still charged for the storage costs for that snapshot until the export task has completed.
• You can't restore exported snapshot data from S3 to a new DB cluster.

Overview of exporting snapshot data

You use the following process to export DB snapshot data to an Amazon S3 bucket. For more details, see the following sections.

1. Identify the snapshot to export.
   Use an existing automated or manual snapshot, or create a manual snapshot of a DB instance.

2. Set up access to the Amazon S3 bucket.
   A bucket is a container for Amazon S3 objects or files. To provide the information to access a bucket, take the following steps:
   a. Identify the S3 bucket where the snapshot is to be exported to. The S3 bucket must be in the same AWS Region as the snapshot. For more information, see Identifying the Amazon S3 bucket for export (p. 473).
   b. Create an AWS Identity and Access Management (IAM) role that grants the snapshot export task access to the S3 bucket. For more information, see Providing access to an Amazon S3 bucket using an IAM role (p. 473).

3. Create a symmetric encryption AWS KMS key for the server-side encryption. The KMS key is used by the snapshot export task to set up AWS KMS server-side encryption when writing the export data to S3. The KMS key policy must include both the kms:Encrypt and kms:Decrypt permissions. For more information on using KMS keys in Amazon Aurora, see AWS KMS key management (p. 2384).

   If you have a deny statement in your KMS key policy, make sure to explicitly exclude the AWS service principal export.rds.amazonaws.com.

   You can use a KMS key within your AWS account, or you can use a cross-account KMS key. For more information, see Using a cross-account AWS KMS key (p. 475).

4. Export the snapshot to Amazon S3 using the console or the start-export-task CLI command. For more information, see Exporting a snapshot to an Amazon S3 bucket (p. 476).

5. To access your exported data in the Amazon S3 bucket, see Uploading, downloading, and managing objects in the Amazon Simple Storage Service User Guide.
Setting up access to an Amazon S3 bucket

You identify the Amazon S3 bucket, then you give the snapshot permission to access it.

Topics

• Identifying the Amazon S3 bucket for export (p. 473)
• Providing access to an Amazon S3 bucket using an IAM role (p. 473)
• Using a cross-account Amazon S3 bucket (p. 475)
• Using a cross-account AWS KMS key (p. 475)

Identifying the Amazon S3 bucket for export

Identify the Amazon S3 bucket to export the DB snapshot to. Use an existing S3 bucket or create a new S3 bucket.

Note

The S3 bucket to export to must be in the same AWS Region as the snapshot.

For more information about working with Amazon S3 buckets, see the following in the Amazon Simple Storage Service User Guide:

• How do I view the properties for an S3 bucket?
• How do I enable default encryption for an Amazon S3 bucket?
• How do I create an S3 bucket?

Providing access to an Amazon S3 bucket using an IAM role

Before you export DB snapshot data to Amazon S3, give the snapshot export tasks write-access permission to the Amazon S3 bucket.

To grant this permission, create an IAM policy that provides access to the bucket, then create an IAM role and attach the policy to the role. Later, you can assign the IAM role to your snapshot export task.

Important

If you plan to use the AWS Management Console to export your snapshot, you can choose to create the IAM policy and the role automatically when you export the snapshot. For instructions, see Exporting a snapshot to an Amazon S3 bucket (p. 476).

To give DB snapshot tasks access to Amazon S3

1. Create an IAM policy. This policy provides the bucket and object permissions that allow your snapshot export task to access Amazon S3.

   In the policy, include the following required actions to allow the transfer of files from Amazon Aurora to an S3 bucket:

   • s3:PutObject*
   • s3:GetObject*
   • s3:ListBucket
   • s3:DeleteObject*
   • s3:GetBucketLocation

   In the policy, include the following resources to identify the S3 bucket and objects in the bucket. The following list of resources shows the Amazon Resource Name (ARN) format for accessing Amazon S3.
• arn:aws:s3:::your-s3-bucket
• arn:aws:s3:::your-s3-bucket/*

For more information on creating an IAM policy for Amazon Aurora, see Creating and using an IAM policy for IAM database access (p. 2436). See also Tutorial: Create and attach your first customer managed policy in the IAM User Guide.

The following AWS CLI command creates an IAM policy named ExportPolicy with these options. It grants access to a bucket named your-s3-bucket.

Note
After you create the policy, note the ARN of the policy. You need the ARN for a subsequent step when you attach the policy to an IAM role.

```
aws iam create-policy  --policy-name ExportPolicy --policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ExportPolicy",
      "Effect": "Allow",
      "Action": [
        "s3:PutObject*",
        "s3:ListBucket",
        "s3:GetObject*",
        "s3:DeleteObject*",
        "s3:GetBucketLocation"
      ],
      "Resource": [
        "arn:aws:s3:::your-s3-bucket",
        "arn:aws:s3:::your-s3-bucket/*"
      ]
    }
  ]
}'
```

2. Create an IAM role, so that Aurora can assume this IAM role on your behalf to access your Amazon S3 buckets. For more information, see Creating a role to delegate permissions to an IAM user in the IAM User Guide.

The following example shows using the AWS CLI command to create a role named rds-s3-export-role.

```
aws iam create-role  --role-name rds-s3-export-role  --assume-role-policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "export.rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}'
```

3. Attach the IAM policy that you created to the IAM role that you created.

The following AWS CLI command attaches the policy created earlier to the role named rds-s3-export-role. Replace your-policy-arn with the policy ARN that you noted in an earlier step.
Using a cross-account Amazon S3 bucket

You can use Amazon S3 buckets across AWS accounts. To use a cross-account bucket, add a bucket policy to allow access to the IAM role that you’re using for the S3 exports. For more information, see Example 2: Bucket owner granting cross-account bucket permissions.

- Attach a bucket policy to your bucket, as shown in the following example.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Principal": {
            "AWS": "arn:aws:iam::123456789012:role/Admin"
         },
         "Action": [
            "s3:PutObject*",
            "s3:ListBucket",
            "s3:GetObject*",
            "s3:DeleteObject*",
            "s3:GetBucketLocation"
         ],
         "Resource": [
            "arn:aws:s3:::mycrossaccountbucket",
            "arn:aws:s3:::mycrossaccountbucket/*"
         ]
      }
   ]
}
```

Using a cross-account AWS KMS key

You can use a cross-account AWS KMS key to encrypt Amazon S3 exports. First, you add a key policy to the local account; then you add IAM policies in the external account. For more information, see Allowing users in other accounts to use a KMS key.

To use a cross-account KMS key

1. Add a key policy to the local account.

   The following example gives ExampleRole and ExampleUser in the external account 444455556666 permissions in the local account 123456789012.

```json
{
   "Sid": "Allow an external account to use this KMS key",
   "Effect": "Allow",
   "Principal": {
      "AWS": [
         "arn:aws:iam::444455556666:role/ExampleRole",
         "arn:aws:iam::444455556666:user/ExampleUser"
      ]
   },
   "Action": [
```
Exporting a snapshot to an Amazon S3 bucket

You can have up to five concurrent DB snapshot export tasks in progress per AWS account.

**Note**
Exporting RDS snapshots can take a while depending on your database type and size. The export task first restores and scales the entire database before extracting the data to Amazon S3. The task’s progress during this phase displays as **Starting**. When the task switches to exporting data to S3, progress displays as **In progress**.

The time it takes for the export to complete depends on the data stored in the database. For example, tables with well-distributed numeric primary key or index columns export the fastest. Tables that don't contain a column suitable for partitioning and tables with only one index on a string-based column take longer. This longer export time occurs because the export uses a slower single-threaded process.

You can export a DB snapshot to Amazon S3 using the AWS Management Console, the AWS CLI, or the RDS API. If you use a Lambda function to export a snapshot, add the `kms:DescribeKey` action to the Lambda function policy. For more information, see [AWS Lambda permissions](https://docs.aws.amazon.com/lambda/latest/dg/permissions.html).

**Console**

The **Export to Amazon S3** console option appears only for snapshots that can be exported to Amazon S3. A snapshot might not be available for export because of the following reasons:

- The DB engine isn't supported for S3 export.
• The DB instance version isn’t supported for S3 export.
• S3 export isn’t supported in the AWS Region where the snapshot was created.

**To export a DB snapshot**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. From the tabs, choose the type of snapshot that you want to export.
4. In the list of snapshots, choose the snapshot that you want to export.
5. For **Actions**, choose **Export to Amazon S3**.

    The **Export to Amazon S3** window appears.
6. For **Export identifier**, enter a name to identify the export task. This value is also used for the name of the file created in the S3 bucket.
7. Choose the data to be exported:
   • Choose **All** to export all data in the snapshot.
   • Choose **Partial** to export specific parts of the snapshot. To identify which parts of the snapshot to export, enter one or more databases, schemas, or tables for **Identifiers**, separated by spaces.

     Use the following format:

```
database[.schema][.table] database2[.schema2][.table2] ... databasesn[.schema][.table]
```

For example:

```
mydatabase mydatabase2.myschema1 mydatabase2.myschema2.mytable1
mydatabase2.myschema2.mytable2
```

8. For **S3 bucket**, choose the bucket to export to.

    To assign the exported data to a folder path in the S3 bucket, enter the optional path for **S3 prefix**.
9. For **IAM role**, either choose a role that grants you write access to your chosen S3 bucket, or create a new role.

    • If you created a role by following the steps in **Providing access to an Amazon S3 bucket using an IAM role** (p. 473), choose that role.

    • If you didn't create a role that grants you write access to your chosen S3 bucket, then choose **Create a new role** to create the role automatically. Next, enter a name for the role in **IAM role name**.

10. For **AWS KMS key**, enter the ARN for the key to use for encrypting the exported data.
11. Choose **Export to Amazon S3**.

**AWS CLI**

To export a DB snapshot to Amazon S3 using the AWS CLI, use the `start-export-task` command with the following required options:

• `--export-task-identifier`

• `--source-arn`
Exporting a snapshot to an S3 bucket

- --s3-bucket-name
- --iam-role-arn
- --kms-key-id

In the following examples, the snapshot export task is named *my-snapshot-export*, which exports a snapshot to an S3 bucket named *my-export-bucket*.

**Example**

For Linux, macOS, or Unix:

```
aws rds start-export-task
  --export-task-identifier my-snapshot-export
  --s3-bucket-name my-export-bucket
  --iam-role-arn iam-role
  --kms-key-id my-key
```

For Windows:

```
aws rds start-export-task
  --export-task-identifier my-snapshot-export
  --s3-bucket-name my-export-bucket
  --iam-role-arn iam-role
  --kms-key-id my-key
```

Sample output follows.

```
{
  "Status": "STARTING",
  "IamRoleArn": "iam-role",
  "ExportTime": "2019-08-12T01:23:53.109Z",
  "S3Bucket": "my-export-bucket",
  "PercentProgress": 0,
  "KmsKeyId": "my-key",
  "ExportTaskIdentifier": "my-snapshot-export",
  "TotalExtractedDataInGB": 0,
  "SourceArn": "arn:aws:rds:AWS_Region:123456789012:snapshot:snapshot-name"
}
```

To provide a folder path in the S3 bucket for the snapshot export, include the --s3-prefix option in the `start-export-task` command.

**RDS API**

To export a DB snapshot to Amazon S3 using the Amazon RDS API, use the `StartExportTask` operation with the following required parameters:

- ExportTaskIdentifier
- SourceArn
- S3BucketName
- IamRoleArn
- KmsKeyId
Export performance in Aurora MySQL

Aurora MySQL version 2 and version 3 DB cluster snapshots use an advanced export mechanism to improve performance and reduce export time. The mechanism includes optimizations such as multiple export threads and Aurora MySQL parallel query to take advantage of the Aurora shared storage architecture. The optimizations are applied adaptively, depending on the data set size and structure.

You don't need to turn on parallel query to use the faster export process, but the process does have the same limitations as parallel query. In addition, some data values aren't supported, such as dates where the day of the month is 0 or the year is 0000. For more information, see Working with parallel query for Amazon Aurora MySQL (p. 948).

When performance optimizations are applied, you might also see much larger (~200 GB) Parquet files for Aurora MySQL version 2 and 3 exports.

If the faster export process can't be used, for example because of incompatible data types or values, Aurora automatically switches to a single-threaded export mode without parallel query. Depending on which process is used, and the amount of data to be exported, export performance can vary.

Monitoring snapshot exports

You can monitor DB snapshot exports using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To monitor DB snapshot exports

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Exports in Amazon S3.
   - DB snapshot exports are indicated in the Source type column. Export status is displayed in the Status column.
3. To view detailed information about a specific snapshot export, choose the export task.

AWS CLI

To monitor DB snapshot exports using the AWS CLI, use the describe-export-tasks command.

The following example shows how to display current information about all of your snapshot exports.

Example

```
aws rds describe-export-tasks
{
  "ExportTasks": [
    {
      "Status": "CANCELED",
      "TaskEndTime": "2019-11-01T17:36:46.961Z",
      "S3Prefix": "something",
      "S3Bucket": "examplebucket",
      "PercentProgress": 0,
      "KmsKeyId": "arn:aws:kms:AWS_Region:123456789012:key/K7MDENG/ bPxRfiCYEXAMPELKEY",
      "ExportTaskIdentifier": "anewtest",
```
To display information about a specific snapshot export, include the --export-task-identifier option with the describe-export-tasks command. To filter the output, include the --Filters option. For more options, see the describe-export-tasks command.

**RDS API**

To display information about DB snapshot exports using the Amazon RDS API, use the DescribeExportTasks operation.

To track completion of the export workflow or to initiate another workflow, you can subscribe to Amazon Simple Notification Service topics. For more information on Amazon SNS, see Working with Amazon RDS event notification (p. 690).

### Canceling a snapshot export task

You can cancel a DB snapshot export task using the AWS Management Console, the AWS CLI, or the RDS API.
Note
Canceling a snapshot export task doesn’t remove any data that was exported to Amazon S3. For information about how to delete the data using the console, see How do I delete objects from an S3 bucket? To delete the data using the CLI, use the delete-object command.

Console

To cancel a snapshot export task

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Exports in Amazon S3.
   DB snapshot exports are indicated in the Source type column. Export status is displayed in the Status column.
3. Choose the snapshot export task that you want to cancel.
4. Choose Cancel.
5. Choose Cancel export task on the confirmation page.

AWS CLI

To cancel a snapshot export task using the AWS CLI, use the cancel-export-task command. The command requires the --export-task-identifier option.

Example

```
aws rds cancel-export-task --export-task-identifier my_export
{
   "Status": "CANCELING",
   "S3Prefix": "",
   "ExportTime": "2019-08-12T01:23:53.109Z",
   "S3Bucket": "examplebucket",
   "PercentProgress": 0,
   "KmsKeyId": "arn:aws:kms:AWS_Region:123456789012:key/K7MDENG/bPxRfiCYEXAMPLEKEY",
   "ExportTaskIdentifier": "my_export",
   "IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
   "TotalExtractedDataInGB": 0,
   "SourceArn": "arn:aws:rds:AWS_Region:123456789012:snapshot:export-example-1"
}
```

RDS API

To cancel a snapshot export task using the Amazon RDS API, use the CancelExportTask operation with the ExportTaskIdentifier parameter.

Failure messages for Amazon S3 export tasks

The following table describes the messages that are returned when Amazon S3 export tasks fail.

<table>
<thead>
<tr>
<th>Failure message</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>An unknown internal error occurred.</td>
<td>The task has failed because of an unknown error, exception, or failure.</td>
</tr>
</tbody>
</table>
## Failure message | Description
---|---
An unknown internal error occurred writing the export task's metadata to the S3 bucket [bucket name]. | The task has failed because of an unknown error, exception, or failure.
The RDS export failed to write the export task's metadata because it can't assume the IAM role [role ARN]. | The export task assumes your IAM role to validate whether it is allowed to write metadata to your S3 bucket. If the task can't assume your IAM role, it fails.
The RDS export failed to write the export task's metadata to the S3 bucket [bucket name] using the IAM role [role ARN] with the KMS key [key ID]. Error code: [error code] | One or more permissions are missing, so the export task can't access the S3 bucket. This failure message is raised when receiving one of the following error codes:
- AWSSecurityTokenServiceException with the error code AccessDenied
- AmazonS3Exception with the error code NoSuchBucket, AccessDenied, KMS.KMSInvalidStateException, 403 Forbidden, or KMS.DisabledException
The IAM role [role ARN] isn't authorized to call [S3 action] on the S3 bucket [bucket name]. Review your permissions and retry the export. | The IAM policy is misconfigured. Permission for the specific S3 action on the S3 bucket is missing, which causes the export task to fail.
KMS key check failed. Check the credentials on your KMS key and try again. | The KMS key credential check failed.
S3 credential check failed. Check the permissions on your S3 bucket and IAM policy. | The S3 credential check failed.
The S3 bucket [bucket name] isn't valid. Either it isn't located in the current AWS Region or it doesn't exist. Review your S3 bucket name and retry the export. | The S3 bucket is invalid.
The S3 bucket [bucket name] isn't located in the current AWS Region. Review your S3 bucket name and retry the export. | The S3 bucket is in the wrong AWS Region.

## Troubleshooting PostgreSQL permissions errors

When exporting PostgreSQL databases to Amazon S3, you might see a PERMISSIONS_DO_NOT_EXIST error stating that certain tables were skipped. This error usually occurs when the superuser, which you specified when creating the DB instance, doesn't have permissions to access those tables.

To fix this error, run the following command:

```
GRANT ALL PRIVILEGES ON ALL TABLES IN SCHEMA schema_name TO superuser_name
```

For more information on superuser privileges, see [Master user account privileges](p. 2474).
File naming convention

Exported data for specific tables is stored in the format `base_prefix/files`, where the base prefix is the following:

```
export_identifier/database_name/schema_name.table_name/
```

For example:

```
export-1234567890123-459/rdststdb/rdststdb.DataInsert_7ADB5D19965123A2/
```

There are two conventions for how files are named.

- **Current convention**:

  `batch_index/partition_index-random_uuid.format-based_extension`

  The batch index is a sequence number that represents a batch of data read from the table. If we can't partition your table into small chunks to be exported in parallel, there will be multiple batch indexes. The same thing happens if your table is partitioned into multiple tables. There will be multiple batch indexes, one for each of the table partitions of your main table.

  If we can partition your table into small chunks to be read in parallel, there will be only the batch index 1 folder.

  Inside the batch index folder, there are one or more Parquet files that contain your table's data. The prefix of the Parquet filename is `partition_index`. If your table is partitioned, there will be multiple files starting with the partition index 00000.

  There can be gaps in the partition index sequence. This happens because each partition is obtained from a ranged query in your table. If there is no data in the range of that partition, then that sequence number is skipped.

  For example, suppose that the `id` column is the table's primary key, and its minimum and maximum values are 100 and 1000. When we try to export this table with nine partitions, we read it with parallel queries such as the following:

  ```
  SELECT * FROM table WHERE id <= 100 AND id < 200  
  SELECT * FROM table WHERE id <= 200 AND id < 300
  ```

  This should generate nine files, from `part-00000-random_uuid.gz.parquet` to `part-00008-random_uuid.gz.parquet`. However, if there are no rows with IDs between 200 and 350, one of the completed partitions is empty, and no file is created for it. In the previous example, `part-00001-random_uuid.gz.parquet` isn't created.

- **Older convention**:

  `partition_index-random_uuid.format-based_extension`

  This is the same as the current convention, but without the `batch_index` prefix, for example:

  ```
  part-00000-c5a881bb-58ff-4ee6-1111-b41ecff340a3-c000.gz.parquet  
  part-00001-d7a881cc-88cc-5ab7-2222-c41ecab340a4-c000.gz.parquet  
  part-00002-f5a991ab-59aa-7fa6-3333-d41ecdd340a7-c000.gz.parquet
  ```
Data conversion when exporting to an Amazon S3 bucket

When you export a DB snapshot to an Amazon S3 bucket, Amazon Aurora converts data to, exports data in, and stores data in the Parquet format. For more information about Parquet, see the Apache Parquet website.

Parquet stores all data as one of the following primitive types:

- BOOLEAN
- INT32
- INT64
- INT96
- FLOAT
- DOUBLE
- BYTE_ARRAY – A variable-length byte array, also known as binary
- FIXED_LEN_BYTE_ARRAY – A fixed-length byte array used when the values have a constant size

The Parquet data types are few to reduce the complexity of reading and writing the format. Parquet provides logical types for extending primitive types. A logical type is implemented as an annotation with the data in a LogicalType metadata field. The logical type annotation explains how to interpret the primitive type.

When the STRING logical type annotates a BYTE_ARRAY type, it indicates that the byte array should be interpreted as a UTF-8 encoded character string. After an export task completes, Amazon Aurora notifies you if any string conversion occurred. The underlying data exported is always the same as the data from the source. However, due to the encoding difference in UTF-8, some characters might appear different from the source when read in tools such as Athena.

For more information, see Parquet logical type definitions in the Parquet documentation.

Restoring a DB cluster to a specified time

You can restore a DB cluster to a specific point in time, creating a new DB cluster.

When you restore a DB cluster to a point in time, you can choose the default virtual private cloud (VPC) security group. Or you can apply a custom VPC security group to your DB cluster.

Restored DB clusters are automatically associated with the default DB cluster and DB parameter groups. However, you can apply custom parameter groups by specifying them during a restore.

Amazon Aurora uploads log records for DB clusters to Amazon S3 continuously. To see the latest restorable time for a DB cluster, use the AWS CLI `describe-db-clusters` command and look at the value returned in the `LatestRestorableTime` field for the DB cluster.

You can restore to any point in time within your backup retention period. To see the earliest restorable time for a DB cluster, use the AWS CLI `describe-db-clusters` command and look at the value returned in the `EarliestRestorableTime` field for the DB cluster.

The backup retention period of the restored DB cluster is the same as that of the source DB cluster.

Note
Information in this topic applies to Amazon Aurora. For information on restoring an Amazon RDS DB instance, see [Restoring a DB instance to a specified time](https://docs.aws.amazon.com/ru-ru/rds/latest/userguide/Amazon-Aurora-Point-in-Time-Restore.html). For more information about backing up and restoring an Aurora DB cluster, see [Overview of backing up and restoring an Aurora DB cluster](https://docs.aws.amazon.com/ru-ru/rds/latest/userguide/Overview-of-backup-and-restore.html). For Aurora MySQL, you can restore a provisioned DB cluster to an Aurora Serverless DB cluster. For more information, see [Restoring an Aurora Serverless v1 DB cluster](https://docs.aws.amazon.com/ru-ru/rds/latest/userguide/Overview-of-backup-and-restore.html). You can also use AWS Backup to manage backups of Amazon Aurora DB clusters. If your DB cluster is associated with a backup plan in AWS Backup, that backup plan is used for point-in-time recovery. For information, see [Restoring a DB cluster to a specified time using AWS Backup](https://docs.aws.amazon.com/ru-ru/backup/latest/userguide/Backup-Databases-with-DB.html).

You can restore a DB cluster to a point in time using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To restore a DB cluster to a specified time

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Automated backups**.

The automated backups are displayed on the **Current Region** tab.

3. Choose the DB cluster that you want to restore.
4. For **Actions**, choose **Restore to point in time**.

The **Restore to point in time** window appears.
5. Choose **Latest restorable time** to restore to the latest possible time, or choose **Custom** to choose a time.

   If you chose **Custom**, enter the date and time to which you want to restore the cluster.

   **Note**
   Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/Central Daylight Time.

6. For **DB cluster identifier**, enter the name of the target restored DB cluster. The name must be unique.

7. Choose other options as needed, such as the DB instance class and DB cluster storage configuration.

   For information about each setting, see [Settings for Aurora DB clusters](p. 190).

8. Choose **Restore to point in time**.

**AWS CLI**

To restore a DB cluster to a specified time, use the AWS CLI command `restore-db-cluster-to-point-in-time` to create a new DB cluster.

You can specify other settings. For information about each setting, see [Settings for Aurora DB clusters](p. 190).

Resource tagging is supported for this operation. When you use the `--tags` option, the source DB cluster tags are ignored and the provided ones are used. Otherwise, the latest tags from the source cluster are used.

**Example**

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-to-point-in-time \
  --source-db-cluster-identifier mysourcedbcluster \
  --db-cluster-identifier mytargetdbcluster \
  --restore-to-time 2017-10-14T23:45:00.000Z
```

For Windows:

```
aws rds restore-db-cluster-to-point-in-time ^
  --source-db-cluster-identifier mysourcedbcluster ^
  --db-cluster-identifier mytargetdbcluster ^
  --restore-to-time 2017-10-14T23:45:00.000Z
```

**Important**

If you use the console to restore a DB cluster to a specified time, then Amazon RDS automatically creates the primary instance (writer) for your DB cluster. If you use the AWS CLI to restore a DB cluster to a specified time, you must explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster.

To create the primary instance for your DB cluster, call the `create-db-instance` AWS CLI command. Include the name of the DB cluster as the `--db-cluster-identifier` option value.

**RDS API**

To restore a DB cluster to a specified time, call the Amazon RDS API `RestoreDBClusterToPointInTime` operation with the following parameters:
Point-in-time recovery from a retained automated backup

- `SourceDBClusterIdentifier`
- `DBClusterIdentifier`
- `RestoreToTime`

**Important**
If you use the console to restore a DB cluster to a specified time, then Amazon RDS automatically creates the primary instance (writer) for your DB cluster. If you use the RDS API to restore a DB cluster to a specified time, make sure to explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster.
To create the primary instance for your DB cluster, call the RDS API operation `CreateDBInstance`. Include the name of the DB cluster as the `DBClusterIdentifier` parameter value.

**Restoring a DB cluster to a specified time from a retained automated backup**

You can restore a DB cluster from a retained automated backup after you delete the source DB cluster, if the backup is within the retention period of the source cluster. The process is similar to restoring a DB cluster from an automated backup.

**Note**
You can't restore an Aurora Serverless v1 DB cluster using this procedure, because automated backups for Aurora Serverless v1 clusters aren't retained.

**Console**

**To restore a DB cluster to a specified time**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Automated backups**.
3. Choose the **Retained** tab.
4. Choose the DB cluster that you want to restore.
5. For **Actions**, choose **Restore to point in time**.
   
The **Restore to point in time** window appears.
6. Choose **Latest restorable time** to restore to the latest possible time, or choose **Custom** to choose a time.
   
   If you chose **Custom**, enter the date and time to which you want to restore the cluster.
   
   **Note**
   Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/Central Daylight Time.
7. For **DB cluster identifier**, enter the name of the target restored DB cluster. The name must be unique.
8. Choose other options as needed, such as DB instance class.

For information about each setting, see Settings for Aurora DB clusters (p. 190).

9. Choose Restore to point in time.

AWS CLI

To restore a DB cluster to a specified time, use the AWS CLI command `restore-db-cluster-to-point-in-time` to create a new DB cluster.

You can specify other settings. For information about each setting, see Settings for Aurora DB clusters (p. 190).

Resource tagging is supported for this operation. When you use the `--tags` option, the source DB cluster tags are ignored and the provided ones are used. Otherwise, the latest tags from the source cluster are used.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-to-point-in-time
  --source-db-cluster-resource-id cluster-123ABCEXAMPLE
  --db-cluster-identifier mytargetdbcluster
  --restore-to-time 2017-10-14T23:45:00.000Z
```

For Windows:

```
aws rds restore-db-cluster-to-point-in-time ^
  --source-db-cluster-resource-id cluster-123ABCEXAMPLE ^
  --db-cluster-identifier mytargetdbcluster ^
  --restore-to-time 2017-10-14T23:45:00.000Z
```

Important

If you use the console to restore a DB cluster to a specified time, then Amazon RDS automatically creates the primary instance (writer) for your DB cluster. If you use the AWS CLI to restore a DB cluster to a specified time, you must explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster.

To create the primary instance for your DB cluster, call the `create-db-instance` AWS CLI command. Include the name of the DB cluster as the `--db-cluster-identifier` option value.

RDS API

To restore a DB cluster to a specified time, call the Amazon RDS API `RestoreDBClusterToPointInTime` operation with the following parameters:

- `SourceDbClusterResourceId`
- `DBClusterIdentifier`
- `RestoreToTime`

Important

If you use the console to restore a DB cluster to a specified time, then Amazon RDS automatically creates the primary instance (writer) for your DB cluster. If you use the RDS API to
restore a DB cluster to a specified time, make sure to explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster.

To create the primary instance for your DB cluster, call the RDS API operation `CreateDBInstance`. Include the name of the DB cluster as the `DBClusterIdentifier` parameter value.

**Restoring a DB cluster to a specified time using AWS Backup**

You can use AWS Backup to manage your automated backups, and then to restore them to a specified time. To do this, you create a backup plan in AWS Backup and assign your DB cluster as a resource. Then you enable continuous backups for PITR in the backup rule. For more information on backup plans and backup rules, see the *AWS Backup Developer Guide*.

**Enabling continuous backups in AWS Backup**

You enable continuous backups in backup rules.

**To enable continuous backups for PITR**

2. In the navigation pane, choose *Backup plans*.
3. Under *Backup plan name*, select the backup plan that you use to back up your DB cluster.
4. Under the *Backup rules* section, choose *Add backup rule*.

   The *Add backup rule* page displays.
5. Select the *Enable continuous backups for point-in-time recovery (PITR)* check box.
6. Choose other settings as needed, then choose **Add backup rule**.

**Restoring from a continuous backup in AWS Backup**

You restore to a specified time from a backup vault.
**Console**

You can use the AWS Management Console to restore a DB cluster to a specified time.

**To restore from a continuous backup in AWS Backup**

2. In the navigation pane, choose **Backup vaults**.
3. Choose the backup vault that contains your continuous backup, for example **Default**.
   
   The backup vault detail page displays.
4. Under **Recovery points**, select the recovery point for the automated backup.
   
   It has a backup type of **Continuous** and a name with `continuous:cluster-AWS-Backup-job-number`.
5. For **Actions**, choose **Restore**.
   
   The **Restore backup** page displays.
Restore to point in time

Restore backup from
- August 31, 2023, 10:45:56 (UTC-04:00) or later.
- Latest restorable time
- Specify date and time
  - Select a time between 6 minutes and 7 days ago.

Instance specifications

DB engine
Name of the database engine to be used for this instance
- Aurora MySQL

DB engine version
Version Number of the Database Engine to be used for this instance
- Aurora (MySQL 5.7) 2.11.1

Capacity type
- Provisioned
  - You provision and manage the server instance sizes.
- Serverless
  - You specify the minimum and maximum of resources for a DB cluster. Aurora scales the capacity based on database load.
- Global
  - You can provision your Aurora database in multiple regions. Writes in the primary region are replicated with typical latency of <1 sec to secondary regions.

Availability and durability

Deployment options
The deployment options below are limited to those supported by the engine you selected above.
- Create an Aurora Replica or Reader node in a different AZ (recommended for scaled availability)
  - Creates an Aurora Replica for fast follower and high availability.
- Don't create an Aurora Replica

Settings

DB cluster snapshot ID
The identifier for the DB Snapshot.
rdsmysdbcluster-2023-08-31-02-02

DB cluster identifier
Type a name for your DB cluster. The name must be unique across all DB clusters owned by your AWS account, in the current AWS Region.
Enter a name for the DB cluster
497

The DB cluster identifier is case-insensitive, but is stored as all lowercase (as in "mysdbcluster"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.
6. For **Restore to point in time**, select **Specify date and time** to restore to a specific point in time.
7. Choose other settings as needed for restoring the DB cluster, then choose **Restore backup**.

The **Jobs** page displays, showing the **Restore jobs** pane. A message at the top of the page provides information about the restore job.

After the DB cluster is restored, you must add the primary (writer) DB instance to it. To create the primary instance for your DB cluster, call the `create-db-instance` AWS CLI command. Include the name of the DB cluster as the `--db-cluster-identifier` parameter value.

**CLI**

You use the `start-restore-job` AWS CLI command to restore the DB cluster to a specified time. The following parameters are required:

- `--recovery-point-arn` – The Amazon Resource Name (ARN) for the recovery point from which to restore.
- `--resource-type` – Use `Aurora`.
- `--iam-role-arn` – The ARN for the IAM role that you use for AWS Backup operations.
- `--metadata` – The metadata that you use to restore the DB cluster. The following parameters are required:
  - `DBClusterIdentifier`
  - `Engine`
  - `RestoreToTime` or `UseLatestRestorableTime`

The following example shows how to restore a DB cluster to a specified time.

```bash
aws backup start-restore-job \
--resource-type Aurora \
--iam-role-arn arn:aws:iam::123456789012:role/service-role/AWSBackupDefaultServiceRole \
--metadata '{"DBClusterIdentifier":"backup-pitr-test","Engine":"aurora-mysql","RestoreToTime":"2023-09-01T17:00:00.000Z"}'
```

The following example shows how to restore a DB cluster to the latest restorable time.

```bash
aws backup start-restore-job \
--resource-type Aurora \
--iam-role-arn arn:aws:iam::123456789012:role/service-role/AWSBackupDefaultServiceRole \
--metadata '{"DBClusterIdentifier":"backup-pitr-latest","Engine":"aurora-mysql","UseLatestRestorableTime":true}''
```

After the DB cluster is restored, you must add the primary (writer) DB instance to it. To create the primary instance for your DB cluster, call the `create-db-instance` AWS CLI command. Include the name of the DB cluster as the `--db-cluster-identifier` parameter value.
Deleting a DB cluster snapshot

You can delete DB cluster snapshots managed by Amazon RDS when you no longer need them.

Note
To delete backups managed by AWS Backup, use the AWS Backup console. For information about AWS Backup, see the AWS Backup Developer Guide.

Deleting a DB cluster snapshot

You can delete a DB cluster snapshot using the console, the AWS CLI, or the RDS API.

To delete a shared or public snapshot, you must sign in to the AWS account that owns the snapshot.

Console

To delete a DB cluster snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Choose the DB cluster snapshot that you want to delete.
4. For Actions, choose Delete snapshot.
5. Choose Delete on the confirmation page.

AWS CLI

You can delete a DB cluster snapshot by using the AWS CLI command delete-db-cluster-snapshot.

The following options are used to delete a DB cluster snapshot.

• --db-cluster-snapshot-identifier – The identifier for the DB cluster snapshot.

Example

The following code deletes the mydbclusternsnapshot DB cluster snapshot.

For Linux, macOS, or Unix:

```bash
aws rds delete-db-cluster-snapshot \    --db-cluster-snapshot-identifier mydbclusternsnapshot
```

For Windows:

```bash
aws rds delete-db-cluster-snapshot ^    --db-cluster-snapshot-identifier mydbclusternsnapshot
```

RDS API

You can delete a DB cluster snapshot by using the Amazon RDS API operation DeleteDBClusterSnapshot.

The following parameters are used to delete a DB cluster snapshot.
• `DBClusterSnapshotIdentifier` – The identifier for the DB cluster snapshot.
Tutorial: Restore an Amazon Aurora DB cluster from a DB cluster snapshot

A common scenario when working with Amazon Aurora is to have a DB instance that you work with occasionally but that you don't need full time. For example, you might use a DB cluster to hold the data for a report that you run only quarterly. One way to save money on such a scenario is to take a DB cluster snapshot of the DB cluster after the report is completed. Then you delete the DB cluster, and restore it when you need to upload new data and run the report during the next quarter.

When you restore a DB cluster, you provide the name of the DB cluster snapshot to restore from. You then provide a name for the new DB cluster that's created from the restore operation. For more detailed information on restoring DB clusters from snapshots, see Restoring from a DB cluster snapshot (p. 439).

In this tutorial, we also upgrade the restored DB cluster from Aurora MySQL version 2 (compatible with MySQL 5.7) to Aurora MySQL version 3 (compatible with MySQL 8.0).

Restoring a DB cluster from a DB cluster snapshot using the Amazon RDS console

When you restore a DB cluster from a snapshot using the AWS Management Console, the primary (writer) DB instance is also created.

**Note**
While the primary DB instance is being created, it appears as a reader instance, but after creation it's a writer instance.

To restore a DB cluster from a DB cluster snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Choose the DB cluster snapshot that you want to restore from.
4. For Actions, choose Restore snapshot.

   ![Snapshots](image)

   The Restore snapshot page appears.
5. Under **DB instance settings**, do the following:
   a. Use the default setting for **DB engine**.
   b. For **Available versions**, choose a MySQL-8.0 compatible version, such as **Aurora MySQL 3.02.0** (compatible with MySQL 8.0.23).
6. Under **Settings**, for **DB cluster identifier** enter the unique name that you want to use for the restored DB cluster, for example **my-80-cluster**.

7. Under **Connectivity**, use the default settings for the following:
   - Virtual private cloud (VPC)
   - DB subnet group
   - Public access
   - VPC security group (firewall)

8. Choose the **DB instance class**.
   For this tutorial, choose **Burstable classes (includes t classes)**, and then choose **db.t3.medium**.

   **Note**
   We recommend using the T DB instance classes only for development and test servers, or other non-production servers. For more details on the T instance classes, see **DB instance class types** (p. 84).
9. For **Database authentication**, use the default setting.
10. For **Encryption**, use the default settings.
    
    If the source DB cluster for the snapshot was encrypted, the restored DB cluster is also encrypted. You can’t make it unencrypted.

11. Expand **Additional configuration** at the bottom of the page.

12. Make the following choices:

   a. For this tutorial, use the default value for **DB cluster parameter group**.

   b. For this tutorial, use the default value for **DB parameter group**.

   c. For **Log exports**, select all of the check boxes.
d. For **Deletion protection**, select the **Enable deletion protection** check box.

13. Choose **Restore DB instance**.

The **Databases** page displays the restored DB cluster, with a status of **Creating**.

While the primary DB instance is being created, it appears as a reader instance, but after creation it’s a writer instance.

**Restoring a DB cluster from a DB cluster snapshot using the AWS CLI**

Restoring a DB cluster from a snapshot using the AWS CLI has two steps:

1. **Restoring the DB cluster** (p. 504) using the **restore-db-cluster-from-snapshot** command

2. **Creating the primary (writer) DB instance** (p. 506) using the **create-db-instance** command

**Restoring the DB cluster**

You use the **restore-db-cluster-from-snapshot** command. The following options are required:

- **--db-cluster-identifier** – The name of the restored DB cluster.
- **--snapshot-identifier** – The name of the DB snapshot to restore from.
- **--engine** – The database engine of the restored DB cluster. It must be compatible with the database engine of the source DB cluster.

The choices are the following:

- **aurora-mysql** – Aurora MySQL 5.7 and 8.0 compatible.
- **aurora-postgresql** – Aurora PostgreSQL compatible.

In this example, we use **aurora-mysql**.

- **--engine-version** – The version of the restored DB cluster. In this example, we use a MySQL-8.0 compatible version.

The following example restores an Aurora MySQL 8.0–compatible DB cluster named **my-new-80-cluster** from a DB cluster snapshot named **my-57-cluster-snapshot**.

**To restore the DB cluster**

- Use one of the following commands.

  For Linux, macOS, or Unix:
aws rds restore-db-cluster-from-snapshot \
--db-cluster-identifier my-new-80-cluster \
--snapshot-identifier my-57-cluster-snapshot \
--engine aurora-mysql \
--engine-version 8.0.mysql_aurora.3.02.0

For Windows:

aws rds restore-db-cluster-from-snapshot ^
--db-cluster-identifier my-new-80-cluster ^
--snapshot-identifier my-57-cluster-snapshot ^
--engine aurora-mysql ^
--engine-version 8.0.mysql_aurora.3.02.0

The output resembles the following.

```
{
  "DBCluster": {
    "AllocatedStorage": 1,
    "AvailabilityZones": [
      "eu-central-1b",
      "eu-central-1c",
      "eu-central-1a"
    ],
    "BackupRetentionPeriod": 14,
    "DatabaseName": "",
    "DBClusterIdentifier": "my-new-80-cluster",
    "DBClusterParameterGroup": "default.aurora-mysql8.0",
    "DBSubnetGroup": "default",
    "Status": "creating",
    "Endpoint": "my-new-80-cluster.cluster-############.eu-central-1.rds.amazonaws.com",
    "ReaderEndpoint": "my-new-80-cluster.cluster-ro-############.eu-central-1.rds.amazonaws.com",
    "MultiAZ": false,
    "Engine": "aurora-mysql",
    "EngineVersion": "8.0.mysql_aurora.3.02.0",
    "Port": 3306,
    "MasterUsername": "admin",
    "PreferredBackupWindow": "01:55-02:25",
    "ReadReplicaIdentifiers": [],
    "DBClusterMembers": [],
    "VpcSecurityGroups": [
      {
        "VpcSecurityGroupId": "sg-############",
        "Status": "active"
      }
    ],
    "HostedZoneId": "Z1RLNU0EXAMPLE",
    "StorageEncrypted": true,
    "KmsKeyId": "arn:aws:kms:eu-central-1:123456789012:key/########-5ccc-49cc-8aa-############",
    "DbClusterResourceId": "cluster-ZZ12345678ITSJUSTANEXAMPLE",
    "AssociatedRoles": [],
    "IAMDatabaseAuthenticationEnabled": false,
    "ClusterCreateTime": "2022-07-05T20:45:42.171000+00:00",
    "EngineMode": "provisioned",
    "DeletionProtection": false,
    "HttpEndpointEnabled": false
  }
}
```
Creating the primary (writer) DB instance

To create the primary (writer) DB instance, you use the `create-db-instance` command. The following options are required:

- `--db-cluster-identifier` – The name of the restored DB cluster.
- `--db-instance-identifier` – The name of the primary DB instance.
- `--db-instance-class` – The instance class of the primary DB instance. In this example, we use `db.t3.medium`.
  
  Note
  We recommend using the T DB instance classes only for development and test servers, or other non-production servers. For more details on the T instance classes, see [DB instance class types](p. 84).

- `--engine` – The database engine of the primary DB instance. It must be the same database engine as the restored DB cluster uses.

The choices are the following:

- `aurora-mysql` – Aurora MySQL 5.7 and 8.0 compatible.
- `aurora-postgresql` – Aurora PostgreSQL compatible.

In this example, we use `aurora-mysql`.

The following example creates a primary (writer) DB instance named `my-new-80-cluster-instance` in the restored Aurora MySQL 8.0-compatible DB cluster named `my-new-80-cluster`.

To create the primary DB instance

- Use one of the following commands.

  For Linux, macOS, or Unix:

  ```bash
  aws rds create-db-instance \
  --db-cluster-identifier my-new-80-cluster \
  --db-instance-identifier my-new-80-cluster-instance \
  --db-instance-class db.t3.medium \
  --engine aurora-mysql
  ```

  For Windows:

  ```bash
  aws rds create-db-instance ^
  --db-cluster-identifier my-new-80-cluster ^
  --db-instance-identifier my-new-80-cluster-instance ^
  --db-instance-class db.t3.medium ^
  --engine aurora-mysql
  ```

  The output resembles the following.

  ```json
  {}
  ```
"DBInstance": {
    "DBInstanceIdentifier": "my-new-80-cluster-instance",
    "DBInstanceClass": "db.t3.medium",
    "Engine": "aurora-mysql",
    "DBInstanceStatus": "creating",
    "MasterUsername": "admin",
    "AllocatedStorage": 1,
    "PreferredBackupWindow": "01:55-02:25",
    "BackupRetentionPeriod": 14,
    "DBSecurityGroups": [],
    "VpcSecurityGroups": [
        {
            "VpcSecurityGroupId": "sg-########",
            "Status": "active"
        }
    ],
    "DBParameterGroups": [
        {
            "DBParameterGroupName": "default.aurora-mysql8.0",
            "ParameterApplyStatus": "in-sync"
        }
    ],
    "DBSubnetGroup": {
        "DBSubnetGroupName": "default",
        "DBSubnetGroupDescription": "default",
        "VpcId": "vpc-2305ca49",
        "SubnetGroupStatus": "Complete",
        "Subnets": [
            {
                "SubnetIdentifier": "subnet-########",
                "SubnetAvailabilityZone": {
                    "Name": "eu-central-1a"
                },
                "SubnetOutpost": {},
                "SubnetStatus": "Active"
            },
            {
                "SubnetIdentifier": "subnet-########",
                "SubnetAvailabilityZone": {
                    "Name": "eu-central-1b"
                },
                "SubnetOutpost": {},
                "SubnetStatus": "Active"
            },
            {
                "SubnetIdentifier": "subnet-########",
                "SubnetAvailabilityZone": {
                    "Name": "eu-central-1c"
                },
                "SubnetOutpost": {},
                "SubnetStatus": "Active"
            }
        ]
    },
    "PreferredMaintenanceWindow": "sat:02:41-sat:03:11",
    "PendingModifiedValues": {},

Monitoring metrics in an Amazon Aurora cluster

Amazon Aurora uses a cluster of replicated database servers. Typically, monitoring an Aurora cluster requires checking the health of multiple DB instances. The instances might have specialized roles, handling mostly write operations, only read operations, or a combination. You also monitor the overall health of the cluster by measuring the replication lag. This is the amount of time for changes made by one DB instance to be available to the other instances.

Topics
- Overview of monitoring metrics in Amazon Aurora (p. 510)
- Viewing cluster status and recommendations (p. 514)
- Viewing metrics in the Amazon RDS console (p. 535)

Overview of monitoring metrics in Amazon Aurora

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon Aurora and your AWS solutions. To more easily debug multi-point failures, we recommend that you collect monitoring data from all parts of your AWS solution.

**Topics**
- Monitoring plan (p. 510)
- Performance baseline (p. 510)
- Performance guidelines (p. 510)
- Monitoring tools (p. 511)

**Monitoring plan**

Before you start monitoring Amazon Aurora, create a monitoring plan. This plan should answer the following questions:

- What are your monitoring goals?
- Which resources will you monitor?
- How often will you monitor these resources?
- Which monitoring tools will you use?
- Who will perform the monitoring tasks?
- Whom should be notified when something goes wrong?

**Performance baseline**

To achieve your monitoring goals, you need to establish a baseline. To do this, measure performance under different load conditions at various times in your Amazon Aurora environment. You can monitor metrics such as the following:

- Network throughput
- Client connections
- I/O for read, write, or metadata operations
- Burst credit balances for your DB instances

We recommend that you store historical performance data for Amazon Aurora. Using the stored data, you can compare current performance against past trends. You can also distinguish normal performance patterns from anomalies, and devise techniques to address issues.

**Performance guidelines**

In general, acceptable values for performance metrics depend on what your application is doing relative to your baseline. Investigate consistent or trending variances from your baseline. The following metrics are often the source of performance issues:

- **High CPU or RAM consumption** – High values for CPU or RAM consumption might be appropriate, if they're in keeping with your goals for your application (like throughput or concurrency) and are expected.
• **Disk space consumption** – Investigate disk space consumption if space used is consistently at or above 85 percent of the total disk space. See if it is possible to delete data from the instance or archive data to a different system to free up space.

• **Network traffic** – For network traffic, talk with your system administrator to understand what expected throughput is for your domain network and internet connection. Investigate network traffic if throughput is consistently lower than expected.

• **Database connections** – If you see high numbers of user connections and also decreases in instance performance and response time, consider constraining database connections. The best number of user connections for your DB instance varies based on your instance class and the complexity of the operations being performed. To determine the number of database connections, associate your DB instance with a parameter group where the User Connections parameter is set to a value other than 0 (unlimited). You can either use an existing parameter group or create a new one. For more information, see [Working with parameter groups](p. 212).

• **IOPS metrics** – The expected values for IOPS metrics depend on disk specification and server configuration, so use your baseline to know what is typical. Investigate if values are consistently different than your baseline. For best IOPS performance, make sure that your typical working set fits into memory to minimize read and write operations.

When performance falls outside your established baseline, you might need to make changes to optimize your database availability for your workload. For example, you might need to change the instance class of your DB instance. Or you might need to change the number of DB instances and read replicas that are available for clients.

### Monitoring tools

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon Aurora and your other AWS solutions. AWS provides various monitoring tools to watch Amazon Aurora, report when something is wrong, and take automatic actions when appropriate.

**Topics**

- [Automated monitoring tools](p. 511)

- [Manual monitoring tools](p. 512)

### Automated monitoring tools

We recommend that you automate monitoring tasks as much as possible.

**Topics**

- [Amazon Aurora cluster status and recommendations](p. 511)

- [Amazon CloudWatch metrics for Amazon Aurora](p. 512)

- [Amazon RDS Performance Insights and operating-system monitoring](p. 512)

- [Integrated services](p. 512)

### Amazon Aurora cluster status and recommendations

You can use the following automated tools to watch Amazon Aurora and report when something is wrong:

- **Amazon Aurora cluster status** — View details about the current status of your cluster by using the Amazon RDS console, the AWS CLI, or the RDS API.
Amazon Aurora recommendations — Respond to automated recommendations for database resources, such as DB instances, DB clusters, and DB cluster parameter groups. For more information, see Viewing Amazon Aurora recommendations (p. 527).

Amazon CloudWatch metrics for Amazon Aurora

Amazon Aurora integrates with Amazon CloudWatch for additional monitoring capabilities.

- **Amazon CloudWatch** – This service monitors your AWS resources and the applications you run on AWS in real time. You can use the following Amazon CloudWatch features with Amazon Aurora:
  - **Amazon CloudWatch metrics** – Amazon Aurora automatically sends metrics to CloudWatch every minute for each active database. You don't get additional charges for Amazon RDS metrics in CloudWatch. For more information, see Amazon CloudWatch metrics for Amazon Aurora (p. 638).
  - **Amazon CloudWatch alarms** – You can watch a single Amazon Aurora metric over a specific time period. You can then perform one or more actions based on the value of the metric relative to a threshold that you set.

Amazon RDS Performance Insights and operating-system monitoring

You can use the following automated tools to monitor Amazon Aurora performance:

- **Amazon RDS Performance Insights** – Assess the load on your database, and determine when and where to take action. For more information, see Monitoring DB load with Performance Insights on Amazon Aurora (p. 559).
- **Amazon RDS Enhanced Monitoring** – Look at metrics in real time for the operating system. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 631).

Integrated services

The following AWS services are integrated with Amazon Aurora:

- **Amazon EventBridge** is a serverless event bus service that makes it easy to connect your applications with data from a variety of sources. For more information, see Monitoring Amazon Aurora events (p. 685).
- **Amazon CloudWatch Logs** lets you monitor, store, and access your log files from Amazon Aurora instances, CloudTrail, and other sources. For more information, see Monitoring Amazon Aurora log files (p. 722).
- **AWS CloudTrail** captures API calls and related events made by or on behalf of your AWS account and delivers the log files to an Amazon S3 bucket that you specify. For more information, see Monitoring Amazon Aurora API calls in AWS CloudTrail (p. 742).
- **Database Activity Streams** is an Amazon Aurora feature that provides a near-real-time stream of the activity in your DB cluster. For more information, see Monitoring Amazon Aurora with Database Activity Streams (p. 746).
- **DevOps Guru for RDS** is a capability of Amazon DevOps Guru that applies machine learning to Performance Insights metrics for Amazon Aurora databases. For more information, see Analyzing performance anomalies with Amazon DevOps Guru for Amazon RDS (p. 622).

Manual monitoring tools

You need to manually monitor those items that the CloudWatch alarms don't cover. The Amazon RDS, CloudWatch, AWS Trusted Advisor and other AWS console dashboards provide an at-a-glance view of the state of your AWS environment. We recommend that you also check the log files on your DB instance.
• From the Amazon RDS console, you can monitor the following items for your resources:
  • The number of connections to a DB instance
  • The amount of read and write operations to a DB instance
  • The amount of storage that a DB instance is currently using
  • The amount of memory and CPU being used for a DB instance
  • The amount of network traffic to and from a DB instance
• From the Trusted Advisor dashboard, you can review the following cost optimization, security, fault
tolerance, and performance improvement checks:
  • Amazon RDS Idle DB Instances
  • Amazon RDS Security Group Access Risk
  • Amazon RDS Backups
  • Amazon RDS Multi-AZ
  • Aurora DB Instance Accessibility

For more information on these checks, see Trusted Advisor best practices (checks).
• CloudWatch home page shows:
  • Current alarms and status
  • Graphs of alarms and resources
  • Service health status

In addition, you can use CloudWatch to do the following:
• Create customized dashboards to monitor the services that you care about.
• Graph metric data to troubleshoot issues and discover trends.
• Search and browse all your AWS resource metrics.
• Create and edit alarms to be notified of problems.
Viewing cluster status and recommendations

Using the Amazon RDS console, you can quickly access the status of your DB cluster and respond to Amazon Aurora recommendations.

Topics

- Viewing an Amazon Aurora DB cluster (p. 515)
- Viewing DB cluster status (p. 520)
- Viewing DB instance status in an Aurora cluster (p. 523)
- Viewing Amazon Aurora recommendations (p. 527)
Viewing an Amazon Aurora DB cluster

You have several options for viewing information about your Amazon Aurora DB clusters and the DB instances in your DB clusters.

- You can view DB clusters and DB instances in the Amazon RDS console by choosing Databases from the navigation pane.
- You can get DB cluster and DB instance information using the AWS Command Line Interface (AWS CLI).
- You can get DB cluster and DB instance information using the Amazon RDS API.

Console

In the Amazon RDS console, you can see details about a DB cluster by choosing Databases from the console’s navigation pane. You can also see details about DB instances that are members of an Amazon Aurora DB cluster.

To view or modify DB clusters in the Amazon RDS console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the name of the Aurora DB cluster that you want to view from the list.

   For example, the following image shows the details page for the DB cluster named aurora-test. The DB cluster has four DB instances shown in the DB identifier list. The writer DB instance, dbinstance4, is the primary DB instance for the DB cluster.
To modify a DB cluster, select the DB cluster from the list and choose Modify.

**To view or modify DB instances of a DB cluster in the Amazon RDS console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Databases.
3. Do one of the following:
   - To view a DB instance, choose one from the list that is a member of the Aurora DB cluster.

   For example, if you choose the dbinstance4 DB instance identifier, the console shows the details page for the dbinstance4 DB instance, as shown in the following image.
To modify a DB instance, choose the DB instance from the list and choose **Modify**. For more information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster](p. 269).

**AWS CLI**

To view DB cluster information by using the AWS CLI, use the `describe-db-clusters` command. For example, the following AWS CLI command lists the DB cluster information for all of the DB clusters in the `us-east-1` region for the configured AWS account.

```
aws rds describe-db-clusters --region us-east-1
```

The command returns the following output if your AWS CLI is configured for JSON output.

```
{
    "DBClusters": [
        {
            "Status": "available",
            "Engine": "aurora-mysql",

        }
    ],
    "DBSubnetGroup": "default"
RDS API

To view DB cluster information using the Amazon RDS API, use the DescribeDBClusters operation.
Viewing DB cluster status

The status of a DB cluster indicates its health. You can view the status of a DB cluster and the cluster instances by using the Amazon RDS console, the AWS CLI, or the API.

**Note**
Aurora also uses another status called *maintenance status*, which is shown in the **Maintenance** column of the Amazon RDS console. This value indicates the status of any maintenance patches that need to be applied to a DB cluster. Maintenance status is independent of DB cluster status. For more information about maintenance status, see [Applying updates for a DB cluster](#).

Find the possible status values for DB clusters in the following table.

<table>
<thead>
<tr>
<th>DB cluster status</th>
<th>Billed</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Available</td>
<td>Billed</td>
<td>The DB cluster is healthy and available. When an Aurora Serverless cluster is available and paused, you're billed for storage only.</td>
</tr>
<tr>
<td>Backing-up</td>
<td>Billed</td>
<td>The DB cluster is currently being backed up.</td>
</tr>
<tr>
<td>Backtracking</td>
<td>Billed</td>
<td>The DB cluster is currently being backtracked. This status only applies to Aurora MySQL.</td>
</tr>
<tr>
<td>Cloning-failed</td>
<td>Not billed</td>
<td>Cloning a DB cluster failed.</td>
</tr>
<tr>
<td>Creating</td>
<td>Not billed</td>
<td>The DB cluster is being created. The DB cluster is inaccessible while it is being created.</td>
</tr>
<tr>
<td>Deleting</td>
<td>Not billed</td>
<td>The DB cluster is being deleted.</td>
</tr>
<tr>
<td>Failing-over</td>
<td>Billed</td>
<td>A failover from the primary instance to an Aurora Replica is being performed.</td>
</tr>
<tr>
<td>Inaccessible-encryption-credentials</td>
<td>Not billed</td>
<td>The AWS KMS key used to encrypt or decrypt the DB cluster can't be accessed or recovered.</td>
</tr>
<tr>
<td>Inaccessible-encryption-credentials-recoverable</td>
<td>Billed for storage</td>
<td>The KMS key used to encrypt or decrypt the DB cluster can't be accessed. However, if the KMS key is active, restarting the DB cluster can recover it. For more information, see <a href="#">Encrypting an Amazon Aurora DB cluster</a>.</td>
</tr>
<tr>
<td>Maintenance</td>
<td>Billed</td>
<td>Amazon RDS is applying a maintenance update to the DB cluster. This status is used for DB cluster-level maintenance that RDS schedules well in advance.</td>
</tr>
<tr>
<td>Migrating</td>
<td>Billed</td>
<td>A DB cluster snapshot is being restored to a DB cluster.</td>
</tr>
<tr>
<td>Migration-failed</td>
<td>Not billed</td>
<td>A migration failed.</td>
</tr>
<tr>
<td>Modifying</td>
<td>Billed</td>
<td>The DB cluster is being modified because of a customer request to modify the DB cluster.</td>
</tr>
<tr>
<td>Promoting</td>
<td>Billed</td>
<td>A read replica is being promoted to a standalone DB cluster.</td>
</tr>
</tbody>
</table>
### DB cluster status

<table>
<thead>
<tr>
<th>DB cluster status</th>
<th>Billed</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Renaming</td>
<td>Billed</td>
<td>The DB cluster is being renamed because of a customer request to rename it.</td>
</tr>
<tr>
<td>Resetting-master-credentials</td>
<td>Billed</td>
<td>The master credentials for the DB cluster are being reset because of a customer request to reset them.</td>
</tr>
<tr>
<td>Starting</td>
<td>Billed for storage</td>
<td>The DB cluster is starting.</td>
</tr>
<tr>
<td>Stopped</td>
<td>Billed for storage</td>
<td>The DB cluster is stopped.</td>
</tr>
<tr>
<td>Stopping</td>
<td>Billed for storage</td>
<td>The DB cluster is being stopped.</td>
</tr>
<tr>
<td>Storage-optimization</td>
<td>Billed</td>
<td>Your DB instance is being modified to change the storage size or type. The DB instance is fully operational. However, while the status of your DB instance is <code>storage-optimization</code>, you can't request any changes to the storage of your DB instance. The storage optimization process is usually short, but can sometimes take up to and even beyond 24 hours.</td>
</tr>
<tr>
<td>Update-iam-db-auth</td>
<td>Billed</td>
<td>IAM authorization for the DB is being updated.</td>
</tr>
<tr>
<td>Upgrading</td>
<td>Billed</td>
<td>The DB cluster engine version is being upgraded.</td>
</tr>
</tbody>
</table>

### Console

#### To view the status of a DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Databases.

The Databases page appears with the list of DB clusters. For each DB cluster, the status value is displayed.
CLI

To view just the status of the DB clusters, use the following query in AWS CLI.

```
aws rds describe-db-clusters --query 'DBClusters[*].[DBClusterIdentifier,Status]' --output table
```
Viewing DB instance status in an Aurora cluster

The status of a DB instance in an Aurora cluster indicates the health of the DB instance. You can use the following procedures to view the DB instance status of a cluster in the Amazon RDS console, the AWS CLI command, or the API operation.

**Note**
Amazon RDS also uses another status called *maintenance status*, which is shown in the Maintenance column of the Amazon RDS console. This value indicates the status of any maintenance patches that need to be applied to a DB instance. Maintenance status is independent of DB instance status. For more information about maintenance status, see Applying updates for a DB cluster (p. 347).

Find the possible status values for DB instances in the following table. This table also shows whether you will be billed for the DB instance and storage, billed only for storage, or not billed. For all DB instance statuses, you are always billed for backup usage.

<table>
<thead>
<tr>
<th>DB instance status</th>
<th>Billed</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Available</td>
<td>Billed</td>
<td>The DB instance is healthy and available.</td>
</tr>
<tr>
<td>Backing-up</td>
<td>Billed</td>
<td>The DB instance is currently being backed up.</td>
</tr>
<tr>
<td>Backtracking</td>
<td>Billed</td>
<td>The DB instance is currently being backtracked. This status only applies to Aurora MySQL.</td>
</tr>
<tr>
<td>Configuring-enhanced-monitoring</td>
<td>Billed</td>
<td>Enhanced Monitoring is being enabled or disabled for this DB instance.</td>
</tr>
<tr>
<td>Configuring-iam-database-auth</td>
<td>Billed</td>
<td>AWS Identity and Access Management (IAM) database authentication is being enabled or disabled for this DB instance.</td>
</tr>
<tr>
<td>Configuring-log-exports</td>
<td>Billed</td>
<td>Publishing log files to Amazon CloudWatch Logs is being enabled or disabled for this DB instance.</td>
</tr>
<tr>
<td>Converting-to-vpc</td>
<td>Billed</td>
<td>The DB instance is being converted from a DB instance that is not in an Amazon Virtual Private Cloud (Amazon VPC) to a DB instance that is in an Amazon VPC.</td>
</tr>
<tr>
<td>Creating</td>
<td>Not billed</td>
<td>The DB instance is being created. The DB instance is inaccessible while it is being created.</td>
</tr>
<tr>
<td>Delete-precheck</td>
<td>Not billed</td>
<td>Amazon RDS is validating that read replicas are healthy and are safe to delete.</td>
</tr>
<tr>
<td>Deleting</td>
<td>Not billed</td>
<td>The DB instance is being deleted.</td>
</tr>
<tr>
<td>Failed</td>
<td>Not billed</td>
<td>The DB instance has failed and Amazon RDS can't recover it. Perform a point-in-time restore to the latest restorable time of the DB instance to recover the data.</td>
</tr>
<tr>
<td>Inaccessible-encryption-credentials</td>
<td>Not billed</td>
<td>The AWS KMS key used to encrypt or decrypt the DB instance can't be accessed or recovered.</td>
</tr>
<tr>
<td>Inaccessible-encryption-credentials-recoverable</td>
<td>Billed for storage</td>
<td>The KMS key used to encrypt or decrypt the DB instance can't be accessed. However, if the KMS key is active, restarting the DB instance can recover it.</td>
</tr>
<tr>
<td>DB instance status</td>
<td>Billed</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------</td>
<td>---------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Incompatible-network</td>
<td>Not billed</td>
<td>Amazon RDS is attempting to perform a recovery action on a DB instance but can't do so because the VPC is in a state that prevents the action from being completed. This status can occur if, for example, all available IP addresses in a subnet are in use and Amazon RDS can't get an IP address for the DB instance.</td>
</tr>
<tr>
<td>Incompatible-option-group</td>
<td>Billed</td>
<td>Amazon RDS attempted to apply an option group change but can't do so, and Amazon RDS can't roll back to the previous option group state. For more information, check the Recent Events list for the DB instance. This status can occur if, for example, the option group contains an option such as TDE and the DB instance doesn't contain encrypted information.</td>
</tr>
<tr>
<td>Incompatible-parameters</td>
<td>Billed</td>
<td>Amazon RDS can't start the DB instance because the parameters specified in the DB instance's DB parameter group aren't compatible with the DB instance. Revert the parameter changes or make them compatible with the DB instance to regain access to your DB instance. For more information about the incompatible parameters, check the Recent Events list for the DB instance.</td>
</tr>
<tr>
<td>Incompatible-restore</td>
<td>Not billed</td>
<td>Amazon RDS can't do a point-in-time restore. Common causes for this status include using temp tables or using MyISAM tables with MySQL.</td>
</tr>
<tr>
<td>Insufficient-capacity</td>
<td>Not billed</td>
<td>Amazon RDS can't create your instance because sufficient capacity isn't currently available. To create your DB instance in the same AZ with the same instance type, delete your DB instance, wait a few hours, and try to create again. Alternatively, create a new instance using a different instance class or AZ.</td>
</tr>
<tr>
<td>Maintenance</td>
<td>Billed</td>
<td>Amazon RDS is applying a maintenance update to the DB instance. This status is used for instance-level maintenance that RDS schedules well in advance.</td>
</tr>
<tr>
<td>Modifying</td>
<td>Billed</td>
<td>The DB instance is being modified because of a customer request to modify the DB instance.</td>
</tr>
<tr>
<td>Moving-to-vpc</td>
<td>Billed</td>
<td>The DB instance is being moved to a new Amazon Virtual Private Cloud (Amazon VPC).</td>
</tr>
<tr>
<td>Rebooting</td>
<td>Billed</td>
<td>The DB instance is being rebooted because of a customer request or an Amazon RDS process that requires the rebooting of the DB instance.</td>
</tr>
<tr>
<td>Resetting-master-credentials</td>
<td>Billed</td>
<td>The master credentials for the DB instance are being reset because of a customer request to reset them.</td>
</tr>
<tr>
<td>Renaming</td>
<td>Billed</td>
<td>The DB instance is being renamed because of a customer request to rename it.</td>
</tr>
<tr>
<td>Restore-error</td>
<td>Billed</td>
<td>The DB instance encountered an error attempting to restore to a point-in-time or from a snapshot.</td>
</tr>
</tbody>
</table>

</tbody>
</table>

#### Console

**To view the status of a DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.

The **Databases page** appears with the list of DB instances. For each DB instance in a cluster, the status value is displayed.
CLI

To view DB instance and its status information by using the AWS CLI, use the `describe-db-instances` command. For example, the following AWS CLI command lists all the DB instances information.

```
aws rds describe-db-instances
```

To view a specific DB instance and its status, call the `describe-db-instances` command with the following option:

- **DBInstanceIdentifier** – The name of the DB instance.

```
aws rds describe-db-instances --db-instance-identifier mydbinstance
```

To view just the status of all the DB instances, use the following query in AWS CLI.

```
aws rds describe-db-instances --query 'DBInstances[*].[DBInstanceIdentifier,DBInstanceStatus]' --output table
```

API

To view the status of the DB instance using the Amazon RDS API, call the `DescribeDBInstances` operation.
Viewing Amazon Aurora recommendations

Amazon Aurora provides automated recommendations for database resources, such as DB instances, DB clusters, and DB cluster parameter groups. These recommendations provide best practice guidance by analyzing DB cluster configuration, DB instance configuration, usage, and performance data.

You can find examples of these recommendations in the following table.

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th>Recommendation</th>
<th>Additional information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reader instances in the cluster are in the same Availability Zone</td>
<td>Your DB cluster has all the reader instances in the same Availability Zone.</td>
<td>We recommend that you distribute the Reader instances across multiple Availability Zones. Distribution increases the availability of the database, and improves the response time by reducing network latency between clients and database.</td>
<td>High availability for Amazon Aurora (p. 102)</td>
</tr>
<tr>
<td>Enhanced Monitoring disabled</td>
<td>Your DB instance doesn’t have Enhanced Monitoring enabled.</td>
<td>We recommend enabling Enhanced Monitoring. Enhanced Monitoring provides real-time operating system metrics for monitoring and troubleshooting.</td>
<td>Monitoring OS metrics with Enhanced Monitoring (p. 631)</td>
</tr>
<tr>
<td>Performance Insights disabled</td>
<td>Your DB instance doesn’t have Performance Insights enabled.</td>
<td>We recommend enabling Performance Insights. Performance Insights monitors your database load for better analysis and troubleshooting.</td>
<td>Overview of Performance Insights on Amazon Aurora (p. 559)</td>
</tr>
<tr>
<td>Encryption isn’t enabled for the DB Cluster</td>
<td>Your DB clusters don’t have the encryption enabled.</td>
<td>We recommend that you enable encryption of data at rest for your DB Cluster. You can turn on encryption while creating a DB cluster. You can’t convert an unencrypted DB cluster to an encrypted one. However, you can restore an unencrypted snapshot to an encrypted Aurora DB cluster. To do this, specify a KMS key when you restore from the unencrypted snapshot.</td>
<td>Encrypting Amazon Aurora resources (p. 2381)</td>
</tr>
<tr>
<td>Nondefault custom memory parameters</td>
<td>Your DB parameter group sets memory parameters that diverge too much from the default values.</td>
<td>Settings that diverge too much from the default values can cause poor performance and errors. We recommend setting custom memory parameters to their default values in the DB parameter group used by the DB instance.</td>
<td>Working with parameter groups (p. 212)</td>
</tr>
<tr>
<td>Found an unsafe durability parameter value for a</td>
<td>Your DB instance has an unsafe value for the innodb_flush_log_at_trx_commit parameter. This parameter controls</td>
<td>We recommend that you set the value of the innodb_flush_log_at_trx_commit parameter. The current value might improve performance but</td>
<td>Best practices for configuring parameters for Amazon RDS for MySQL, part 1: Parameters related to</td>
</tr>
</tbody>
</table>

527
<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th>Recommendation</th>
<th>Additional information</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL DB instance</td>
<td>the persistence of commit operations to disk.</td>
<td>transactions can be lost if the database crashes.</td>
<td>performance on the AWS Database Blog</td>
</tr>
<tr>
<td>Optimizer statistics aren't persisted to the disk for a MySQL DB instance</td>
<td>Your DB instance isn't configured to persist the InnoDB statistics to the disk. When it isn't configured, the statistics may recalculate frequently, which leads to variations in query execution plan. You can modify the value of this global parameter at the table level.</td>
<td>Global statistics persistence is disabled. We recommend that you set the <code>innodb_stats_persistent</code> parameter to ON.</td>
<td>Best practices for configuring parameters for Amazon RDS for MySQL, part 1: Parameters related to performance on the AWS Database Blog</td>
</tr>
<tr>
<td>General logging is enabled for a MySQL DB instance</td>
<td>Your DB instance has the general logging turned on. Turning on general logging increases the amount of I/O operations and allocated storage space, which can lead to contention and performance degradation.</td>
<td>Evaluate your required general logging usage. General logging can increase the amount of I/O operations and allocated storage space, and lead to contention and performance degradation.</td>
<td>Managing table-based Aurora MySQL logs (p. 731)</td>
</tr>
<tr>
<td>Maximum InnoDB open files setting is misconfigured for a MySQL DB instance</td>
<td>Your DB instance has a low value for the maximum number of files InnoDB can open at one time.</td>
<td>We recommend that you set the <code>innodb_open_files</code> parameter to a minimum value of 65.</td>
<td><code>innodb_open_files</code></td>
</tr>
<tr>
<td>Number of allowed simultaneous connections for a given database user is misconfigured for a MySQL DB instance</td>
<td>Your DB instance has a low value for the maximum number of simultaneous connections for each database account.</td>
<td>We recommend that you increase the setting of the <code>max_user_connections</code> parameter to a number greater than 5. The current <code>max_user_connections</code> value is low which impacts the database health checks and regular operations.</td>
<td>Setting Account Resource Limits</td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td>Recommendation</td>
<td>Additional information</td>
</tr>
<tr>
<td>-----------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Found an unsafe durability parameter value for a MySQL DB instance</td>
<td>The synchronization of the binary log to disk isn’t enforced before the acknowledgement of the transactions commit in your DB instance.</td>
<td>We recommend that you set the sync_binlog parameter to 1. Currently, the synchronization of the binary log to disk isn’t enforced before acknowledgement of the transactions commit. If there is a power failure or the operating system crashes, the committed transactions can be lost.</td>
<td>Best practices for configuring parameters for Amazon RDS for MySQL, part 2: Parameters related to replication on the AWS Database Blog</td>
</tr>
<tr>
<td>Change buffering enabled for a MySQL DB instance</td>
<td>Your DB parameter group has change buffering enabled.</td>
<td>Change buffering allows a MySQL DB instance to defer some writes necessary to maintain secondary indexes. This configuration can improve performance slightly, but it can create a large delay in crash recovery. During crash recovery, the secondary index must be brought up to date. So, the benefits of change buffering are outweighed by the potentially very long crash recovery events. We recommend disabling change buffering.</td>
<td>Best practices for configuring parameters for Amazon RDS for MySQL, part 1: Parameters related to performance on the AWS Database Blog</td>
</tr>
<tr>
<td>Autovacuum is disabled for a PostgreSQL DB instance</td>
<td>Your DB instance has autovacuum turned off. Turning off autovacuum increases table and index bloat and impacts performance.</td>
<td>We recommend that you set the autovacuum parameter to on.</td>
<td>Understanding autovacuum in Amazon RDS for PostgreSQL environments</td>
</tr>
<tr>
<td>Synchronous commit is turned off for a PostgreSQL DB instance</td>
<td>When the synchronous_commit parameter is set to OFF, it causes data loss when the database crashes, which can impact the durability of the database.</td>
<td>We recommend that you turn on the synchronous_commit parameter.</td>
<td>Asynchronous Commit</td>
</tr>
<tr>
<td>track_counts parameter is disabled for a PostgreSQL DB instance</td>
<td>If the track_counts parameter is turned off, the database doesn’t collect the database activity statistics. Autovacuum requires these statistics to work correctly.</td>
<td>We recommend that you set track_counts parameter to ON.</td>
<td>track_counts (boolean)</td>
</tr>
<tr>

<tr>
<th>Type</th>
<th>Description</th>
<th>Recommendation</th>
<th>Additional information</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB cluster with different DB instance classes</td>
<td>Your DB cluster has DB instances that use different DB instance classes.</td>
<td>Using different DB instance classes for DB instances can cause problems. For example, performance might suffer if a less powerful DB instance class is promoted to replace a more powerful DB instance class. To avoid problems and for easier maintenance, we recommend using the same DB instance class for all of the DB instances in the DB cluster.</td>
<td>Aurora Replicas (p. 104)</td>
</tr>
</tbody>
</table>

Amazon Aurora generates recommendations for a resource when the resource is created or modified. Amazon Aurora also periodically scans your resources and generates recommendations.

**To view Amazon Aurora recommendations**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Recommendations**.
3. On the Recommendations page, choose one of the following:

- **Active** – Shows the current recommendations that you can apply, dismiss, or schedule.
- **Dismissed** – Shows the recommendations that have been dismissed. When you choose Dismissed, you can apply these dismissed recommendations.
- **Scheduled** – Shows the recommendations that are scheduled but not yet applied. These recommendations will be applied in the next scheduled maintenance window.
- **Applied** – Shows the recommendations that are currently applied.
From any list of recommendations, you can open a section to view the recommendations in that section.

To configure preferences for displaying recommendations in each section, choose the Preferences icon.

From the Preferences window that appears, you can set display options. These options include the visible columns and the number of recommendations to display on the page.

4. (optional) Respond to your active recommendations as follows:

   a. Choose Active and open one or more sections to view the recommendations in them.
   b. Choose one or more recommendations and choose Apply now (to apply them immediately), Schedule (to apply them in next maintenance window), or Dismiss.

   If the Apply now button appears for a recommendation but is unavailable (grayed out), the DB instance is not available. You can apply recommendations immediately only if the DB instance status is available. For example, you can't apply recommendations immediately to the DB
instance if its status is **modifying**. In this case, wait for the DB instance to be available and then apply the recommendation.

If the **Apply now** button doesn't appear for a recommendation, you can't apply the recommendation using the **Recommendations** page. You can modify the DB instance to apply the recommendation manually.

For more information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster](p. 269).

**Note**

When you choose **Apply now**, a brief DB instance outage might result.
Viewing metrics in the Amazon RDS console

Amazon RDS integrates with Amazon CloudWatch to display a variety of Aurora DB cluster metrics in the RDS console. Some metrics are apply at the cluster level, whereas others apply at the instance level. For descriptions of the instance-level and cluster-level metrics, see Metrics reference for Amazon Aurora (p. 638).

For your Aurora DB cluster, the following categories of metrics are monitored:

- **CloudWatch** – Shows the Amazon CloudWatch metrics for Aurora that you can access in the RDS console. You can also access these metrics in the CloudWatch console. Each metric includes a graph that shows the metric monitored over a specific time span. For a list of CloudWatch metrics, see Amazon CloudWatch metrics for Amazon Aurora (p. 638).

- **Enhanced monitoring** – Shows a summary of operating-system metrics when your Aurora DB cluster has turned on Enhanced Monitoring. RDS delivers the metrics from Enhanced Monitoring to your Amazon CloudWatch Logs account. Each OS metric includes a graph showing the metric monitored over a specific time span. For an overview, see Monitoring OS metrics with Enhanced Monitoring (p. 631). For a list of Enhanced Monitoring metrics, see OS metrics in Enhanced Monitoring (p. 675).

- **OS Process list** – Shows details for each process running in your DB cluster.

- **Performance Insights** – Opens the Amazon RDS Performance Insights dashboard for a DB instance in your Aurora DB cluster. Performance Insights isn't supported at the cluster level. For an overview of Performance Insights, see Monitoring DB load with Performance Insights on Amazon Aurora (p. 559). For a list of Performance Insights metrics, see Amazon CloudWatch metrics for Performance Insights (p. 657).

Amazon RDS now provides a consolidated view of Performance Insights and CloudWatch metrics in the Performance Insights dashboard. Performance Insights must be turned on for your DB cluster to use this view. You can choose the new monitoring view in the Monitoring tab or Performance Insights in the navigation pane. To view the instructions for choosing this view, see Viewing combined metrics in the Amazon RDS console (p. 538).

If you want to continue with the legacy monitoring view, continue with this procedure.

**Note**

The legacy monitoring view will be discontinued on December 15, 2023.

**To view metrics for your DB cluster in the legacy monitoring view:**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the name of the Aurora DB cluster that you want to monitor.

The database page appears. The following example shows an Amazon Aurora PostgreSQL database named apga.
4. Scroll down and choose **Monitoring**.

The monitoring section appears. By default, CloudWatch metrics are shown. For descriptions of these metrics, see [Amazon CloudWatch metrics for Amazon Aurora](p. 638).

5. Choose **Monitoring** to see the metric categories.

6. Choose the category of metrics that you want to see.

The following example shows Enhanced Monitoring metrics. For descriptions of these metrics, see [OS metrics in Enhanced Monitoring](p. 675).
Tip
To choose the time range of the metrics represented by the graphs, you can use the time range list.
To bring up a more detailed view, you can choose any graph. You can also apply metric-specific filters to the data.
Viewing combined metrics in the Amazon RDS console

Amazon RDS now provides a consolidated view of Performance Insights and CloudWatch metrics for your DB instance in the Performance Insights dashboard. You can use the preconfigured dashboard or create a custom dashboard. The preconfigured dashboard provides the most commonly used metrics to help diagnose performance issues for a database engine. Alternatively, you can create a custom dashboard with the metrics for a database engine that meet your analysis requirements. Then, use this dashboard for all the DB instances of that database engine type in your AWS account.

You can choose the new monitoring view in the Monitoring tab or Performance Insights in the navigation pane. When you navigate to the Performance Insights page, you see the options to choose between the new monitoring view and legacy view. The option you choose is saved as the default view.

Performance Insights must be turned on for your DB cluster to view the combined metrics in the Performance Insights dashboard. For more information about turning on Performance Insights, see Turning Performance Insights on and off (p. 565).

Note
We recommend that you choose the new monitoring view. You can continue to use the legacy monitoring view until it is discontinued on December 15, 2023.

Choosing the new monitoring view in the Monitoring tab

To choose the new monitoring view in the Monitoring tab:

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose Databases.
3. Choose the Aurora DB cluster that you want to monitor.
   The database page appears.
4. Scroll down and choose the Monitoring tab.
   A banner appears with the option to choose the new monitoring view. The following example shows the banner to choose the new monitoring view.

5. Choose Go to new monitoring view to open the Performance Insights dashboard with Performance Insights and CloudWatch metrics for your DB cluster.
6. (Optional) If Performance Insights is turned off for your DB instance, a banner appears with the option to modify your DB instance and turn on Performance Insights.
   The following example shows the banner to modify the DB instance in the Monitoring tab.
Choosing the new monitoring view with **Performance Insights** in the navigation pane

To choose the new monitoring view with **Performance Insights** in the navigation pane:

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose **Performance Insights**.
3. Choose a DB instance to open a window that has the monitoring view options.

The following example shows the window with the monitoring view options.

4. Choose the **Performance Insights and CloudWatch metrics view (New)** option, and then choose **Continue**.

You can now view the Performance Insights dashboard that shows both Performance Insights and CloudWatch metrics for your DB instance. The following example shows the Performance Insights and CloudWatch metrics in the dashboard.
Choosing the legacy view with **Performance Insights** in the navigation pane

You can choose the legacy monitoring view to view only the Performance Insights metrics for your DB instance.

**Note**

This view will be discontinued on December 15, 2023.

**To choose the legacy monitoring view with Performance Insights in the navigation pane:**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the left navigation pane, choose **Performance Insights**.
3. Choose a DB instance.

   You can now see the **Settings** window that shows the option to choose the legacy Performance Insights view.

   The following example shows the window with the option for the legacy monitoring view.
Creating a custom dashboard with Performance Insights in the navigation pane

In the new monitoring view, you can create a custom dashboard with the metrics you need to meet your analysis requirements.

You can create a custom dashboard by selecting Performance Insights and CloudWatch metrics for your DB instance. You can use this custom dashboard for other DB instances of the same database engine type in your AWS account.

Note
The customized dashboard supports up to 50 metrics.

Use the widget settings menu to edit or delete the dashboard, and move or resize the widget window.

To create a custom dashboard with Performance Insights in the navigation pane:

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose Performance Insights.
3. Choose a DB instance.

4. Scroll down to the **Metrics tab** in the window.

5. Select the custom dashboard from the drop down list. The following example shows the custom dashboard creation.

6. Choose **Add widget** to open the **Add widget** window. You can open and view the available operating system (OS) metrics, database metrics, and CloudWatch metrics in the window.

   The following example shows the **Add widget** window with the metrics.
7. Select the metrics that you want to view in the dashboard and choose **Add widget**. You can use the search field to find a specific metric.

The selected metrics appear on your dashboard.
8. **(Optional)** If you want to modify or delete your dashboard, choose the settings icon on the upper right of the widget, and then select one of the following actions in the menu.

- **Edit** – Modify the metrics list in the window. Choose **Update widget** after you select the metrics for your dashboard.
- **Delete** – Deletes the widget. Choose **Delete** in the confirmation window.

---

### Choosing the preconfigured dashboard with **Performance Insights** in the navigation pane

You can view the most commonly used metrics with the preconfigured dashboard. This dashboard helps diagnose performance issues with a database engine and reduce the average recovery time from hours to minutes.

**Note**  
This dashboard can’t be edited.

**To choose the preconfigured dashboard with Performance Insights in the navigation pane:**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the left navigation pane, choose **Performance Insights**.
3. Choose a DB instance.
4. Scroll down to the **Metrics tab** in the window.
5. Select a preconfigured dashboard from the drop down list.

You can view the metrics for the DB instance in the dashboard. The following example shows a preconfigured metrics dashboard.
Monitoring Amazon Aurora metrics with Amazon CloudWatch

Amazon CloudWatch is a metrics repository. The repository collects and processes raw data from Amazon Aurora into readable, near real-time metrics. For a complete list of Amazon Aurora metrics sent to CloudWatch, see Metrics reference for Amazon Aurora.

Topics
- Overview of Amazon Aurora and Amazon CloudWatch (p. 546)
- Viewing DB cluster metrics in the CloudWatch console and AWS CLI (p. 547)
- Exporting Performance Insights metrics to CloudWatch (p. 552)
- Creating CloudWatch alarms to monitor Amazon Aurora (p. 558)
Overview of Amazon Aurora and Amazon CloudWatch

By default, Amazon Aurora automatically sends metric data to CloudWatch in 1-minute periods. For example, the CPUUtilization metric records the percentage of CPU utilization for a DB instance over time. Data points with a period of 60 seconds (1 minute) are available for 15 days. This means that you can access historical information and see how your web application or service is performing.

You can now export Performance Insights metrics dashboards from Amazon RDS to Amazon CloudWatch. You can export either the preconfigured or customized metrics dashboards as a new dashboard or add them to an existing CloudWatch dashboard. The exported dashboard is available to view in the CloudWatch console. For more information on how to export the Performance Insights metrics dashboards to CloudWatch, see Exporting Performance Insights metrics to CloudWatch (p. 552).

As shown in the following diagram, you can set up alarms for your CloudWatch metrics. For example, you might create an alarm that signals when the CPU utilization for an instance is over 70%. You can configure Amazon Simple Notification Service to email you when the threshold is passed.

Amazon RDS publishes the following types of metrics to Amazon CloudWatch:
• Aurora metrics at both the cluster and instance level

For a table of these metrics, see Amazon CloudWatch metrics for Amazon Aurora (p. 638).

• Performance Insights metrics

For a table of these metrics, see Amazon CloudWatch metrics for Performance Insights (p. 657) and Performance Insights counter metrics (p. 658).

• Enhanced Monitoring metrics (published to Amazon CloudWatch Logs)

For a table of these metrics, see OS metrics in Enhanced Monitoring (p. 657).

• Usage metrics for the Amazon RDS service quotas in your AWS account

For a table of these metrics, see Amazon CloudWatch usage metrics for Amazon Aurora (p. 653). For more information about Amazon RDS quotas, see Quotas and constraints for Amazon Aurora (p. 2506).

For more information about CloudWatch, see What is Amazon CloudWatch? in the Amazon CloudWatch User Guide. For more information about CloudWatch metrics retention, see Metrics retention.

Viewing DB cluster metrics in the CloudWatch console and AWS CLI

Following, you can find details about how to view metrics for your DB instance using CloudWatch. For information on monitoring metrics for your DB instance's operating system in real time using CloudWatch Logs, see Monitoring OS metrics with Enhanced Monitoring (p. 631).

When you use Amazon Aurora resources, Amazon Aurora sends metrics and dimensions to Amazon CloudWatch every minute.

You can now export Performance Insights metrics dashboards from Amazon RDS to Amazon CloudWatch and view these metrics in the CloudWatch console. For more information on how to export the Performance Insights metrics dashboards to CloudWatch, see Exporting Performance Insights metrics to CloudWatch (p. 552).

Use the following procedures to view the metrics for Amazon Aurora in the CloudWatch console and CLI.

Console

To view metrics using the Amazon CloudWatch console

Metrics are grouped first by the service namespace, and then by the various dimension combinations within each namespace.

The CloudWatch overview home page appears.
2. If necessary, change the AWS Region. From the navigation bar, choose the AWS Region where your AWS resources are. For more information, see Regions and endpoints.

3. In the navigation pane, choose Metrics and then All metrics.

   
   ![Metrics](image)

   - EBS 9
   - EC2 17
   - Events
   - Lambda 26
   - Logs 35
   - RDS
   - S3 8
   - SSM Run Command 3
   - Usage

4. Scroll down and choose the RDS metric namespace.

   The page displays the Amazon Aurora dimensions. For descriptions of these dimensions, see Amazon CloudWatch dimensions for Aurora (p. 654).

   
   ![Metrics](image)

   - DBClusterIdentifier, Role 153
   - DbClusterIdentifier, EngineName 6
   - DBClusterIdentifier
   - Per-Database Metrics 332
   - By Database Class 191
   - By Database Engine
   - Across All Databases 114

5. Choose a metric dimension, for example By Database Class.
6. Do any of the following actions:

- To sort the metrics, use the column heading.
- To graph a metric, select the check box next to the metric.
- To filter by resource, choose the resource ID, and then choose Add to search.
- To filter by metric, choose the metric name, and then choose Add to search.

The following example filters on the db.t3.medium class and graphs the CPUUtilization metric.
You can find details about how to analyze resource usage for Aurora PostgreSQL using CloudWatch metrics. For more information, see Using Amazon CloudWatch metrics to analyze resource usage for Aurora PostgreSQL (p. 1494)

AWS CLI

To obtain metric information by using the AWS CLI, use the CloudWatch command `list-metrics`. In the following example, you list all metrics in the AWS/RDS namespace.

```
aws cloudwatch list-metrics --namespace AWS/RDS
```

To obtain metric statistics, use the command `get-metric-statistics`. The following command gets CPUUtilization statistics for instance `my-instance` over the specific 24-hour period, with a 5-minute granularity.

**Example**

For Linux, macOS, or Unix:

```
aws cloudwatch get-metric-statistics --namespace AWS/RDS \
  --metric-name CPUUtilization \
  --start-time 2021-12-15T00:00:00Z \
  --end-time 2021-12-16T00:00:00Z \
  --period 360 \
  --statistics Minimum \
  --dimensions Name=DBInstanceIdentifier,Value=my-instance
```

For Windows:

```
aws cloudwatch get-metric-statistics --namespace AWS/RDS ^
  --metric-name CPUUtilization ^
  --start-time 2021-12-15T00:00:00Z ^
  --end-time 2021-12-16T00:00:00Z ^
  --period 360 ^
  --statistics Minimum ^
  --dimensions Name=DBInstanceIdentifier,Value=my-instance
```

Sample output appears as follows:

```
[
  {
    "Datapoints": [
      {
        "Timestamp": "2021-12-15T18:00:00Z",
        "Minimum": 8.7,
        "Unit": "Percent"
      },
      {
        "Timestamp": "2021-12-15T23:54:00Z",
        "Minimum": 8.12486458559024,
        "Unit": "Percent"
      },
      {
        "Timestamp": "2021-12-15T23:54:00Z",
        "Minimum": 8.12486458559024,
        "Unit": "Percent"
      },
      {
        "Timestamp": "2021-12-15T22:48:00Z",
        "Minimum": 8.841666666666667,
        "Unit": "Percent"
      }, ...
    ]
  }
]```
Exporting Performance Insights metrics to CloudWatch

Performance Insights lets you export the preconfigured or custom metrics dashboard for your DB instance to Amazon CloudWatch. You can export the metrics dashboard as a new dashboard or add it to an existing CloudWatch dashboard. When you choose to add the dashboard to an existing CloudWatch dashboard, you can create a header label so that the metrics appear in a separate section in the CloudWatch dashboard.

You can view the exported metrics dashboard in the CloudWatch console. If you add new metrics to a Performance Insights metrics dashboard after you export it, you must export this dashboard again to view the new metrics in the CloudWatch console.

You can also select a metric widget in the Performance Insights dashboard and view the metrics data in the CloudWatch console.

For more information about viewing the metrics in the CloudWatch console, see Viewing DB cluster metrics in the CloudWatch console and AWS CLI (p. 547).

This feature isn't available in the following AWS Regions: China (Beijing), China (Ningxia), AWS GovCloud (US-East), and AWS GovCloud (US-West).

Exporting Performance Insights metrics as a new dashboard to CloudWatch

Choose a preconfigured or custom metrics dashboard from the Performance Insights dashboard and export it as a new dashboard to CloudWatch. You can view the exported dashboard in the CloudWatch console.

To export a Performance Insights metric dashboard as a new dashboard to CloudWatch

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose Performance Insights.
3. Choose a DB instance.
   
   The Performance Insights dashboard appears for the DB instance.
4. Scroll down and choose Metrics.
   
   By default, the preconfigured dashboard with Performance Insights metrics appears.
5. Choose a preconfigured or custom dashboard and then choose Export to CloudWatch.
   
   The Export to CloudWatch window appears.

For more information, see Getting statistics for a metric in the Amazon CloudWatch User Guide.
6. Choose Export as new dashboard.
Export to CloudWatch

Dashboard export destination
Select an option to export your dashboard to CloudWatch. CloudWatch charts.

Export as new dashboard
Creates a new CloudWatch dashboard with the contents from the selected dashboard.

Add to existing
Appends the view to an existing CloudWatch dashboard.

Dashboard name

MySQL_database_health_summary

Valid characters in the name include "0-9 A-Z a-z - _".

7. Enter a name for the new dashboard in the Dashboard name field and choose Confirm.

A banner displays a message after the dashboard export is successful.

Dashboard export successful
MySQL database health summary is successfully exported to CloudWatch.
MySQL_database_health_summary [View] dashboard.

8. Choose the link or View in CloudWatch in the banner to view the metrics dashboard in the CloudWatch console.
Adding Performance Insights metrics to an existing CloudWatch dashboard

Add a preconfigured or custom metrics dashboard to an existing CloudWatch dashboard. You can add a label to the metrics dashboard to appear in a separate section in the CloudWatch dashboard.

To export the metrics to an existing CloudWatch dashboard

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose Performance Insights.
3. Choose a DB instance.
   The Performance Insights dashboard appears for the DB instance.
4. Scroll down and choose Metrics.
   By default, the preconfigured dashboard with Performance Insights metrics appears.
5. Choose the preconfigured or custom dashboard and then choose Export to CloudWatch.
   The Export to CloudWatch window appears.
6. Choose Add to existing dashboard.
7. Specify the dashboard destination and label, and then choose Confirm.

- **CloudWatch dashboard destination** - Choose an existing CloudWatch dashboard.
- **CloudWatch dashboard section label - optional** - Enter a name for the Performance Insights metrics to appear in this section in the CloudWatch dashboard.
A banner displays a message after the dashboard export is successful.

8. Choose the link or View in CloudWatch in the banner to view the metrics dashboard in the CloudWatch console.

### Viewing a Performance Insights metric widget in CloudWatch

Select a Performance Insights metric widget in the Amazon RDS Performance Insights dashboard and view the metric data in the CloudWatch console.

**To export a metric widget and view the metrics data in the CloudWatch console**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose Performance Insights.
3. Choose a DB instance.

   The Performance Insights dashboard appears for the DB instance.

4. Scroll down to Metrics.

   By default, the preconfigured dashboard with Performance Insights metrics appears.

5. Choose a metric widget and then choose View in CloudWatch in the menu.

   The metric data appears in the CloudWatch console.
Creating CloudWatch alarms to monitor Amazon Aurora

You can create a CloudWatch alarm that sends an Amazon SNS message when the alarm changes state. An alarm watches a single metric over a time period that you specify. The alarm can also perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon SNS topic or Amazon EC2 Auto Scaling policy.

Alarms invoke actions for sustained state changes only. CloudWatch alarms don't invoke actions simply because they are in a particular state. The state must have changed and have been maintained for a specified number of time periods.

Note
For Aurora, use WRITER or READER role metrics to set up alarms instead of relying on metrics for specific DB instances. Aurora DB instance roles can change roles over time. You can find these role-based metrics in the CloudWatch console.
Aurora Auto Scaling automatically sets alarms based on READER role metrics. For more information about Aurora Auto Scaling, see Using Amazon Aurora Auto Scaling with Aurora Replicas (p. 328).

You can use the DB_PERF_INSIGHTS metric math function in the CloudWatch console to query Amazon RDS for Performance Insights counter metrics. The DB_PERF_INSIGHTS function also includes the DBLoad metric at sub-minute intervals. You can set CloudWatch alarms on these metrics.

For more details on how to create an alarm, see Create an alarm on Performance Insights counter metrics from an AWS database.

To set an alarm using the AWS CLI

- Call put-metric-alarm. For more information, see AWS CLI Command Reference.

To set an alarm using the CloudWatch API

- Call PutMetricAlarm. For more information, see Amazon CloudWatch API Reference.

For more information about setting up Amazon SNS topics and creating alarms, see Using Amazon CloudWatch alarms.
Monitoring DB load with Performance Insights on Amazon Aurora

Performance Insights expands on existing Amazon Aurora monitoring features to illustrate and help you analyze your cluster performance. With the Performance Insights dashboard, you can visualize the database load on your Amazon Aurora cluster load and filter the load by waits, SQL statements, hosts, or users. For information about using Performance Insights with Amazon DocumentDB, see Amazon DocumentDB Developer Guide.

Topics
- Overview of Performance Insights on Amazon Aurora (p. 559)
- Turning Performance Insights on and off (p. 565)
- Turning on the Performance Schema for Performance Insights on Aurora MySQL (p. 568)
- Configuring access policies for Performance Insights (p. 571)
- Analyzing metrics with the Performance Insights dashboard (p. 576)
- Retrieving metrics with the Performance Insights API (p. 602)
- Logging Performance Insights calls using AWS CloudTrail (p. 619)

Overview of Performance Insights on Amazon Aurora

By default, Performance Insights is turned on in the console create wizard for all Amazon RDS engines. If you turn on Performance Insights at the DB cluster level, Performance Insights is turned on for every DB instance in the cluster. If you have more than one database on a DB instance, Performance Insights aggregates performance data.

You can find an overview of Performance Insights for Amazon Aurora in the following video.

Using Performance Insights to Analyze Performance of Amazon Aurora PostgreSQL

Topics
- Database load (p. 559)
- Maximum CPU (p. 562)
- Amazon Aurora DB engine, Region, and instance class support for Performance Insights (p. 562)
- Pricing and data retention for Performance Insights (p. 564)

Database load

*Database load (DB load)* measures the level of session activity in your database. The key metric in Performance Insights is DBLoad, which is collected every second.

Topics
- Active sessions (p. 560)
- Average active sessions (p. 560)
- Average active executions (p. 560)
- Dimensions (p. 561)
Active sessions

A *database session* represents an application's dialogue with a relational database. An *active session* is a connection that has submitted work to the DB engine and is waiting for a response.

A session is active when it's either running on CPU or waiting for a resource to become available so that it can proceed. For example, an active session might wait for a page (or block) to be read into memory, and then consume CPU while it reads data from the page.

Average active sessions

The *average active sessions* (AAS) is the unit for the DBLoad metric in Performance Insights. It measures how many sessions are concurrently active on the database.

Every second, Performance Insights samples the number of sessions concurrently running a query. For each active session, Performance Insights collects the following data:

- SQL statement
- Session state (running on CPU or waiting)
- Host
- User running the SQL

Performance Insights calculates the AAS by dividing the total number of sessions by the number of samples for a specific time period. For example, the following table shows 5 consecutive samples of a running query taken at 1-second intervals.

<table>
<thead>
<tr>
<th>Sample</th>
<th>Number of sessions running query</th>
<th>AAS</th>
<th>Calculation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>2</td>
<td>2 total sessions / 1 sample</td>
</tr>
<tr>
<td>2</td>
<td>0</td>
<td>1</td>
<td>2 total sessions / 2 samples</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>2</td>
<td>6 total sessions / 3 samples</td>
</tr>
<tr>
<td>4</td>
<td>0</td>
<td>1.5</td>
<td>6 total sessions / 4 samples</td>
</tr>
<tr>
<td>5</td>
<td>4</td>
<td>2</td>
<td>10 total sessions / 5 samples</td>
</tr>
</tbody>
</table>

In the preceding example, the DB load for the time interval was 2 AAS. This measurement means that, on average, 2 sessions were active at any given time during the interval when the 5 samples were taken.

An analogy for DB load is worker activity in a warehouse. Suppose that the warehouse employs 100 workers. If 1 order comes in, 1 worker fulfills the order while 99 workers are idle. If 100 orders come in, all 100 workers fulfill orders simultaneously. If every 15 minutes a manager writes down how many workers are simultaneously active, adds these numbers at the end of the day, and then divides the total by the number of samples, the manager calculates the average number of workers active at any given time. If the average was 50 workers yesterday and 75 workers today, then the average activity level in the warehouse increased. Similarly, DB load increases as database session activity increases.

Average active executions

The *average active executions* (AAE) per second is related to AAS. To calculate the AAE, Performance Insights divides the total execution time of a query by the time interval. The following table shows the AAE calculation for the same query in the preceding table.
Overview of Performance Insights

In most cases, the AAS and AAE for a query are approximately the same. However, because the inputs to the calculations are different data sources, the calculations often vary slightly.

### Dimensions

The `db.load` metric is different from the other time-series metrics because you can break it into subcomponents called `dimensions`. You can think of dimensions as "slice by" categories for the different characteristics of the `DBLoad` metric.

When you are diagnosing performance issues, the following dimensions are often the most useful:

#### Topics
- [Wait events](#)
- [Top SQL](#)

For a complete list of dimensions for the Aurora engines, see [DB load sliced by dimensions](#).

### Wait events

A *wait event* causes a SQL statement to wait for a specific event to happen before it can continue running. Wait events are an important dimension, or category, for DB load because they indicate where work is impeded.

Every active session is either running on the CPU or waiting. For example, sessions consume CPU when they search memory for a buffer, perform a calculation, or run procedural code. When sessions aren't consuming CPU, they might be waiting for a memory buffer to become free, a data file to be read, or a log to be written to. The more time that a session waits for resources, the less time it runs on the CPU.

When you tune a database, you often try to find out the resources that sessions are waiting for. For example, two or three wait events might account for 90 percent of DB load. This measure means that, on average, active sessions are spending most of their time waiting for a small number of resources. If you can find out the cause of these waits, you can attempt a solution.

Consider the analogy of a warehouse worker. An order comes in for a book. The worker might be delayed in fulfilling the order. For example, a different worker might be currently restocking the shelves, a trolley...

---

### Table

<table>
<thead>
<tr>
<th>Elapsed time (sec)</th>
<th>Total execution time (sec)</th>
<th>AAE</th>
<th>Calculation</th>
</tr>
</thead>
<tbody>
<tr>
<td>60</td>
<td>120</td>
<td>2</td>
<td>120 execution seconds/60 elapsed seconds</td>
</tr>
<tr>
<td>120</td>
<td>120</td>
<td>1</td>
<td>120 execution seconds/120 elapsed seconds</td>
</tr>
<tr>
<td>180</td>
<td>380</td>
<td>2.11</td>
<td>380 execution seconds/180 elapsed seconds</td>
</tr>
<tr>
<td>240</td>
<td>380</td>
<td>1.58</td>
<td>380 execution seconds/240 elapsed seconds</td>
</tr>
<tr>
<td>300</td>
<td>600</td>
<td>2</td>
<td>600 execution seconds/300 elapsed seconds</td>
</tr>
</tbody>
</table>
might not be available. Or the system used to enter the order status might be slow. The longer the worker waits, the longer it takes to fulfill the order. Waiting is a natural part of the warehouse workflow, but if wait time becomes excessive, productivity decreases. In the same way, repeated or lengthy session waits can degrade database performance. For more information, see Tuning with wait events for Aurora PostgreSQL and Tuning with wait events for Aurora MySQL in the Amazon Aurora User Guide.

Wait events vary by DB engine:

- For a list of the common wait events for Aurora MySQL, see Aurora MySQL wait events (p. 1151). To learn how to tune using these wait events, see Tuning Aurora MySQL (p. 903).
- For information about all MySQL wait events, see Wait Event Summary Tables in the MySQL documentation.
- For a list of common wait events for Aurora PostgreSQL, see Amazon Aurora PostgreSQL wait events (p. 1762). To learn how to tune using these wait events, see Tuning with wait events for Aurora PostgreSQL (p. 1410).
- For information about all PostgreSQL wait events, see The Statistics Collector > Wait Event tables in the PostgreSQL documentation.

**Top SQL**

Where wait events show bottlenecks, top SQL shows which queries are contributing the most to DB load. For example, many queries might be currently running on the database, but a single query might consume 99 percent of the DB load. In this case, the high load might indicate a problem with the query.

By default, the Performance Insights console displays top SQL queries that are contributing to the database load. The console also shows relevant statistics for each statement. To diagnose performance problems for a specific statement, you can examine its execution plan.

**Maximum CPU**

In the dashboard, the Database load chart collects, aggregates, and displays session information. To see whether active sessions are exceeding the maximum CPU, look at their relationship to the Max vCPU line. The Max vCPU value is determined by the number of vCPU (virtual CPU) cores for your DB instance. For Aurora Serverless v2, Max vCPU represents the estimated number of vCPUs.

One process can run on a vCPU at a time. If the number of processes exceed the number of vCPUs, the processes start queuing. When the queuing increase, the performance is impacted. If the DB load is often above the Max vCPU line, and the primary wait state is CPU, the CPU is overloaded. In this case, you might want to throttle connections to the instance, tune any SQL queries with a high CPU load, or consider a larger instance class. High and consistent instances of any wait state indicate that there might be bottlenecks or resource contention issues to resolve. This can be true even if the DB load doesn't cross the Max vCPU line.

**Amazon Aurora DB engine, Region, and instance class support for Performance Insights**

The following table provides Amazon Aurora DB engines that support Performance Insights.

<table>
<thead>
<tr>
<th>Amazon Aurora DB engine</th>
<th>Supported engine versions and Regions</th>
<th>Instance class restrictions</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>
Pricing and data retention for Performance Insights

By default, Performance Insights offers a free tier that includes 7 days of performance data history and 1 million API requests per month. You can also purchase longer retention periods. For complete pricing information, see Performance Insights Pricing.

In the RDS console, you can choose any of the following retention periods for your Performance Insights data:

- Default (7 days)
- \( n \) months, where \( n \) is a number from 1–24

To learn how to set a retention period using the AWS CLI, see AWS CLI (p. 566).
Turning Performance Insights on and off

You can turn on Performance Insights for your DB cluster when you create it. If needed, you can turn it off later at the instance level for any instance in your DB cluster. Turning Performance Insights on and off doesn't cause downtime, a reboot, or a failover.

Note
Performance Schema is an optional performance tool used by Aurora MySQL. If you turn Performance Schema on or off, you need to reboot. If you turn Performance Insights on or off, however, you don't need to reboot. For more information, see Turning on the Performance Schema for Performance Insights on Aurora MySQL (p. 568).

If you use Performance Insights with Aurora global databases, turn on Performance Insights individually for the DB instances in each AWS Region. For details, see Monitoring an Amazon Aurora global database with Amazon RDS Performance Insights (p. 1870).

The Performance Insights agent consumes limited CPU and memory on the DB host. When the DB load is high, the agent limits the performance impact by collecting data less frequently.

Console

In the console, you can turn Performance Insights on or off when you create a DB cluster. You can modify a DB instance in the cluster to turn Performance Insights on or off for the instance.

Turning Performance Insights on or off when creating a DB cluster

When you create a new DB cluster, turn on Performance Insights by choosing Enable Performance Insights in the Performance Insights section. Or choose Disable Performance Insights. To create a DB cluster, follow the instructions for your DB engine in Creating an Amazon Aurora DB cluster (p. 179).

The following screenshot shows the Performance Insights section.

If you choose Enable Performance Insights, you have the following options:

- **Retention** – The amount of time to retain Performance Insights data. The retention setting in the free tier is Default (7 days). To retain your performance data for longer, specify 1–24 months. For more information about retention periods, see Pricing and data retention for Performance Insights (p. 564).
- **AWS KMS key** – Specify your AWS KMS key. Performance Insights encrypts all potentially sensitive data using your KMS key. Data is encrypted in flight and at rest. For more information, see Configuring an AWS KMS policy for Performance Insights (p. 573).

Turning Performance Insights on or off when modifying a DB instance in your DB cluster

In the console, you can modify a DB instance in your DB cluster to turn Performance Insights on or off. You can't turn Performance Insights on or off at the cluster level: you must do it for each instance in the cluster.
To turn Performance Insights on or off for a DB instance in your DB cluster using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Databases.
3. Choose a DB instance, and choose Modify.
4. In the Performance Insights section, choose either Enable Performance Insights or Disable Performance Insights.

   If you choose Enable Performance Insights, you have the following options:
   - **Retention** – The amount of time to retain Performance Insights data. The retention setting in the free tier is Default (7 days). To retain your performance data for longer, specify 1–24 months. For more information about retention periods, see Pricing and data retention for Performance Insights (p. 564).
   - **AWS KMS key** – Specify your KMS key. Performance Insights encrypts all potentially sensitive data using your KMS key. Data is encrypted in flight and at rest. For more information, see Encrypting Amazon Aurora resources (p. 2381).

5. Choose Continue.
6. For Scheduling of Modifications, choose Apply immediately. If you choose Apply during the next scheduled maintenance window, your instance ignores this setting and turns on Performance Insights immediately.
7. Choose Modify instance.

AWS CLI

You can also specify these values using the following AWS CLI commands:

- create-db-instance-read-replica
- modify-db-instance
- restore-db-instance-from-s3

The following procedure describes how to turn Performance Insights on or off for an existing DB instance in your DB cluster using the AWS CLI.

To turn Performance Insights on or off for a DB instance in your DB cluster using the AWS CLI

- Call the modify-db-instance AWS CLI command and supply the following values:
  - --db-instance-identifier – The name of the DB instance in your DB cluster.
  - --enable-performance-insights to turn on or --no-enable-performance-insights to turn off

The following example turns on Performance Insights for sample-db-instance.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier sample-db-instance \
```
Turning Performance Insights on and off

--enable-performance-insights

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier sample-db-instance ^
  --enable-performance-insights
```

When you turn on Performance Insights in the CLI, you can optionally specify the number of days to retain Performance Insights data with the `--performance-insights-retention-period` option. You can specify 7, month * 31 (where month is a number from 1–23), or 731. For example, if you want to retain your performance data for 3 months, specify 93, which is 3 * 31. The default is 7 days. For more information about retention periods, see Pricing and data retention for Performance Insights (p. 564).

The following example turns on Performance Insights for `sample-db-instance` and specifies that Performance Insights data is retained for 93 days (3 months).

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \  
  --db-instance-identifier sample-db-instance \  
  --enable-performance-insights \  
  --performance-insights-retention-period 93
```

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier sample-db-instance ^
  --enable-performance-insights ^
  --performance-insights-retention-period 93
```

If you specify a retention period such as 94 days, which isn't a valid value, RDS issues an error.

```
An error occurred (InvalidParameterValue) when calling the CreateDBInstance operation: Invalid Performance Insights retention period. Valid values are: [7, 31, 62, 93, 124, 155, 186, 217, 248, 279, 310, 341, 372, 403, 434, 465, 496, 527, 558, 589, 620, 651, 682, 713, 731]
```

RDS API

When you create a new DB instance in your DB cluster using the CreateDBInstance operation Amazon RDS API operation, turn on Performance Insights by setting EnablePerformanceInsights to True. To turn off Performance Insights, set EnablePerformanceInsights to False.

You can also specify the EnablePerformanceInsights value using the following API operations:

- ModifyDBInstance
- CreateDBInstanceReadReplica
- RestoreDBInstanceFromS3

When you turn on Performance Insights, you can optionally specify the amount of time, in days, to retain Performance Insights data with the PerformanceInsightsRetentionPeriod parameter. You can specify 7, month * 31 (where month is a number from 1–23), or 731. For example, if you want to retain your performance data for 3 months, specify 93, which is 3 * 31. The default is 7 days. For more information about retention periods, see Pricing and data retention for Performance Insights (p. 564).
Turning on the Performance Schema for Performance Insights on Aurora MySQL

The Performance Schema is an optional feature for monitoring Aurora MySQL runtime performance at a low level of detail. The Performance Schema is designed to have minimal impact on database performance. Performance Insights is a separate feature that you can use with or without the Performance Schema.

Topics
- Overview of the Performance Schema (p. 568)
- Performance Insights and the Performance Schema (p. 568)
- Automatic management of the Performance Schema by Performance Insights (p. 569)
- Effect of a reboot on the Performance Schema (p. 570)
- Determining whether Performance Insights is managing the Performance Schema (p. 570)
- Configuring the Performance Schema for automatic management (p. 570)

Overview of the Performance Schema

The Performance Schema monitors events in Aurora MySQL databases. An event is a database server action that consumes time and has been instrumented so that timing information can be collected. Examples of events include the following:

- Function calls
- Waits for the operating system
- Stages of SQL execution
- Groups of SQL statements

The PERFORMANCE_SCHEMA storage engine is a mechanism for implementing the Performance Schema feature. This engine collects event data using instrumentation in the database source code. The engine stores events in memory-only tables in the performance_schema database. You can query performance_schema just as you can query any other tables. For more information, see MySQL Performance Schema in the MySQL Reference Manual.

Performance Insights and the Performance Schema

Performance Insights and the Performance Schema are separate features, but they are connected. The behavior of Performance Insights for Aurora MySQL depends on whether the Performance Schema is turned on, and if so, whether Performance Insights manages the Performance Schema automatically. The following table describes the behavior.

<table>
<thead>
<tr>
<th>Performance Schema turned on</th>
<th>Performance Insights management mode</th>
<th>Performance Insights behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yes</td>
<td>Automatic</td>
<td>• Collects detailed, low-level monitoring information&lt;br&gt;• Collects active session metrics every second&lt;br&gt;• Displays DB load categorized by detailed wait events, which you can use to identify bottlenecks</td>
</tr>
<tr>
<td>Yes</td>
<td>Manual</td>
<td>• Collects wait events and per-SQL metrics</td>
</tr>
</tbody>
</table>
Turning on the Performance Schema for Aurora MySQL

### Performance Schema turned on

<table>
<thead>
<tr>
<th>Performance Schema turned on</th>
<th>Performance Insights management mode</th>
<th>Performance Insights behavior</th>
</tr>
</thead>
</table>
| No                           | N/A                                  | - Collects active session metrics every five seconds instead of every second  
|                              |                                      | - Reports user states such as inserting and sending, which don't help you identify bottlenecks |

### Automatic management of the Performance Schema by Performance Insights

When you create an Aurora MySQL DB instance with Performance Insights turned on, the Performance Schema is also turned on. In this case, Performance Insights automatically manages your Performance Schema parameters. This is the recommended configuration.

**Note**

Automatic management of the Performance Schema isn't supported for the t4g.medium instance class.

For Performance Insights to manage the Performance Schema automatically, the `performance_schema` must be set to 0. By default, the value of `Source` is `system`.

You can also manage the Performance Schema manually. If you choose this option, set the parameters according to the values in the following table.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Parameter value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>performance_schema</code></td>
<td>1 (<em>Source</em> column has the value <code>system</code>)</td>
</tr>
<tr>
<td><code>performance-schema-consumer-events-waits-current</code></td>
<td>ON</td>
</tr>
<tr>
<td><code>performance-schema-instrument</code></td>
<td><code>wait/%=ON</code></td>
</tr>
<tr>
<td><code>performance_schema_consumer_global_instrumentation</code></td>
<td></td>
</tr>
<tr>
<td><code>performance_schema_consumer_thread_instrumentation</code></td>
<td></td>
</tr>
</tbody>
</table>

If you change the `performance_schema` parameter value manually, and then later want to change to automatic management, see [Configuring the Performance Schema for automatic management](#).

**Important**

When Performance Insights turns on the Performance Schema, it doesn't change the parameter group values. However, the values are changed on the DB instances that are running. The only way to see the changed values is to run the `SHOW GLOBAL VARIABLES` command.
Effect of a reboot on the Performance Schema

Performance Insights and the Performance Schema differ in their requirements for DB instance reboots:

Performance Schema

To turn this feature on or off, you must reboot the DB instance.

Performance Insights

To turn this feature on or off, you don't need to reboot the DB instance.

If the Performance Schema isn't currently turned on, and you turn on Performance Insights without rebooting the DB instance, the Performance Schema won't be turned on.

Determining whether Performance Insights is managing the Performance Schema

To find out whether Performance Insights is currently managing the Performance Schema for major engine versions 5.6, 5.7, and 8.0, review the following table.

<table>
<thead>
<tr>
<th>Setting of performance_schema parameter</th>
<th>Setting of the Source column</th>
<th>Performance Insights is managing the Performance Schema?</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>system</td>
<td>Yes</td>
</tr>
<tr>
<td>0 or 1</td>
<td>user</td>
<td>No</td>
</tr>
</tbody>
</table>

To determine whether Performance Insights is managing the Performance Schema automatically

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Parameter groups.
3. Select the name of the parameter group for your DB instance.
4. Enter performance_schema in the search bar.
5. Check whether Source is the system default and Values is 0. If so, Performance Insights is managing the Performance Schema automatically. If not, Performance Insights isn't managing the Performance Schema automatically.

Configuring the Performance Schema for automatic management

Assume that Performance Insights is turned on for your DB instance but isn't currently managing the Performance Schema. If you want to allow Performance Insights to manage the Performance Schema automatically, complete the following steps.
To configure the Performance Schema for automatic management

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Parameter groups.
3. Select the name of the parameter group for your DB instance.
4. Enter performance_schema in the search bar.
5. Select the performance_schema parameter.
6. Choose Edit parameters.
7. Select the performance_schema parameter.
8. In Values, choose 0.
9. Choose Reset and then Reset parameters.
10. Reboot the DB instance.

Important
Whenever you turn the Performance Schema on or off, make sure to reboot the DB instance.

For more information about modifying instance parameters, see Modifying parameters in a DB parameter group (p. 229). For more information about the dashboard, see Analyzing metrics with the Performance Insights dashboard (p. 576). For more information about the MySQL performance schema, see MySQL 8.0 Reference Manual.

Configuring access policies for Performance Insights

To access Performance Insights, a principal must have the appropriate permissions from AWS Identity and Access Management (IAM). You can grant access in the following ways:

- Attach the AmazonRDSPerformanceInsightsReadOnly managed policy to a permission set or role to access all read-only operations of the Performance Insights API.
- Attach the AmazonRDSPerformanceInsightsFullAccess managed policy to a permission set or role to access all operations of the Performance Insights API.
- Create a custom IAM policy and attach it to a permission set or role.

If you specified a customer managed key when you turned on Performance Insights, make sure that users in your account have the kms:Decrypt and kms:GenerateDataKey permissions on the KMS key.

Attaching the AmazonRDSPerformanceInsightsReadOnly policy to an IAM principal

AmazonRDSPerformanceInsightsReadOnly is an AWS-managed policy that grants access to all read-only operations of the Amazon RDS Performance Insights API.

If you attach AmazonRDSPerformanceInsightsReadOnly to a permission set or role, the recipient can use Performance Insights with other console features.

For more information, see AWS managed policy: AmazonRDSPerformanceInsightsReadOnly (p. 2424).
Attaching the AmazonRDSPerformanceInsightsFullAccess policy to an IAM principal

AmazonRDSPerformanceInsightsFullAccess is an AWS-managed policy that grants access to all operations of the Amazon RDS Performance Insights API.

If you attach AmazonRDSPerformanceInsightsFullAccess to a permission set or role, the recipient can use Performance Insights with other console features.

For more information, see AWS managed policy: AmazonRDSPerformanceInsightsFullAccess (p. 2424).

Creating a custom IAM policy for Performance Insights

For users who don't have the AmazonRDSPerformanceInsightsReadOnly or AmazonRDSPerformanceInsightsFullAccess policy, you can grant access to Performance Insights by creating or modifying a user-managed IAM policy. When you attach the policy to an IAM permission set or role, the recipient can use Performance Insights.

To create a custom policy

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Policies.
3. Choose Create policy.
4. On the Create Policy page, choose the JSON tab.
5. Copy and paste the text provided in the JSON policy document section in the AWS Managed Policy Reference Guide for AmazonRDSPerformanceInsightsReadOnly or AmazonRDSPerformanceInsightsFullAccess policy.
7. Provide a name for the policy and optionally a description, and then choose Create policy.

You can now attach the policy to a permission set or role. The following procedure assumes that you already have a user available for this purpose.

To attach the policy to a user

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Users.
3. Choose an existing user from the list.
   Important
   To use Performance Insights, make sure that you have access to Amazon RDS in addition to the custom policy. For example, the AmazonRDSPerformanceInsightsReadOnly predefined policy provides read-only access to Amazon RDS. For more information, see Managing access using policies (p. 2403).
4. On the Summary page, choose Add permissions.
5. Choose Attach existing policies directly. For Search, type the first few characters of your policy name, as shown following.
6. Choose your policy, and then choose **Next: Review**.

7. Choose **Add permissions**.

### Configuring an AWS KMS policy for Performance Insights

Performance Insights uses an AWS KMS key to encrypt sensitive data. When you enable Performance Insights through the API or the console, you can do either of the following:

- Choose the default AWS managed key.

  Amazon RDS uses the AWS managed key for your new DB instance. Amazon RDS creates an AWS managed key for your AWS account. Your AWS account has a different AWS managed key for Amazon RDS for each AWS Region.

- Choose a customer managed key.

  If you specify a customer managed key, users in your account that call the Performance Insights API need the `kms:Decrypt` and `kms:GenerateDataKey` permissions on the KMS key. You can configure these permissions through IAM policies. However, we recommend that you manage these permissions through your KMS key policy. For more information, see [Using key policies in AWS KMS](#).

### Example

The following example shows how to add statements to your KMS key policy. These statements allow access to Performance Insights. Depending on how you use the KMS key, you might want to change some restrictions. Before adding statements to your policy, remove all comments.

```json
{
  "Version": "2012-10-17",
  "Id": "your-policy",
  "Statement": [
    //This represents a statement that currently exists in your policy.
    
    //Starting here, add new statement to your policy for Performance Insights.
    //We recommend that you add one new statement for every RDS instance
    {
      "Sid": "Allow viewing RDS Performance Insights",
      "Effect": "Allow",
```
"Principal": {  
  "AWS": [
    //One or more principals allowed to access Performance Insights
    "arn:aws:iam::444455556666:role/Role1"
  ],
  "Action": [
    "kms:Decrypt",
    "kms:GenerateDataKey"
  ],
  "Resource": "*",
  "Condition": {
    "StringEquals": {
      //Restrict access to only RDS APIs (including Performance Insights).
      //Replace region with your AWS Region.
      //For example, specify us-west-2.
      "kms:ViaService": "rds.region.amazonaws.com"
    },
    "ForAnyValue:StringEquals": {
      //Restrict access to only data encrypted by Performance Insights.
      "kms:EncryptionContext:aws:pi:service": "rds",
      "kms:EncryptionContext:service": "pi",
      //Restrict access to a specific RDS instance.
      //The value is a DbiResourceId.
      "kms:EncryptionContext:aws:rds:db-id": "db-AAAAABBBBBCCCCDDDDDEEEE"
    }
  }
}

How Performance Insights uses AWS KMS customer managed key

Performance Insights uses customer managed keys to encrypt sensitive data. When you turn on Performance Insights, you can provide an AWS KMS key through the API. Performance Insights creates KMS permissions on this key. It uses the key and performs the necessary operations to process sensitive data. Sensitive data includes fields such as user, database, application, and SQL query text. Performance Insights ensures that the data remains encrypted both at rest and in-flight.

How Performance Insights IAM works with AWS KMS

IAM gives permissions to specific APIs. Performance Insights has the following public APIs, which you can restrict using IAM policies:

- DescribeDimensionKeys
- GetDimensionKeyDetails
- GetResourceMetadata
- GetResourceMetrics
- ListAvailableResourceDimensions
- ListAvailableResourceMetrics

You can use the following API requests to get sensitive data.

- DescribeDimensionKeys
- GetDimensionKeyDetails
- GetResourceMetrics

When you use the API to get sensitive data, Performance Insights leverages the caller's credentials. This check ensures that access to sensitive data is limited to those with access to the KMS key.
When calling these APIs, you need permissions to call the API through the IAM policy and permissions to invoke the kms:decrypt action through the AWS KMS key policy.

The GetResourceMetrics API can return both sensitive and non-sensitive data. The request parameters determine whether the response should include sensitive data. The API returns sensitive data when the request includes a sensitive dimension in either the filter or group-by parameters.

For more information about the dimensions that you can use with the GetResourceMetrics API, see DimensionGroup.

Example Examples

The following example requests the sensitive data for the db.user group:

```json
POST / HTTP/1.1
Host: <Hostname>
Accept-Encoding: identity
X-Amz-Target: PerformanceInsightsv20180227.GetResourceMetrics
Content-Type: application/x-amz-json-1.1
User-Agent: <UserAgentString>
X-Amz-Date: <Date>
Authorization: AWS4-HMAC-SHA256 Credential=<Credential>, SignedHeaders=<Headers>, Signature=<Signature>
Content-Length: <PayloadSizeBytes>
{
    "ServiceType": "RDS",
    "Identifier": "db-ABC1DEFGHIJKLMNOPQRSTUVWXYZ",
    "MetricQueries": [
        {
            "Metric": "db.load.avg",
            "GroupBy": {
                "Group": "db.user",
                "Limit": 2
            }
        }
    ],
    "StartTime": 1693872000,
    "EndTime": 1694044800,
    "PeriodInSeconds": 86400
}
```

Example

The following example requests the non-sensitive data for the db.load.avg metric:

```json
POST / HTTP/1.1
Host: <Hostname>
Accept-Encoding: identity
X-Amz-Target: PerformanceInsightsv20180227.GetResourceMetrics
Content-Type: application/x-amz-json-1.1
User-Agent: <UserAgentString>
X-Amz-Date: <Date>
Authorization: AWS4-HMAC-SHA256 Credential=<Credential>, SignedHeaders=<Headers>, Signature=<Signature>
Content-Length: <PayloadSizeBytes>
{
    "ServiceType": "RDS",
    "Identifier": "db-ABC1DEFGHIJKLMNOPQRSTUVWXYZ",
    "MetricQueries": [
        {
            "Metric": "db.load.avg",
            "GroupBy": {
                "Group": "db.load.avg",
                "Limit": 2
            }
        }
    ],
    "StartTime": 1693872000,
    "EndTime": 1694044800,
    "PeriodInSeconds": 86400
}
```
Analyzing metrics with the Performance Insights dashboard

The Performance Insights dashboard contains database performance information to help you analyze and troubleshoot performance issues. On the main dashboard page, you can view information about the database load. You can “slice” DB load by dimensions such as wait events or SQL.

Performance Insights dashboard
- Overview of the Performance Insights dashboard (p. 576)
- Accessing the Performance Insights dashboard (p. 582)
- Analyzing DB load by wait events (p. 585)
- Analyzing database performance for a period of time (p. 586)
- Analyzing queries in the Performance Insights dashboard (p. 592)

Overview of the Performance Insights dashboard

The dashboard is the easiest way to interact with Performance Insights. The following example shows the dashboard for a MySQL DB instance.
Topics

- Time range filter (p. 577)
- Counter metrics chart (p. 577)
- Database load chart (p. 578)
- Top dimensions table (p. 581)

Time range filter

By default, the Performance Insights dashboard shows DB load for the last hour. You can adjust this range to be as short as 5 minutes or as long as 2 years. You can also select a custom relative range.

You can select an absolute range with a beginning and ending date and time. The following example shows the time range beginning at midnight on 4/11/22 and ending at 11:59 PM on 4/14/22.

Counter metrics chart

With counter metrics, you can customize the Performance Insights dashboard to include up to 10 additional graphs. These graphs show a selection of dozens of operating system and database performance metrics. You can correlate this information with DB load to help identify and analyze performance problems.

The Counter metrics chart displays data for performance counters. The default metrics depend on the DB engine:

- Aurora MySQL– db.SQL.Innodb_rows_read.avg
- Aurora PostgreSQL – db.Transactions.xact_commit.avg

To change the performance counters, choose Manage Metrics. You can select multiple OS metrics or Database metrics, as shown in the following screenshot. To see details for any metric, hover over the metric name.
For descriptions of the counter metrics that you can add for each DB engine, see Performance Insights counter metrics (p. 658).

Database load chart

The Database load chart shows how the database activity compares to DB instance capacity as represented by the Max vCPU line. By default, the stacked line chart represents DB load as average active sessions per unit of time. The DB load is sliced (grouped) by wait states.
DB load sliced by dimensions

You can choose to display load as active sessions grouped by any supported dimensions. The following table shows which dimensions are supported for the different engines.

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Aurora PostgreSQL</th>
<th>Aurora MySQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>SQL</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>User</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Waits</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Application</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Database</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Session type</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

The following image shows the dimensions for a PostgreSQL DB instance.
Analyzing metrics with the Performance Insights dashboard

To see details about a DB load item within a dimension, hover over the item name. The following image shows details for a SQL statement.

To see details for any item for the selected time period in the legend, hover over that item.
Top dimensions table

The Top dimensions table slices DB load by different dimensions. A dimension is a category or "slice by" for different characteristics of DB load. If the dimension is SQL, Top SQL shows the SQL statements that contribute the most to DB load.

<table>
<thead>
<tr>
<th>Tab</th>
<th>Description</th>
<th>Supported engines</th>
</tr>
</thead>
<tbody>
<tr>
<td>Top SQL</td>
<td>The SQL statements that are currently running</td>
<td>All</td>
</tr>
<tr>
<td>Top waits</td>
<td>The event for which the database backend is waiting</td>
<td>All</td>
</tr>
</tbody>
</table>
Analyzing metrics with the Performance Insights dashboard

<table>
<thead>
<tr>
<th>Tab</th>
<th>Description</th>
<th>Supported engines</th>
</tr>
</thead>
<tbody>
<tr>
<td>Top hosts</td>
<td>The host name of the connected client</td>
<td>All</td>
</tr>
<tr>
<td>Top users</td>
<td>The user logged in to the database</td>
<td>All</td>
</tr>
<tr>
<td>The name of the database to which the client is connected</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Top applications</td>
<td>The name of the application that is connected to the database</td>
<td>Aurora PostgreSQL only</td>
</tr>
<tr>
<td>Top session types</td>
<td>The type of the current session</td>
<td>Aurora PostgreSQL only</td>
</tr>
</tbody>
</table>

To learn how to analyze queries by using the Top SQL tab, see Overview of the Top SQL tab (p. 592).

Accessing the Performance Insights dashboard

Amazon RDS provides a consolidated view of Performance Insights and CloudWatch metrics in the Performance Insights dashboard.

To access the Performance Insights dashboard, use the following procedure.

To view the Performance Insights dashboard in the AWS Management Console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose Performance Insights.
3. Choose a DB instance.
4. Choose the default monitoring view in the displayed window.
   - Select the Performance Insights and CloudWatch metrics view (New) option and choose Continue to view Performance Insights and CloudWatch metrics.
   - Select the Performance Insights view option and choose Continue for the legacy monitoring view. Then, continue with this procedure.

   **Note**
   This view will be discontinued on December 15, 2023.

The Performance Insights dashboard appears for the DB instance.

For DB instances with Performance Insights turned on, you can also access the dashboard by choosing the Sessions item in the list of DB instances. Under Current activity, the Sessions item shows the database load in average active sessions over the last five minutes. The bar graphically shows the load. When the bar is empty, the DB instance is idle. As the load increases, the bar fills with blue. When the load passes the number of virtual CPUs (vCPUs) on the DB instance class, the bar turns red, indicating a potential bottleneck.
5. (Optional) Choose the date or time range in the upper right and specify a different relative or absolute time interval. You can now specify a time period, and generate a database performance analysis report. The report provides the identified insights and recommendations. For more information, see Creating a performance analysis report (p. 586).

In the following screenshot, the DB load interval is 5 hours.
6. (Optional) To zoom in on a portion of the DB load chart, choose the start time and drag to the end of the time period you want.

The selected area is highlighted in the DB load chart.

When you release the mouse, the DB load chart zooms in on the selected AWS Region, and the Top dimensions table is recalculated.
7. (Optional) To refresh your data automatically, select Auto refresh.

The Performance Insights dashboard automatically refreshes with new data. The refresh rate depends on the amount of data displayed:

- 5 minutes refreshes every 10 seconds.
- 1 hour refreshes every 5 minutes.
- 5 hours refreshes every 5 minutes.
- 24 hours refreshes every 30 minutes.
- 1 week refreshes every day.
- 1 month refreshes every day.

**Analyzing DB load by wait events**

If the Database load chart shows a bottleneck, you can find out where the load is coming from. To do so, look at the top load items table below the Database load chart. Choose a particular item, like a SQL query or a user, to drill down into that item and see details about it.

DB load grouped by waits and top SQL queries is the default Performance Insights dashboard view. This combination typically provides the most insight into performance issues.
shows if there are any resource or concurrency bottlenecks in the database. In this case, the SQL tab of the top load items table shows which queries are driving that load.

Your typical workflow for diagnosing performance issues is as follows:

1. Review the Database load chart and see if there are any incidents of database load exceeding the Max CPU line.
2. If there is, look at the Database load chart and identify which wait state or states are primarily responsible.
3. Identify the digest queries causing the load by seeing which of the queries the SQL tab on the top load items table are contributing most to those wait states. You can identify these by the **DB Load by Wait** column.
4. Choose one of these digest queries in the SQL tab to expand it and see the child queries that it is composed of.

For example, in the dashboard following, log file sync waits account for most of the DB load. The **LGWR all worker groups** wait is also high. The Top SQL chart shows what is causing the log file sync waits: frequent COMMIT statements. In this case, committing less frequently will reduce DB load.

**Analyzing database performance for a period of time**

You can create a performance analysis report for a period of time and find out any performance issues such as resource bottlenecks or changes in a query in your DB instance. The Performance Insights dashboard allows you to select a time period and create a performance analysis report. You can also add one or more tags to the report.

To use this feature, you must be using the paid tier retention period. For more information, see [Pricing and data retention for Performance Insights](p. 564)
Analyzing metrics with the Performance Insights dashboard

The report is available in the **Performance analysis reports - new** tab to select and view. The report contains the insights, related metrics, and recommendations to resolve the performance issue. The report is available to view for the duration of Performance Insights retention period.

The report is deleted if the start time of the report analysis period is outside of the retention period. You can also delete the report before the retention period ends.

To detect the performance issues and generate the analysis report for your DB instance, you must turn on Performance Insights. For more information about turning on Performance Insights, see [Turning Performance Insights on and off](p. 565).

For the region, DB engine, and instance class support information for this feature, see [Amazon Aurora DB engine, Region, and instance class support for Performance Insights features](p. 563).

### Creating a performance analysis report

You can create a performance analysis report for a specific period in the Performance Insights dashboard. You can select a time period and add one or more tags to the analysis report.

The analysis period can range from 5 minutes to 6 days. There must be at least 24 hours of performance data before the analysis start time.

**To create a performance analysis report for a time period**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the left navigation pane, choose **Performance Insights**.
3. Choose a DB instance.
   
   The Performance Insights dashboard appears for the DB instance.
4. Choose **Analyze performance** in **Database load** section on the dashboard.
   
   The fields to set the time period and add one or more tags to the performance analysis report are displayed.

5. Choose the time period. If you set a time period in the **Relative range** or **Absolute range** in the upper right, you can only enter or select the analysis report date and time within this time period. If you select the analysis period outside of this time period, an error message displays.

   To set the time period, you can do any of the following:

   - Press and drag any of the sliders on the DB load chart.
     
     The **Performance analysis period** box displays the selected time period and DB load chart highlights the selected time period.
   - Choose the **Start date**, **Start time**, **End date**, and **End time** in the **Performance analysis period** box.
6. (Optional) Enter **Key** and **Value-optional** to add a tag for the report.

7. Choose **Analyze performance**.

A banner displays a message whether the report generation is successful or failed. The message also provides the link to view the report.

The following example shows the banner with the report creation successful message.
Analyzing metrics with the Performance Insights dashboard

The report is available to view in **Performance analysis reports - new** tab.

You can create a performance analysis report using the AWS CLI. For an example on how to create a report using AWS CLI, see [Creating a performance analysis report for a time period](p. 616).

**Viewing a performance analysis report**

The **Performance analysis reports - new** tab lists all the reports that are created for the DB instance. The following are displayed for each report:

- **ID**: Unique identifier of the report.
- **Name**: Tag key added to the report.
- **Report creation time**: Time you created the report.
- **Analysis start time**: Start time of the analysis in the report.
- **Analysis end time**: End time of the analysis in the report.

To view a performance analysis report

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the left navigation pane, choose **Performance Insights**.
3. Choose a DB instance for which you want to view the analysis report.

   The Performance Insights dashboard appears for the DB instance.

4. Scroll down and choose **Performance analysis reports - new** tab.

   All the analysis reports for the different time periods are displayed.

5. Choose **ID** of the report you want to view.

   The DB load chart displays the entire analysis period by default if more than one insight is identified. If the report has identified one insight then the DB load chart displays the insight by default.

   The dashboard also lists the tags for the report in the **Tags** section.

   The following example shows the entire analysis period for the report.

6. Choose the insight in the **Database load insights** list you want to view if more than one insight is identified in the report.
The dashboard displays the insight message, DB load chart highlighting the time period of the insight, analysis and recommendations, and the list of report tags.

The following example shows the DB load insight in the report.

Adding tags to a performance analysis report

You can add a tag when you create or view a report. You can add up to 50 tags for a report.

You need permissions to add the tags. For more information about the access policies for Performance Insights, see Configuring access policies for Performance Insights (p. 571)

To add one or more tags while creating a report, see step 6 in the procedure Creating a performance analysis report (p. 587).

To add one or more tags when viewing a report

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose Performance Insights.
3. Choose a DB instance.
   
   The Performance Insights dashboard appears for the DB instance.
4. Scroll down and choose Performance analysis reports - new tab.
5. Choose the report for which you want to add the tags.
6. The dashboard displays the report.
7. Scroll down to Tags and choose Manage tags.
8. Enter the Key and Value - optional, and choose Add new tag.
   
   The following example provides the option to add a new tag for the selected report.
A new tag is created for the report.

The list of tags for the report is displayed in the Tags section on the dashboard. If you want to remove a tag from the report, choose Remove next to the tag.

**Deleting a performance analysis report**

You can delete a report from the list of reports displayed in the Performance analysis reports tab or while viewing a report.

**To delete a report**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the left navigation pane, choose Performance Insights.
3. Choose a DB instance.

   The Performance Insights dashboard appears for the DB instance.
4. Scroll down and choose Performance analysis reports - new tab.
5. Select the report you want to delete and choose Delete in the upper right.

   A confirmation window is displayed. The report is deleted after you choose confirm.
6. (Optional) Choose ID of the report you want to delete.

   In the report page, choose Delete in the upper right.
A confirmation window is displayed. The report is deleted after you choose confirm.

Analyzing queries in the Performance Insights dashboard

In the Amazon RDS Performance Insights dashboard, you can find information about running and recent queries in the Top SQL tab in the Top dimensions table. You can use this information to tune your queries.

Topics
- Overview of the Top SQL tab (p. 592)
- Accessing more SQL text in the Performance Insights dashboard (p. 597)
- Viewing SQL statistics in the Performance Insights dashboard (p. 599)

Overview of the Top SQL tab

By default, the Top SQL tab shows the 25 queries that are contributing the most to DB load. To help tune your queries, you can analyze information such as the query text and SQL statistics. You can also choose the statistics that you want to appear in the Top SQL tab.

Topics
- SQL text (p. 592)
- SQL statistics (p. 593)
- Load by waits (AAS) (p. 594)
- SQL information (p. 594)
- Preferences (p. 595)

SQL text

By default, each row in the Top SQL table shows 500 bytes of text for each statement.

A SQL digest is a composite of multiple actual queries that are structurally similar but might have different literal values. The digest replaces hardcoded values with a question mark. For example, a digest might be SELECT * FROM emp WHERE lname= ?. This digest might include the following child queries:

```
SELECT * FROM emp WHERE lname = 'Sanchez'
```
To see the literal SQL statements in a digest, select the query, and then choose the plus symbol (+). In the following example, the selected query is a digest.

```
SELECT * FROM emp WHERE lname = 'Olagappan'
SELECT * FROM emp WHERE lname = 'Wu'
```

**Note**

A SQL digest groups similar SQL statements, but doesn't redact sensitive information.

**SQL statistics**

SQL statistics are performance-related metrics about SQL queries. For example, Performance Insights might show executions per second or rows processed per second. Performance Insights collects statistics for only the most common queries. Typically, these match the top queries by load shown in the Performance Insights dashboard.

Every line in the **Top SQL** table shows relevant statistics for the SQL statement or digest, as shown in the following example.

Performance Insights can report 0.00 and - (unknown) for SQL statistics. This situation occurs under the following conditions:

- Only one sample exists. For example, Performance Insights calculates rates of change for Aurora PostgreSQL queries based on multiple samples from the `pg_stats_statements` view. When a workload runs for a short time, Performance Insights might collect only one sample, which means that it can't calculate a rate of change. The unknown value is represented with a dash (-).
- Two samples have the same values. Performance Insights can't calculate a rate of change because no change has occurred, so it reports the rate as 0.00.
- An Aurora PostgreSQL statement lacks a valid identifier. PostgreSQL creates a identifier for a statement only after parsing and analysis. Thus, a statement can exist in the PostgreSQL internal in-memory structures with no identifier. Because Performance Insights samples internal in-memory structures once per second, low-latency queries might appear for only a single sample. If the query identifier isn't available for this sample, Performance Insights can't associate this statement with its statistics. The unknown value is represented with a dash (-).
For a description of the SQL statistics for the Aurora engines, see SQL statistics for Performance Insights (p. 671).

**Load by waits (AAS)**

In **Top SQL**, the **Load by waits (AAS)** column illustrates the percentage of the database load associated with each top load item. This column reflects the load for that item by whatever grouping is currently selected in the **DB Load Chart**. For more information about Average active sessions (AAS), see Average active sessions (p. 560).

For example, you might group the **DB load** chart by wait states. You examine SQL queries in the top load items table. In this case, the **DB Load by Waits** bar is sized, segmented, and color-coded to show how much of a given wait state that query is contributing to. It also shows which wait states are affecting the selected query.

**SQL information**

In the **Top SQL** table, you can open a statement to view its information. The information appears in the bottom pane.
The following types of identifiers (IDs) that are associated with SQL statements:

- **Support SQL ID** – A hash value of the SQL ID. This value is only for referencing a SQL ID when you are working with AWS Support. AWS Support doesn't have access to your actual SQL IDs and SQL text.

- **Support Digest ID** – A hash value of the digest ID. This value is only for referencing a digest ID when you are working with AWS Support. AWS Support doesn't have access to your actual digest IDs and SQL text.

**Preferences**

You can control the statistics displayed in the Top SQL tab by choosing the Preferences icon.
When you choose the **Preferences** icon, the **Preferences** window opens. The following screenshot is an example of the **Preferences** window.

To enable the statistics that you want to appear in the **Top SQL** tab, use your mouse to scroll to the bottom of the window, and then choose **Continue**.
For more information about per-second or per-call statistics for the Aurora engines, see the engine specific SQL statistics section in SQL statistics for Performance Insights (p. 671)

**Accessing more SQL text in the Performance Insights dashboard**

By default, each row in the **Top SQL** table shows 500 bytes of SQL text for each SQL statement.

When a SQL statement exceeds 500 bytes, you can view more text in the **SQL text** section below the **Top SQL** table. In this case, the maximum length for the text displayed in **SQL text** is 4 KB. This limit is introduced by the console and is subject to the limits set by the database engine. To save the text shown in **SQL text**, choose **Download**.

**Topics**

- [Text size limits for Aurora MySQL](#)
- [Setting the SQL text limit for Aurora PostgreSQL DB instances](#)
- [Viewing and downloading SQL text in the Performance Insights dashboard](#)

**Text size limits for Aurora MySQL**

When you download SQL text, the database engine determines its maximum length. You can download SQL text up to the following per-engine limits.

<table>
<thead>
<tr>
<th>DB engine</th>
<th>Maximum length of downloaded text</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL</td>
<td>4,096 bytes</td>
</tr>
</tbody>
</table>

The **SQL text** section of the Performance Insights console displays up to the maximum that the engine returns. For example, if Aurora MySQL returns at most 1 KB to Performance Insights, it can only collect and show 1 KB, even if the original query is larger. Thus, when you view the query in **SQL text** or download it, Performance Insights returns the same number of bytes.

If you use the AWS CLI or API, Performance Insights doesn't have the 4 KB limit enforced by the console. DescribeDimensionKeys and GetResourceMetrics return at most 500 bytes. GetDimensionKeyDetails returns the full query, but the size is subject to the engine limit.

**Setting the SQL text limit for Aurora PostgreSQL DB instances**

Aurora PostgreSQL handles text differently. You can set the text size limit with the DB instance parameter `track_activity_query_size`. This parameter has the following characteristics:

**Default text size**

On Aurora PostgreSQL version 9.6, the default setting for the `track_activity_query_size` parameter is 1,024 bytes. On Aurora PostgreSQL version 10 or higher, the default is 4,096 bytes.

**Maximum text size**

The limit for `track_activity_query_size` is 102,400 bytes for Aurora PostgreSQL version 12 and lower. The maximum is 1 MB for version 13 and higher.

If the engine returns 1 MB to Performance Insights, the console displays only the first 4 KB. If you download the query, you get the full 1 MB. In this case, viewing and downloading return different numbers of bytes. For more information about the `track_activity_query_size` DB instance parameter, see [Run-time Statistics](#) in the PostgreSQL documentation.
To increase the SQL text size, increase the `track_activity_query_size` limit. To modify the parameter, change the parameter setting in the parameter group that is associated with the Aurora PostgreSQL DB instance.

**To change the setting when the instance uses the default parameter group**

1. Create a new DB instance parameter group for the appropriate DB engine and DB engine version.
2. Set the parameter in the new parameter group.
3. Associate the new parameter group with the DB instance.

For information about setting a DB instance parameter, see Modifying parameters in a DB parameter group (p. 229).

**Viewing and downloading SQL text in the Performance Insights dashboard**

In the Performance Insights dashboard, you can view or download SQL text.

**To view more SQL text in the Performance Insights dashboard**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Performance Insights.
3. Choose a DB instance.
   
The Performance Insights dashboard is displayed for your DB instance.
4. Scroll down to the Top SQL tab.
5. Choose a SQL statement.

SQL statements with text larger than 500 bytes look similar to the following image.

6. Scroll down to the SQL text tab.
Analyzing metrics with the Performance Insights dashboard

The Performance Insights dashboard can display up to 4,096 bytes for each SQL statement.

7. (Optional) Choose Copy to copy the displayed SQL statement, or choose Download to download the SQL statement to view the SQL text up to the DB engine limit.

   **Note**
   To copy or download the SQL statement, disable pop-up blockers.

**Viewing SQL statistics in the Performance Insights dashboard**

In the Performance Insights dashboard, SQL statistics are available in the Top SQL tab of the Database load chart.

**To view SQL statistics**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose Performance Insights.
3. At the top of the page, choose the database whose SQL statistics you want to see.
4. Scroll to the bottom of the page and choose the Top SQL tab.
5. Choose an individual statement (Aurora MySQL only) or digest query.
6. Choose which statistics to display by choosing the gear icon in the upper-right corner of the chart. For descriptions of the SQL statistics for the Amazon RDS Aurora engines, see SQL statistics for Performance Insights (p. 671).

The following example shows the preferences for Aurora PostgreSQL.
The following example shows the preferences for Aurora MySQL DB instances.
Retrieving metrics with the Performance Insights API

When Performance Insights is turned on, the API provides visibility into instance performance. Amazon CloudWatch Logs provides the authoritative source for vended monitoring metrics for AWS services.

Performance Insights offers a domain-specific view of database load measured as average active sessions (AAS). This metric appears to API consumers as a two-dimensional time-series dataset. The time dimension of the data provides DB load data for each time point in the queried time range. Each time point decomposes overall load in relation to the requested dimensions, such as SQL, Wait-event, User, or Host, measured at that time point.

Amazon RDS Performance Insights monitors your Amazon Aurora cluster so that you can analyze and troubleshoot database performance. One way to view Performance Insights data is in the AWS Management Console. Performance Insights also provides a public API so that you can query your own data. You can use the API to do the following:

- Offload data into a database
- Add Performance Insights data to existing monitoring dashboards
- Build monitoring tools

To use the Performance Insights API, enable Performance Insights on one of your Amazon RDS DB instances. For information about enabling Performance Insights, see Turning Performance Insights on and off (p. 565). For more information about the Performance Insights API, see the Amazon RDS Performance Insights API Reference.
The Performance Insights API provides the following operations.

<table>
<thead>
<tr>
<th>Performance Insights action</th>
<th>AWS CLI command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CreatePerformanceAnalysisReport</td>
<td><code>aws pi create-performance-analysis-report</code></td>
<td>Creates a performance analysis report for a specific time period for the DB instance. The result is AnalysisReportId which is the unique identifier of the report.</td>
</tr>
<tr>
<td>DescribeDimensionKeys</td>
<td><code>aws pi describe-dimension-keys</code></td>
<td>Retrieves the top N dimension keys for a metric for a specific time period.</td>
</tr>
<tr>
<td>GetDimensionKeyDetails</td>
<td><code>aws pi get-dimension-key-details</code></td>
<td>Retrieves the attributes of the specified dimension group for a DB instance or data source. For example, if you specify a SQL ID, and if the dimension details are available, GetDimensionKeyDetails retrieves the full text of the dimension db.sql.statement associated with this ID. This operation is useful because GetResourceMetrics and DescribeDimensionKeys don't support retrieval of large SQL statement text.</td>
</tr>
<tr>
<td>GetPerformanceAnalysisReport</td>
<td><code>aws pi get-performance-analysis-report</code></td>
<td>Retrieves the report including the insights for the report. The result includes the report status, report ID, report time details, insights, and recommendations.</td>
</tr>
<tr>
<td>GetResourceMetadata</td>
<td><code>aws pi get-resource-metadata</code></td>
<td>Retrieve the metadata for different features. For example, the metadata might indicate that a feature is turned on or off on a specific DB instance.</td>
</tr>
<tr>
<td>GetResourceMetrics</td>
<td><code>aws pi get-resource-metrics</code></td>
<td>Retrieves Performance Insights metrics for a set of data sources over a time period. You can provide specific dimension groups and dimensions, and provide aggregation and filtering criteria for each group.</td>
</tr>
<tr>
<td>ListAvailableResourceDimensions</td>
<td><code>aws pi list-available-resource-dimensions</code></td>
<td>Retrieve the dimensions that can be queried for each specified metric type on a specified instance.</td>
</tr>
</tbody>
</table>
### Performance Insights actions

<table>
<thead>

- [Retrieving time-series metrics](#) (p. 604)
- [AWS CLI examples for Performance Insights](#) (p. 606)

### AWS CLI for Performance Insights

You can view Performance Insights data using the AWS CLI. You can view help for the AWS CLI commands for Performance Insights by entering the following on the command line.

```sh
aws pi help
```

If you don't have the AWS CLI installed, see [Installing the AWS Command Line Interface](#) in the [AWS CLI User Guide](#) for information about installing it.

### Retrieving time-series metrics

The `GetResourceMetrics` operation retrieves one or more time-series metrics from the Performance Insights data. `GetResourceMetrics` requires a metric and time period, and returns a response with a list of data points.

For example, the AWS Management Console uses `GetResourceMetrics` to populate the **Counter Metrics** chart and the **Database Load** chart, as seen in the following image.
All metrics returned by GetResourceMetrics are standard time-series metrics, with the exception of `db.load`. This metric is displayed in the Database Load chart. The `db.load` metric is different from the other time-series metrics because you can break it into subcomponents called dimensions. In the previous image, `db.load` is broken down and grouped by the waits states that make up the `db.load`.

**Note**
GetResourceMetrics can also return the `db.sampleload` metric, but the `db.load` metric is appropriate in most cases.

For information about the counter metrics returned by GetResourceMetrics, see [Performance Insights counter metrics](p. 658).

The following calculations are supported for the metrics:

- **Average** – The average value for the metric over a period of time. Append `.avg` to the metric name.
- **Minimum** – The minimum value for the metric over a period of time. Append `.min` to the metric name.
- **Maximum** – The maximum value for the metric over a period of time. Append `.max` to the metric name.
- **Sum** – The sum of the metric values over a period of time. Append `.sum` to the metric name.
- **Sample count** – The number of times the metric was collected over a period of time. Append `.sample_count` to the metric name.

For example, assume that a metric is collected for 300 seconds (5 minutes), and that the metric is collected one time each minute. The values for each minute are 1, 2, 3, 4, and 5. In this case, the following calculations are returned:

- **Average** – 3
- **Minimum** – 1
- **Maximum** – 5
- **Sum** – 15
- **Sample count** – 5

For information about using the `get-resource-metrics` AWS CLI command, see [get-resource-metrics](p. 605).
For the `--metric-queries` option, specify one or more queries that you want to get results for. Each query consists of a mandatory `Metric` and optional `GroupBy` and `Filter` parameters. The following is an example of a `--metric-queries` option specification.

```json
{
  "Metric": "string",
  "GroupBy": {
    "Group": "string",
    "Dimensions": ["string", ...],
    "Limit": integer
  },
  "Filter": {"string": "string"
  ...}
}
```

AWS CLI examples for Performance Insights

The following examples show how to use the AWS CLI for Performance Insights.

**Topics**

- Retrieving counter metrics (p. 606)
- Retrieving the DB load average for top wait events (p. 609)
- Retrieving the DB load average for top SQL (p. 610)
- Retrieving the DB load average filtered by SQL (p. 613)
- Retrieving the full text of a SQL statement (p. 616)
- Creating a performance analysis report for a time period (p. 616)
- Retrieving a performance analysis report (p. 617)
- Listing all the performance analysis reports for the DB instance (p. 617)
- Deleting a performance analysis report (p. 618)
- Adding tag to a performance analysis report (p. 618)
- Listing all the tags for a performance analysis report (p. 618)
- Deleting tags from a performance analysis report (p. 619)

**Retrieving counter metrics**

The following screenshot shows two counter metrics charts in the AWS Management Console.
The following example shows how to gather the same data that the AWS Management Console uses to generate the two counter metric charts.

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics
    --service-type RDS
    --identifier db-ID
    --start-time 2018-10-30T00:00:00Z
    --end-time 2018-10-30T01:00:00Z
    --period-in-seconds 60
    --metric-queries '[["Metric": "os.cpuUtilization.user.avg" ],
                      {"Metric": "os.cpuUtilization.idle.avg"}]'
```

For Windows:

```
aws pi get-resource-metrics
    --service-type RDS
    --identifier db-ID
    --start-time 2018-10-30T00:00:00Z
    --end-time 2018-10-30T01:00:00Z
    --period-in-seconds 60
    --metric-queries file://query.json
```

You can also make a command easier to read by specifying a file for the `--metrics-query` option. The following example uses a file called `query.json` for the option. The file has the following contents.

```
[
    { "Metric": "os.cpuUtilization.user.avg" },
    { "Metric": "os.cpuUtilization.idle.avg" }
]
```

Run the following command to use the file.

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics
    --service-type RDS
    --identifier db-ID
    --start-time 2018-10-30T00:00:00Z
    --end-time 2018-10-30T01:00:00Z
    --period-in-seconds 60
    --metric-queries file://query.json
```

For Windows:

```
aws pi get-resource-metrics
    --service-type RDS
    --identifier db-ID
    --start-time 2018-10-30T00:00:00Z
    --end-time 2018-10-30T01:00:00Z
    --period-in-seconds 60
    --metric-queries file://query.json
```
The preceding example specifies the following values for the options:

- **--service-type** – RDS for Amazon RDS
- **--identifier** – The resource ID for the DB instance
- **--start-time** and **--end-time** – The ISO 8601 DateTime values for the period to query, with multiple supported formats

It queries for a one-hour time range:

- **--period-in-seconds** – 60 for a per-minute query
- **--metric-queries** – An array of two queries, each just for one metric.

The metric name uses dots to classify the metric in a useful category, with the final element being a function. In the example, the function is avg for each query. As with Amazon CloudWatch, the supported functions are min, max, total, and avg.

The response looks similar to the following.

```json
{
  "Identifier": "db-XXX",
  "AlignedStartTime": 1540857600.0,
  "AlignedEndTime": 1540861200.0,
  "MetricList": [
    {
      "Key": {
        "Metric": "os.cpuUtilization.user.avg" //Metric1
      },
      "DataPoints": [
        { //Each list of datapoints has the same timestamps and same number of items
          "Timestamp": 1540857660.0, //Minute1
          "Value": 4.0
        },
        { //... 60 datapoints for the os.cpuUtilization.user.avg metric
          "Timestamp": 1540857720.0, //Minute2
          "Value": 4.0
        },
        { //... 60 datapoints for the os.cpuUtilization.user.avg metric
          "Timestamp": 1540857780.0, //Minute 3
          "Value": 10.0
        }
      ]
    },
    {
      "Key": {
        "Metric": "os.cpuUtilization.idle.avg" //Metric2
      },
      "DataPoints": [
        { //... 60 datapoints for the os.cpuUtilization.idle.avg metric
          "Timestamp": 1540857660.0, //Minute1
          "Value": 12.0
        },
        { //... 60 datapoints for the os.cpuUtilization.idle.avg metric
          "Timestamp": 1540857720.0, //Minute2
          "Value": 13.5
        },
        { //... 60 datapoints for the os.cpuUtilization.idle.avg metric
          "Timestamp": 1540857780.0, //Minute 3
          "Value": 19.0
        }
      ]
    }
  ] //end of MetricList
}
The response has an Identifier, AlignedStartime, and AlignedEndTime. By the --period-in-seconds value was 60, the start and end times have been aligned to the minute. If the --period-in-seconds was 3600, the start and end times would have been aligned to the hour.

The MetricList in the response has a number of entries, each with a Key and a DataPoints entry. Each DataPoint has a Timestamp and a Value. Each Datapoints list has 60 data points because the queries are for per-minute data over an hour, with Timestamp1/Minute1, Timestamp2/Minute2, and so on, up to Timestamp60/Minute60.

Because the query is for two different counter metrics, there are two elements in the response MetricList.

**Retrieving the DB load average for top wait events**

The following example is the same query that the AWS Management Console uses to generate a stacked area line graph. This example retrieves the db.load.avg for the last hour with load divided according to the top seven wait events. The command is the same as the command in Retrieving counter metrics (p. 606). However, the query.json file has the following contents.

```
[
  {
    "Metric": "db.load.avg",
    "GroupBy": { "Group": "db.wait_event", "Limit": 7 }
  }
]
```

Run the following command.

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics \
  --service-type RDS \
  --identifier db-ID \
  --start-time 2018-10-30T00:00:00Z \
  --end-time 2018-10-30T01:00:00Z \
  --period-in-seconds 60 \
  --metric-queries file://query.json
```

For Windows:

```
aws pi get-resource-metrics ^
  --service-type RDS ^
  --identifier db-ID ^
  --start-time 2018-10-30T00:00:00Z ^
  --end-time 2018-10-30T01:00:00Z ^
  --period-in-seconds 60 ^
  --metric-queries file://query.json
```

The example specifies the metric of db.load.avg and a GroupBy of the top seven wait events. For details about valid values for this example, see DimensionGroup in the Performance Insights API Reference.

The response looks similar to the following.

```
{
  "Identifier": "db-XXX",
```
In this response, there are eight entries in the MetricList. There is one entry for the total `db.load.avg`, and seven entries each for the `db.load.avg` divided according to one of the top seven wait events. Unlike in the first example, because there was a grouping dimension, there must be one key for each grouping of the metric. There can't be only one key for each metric, as in the basic counter metric use case.

**Retrieving the DB load average for top SQL**

The following example groups `db.wait_events` by the top 10 SQL statements. There are two different groups for SQL statements:

- `db.sql` - The full SQL statement, such as `select * from customers where customer_id = 123`
db.sql_tokenized – The tokenized SQL statement, such as select * from customers where customer_id = ?

When analyzing database performance, it can be useful to consider SQL statements that only differ by their parameters as one logic item. So, you can use db.sql_tokenized when querying. However, especially when you're interested in explain plans, sometimes it's more useful to examine full SQL statements with parameters, and query grouping by db.sql. There is a parent-child relationship between tokenized and full SQL, with multiple full SQL (children) grouped under the same tokenized SQL (parent).

The command in this example is similar to the command in Retrieving the DB load average for top wait events (p. 609). However, the query.json file has the following contents.

```json
[
  {
    "Metric": "db.load.avg",
    "GroupBy": { "Group": "db.sql_tokenized", "Limit": 10 }
  }
]
```

The following example uses db.sql_tokenized.

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics \
  --service-type RDS \
  --identifier db-ID \
  --start-time 2018-10-29T00:00:00Z \
  --end-time 2018-10-30T00:00:00Z \
  --period-in-seconds 3600 \
  --metric-queries file://query.json
```

For Windows:

```
aws pi get-resource-metrics ^
  --service-type RDS ^
  --identifier db-ID ^
  --start-time 2018-10-29T00:00:00Z ^
  --end-time 2018-10-30T00:00:00Z ^
  --period-in-seconds 3600 ^
  --metric-queries file://query.json
```

This example queries over 24 hours, with a one hour period-in-seconds.

The example specifies the metric of db.load.avg and a GroupBy of the top seven wait events. For details about valid values for this example, see DimensionGroup in the Performance Insights API Reference.

The response looks similar to the following.

```
{
  "AlignedStartTime": 1540771200.0,
  "AlignedEndTime": 1540857600.0,
  "Identifier": "db-XXX",
  "MetricList": [ //11 entries in the MetricList
```
"Key": { //First key is total
  "Metric": "db.load.avg"
}
"DataPoints": [ //Each DataPoints list has 24 per-hour Timestamps and a value
  {
    "Value": 1.6964980544747081,
    "Timestamp": 1540774800.0
  }, //... 24 datapoints
},
{
  "Key": { //Next key is the top tokenized SQL
    "Dimensions": {
      "db.sql_tokenized.statement": "INSERT INTO authors (id,name,email)
VALUES
( nextval(?)  ,?,?)",
      "db.sql_tokenized.db_id": "pi-2372568224",
      "db.sql_tokenized.id": "AKIAIOSFODNN7EXAMPLE"
    },
    "Metric": "db.load.avg"
  },
  "DataPoints": [ //... 24 datapoints
  ]
}, // In total 11 entries, 10 Keys of top tokenized SQL, 1 total key
] //End of MetricList
} //End of response

This response has 11 entries in the MetricList (1 total, 10 top tokenized SQL), with each entry having 24 per-hour DataPoints.

For tokenized SQL, there are three entries in each dimensions list:

- `db.sql_tokenized.statement` – The tokenized SQL statement.
- `db.sql_tokenized.db_id` – Either the native database ID used to refer to the SQL, or a synthetic ID that Performance Insights generates for you if the native database ID isn't available. This example returns the `pi-2372568224` synthetic ID.
- `db.sql_tokenized.id` – The ID of the query inside Performance Insights.

In the AWS Management Console, this ID is called the Support ID. It's named this because the ID is data that AWS Support can examine to help you troubleshoot an issue with your database. AWS takes the security and privacy of your data extremely seriously, and almost all data is stored encrypted with your AWS KMS customer master key (CMK). Therefore, nobody inside AWS can look at this data. In the example preceding, both the `tokenized.statement` and the `tokenized.db_id` are stored encrypted. If you have an issue with your database, AWS Support can help you by referencing the Support ID.

When querying, it might be convenient to specify a Group in GroupBy. However, for finer-grained control over the data that's returned, specify the list of dimensions. For example, if all that is needed is the `db.sql_tokenized.statement`, then a Dimensions attribute can be added to the query.json file.

```json
[
  {
    "Metric": "db.load.avg",
    "GroupBy": {
      "Group": "db.sql_tokenized",
      "Dimensions": ["db.sql_tokenized.statement"],
      "Limit": 10
    }
  }
]```
Retrieving metrics with the Performance Insights API

[Image of a database load average graph]

Retrieving the DB load average filtered by SQL

The preceding image shows that a particular query is selected, and the top average active sessions stacked area line graph is scoped to that query. Although the query is still for the top seven overall wait events, the value of the response is filtered. The filter causes it to take into account only sessions that are a match for the particular filter.

The corresponding API query in this example is similar to the command in Retrieving the DB load average for top SQL (p. 610). However, the query.json file has the following contents.

```json
[
  {
    "Metric": "db.load.avg",
    "GroupBy": { "Group": "db.wait_event", "Limit": 5 },
    "Filter": { "db.sql_tokenized.id": "AKIAIOSFODNN7EXAMPLE" }
  }
]
```

For Linux, macOS, or Unix:

```bash
aws pi get-resource-metrics \
  --service-type RDS \
  --identifier db-ID \
  --start-time 2018-10-30T00:00:00Z \
  --end-time 2018-10-30T01:00:00Z \
  --period-in-seconds 60 \
  --metric-queries file://query.json
```

For Windows:

```bash
aws pi get-resource-metrics ^
  --service-type RDS ^
  --identifier db-ID ^
```
The response looks similar to the following.

```json
{
  "Identifier": "db-XXX",
  "AlignedStartTime": 1556215200.0,
  "MetricList": [
    {
      "Key": {
        "Metric": "db.load.avg"
      },
      "DataPoints": [
        {
          "Timestamp": 1556218800.0,
          "Value": 1.4878117913832196
        },
        {
          "Timestamp": 1556222400.0,
          "Value": 1.192823803967328
        }
      ]
    },
    {
      "Key": {
        "Metric": "db.load.avg",
        "Dimensions": {
          "db.wait_event.type": "io",
          "db.wait_event.name": "wait/io/aurora_redo_log_flush"
        }
      },
      "DataPoints": [
        {
          "Timestamp": 1556218800.0,
          "Value": 1.1360544217687074
        },
        {
          "Timestamp": 1556222400.0,
          "Value": 1.058051341890315
        }
      ]
    },
    {
      "Key": {
        "Metric": "db.load.avg",
        "Dimensions": {
          "db.wait_event.type": "io",
          "db.wait_event.name": "wait/io/table/sql/handler"
        }
      },
      "DataPoints": [
        {
          "Timestamp": 1556218800.0,
          "Value": 0.16241496598639457
        },
        {
          "Timestamp": 1556222400.0,
          "Value": 0.05163360560093349
        }
      ]
    }
  ]
}
```
In this response, all values are filtered according to the contribution of tokenized SQL
`AKIAIOSFODNN7EXAMPLE` specified in the `query.json` file. The keys also might follow a different order
than a query without a filter, because it’s the top five wait events that affected the filtered SQL.
Retrieving the full text of a SQL statement

The following example retrieves the full text of a SQL statement for DB instance db-10BCD2EFGH1J3KL4M5NO6PQRS5. The --group is db.sql, and the --group-identifier is db.sql.id. In this example, my-sql-id represents a SQL ID retrieved by invoking pi get-resource-metrics or pi describe-dimension-keys.

Run the following command.

For Linux, macOS, or Unix:

```
aws pi get-dimension-key-details \
  --service-type RDS \
  --identifier db-10BCD2EFGH1J3KL4M5NO6PQRS5 \
  --group db.sql \
  --group-identifier my-sql-id \
  --requested-dimensions statement
```

For Windows:

```
aws pi get-dimension-key-details ^
  --service-type RDS ^
  --identifier db-10BCD2EFGH1J3KL4M5NO6PQRS5 ^
  --group db.sql ^
  --group-identifier my-sql-id ^
  --requested-dimensions statement
```

In this example, the dimensions details are available. Thus, Performance Insights retrieves the full text of the SQL statement, without truncating it.

```
{
  "Dimensions": [
    {
      "Value": "SELECT e.last_name, d.department_name FROM employees e, departments d
      WHERE e.department_id=d.department_id",
      "Dimension": "db.sql.statement",
      "Status": "AVAILABLE"
    },
    ...
  ]
}
```

Creating a performance analysis report for a time period

The following example creates a performance analysis report with the 1682969503 start time and 1682979503 end time for the db-loadtest-0 database.

```
aws pi-test create-performance-analysis-report \
  --service-type RDS \
  --identifier db-loadtest-0 \
  --start-time 1682969503 \
  --end-time 1682979503 \
  --endpoint-url https://api.titan.pi.a2z.com \
  --region us-west-2
```

The response is the unique identifier report-0234d3ed98e28fb17 for the report.
Retrieving a performance analysis report

The following example retrieves the analysis report details for the report-0d99cc91c4422ee61 report.

```bash
aws pi-test get-performance-analysis-report
--service-type RDS
--identifier db-loadtest-0
--analysis-report-id report-0d99cc91c4422ee61
--endpoint-url https://api.titan.pi.a2z.com
--region us-west-2
```

The response provides the report status, ID, time details, and insights.

```json
{
  "AnalysisReport": {
    "Status": "Succeeded",
    "ServiceType": "RDS",
    "Identifier": "db-loadtest-0",
    "StartTime": 1680583486.584,
    "AnalysisReportId": "report-0d99cc91c4422ee61",
    "EndTime": 1680587086.584,
    "CreateTime": 1680587087.139,
    "Insights": [ ... (Condensed for space)
    ]
  }
}
```

Listing all the performance analysis reports for the DB instance

The following example lists all the available performance analysis reports for the db-loadtest-0 database.

```bash
aws pi-test list-performance-analysis-reports
--service-type RDS
--identifier db-loadtest-0
--endpoint-url https://api.titan.pi.a2z.com
--region us-west-2
```

The response lists all the reports with the report ID, status, and time period details.

```json
{
  "AnalysisReports": [
    {
      "Status": "Succeeded",
      "EndTime": 1680587086.584,
      "CreationTime": 1680587087.139,
    }...
  ]
}
```
Deleting a performance analysis report

The following example deletes the analysis report for the `db-loadtest-0` database.

```bash
aws pi-test delete-performance-analysis-report \
   --service-type RDS \ 
   --identifier db-loadtest-0 \ 
   --analysis-report-id report-0d99cc91c4422ee61 \ 
   --endpoint-url https://api.titan.pi.a2z.com \ 
   --region us-west-2
```

Adding tag to a performance analysis report

The following example adds a tag with a key `name` and value `test-tag` to the `report-01ad15f9b88bcbd56` report.

```bash
aws pi-test tag-resource \
   --service-type RDS \ 
   --resource-arn arn:aws:pi:us-west-2:356798100956:perf-reports/RDS/db-loadtest-0/\report-01ad15f9b88bcbd56 \ 
   --tags Key=name,Value=test-tag \ 
   --endpoint-url https://api.titan.pi.a2z.com \ 
   --region us-west-2
```

Listing all the tags for a performance analysis report

The following example lists all the tags for the `report-01ad15f9b88bcbd56` report.
aws pi-test list-tags-for-resource \
--service-type RDS \
--resource-arn arn:aws:pi:us-west-2:356798100956:perf-reports/RDS/db-loadtest-0/report-01ad15f9b88bcbd56 \
--endpoint-url https://api.titan.pi.a2z.com \
--region us-west-2

The response lists the value and key for all the tags added to the report:

```json
{
  "Tags": [
    {
      "Value": "test-tag",
      "Key": "name"
    }
  ]
}
```

Deleting tags from a performance analysis report

The following example deletes the name tag from the report-01ad15f9b88bcbd56 report.

aws pi-test untag-resource \
--service-type RDS \
--resource-arn arn:aws:pi:us-west-2:356798100956:perf-reports/RDS/db-loadtest-0/report-01ad15f9b88bcbd56 \
--tag-keys name \
--endpoint-url https://api.titan.pi.a2z.com \
--region us-west-2

After the tag is deleted, calling the list-tags-for-resource API doesn't list this tag.

Logging Performance Insights calls using AWS CloudTrail

Performance Insights runs with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Performance Insights. CloudTrail captures all API calls for Performance Insights as events. This capture includes calls from the Amazon RDS console and from code calls to the Performance Insights API operations.

If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Performance Insights. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in Event history. Using the data collected by CloudTrail, you can determine certain information. This information includes the request that was made to Performance Insights, the IP address the request was made from, who made the request, and when it was made. It also includes additional details.

To learn more about CloudTrail, see the AWS CloudTrail User Guide.

Working with Performance Insights information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Performance Insights, that activity is recorded in a CloudTrail event along with other AWS service events.
in the CloudTrail console in Event history. You can view, search, and download recent events in your AWS account. For more information, see Viewing Events with CloudTrail Event History in AWS CloudTrail User Guide.

For an ongoing record of events in your AWS account, including events for Performance Insights, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all AWS Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following topics in AWS CloudTrail User Guide:

- Overview for Creating a Trail
- CloudTrail Supported Services and Integrations
- Configuring Amazon SNS Notifications for CloudTrail
- Receiving CloudTrail Log Files from Multiple Regions and Receiving CloudTrail Log Files from Multiple Accounts

All Performance Insights operations are logged by CloudTrail and are documented in the Performance Insights API Reference. For example, calls to the DescribeDimensionKeys and GetResourceMetrics operations generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentity Element.

Performance Insights log file entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source. Each event includes information about the requested operation, the date and time of the operation, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the GetResourceMetrics operation.

```json
{
    "eventVersion": "1.05",
    "userIdentity": {
        "type": "IAMUser",
        "principalId": "AKIAIOSFODNN7EXAMPLE",
        "arn": "arn:aws:iam::123456789012:user/johndoe",
        "accountId": "123456789012",
        "accessKeyId": "AKIAI44QH8DHBEXAMPLE",
        "userName": "johndoe"
    },
    "eventTime": "2019-12-18T19:28:46Z",
    "eventSource": "pi.amazonaws.com",
    "eventName": "GetResourceMetrics",
    "awsRegion": "us-east-1",
    "sourceIPAddress": "72.21.198.67",
    "userAgent": "aws-cli/1.16.240 Python/3.7.4 Darwin/18.7.0 botocore/1.12.230",
}```
"requestParameters": {
  "identifier": "db-YTDUSJ5V6X7CXSCVDFD2V3SZM",
  "metricQueries": [
    {
      "metric": "os.cpuUtilization.user.avg"
    },
    {
      "metric": "os.cpuUtilization.idle.avg"
    }
  ],
  "startTime": "Dec 18, 2019 5:28:46 PM",
  "periodInSeconds": 60,
  "endTime": "Dec 18, 2019 7:28:46 PM",
  "serviceType": "RDS"
},
"responseElements": null,
"requestID": "9ffbe15c-96b5-4fe6-bed9-9fccff1a0525",
"eventID": "08908de0-2431-4e2e-ba7b-f5424f908433",
"eventType": "AwsApiCall",
"recipientAccountId": "123456789012"}
Analyzing performance anomalies with Amazon DevOps Guru for Amazon RDS

Amazon DevOps Guru is a fully managed operations service that helps developers and operators improve the performance and availability of their applications. DevOps Guru offloads the tasks associated with identifying operational issues so that you can quickly implement recommendations to improve your application. For more information, see What is Amazon DevOps Guru? in the Amazon DevOps Guru User Guide.

DevOps Guru detects, analyzes, and makes recommendations for existing operational issues for all Amazon RDS DB engines. DevOps Guru for RDS extends this capability by applying machine learning to Performance Insights metrics for Amazon Aurora databases. These monitoring features allow DevOps Guru for RDS to detect and diagnose performance bottlenecks and recommend specific corrective actions. DevOps Guru for RDS can also detect problematic conditions in your Aurora databases before they occur.

The following video is an overview of DevOps Guru for RDS.

For a deep dive on this subject, see Amazon DevOps Guru for RDS under the hood.

Topics
- Benefits of DevOps Guru for RDS (p. 622)
- How DevOps Guru for RDS works (p. 623)
- Setting up DevOps Guru for RDS (p. 624)

Benefits of DevOps Guru for RDS

If you’re responsible for an Amazon Aurora database, you might not know that an event or regression that is affecting that database is occurring. When you learn about the issue, you might not know why it's occurring or what to do about it. Rather than turning to a database administrator (DBA) for help or relying on third-party tools, you can follow recommendations from DevOps Guru for RDS.

You gain the following advantages from the detailed analysis of DevOps Guru for RDS:

Fast diagnosis

DevOps Guru for RDS continuously monitors and analyzes database telemetry. Performance Insights, Enhanced Monitoring, and Amazon CloudWatch collect telemetry data for your database cluster. DevOps Guru for RDS uses statistical and machine learning techniques to mine this data and detect anomalies. To learn more about telemetry data, see Monitoring DB load with Performance Insights on Amazon Aurora and Monitoring OS metrics with Enhanced Monitoring in the Amazon Aurora User Guide.

Fast resolution

Each anomaly identifies the performance issue and suggests avenues of investigation or corrective actions. For example, DevOps Guru for RDS might recommend that you investigate specific wait events. Or it might recommend that you tune your application pool settings to limit the number of database connections. Based on these recommendations, you can resolve performance issues more quickly than by troubleshooting manually.

Proactive insights

DevOps Guru for RDS uses metrics from your resources to detect potentially problematic behavior before it becomes a bigger problem. For example, it can detect when your database is using an increasing number of on-disk temporary tables, which could start to impact performance.
DevOps Guru then provides recommendations to help you address issues before they become bigger problems.

**Deep knowledge of Amazon engineers and machine learning**

To detect performance issues and help you resolve bottlenecks, DevOps Guru for RDS relies on machine learning (ML) and advanced mathematical formulas. Amazon database engineers contributed to the development of the DevOps Guru for RDS findings, which encapsulate many years of managing hundreds of thousands of databases. By drawing on this collective knowledge, DevOps Guru for RDS can teach you best practices.

**How DevOps Guru for RDS works**

DevOps Guru for RDS collects data about your Aurora databases from Amazon RDS Performance Insights. The most important metric is DBLoad. DevOps Guru for RDS consumes the Performance Insights metrics, analyzes them with machine learning, and publishes insights to the dashboard.

An **insight** is a collection of related anomalies that were detected by DevOps Guru.

In DevOps Guru for RDS, an **anomaly** is a pattern that deviates from what is considered normal performance for your Amazon Aurora database.

**Proactive insights**

A **proactive insight** lets you know about problematic behavior before it occurs. It contains anomalies with recommendations and related metrics to help you address issues in your Amazon Aurora databases before become bigger problems. These insights are published in the DevOps Guru dashboard.

For example, DevOps Guru might detect that your Aurora PostgreSQL database is creating many on-disk temporary tables. If not addressed, this trend might lead to performance issues. Each proactive insight includes recommendations for corrective behavior and links to relevant topics in either Tuning Aurora MySQL with Amazon DevOps Guru proactive insights (p. 944) or Tuning Aurora PostgreSQL with Amazon DevOps Guru proactive insights (p. 1463). For more information, see Working with insights in DevOps Guru in the Amazon DevOps Guru User Guide.

**Reactive insights**

A **reactive insight** identifies anomalous behavior as it occurs. If DevOps Guru for RDS finds performance issues in your Amazon Aurora DB instances, it publishes a reactive insight in the DevOps Guru dashboard. For more information, see Working with insights in DevOps Guru in the Amazon DevOps Guru User Guide.

**Causal anomalies**

A **causal anomaly** is a top-level anomaly within a reactive insight. **Database load (DB load)** is the causal anomaly for DevOps Guru for RDS.

An anomaly measures performance impact by assigning a severity level of High, Medium, or Low. To learn more, see Key concepts for DevOps Guru for RDS in the Amazon DevOps Guru User Guide.

If DevOps Guru detects a current anomaly on your DB instance, you're alerted in the Databases page of the RDS console. The console also alerts you to anomalies that occurred in the past 24 hours. To go to the anomaly page from the RDS console, choose the link in the alert message. The RDS console also alerts you in the page for your Amazon Aurora DB cluster.

**Contextual anomalies**

A **contextual anomaly** is a finding within Database load (DB load) that is related to a reactive insight. Each contextual anomaly describes a specific Amazon Aurora performance issue that requires
Investigation. For example, DevOps Guru for RDS might recommend that you consider increasing CPU
capacity or investigate wait events that are contributing to DB load.

**Important**

We recommend that you test any changes on a test instance before modifying a production
instance. In this way, you understand the impact of the change.

To learn more, see [Analyzing anomalies in Amazon RDS](#) in the *Amazon DevOps Guru User Guide*.

## Setting up DevOps Guru for RDS

To allow DevOps Guru for Amazon RDS to publish insights for an Amazon Aurora database, complete the
following tasks.

**Topics**

- [Configuring IAM access policies for DevOps Guru for RDS](#)
- [Turning on Performance Insights for your Aurora DB instances](#)
- [Turning on DevOps Guru and specifying resource coverage](#)

### Configuring IAM access policies for DevOps Guru for RDS

To view alerts from DevOps Guru in the RDS console, your AWS Identity and Access Management (IAM)
user or role must have either of the following policies:

- The AWS managed policy `AmazonDevOpsGuruConsoleFullAccess`
- The AWS managed policy `AmazonDevOpsGuruConsoleReadOnlyAccess` and either of the following
  policies:
  - The AWS managed policy `AmazonRDSFullAccess`
  - A customer managed policy that includes `pi:GetResourceMetrics` and `pi:DescribeDimensionKeys`

For more information, see [Configuring access policies for Performance Insights](#).

### Turning on Performance Insights for your Aurora DB instances

DevOps Guru for RDS relies on Performance Insights for its data. Without Performance Insights,
DevOps Guru publishes anomalies, but doesn't include the detailed analysis and recommendations.

When you create an Aurora DB cluster or modify a cluster instance, you can turn on Performance
Insights. For more information, see [Turning Performance Insights on and off](#).

### Turning on DevOps Guru and specifying resource coverage

You can turn on DevOps Guru to have it monitor your Amazon Aurora databases in either of the
following ways.

**Topics**

- [Turning on DevOps Guru in the RDS console](#)
- [Adding Aurora resources in the DevOps Guru console](#)
- [Adding Aurora resources using AWS CloudFormation](#)

### Turning on DevOps Guru in the RDS console

You can take multiple paths in the Amazon RDS console to turn on DevOps Guru.
Turning on DevOps Guru when you create an Aurora database

The creation workflow includes a setting that turns on DevOps Guru coverage for your database. This setting is turned on by default when you choose the Production template.

To turn on DevOps Guru when you create an Aurora database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Follow the steps in Creating a DB cluster (p. 183), up to but not including the step where you choose monitoring settings.
3. In Monitoring, choose Turn on Performance Insights. For DevOps Guru for RDS to provide detailed analysis of performance anomalies, Performance Insights must be turned on.
4. Choose Turn on DevOps Guru.

5. Create a tag for your database so that DevOps Guru can monitor it. Do the following:
• In the text field for Tag key, enter a name that begins with **Devops-Guru-**.
• In the text field for Tag value, enter any value. For example, if you enter `rds-database-1` for the name of your Aurora database, you can also enter `rds-database-1` as the tag value.

For more information about tags, see "Use tags to identify resources in your DevOps Guru applications" in the Amazon DevOps Guru User Guide.

6. Complete the remaining steps in **Creating a DB cluster (p. 183)**.

Turning on DevOps Guru from the notification banner

If your resources aren't covered by DevOps Guru, Amazon RDS notifies you with a banner in the following locations:

• The Monitoring tab of a DB cluster instance
• The Performance Insights dashboard

To turn on DevOps Guru for your Aurora database

1. In the banner, choose **Turn on DevOps Guru for RDS**.
2. Enter a tag key name and value. For more information about tags, see "Use tags to identify resources in your DevOps Guru applications" in the Amazon DevOps Guru User Guide.

3. Choose **Turn on DevOps Guru**.
Responding to a permissions error when you turn on DevOps Guru

If you turn on DevOps Guru from the RDS console when you create a database, RDS might display the following banner about missing permissions.

![Failed to turn on DevOps Guru for database-9-instance-1 because of missing permissions](image)

To respond to a permissions error

1. Grant your IAM user or role the user managed role AmazonDevOpsGuruConsoleFullAccess. For more information, see Configuring IAM access policies for DevOps Guru for RDS (p. 624).
2. Open the RDS console.
3. In the navigation pane, choose Performance Insights.
4. Choose a DB instance in the cluster that you just created.
5. Turn on DevOps Guru for RDS.
6. Choose a tag value. For more information, see "Use tags to identify resources in your DevOps Guru applications" in the Amazon DevOps Guru User Guide.
7. Choose Turn on DevOps Guru.

Adding Aurora resources in the DevOps Guru console

You can specify your DevOps Guru resource coverage on the DevOps Guru console. Follow the step described in Specify your DevOps Guru resource coverage in the Amazon DevOps Guru User Guide. When you edit your analyzed resources, choose one of the following options:

- Choose All account resources to analyze all supported resources, including the Aurora databases, in your AWS account and Region.
Choose **CloudFormation stacks** to analyze the Aurora databases that are in stacks you choose. For more information, see Use AWS CloudFormation stacks to identify resources in your DevOps Guru applications in the Amazon DevOps Guru User Guide.

Choose **Tags** to analyze the Aurora databases that you have tagged. For more information, see Use tags to identify resources in your DevOps Guru applications in the Amazon DevOps Guru User Guide.

For more information, see Enable DevOps Guru in the Amazon DevOps Guru User Guide.

**Adding Aurora resources using AWS CloudFormation**

You can use tags to add coverage for your Aurora resources to your CloudFormation templates. The following procedure assumes that you have a CloudFormation template both for your Aurora DB instance and DevOps Guru stack.

**To specify an Aurora DB instance using a CloudFormation tag**

1. In the CloudFormation template for your DB instance, define a tag using a key/value pair.

   The following example assigns the value `my-aurora-db-instance1` to `Devops-guru-cfn-default` for an Aurora DB instance.

   ```
   MyAuroraDBInstance1:
   Type: "AWS::RDS::DBInstance"
   Properties:
   - DBClusterIdentifier: my-aurora-db-cluster
   - DBInstanceIdentifier: my-aurora-db-instance1
   Tags:
   - Key: Devops-guru-cfn-default
   - Value: devopsguru-my-aurora-db-instance1
   ```

2. In the CloudFormation template for your DevOps Guru stack, specify the same tag in your resource collection filter.

   The following example configures DevOps Guru to provide coverage for the resource with the tag value `my-aurora-db-instance1`.

   ```
   DevOpsGuruResourceCollection:
   Type: AWS::DevOpsGuru::ResourceCollection
   Properties:
   - ResourceCollectionFilter:
     Tags:
     - AppBoundaryKey: "Devops-guru-cfn-default"
     - TagValues:
       - "devopsguru-my-aurora-db-instance1"
   ```

   The following example provides coverage for all resources within the application boundary Devops-guru-cfn-default.

   ```
   DevOpsGuruResourceCollection:
   Type: AWS::DevOpsGuru::ResourceCollection
   Properties:
   - ResourceCollectionFilter:
     Tags:
     - AppBoundaryKey: "Devops-guru-cfn-default"
     - TagValues:
       - "*"
   ```
For more information, see AWS::DevOpsGuru::ResourceCollection and AWS::RDS::DBInstance in the AWS CloudFormation User Guide.
Monitoring threats with Amazon GuardDuty RDS Protection

Amazon GuardDuty is a continuous security monitoring service that analyzes and processes various data sources, including RDS login activity. It uses threat intelligence feeds and machine learning to identify unexpected, potentially unauthorized, and malicious activity within your AWS environment.

GuardDuty RDS Protection analyzes and profiles login events for potential access threats to your Amazon Aurora databases. When you turn on RDS Protection, GuardDuty consumes RDS login events from your Aurora databases. RDS Protection monitors these events and profiles them for potential insider threats or external actors.

For more information about enabling GuardDuty RDS Protection, see GuardDuty RDS Protection in the Amazon GuardDuty User Guide.

When RDS Protection detects a potential threat, such as an unusual pattern in successful or failed login attempts, GuardDuty generates a new finding with details about the potentially compromised database. You can view the finding details in the finding summary section in the Amazon GuardDuty console. The finding details vary based on the finding type. The primary details, resource type and resource role, determine the kind of information available for any finding. For more information about the commonly available details for findings and the finding types, see Finding details and GuardDuty RDS Protection finding types respectively in the Amazon GuardDuty User Guide.

You can turn the RDS Protection feature on or off for any AWS account in any AWS Region where this feature is available. When RDS Protection isn't enabled, GuardDuty doesn't detect potentially compromised Aurora databases or provide details of the compromise.

An existing GuardDuty account can enable RDS Protection with a 30-day trial period. For a new GuardDuty account, RDS Protection is already enabled and included in the 30-day free trial period. For more information, see Estimating GuardDuty cost in the Amazon GuardDuty User Guide.

For information about the AWS Regions where GuardDuty doesn't yet support RDS Protection, see Region-specific feature availability in the Amazon GuardDuty User Guide.

The following table provides the Aurora database versions that GuardDuty RDS Protection supports:

<table>
<thead>
<tr>
<th>Amazon Aurora DB engine</th>
<th>Supported engine versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL</td>
<td>• 2.10.2 or later</td>
</tr>
<tr>
<td></td>
<td>• 3.2.1 or later</td>
</tr>
<tr>
<td>Aurora PostgreSQL</td>
<td>• 10.17 or later</td>
</tr>
<tr>
<td></td>
<td>• 11.12 or later</td>
</tr>
<tr>
<td></td>
<td>• 12.7 or later</td>
</tr>
<tr>
<td></td>
<td>• 13.3 or later</td>
</tr>
<tr>
<td></td>
<td>• 14.3 or later</td>
</tr>
</tbody>
</table>
Monitoring OS metrics with Enhanced Monitoring

With Enhanced Monitoring, you can monitor the operating system of your DB instance in real time. When you want to see how different processes or threads use the CPU, Enhanced Monitoring metrics are useful.

Topics
- Overview of Enhanced Monitoring (p. 631)
- Setting up and enabling Enhanced Monitoring (p. 632)
- Viewing OS metrics in the RDS console (p. 636)
- Viewing OS metrics using CloudWatch Logs (p. 637)

Overview of Enhanced Monitoring

Amazon RDS provides metrics in real time for the operating system (OS) that your DB instance runs on. You can view all the system metrics and process information for your RDS DB instances on the console. You can manage which metrics you want to monitor for each instance and customize the dashboard according to your requirements. For descriptions of the Enhanced Monitoring metrics, see OS metrics in Enhanced Monitoring (p. 675).

RDS delivers the metrics from Enhanced Monitoring into your Amazon CloudWatch Logs account. You can create metrics filters in CloudWatch from CloudWatch Logs and display the graphs on the CloudWatch dashboard. You can consume the Enhanced Monitoring JSON output from CloudWatch Logs in a monitoring system of your choice. For more information, see Enhanced Monitoring in the Amazon RDS FAQs.

Topics
- Differences between CloudWatch and Enhanced Monitoring metrics (p. 631)
- Retention of Enhanced Monitoring metrics (p. 631)
- Cost of Enhanced Monitoring (p. 632)

Differences between CloudWatch and Enhanced Monitoring metrics

A hypervisor creates and runs virtual machines (VMs). Using a hypervisor, an instance can support multiple guest VMs by virtually sharing memory and CPU. CloudWatch gathers metrics about CPU utilization from the hypervisor for a DB instance. In contrast, Enhanced Monitoring gathers its metrics from an agent on the DB instance.

You might find differences between the CloudWatch and Enhanced Monitoring measurements, because the hypervisor layer performs a small amount of work. The differences can be greater if your DB instances use smaller instance classes. In this scenario, more virtual machines (VMs) are probably managed by the hypervisor layer on a single physical instance.

For descriptions of the Enhanced Monitoring metrics, see OS metrics in Enhanced Monitoring (p. 675). For more information about CloudWatch metrics, see the Amazon CloudWatch User Guide.

Retention of Enhanced Monitoring metrics

By default, Enhanced Monitoring metrics are stored for 30 days in the CloudWatch Logs. This retention period is different from typical CloudWatch metrics.
To modify the amount of time the metrics are stored in the CloudWatch Logs, change the retention for the RDSOSMetrics log group in the CloudWatch console. For more information, see Change log data retention in CloudWatch logs in the Amazon CloudWatch Logs User Guide.

Cost of Enhanced Monitoring

Enhanced Monitoring metrics are stored in the CloudWatch Logs instead of in CloudWatch metrics. The cost of Enhanced Monitoring depends on the following factors:

- You are charged for Enhanced Monitoring only if you exceed the free tier provided by Amazon CloudWatch Logs. Charges are based on CloudWatch Logs data transfer and storage rates.
- The amount of information transferred for an RDS instance is directly proportional to the defined granularity for the Enhanced Monitoring feature. A smaller monitoring interval results in more frequent reporting of OS metrics and increases your monitoring cost. To manage costs, set different granularities for different instances in your accounts.
- Usage costs for Enhanced Monitoring are applied for each DB instance that Enhanced Monitoring is enabled for. Monitoring a large number of DB instances is more expensive than monitoring only a few.
- DB instances that support a more compute-intensive workload have more OS process activity to report and higher costs for Enhanced Monitoring.

For more information about pricing, see Amazon CloudWatch pricing.

Setting up and enabling Enhanced Monitoring

To use Enhanced Monitoring, you must create an IAM role, and then enable Enhanced Monitoring.

Topics
- Creating an IAM role for Enhanced Monitoring (p. 632)
- Turning Enhanced Monitoring on and off (p. 633)
- Protecting against the confused deputy problem (p. 635)

Creating an IAM role for Enhanced Monitoring

Enhanced Monitoring requires permission to act on your behalf to send OS metric information to CloudWatch Logs. You grant Enhanced Monitoring permissions using an AWS Identity and Access Management (IAM) role. You can either create this role when you enable Enhanced Monitoring or create it beforehand.

Topics
- Creating the IAM role when you enable Enhanced Monitoring (p. 632)
- Creating the IAM role before you enable Enhanced Monitoring (p. 633)

Creating the IAM role when you enable Enhanced Monitoring

When you enable Enhanced Monitoring in the RDS console, Amazon RDS can create the required IAM role for you. The role is named rds-monitoring-role. RDS uses this role for the specified DB instance, read replica, or Multi-AZ DB cluster.

To create the IAM role when enabling Enhanced Monitoring

1. Follow the steps in Turning Enhanced Monitoring on and off (p. 633).
2. Set Monitoring Role to Default in the step where you choose a role.
Creating the IAM role before you enable Enhanced Monitoring

You can create the required role before you enable Enhanced Monitoring. When you enable Enhanced Monitoring, specify your new role's name. You must create this required role if you enable Enhanced Monitoring using the AWS CLI or the RDS API.

The user that enables Enhanced Monitoring must be granted the `PassRole` permission. For more information, see Example 2 in Granting a user permissions to pass a role to an AWS service in the IAM User Guide.

To create an IAM role for Amazon RDS enhanced monitoring

2. In the navigation pane, choose Roles.
3. Choose Create role.
4. Choose the AWS service tab, and then choose RDS from the list of services.
5. Choose RDS - Enhanced Monitoring, and then choose Next.
6. Ensure that the Permissions policies shows AmazonRDSEnhancedMonitoringRole, and then choose Next.
7. For Role name, enter a name for your role. For example, enter emaccess.
   
   The trusted entity for your role is the AWS service monitoring.rds.amazonaws.com.
8. Choose Create role.

Turning Enhanced Monitoring on and off

You can turn Enhanced Monitoring on and off using the AWS Management Console, AWS CLI, or RDS API. You choose the RDS DB instances on which you want to turn on Enhanced Monitoring. You can set different granularities for metric collection on each DB instance.

Console

You can turn on Enhanced Monitoring when you create a DB cluster or read replica, or when you modify a DB instance. If you modify a DB instance to turn on Enhanced Monitoring, you don't need to reboot your DB instance for the change to take effect.

You can turn on Enhanced Monitoring in the RDS console when you do one of the following actions in the Databases page:

- Create a DB cluster – Choose Create database.
- Create a read replica – Choose Actions, then Create read replica.
- Modify a DB instance – Choose Modify.

To turn Enhanced Monitoring on or off in the RDS console

1. Scroll to Additional configuration.
2. In Monitoring, choose Enable Enhanced Monitoring for your DB instance or read replica. To turn Enhanced Monitoring off, choose Disable Enhanced Monitoring.
3. Set the Monitoring Role property to the IAM role that you created to permit Amazon RDS to communicate with Amazon CloudWatch Logs for you, or choose Default to have RDS create a role for you named rds-monitoring-role.
4. Set the Granularity property to the interval, in seconds, between points when metrics are collected for your DB instance or read replica. The Granularity property can be set to one of the following values: 1, 5, 10, 15, 30, or 60.
The fastest that the RDS console refreshes is every 5 seconds. If you set the granularity to 1 second in the RDS console, you still see updated metrics only every 5 seconds. You can retrieve 1-second metric updates by using CloudWatch Logs.

**AWS CLI**

To turn on Enhanced Monitoring using the AWS CLI, in the following commands, set the `--monitoring-interval` option to a value other than 0 and set the `--monitoring-role-arn` option to the role you created in *Creating an IAM role for Enhanced Monitoring (p. 632).*

- `create-db-instance`
- `create-db-instance-read-replica`
- `modify-db-instance`

The `--monitoring-interval` option specifies the interval, in seconds, between points when Enhanced Monitoring metrics are collected. Valid values for the option are 0, 1, 5, 10, 15, 30, and 60.

To turn off Enhanced Monitoring using the AWS CLI, set the `--monitoring-interval` option to 0 in these commands.

**Example**

The following example turns on Enhanced Monitoring for a DB instance:

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \   
   --db-instance-identifier mydbinstance \   
   --monitoring-interval 30 \   
   --monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

For Windows:

```bash
aws rds modify-db-instance ^   
   --db-instance-identifier mydbinstance ^   
   --monitoring-interval 30 ^   
   --monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

**Example**

The following example turns on Enhanced Monitoring for a Multi-AZ DB cluster:

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster \   
   --db-cluster-identifier mydbcluster \   
   --monitoring-interval 30 \   
   --monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

For Windows:

```bash
aws rds modify-db-cluster ^   
   --db-cluster-identifier mydbcluster ^   
   --monitoring-interval 30 ^
```
Setting up and enabling Enhanced Monitoring

--monitoring-role-arn arn:aws:iam::123456789012:role/emaccess

RDS API

To turn on Enhanced Monitoring using the RDS API, set the MonitoringInterval parameter to a value other than 0 and set the MonitoringRoleArn parameter to the role you created in Creating an IAM role for Enhanced Monitoring (p. 632). Set these parameters in the following actions:

- CreateDBInstance
- CreateDBInstanceReadReplica
- ModifyDBInstance

The MonitoringInterval parameter specifies the interval, in seconds, between points when Enhanced Monitoring metrics are collected. Valid values are 0, 1, 5, 10, 15, 30, and 60.

To turn off Enhanced Monitoring using the RDS API, set MonitoringInterval to 0.

Protecting against the confused deputy problem

The confused deputy problem is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem. Cross-service impersonation can occur when one service (the calling service) calls another service (the called service). The calling service can be manipulated to use its permissions to act on another customer's resources in a way it should not otherwise have permission to access. To prevent this, AWS provides tools that help you protect your data for all services with service principals that have been given access to resources in your account. For more information, see The confused deputy problem.

To limit the permissions to the resource that Amazon RDS can give another service, we recommend using the aws:SourceArn and aws:SourceAccount global condition context keys in a trust policy for your Enhanced Monitoring role. If you use both global condition context keys, they must use the same account ID.

The most effective way to protect against the confused deputy problem is to use the aws:SourceArn global condition context key with the full ARN of the resource. For Amazon RDS, set aws:SourceArn to arn:aws:rds:Region:my-account-id:db:dbname.

The following example uses the aws:SourceArn and aws:SourceAccount global condition context keys in a trust policy to prevent the confused deputy problem.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringLike": {
          "aws:SourceArn": "arn:aws:rds:Region:my-account-id:db:dbname"
        },
        "StringEquals": {
          "aws:SourceAccount": "my-account-id"
        }
      }
    }
  ]
}
```
Viewing OS metrics in the RDS console

You can view OS metrics reported by Enhanced Monitoring in the RDS console by choosing Enhanced monitoring for Monitoring.

The following example shows the Enhanced Monitoring page. For descriptions of the Enhanced Monitoring metrics, see OS metrics in Enhanced Monitoring (p. 675).

If you want to see details for the processes running on your DB instance, choose OS process list for Monitoring.

The Process List view is shown following.

The Enhanced Monitoring metrics shown in the Process list view are organized as follows:

- **RDS child processes** – Shows a summary of the RDS processes that support the DB instance, for example aurora for Amazon Aurora DB clusters. Process threads appear nested beneath the parent
process. Process threads show CPU utilization only as other metrics are the same for all threads for the process. The console displays a maximum of 100 processes and threads. The results are a combination of the top CPU consuming and memory consuming processes and threads. If there are more than 50 processes and more than 50 threads, the console displays the top 50 consumers in each category. This display helps you identify which processes are having the greatest impact on performance.

- **RDS processes** – Shows a summary of the resources used by the RDS management agent, diagnostics monitoring processes, and other AWS processes that are required to support RDS DB instances.
- **OS processes** – Shows a summary of the kernel and system processes, which generally have minimal impact on performance.

The items listed for each process are:

- **VIRT** – Displays the virtual size of the process.
- **RES** – Displays the actual physical memory being used by the process.
- **CPU%** – Displays the percentage of the total CPU bandwidth being used by the process.
- **MEM%** – Displays the percentage of the total memory being used by the process.

The monitoring data that is shown in the RDS console is retrieved from Amazon CloudWatch Logs. You can also retrieve the metrics for a DB instance as a log stream from CloudWatch Logs. For more information, see Viewing OS metrics using CloudWatch Logs (p. 637).

Enhanced Monitoring metrics are not returned during the following:

- A failover of the DB instance.
- Changing the instance class of the DB instance (scale compute).

Enhanced Monitoring metrics are returned during a reboot of a DB instance because only the database engine is rebooted. Metrics for the operating system are still reported.

**Viewing OS metrics using CloudWatch Logs**

After you have enabled Enhanced Monitoring for your DB cluster, you can view the metrics for it using CloudWatch Logs, with each log stream representing a single DB instance or DB cluster being monitored. The log stream identifier is the resource identifier (DbiResourceId) for the DB instance or DB cluster.

**To view Enhanced Monitoring log data**

2. If necessary, choose the AWS Region that your DB cluster is in. For more information, see Regions and endpoints in the Amazon Web Services General Reference.
3. Choose Logs in the navigation pane.
4. Choose RDSOSMetrics from the list of log groups.
5. Choose the log stream that you want to view from the list of log streams.
Metrics reference for Amazon Aurora

In this reference, you can find descriptions of Amazon Aurora metrics for Amazon CloudWatch, Performance Insights, and Enhanced Monitoring.

Topics
- Amazon CloudWatch metrics for Amazon Aurora (p. 638)
- Amazon CloudWatch dimensions for Aurora (p. 654)
- Availability of Aurora metrics in the Amazon RDS console (p. 654)
- Amazon CloudWatch metrics for Performance Insights (p. 657)
- Performance Insights counter metrics (p. 658)
- SQL statistics for Performance Insights (p. 671)

Amazon CloudWatch metrics for Amazon Aurora

The AWS/RDS namespace includes the following metrics that apply to database entities running on Amazon Aurora. Some metrics apply to either Aurora MySQL, Aurora PostgreSQL, or both. Furthermore, some metrics are specific to a DB cluster, primary DB instance, replica DB instance, or all DB instances.

For Aurora global database metrics, see Amazon CloudWatch metrics for write forwarding in Aurora MySQL (p. 1840) and Amazon CloudWatch metrics for write forwarding in Aurora PostgreSQL (p. 1850).

For Aurora parallel query metrics, see Monitoring parallel query (p. 962).

Topics
- Cluster-level metrics for Amazon Aurora (p. 638)
- Instance-level metrics for Amazon Aurora (p. 643)
- Amazon CloudWatch usage metrics for Amazon Aurora (p. 653)

Cluster-level metrics for Amazon Aurora

The following table describes metrics that are specific to Aurora clusters.

Amazon Aurora cluster-level metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
<th>Applies to</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>AuroraGlobalDBDataTransferBytes</td>
<td>In an Aurora Global Database, the amount of redo log data transferred from the master AWS Region to a secondary AWS Region.</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Bytes</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>&lt;br&gt;This metric is available only in secondary AWS Region.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>AuroraGlobalDBProgressLag</td>
<td>In an Aurora Global Database, the measure of how far the secondary cluster is behind the primary cluster for both user transactions and system transactions.</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Milliseconds</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
<td>Applies to</td>
<td>Units</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>------------</td>
<td>-------</td>
</tr>
<tr>
<td><strong>Note</strong>&lt;br&gt;This metric is available only in secondary AWS Region.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>AuroraGlobalDBReplicatedWriteIO</td>
<td>In an Aurora Global Database, the number of write I/O operations replicated from the primary AWS Region to the cluster volume in a secondary AWS Region. The billing calculations for the secondary AWS Regions in a global database use VolumeWriteIOPs to account for writes performed within the cluster. The billing calculations for the primary AWS Region in a global database use VolumeWriteIOPs to account for the write activity within that cluster, and AuroraGlobalDBReplicatedWriteIO to account for cross-Region replication within the global database.</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Count</td>
</tr>
<tr>
<td><strong>Note</strong>&lt;br&gt;This metric is available only in secondary AWS Region.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>AuroraGlobalDBReplicationLag</td>
<td>For an Aurora Global Database, the amount of lag when replicating updates from the primary AWS Region.</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Milliseconds</td>
</tr>
<tr>
<td><strong>Note</strong>&lt;br&gt;This metric is available only in secondary AWS Region.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>AuroraGlobalDBRPOLag</td>
<td>In an Aurora Global Database, the recovery point objective (RPO) lag time. This metric measures how far the secondary cluster is behind the primary cluster for user transactions.</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Milliseconds</td>
</tr>
<tr>
<td><strong>Note</strong>&lt;br&gt;This metric is available only in secondary AWS Region.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
<td>Applies to</td>
<td>Units</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>AuroraVolumeBytesLeftTotal</td>
<td>The remaining available space for the cluster volume. As the cluster volume grows, this value decreases. If it reaches zero, the cluster reports an out-of-space error. If you want to detect whether your Aurora MySQL cluster is approaching the size limit of 128 tebibytes (TiB), this value is simpler and more reliable to monitor than VolumeBytesUsed. AuroraVolumeBytesLeftTotal takes into account storage used for internal housekeeping and other allocations that don't affect your storage billing.</td>
<td>Aurora MySQL</td>
<td>Bytes</td>
</tr>
<tr>
<td>BacktrackChangeRecordsCreationRate</td>
<td>The number of backtrack change records created over 5 minutes for your DB cluster.</td>
<td>Aurora MySQL</td>
<td>Count per 5 minutes</td>
</tr>
<tr>
<td>BacktrackChangeRecordsStored</td>
<td>The number of backtrack change records used by your DB cluster.</td>
<td>Aurora MySQL</td>
<td>Count</td>
</tr>
<tr>
<td>BackupRetentionPeriodStorageUsed</td>
<td>The total amount of backup storage used to support the point-in-time restore feature within the Aurora DB cluster's backup retention window. This amount is included in the total reported by the TotalBackupStorageBilled metric. It is computed separately for each Aurora cluster. For instructions, see [Understanding Amazon Aurora backup storage usage](p. 433).</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Bytes</td>
</tr>
<tr>
<td>ServerlessDatabaseCapacity</td>
<td>The current capacity of an Aurora Serverless DB cluster.</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Count</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
<td>Applies to</td>
<td>Units</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------------------------</td>
<td>-------</td>
</tr>
<tr>
<td>SnapshotStorageUsed</td>
<td>The total amount of backup storage consumed by all Aurora snapshots for an Aurora DB cluster outside its backup retention window. This amount is included in the total reported by the TotalBackupStorageBilled metric. It is computed separately for each Aurora cluster. For instructions, see Understanding Amazon Aurora backup storage usage (p. 433).</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Bytes</td>
</tr>
<tr>
<td>TotalBackupStorageBilled</td>
<td>The total amount of backup storage in bytes for which you are billed for a given Aurora DB cluster. The metric includes the backup storage measured by the BackupRetentionPeriodStorageUsed and SnapshotStorageUsed metrics. This metric is computed separately for each Aurora cluster. For instructions, see Understanding Amazon Aurora backup storage usage (p. 433).</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Bytes</td>
</tr>
<tr>
<td>VolumeBytesUsed</td>
<td>The amount of storage used by your Aurora DB instance. This value affects the cost of the Aurora DB cluster (for pricing information, see the Amazon RDS pricing page). This value doesn't reflect some internal storage allocations that don't affect storage billing. For Aurora MySQL you can anticipate out-of-space issues more accurately by testing whether AuroraVolumeBytesLeftTotal is approaching zero instead of comparing VolumeBytesUsed against the storage limit of 128 TiB.</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Bytes</td>
</tr>
</tbody>
</table>

641
<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
<th>Applies to</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>VolumeReadIOPs</td>
<td>The number of billed read I/O operations from a cluster volume within a 5-minute interval. Billed read operations are calculated at the cluster volume level, aggregated from all instances in the Aurora DB cluster, and then reported at 5-minute intervals. The value is calculated by taking the value of the Read operations metric over a 5-minute period. You can determine the amount of billed read operations per second by taking the value of the Billed read operations metric and dividing by 300 seconds. For example, if the Billed read operations returns 13,686, then the billed read operations per second is 45 (13,686 / 300 = 45.62). You accrue billed read operations for queries that request database pages that aren't in the buffer cache and must be loaded from storage. You might see spikes in billed read operations as query results are read from storage and then loaded into the buffer cache. <strong>Tip</strong> If your Aurora MySQL cluster uses parallel query, you might see an increase in VolumeReadIOPs values. Parallel queries don't use the buffer pool. Thus, although the queries are fast, this optimized processing can result in an increase in read operations and associated charges.</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Count per 5 minutes</td>
</tr>
<tr>
<td>VolumeWriteIOPs</td>
<td>The number of write disk I/O operations to the cluster volume, reported at 5-minute intervals. For a detailed description of how billed write operations are calculated, see VolumeReadIOPs.</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Count per 5 minutes</td>
</tr>
</tbody>
</table>
## Instance-level metrics for Amazon Aurora

The following instance-specific CloudWatch metrics apply to all Aurora MySQL and Aurora PostgreSQL instances unless noted otherwise.

### Amazon Aurora instance-level metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
<th>Applies to</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>AbortedClients</td>
<td>The number of client connections that have not been closed properly.</td>
<td>Aurora MySQL</td>
<td>Count</td>
</tr>
<tr>
<td>ActiveTransactions</td>
<td>The average number of current transactions executing on an Aurora database instance per second. By default, Aurora doesn't enable this metric. To begin measuring this value, set <code>innodb_monitor_enable='all'</code> in the DB parameter group for a specific DB instance.</td>
<td>Aurora MySQL</td>
<td>Count per second</td>
</tr>
<tr>
<td>ACUUtilization</td>
<td>The value of the <code>ServerlessDatabaseCapacity</code> metric divided by the maximum ACU value of the DB cluster. This metric is applicable for Aurora Serverless v1 and Aurora Serverless v2.</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Percentage</td>
</tr>
<tr>
<td>AuroraBinlogReplicaLag</td>
<td>The amount of time that a binary log replica DB cluster running on Aurora MySQL-Compatible Edition lags behind the binary log replication source. A lag means that the source is generating records faster than the replica can apply them. This metric reports different values depending on the engine version: Aurora MySQL version 2: The <code>Seconds_Behind_Master</code> field of the MySQL SHOW SLAVE STATUS. Aurora MySQL version 3: <code>SHOW REPLICA STATUS</code>. You can use this metric to monitor errors and replica lag in a cluster that acts as a binary log replica.</td>
<td>Primary for Aurora MySQL</td>
<td>Seconds</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
<td>Applies to</td>
<td>Units</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>--------------------------------------</td>
<td>---------------</td>
</tr>
<tr>
<td>AuroraOptimizedReadsCacheHitRatio</td>
<td>The percentage of requests that are served by the Optimized reads cache.</td>
<td>Primary for Aurora PostgreSQL</td>
<td>Percentage</td>
</tr>
<tr>
<td>AuroraReplicaLag</td>
<td>For an Aurora replica, the amount of lag when replicating updates from the primary instance.</td>
<td>Replica for Aurora MySQL and Aurora PostgreSQL</td>
<td>Milliseconds</td>
</tr>
<tr>
<td>AuroraReplicaLagMaximum</td>
<td>The maximum amount of lag between the primary instance and any of the Aurora DB instance in the DB cluster.</td>
<td>Primary for Aurora MySQL and Aurora PostgreSQL</td>
<td>Milliseconds</td>
</tr>
<tr>
<td>AuroraReplicaLagMinimum</td>
<td>The minimum amount of lag between the primary instance and any of the Aurora DB instance in the DB cluster.</td>
<td>Primary for Aurora MySQL and Aurora PostgreSQL</td>
<td>Milliseconds</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
<td>Applies to</td>
<td>Units</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------------------------------</td>
<td>---------------------</td>
</tr>
<tr>
<td>AuroraSlowConnectionHandleCount</td>
<td>The number of connections that have waited two seconds or longer to start the handshake. This metric applies only to Aurora MySQL version 3.</td>
<td>Aurora MySQL</td>
<td>Count</td>
</tr>
<tr>
<td>AuroraSlowHandshakeCount</td>
<td>The number of connections that have taken 50 milliseconds or longer to finish the handshake. This metric applies only to Aurora MySQL version 3.</td>
<td>Aurora MySQL</td>
<td>Count</td>
</tr>
<tr>
<td>BacktrackWindowActual</td>
<td>The difference between the target backtrack window and the actual backtrack window.</td>
<td>Primary for Aurora MySQL</td>
<td>Minutes</td>
</tr>
<tr>
<td>BacktrackWindowAlert</td>
<td>The number of times that the actual backtrack window is smaller than the target backtrack window for a given period of time.</td>
<td>Primary for Aurora MySQL</td>
<td>Count</td>
</tr>
<tr>
<td>BlockedTransactions</td>
<td>The average number of transactions in the database that are blocked per second.</td>
<td>Aurora MySQL</td>
<td>Count per second</td>
</tr>
<tr>
<td>BufferCacheHitRatio</td>
<td>The percentage of requests that are served by the buffer cache.</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Percentage</td>
</tr>
<tr>
<td>CommitLatency</td>
<td>The average duration taken by the engine and storage to complete the commit operations.</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Milliseconds</td>
</tr>
<tr>
<td>CommitThroughput</td>
<td>The average number of commit operations per second.</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Count per second</td>
</tr>
<tr>
<td>ConnectionAttempts</td>
<td>The number of attempts to connect to an instance, whether successful or not.</td>
<td>Aurora MySQL</td>
<td>Count</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
<td>Applies to</td>
<td>Units</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>CPUCreditBalance</td>
<td>The number of CPU credits that an instance has accumulated, reported at 5-minute intervals. You can use this metric to determine how long a DB instance can burst beyond its baseline performance level at a given rate.</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Count</td>
</tr>
</tbody>
</table>

This metric applies only to these instance class:
- Aurora MySQL: db.t2.small, db.t2.medium, db.t3, and db.t4g
- Aurora PostgreSQL: db.t3 and db.t4g

**Note**
We recommend using the T DB instance classes only for development and test servers, or other non-production servers. For more details on the T instance classes, see [DB instance class types](#) (p. 84).

Launch credits work the same way in Amazon RDS as they do in Amazon EC2. For more information, see [Launch credits](#) in the Amazon Elastic Compute Cloud User Guide for Linux Instances.
<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>

<tr>
<td>EngineUptime</td>
<td>The amount of time that the instance has been running.</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Seconds</td>
</tr>
<tr>
<td>FreeableMemory</td>
<td>The amount of available random access memory.</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Bytes</td>
</tr>
<tr>
<td>FreeEphemeralStorage</td>
<td>The amount of available Ephemeral NVMe storage.</td>
<td>Aurora PostgreSQL</td>
<td>Bytes</td>
</tr>
<tr>
<td>FreeLocalStorage</td>
<td>The amount of local storage available.</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Bytes</td>
</tr>
</tbody>
</table>

   Unlike for other DB engines, for Aurora DB instances this metric reports the amount of storage available to each DB instance. This value depends on the DB instance class (for pricing information, see the Amazon RDS pricing page). You can increase the amount of free storage space for an instance by choosing a larger DB instance class for your instance.

   (This doesn't apply to Aurora Serverless v2.)

<p>| InsertLatency    | The average duration of insert operations.                                  | Aurora MySQL                      | Milliseconds |
| InsertThroughput | The average number of insert operations per second.                         | Aurora MySQL                      | Count per second |
| LoginFailures    | The average number of failed login attempts per second.                     | Aurora MySQL                      | Count per second |</p>

<td>The average amount of time taken per disk write I/O operation for Ephemeral NVMe storage.</td>
<td>Aurora PostgreSQL</td>
<td>Milliseconds</td>
</tr>
<tr>
<td>WriteThroughput</td>
<td>The average number of bytes written to persistent storage every second.</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Bytes per second</td>
</tr>
<tr>
<td>WriteThroughputEphemeralStorage</td>
<td>The average number of bytes written to disk per second for Ephemeral NVMe storage.</td>
<td>Aurora PostgreSQL</td>
<td>Bytes per second</td>
</tr>
</tbody>
</table>

**Amazon CloudWatch usage metrics for Amazon Aurora**

The AWS/Usage namespace in Amazon CloudWatch includes account-level usage metrics for your Amazon RDS service quotas. CloudWatch collects usage metrics automatically for all AWS Regions.

For more information, see [CloudWatch usage metrics](#) in the [Amazon CloudWatch User Guide](#). For more information about quotas, see [Quotas and constraints for Amazon Aurora (p. 2506)](#) and [Requesting a quota increase](#) in the [Service Quotas User Guide](#).
<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
<th>Units*</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBSubnetGroups</td>
<td>The number of DB subnet groups in your AWS account. The count excludes the default subnet group.</td>
<td>Count</td>
</tr>
<tr>
<td>ManualClusterSnapshots</td>
<td>The number of manually created DB cluster snapshots in your AWS account. The count excludes invalid snapshots.</td>
<td>Count</td>
</tr>
<tr>
<td>OptionGroups</td>
<td>The number of option groups in your AWS account. The count excludes the default option groups.</td>
<td>Count</td>
</tr>
<tr>
<td>ReservedDBInstances</td>
<td>The number of reserved DB instances in your AWS account. The count excludes retired or declined instances.</td>
<td>Count</td>
</tr>
</tbody>
</table>

* Amazon RDS doesn't publish units for usage metrics to CloudWatch. The units only appear in the documentation.

Amazon CloudWatch dimensions for Aurora

You can filter Aurora metrics data by using any dimension in the following table.

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Filters the requested data for . . .</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBInstanceIdentifier</td>
<td>A specific DB instance.</td>
</tr>
<tr>
<td>DBClusterIdentifier</td>
<td>A specific Aurora DB cluster.</td>
</tr>
<tr>
<td>DBClusterIdentifier, Role</td>
<td>A specific Aurora DB cluster, aggregating the metric by instance role (WRITER/READER). For example, you can aggregate metrics for all READER instances that belong to a cluster.</td>
</tr>
<tr>
<td>DBClusterIdentifier, EngineName</td>
<td>A specific Aurora DB cluster and engine name combination. For example, you can view the VolumeReadIOPs metric for cluster ams1 and engine aurora.</td>
</tr>
<tr>
<td>DatabaseClass</td>
<td>All instances in a database class. For example, you can aggregate metrics for all instances that belong to the database class db.r5.large.</td>
</tr>
<tr>
<td>EngineName</td>
<td>The identified engine name only. For example, you can aggregate metrics for all instances that have the engine name aurora-postgresql.</td>
</tr>
<tr>
<td>SourceRegion</td>
<td>The specified Region only. For example, you can aggregate metrics for all DB instances in the us-east-1 Region.</td>
</tr>
</tbody>
</table>

Availability of Aurora metrics in the Amazon RDS console

Not all metrics provided by Amazon Aurora are available in the Amazon RDS console. You can view these metrics using tools such as the AWS CLI and CloudWatch API. Also, some metrics in the Amazon RDS console are either shown only for specific instance classes, or with different names and units of measurement.
- Aurora metrics available in the Last Hour view (p. 655)
- Aurora metrics available in specific cases (p. 656)
- Aurora metrics that aren't available in the console (p. 656)

### Aurora metrics available in the Last Hour view

You can view a subset of categorized Aurora metrics in the default Last Hour view in the Amazon RDS console. The following table lists the categories and associated metrics displayed in the Amazon RDS console for an Aurora instance.

<table>
<thead>
<tr>
<th>Category</th>
<th>Metrics</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL</td>
<td>ActiveTransactions</td>
</tr>
<tr>
<td></td>
<td>BlockedTransactions</td>
</tr>
<tr>
<td></td>
<td>BufferCacheHitRatio</td>
</tr>
<tr>
<td></td>
<td>CommitLatency</td>
</tr>
<tr>
<td></td>
<td>CommitThroughput</td>
</tr>
<tr>
<td></td>
<td>DatabaseConnections</td>

<tr>
<td></td>
<td>DDLLatency</td>
</tr>
<tr>
<td></td>
<td>DDLThroughput</td>
</tr>
<tr>
<td></td>
<td>Deadlocks</td>
</tr>
<tr>
<td></td>
<td>DMLLatency</td>
</tr>
<tr>
<td></td>
<td>DMLThroughput</td>
</tr>
<tr>
<td></td>
<td>LoginFailures</td>
</tr>
<tr>
<td></td>
<td>ResultSetCacheHitRatio</td>
</tr>
<tr>
<td></td>
<td>SelectLatency</td>
</tr>
<tr>
<td></td>
<td>SelectThroughput</td>
</tr>
<tr>
<td>System</td>
<td>AuroraReplicaLag</td>
</tr>
<tr>
<td></td>
<td>AuroraReplicaLagMaximum</td>
</tr>
<tr>
<td></td>
<td>AuroraReplicaLagMinimum</td>
</tr>
<tr>
<td></td>
<td>CPUCreditBalance</td>
</tr>
<tr>
<td></td>
<td>CPUCreditUsage</td>
</tr>
<tr>
<td></td>
<td>CPUUtilization</td>
</tr>
<tr>
<td></td>
<td>FreeableMemory</td>
</tr>
<tr>
<td></td>
<td>FreeLocalStorage (This doesn't apply to Aurora Serverless v2.)</td>
</tr>
<tr>
<td>Category</td>
<td>Metrics</td>
</tr>
<tr>
<td>---------------</td>
<td>----------------------------------</td>
</tr>
<tr>
<td></td>
<td>NetworkReceiveThroughput</td>
</tr>
<tr>
<td>Deployment</td>
<td>AuroraReplicaLag</td>
</tr>
<tr>
<td></td>
<td>BufferCacheHitRatio</td>
</tr>
<tr>
<td></td>
<td>ResultSetCacheHitRatio</td>
</tr>
<tr>
<td></td>
<td>SelectThroughput</td>
</tr>
</tbody>
</table>

### Aurora metrics available in specific cases

In addition, some Aurora metrics are either shown only for specific instance classes, or only for DB instances, or with different names and different units of measurement:

- The CPUCreditBalance and CPUCreditUsage metrics are displayed only for Aurora MySQL `db.t2` instance classes and for Aurora PostgreSQL `db.t3` instance classes.
- The following metrics that are displayed with different names, as listed:

<table>
<thead>
<tr>
<th>Metric</th>
<th>Display name</th>
</tr>
</thead>
<tbody>
<tr>
<td>AuroraReplicaLagMaximum</td>
<td>Replica lag maximum</td>
</tr>
<tr>
<td>AuroraReplicaLagMinimum</td>
<td>Replica lag minimum</td>
</tr>
<tr>
<td>DDLThroughput</td>
<td>DDL</td>
</tr>
<tr>
<td>NetworkReceiveThroughput</td>
<td>Network throughput</td>
</tr>
<tr>
<td>VolumeBytesUsed</td>
<td>[Billed] Volume bytes used</td>
</tr>
<tr>
<td>VolumeReadIOPs</td>
<td>[Billed] Volume read IOPS</td>
</tr>
<tr>
<td>VolumeWriteIOPs</td>
<td>[Billed] Volume write IOPS</td>
</tr>
</tbody>
</table>

- The following metrics apply to an entire Aurora DB cluster, but are displayed only when viewing DB instances for an Aurora DB cluster in the Amazon RDS console:
  - VolumeBytesUsed
  - VolumeReadIOPs
  - VolumeWriteIOPs
- The following metrics are displayed in megabytes, instead of bytes, in the Amazon RDS console:
  - FreeableMemory
  - FreeLocalStorage
  - NetworkReceiveThroughput
  - NetworkTransmitThroughput

### Aurora metrics that aren't available in the console

The following Aurora metrics aren't available in the Amazon RDS console:

- AuroraBinlogReplicaLag
- DeleteLatency
Amazon CloudWatch metrics for Performance Insights

Performance Insights automatically publishes metrics to Amazon CloudWatch. The same data can be queried from Performance Insights, but having the metrics in CloudWatch makes it easy to add CloudWatch alarms. It also makes it easy to add the metrics to existing CloudWatch Dashboards.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DBLoad</strong></td>
<td>The number of active sessions for the DB engine. Typically, you want the data for the average number of active sessions. In Performance Insights, this data is queried as <code>db.load.avg</code>.</td>
</tr>
<tr>
<td><strong>DBLoadCPU</strong></td>
<td>The number of active sessions where the wait event type is CPU. In Performance Insights, this data is queried as <code>db.load.avg</code>, filtered by the wait event type <code>CPU</code>.</td>
</tr>
<tr>
<td><strong>DBLoadNonCPU</strong></td>
<td>The number of active sessions where the wait event type is not CPU.</td>
</tr>
</tbody>
</table>

**Note**
These metrics are published to CloudWatch only if there is load on the DB instance.

You can examine these metrics using the CloudWatch console, the AWS CLI, or the CloudWatch API.

For example, you can get the statistics for the DBLoad metric by running the `get-metric-statistics` command.

```bash
aws cloudwatch get-metric-statistics \
  --region us-west-2 \
  --namespace AWS/RDS \
  --metric-name DBLoad \
  --period 60 \
  --statistics Average \
  --start-time 1532035185 \
  --end-time 1532036185 \
  --dimensions Name=DBInstanceIdentifier,Value=db-loadtest-0
```

This example generates output similar to the following.

```json
{
}
```
"Datapoints": [
  {
    "Timestamp": "2021-07-19T21:30:00Z",
    "Unit": "None",
    "Average": 2.1
  },
  {
    "Timestamp": "2021-07-19T21:34:00Z",
    "Unit": "None",
    "Average": 1.7
  },
  {
    "Timestamp": "2021-07-19T21:35:00Z",
    "Unit": "None",
    "Average": 2.8
  },
  {
    "Timestamp": "2021-07-19T21:31:00Z",

    "Unit": "None",
    "Average": 2.4
  }
],
"Label": "DBLoad"

For more information about CloudWatch, see What is Amazon CloudWatch? in the Amazon CloudWatch User Guide.

Performance Insights counter metrics

Counter metrics are operating system and database performance metrics in the Performance Insights dashboard. To help identify and analyze performance problems, you can correlate counter metrics with DB load. You can add a statistic function to the metric to get the metric values. For example, the supported functions for os.memory.active metric are .avg, .min, .max, .sum, and .sample_count.

The counter metrics are collected one time each minute. The OS metrics collection depends on whether Enhanced Monitoring is turned on or off. If Enhanced Monitoring is turned off, the OS metrics are collected one time each minute. If Enhanced Monitoring is turned on, the OS metrics are collected for the selected time period. For more information about turning Enhanced Monitoring on or off, see Turning Enhanced Monitoring on and off (p. 633).

Topics

- Performance Insights operating system counters (p. 659)
- Performance Insights counters for Aurora MySQL (p. 664)
- Performance Insights counters for Aurora PostgreSQL (p. 668)
Performance Insights operating system counters

The following operating system counters, which are prefixed with `os`, are available with Performance Insights for Aurora PostgreSQL and Aurora MySQL.

You can use `ListAvailableResourceMetrics` API for the list of available counter metrics for your DB instance. For more information, see the `ListAvailableResourceMetrics` in the Amazon RDS Performance Insights API Reference guide.

<table>
<thead>
<tr>
<th>Counter</th>
<th>Type</th>
<th>Metric</th>

Non-native counters for Aurora MySQL

Non-native counter metrics are counters defined by Amazon RDS. A non-native metric can be a metric that you get with a specific query. A non-native metric also can be a derived metric, where two or more native counters are used in calculations for ratios, hit rates, or latencies.

<td>-</td>
</tr>
</tbody>
</table>
### SQL statistics for Performance Insights

**SQL statistics** are performance-related metrics about SQL queries that are collected by Performance Insights. Performance Insights gathers statistics for each second that a query is running and for each SQL call. The SQL statistics are an average for the selected time range.

A SQL digest is a composite of all queries having a given pattern but not necessarily having the same literal values. The digest replaces literal values with a question mark. For example, `SELECT * FROM emp WHERE lname= ?`. This digest might consist of the following child queries:

```
SELECT * FROM emp WHERE lname = 'Sanchez'
SELECT * FROM emp WHERE lname = 'Olagappan'
SELECT * FROM emp WHERE lname = 'Wu'
```

All engines support SQL statistics for digest queries.

For the region, DB engine, and instance class support information for this feature, see [Amazon Aurora DB engine, Region, and instance class support for Performance Insights features](p. 563)

**Topics**
- SQL statistics for Aurora MySQL (p. 671)
- SQL statistics for Aurora PostgreSQL (p. 673)

### SQL statistics for Aurora MySQL

Aurora MySQL collect SQL statistics only at the digest level. No statistics are shown at the statement level.
Topics

- Digest statistics for Aurora MySQL (p. 672)
- Per-second statistics for Aurora MySQL (p. 672)
- Per-call statistics for Aurora MySQL (p. 673)

Digest statistics for Aurora MySQL

Performance Insights collects SQL digest statistics from the `events_statements_summary_by_digest` table. The `events_statements_summary_by_digest` table is managed by your database.

The digest table doesn't have an eviction policy. When the table is full, the AWS Management Console shows the following message:

```
Performance Insights is unable to collect SQL Digest statistics on new queries because the table events_statements_summary_by_digest is full. Please truncate events_statements_summary_by_digest table to clear the issue. Check the User Guide for more details.
```

In this situation, Aurora MySQL doesn't track SQL queries. To address this issue, Performance Insights automatically truncates the digest table when both of the following conditions are met:

- The table is full.
- Performance Insights manages the Performance Schema automatically.

For automatic management, the `performance_schema` parameter must be set to 0 and the `Source` must not be set to `user`. If Performance Insights isn't managing the Performance Schema automatically, see Turning on the Performance Schema for Performance Insights on Aurora MySQL (p. 568).

In the AWS CLI, check the source of a parameter value by running the `describe-db-parameters` command.

Per-second statistics for Aurora MySQL

The following SQL statistics are available for Aurora MySQL DB clusters.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db.sql_tokenized.stats.count_star_per_sec</code></td>
<td>Calls per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_timer_wait_per_sec</code></td>
<td>Average active executions per second (AAE)</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_select_full_join_per_sec</code></td>
<td>Select full join per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_select_range_check_per_select</code></td>
<td>Select range check per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_select_scan_per_sec</code></td>
<td>Select scan per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_sort_merge_passes_per_sort</code></td>
<td>Sort merge passes per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_sort_scan_per_sec</code></td>
<td>Sort scans per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_sort_range_per_sec</code></td>
<td>Sort ranges per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_sort_rows_per_sec</code></td>
<td>Sort rows per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_rows_affected_per_sec</code></td>
<td>Rows affected per second</td>
</tr>
</tbody>
</table>
### SQL statistics for Performance Insights

#### Metric

<table>
<thead>
<tr>
<th>Metric</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db.sql_tokenized.stats.sum_rows_examined_per_sec</code></td>
<td>Rows examined per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_rows_sent_per_sec</code></td>
<td>Rows sent per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_created_tmp_disk_tables_per_sec</code></td>
<td>Created temporary disk tables per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_created_tmp_tables_per_call</code></td>
<td>Created temporary tables per call</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_lock_time_per_sec</code></td>
<td>Lock time per second (in ms)</td>
</tr>
</tbody>
</table>

#### Per-call statistics for Aurora MySQL

The following metrics provide per call statistics for a SQL statement.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db.sql_tokenized.stats.sum_timer_wait_per_call</code></td>
<td>Average latency per call (in ms)</td>

<td><code>db.sql_tokenized.stats.sum_select_full_join_per_call</code></td>
<td>Select full joins per call</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_select_range_check_per_call</code></td>
<td>Select range check per call</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_select_scan_per_call</code></td>
<td>Select scans per call</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_sort_merge_passes_per_call</code></td>
<td>Sort merge passes per call</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_sort_scan_per_call</code></td>
<td>Sort scans per call</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_sort_range_per_call</code></td>
<td>Sort ranges per call</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_sort_rows_per_call</code></td>
<td>Sort rows per call</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_rows_affected_per_call</code></td>
<td>Rows affected per call</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_rows_examined_per_call</code></td>
<td>Rows examined per call</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_rows_sent_per_call</code></td>
<td>Rows sent per call</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_created_tmp_disk_tables_per_call</code></td>
<td>Created temporary disk tables per call</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_created_tmp_tables_per_call</code></td>
<td>Created temporary tables per call</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_lock_time_per_call</code></td>
<td>Lock time per call (in ms)</td>
</tr>
</tbody>
</table>

### SQL statistics for Aurora PostgreSQL

For each SQL call and for each second that a query runs, Performance Insights collects SQL statistics. All Aurora engines collect statistics only at the digest-level.

Following, you can find information about digest-level statistics for Aurora PostgreSQL.

**Topics**

- [Digest statistics for Aurora PostgreSQL](p. 674)
- [Per-second digest statistics for Aurora PostgreSQL](p. 674)
- [Per-call digest statistics for Aurora PostgreSQL](p. 674)
Digest statistics for Aurora PostgreSQL

To view SQL digest statistics, the `pg_stat_statements` library must be loaded. For Aurora PostgreSQL DB clusters that are compatible with PostgreSQL 10, this library is loaded by default. For Aurora PostgreSQL DB clusters that are compatible with PostgreSQL 9.6, you enable this library manually. To enable it manually, add `pg_stat_statements` to `shared_preload_libraries` in the DB parameter group associated with the DB instance. Then reboot your DB instance. For more information, see Working with parameter groups (p. 212).

**Note**
Performance Insights can only collect statistics for queries in `pg_stat_activity` that aren't truncated. By default, PostgreSQL databases truncate queries longer than 1,024 bytes. To increase the query size, change the `track_activity_query_size` parameter in the DB parameter group associated with your DB instance. When you change this parameter, a DB instance reboot is required.

Per-second digest statistics for Aurora PostgreSQL

The following SQL digest statistics are available for Aurora PostgreSQL DB instances.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db.sql_tokenized.stats.calls_per_sec</code></td>
<td>Calls per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.rows_per_sec</code></td>
<td>Rows per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.total_time_per_sec</code></td>
<td>Average active executions per second (AAE)</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.shared_blks_hit_per_sec</code></td>
<td>Block hits per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.shared_blks_read_per_sec</code></td>
<td>Block reads per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.shared_blks_dirtied_per_sec</code></td>
<td>Blocks dirtied per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.shared_blks_written_per_sec</code></td>
<td>Block writes per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.local_blks_hit_per_sec</code></td>
<td>Local block hits per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.local_blks_read_per_sec</code></td>
<td>Local block reads per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.local_blks_dirtied_per_sec</code></td>
<td>Local block dirty per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.local_blks_written_per_sec</code></td>
<td>Local block writes per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.temp_blks_written_per_sec</code></td>
<td>Temporary writes per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.temp_blks_read_per_sec</code></td>
<td>Temporary reads per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.blk_read_time_per_sec</code></td>
<td>Average concurrent reads per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.blk_write_time_per_sec</code></td>
<td>Average concurrent writes per second</td>
</tr>
</tbody>
</table>

Per-call digest statistics for Aurora PostgreSQL

The following metrics provide per call statistics for a SQL statement.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db.sql_tokenized.stats.rows_per_call</code></td>
<td>Rows per call</td>

### OS metrics in Enhanced Monitoring

Amazon Aurora provides metrics in real time for the operating system (OS) that your DB cluster runs on. Aurora delivers the metrics from Enhanced Monitoring to your Amazon CloudWatch Logs account. The following tables list the OS metrics available using Amazon CloudWatch Logs.

#### Topics
- [OS metrics for Aurora (p. 675)]

### OS metrics for Aurora

<table>
<thead>
<tr>
<th>Group</th>
<th>Metric</th>
<th>Console name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>General</td>
<td>engine</td>
<td>Not applicable</td>
<td>The database engine for the DB instance.</td>
</tr>
<tr>
<td></td>
<td>instanceID</td>
<td>Not applicable</td>
<td>The DB instance identifier.</td>
</tr>
<tr>
<td></td>
<td>instanceResourceID</td>
<td>Not applicable</td>
<td>An immutable identifier for the DB instance that is unique to an AWS Region, also used as the log stream identifier.</td>
</tr>
<tr>
<td></td>
<td>numVCpus</td>
<td>Not applicable</td>
<td>The number of virtual CPUs for the DB instance.</td>
</tr>
<tr>
<td>Group</td>
<td>Metric</td>
<td>Console name</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>--------</td>
<td>--------------</td>
<td>-------------</td>
</tr>
<tr>
<td></td>
<td>timestamp</td>
<td>Not applicable</td>
<td>The time at which the metrics were taken.</td>
</tr>
<tr>
<td></td>
<td>uptime</td>
<td>Not applicable</td>
<td>The amount of time that the DB instance has been active.</td>
</tr>
<tr>
<td></td>
<td>version</td>
<td>Not applicable</td>
<td>The version of the OS metrics' stream JSON format.</td>
</tr>
<tr>
<td></td>
<td>cpuUtilization</td>
<td>guest</td>
<td>The percentage of CPU in use by guest programs.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>idle</td>
<td>The percentage of CPU that is idle.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>irq</td>
<td>The percentage of CPU in use by software interrupts.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>nice</td>
<td>The percentage of CPU in use by programs running at lowest priority.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>steal</td>
<td>The percentage of CPU in use by other virtual machines.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>system</td>
<td>The percentage of CPU in use by the kernel.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>total</td>
<td>The total percentage of the CPU in use. This value includes the nice value.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>user</td>
<td>The percentage of CPU in use by user programs.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>wait</td>
<td>The percentage of CPU unused while waiting for I/O access.</td>
</tr>
<tr>
<td></td>
<td>diskIO</td>
<td>avgQueueLen</td>
<td>The number of requests waiting in the I/O device's queue.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>avgReqSz</td>
<td>The average request size, in kilobytes.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>await</td>
<td>The number of milliseconds required to respond to requests, including queue time and service time.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>device</td>
<td>The identifier of the disk device in use.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>readIOsPS</td>
<td>The number of read operations per second.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>readKbPS</td>
<td>The total number of kilobytes read.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>readLatency</td>
<td>The elapsed time between the submission of a read I/O request and its completion, in milliseconds. This metric is only available for Amazon Aurora.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>readThroughput</td>
<td>The amount of network throughput used by requests to the DB cluster, in bytes per second. This metric is only available for Amazon Aurora.</td>
</tr>
</tbody>
</table>
### Amazon Aurora User Guide for Aurora

#### OS metrics in Enhanced Monitoring

<table>
<thead>

<tr>
<td></td>
<td>used</td>
<td>Used Filesystem</td>
<td>The amount of disk space used by files in the file system, in kilobytes.</td>
</tr>
<tr>
<td></td>
<td>usedFiles</td>
<td>Used%</td>
<td>The number of files in the file system.</td>
</tr>
<tr>
<td></td>
<td>usedPercent</td>
<td>Used Filesystem</td>
<td>The percentage of the file-system disk space in use.</td>
</tr>
<tr>
<td>loadAverage</td>
<td>fifteen</td>
<td>Load Avg 15 min</td>
<td>The number of processes requesting CPU time over the last 15 minutes.</td>
</tr>
<tr>
<td></td>
<td>five</td>
<td>Load Avg 5 min</td>
<td>The number of processes requesting CPU time over the last 5 minutes.</td>
</tr>
<tr>
<td></td>
<td>one</td>
<td>Load Avg 1 min</td>
<td>The number of processes requesting CPU time over the last minute.</td>
</tr>
<tr>
<td>memory</td>
<td>active</td>
<td>Active Memory</td>
<td>The amount of assigned memory, in kilobytes.</td>
</tr>
<tr>
<td>Group</td>
<td>Metric</td>
<td>Console name</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-----------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>buffers</td>
<td>Buffered Memory</td>
<td>The amount of memory used for buffering I/O requests prior to writing to the storage device, in kilobytes.</td>
</tr>
<tr>
<td></td>
<td>cached</td>
<td>Cached Memory</td>
<td>The amount of memory used for caching file system-based I/O.</td>
</tr>
<tr>
<td></td>
<td>dirty</td>
<td>Dirty Memory</td>
<td>The amount of memory pages in RAM that have been modified but not written to their related data block in storage, in kilobytes.</td>
</tr>
<tr>
<td></td>
<td>free</td>
<td>Free Memory</td>
<td>The amount of unassigned memory, in kilobytes.</td>
</tr>
<tr>
<td></td>
<td>hugePagesFree</td>
<td>Huge Pages Free</td>
<td>The number of free huge pages. Huge pages are a feature of the Linux kernel.</td>
</tr>
<tr>
<td></td>
<td>hugePagesRsvd</td>
<td>Huge Pages Rsvd</td>
<td>The number of committed huge pages.</td>
</tr>
<tr>
<td></td>
<td>hugePagesSize</td>
<td>Huge Pages Size</td>
<td>The size for each huge pages unit, in kilobytes.</td>
</tr>
<tr>
<td></td>
<td>hugePagesSurp</td>
<td>Huge Pages Surp</td>
<td>The number of available surplus huge pages over the total.</td>
</tr>
<tr>
<td></td>
<td>hugePagesTotal</td>
<td>Huge Pages Total</td>
<td>The total number of huge pages.</td>
</tr>
<tr>
<td></td>
<td>inactive</td>
<td>Inactive Memory</td>
<td>The amount of least-frequently used memory pages, in kilobytes.</td>
</tr>
<tr>
<td></td>
<td>mapped</td>
<td>Mapped Memory</td>
<td>The total amount of file-system contents that is memory mapped inside a process address space, in kilobytes.</td>
</tr>
<tr>
<td></td>
<td>pageTables</td>
<td>Page Tables</td>
<td>The amount of memory used by page tables, in kilobytes.</td>
</tr>
<tr>
<td></td>
<td>slab</td>
<td>Slab Memory</td>
<td>The amount of reusable kernel data structures, in kilobytes.</td>
</tr>
<tr>
<td></td>
<td>total</td>
<td>Total Memory</td>
<td>The total amount of memory, in kilobytes.</td>
</tr>
<tr>
<td></td>
<td>writeback</td>
<td>Writeback Memory</td>
<td>The amount of dirty pages in RAM that are still being written to the backing storage, in kilobytes.</td>
</tr>
<tr>
<td></td>
<td>network</td>
<td>Not applicable</td>
<td>The identifier for the network interface being used for the DB instance.</td>
</tr>
<tr>
<td></td>
<td>interface</td>
<td>Not applicable</td>
<td>The identifier for the network interface being used for the DB instance.</td>
</tr>
<tr>
<td></td>
<td>rx</td>
<td>RX</td>
<td>The number of bytes received per second.</td>
</tr>
<tr>
<td></td>
<td>tx</td>
<td>TX</td>
<td>The number of bytes uploaded per second.</td>
</tr>
<tr>
<td></td>
<td>processList</td>
<td>cpuUsedPc</td>
<td>CPU %</td>
</tr>
<tr>
<td></td>
<td>id</td>
<td>Not applicable</td>
<td>The identifier of the process.</td>
</tr>
<tr>
<td></td>
<td>memoryUsed</td>
<td>Not applicable</td>
<td>The percentage of memory used by the process.</td>
</tr>
<tr>
<td>Group</td>
<td>Metric</td>
<td>Console name</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>--------</td>
<td>--------------</td>
<td>-------------</td>
</tr>
<tr>
<td></td>
<td>name</td>
<td>Not applicable</td>
<td>The name of the process.</td>
</tr>
<tr>
<td></td>
<td>parentID</td>
<td>Not applicable</td>
<td>The process identifier for the parent process of the process.</td>
</tr>
<tr>
<td></td>
<td>rss</td>
<td>RES</td>
<td>The amount of RAM allocated to the process, in kilobytes.</td>
</tr>
<tr>
<td></td>
<td>tgid</td>
<td>Not applicable</td>
<td>The thread group identifier, which is a number representing the process ID to which a thread belongs. This identifier is used to group threads from the same process.</td>
</tr>
<tr>
<td></td>
<td>vss</td>
<td>VIRT</td>
<td>The amount of virtual memory allocated to the process, in kilobytes.</td>
</tr>
<tr>
<td>swap</td>
<td>swap</td>
<td>Swap</td>
<td>The amount of swap memory available, in kilobytes.</td>
</tr>
<tr>
<td></td>
<td>swap in</td>
<td>Swaps in</td>
<td>The amount of memory, in kilobytes, swapped in from disk.</td>
</tr>
<tr>
<td></td>
<td>swap out</td>
<td>Swaps out</td>
<td>The amount of memory, in kilobytes, swapped out to disk.</td>
</tr>
<tr>
<td></td>
<td>free</td>
<td>Free Swap</td>
<td>The amount of swap memory free, in kilobytes.</td>
</tr>
<tr>
<td></td>
<td>committed</td>
<td>Committed Swap</td>
<td>The amount of swap memory, in kilobytes, used as cache memory.</td>
</tr>
<tr>
<td>tasks</td>
<td>blocked</td>
<td>Tasks Blocked</td>
<td>The number of tasks that are blocked.</td>
</tr>
<tr>
<td></td>
<td>running</td>

<td>sleeping</td>
<td>Tasks Sleeping</td>
<td>The number of tasks that are sleeping.</td>
</tr>
<tr>
<td></td>
<td>stopped</td>
<td>Tasks Stopped</td>
<td>The number of tasks that are stopped.</td>
</tr>
<tr>
<td></td>
<td>total</td>
<td>Tasks Total</td>
<td>The total number of tasks.</td>
</tr>
<tr>
<td></td>
<td>zombie</td>
<td>Tasks Zombie</td>
<td>The number of child tasks that are inactive with an active parent task.</td>
</tr>
</tbody>
</table>
Monitoring events, logs, and streams in an Amazon Aurora DB cluster

When you monitor your Amazon Aurora databases and your other AWS solutions, your goal is to maintain the following:

- Reliability
- Availability
- Performance
- Security

Monitoring metrics in an Amazon Aurora cluster (p. 509) explains how to monitor your cluster using metrics. A complete solution must also monitor database events, log files, and activity streams. AWS provides you with the following monitoring tools:

- **Amazon EventBridge** is a serverless event bus service that makes it easy to connect your applications with data from a variety of sources. EventBridge delivers a stream of real-time data from your own applications, Software-as-a-Service (SaaS) applications, and AWS services. EventBridge routes that data to targets such as AWS Lambda. This way, you can monitor events that happen in services and build event-driven architectures. For more information, see the Amazon EventBridge User Guide.

- **Amazon CloudWatch Logs** provides a way to monitor, store, and access your log files from Amazon Aurora instances, AWS CloudTrail, and other sources. Amazon CloudWatch Logs can monitor information in the log files and notify you when certain thresholds are met. You can also archive your log data in highly durable storage. For more information, see the Amazon CloudWatch Logs User Guide.

- **AWS CloudTrail** captures API calls and related events made by or on behalf of your AWS account. CloudTrail delivers the log files to an Amazon S3 bucket that you specify. You can identify which users and accounts called AWS, the source IP address from which the calls were made, and when the calls occurred. For more information, see the AWS CloudTrail User Guide.

- **Database Activity Streams** is an Amazon Aurora feature that provides a near real-time stream of the activity in your DB cluster. Amazon Aurora pushes activities to an Amazon Kinesis data stream. The Kinesis stream is created automatically. From Kinesis, you can configure AWS services such as Amazon Kinesis Data Firehose and AWS Lambda to consume the stream and store the data.

Topics

- Viewing logs, events, and streams in the Amazon RDS console (p. 680)
- Monitoring Amazon Aurora events (p. 685)
- Monitoring Amazon Aurora log files (p. 722)
- Monitoring Amazon Aurora API calls in AWS CloudTrail (p. 742)
- Monitoring Amazon Aurora with Database Activity Streams (p. 746)

Viewing logs, events, and streams in the Amazon RDS console

Amazon RDS integrates with AWS services to show information about logs, events, and database activity streams in the RDS console.
The **Logs & events** tab for your Aurora DB cluster shows the following information:

- **Auto scaling policies and activities** – Shows policies and activities relating to the Aurora Auto Scaling feature. This information only appears in the **Logs & events** tab at the cluster level.

- **Amazon CloudWatch alarms** – Shows any metric alarms that you have configured for the DB instance in your Aurora cluster. If you haven’t configured alarms, you can create them in the RDS console.

- **Recent events** – Shows a summary of events (environment changes) for your Aurora DB instance or cluster. For more information, see Viewing Amazon RDS events (p. 687).

- **Logs** – Shows database log files generated by a DB instance in your Aurora cluster. For more information, see Monitoring Amazon Aurora log files (p. 722).

The **Configuration** tab displays information about database activity streams.

**To view logs, events, and streams for your Aurora DB cluster in the RDS console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the name of the Aurora DB cluster that you want to monitor.

   The database page appears. The following example shows an Amazon Aurora PostgreSQL DB cluster named `apg`.

   ![Database page example](image)

4. Scroll down and choose **Configuration**.

   The following example shows the status of the database activity streams for your cluster.
5. Choose **Logs & events**.

   The Logs & events section appears.
6. Choose a DB instance in your Aurora cluster, and then choose **Logs & events** for the instance.

The following example shows that the contents are different between the DB instance page and the DB cluster page. The DB instance page shows logs and alarms.
### Logs

<table>
<thead>
<tr>
<th>Name</th>
<th>Last written</th>

</tbody>
</table>
Monitoring Amazon Aurora events

An event indicates a change in an environment. This can be an AWS environment, an SaaS partner service or application, or a custom application or service. For descriptions of the Aurora events, see Amazon RDS event categories and event messages (p. 709).

Topics

- Overview of events for Aurora (p. 685)
- Viewing Amazon RDS events (p. 687)
- Working with Amazon RDS event notification (p. 690)
- Creating a rule that triggers on an Amazon Aurora event (p. 706)
- Amazon RDS event categories and event messages (p. 709)

Overview of events for Aurora

An RDS event indicates a change in the Aurora environment. For example, Amazon Aurora generates an event when a DB cluster is patched. Amazon Aurora delivers events to CloudWatch Events and EventBridge in near-real time.

**Note**

Amazon RDS emits events on a best effort basis. We recommend that you avoid writing programs that depend on the order or existence of notification events, because they might be out of sequence or missing.

Amazon RDS records events that relate to the following resources:

- DB clusters
  
  For a list of cluster events, see DB cluster events (p. 709).
- DB instances
  
  For a list of DB instance events, see DB instance events (p. 713).
- DB parameter groups
  
  For a list of DB parameter group events, see DB parameter group events (p. 718).
- DB security groups
  
  For a list of DB security group events, see DB security group events (p. 718).
- DB cluster snapshots
  
  For a list of DB cluster snapshot events, see DB cluster snapshot events (p. 718).
- RDS Proxy events
  
  For a list of RDS Proxy events, see RDS Proxy events (p. 719).
- Blue/green deployment events
  
  For a list of blue/green deployment events, see Blue/green deployment events (p. 720).

This information includes the following:

- The date and time of the event
- The source name and source type of the event
- A message associated with the event
• Event notifications include tags from when the message was sent and may not reflect tags at the time when the event occurred
Viewing Amazon RDS events

You can retrieve the following event information for your Amazon Aurora resources:

- Resource name
- Resource type
- Time of the event
- Message summary of the event

Access the events through the AWS Management Console, which shows events from the past 24 hours. You can also retrieve events by using the `describe-events` AWS CLI command, or the `DescribeEvents` RDS API operation. If you use the AWS CLI or the RDS API to view events, you can retrieve events for up to the past 14 days.

**Note**
If you need to store events for longer periods of time, you can send Amazon RDS events to CloudWatch Events. For more information, see [Creating a rule that triggers on an Amazon Aurora event](p. 706).

For descriptions of the Amazon Aurora events, see Amazon RDS event categories and event messages (p. 709).

To access detailed information about events using AWS CloudTrail, including request parameters, see CloudTrail events (p. 742).

**Console**

**To view all Amazon RDS events for the past 24 hours**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Events**.
   The available events appear in a list.
3. (Optional) Enter a search term to filter your results.
   The following example shows a list of events filtered by the characters **apg**.
AWS CLI

To view all events generated in the last hour, call `describe-events` with no parameters.

```
aws rds describe-events
```

The following sample output shows that a DB cluster instance has started recovery.

```
{
    "Events": [
        {
            "EventCategories": [
                "recovery"
            ],
            "SourceType": "db-instance",
            "Date": "2022-04-20T15:02:38.416Z",
            "Message": "Recovery of the DB instance has started. Recovery time will vary with the amount of data to be recovered.",
            "SourceIdentifier": "mycluster-instance-1"
        }, ...
```

To view all Amazon RDS events for the past 10080 minutes (7 days), call the `describe-events` AWS CLI command and set the `--duration` parameter to `10080`.

```
aws rds describe-events --duration 10080
```
The following example shows the events in the specified time range for DB instance test-instance.

```bash
aws rds describe-events
   --source-identifier test-instance
   --source-type db-instance
   --start-time 2022-03-13T22:00Z
   --end-time 2022-03-13T23:59Z
```

The following sample output shows the status of a backup.

```json
{
   "Events": [
      {
         "SourceType": "db-instance",
         "SourceIdentifier": "test-instance",
         "EventCategories": ["backup"],
         "Message": "Backing up DB instance",
         "Date": "2022-03-13T23:09:23.983Z",
         "SourceArn": "arn:aws:rds:us-east-1:123456789012:db:test-instance"
      },
      {
         "SourceType": "db-instance",
         "SourceIdentifier": "test-instance",
         "EventCategories": ["backup"],
         "Message": "Finished DB Instance backup",
         "Date": "2022-03-13T23:15:13.049Z",
         "SourceArn": "arn:aws:rds:us-east-1:123456789012:db:test-instance"
      }
   ]
}
```

**API**

You can view all Amazon RDS instance events for the past 14 days by calling the [DescribeEvents RDS API operation](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/USER_AmazonRDSAPI.html#rds-api-events) and setting the `Duration` parameter to 20160.
Working with Amazon RDS event notification

Amazon RDS uses the Amazon Simple Notification Service (Amazon SNS) to provide notification when an Amazon RDS event occurs. These notifications can be in any notification form supported by Amazon SNS for an AWS Region, such as an email, a text message, or a call to an HTTP endpoint.

Topics

- Overview of Amazon RDS event notification (p. 690)
- Granting permissions to publish notifications to an Amazon SNS topic (p. 695)
- Subscribing to Amazon RDS event notification (p. 696)
- Amazon RDS event notification tags and attributes (p. 699)
- Listing Amazon RDS event notification subscriptions (p. 700)
- Modifying an Amazon RDS event notification subscription (p. 701)
- Adding a source identifier to an Amazon RDS event notification subscription (p. 702)
- Removing a source identifier from an Amazon RDS event notification subscription (p. 703)
- Listing the Amazon RDS event notification categories (p. 704)
- Deleting an Amazon RDS event notification subscription (p. 705)

Overview of Amazon RDS event notification

Amazon RDS groups events into categories that you can subscribe to so that you can be notified when an event in that category occurs.

Topics

- RDS resources eligible for event subscription (p. 690)
- Basic process for subscribing to Amazon RDS event notifications (p. 691)
- Delivery of RDS event notifications (p. 691)
- Billing for Amazon RDS event notifications (p. 691)
- Examples of Aurora events (p. 692)

RDS resources eligible for event subscription

For Amazon Aurora, events occur at both the DB cluster and the DB instance level. You can subscribe to an event category for the following resources:

- DB instance
- DB cluster
- DB cluster snapshot
- DB parameter group
- DB security group
- RDS Proxy
- Custom engine version

For example, if you subscribe to the backup category for a given DB instance, you’re notified whenever a backup-related event occurs that affects the DB instance. If you subscribe to a configuration change category for a DB instance, you’re notified when the DB instance is changed. You also receive notification when an event notification subscription changes.
You might want to create several different subscriptions. For example, you might create one subscription that receives all event notifications for all DB instances and another subscription that includes only critical events for a subset of the DB instances. For the second subscription, specify one or more DB instances in the filter.

**Basic process for subscribing to Amazon RDS event notifications**

The process for subscribing to Amazon RDS event notification is as follows:

1. You create an Amazon RDS event notification subscription by using the Amazon RDS console, AWS CLI, or API.
   
   Amazon RDS uses the ARN of an Amazon SNS topic to identify each subscription. The Amazon RDS console creates the ARN for you when you create the subscription. Create the ARN by using the Amazon SNS console, the AWS CLI, or the Amazon SNS API.
2. Amazon RDS sends an approval email or SMS message to the addresses you submitted with your subscription.
3. You confirm your subscription by choosing the link in the notification you received.
4. The Amazon RDS console updates the **My Event Subscriptions** section with the status of your subscription.
5. Amazon RDS begins sending the notifications to the addresses that you provided when you created the subscription.

To learn about identity and access management when using Amazon SNS, see [Identity and access management in Amazon SNS](https://docs.aws.amazon.com/sns/latest/dg/sns-access-management.html) in the *Amazon Simple Notification Service Developer Guide*.

You can use AWS Lambda to process event notifications from a DB instance. For more information, see *Using AWS Lambda with Amazon RDS* in the *AWS Lambda Developer Guide*.

**Delivery of RDS event notifications**

Amazon RDS sends notifications to the addresses that you provide when you create the subscription. The notification can include message attributes which provide structured metadata about the message. For more information about message attributes, see *Amazon RDS event categories and event messages* (p. 709).

Event notifications might take up to five minutes to be delivered.

**Important**

Amazon RDS doesn't guarantee the order of events sent in an event stream. The event order is subject to change.

When Amazon SNS sends a notification to a subscribed HTTP or HTTPS endpoint, the POST message sent to the endpoint has a message body that contains a JSON document. For more information, see *Amazon SNS message and JSON formats* in the *Amazon Simple Notification Service Developer Guide*.

You can configure SNS to notify you with text messages. For more information, see *Mobile text messaging (SMS)* in the *Amazon Simple Notification Service Developer Guide*.

To turn off notifications without deleting a subscription, choose **No** for **Enabled** in the Amazon RDS console. Or you can set the **Enabled** parameter to `false` using the AWS CLI or Amazon RDS API.

**Billing for Amazon RDS event notifications**

Billing for Amazon RDS event notification is through Amazon SNS. Amazon SNS fees apply when using event notification. For more information about Amazon SNS billing, see *Amazon Simple Notification Service pricing*. 
Examples of Aurora events

The following examples illustrate different types of Aurora events in JSON format. For a tutorial that shows you how to capture and view events in JSON format, see Tutorial: Log DB instance state changes using Amazon EventBridge (p. 706).

Topics

- Example of a DB cluster event (p. 692)
- Example of a DB instance event (p. 692)
- Example of a DB parameter group event (p. 693)
- Example of a DB cluster snapshot event (p. 693)

Example of a DB cluster event

The following is an example of a DB cluster event in JSON format. The event shows that the cluster named my-db-cluster was patched. The event ID is RDS-EVENT-0173.

```json
{
    "version": "0",
    "id": "844e2571-85d4-695f-b930-0153b71dcb42",
    "detail-type": "RDS DB Cluster Event",
    "source": "aws.rds",
    "account": "123456789012",
    "time": "2018-10-06T12:26:13Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:rds:us-east-1:123456789012:cluster:my-db-cluster"
    ],
    "detail": {
        "EventCategories": [
            "notification"
        ],
        "SourceType": "CLUSTER",
        "SourceArn": "arn:aws:rds:us-east-1:123456789012:cluster:my-db-cluster",
        "Date": "2018-10-06T12:26:13.882Z",
        "Message": "Database cluster has been patched",
        "SourceIdentifier": "my-db-cluster",
        "EventID": "RDS-EVENT-0173"
    }
}
```

Example of a DB instance event

The following is an example of a DB instance event in JSON format. The event shows that RDS performed a multi-AZ failover for the instance named my-db-instance. The event ID is RDS-EVENT-0049.

```json
{
    "version": "0",
    "id": "68f6e973-1a0c-d37b-f2f2-94a7f62fffd4e",
    "detail-type": "RDS DB Instance Event",
    "source": "aws.rds",
    "account": "123456789012",
    "time": "2018-09-27T22:36:43Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:rds:us-east-1:123456789012:db:my-db-instance"
    ],
    "detail": {
```
Example of a DB parameter group event

The following is an example of a DB parameter group event in JSON format. The event shows that the parameter `time_zone` was updated in parameter group `my-db-param-group`. The event ID is RDS-EVENT-0037.

```json
{
  "version": "0",
  "id": "844e2571-85d4-695f-b930-0153b71dcb42",
  "detail-type": "RDS DB Parameter Group Event",
  "source": "aws.rds",
  "account": "123456789012",
  "time": "2018-10-06T12:26:13Z",
  "region": "us-east-1",
  "resources": [
    "arn:aws:rds:us-east-1:123456789012:pg:my-db-param-group"
  ],
  "detail": {
    "EventCategories": ["configuration change"],
    "SourceType": "DB_PARAM",
    "Date": "2018-10-06T12:26:13.882Z",
    "Message": "Updated parameter time_zone to UTC with apply method immediate",
    "SourceIdentifier": "my-db-param-group",
    "EventID": "RDS-EVENT-0037"
  }
}
```

Example of a DB cluster snapshot event

The following is an example of a DB cluster snapshot event in JSON format. The event shows the creation of the snapshot named `my-db-cluster-snapshot`. The event ID is RDS-EVENT-0074.

```json
{
  "version": "0",
  "id": "844e2571-85d4-695f-b930-0153b71dcb42",
  "detail-type": "RDS DB Cluster Snapshot Event",
  "source": "aws.rds",
  "account": "123456789012",
  "time": "2018-10-06T12:26:13Z",
  "region": "us-east-1",
  "resources": [
  ],
  "detail": {
    "EventCategories": ["backup"],
    "SourceType": "CLUSTER_SNAPSHOT"
  }
}
```
"Date": "2018-10-06T12:26:13.882Z",
"SourceIdentifier": "my-db-cluster-snapshot",
"Message": "Creating manual cluster snapshot",
"EventID": "RDS-EVENT-0074"
}
Granting permissions to publish notifications to an Amazon SNS topic

To grant Amazon RDS permissions to publish notifications to an Amazon Simple Notification Service (Amazon SNS) topic, attach an AWS Identity and Access Management (IAM) policy to the destination topic. For more information about permissions, see Example cases for Amazon Simple Notification Service access control in the Amazon Simple Notification Service Developer Guide.

By default, an Amazon SNS topic has a policy allowing all Amazon RDS resources within the same account to publish notifications to it. You can attach a custom policy to allow cross-account notifications, or to restrict access to certain resources.

The following is an example of an IAM policy that you attach to the destination Amazon SNS topic. It restricts the topic to DB instances with names that match the specified prefix. To use this policy, specify the following values:

- **Resource** – The Amazon Resource Name (ARN) for your Amazon SNS topic
- **SourceARN** – Your RDS resource ARN
- **SourceAccount** – Your AWS account ID

To see a list of resource types and their ARNs, see Resources Defined by Amazon RDS in the Service Authorization Reference.

```json
{
    "Version": "2008-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "events.rds.amazonaws.com"
            },
            "Action": [
                "sns:Publish"
            ],
            "Condition": {
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:rds:us-east-1:123456789012:db:prefix-*
                },
                "StringEquals": {
                    "aws:SourceAccount": "123456789012"
                }
            }
        }
    ]
}
```
Subscribing to Amazon RDS event notification

The simplest way to create a subscription is with the RDS console. If you choose to create event notification subscriptions using the CLI or API, you must create an Amazon Simple Notification Service topic and subscribe to that topic with the Amazon SNS console or Amazon SNS API. You will also need to retain the Amazon Resource Name (ARN) of the topic because it is used when submitting CLI commands or API operations. For information on creating an SNS topic and subscribing to it, see Getting started with Amazon SNS in the Amazon Simple Notification Service Developer Guide.

You can specify the type of source you want to be notified of and the Amazon RDS source that triggers the event:

**Source type**

The type of source. For example, **Source type** might be **Instances**. You must choose a source type.

**Resources to include**

The Amazon RDS resources that are generating the events. For example, you might choose **Select specific instances** and then **myDBInstance1**.

The following table explains the result when you specify or don't specify **Resources to include**.

<table>
<thead>
<tr>
<th>Resources to include</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specified</td>
<td>RDS notifies you about all events for the specified resource only.</td>
<td>If your <strong>Source type</strong> is <strong>Instances</strong> and your resource is <strong>myDBInstance1</strong>, RDS notifies you about all events for myDBInstance1 only.</td>
</tr>
<tr>
<td>Not specified</td>
<td>RDS notifies you about the events for the specified source type for all your Amazon RDS resources.</td>
<td>If your <strong>Source type</strong> is <strong>Instances</strong>, RDS notifies you about all instance-related events in your account.</td>
</tr>
</tbody>
</table>

An Amazon SNS topic subscriber receives every message published to the topic by default. To receive only a subset of the messages, the subscriber must assign a filter policy to the topic subscription. For more information about SNS message filtering, see Amazon SNS message filtering in the Amazon Simple Notification Service Developer Guide.

**Console**

**To subscribe to RDS event notification**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In navigation pane, choose **Event subscriptions**.
3. In the **Event subscriptions** pane, choose **Create event subscription**.
4. Enter your subscription details as follows:
   a. For **Name**, enter a name for the event notification subscription.
   b. For **Send notifications to**, do one of the following:
      - Choose **New email topic**. Enter a name for your email topic and a list of recipients. We recommend that you configure the events subscriptions to the same email address as
your primary account contact. The recommendations, service events, and personal health messages are sent using different channels. The subscriptions to the same email address ensures that all the messages are consolidated in one location.

- **Choose Amazon Resource Name (ARN).** Then choose existing Amazon SNS ARN for an Amazon SNS topic.

If you want to use a topic that has been enabled for server-side encryption (SSE), grant Amazon RDS the necessary permissions to access the AWS KMS key. For more information, see Enable compatibility between event sources from AWS services and encrypted topics in the Amazon Simple Notification Service Developer Guide.

c. **For Source type,** choose a source type. For example, choose **Clusters** or **Cluster snapshots**.

d. Choose the event categories and resources that you want to receive event notifications for.

The following example configures event notifications for the DB instance named testinst.

```
Source

Source type
Source type of resource this subscription will consume events from

- Instances

Instances to include
Instances that this subscription will consume events from

- All instances
- Select specific instances

Specific instances
Select instances

- testinst

Event categories to include
Event categories that this subscription will consume events from

- All event categories
- Select specific event categories
```

e. Choose **Create**.

The Amazon RDS console indicates that the subscription is being created.

**AWS CLI**

To subscribe to RDS event notification, use the AWS CLI `create-event-subscription` command. Include the following required parameters:

- `--subscription-name`
- `--sns-topic-arn`
Example

For Linux, macOS, or Unix:

```bash
aws rds create-event-subscription
   --subscription-name myeventsubscription
   --sns-topic-arn arn:aws:sns:us-east-1:123456789012:myawsuser-RDS
   --enabled
```

For Windows:

```bash
aws rds create-event-subscription
   --subscription-name myeventsubscription
   --sns-topic-arn arn:aws:sns:us-east-1:123456789012:myawsuser-RDS
   --enabled
```

API

To subscribe to Amazon RDS event notification, call the Amazon RDS API function `CreateEventSubscription`. Include the following required parameters:

- SubscriptionName
- SnsTopicArn
Amazon RDS event notification tags and attributes

When Amazon RDS sends an event notification to Amazon Simple Notification Service (SNS) or Amazon EventBridge, the notification contains message attributes and event tags. RDS sends the message attributes separately along with the message, while the event tags are in the body of the message. Use the message attributes and the Amazon RDS tags to add metadata to your resources. You can modify these tags with your own notations about the DB instances, Aurora clusters, and so on. For more information about tagging Amazon RDS resources, see Tagging Amazon RDS resources (p. 382).

By default, the Amazon SNS and Amazon EventBridge receives every message sent to them. SNS and EventBridge can filter the message and send the notifications to the preferred communication mode, such as an email, a text message, or a call to an HTTP endpoint.

Note
The notification sent in an email or a text message will not have event tags.

The following table shows the message attributes for RDS events sent to the topic subscriber.

<table>
<thead>
<tr>
<th>Amazon RDS event attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EventID</td>
<td>Identifier for the RDS event message, for example, RDS-EVENT-0006.</td>
</tr>
<tr>
<td>Resource</td>
<td>The ARN identifier for the resource emitting the event, for example, arn:aws:rds:ap-southeast-2:123456789012:db:database-1.</td>
</tr>
</tbody>
</table>

The RDS tags provide data about the resource that was affected by the service event. RDS adds the current state of the tags in the message body when the notification is sent to SNS or EventBridge.

For more information about filtering message attributes for SNS, see Amazon SNS message filtering in the Amazon Simple Notification Service Developer Guide.

For more information about filtering event tags for EventBridge, see Content filtering in Amazon EventBridge event patterns in the Amazon EventBridge User Guide.

For more information about filtering payload-based tags for SNS, see https://aws.amazon.com/blogs/compute/introducing-payload-based-message-filtering-for-amazon-sns/
Listing Amazon RDS event notification subscriptions

You can list your current Amazon RDS event notification subscriptions.

Console

To list your current Amazon RDS event notification subscriptions
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Event subscriptions. The Event subscriptions pane shows all your event notification subscriptions.

AWS CLI

To list your current Amazon RDS event notification subscriptions, use the AWS CLI describe-event-subscriptions command.

Example

The following example describes all event subscriptions.

```
aws rds describe-event-subscriptions
```

The following example describes the myfirsteventsubscription.

```
aws rds describe-event-subscriptions --subscription-name myfirsteventsubscription
```

API

To list your current Amazon RDS event notification subscriptions, call the Amazon RDS API DescribeEventSubscriptions action.
Modifying an Amazon RDS event notification subscription

After you have created a subscription, you can change the subscription name, source identifier, categories, or topic ARN.

Console

To modify an Amazon RDS event notification subscription

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Event subscriptions.
3. In the Event subscriptions pane, choose the subscription that you want to modify and choose Edit.
4. Make your changes to the subscription in either the Target or Source section.
5. Choose Edit. The Amazon RDS console indicates that the subscription is being modified.

AWS CLI

To modify an Amazon RDS event notification subscription, use the AWS CLI modify-event-subscription command. Include the following required parameter:

- --subscription-name

Example

The following code enables myeventsubscription.

For Linux, macOS, or Unix:

```
aws rds modify-event-subscription \\
    --subscription-name myeventsubscription \\
    --enabled
```

For Windows:

```
aws rds modify-event-subscription ^
    --subscription-name myeventsubscription ^
    --enabled
```

API

To modify an Amazon RDS event, call the Amazon RDS API operation ModifyEventSubscription. Include the following required parameter:

- SubscriptionName
Adding a source identifier to an Amazon RDS event notification subscription

You can add a source identifier (the Amazon RDS source generating the event) to an existing subscription.

Console

You can easily add or remove source identifiers using the Amazon RDS console by selecting or deselecting them when modifying a subscription. For more information, see [Modifying an Amazon RDS event notification subscription](p. 701).

AWS CLI

To add a source identifier to an Amazon RDS event notification subscription, use the AWS CLI `add-source-identifier-to-subscription` command. Include the following required parameters:

- `--subscription-name`
- `--source-identifier`

Example

The following example adds the source identifier `mysqldb` to the `myrdseventsubscription` subscription.

For Linux, macOS, or Unix:

```bash
aws rds add-source-identifier-to-subscription \ 
   --subscription-name myrdseventsubscription \ 
   --source-identifier mysql
```

For Windows:

```bash
aws rds add-source-identifier-to-subscription ^
   --subscription-name myrdseventsubscription ^
   --source-identifier mysql
```

API

To add a source identifier to an Amazon RDS event notification subscription, call the Amazon RDS API `AddSourceIdentifierToSubscription`. Include the following required parameters:

- `SubscriptionName`
- `SourceIdentifier`
Removing a source identifier from an Amazon RDS event notification subscription

You can remove a source identifier (the Amazon RDS source generating the event) from a subscription if you no longer want to be notified of events for that source.

**Console**

You can easily add or remove source identifiers using the Amazon RDS console by selecting or deselecting them when modifying a subscription. For more information, see [Modifying an Amazon RDS event notification subscription](p. 701).

**AWS CLI**

To remove a source identifier from an Amazon RDS event notification subscription, use the AWS CLI `remove-source-identifier-from-subscription` command. Include the following required parameters:

- `--subscription-name`
- `--source-identifier`

**Example**

The following example removes the source identifier `mysql`db from the `myrdseventsubscription` subscription.

For Linux, macOS, or Unix:

```bash
aws rds remove-source-identifier-from-subscription \
   --subscription-name myrdseventsubscription \
   --source-identifier mysql
```

For Windows:

```bash
aws rds remove-source-identifier-from-subscription ^
   --subscription-name myrdseventsubscription ^
   --source-identifier mysql
```

**API**

To remove a source identifier from an Amazon RDS event notification subscription, use the Amazon RDS API `RemoveSourceIdentifierFromSubscription` command. Include the following required parameters:

- `SubscriptionName`
- `SourceIdentifier`
Listing the Amazon RDS event notification categories

All events for a resource type are grouped into categories. To view the list of categories available, use the following procedures.

**Console**

When you create or modify an event notification subscription, the event categories are displayed in the Amazon RDS console. For more information, see [Modifying an Amazon RDS event notification subscription](p. 701).

**AWS CLI**

To list the Amazon RDS event notification categories, use the AWS CLI `describe-event-categories` command. This command has no required parameters.

**Example**

```
aws rds describe-event-categories
```

**API**

To list the Amazon RDS event notification categories, use the Amazon RDS API `DescribeEventCategories` command. This command has no required parameters.
Deleting an Amazon RDS event notification subscription

You can delete a subscription when you no longer need it. All subscribers to the topic will no longer receive event notifications specified by the subscription.

Console

To delete an Amazon RDS event notification subscription

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose DB Event Subscriptions.
3. In the My DB Event Subscriptions pane, choose the subscription that you want to delete.
4. Choose Delete.
5. The Amazon RDS console indicates that the subscription is being deleted.

AWS CLI

To delete an Amazon RDS event notification subscription, use the AWS CLI delete-event-subscription command. Include the following required parameter:

- --subscription-name

Example

The following example deletes the subscription myrdssubscription.

```
aws rds delete-event-subscription --subscription-name myrdssubscription
```

API

To delete an Amazon RDS event notification subscription, use the RDS API DeleteEventSubscription command. Include the following required parameter:

- SubscriptionName
Creating a rule that triggers on an Amazon Aurora event

Using Amazon CloudWatch Events and Amazon EventBridge, you can automate AWS services and respond to system events such as application availability issues or resource changes.

Topics
- Tutorial: Log DB instance state changes using Amazon EventBridge (p. 706)

Tutorial: Log DB instance state changes using Amazon EventBridge

In this tutorial, you create an AWS Lambda function that logs the state changes for an instance. You then create a rule that runs the function whenever there is a state change of an existing RDS DB instance. The tutorial assumes that you have a small running test instance that you can shut down temporarily.

**Important**
Don’t perform this tutorial on a running production DB instance.

Topics
- Step 1: Create an AWS Lambda function (p. 706)
- Step 2: Create a rule (p. 707)
- Step 3: Test the rule (p. 707)

Step 1: Create an AWS Lambda function

Create a Lambda function to log the state change events. You specify this function when you create your rule.

To create a Lambda function

1. Open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. If you're new to Lambda, you see a welcome page. Choose Get Started Now. Otherwise, choose Create function.
3. Choose Author from scratch.
4. On the Create function page, do the following:
   a. Enter a name and description for the Lambda function. For example, name the function RDSInstanceStateChange.
   b. In Runtime, select Node.js 16x.
   c. For Architecture, choose x86_64.
   d. For Execution role, do either of the following:
      - Choose Create a new role with basic Lambda permissions.
      - For Existing role, choose Use an existing role. Choose the role that you want to use.
   e. Choose Create function.
5. On the RDSInstanceStateChange page, do the following:
   a. In Code source, select index.js.
   b. In the index.js pane, delete the existing code.
   c. Enter the following code:
console.log('Loading function');
exports.handler = async (event, context) => {
    console.log('Received event: ', JSON.stringify(event));
};

d. Choose Deploy.

**Step 2: Create a rule**

Create a rule to run your Lambda function whenever you launch an Amazon RDS instance.

**To create the EventBridge rule**

1. Open the Amazon EventBridge console at [https://console.aws.amazon.com/events/](https://console.aws.amazon.com/events/).
2. In the navigation pane, choose Rules.
3. Choose Create rule.
4. Enter a name and description for the rule. For example, enter **RDSInstanceStateChangeRule**.
5. Choose Rule with an event pattern, and then choose Next.
6. For Event source, choose AWS events or EventBridge partner events.
7. Scroll down to the Event pattern section.
8. For Event source, choose AWS services.
9. For AWS service, choose Relational Database Service (RDS).
10. For Event type, choose RDS DB Instance Event.
11. Leave the default event pattern. Then choose Next.
12. For Target types, choose AWS service.
13. For Select a target, choose Lambda function.
14. For Function, choose the Lambda function that you created. Then choose Next.
15. In Configure tags, choose Next.
16. Review the steps in your rule. Then choose Create rule.

**Step 3: Test the rule**

To test your rule, shut down an RDS DB instance. After waiting a few minutes for the instance to shut down, verify that your Lambda function was invoked.

**To test your rule by stopping a DB instance**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Stop an RDS DB instance.
3. Open the Amazon EventBridge console at [https://console.aws.amazon.com/events/](https://console.aws.amazon.com/events/).
4. In the navigation pane, choose Rules, choose the name of the rule that you created.
5. In Rule details, choose Monitoring.

You are redirected to the Amazon CloudWatch console. If you are not redirected, click View the metrics in CloudWatch.
6. In All metrics, choose the name of the rule that you created.

The graph should indicate that the rule was invoked.
7. In the navigation pane, choose Log groups.
8. Choose the name of the log group for your Lambda function (/aws/lambda/function-name).

9. Choose the name of the log stream to view the data provided by the function for the instance that you launched. You should see a received event similar to the following:

```json
{
    "version": "0",
    "id": "12a345b6-78c9-01d2-34e5-123f4ghi5j6k",
    "detail-type": "RDS DB Instance Event",
    "source": "aws.rds",
    "account": "111111111111",
    "time": "2021-03-19T19:34:09Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:rds:us-east-1:111111111111:db:testdb"
    ],
    "detail": {
        "EventCategories": [
            "notification"
        ],
        "SourceType": "DB_INSTANCE",
        "Date": "2021-03-19T19:34:09.293Z",
        "Message": "DB instance stopped",
        "SourceIdentifier": "testdb",
        "EventID": "RDS-EVENT-0087"
    }
}
```

For more examples of RDS events in JSON format, see [Overview of events for Aurora](p. 685).

10. (Optional) When you're finished, you can open the Amazon RDS console and start the instance that you stopped.
Amazon RDS event categories and event messages

Amazon RDS generates a significant number of events in categories that you can subscribe to using the Amazon RDS Console, AWS CLI, or the API.

**Topics**

- **DB cluster events** (p. 709)
- **DB instance events** (p. 713)
- **DB parameter group events** (p. 718)
- **DB security group events** (p. 718)
- **DB cluster snapshot events** (p. 718)
- **RDS Proxy events** (p. 719)
- **Blue/green deployment events** (p. 720)

### DB cluster events

The following table shows the event category and a list of events when a DB cluster is the source type.

**Note**

No event category exists for Aurora Serverless in the DB cluster event type. The Aurora Serverless events range from RDS-EVENT-0141 to RDS-EVENT-0149.

<table>
<thead>
<tr>
<th>Category</th>

</tr>
</tbody>
</table>

### DB security group events

The following table shows the event category and a list of events when a DB security group is the source type.

**Note**

DB security groups are resources for EC2-Classic. EC2-Classic was retired on August 15, 2022. If you haven’t migrated from EC2-Classic to a VPC, we recommend that you migrate as soon as possible. For more information, see Migrate from EC2-Classic to a VPC in the Amazon EC2 User Guide and the blog EC2-Classic Networking is Retiring – Here’s How to Prepare.

<table>
<thead>
<tr>
<th>Category</th>

</table>
Monitoring Amazon Aurora log files

Every RDS database engine generates logs that you can access for auditing and troubleshooting. The type of logs depends on your database engine.

You can access database logs using the AWS Management Console, the AWS Command Line Interface (AWS CLI), or the Amazon RDS API. You can't view, watch, or download transaction logs.

**Note**
In some cases, logs contain hidden data. Therefore, the AWS Management Console might show content in a log file, but the log file might be empty when you download it.

**Topics**
- Viewing and listing database log files (p. 722)
- Downloading a database log file (p. 723)
- Watching a database log file (p. 724)
- Publishing database logs to Amazon CloudWatch Logs (p. 726)
- Reading log file contents using REST (p. 727)
- Aurora MySQL database log files (p. 729)
- Aurora PostgreSQL database log files (p. 735)

**Viewing and listing database log files**

You can view database log files for your Amazon Aurora DB engine by using the AWS Management Console. You can list what log files are available for download or monitoring by using the AWS CLI or Amazon RDS API.

**Note**
You can't view the log files for Aurora Serverless v1 DB clusters in the RDS console. However, you can view them in the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

**Console**

**To view a database log file**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the **Logs & events** tab.
5. Scroll down to the **Logs** section.
6. (Optional) Enter a search term to filter your results.

   The following example lists logs filtered by the text **error**.
7. Choose the log that you want to view, and then choose View.

**AWS CLI**

To list the available database log files for a DB instance, use the AWS CLI `describe-db-log-files` command.

The following example returns a list of log files for a DB instance named `my-db-instance`.

**Example**

```
aws rds describe-db-log-files --db-instance-identifier my-db-instance
```

**RDS API**

To list the available database log files for a DB instance, use the Amazon RDS API `DescribeDBLogFileEvents` action.

**Downloading a database log file**

You can use the AWS Management Console, AWS CLI, or API to download a database log file.

**Console**

**To download a database log file**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Databases.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the Logs & events tab.
5. Scroll down to the Logs section.
6. In the Logs section, choose the button next to the log that you want to download, and then choose Download.
7. Open the context (right-click) menu for the link provided, and then choose Save Link As. Enter the location where you want the log file to be saved, and then choose Save.
To download a database log file, use the AWS CLI command `download-db-log-file-portion`. By default, this command downloads only the latest portion of a log file. However, you can download an entire file by specifying the parameter `--starting-token 0`.

The following example shows how to download the entire contents of a log file called `log/ERROR.4` and store it in a local file called `errorlog.txt`.

**Example**

For Linux, macOS, or Unix:

```
aws rds download-db-log-file-portion \
   --db-instance-identifier myexampledb \
   --starting-token 0 --output text \
   --log-file-name log/ERROR.4 > errorlog.txt
```

For Windows:

```
aws rds download-db-log-file-portion ^
   --db-instance-identifier myexampledb ^
   --starting-token 0 --output text ^
   --log-file-name log/ERROR.4 > errorlog.txt
```

To download a database log file, use the Amazon RDS API `DownloadDBLogFilePortion` action.

**Watching a database log file**

Watching a database log file is equivalent to tailing the file on a UNIX or Linux system. You can watch a log file by using the AWS Management Console. RDS refreshes the tail of the log every 5 seconds.

**To watch a database log file**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the **Logs & events** tab.
5. In the Logs section, choose a log file, and then choose Watch.

RDS shows the tail of the log, as in the following MySQL example.
Publishing database logs to Amazon CloudWatch Logs

In an on-premises database, the database logs reside on the file system. Amazon RDS doesn't provide host access to the database logs on the file system of your DB cluster. For this reason, Amazon RDS lets you export database logs to Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data. You can also store the data in highly durable storage and manage the data with the CloudWatch Logs Agent.

Topics

- Overview of RDS integration with CloudWatch Logs (p. 726)
- Deciding which logs to publish to CloudWatch Logs (p. 726)
- Specifying the logs to publish to CloudWatch Logs (p. 726)
- Searching and filtering your logs in CloudWatch Logs (p. 727)

Overview of RDS integration with CloudWatch Logs

In CloudWatch Logs, a log stream is a sequence of log events that share the same source. Each separate source of logs in CloudWatch Logs makes up a separate log stream. A log group is a group of log streams that share the same retention, monitoring, and access control settings.

Amazon Aurora continuously streams your DB cluster log records to a log group. For example, you have a log group /aws/rds/cluster/cluster_name/log_type for each type of log that you publish. This log group is in the same AWS Region as the database instance that generates the log.

AWS retains log data published to CloudWatch Logs for an indefinite time period unless you specify a retention period. For more information, see Change log data retention in CloudWatch Logs.

Deciding which logs to publish to CloudWatch Logs

Each RDS database engine supports its own set of logs. To learn about the options for your database engine, review the following topics:

- the section called “Publishing Aurora MySQL logs to CloudWatch Logs” (p. 1083)
- the section called “Publishing Aurora PostgreSQL logs to CloudWatch Logs” (p. 1548)

Specifying the logs to publish to CloudWatch Logs

You specify which logs to publish in the console. Make sure that you have a service-linked role in AWS Identity and Access Management (IAM). For more information about service-linked roles, see Using service-linked roles for Amazon Aurora (p. 2475).

To specify the logs to publish

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Do either of the following:
   - Choose Create database.
   - Choose a database from the list, and then choose Modify.
4. In Logs exports, choose which logs to publish.
The following example specifies the audit log, error logs, general log, and slow query log.

```
Log exports

Select the log types to publish to Amazon CloudWatch Logs

- Audit log
- Error log
- General log
- Slow query log

IAM role
The following service-linked role is used for publishing logs to CloudWatch Logs.

RDS Service Linked Role

Ensure that General, Slow Query and Audit Logs are turned on. Error logs are enabled by default.
```

**Searching and filtering your logs in CloudWatch Logs**

You can search for log entries that meet a specified criteria using the CloudWatch Logs console. You can access the logs either through the RDS console, which leads you to the CloudWatch Logs console, or from the CloudWatch Logs console directly.

**To search your RDS logs using the RDS console**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose a DB cluster or a DB instance.
4. Choose **Configuration**.
5. Under **Published logs**, choose the database log that you want to view.

**To search your RDS logs using the CloudWatch Logs console**

2. In the navigation pane, choose **Log groups**.
3. In the filter box, enter `/aws/rds`.
4. For **Log Groups**, choose the name of the log group containing the log stream to search.
5. For **Log Streams**, choose the name of the log stream to search.
6. Under **Log events**, enter the filter syntax to use.

**Reading log file contents using REST**

Amazon RDS provides a REST endpoint that allows access to DB instance log files. This is useful if you need to write an application to stream Amazon RDS log file contents.
The syntax is:

```
GET /v13/downloadCompleteLogFile/DBInstanceIdentifier/LogFileName HTTP/1.1
Content-type: application/json
host: rds.region.amazonaws.com
```

The following parameters are required:

- **DBInstanceIdentifier**—the name of the DB instance that contains the log file you want to download.
- **LogFileName**—the name of the log file to be downloaded.

The response contains the contents of the requested log file, as a stream.

The following example downloads the log file named `log/ERROR.6` for the DB instance named `sample-sql` in the `us-west-2` region.

```
GET /v13/downloadCompleteLogFile/sample-sql/log/ERROR.6 HTTP/1.1
host: rds.us-west-2.amazonaws.com
X-Amz-Security-Token: AQoDYXdzEIH/////////
wEa0AIXLhng5zp9Cy81R6abwKt/XHVR5efnAWN3Xv7IwqKYalSfn6UyJufEFTft9nObglx4QJ+GVV9cpACkETq=
X-Amz-Date: 20140903T233749Z
X-Amz-Algorithm: AWS4-HMAC-SHA256
X-Amz-Credential: AKIADQKE4SARGYLE/20140903/us-west-2/rds/aws4_request
X-Amz-SignedHeaders: host
X-Amz-Content-SHA256: e3b0c44298fc1c229afbf4c8996fb92427ae41e4649b934de495991b7852b855
X-Amz-Expires: 86400
X-Amz-Signature: 353a4f14b3f250142d9afc34f9f9948154d6ce7d4ec091d0cdabbcd88b40c558
```

If you specify a nonexistent DB instance, the response consists of the following error:

- **DBInstanceNotFound**—**DBInstanceIdentifier** does not refer to an existing DB instance. (HTTP status code: 404)
Aurora MySQL database log files

You can monitor the Aurora MySQL logs directly through the Amazon RDS console, Amazon RDS API, AWS CLI, or AWS SDKs. You can also access MySQL logs by directing the logs to a database table in the main database and querying that table. You can use the mysqlbinlog utility to download a binary log.

For more information about viewing, downloading, and watching file-based database logs, see Monitoring Amazon Aurora log files (p. 722).

Topics
- Overview of Aurora MySQL database logs (p. 729)
- Publishing Aurora MySQL logs to Amazon CloudWatch Logs (p. 731)
- Managing table-based Aurora MySQL logs (p. 731)
- Configuring Aurora MySQL binary logging (p. 732)
- Accessing MySQL binary logs (p. 733)

Overview of Aurora MySQL database logs

You can monitor the following types of Aurora MySQL log files:

- Error log
- Slow query log
- General log
- Audit log

The Aurora MySQL error log is generated by default. You can generate the slow query and general logs by setting parameters in your DB parameter group.

Topics
- Aurora MySQL error logs (p. 729)
- Aurora MySQL slow query and general logs (p. 730)
- Aurora MySQL audit log (p. 730)
- Log rotation and retention for Aurora MySQL (p. 730)

Aurora MySQL error logs

Aurora MySQL writes errors in the mysql-error.log file. Each log file has the hour it was generated (in UTC) appended to its name. The log files also have a timestamp that helps you determine when the log entries were written.

Aurora MySQL writes to the error log only on startup, shutdown, and when it encounters errors. A DB instance can go hours or days without new entries being written to the error log. If you see no recent entries, it's because the server didn't encounter an error that would result in a log entry.

By design, the error logs are filtered so that only unexpected events such as errors are shown. However, the error logs also contain some additional database information, for example query progress, which isn't shown. Therefore, even without any actual errors the size of the error logs might increase because of ongoing database activities. And while you might see a certain size in bytes or kilobytes for the error logs in the AWS Management Console, they might have 0 bytes when you download them.

Aurora MySQL writes mysql-error.log to disk every 5 minutes. It appends the contents of the log to mysql-error-running.log.
Aurora MySQL rotates the mysql-error-running.log file every hour.

**Note**
The log retention period is different between Amazon RDS and Aurora.

### Aurora MySQL slow query and general logs

You can write the Aurora MySQL slow query log and the general log to a file or a database table. To do so, set parameters in your DB parameter group. For information about creating and modifying a DB parameter group, see [Working with parameter groups](#). You must set these parameters before you can view the slow query log or general log in the Amazon RDS console or by using the Amazon RDS API, Amazon RDS CLI, or AWS SDKs.

You can control Aurora MySQL logging by using the parameters in this list:

- slow_query_log: To create the slow query log, set to 1. The default is 0.
- general_log: To create the general log, set to 1. The default is 0.
- long_query_time: To prevent fast-running queries from being logged in the slow query log, specify a value for the shortest query runtime to be logged, in seconds. The default is 10 seconds; the minimum is 0. If log_output = FILE, you can specify a floating point value that goes to microsecond resolution. If log_output = TABLE, you must specify an integer value with second resolution. Only queries whose runtime exceeds the long_query_time value are logged. For example, setting long_query_time to 0.1 prevents any query that runs for less than 100 milliseconds from being logged.
- log_queries_not_using_indexes: To log all queries that do not use an index to the slow query log, set to 1. Queries that don't use an index are logged even if their runtime is less than the value of the long_query_time parameter. The default is 0.
- log_output option: You can specify one of the following options for the log_output parameter.
  - TABLE – Write general queries to the mysql.general_log table, and slow queries to the mysql.slow_log table.
  - FILE – Write both general and slow query logs to the file system.
  - NONE – Disable logging.

For Aurora MySQL version 2, the default for log_output is FILE.

For more information about the slow query and general logs, go to the following topics in the MySQL documentation:

- [The slow query log](#)
- [The general query log](#)

### Aurora MySQL audit log

Audit logging for Aurora MySQL is called Advanced Auditing. To turn on Advanced Auditing, you set certain DB cluster parameters. For more information, see [Using Advanced Auditing with an Amazon Aurora MySQL DB cluster](#).

### Log rotation and retention for Aurora MySQL

When logging is enabled, Amazon Aurora rotates or deletes log files at regular intervals. This measure is a precaution to reduce the possibility of a large log file either blocking database use or affecting performance. Aurora MySQL handles rotation and deletion as follows:

- The Aurora MySQL error log file sizes are constrained to no more than 15 percent of the local storage for a DB instance. To maintain this threshold, logs are automatically rotated every hour. Aurora MySQL
removes logs after 30 days or when 15% of disk space is reached. If the combined log file size exceeds the threshold after removing old log files, then the oldest log files are deleted until the log file size no longer exceeds the threshold.

- Aurora MySQL removes the audit, general, and slow query logs after either 24 hours or when 15% of storage has been consumed.
- When FILE logging is enabled, general log and slow query log files are examined every hour and log files more than 24 hours old are deleted. In some cases, the remaining combined log file size after the deletion might exceed the threshold of 15 percent of a DB instance's local space. In these cases, the oldest log files are deleted until the log file size no longer exceeds the threshold.
- When TABLE logging is enabled, log tables aren't rotated or deleted. Log tables are truncated when the size of all logs combined is too large. You can subscribe to the low_free_storage event to be notified when log tables should be manually rotated or deleted to free up space. For more information, see Working with Amazon RDS event notification (p. 690).

You can rotate the mysql.general_log table manually by calling the mysql.rds_rotate_general_log procedure. You can rotate the mysql.slow_log table by calling the mysql.rds_rotate_slow_log procedure.

When you rotate log tables manually, the current log table is copied to a backup log table and the entries in the current log table are removed. If the backup log table already exists, then it is deleted before the current log table is copied to the backup. You can query the backup log table if needed. The backup log table for the mysql.general_log table is named mysql.general_log_backup. The backup log table for the mysql.slow_log table is named mysql.slow_log_backup.

- The Aurora MySQL audit logs are rotated when the file size reaches 100 MB, and removed after 24 hours.

To work with the logs from the Amazon RDS console, Amazon RDS API, Amazon RDS CLI, or AWS SDKs, set the log_output parameter to FILE. Like the Aurora MySQL error log, these log files are rotated hourly. The log files that were generated during the previous 24 hours are retained. Note that the retention period is different between Amazon RDS and Aurora.

**Publishing Aurora MySQL logs to Amazon CloudWatch Logs**

You can configure your Aurora MySQL DB cluster to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage. For more information, see Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs (p. 1083).

**Managing table-based Aurora MySQL logs**

You can direct the general and slow query logs to tables on the DB instance by creating a DB parameter group and setting the log_output server parameter to TABLE. General queries are then logged to the mysql.general_log table, and slow queries are logged to the mysql.slow_log table. You can query the tables to access the log information. Enabling this logging increases the amount of data written to the database, which can degrade performance.

Both the general log and the slow query logs are disabled by default. In order to enable logging to tables, you must also set the general_log and slow_query_log server parameters to 1.

Log tables keep growing until the respective logging activities are turned off by resetting the appropriate parameter to 0. A large amount of data often accumulates over time, which can use up a considerable percentage of your allocated storage space. Amazon Aurora doesn't allow you to truncate the log tables, but you can move their contents. Rotating a table saves its contents to a backup table and then creates a new empty log table. You can manually rotate the log tables with the following command line procedures, where the command prompt is indicated by PROMPT>: 
To completely remove the old data and reclaim the disk space, call the appropriate procedure twice in succession.

### Configuring Aurora MySQL binary logging

The **binary log** is a set of log files that contain information about data modifications made to an Aurora MySQL server instance. The binary log contains information such as the following:

- Events that describe database changes such as table creation or row modifications
- Information about the duration of each statement that updated data
- Events for statements that could have updated data but didn’t

The binary log records statements that are sent during replication. It is also required for some recovery operations. For more information, see The Binary Log and Binary Log Overview in the MySQL documentation.

Binary logs are accessible only from the primary DB instance, not from the replicas.

MySQL on Amazon Aurora supports the *row-based*, statement-based, and mixed binary logging formats. We recommend mixed unless you need a specific binlog format. For details on the different Aurora MySQL binary log formats, see Binary logging formats in the MySQL documentation.

If you plan to use replication, the binary logging format is important because it determines the record of data changes that is recorded in the source and sent to the replication targets. For information about the advantages and disadvantages of different binary logging formats for replication, see Advantages and disadvantages of statement-based and row-based replication in the MySQL documentation.

**Important**

Setting the binary logging format to row-based can result in very large binary log files. Large binary log files reduce the amount of storage available for a DB cluster and can increase the amount of time to perform a restore operation of a DB cluster.

Statement-based replication can cause inconsistencies between the source DB cluster and a read replica. For more information, see Determination of safe and unsafe statements in binary logging in the MySQL documentation.

Enabling binary logging increases the number of write disk I/O operations to the DB cluster. You can monitor IOPS usage with the VolumeWriteIOPs CloudWatch metric.

### To set the MySQL binary logging format

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Parameter groups**.
3. Choose the parameter group used by the DB cluster you want to modify.

   You can’t modify a default parameter group. If the DB cluster is using a default parameter group, create a new parameter group and associate it with the DB cluster.

   For more information on parameter groups, see Working with parameter groups (p. 212).

4. From **Parameter group actions**, choose **Edit**.
5. Set the `binlog_format` parameter to the binary logging format of your choice (ROW, STATEMENT, or MIXED). You can also use the value OFF to turn off binary logging.
6. Choose **Save changes** to save the updates to the DB cluster parameter group.
After you perform these steps, you must reboot the writer instance in the DB cluster for your changes to apply. In Aurora MySQL version 2.09 and lower, when you reboot the writer instance, all of the reader instances in the DB cluster are also rebooted. In Aurora MySQL version 2.10 and higher, you must reboot all of the reader instances manually. For more information, see Rebooting an Amazon Aurora DB cluster or Amazon Aurora DB instance (p. 358).

**Important**

Changing a DB cluster parameter group affects all DB clusters that use that parameter group. If you want to specify different binary logging formats for different Aurora MySQL DB clusters in an AWS Region, the DB clusters must use different DB cluster parameter groups. These parameter groups identify different logging formats. Assign the appropriate DB cluster parameter group to each DB clusters. For more information about Aurora MySQL parameters, see Aurora MySQL configuration parameters (p. 1115).

### Accessing MySQL binary logs

You can use the mysqlbinlog utility to download or stream binary logs from RDS for MySQL DB instances. The binary log is downloaded to your local computer, where you can perform actions such as replaying the log using the mysql utility. For more information about using the mysqlbinlog utility, see Using mysqlbinlog to back up binary log files in the MySQL documentation.

To run the mysqlbinlog utility against an Amazon RDS instance, use the following options:

- `--read-from-remote-server` – Required.
- `--host` – The DNS name from the endpoint of the instance.
- `--port` – The port used by the instance.
- `--user` – A MySQL user that has been granted the REPLICATION SLAVE permission.
- `--password` – The password for the MySQL user, or omit a password value so that the utility prompts you for a password.
- `--raw` – Download the file in binary format.
- `--result-file` – The local file to receive the raw output.
- `--stop-never` – Stream the binary log files.
- `--verbose` – When you use the ROW binlog format, include this option to see the row events as pseudo-SQL statements. For more information on the `--verbose` option, see mysqlbinlog row event display in the MySQL documentation.
- Specify the names of one or more binary log files. To get a list of the available logs, use the SQL command `SHOW BINARY LOGS`.

For more information about mysqlbinlog options, see mysqlbinlog — Utility for processing binary log files in the MySQL documentation.

The following examples show how to use the mysqlbinlog utility.

For Linux, macOS, or Unix:

```bash
mysqlbinlog
    --read-from-remote-server
    --host=MySQLInstance1.cg034hpkmjt.region.rds.amazonaws.com
    --port=3306
    --user ReplUser
    --password
    --raw
    --verbose
    --result-file=/tmp/
    binlog.00098
```
For Windows:

```
mysqlbinlog ^
   --read-from-remote-server ^
   --host=MySQLInstance1.cg034hpkmjtt.region.rds.amazonaws.com ^
   --port=3306 ^
   --user ReplUser ^
   --password ^
   --raw ^
   --verbose ^
   --result-file=/tmp/ ^
binlog.00098
```

Amazon RDS normally purges a binary log as soon as possible, but the binary log must still be available on the instance to be accessed by mysqlbinlog. To specify the number of hours for RDS to retain binary logs, use the `mysql.rds_set_configuration` (p. 1166) stored procedure and specify a period with enough time for you to download the logs. After you set the retention period, monitor storage usage for the DB instance to ensure that the retained binary logs don't take up too much storage.

The following example sets the retention period to 1 day.

```
call mysql.rds_set_configuration('binlog retention hours', 24);
```

To display the current setting, use the `mysql.rds_show_configuration` (p. 1167) stored procedure.

```
call mysql.rds_show_configuration;
```
Aurora PostgreSQL database log files

Aurora PostgreSQL logs database activities to the default PostgreSQL log file. For an on-premises PostgreSQL DB instance, these messages are stored locally in `log/postgresql.log`. For an Aurora PostgreSQL DB cluster, the log file is available on the Aurora cluster. Also, you must use the Amazon RDS Console to view or download its contents. The default logging level captures login failures, fatal server errors, deadlocks, and query failures.

For more information about how you can view, download, and watch file-based database logs, see Monitoring Amazon Aurora log files (p. 722). To learn more about PostgreSQL logs, see Working with Amazon RDS and Aurora PostgreSQL logs: Part 1 and Working with Amazon RDS and Aurora PostgreSQL logs: Part 2.

In addition to the standard PostgreSQL logs discussed in this topic, Aurora PostgreSQL also supports the PostgreSQL Audit extension (pgAudit). Most regulated industries and government agencies need to maintain an audit log or audit trail of changes made to data to comply with legal requirements. For information about installing and using pgAudit, see Using pgAudit to log database activity (p. 1635).

**Topics**
- Parameters that affect logging behavior (p. 735)
- Turning on query logging for your Aurora PostgreSQL DB cluster (p. 738)

### Parameters that affect logging behavior

You can customize the logging behavior for your Aurora PostgreSQL DB cluster by modifying various parameters. In the following table you can find the parameters that affect how long the logs are stored, when to rotate the log, and whether to output the log as a CSV (comma-separated value) format.

You can also find the text output sent to STDERR, among other settings. To change settings for the parameters that are modifiable, use a custom DB cluster parameter group for your Aurora PostgreSQL DB cluster. For more information, see Working with parameter groups (p. 212). As noted in the table, the log_line_prefix can't be changed.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>log_destination</td>
<td>stderr</td>
<td>Sets the output format for the log. The default is stderr but you can also specify comma-separated value (CSV) by adding csvlog to the setting. For more information, see Setting the log destination (stderr, csvlog) (p. 737)</td>
</tr>
<tr>
<td>log_filename</td>
<td>postgresql.log.%Y-%m-%d-%H%M</td>
<td>Specifies the pattern for the log file name. In addition to the default, this parameter supports postgresql.log.%Y-%m-%d and postgresql.log.%Y-%m-%d-%H for the filename pattern.</td>
</tr>
<tr>
<td>log_line_prefix</td>
<td>%t:%r:%u@%d:[%p]:</td>
<td>Defines the prefix for each log line that gets written to stderr, to note the time (%t), remote host (%r), user (%u), database (%d), and process ID (%p). You can't modify this parameter.</td>
</tr>
<tr>
<td>log_rotation_age</td>
<td>60</td>
<td>Minutes after which log file is automatically rotated. You can change this value to between 1 and 1440 minutes. For more information, see Setting log file rotation (p. 737).</td>
</tr>
</tbody>
</table>
### Parameter | Default | Description
--- | --- | ---
log_rotation_size | – | The size (kB) at which the log is automatically rotated. By default, this parameter isn’t used because logs are rotated based on the log_rotation_age parameter. To learn more, see Setting log file rotation (p. 737).

rds.log_retention_period | 4320 | PostgreSQL logs that are older than the specified number of minutes are deleted. The default value of 4320 minutes deletes log files after 3 days. For more information, see Setting the log retention period (p. 736).

To identify application issues, you can look for query failures, login failures, deadlocks, and fatal server errors in the log. For example, suppose that you converted a legacy application from Oracle to Aurora PostgreSQL, but not all queries converted correctly. These incorrectly formatted queries generate error messages that you can find in the logs to help identify problems. For more information about logging queries, see Turning on query logging for your Aurora PostgreSQL DB cluster (p. 738).

In the following topics, you can find information about how to set various parameters that control the basic details for your PostgreSQL logs.

**Topics**

- Setting the log retention period (p. 736)
- Setting log file rotation (p. 737)
- Setting the log destination (stderr, csvlog) (p. 737)
- Understanding the log_line_prefix parameter (p. 738)

### Setting the log retention period

The rds.log_retention_period parameter specifies how long your Aurora PostgreSQL DB cluster keeps its log files. The default setting is 3 days (4,320 minutes), but you can set this value to anywhere from 1 day (1,440 minutes) to 7 days (10,080 minutes). Be sure that your Aurora PostgreSQL DB cluster has sufficient storage to hold the log files for the period of time.

We recommend that you have your logs routinely published to Amazon CloudWatch Logs so that you can view and analyze system data long after the logs have been removed from your Aurora PostgreSQL DB cluster. For more information, see Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs (p. 1548). After you set up CloudWatch publishing, Aurora doesn’t delete a log until after it’s published to CloudWatch Logs.

Amazon Aurora compresses older PostgreSQL logs when storage for the DB instance reaches a threshold. Aurora compresses the files using the gzip compression utility. For more information, see the gzip website.

When storage for the DB instance is low and all available logs are compressed, you get a warning such as the following:

**Warning:** local storage for PostgreSQL log files is critically low for this Aurora PostgreSQL instance, and could lead to a database outage.

If there's not enough storage, Aurora might delete compressed PostgreSQL logs before the end of a specified retention period. If that happens, you see a message similar to the following:
Amazon Aurora User Guide for Aurora
PostgreSQL database log files

The oldest PostgreSQL log files were deleted due to local storage constraints.

Setting log file rotation

Aurora creates new log files every hour by default. The timing is controlled by the log_rotation_age parameter. This parameter has a default value of 60 (minutes), but you can set it to anywhere from 1 minute to 24 hours (1,440 minutes). When it's time for rotation, a new distinct log file is created. The file is named according to the pattern specified by the log_filename parameter.

Log files can also be rotated according to their size, as specified in the log_rotation_size parameter. This parameter specifies that the log should be rotated when it reaches the specified size (in kilobytes). The default log_rotation_size is 100000 kB (kilobytes) for an Aurora PostgreSQL DB cluster, but you can set this value to anywhere from 50,000 to 1,000,000 kilobytes.

The log file names are based on the file name pattern specified in the log_filename parameter. The available settings for this parameter are as follows:

- postgresql.log.%Y-%m-%d – Default format for the log file name. Includes the year, month, and date in the name of the log file.
- postgresql.log.%Y-%m-%d-%H – Includes the hour in the log file name format.
- postgresql.log.%Y-%m-%d-%H%M – Includes hour:minute in the log file name format.

If you set log_rotation_age parameter to less than 60 minutes, set the log_filename parameter to the minute format.

For more information, see log_rotation_age and log_rotation_size in the PostgreSQL documentation.

Setting the log destination (stderr, csvlog)

By default, Aurora PostgreSQL generates logs in standard error (stderr) format. This format is the default setting for the log_destination parameter. Each message is prefixed using the pattern specified in the log_line_prefix parameter. For more information, see Understanding the log_line_prefix parameter (p. 738).

Aurora PostgreSQL can also generate the logs in csvlog format. The csvlog is useful for analyzing the log data as comma-separated values (CSV) data. For example, suppose that you use the log_fdw extension to work with your logs as foreign tables. The foreign table created on stderr log files contains a single column with log event data. By adding csvlog to the log_destination parameter, you get the log file in the CSV format with demarcations for the multiple columns of the foreign table. You can now sort and analyze your logs more easily.

If you specify csvlog for this parameter, be aware that both stderr and csvlog files are generated. Be sure to monitor the storage consumed by the logs, taking into account the rds.log_retention_period and other settings that affect log storage and turnover. Using stderr and csvlog more than doubles the storage consumed by the logs.

If you add csvlog to log_destination and you want to revert to the stderr alone, you need to reset the parameter. To do so, open the Amazon RDS Console and then open the custom DB cluster parameter group for your instance. Choose the log_destination parameter, choose Edit parameter, and then choose Reset.

For more information about configuring logging, see Working with Amazon RDS and Aurora PostgreSQL logs: Part 1.
Understanding the log_line_prefix parameter

The stderr log format prefixes each log message with the details specified by the log_line_prefix parameter, as follows.

%t: %r: %u@%d: [%p]: t

You can't change this setting. Each log entry sent to stderr includes the following information.

- %t – Time of log entry
- %r – Remote host address
- %u@%d – User name @ database name
- [%p] – Process ID if available

Turning on query logging for your Aurora PostgreSQL DB cluster

You can collect more detailed information about your database activities, including queries, queries waiting for locks, checkpoints, and many other details by setting some of the parameters listed in the following table. This topic focuses on logging queries.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>log_connections</td>
<td>–</td>
<td>Logs each successful connection. To learn how to use this parameter with log_disconnections to detect connection churn, see Managing Aurora PostgreSQL connection churn with pooling (p. 1482).</td>
</tr>
<tr>
<td>log_disconnections</td>
<td>–</td>
<td>Logs the end of each session and its duration. To learn how to use this parameter with log_connections to detect connection churn, see Managing Aurora PostgreSQL connection churn with pooling (p. 1482).</td>
</tr>
<tr>
<td>log_checkpoints</td>
<td>1</td>
<td>Logs each checkpoint.</td>
</tr>
<tr>
<td>log_lock_waits</td>
<td>–</td>
<td>Logs long lock waits. By default, this parameter isn't set.</td>
</tr>
<tr>
<td>log_min_duration_sample</td>
<td>–</td>
<td>(ms) Sets the minimum execution time above which a sample of statements is logged. Sample size is set using the log_statement_sample_rate parameter.</td>
</tr>
<tr>
<td>log_min_duration_statement</td>
<td>–</td>
<td>Any SQL statement that runs at least for the specified amount of time or longer gets logged. By default, this parameter isn't set. Turning on this parameter can help you find unoptimized queries.</td>
</tr>
<tr>
<td>log_statement</td>
<td>–</td>
<td>Sets the type of statements logged. By default, this parameter isn't set, but you can change it to all,ddl, or mod to specify the types of SQL statements that you want logged. If you specify anything other than none for this parameter, you should also take additional steps to prevent</td>
</tr>
</tbody>
</table>
### Using logging to find slow performing queries

You can log SQL statements and queries to help find slow performing queries. You turn on this capability by modifying the settings in the `log_statement` and `log_min_duration` parameters as outlined in this section. Before turning on query logging for your Aurora PostgreSQL DB cluster, you should be aware of possible password exposure in the logs and how to mitigate the risks. For more information, see [Mitigating risk of password exposure when using query logging](p. 740).

Following, you can find reference information about the `log_statement` and `log_min_duration` parameters.

#### log_statement

This parameter specifies the type of SQL statements that should get sent to the log. The default value is `none`. If you change this parameter to `all`, `ddl`, or `mod`, be sure to apply recommended actions to mitigate the risk of exposing passwords in the logs. For more information, see [Mitigating risk of password exposure when using query logging](p. 740).

- **all**
  - Logs all statements. This setting is recommended for debugging purposes.
- **ddl**
  - Logs all data definition language (DDL) statements, such as CREATE, ALTER, DROP, and so on.
- **mod**
  - Logs all DDL statements and data manipulation language (DML) statements, such as INSERT, UPDATE, and DELETE, which modify the data.
- **none**
  - No SQL statements get logged. We recommend this setting to avoid the risk of exposing passwords in the logs.

#### log_min_duration_statement

Any SQL statement that runs at least for the specified amount of time or longer gets logged. By default, this parameter isn’t set. Turning on this parameter can help you find unoptimized queries.

- `-1–2147483647`
  - The number of milliseconds (ms) of runtime over which a statement gets logged.
To set up query logging

These steps assume that your Aurora PostgreSQL DB cluster uses a custom DB cluster parameter group.

1. Set the `log_statement` parameter to all. The following example shows the information that is written to the `postgresql.log` file with this parameter setting.

   ```
   2022-10-05 22:05:52 UTC:52.95.4.1(11335):postgres@labdb:[3639]:LOG: statement: SELECT feedback, s.sentiment,s.confidence FROM support,aws_comprehend.detect_sentiment(feedback, 'en') s ORDER BY s.confidence DESC;
   2022-10-05 22:05:52 UTC:52.95.4.1(11335):postgres@labdb:[3639]:LOG: QUERY STATISTICS
   2022-10-05 22:05:52 UTC:52.95.4.1(11335):postgres@labdb:[3639]:DETAIL: ! system usage stats:
   ![0.017355 s user, 0.000000 s system, 0.168593 s elapsed]
   ![0.025146 s user, 0.000000 s system total]
   ![36644 kB max resident size]
   ![0/8 [0/8] filesystem blocks in/out]
   ![0/793 [0/1364] page faults/reclaims, 0 [0] swaps]
   ![0 [0] signals rcvd, 0/0 [0/0] messages rcvd/sent]
   ![19/0 [27/0] voluntary/involuntary context switches]
   2022-10-05 22:05:52 UTC:52.95.4.1(11335):postgres@labdb:[3639]:STATEMENT: SELECT feedback, s.sentiment,s.confidence FROM support,aws_comprehend.detect_sentiment(feedback, 'en') s ORDER BY s.confidence DESC;
   2022-10-05 22:05:56 UTC:52.95.4.1(11335):postgres@labdb:[3639]:ERROR: syntax error at or near "ORDER" at character 1
   2022-10-05 22:05:56 UTC:52.95.4.1(11335):postgres@labdb:[3639]:STATEMENT: ORDER BY s.confidence DESC;
   ----------------------- END OF LOG ----------------------
   ```

2. Set the `log_min_duration_statement` parameter. The following example shows the information that is written to the `postgresql.log` file when the parameter is set to 1.

   ```
   2022-10-05 19:05:19 UTC:52.95.4.1(6461):postgres@labdb:[6144]:LOG: statement: DROP table comments;
   2022-10-05 19:05:19 UTC:52.95.4.1(6461):postgres@labdb:[6144]:LOG: duration: 167.754 ms
   2022-10-05 19:08:07 UTC:52.95.4.1(6461):postgres@labdb:[6144]:LOG: checkpoint starting: time
   2022-10-05 19:08:08 UTC:52.95.4.1(6461):postgres@labdb:[6144]:LOG: checkpoint complete: wrote 11 buffers (0.0%); 0 WAL file(s) added, 0 removed, 0 recycled; write=1.013 s, sync=0.006 s, total=1.033 s; sync files=8, longest=0.004 s, average=0.001 s; distance=131028 kB, estimate=131028 kB
   ----------------------- END OF LOG ----------------------
   ```

Mitigating risk of password exposure when using query logging

We recommend that you keep `log_statement` set to none to avoid exposing passwords. If you set `log_statement` to all, ddl, or mod, we recommend that you take one or more of the following steps.

- For the client, encrypt sensitive information. For more information, see Encryption Options in the PostgreSQL documentation. Use the ENCRYPTED (and UNENCRYPTED) options of the CREATE and ALTER statements. For more information, see CREATE USER in the PostgreSQL documentation.
- For your Aurora PostgreSQL DB cluster, set up and use the PostgreSQL Auditing (pgAudit) extension. This extension redacts sensitive information in CREATE and ALTER statements sent to the log. For more information, see Using pgAudit to log database activity (p. 1635).
- Restrict access to the CloudWatch logs.
• Use stronger authentication mechanisms such as IAM.
Monitoring Amazon Aurora API calls in AWS CloudTrail

AWS CloudTrail is an AWS service that helps you audit your AWS account. AWS CloudTrail is turned on for your AWS account when you create it. For more information about CloudTrail, see the AWS CloudTrail User Guide.

Topics
- CloudTrail integration with Amazon Aurora (p. 742)
- Amazon Aurora log file entries (p. 742)

CloudTrail integration with Amazon Aurora

All Amazon Aurora actions are logged by CloudTrail. CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon Aurora.

CloudTrail events

CloudTrail captures API calls for Amazon Aurora as events. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. Events include calls from the Amazon RDS console and from code calls to the Amazon RDS API operations.

Amazon Aurora activity is recorded in a CloudTrail event in Event history. You can use the CloudTrail console to view the last 90 days of recorded API activity and events in an AWS Region. For more information, see Viewing events with CloudTrail event history.

CloudTrail trails

For an ongoing record of events in your AWS account, including events for Amazon Aurora, create a trail. A trail is a configuration that enables delivery of events to a specified Amazon S3 bucket. CloudTrail typically delivers log files within 15 minutes of account activity.

Note
If you don't configure a trail, you can still view the most recent events in the CloudTrail console in Event history.

You can create two types of trails for an AWS account: a trail that applies to all Regions, or a trail that applies to one Region. By default, when you create a trail in the console, the trail applies to all Regions.

Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see:

- Overview for creating a trail
- CloudTrail supported services and integrations
- Configuring Amazon SNS notifications for CloudTrail
- Receiving CloudTrail log files from multiple Regions and Receiving CloudTrail log files from multiple accounts

Amazon Aurora log file entries

CloudTrail log files contain one or more log entries. CloudTrail log files are not an ordered stack trace of the public API calls, so they do not appear in any specific order.
The following example shows a CloudTrail log entry that demonstrates the CreateDBInstance action.

```json

"eventID": "797163d3-5726-441d-80a7-6eeb7464acd4"
As shown in the `userIdentity` element in the preceding example, every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information about the `userIdentity`, see the CloudTrail `userIdentity` element. For more information about `CreateDBInstance` and other Amazon Aurora actions, see the Amazon RDS API Reference.
Monitoring Amazon Aurora with Database Activity Streams

By using Database Activity Streams, you can monitor near real-time streams of database activity.

Topics
- Overview of Database Activity Streams (p. 746)
- Network prerequisites for Aurora MySQL database activity streams (p. 749)
- Starting a database activity stream (p. 750)
- Getting the status of a database activity stream (p. 751)
- Stopping a database activity stream (p. 752)
- Monitoring database activity streams (p. 753)
- Managing access to database activity streams (p. 777)

Overview of Database Activity Streams

As an Amazon Aurora database administrator, you need to safeguard your database and meet compliance and regulatory requirements. One strategy is to integrate database activity streams with your monitoring tools. In this way, you monitor and set alarms for auditing activity in your Amazon Aurora cluster. Security threats are both external and internal. To protect against internal threats, you can control administrator access to data streams by configuring the Database Activity Streams feature. DBAs don't have access to the collection, transmission, storage, and processing of the streams.

Topics
- How database activity streams work (p. 746)
- Asynchronous and synchronous mode for database activity streams (p. 747)
- Requirements and limitations for database activity streams (p. 748)
- Region and version availability (p. 748)
- Supported DB instance classes for database activity streams (p. 748)

How database activity streams work

In Amazon Aurora, you start a database activity stream at the cluster level. All DB instances within your cluster have database activity streams enabled.

Your Aurora DB cluster pushes activities to an Amazon Kinesis data stream in near real time. The Kinesis stream is created automatically. From Kinesis, you can configure AWS services such as Amazon Kinesis Data Firehose and AWS Lambda to consume the stream and store the data.

Important
Use of the database activity streams feature in Amazon Aurora is free, but Amazon Kinesis charges for a data stream. For more information, see Amazon Kinesis Data Streams pricing.

If you use an Aurora global database, start a database activity stream on each DB cluster separately. Each cluster delivers audit data to its own Kinesis stream within its own AWS Region. The activity streams don't operate differently during a failover. They continue to audit your global database as usual.
You can configure applications for compliance management to consume database activity streams. For Aurora PostgreSQL, compliance applications include IBM's Security Guardium and Imperva's SecureSphere Database Audit and Protection. These applications can use the stream to generate alerts and audit activity on your Aurora DB cluster.

The following graphic shows an Aurora DB cluster configured with Amazon Kinesis Data Firehose.

Asynchronous and synchronous mode for database activity streams

You can choose to have the database session handle database activity events in either of the following modes:

- **Asynchronous mode** – When a database session generates an activity stream event, the session returns to normal activities immediately. In the background, the activity stream event is made a durable record. If an error occurs in the background task, an RDS event is sent. This event indicates the beginning and end of any time windows where activity stream event records might have been lost.

  Asynchronous mode favors database performance over the accuracy of the activity stream.

  **Note**
  Asynchronous mode is available for both Aurora PostgreSQL and Aurora MySQL.

- **Synchronous mode** – When a database session generates an activity stream event, the session blocks other activities until the event is made durable. If the event can't be made durable for some reason,
the database session returns to normal activities. However, an RDS event is sent indicating that activity
stream records might be lost for some time. A second RDS event is sent after the system is back to a
healthy state.

The synchronous mode favors the accuracy of the activity stream over database performance.

Note
Synchronous mode is available for Aurora PostgreSQL. You can’t use synchronous mode with
Aurora MySQL.

Requirements and limitations for database activity streams

In Aurora, database activity streams have the following requirements and limitations:

- Amazon Kinesis is required for database activity streams.
- AWS Key Management Service (AWS KMS) is required for database activity streams because they are
  always encrypted.
- Applying additional encryption to your Amazon Kinesis data stream is incompatible with database
  activity streams, which are already encrypted with your AWS KMS key.
- Start your database activity stream at the DB cluster level. If you add a DB instance to your cluster, you
don’t need to start an activity stream on the instance: it is audited automatically.
- In an Aurora global database, make sure to start an activity stream on each DB cluster separately. Each
  cluster delivers audit data to its own Kinesis stream within its own AWS Region.
- In Aurora PostgreSQL, make sure to stop database activity stream before an upgrade. You can start the
database activity stream after the upgrade completes.

Region and version availability

Feature availability and support varies across specific versions of each Aurora database engine, and
across AWS Regions. For more information on version and Region availability with Aurora and database
activity streams, see Database activity streams in Aurora (p. 27).

Supported DB instance classes for database activity streams

For Aurora MySQL, you can use database activity streams with the following DB instance classes:

- `db.r7g.*large`
- `db.r6g.*large`
- `db.r6i.*large`
- `db.r5.*large`
- `db.x2g.*`

For Aurora PostgreSQL, you can use database activity streams with the following DB instance classes:

- `db.r7g.*large`
- `db.r6g.*large`
- `db.r6i.*large`
- `db.r6id.*large`
- `db.r5.*large`
- `db.r4.*large`
- `db.x2g.*`
Network prerequisites for Aurora MySQL database activity streams

In the following section, you can find how to configure your virtual private cloud (VPC) for use with database activity streams.

Topics
- Prerequisites for AWS KMS endpoints (p. 749)
- Prerequisites for public availability (p. 749)
- Prerequisites for private availability (p. 749)

Prerequisites for AWS KMS endpoints

Instances in an Aurora MySQL cluster that use activity streams must be able to access AWS KMS endpoints. Make sure this requirement is satisfied before enabling database activity streams for your Aurora MySQL cluster. If the Aurora cluster is publicly available, this requirement is satisfied automatically.

Important
If the Aurora MySQL DB cluster can't access the AWS KMS endpoint, the activity stream stops. In that case, Aurora notifies you about this issue using RDS Events.

Prerequisites for public availability

For an Aurora DB cluster to be public, it must meet the following requirements:

- **Publicly Accessible** is Yes in the AWS Management Console cluster details page.
- The DB cluster is in an Amazon VPC public subnet. For more information about publicly accessible DB instances, see Working with a DB cluster in a VPC (p. 2478). For more information about public Amazon VPC subnets, see Your VPC and Subnets.

Prerequisites for private availability

If your Aurora DB cluster is in a VPC public subnet and isn't publicly accessible, it's private. To keep your cluster private and use it with database activity streams, you have the following options:

- Configure Network Address Translation (NAT) in your VPC. For more information, see NAT Gateways.
- Create an AWS KMS endpoint in your VPC. This option is recommended because it's easier to configure.

To create an AWS KMS endpoint in your VPC

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoints.
3. Choose Create Endpoint.
   
   The Create Endpoint page appears.
4. Do the following:
   - In **Service category**, choose AWS services.
   - In **Service Name**, choose com.amazonaws.region.kms, where `region` is the AWS Region where your cluster is located.
Starting a database activity stream

To monitor database activity for all instances in your Aurora DB cluster, start an activity stream at the cluster level. Any DB instances that you add to the cluster are also automatically monitored. If you use an Aurora global database, start a database activity stream on each DB cluster separately. Each cluster delivers audit data to its own Kinesis stream within its own AWS Region.

When you start an activity stream, each database activity event that you configured in the audit policy generates an activity stream event. SQL commands such as `CONNECT` and `SELECT` generate access events. SQL commands such as `CREATE` and `INSERT` generate change events.

**Console**

**To start a database activity stream**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the DB cluster on which you want to start an activity stream.
4. For **Actions**, choose **Start activity stream**.

The **Start database activity stream**: name window appears, where name is your DB cluster.

5. Enter the following settings:
   - For **AWS KMS key**, choose a key from the list of AWS KMS keys.
     - **Note**
       If your Aurora MySQL cluster can't access KMS keys, follow the instructions in [Network prerequisites for Aurora MySQL database activity streams (p. 749)](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-mysql-activity-streams.html) to enable such access first.

   Aurora uses the KMS key to encrypt the key that in turn encrypts database activity. Choose a KMS key other than the default key. For more information about encryption keys and AWS KMS, see [What is AWS Key Management Service?](https://docs.aws.amazon.com/kms/latest/developerguide/what-is-kms.html) in the [AWS Key Management Service Developer Guide](https://docs.aws.amazon.com/kms/latest/developerguide/what-is-kms.html).
   
   - For **Database activity stream mode**, choose **Asynchronous** or **Synchronous**.
     - **Note**
       This choice applies only to Aurora PostgreSQL. For Aurora MySQL, you can use only asynchronous mode.
   
   - Choose **Immediately**.
     
     When you choose **Immediately**, the DB cluster restarts right away. If you choose **During the next maintenance window**, the DB cluster doesn't restart right away. In this case, the database activity stream doesn't start until the next maintenance window.

6. Choose **Start database activity stream**.

The status for the DB cluster shows that the activity stream is starting.

- For VPC, choose the VPC where your cluster is located.

5. Choose **Create Endpoint**.

For more information about configuring VPC endpoints, see [VPC Endpoints](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/what-is-vpc-endpoints.html).

**Starting a database activity stream**

To monitor database activity for all instances in your Aurora DB cluster, start an activity stream at the cluster level. Any DB instances that you add to the cluster are also automatically monitored. If you use an Aurora global database, start a database activity stream on each DB cluster separately. Each cluster delivers audit data to its own Kinesis stream within its own AWS Region.

When you start an activity stream, each database activity event that you configured in the audit policy generates an activity stream event. SQL commands such as `CONNECT` and `SELECT` generate access events. SQL commands such as `CREATE` and `INSERT` generate change events.

**Console**

**To start a database activity stream**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the DB cluster on which you want to start an activity stream.
4. For **Actions**, choose **Start activity stream**.

The **Start database activity stream**: name window appears, where name is your DB cluster.

5. Enter the following settings:
   - For **AWS KMS key**, choose a key from the list of AWS KMS keys.
     - **Note**
       If your Aurora MySQL cluster can't access KMS keys, follow the instructions in [Network prerequisites for Aurora MySQL database activity streams (p. 749)](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-mysql-activity-streams.html) to enable such access first.

   Aurora uses the KMS key to encrypt the key that in turn encrypts database activity. Choose a KMS key other than the default key. For more information about encryption keys and AWS KMS, see [What is AWS Key Management Service?](https://docs.aws.amazon.com/kms/latest/developerguide/what-is-kms.html) in the [AWS Key Management Service Developer Guide](https://docs.aws.amazon.com/kms/latest/developerguide/what-is-kms.html).
   
   - For **Database activity stream mode**, choose **Asynchronous** or **Synchronous**.
     - **Note**
       This choice applies only to Aurora PostgreSQL. For Aurora MySQL, you can use only asynchronous mode.
   
   - Choose **Immediately**.
     
     When you choose **Immediately**, the DB cluster restarts right away. If you choose **During the next maintenance window**, the DB cluster doesn't restart right away. In this case, the database activity stream doesn't start until the next maintenance window.

6. Choose **Start database activity stream**.

The status for the DB cluster shows that the activity stream is starting.

- For VPC, choose the VPC where your cluster is located.

5. Choose **Create Endpoint**.

For more information about configuring VPC endpoints, see [VPC Endpoints](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/what-is-vpc-endpoints.html).
AWS CLI

To start database activity streams for a DB cluster, configure the DB cluster using the `start-activity-stream` AWS CLI command.

- `--resource-arn arn` – Specifies the Amazon Resource Name (ARN) of the DB cluster.
- `--mode sync-or-async` – Specifies either synchronous (sync) or asynchronous (async) mode. For Aurora PostgreSQL, you can choose either value. For Aurora MySQL, specify async.
- `--kms-key-id key` – Specifies the KMS key identifier for encrypting messages in the database activity stream. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the AWS KMS key.

The following example starts a database activity stream for a DB cluster in asynchronous mode.

For Linux, macOS, or Unix:

```
aws rds start-activity-stream
  --mode async
  --kms-key-id my-kms-key-arn
  --resource-arn my-cluster-arn
  --apply-immediately
```

For Windows:

```
aws rds start-activity-stream ^
  --mode async ^
  --kms-key-id my-kms-key-arn ^
  --resource-arn my-cluster-arn ^
  --apply-immediately
```

RDS API

To start database activity streams for a DB cluster, configure the cluster using the `StartActivityStream` operation.

Call the action with the parameters below:

- Region
- KmsKeyId
- ResourceArn
- Mode

Getting the status of a database activity stream

You can get the status of an activity stream using the console or AWS CLI.

Console

To get the status of a database activity stream

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB cluster link.
3. Choose the Configuration tab, and check Database activity stream for status.
AWS CLI

You can get the activity stream configuration for a DB cluster as the response to a `describe-db-clusters` CLI request.

The following example describes `my-cluster`.

```
aws rds --region my-region describe-db-clusters --db-cluster-identifier my-cluster
```

The following example shows a JSON response. The following fields are shown:

- `ActivityStreamKinesisStreamName`
- `ActivityStreamKmsKeyId`
- `ActivityStreamStatus`
- `ActivityStreamMode`

These fields are the same for Aurora PostgreSQL and Aurora MySQL, except that `ActivityStreamMode` is always `async` for Aurora MySQL, while for Aurora PostgreSQL it might be `sync` or `async`.

```
{
  "DBClusters": [
    {
      "DBClusterIdentifier": "my-cluster",
      ...
      "ActivityStreamKinesisStreamName": "aws-rds-das-cluster-A6TSYXITZCZXJHIRVFUBZ5LTWY",
      "ActivityStreamStatus": "starting",
      "ActivityStreamKmsKeyId": "12345678-abcd-efgh-ijkl-bd041f170262",
      "ActivityStreamMode": "async",
      "DbClusterResourceId": "cluster-ABCD123456"
      ...
    }
  ]
}
```

RDS API

You can get the activity stream configuration for a DB cluster as the response to a `DescribeDBClusters` operation.

Stopping a database activity stream

You can stop an activity stream using the console or AWS CLI.

If you delete your DB cluster, the activity stream is stopped and the underlying Amazon Kinesis stream is deleted automatically.

**Console**

**To turn off an activity stream**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose a DB cluster that you want to stop the database activity stream for.
4. For **Actions**, choose **Stop activity stream**. The **Database Activity Stream** window appears.
   a. Choose **Immediately**.

   When you choose **Immediately**, the DB cluster restarts right away. If you choose **During the next maintenance window**, the DB cluster doesn't restart right away. In this case, the database activity stream doesn't stop until the next maintenance window.
   b. Choose **Continue**.

**AWS CLI**

To stop database activity streams for your DB cluster, configure the DB cluster using the AWS CLI command `stop-activity-stream`. Identify the AWS Region for the DB cluster using the `--region` parameter. The `--apply-immediately` parameter is optional.

For Linux, macOS, or Unix:

```
aws rds --region MY_REGION \
  stop-activity-stream \
  --resource-arn MY_CLUSTER_ARN \
  --apply-immediately
```

For Windows:

```
aws rds --region MY_REGION ^
  stop-activity-stream ^
  --resource-arn MY_CLUSTER_ARN ^
  --apply-immediately
```

**RDS API**

To stop database activity streams for your DB cluster, configure the cluster using the `StopActivityStream` operation. Identify the AWS Region for the DB cluster using the `Region` parameter. The `ApplyImmediately` parameter is optional.

**Monitoring database activity streams**

Database activity streams monitor and report activities. The stream of activity is collected and transmitted to Amazon Kinesis. From Kinesis, you can monitor the activity stream, or other services and applications can consume the activity stream for further analysis. You can find the underlying Kinesis stream name by using the AWS CLI command `describe-db-clusters` or the RDS API `DescribeDBClusters` operation.

Aurora manages the Kinesis stream for you as follows:

- Aurora creates the Kinesis stream automatically with a 24-hour retention period.
- Aurora scales the Kinesis stream if necessary.
- If you stop the database activity stream or delete the DB cluster, Aurora deletes the Kinesis stream.

The following categories of activity are monitored and put in the activity stream audit log:

- **SQL commands** – All SQL commands are audited, and also prepared statements, built-in functions, and functions in PL/SQL. Calls to stored procedures are audited. Any SQL statements issued inside stored procedures or functions are also audited.
• **Other database information** – Activity monitored includes the full SQL statement, the row count of affected rows from DML commands, accessed objects, and the unique database name. For Aurora PostgreSQL, database activity streams also monitor the bind variables and stored procedure parameters.

  **Important**
  The full SQL text of each statement is visible in the activity stream audit log, including any sensitive data. However, database user passwords are redacted if Aurora can determine them from the context, such as in the following SQL statement.

  ```sql
  ALTER ROLE role-name WITH password
  ```

• **Connection information** – Activity monitored includes session and network information, the server process ID, and exit codes.

If an activity stream has a failure while monitoring your DB instance, you are notified through RDS events.

**Topics**
- Accessing an activity stream from Kinesis (p. 754)
- Audit log contents and examples (p. 755)
- databaseActivityEventList JSON array (p. 764)
- Processing a database activity stream using the AWS SDK (p. 771)

### Accessing an activity stream from Kinesis

When you enable an activity stream for a DB cluster, a Kinesis stream is created for you. From Kinesis, you can monitor your database activity in real time. To further analyze database activity, you can connect your Kinesis stream to consumer applications. You can also connect the stream to compliance management applications such as IBM's Security Guardium or Imperva's SecureSphere Database Audit and Protection.

You can access your Kinesis stream either from the RDS console or the Kinesis console.

**To access an activity stream from Kinesis using the RDS console**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose *Databases*.
3. Choose the DB cluster on which you started an activity stream.
4. Choose *Configuration*.
5. Under *Database activity stream*, choose the link under *Kinesis stream*.
6. In the Kinesis console, choose *Monitoring* to begin observing the database activity.

**To access an activity stream from Kinesis using the Kinesis console**

2. Choose your activity stream from the list of Kinesis streams.

An activity stream's name includes the prefix `aws-rds-das-cluster-` followed by the resource ID of the DB cluster. The following is an example.

```plaintext
aws-rds-das-cluster-NHV0V4PCLWHGF52NP
```
To use the Amazon RDS console to find the resource ID for the DB cluster, choose your DB cluster from the list of databases, and then choose the **Configuration** tab.

To use the AWS CLI to find the full Kinesis stream name for an activity stream, use a `describe-db-clusters` CLI request and note the value of `ActivityStreamKinesisStreamName` in the response.

3. Choose **Monitoring** to begin observing the database activity.

For more information about using Amazon Kinesis, see [What Is Amazon Kinesis Data Streams?](#).

### Audit log contents and examples

Monitored events are represented in the database activity stream as JSON strings. The structure consists of a JSON object containing a `DatabaseActivityMonitoringRecord`, which in turn contains a `databaseActivityEventList` array of activity events.

**Topics**

- [Examples of an audit log for an activity stream (p. 755)](#)
- [DatabaseActivityMonitoringRecords JSON object (p. 762)](#)
- [databaseActivityEvents JSON Object (p. 762)](#)

**Examples of an audit log for an activity stream**

Following are sample decrypted JSON audit logs of activity event records.

**Example Activity event record of an Aurora PostgreSQL CONNECT SQL statement**

The following activity event record shows a login with the use of a CONNECT SQL statement (command) by a `psql` client (`clientApplication`).

```json
{
    "type": "DatabaseActivityMonitoringRecords",
    "version": "1.1",
    "databaseActivityEvents": [
        {
            "type": "DatabaseActivityMonitoringRecord",
            "clusterId": "cluster-4HNY5V4RRNPKKY87ICFKE5JBQQ",
            "instanceId": "db-FZJMYKXQBUU26VLU7NW5ITCM",
            "databaseActivityEventList": [
                {
                    "startTime": "2019-10-30 00:39:49.940668+00",
                    "logTime": "2019-10-30 00:39:49.990579+00",
                    "statementId": 1,
                    "substatementId": 1,
                    "command": "CONNECT",
                    "objectType": null,
                    "objectName": null,
                    "databaseName": "postgres",
                    "dbUserName": "rdsadmin",
                    "remoteHost": "172.31.3.195",
                    "remotePort": "49804",
                    "sessionId": "5ce5f7f0.474b",
                    "rowCount": null,
                    "commandText": null,
                    "paramList": [],
                    "pid": 18251,
                    "clientApplication": "psql",
                    "exitCode": null,
                    "class": "MISC",
```

755
Example Activity event record of an Aurora MySQL CONNECT SQL statement

The following activity event record shows a logon with the use of a CONNECT SQL statement (command) by a mysql client (clientApplication).

```json
{
    "type":"DatabaseActivityMonitoringRecord",
    "clusterId":"cluster-some_id",
    "instanceId":"db-some_id",
    "databaseActivityEventList":[
        {
            "logTime":"2020-05-22 18:07:13.267214+00",
            "type":"record",
            "clientApplication":null,
            "pid":2830,
            "dbUserName":"rdsadmin",
            "databaseName":"",
            "remoteHost":"localhost",
            "remotePort":"11053",
            "command":"CONNECT",
            "commandText":"
            "paramList":null,
            "objectType":"TABLE",
            "objectName":"",
            "statementId":0,
            "substatementId":1,
            "exitCode":"0",
            "sessionId":725121,
            "rowCount":0,
            "serverHost":"master",
            "serverType":"MySQL",
            "serviceName":"Amazon Aurora MySQL",
            "serverVersion":"MySQL 5.7.12",
            "startTime":"2020-05-22 18:07:13.267207+00",
            "endTime":"2020-05-22 18:07:13.267213+00",
            "transactionId":0,
            "dbProtocol":"MySQL",
            "netProtocol":"TCP",
            "errorMessage":"
            "class":"MAIN"
        }
    ]
}
```

Example Activity event record of an Aurora PostgreSQL CREATE TABLE statement

The following example shows a CREATE TABLE event for Aurora PostgreSQL.

```json
{
    "serverVersion": "2.3.1",
    "serverType": "PostgreSQL",
    "serviceName": "Amazon Aurora PostgreSQL-Compatible edition",
    "serverHost": "172.31.3.192",
    "netProtocol": "TCP",
    "dbProtocol": "Postgres 3.0",
    "type": "record",
    "errorMessage": null
}
```

Example Activity event record of an Aurora MySQL CREATE TABLE statement

The following example shows a CREATE TABLE statement for Aurora MySQL. The operation is represented as two separate event records. One event has "class" : "MAIN". The other event has "class" : "AUX". The messages might arrive in any order. The logTime field of the MAIN event is always earlier than the logTime fields of any corresponding AUX events.

The following example shows the event with a class value of MAIN.

```json
{
    "type" : "DatabaseActivityMonitoringRecord",
    "clusterId" : "cluster-some_id",
    "instanceId" : "db-some_id",
    "databaseActivityEventList" : [
        {
            "logTime" : "2020-05-22 18:07:12.250221+00",
            "type" : "record",
            "clientApplication" : null,
            "pid" : 2830,
            "dbUserName" : "master",
            "databaseName" : "test",
```
The following example shows the corresponding event with a class value of AUX.

```json
{
  "type": "DatabaseActivityMonitoringRecord",
  "clusterId": "cluster-some_id",
  "instanceId": "db-some_id",
  "databaseActivityEventList": [
    {
      "logTime": "2020-05-22 18:07:12.247182+00",
      "type": "record",
      "clientApplication": null,
      "pid": 2830,
      "dbUserName": "master",
      "databaseName": "test",
      "remoteHost": "localhost",
      "remotePort": "11054",
      "command": "CREATE",
      "commandText": "test1",
      "paramList": null,
      "objectType": "TABLE",
      "objectName": "test1",
      "statementId": 65459278,
      "substatementId": 2,

      "class": "MAIN"
    }
  ]
}
```
DatabaseActivityMonitoringRecords JSON object

The database activity event records are in a JSON object that contains the following information.

<table>
<thead>
<tr>
<th>JSON Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>string</td>
<td>The type of JSON record. The value is DatabaseActivityMonitoringRecords.</td>
</tr>
<tr>
<td>version</td>
<td>string</td>
<td>The version of the database activity monitoring records.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The version of the generated database activity records depends on the engine version of the DB cluster:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Version 1.1 database activity records are generated for Aurora PostgreSQL DB clusters running the engine versions 10.10 and later minor versions and engine versions 11.5 and later.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Version 1.0 database activity records are generated for Aurora PostgreSQL DB clusters running the engine versions 10.7 and 11.4.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>All of the following fields are in both version 1.0 and version 1.1 except where specifically noted.</td>
</tr>
<tr>
<td>databaseActivityEvents</td>
<td>string</td>
<td>A JSON object that contains the activity events.</td>
</tr>
<tr>
<td>key</td>
<td>string</td>
<td>An encryption key that you use to decrypt the databaseActivityEventList.</td>
</tr>
</tbody>
</table>

databaseActivityEvents JSON Object

The databaseActivityEvents JSON object contains the following information.

Top-level fields in JSON record

Each event in the audit log is wrapped inside a record in JSON format. This record contains the following fields.

**type**

This field always has the value DatabaseActivityMonitoringRecords.
version

This field represents the version of the database activity stream data protocol or contract. It defines which fields are available.

Version 1.0 represents the original data activity streams support for Aurora PostgreSQL versions 10.7 and 11.4. Version 1.1 represents the data activity streams support for Aurora PostgreSQL versions 10.10 and higher and Aurora PostgreSQL 11.5 and higher. Version 1.1 includes the additional fields errorMessage and startTime. Version 1.2 represents the data activity streams support for Aurora MySQL 2.08 and higher. Version 1.2 includes the additional fields endTime and transactionId.

databaseActivityEvents

An encrypted string representing one or more activity events. It's represented as a base64 byte array. When you decrypt the string, the result is a record in JSON format with fields as shown in the examples in this section.

key

The encrypted data key used to encrypt the databaseActivityEvents string. This is the same AWS KMS key that you provided when you started the database activity stream.

The following example shows the format of this record.

```
{
    "type":"DatabaseActivityMonitoringRecords",
    "version":"1.1",
    "databaseActivityEvents":"encrypted audit records",
    "key":"encrypted key"
}
```

Take the following steps to decrypt the contents of the databaseActivityEvents field:

1. Decrypt the value in the key JSON field using the KMS key you provided when starting database activity stream. Doing so returns the data encryption key in clear text.
2. Base64-decode the value in the databaseActivityEvents JSON field to obtain the ciphertext, in binary format, of the audit payload.
3. Decrypt the binary ciphertext with the data encryption key that you decoded in the first step.
4. Decompress the decrypted payload.
   - The encrypted payload is in the databaseActivityEvents field.
   - The databaseActivityEventList field contains an array of audit records. The type fields in the array can be record or heartbeat.

The audit log activity event record is a JSON object that contains the following information.

<table>
<thead>
<tr>
<th>JSON Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>string</td>
<td>The type of JSON record. The value is</td>
</tr>
<tr>
<td></td>
<td></td>
<td>DatabaseActivityMonitoringRecord.</td>
</tr>
<tr>
<td>clusterId</td>
<td>string</td>
<td>The DB cluster resource identifier. It corresponds to</td>
</tr>
<tr>
<td></td>
<td></td>
<td>the DB cluster attribute DbClusterResourceId.</td>
</tr>
<tr>
<td>instanceId</td>
<td>string</td>
<td>The DB instance resource identifier. It corresponds to</td>
</tr>
<tr>
<td></td>
<td></td>
<td>the DB instance attribute DbiResourceId.</td>
</tr>
</tbody>
</table>
**databaseActivityEventList JSON array**

The audit log payload is an encrypted `databaseActivityEventList` JSON array. The following tables list alphabetically the fields for each activity event in the decrypted `DatabaseActivityEventList` array of an audit log. The fields differ depending on whether you use Aurora PostgreSQL or Aurora MySQL. Consult the table that applies to your database engine.

**Important**
The event structure is subject to change. Aurora might add new fields to activity events in the future. In applications that parse the JSON data, make sure that your code can ignore or take appropriate actions for unknown field names.

### databaseActivityEventList fields for Aurora PostgreSQL

<table>
<thead>
<tr>
<th>Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>class</code></td>
<td>string</td>
<td>The class of activity event. Valid values for Aurora PostgreSQL are the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- ALL</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- CONNECT – A connect or disconnect event.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- DDL – A DDL statement that is not included in the list of statements for the ROLE class.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- FUNCTION – A function call or a DO block.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- MISC – A miscellaneous command such as DISCARD, FETCH, CHECKPOINT, or VACUUM.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- NONE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- READ – A SELECT or COPY statement when the source is a relation or a query.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- ROLE – A statement related to roles and privileges including GRANT, REVOKE, and CREATE/ALTER/DROP ROLE.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- WRITE – An INSERT, UPDATE, DELETE, TRUNCATE, or COPY statement when the destination is a relation.</td>
</tr>
<tr>
<td><code>clientApplication</code></td>
<td>string</td>
<td>The application the client used to connect as reported by the client. The client doesn't have to provide this information, so the value can be null.</td>
</tr>
<tr>
<td><code>command</code></td>
<td>string</td>
<td>The name of the SQL command without any command details.</td>
</tr>
<tr>
<td><code>commandText</code></td>
<td>string</td>
<td>The actual SQL statement passed in by the user. For Aurora PostgreSQL, the value is identical to the original SQL statement. This field is used for all types of records except for connect or disconnect records, in which case the value is null.</td>
</tr>
</tbody>
</table>

**Important**
The full SQL text of each statement is visible in the activity stream audit log, including any sensitive data. However, database user passwords are redacted if Aurora can determine them from the context, such as in the following SQL statement.
### Field Data Type Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>databaseName</td>
<td>string</td>
<td>The database to which the user connected.</td>
</tr>
<tr>
<td>dbProtocol</td>
<td>string</td>
<td>The database protocol, for example Postgres 3.0.</td>
</tr>
<tr>
<td>dbUserName</td>
<td>string</td>
<td>The database user with which the client authenticated.</td>
</tr>
<tr>
<td>errorMessage</td>
<td>string</td>
<td>If there was any error, this field is populated with the error message that would've been generated by the DB server. The errorMessage value is null for normal statements that didn't result in an error. An error is defined as any activity that would produce a client-visible PostgreSQL error log event at a severity level of ERROR or greater. For more information, see PostgreSQL Message Severity Levels. For example, syntax errors and query cancellations generate an error message. Internal PostgreSQL server errors such as background checkpointer process errors do not generate an error message. However, records for such events are still emitted regardless of the setting of the log severity level. This prevents attackers from turning off logging to attempt avoiding detection. See also the exitCode field.</td>
</tr>
<tr>
<td>exitCode</td>
<td>int</td>
<td>A value used for a session exit record. On a clean exit, this contains the exit code. An exit code can't always be obtained in some failure scenarios. Examples are if PostgreSQL does an exit() or if an operator performs a command such as kill -9. If there was any error, the exitCode field shows the SQL error code, SQLSTATE, as listed in PostgreSQL Error Codes. See also the errorMessage field.</td>
</tr>
<tr>
<td>logTime</td>
<td>string</td>
<td>A timestamp as recorded in the auditing code path. This represents the SQL statement execution end time. See also the startTime field.</td>
</tr>
<tr>
<td>netProtocol</td>
<td>string</td>
<td>The network communication protocol.</td>
</tr>
<tr>
<td>objectName</td>
<td>string</td>
<td>The name of the database object if the SQL statement is operating on one. This field is used only where the SQL statement operates on a database object. If the SQL statement is not operating on an object, this value is null.</td>
</tr>
<tr>
<td>Field</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>objectType</td>
<td>string</td>
<td>The database object type such as table, index, view, and so on. This field is used only where the SQL statement operates on a database object. If the SQL statement is not operating on an object, this value is null. Valid values include the following: • COMPOSITE TYPE • FOREIGN TABLE • FUNCTION • INDEX • MATERIALIZED VIEW • SEQUENCE • TABLE • TOAST TABLE • VIEW • UNKNOWN</td>
</tr>
<tr>
<td>paramList</td>
<td>string</td>
<td>An array of comma-separated parameters passed to the SQL statement. If the SQL statement has no parameters, this value is an empty array.</td>
</tr>
<tr>
<td>pid</td>
<td>int</td>
<td>The process ID of the backend process that is allocated for serving the client connection.</td>
</tr>
<tr>
<td>remoteHost</td>
<td>string</td>
<td>Either the client IP address or hostname. For Aurora PostgreSQL, which one is used depends on the database's log_hostname parameter setting.</td>
</tr>
<tr>
<td>remotePort</td>
<td>string</td>
<td>The client port number.</td>
</tr>
<tr>
<td>rowCount</td>
<td>int</td>
<td>The number of rows returned by the SQL statement. For example, if a SELECT statement returns 10 rows, rowCount is 10. For INSERT or UPDATE statements, rowCount is 0.</td>
</tr>
<tr>
<td>serverHost</td>
<td>string</td>
<td>The database server host IP address.</td>
</tr>
<tr>
<td>serverType</td>
<td>string</td>
<td>The database server type, for example PostgreSQL.</td>
</tr>
<tr>
<td>serverVersion</td>
<td>string</td>
<td>The database server version, for example 2.3.1 for Aurora PostgreSQL.</td>
</tr>
<tr>
<td>serviceName</td>
<td>string</td>
<td>The name of the service, for example Amazon Aurora PostgreSQL-Compatible edition.</td>
</tr>
<tr>
<td>sessionId</td>
<td>int</td>
<td>A pseudo-unique session identifier.</td>
</tr>
<tr>
<td>startTime</td>
<td>string</td>
<td>The time when execution began for the SQL statement. (version 1.1 database activity records only) To calculate the approximate execution time of the SQL statement, use logTime - startTime. See also the logTime field.</td>
</tr>
</tbody>
</table>
## Field | Data Type | Description
---|---|---
statementId | int | An identifier for the client's SQL statement. The counter is at the session level and increments with each SQL statement entered by the client.

substatementId | int | An identifier for a SQL substatement. This value counts the contained substatements for each SQL statement identified by the statementId field.

type | string | The event type. Valid values are record or heartbeat.

#### databaseActivityEventList fields for Aurora MySQL

<table>
<thead>
<tr>
<th>Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>class</td>
<td>string</td>
<td>The class of activity event. Valid values for Aurora MySQL are the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• MAIN – The primary event representing a SQL statement.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• AUX – A supplemental event containing additional details. For example, a statement that renames an object might have an event with class AUX that reflects the new name.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>To find MAIN and AUX events corresponding to the same statement, check for different events that have the same values for the pid field and for the statementId field.</td>
</tr>
<tr>
<td>clientApplication</td>
<td>string</td>
<td>The application the client used to connect as reported by the client. The client doesn't have to provide this information, so the value can be null.</td>
</tr>
<tr>
<td>command</td>
<td>string</td>
<td>The general category of the SQL statement. The values for this field depend on the value of class.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The values when class is MAIN include the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• CONNECT – When a client session is connected.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• QUERY – A SQL statement. Accompanied by one or more events with a class value of AUX.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DISCONNECT – When a client session is disconnected.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• FAILED_CONNECT – When a client attempts to connect but isn't able to.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• CHANGEUSER – A state change that's part of the MySQL network protocol, not from a statement that you issue.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The values when class is AUX include the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• READ – A SELECT or COPY statement when the source is a relation or a query.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• WRITE – An INSERT, UPDATE, DELETE, TRUNCATE, or COPY statement when the destination is a relation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DROP – Deleting an object.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• CREATE – Creating an object.</td>
</tr>
<tr>
<td>Field</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• RENAME – Renaming an object.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ALTER – Changing the properties of an object.</td>
</tr>
<tr>
<td>commandText</td>
<td>string</td>
<td>For events with a class value of MAIN, this field represents the actual SQL statement passed in by the user. This field is used for all types of records except for connect or disconnect records, in which case the value is null.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For events with a class value of AUX, this field contains supplemental information about the objects involved in the event.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For Aurora MySQL, characters such as quotation marks are preceded by a backslash, representing an escape character.</td>
</tr>
</tbody>
</table>
|                    |           | **Important**  
|                    |           | The full SQL text of each statement is visible in the audit log, including any sensitive data. However, database user passwords are redacted if Aurora can determine them from the context, such as in the following SQL statement. |
|                    |           | ```sql  
|                    |           | mysql> SET PASSWORD = 'my-password';                                                      |
|                    |           | **Note**  
|                    |           | Specify a password other than the prompt shown here as a security best practice.       |
| databaseName       | string    | The database to which the user connected.                                                                                                  |
| dbProtocol         | string    | The database protocol. Currently, this value is always MySQL for Aurora MySQL.                                                            |
| dbUserName         | string    | The database user with which the client authenticated.                                                                                     |
| endTime            | string    | The time when execution ended for the SQL statement. It is represented in Coordinated Universal Time (UTC) format.                      |
|                    |           | To calculate the execution time of the SQL statement, use endTime - startTime. See also the startTime field. |
### Field | Data Type | Description
--- | --- | ---
errorMessage | string | If there was any error, this field is populated with the error message that would've been generated by the DB server. The errorMessage value is null for normal statements that didn't result in an error.

An error is defined as any activity that would produce a client-visible MySQL error log event at a severity level of ERROR or greater. For more information, see The Error Log in the MySQL Reference Manual. For example, syntax errors and query cancellations generate an error message.

Internal MySQL server errors such as background checkpoint process errors do not generate an error message. However, records for such events are still emitted regardless of the setting of the log severity level. This prevents attackers from turning off logging to attempt avoiding detection.

See also the exitCode field.

exitCode | int | A value used for a session exit record. On a clean exit, this contains the exit code. An exit code can't always be obtained in some failure scenarios. In such cases, this value might be zero or might be blank.

logTime | string | A timestamp as recorded in the auditing code path. It is represented in Coordinated Universal Time (UTC) format. For the most accurate way to calculate statement duration, see the startTime and endTime fields.

netProtocol | string | The network communication protocol. Currently, this value is always TCP for Aurora MySQL.

objectName | string | The name of the database object if the SQL statement is operating on one. This field is used only where the SQL statement operates on a database object. If the SQL statement isn't operating on an object, this value is blank. To construct the fully qualified name of the object, combine databaseName and objectName. If the query involves multiple objects, this field can be a comma-separated list of names.

objectType | string | The database object type such as table, index, and so on. This field is used only where the SQL statement operates on a database object. If the SQL statement is not operating on an object, this value is null.

Valid values for Aurora MySQL include the following:
- INDEX
- TABLE
- UNKNOWN

paramList | string | This field isn't used for Aurora MySQL and is always null.
<table>
<thead>
<tr>
<th>Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pid</td>
<td>int</td>
<td>The process ID of the backend process that is allocated for serving the client connection. When the database server is restarted, the pid changes and the counter for the statementId field starts over.</td>
</tr>
<tr>
<td>remoteHost</td>
<td>string</td>
<td>Either the IP address or hostname of the client that issued the SQL statement. For Aurora MySQL, which one is used depends on the database's skip_name_resolve parameter setting. The value localhost indicates activity from the rdsadmin special user.</td>
</tr>
<tr>
<td>remotePort</td>
<td>string</td>
<td>The client port number.</td>
</tr>
<tr>
<td>rowCount</td>
<td>int</td>
<td>The number of table rows affected or retrieved by the SQL statement. This field is used only for SQL statements that are data manipulation language (DML) statements. If the SQL statement is not a DML statement, this value is null.</td>
</tr>
<tr>
<td>serverHost</td>
<td>string</td>
<td>The database server instance identifier. This value is represented differently for Aurora MySQL than for Aurora PostgreSQL. Aurora PostgreSQL uses an IP address instead of an identifier.</td>
</tr>
<tr>
<td>serverType</td>
<td>string</td>
<td>The database server type, for example MySQL.</td>
</tr>
<tr>
<td>serverVersion</td>
<td>string</td>
<td>The database server version. Currently, this value is always MySQL 5.7.12 for Aurora MySQL.</td>
</tr>
<tr>
<td>serviceName</td>
<td>string</td>
<td>The name of the service. Currently, this value is always Amazon Aurora MySQL for Aurora MySQL.</td>
</tr>
<tr>
<td>sessionId</td>
<td>int</td>
<td>A pseudo-unique session identifier.</td>
</tr>
<tr>
<td>startTime</td>
<td>string</td>
<td>The time when execution began for the SQL statement. It is represented in Coordinated Universal Time (UTC) format. To calculate the execution time of the SQL statement, use endTime - startTime. See also the endTime field.</td>
</tr>
<tr>
<td>statementId</td>
<td>int</td>
<td>An identifier for the client's SQL statement. The counter increments with each SQL statement entered by the client. The counter is reset when the DB instance is restarted.</td>
</tr>
<tr>
<td>substatementId</td>
<td>int</td>
<td>An identifier for a SQL substatement. This value is 1 for events with class MAIN and 2 for events with class AUX. Use the statementId field to identify all the events generated by the same statement.</td>
</tr>
<tr>
<td>transactionId</td>
<td>int</td>
<td>An identifier for a transaction.</td>
</tr>
<tr>
<td>type</td>
<td>string</td>
<td>The event type. Valid values are record or heartbeat.</td>
</tr>
</tbody>

Processing a database activity stream using the AWS SDK

You can programmatically process an activity stream by using the AWS SDK. The following are fully functioning Java and Python examples of how you might process the Kinesis data stream.

Java

```java
import java.io.ByteArrayInputStream;
import java.io.ByteArrayOutputStream;
import java.io.IOException;
import java.net.InetAddress;
import java.nio.ByteBuffer;
import java.nio.charset.StandardCharsets;
import java.security.NoSuchAlgorithmException;
import java.security.NoSuchProviderException;
import java.security.Security;
import java.util.HashMap;
import java.util.List;
import java.util.Map;
import java.util.UUID;
import java.util.zip.GZIPInputStream;
import javax.crypto.Cipher;
import javax.crypto.NoSuchPaddingException;
import javax.crypto.spec.SecretKeySpec;
import com.amazonaws.auth.AWSStaticCredentialsProvider;
import com.amazonaws.auth.BasicAWSCredentials;
import com.amazonaws.encryptionsdk.AwsCrypto;
import com.amazonaws.encryptionsdk.CryptoInputStream;
import com.amazonaws.encryptionsdk.jce.JceMasterKey;
import com.amazonaws.services.kinesis.clientlibrary.exceptions.InvalidStateException;
import com.amazonaws.services.kinesis.clientlibrary.exceptions.ShutdownException;
import com.amazonaws.services.kinesis.clientlibrary.exceptions.ThrottlingException;
import com.amazonaws.services.kinesis.clientlibrary.interfaces.IRecordProcessor;
import com.amazonaws.services.kinesis.clientlibrary.interfaces.IRecordProcessorCheckpointer;
import com.amazonaws.services.kinesis.clientlibrary.interfaces.IRecordProcessorFactory;
import com.amazonaws.services.kinesis.clientlibrary.lib.worker.InitialPositionInStream;
import com.amazonaws.services.kinesis.clientlibrary.lib.worker.KinesisClientLibConfiguration;

            shard_iters = next_shard_iters
Managing access to database activity streams

Any user with appropriate AWS Identity and Access Management (IAM) role privileges for database activity streams can create, start, stop, and modify the activity stream settings for a DB cluster. These actions are included in the audit log of the stream. For best compliance practices, we recommend that you don’t provide these privileges to DBAs.

You set access to database activity streams using IAM policies. For more information about Aurora authentication, see Identity and access management for Amazon Aurora (p. 2400). For more information about creating IAM policies, see Creating and using an IAM policy for IAM database access (p. 2436).

Example Policy to allow configuring database activity streams

To give users fine-grained access to modify activity streams, use the service-specific operation context keys `rds:StartActivityStream` and `rds:StopActivityStream` in an IAM policy. The following IAM policy example allows a user or role to configure activity streams.

```json
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid":"ConfigureActivityStreams",
            "Effect":"Allow",
            "Action": [ "rds:StartActivityStream", "rds:StopActivityStream"
            ],
            "Resource": "*",
        }
    ]
}
```

Example Policy to allow starting database activity streams

The following IAM policy example allows a user or role to start activity streams.

```json
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid":"AllowStartActivityStreams",
            "Effect":"Allow",
            "Action":"rds:StartActivityStream",
            "Resource": "*"
        }
    ]
}
```

Example Policy to allow stopping database activity streams

The following IAM policy example allows a user or role to stop activity streams.

```json
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid":"AllowStopActivityStreams",
            "Effect":"Allow",
            "Action":"rds:StopActivityStream",
            "Resource": "*"
        }
    ]
}
```
"Statement": [  
  {  
    "Sid":"AllowStopActivityStreams",  
    "Effect":"Allow",  
    "Action":"rds:StopActivityStream",  
    "Resource":"*"  
  }  
]  
}

Example Policy to deny starting database activity streams

The following IAM policy example prevents a user or role from starting activity streams:

{
  "Version":"2012-10-17",
  "Statement": [  
    {  
      "Sid":"DenyStartActivityStreams",  
      "Effect":"Deny",  
      "Action":"rds:StartActivityStream",  
      "Resource":"*"  
    }  
  ]  
}

Example Policy to deny stopping database activity streams

The following IAM policy example prevents a user or role from stopping activity streams:

{
  "Version":"2012-10-17",
  "Statement": [  
    {  
      "Sid":"DenyStopActivityStreams",  
      "Effect":"Deny",  
      "Action":"rds:StopActivityStream",  
      "Resource":"*"  
    }  
  ]  
}
Amazon Aurora MySQL is a fully managed, MySQL-compatible, relational database engine that combines the speed and reliability of high-end commercial databases with the simplicity and cost-effectiveness of open-source databases. Aurora MySQL is a drop-in replacement for MySQL and makes it simple and cost-effective to set up, operate, and scale your new and existing MySQL deployments, thus freeing you to focus on your business and applications. Amazon RDS provides administration for Aurora by handling routine database tasks such as provisioning, patching, backup, recovery, failure detection, and repair. Amazon RDS also provides push-button migration tools to convert your existing Amazon RDS for MySQL applications to Aurora MySQL.

Overview of Amazon Aurora MySQL

The following sections provide an overview of Amazon Aurora MySQL.

Topics

- Amazon Aurora MySQL performance enhancements (p. 779)
- Amazon Aurora MySQL and spatial data (p. 780)
- Aurora MySQL version 3 compatible with MySQL 8.0 (p. 781)
- Aurora MySQL version 2 compatible with MySQL 5.7 (p. 811)
Fast insert

Fast insert accelerates parallel inserts sorted by primary key and applies specifically to LOAD DATA and INSERT INTO ... SELECT ... statements. Fast insert caches the position of a cursor in an index traversal while executing the statement. This avoids unnecessarily traversing the index again.

You can monitor the following metrics to determine the effectiveness of fast insert for your DB cluster:

- `aurora_fast_insert_cache_hits`: A counter that is incremented when the cached cursor is successfully retrieved and verified.
- `aurora_fast_insert_cache_misses`: A counter that is incremented when the cached cursor is no longer valid and Aurora performs a normal index traversal.

You can retrieve the current value of the fast insert metrics using the following command:

```sql
mysql> show global status like 'Aurora_fast_insert%';
```

You will get output similar to the following:

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>aurora_fast_insert_cache_hits</code></td>
<td>3598300</td>
</tr>
<tr>
<td><code>aurora_fast_insert_cache_misses</code></td>
<td>436401336</td>
</tr>
</tbody>
</table>

Amazon Aurora MySQL and spatial data

The following list summarizes the main Aurora MySQL spatial features and explains how they correspond to spatial features in MySQL:

- Aurora MySQL version 2 supports the same spatial data types and spatial relation functions as MySQL 5.7. For more information about these data types and functions, see [Spatial Data Types](#) and [Spatial Relation Functions](#) in the MySQL 5.7 documentation.

- Aurora MySQL version 3 supports the same spatial data types and spatial relation functions as MySQL 8.0. For more information about these data types and functions, see [Spatial Data Types](#) and [Spatial Relation Functions](#) in the MySQL 8.0 documentation.

- Aurora MySQL supports spatial indexing on InnoDB tables. Spatial indexing improves query performance on large datasets for queries on spatial data. In MySQL, spatial indexing for InnoDB tables is available in MySQL 5.7 and 8.0.

Aurora MySQL uses a different spatial indexing strategy from MySQL for high performance with spatial queries. The Aurora spatial index implementation uses a space-filling curve on a B-tree, which is intended to provide higher performance for spatial range scans than an R-tree.

**Note**

In Aurora MySQL, a transaction on a table with a spatial index defined on a column with a spatial reference identifier (SRID) can't insert into an area selected for update by another transaction.

The following data definition language (DDL) statements are supported for creating indexes on columns that use spatial data types.
CREATE TABLE

You can use the SPATIAL INDEX keywords in a CREATE TABLE statement to add a spatial index to a column in a new table. Following is an example.

```
CREATE TABLE test (shape POLYGON NOT NULL, SPATIAL INDEX(shape));
```

ALTER TABLE

You can use the SPATIAL INDEX keywords in an ALTER TABLE statement to add a spatial index to a column in an existing table. Following is an example.

```
ALTER TABLE test ADD SPATIAL INDEX(shape);
```

CREATE INDEX

You can use the SPATIAL keyword in a CREATE INDEX statement to add a spatial index to a column in an existing table. Following is an example.

```
CREATE SPATIAL INDEX shape_index ON test (shape);
```

Aurora MySQL version 3 compatible with MySQL 8.0

You can use Aurora MySQL version 3 to get the latest MySQL-compatible features, performance enhancements, and bug fixes. Following, you can learn about Aurora MySQL version 3, with MySQL 8.0 compatibility. You can learn how to upgrade your clusters and applications to Aurora MySQL version 3.

Some Aurora features, such as Aurora Serverless v2, require Aurora MySQL version 3.

Topics

- Features from MySQL 8.0 Community Edition (p. 781)
- Aurora MySQL version 3 prerequisite for Aurora MySQL Serverless v2 (p. 782)
- Release notes for Aurora MySQL version 3 (p. 782)
- New parallel query optimizations (p. 782)
- Optimizations to reduce database restart time (p. 783)
- New temporary table behavior in Aurora MySQL version 3 (p. 783)
- Comparison of Aurora MySQL version 2 and Aurora MySQL version 3 (p. 791)
- Comparison of Aurora MySQL version 3 and MySQL 8.0 Community Edition (p. 796)
- Upgrading to Aurora MySQL version 3 (p. 799)

Features from MySQL 8.0 Community Edition

The initial release of Aurora MySQL version 3 is compatible with MySQL 8.0.23 Community Edition. MySQL 8.0 introduces several new features, including the following:

- JSON functions. For usage information, see JSON Functions in the MySQL Reference Manual.
- Window functions. For usage information, see Window Functions in the MySQL Reference Manual.
- Common table expressions (CTEs), using the WITH clause. For usage information, see WITH (Common Table Expressions) in the MySQL Reference Manual.
• Optimized ADD COLUMN and RENAME COLUMN clauses for the ALTER TABLE statement. These optimizations are called "instant DDL." Aurora MySQL version 3 is compatible with the community MySQL instant DDL feature. The former Aurora fast DDL feature isn't used. For usage information for instant DDL, see Instant DDL (Aurora MySQL version 3) (p. 897).

• Descending, functional, and invisible indexes. For usage information, see Invisible Indexes, Descending Indexes, and CREATE INDEX Statement in the MySQL Reference Manual.

• Role-based privileges controlled through SQL statements. For more information on changes to the privilege model, see Role-based privilege model (p. 797).

• NOWAIT and SKIP LOCKED clauses with the SELECT ... FOR SHARE statement. These clauses avoid waiting for other transactions to release row locks. For usage information, see Locking Reads in the MySQL Reference Manual.

• Improvements to binary log (binlog) replication. For the Aurora MySQL details, see Binary log replication (p. 795). In particular, you can perform filtered replication. For usage information about filtered replication, see How Servers Evaluate Replication Filtering Rules in the MySQL Reference Manual.

• Hints. Some of the MySQL 8.0–compatible hints were already backported to Aurora MySQL version 2. For information about using hints with Aurora MySQL, see Aurora MySQL hints (p. 1162). For the full list of hints in community MySQL 8.0, see Optimizer Hints in the MySQL Reference Manual.

For the full list of features added to MySQL 8.0 community edition, see the blog post The complete list of new features in MySQL 8.0.

Aurora MySQL version 3 also includes changes to keywords for inclusive language, backported from community MySQL 8.0.26. For details about those changes, see Inclusive language changes for Aurora MySQL version 3 (p. 793).

Aurora MySQL version 3 prerequisite for Aurora MySQL Serverless v2

Aurora MySQL version 3 is a prerequisite for all DB instances in an Aurora MySQL Serverless v2 cluster. Aurora MySQL Serverless v2 includes support for reader instances in a DB cluster, and other Aurora features that aren't available for Aurora MySQL Serverless v1. It also has faster and more granular scaling than Aurora MySQL Serverless v1.

Release notes for Aurora MySQL version 3

For the release notes for all Aurora MySQL version 3 releases, see Database engine updates for Amazon Aurora MySQL version 3 in the Release Notes for Aurora MySQL.

New parallel query optimizations

The Aurora parallel query optimization now applies to more SQL operations:

• Parallel query now applies to tables containing the data types TEXT, BLOB, JSON, GEOMETRY, and VARCHAR and CHAR longer than 768 bytes.

• Parallel query can optimize queries involving partitioned tables.

• Parallel query can optimize queries involving aggregate function calls in the select list and the HAVING clause.

For more information about these enhancements, see Upgrading parallel query clusters to Aurora MySQL version 3 (p. 957). For general information about Aurora parallel query, see Working with parallel query for Amazon Aurora MySQL (p. 948).
Optimizations to reduce database restart time

Your Aurora MySQL DB cluster must be highly available during both planned and unplanned outages.

Database administrators need to perform occasional database maintenance. This maintenance includes database patching, upgrades, database parameter modifications requiring a manual reboot, performing a failover to reduce the time it takes for instance class changes, and so on. These planned actions require downtime.

However, downtime can also be caused by unplanned actions, such as an unexpected failover due to an underlying hardware fault or database resource throttling. All of these planned and unplanned actions result in a database restart.

In Aurora MySQL version 3.05 and higher, we've introduced optimizations that reduce the database restart time. These optimizations provide up to 65% less downtime than without optimizations, and fewer disruptions to your database workloads, after a restart.

During database startup, many internal memory components are initialized. The largest of these is the InnoDB buffer pool, which in Aurora MySQL is 75% of the instance memory size by default. Our testing has found that the initialization time is proportional to the size of InnoDB buffer pool, and therefore scales with the DB instance class size. During this initialization phase, the database can’t accept connections, which causes longer downtime during restarts. The first phase of Aurora MySQL fast restart optimizes the buffer pool initialization, which reduces the time for database initialization and thereby reduces the overall restart time.

For more details, see the blog Reduce downtime with Amazon Aurora MySQL database restart time optimizations.

New temporary table behavior in Aurora MySQL version 3

Aurora MySQL version 3 handles temporary tables differently from earlier Aurora MySQL versions. This new behavior is inherited from MySQL 8.0 Community Edition. There are two types of temporary tables that can be created with Aurora MySQL version 3:

- Internal (or implicit) temporary tables – Created by the Aurora MySQL engine to handle operations such as sorting aggregation, derived tables, or common table expressions (CTEs).
- User-created (or explicit) temporary tables – Created by the Aurora MySQL engine when you use the CREATE TEMPORARY TABLE statement.

There are additional considerations for both internal and user-created temporary tables on Aurora reader DB instances. We discuss these changes in the following sections.

Topics

- Storage engine for internal (implicit) temporary tables (p. 783)
- Limiting the size of internal, in-memory temporary tables (p. 785)
- Mitigating fullness issues for internal temporary tables on Aurora Replicas (p. 789)
- User-created (explicit) temporary tables on reader DB instances (p. 789)
- Temporary table creation errors and mitigation (p. 790)

Storage engine for internal (implicit) temporary tables

When generating intermediate result sets, Aurora MySQL initially attempts to write to in-memory temporary tables. This might be unsuccessful, because of either incompatible data types or configured limits. If so, the temporary table is converted to an on-disk temporary table rather than being held in
memory. More information on this can be found in the Internal Temporary Table Use in MySQL in the MySQL documentation.

In Aurora MySQL version 3, the way internal temporary tables work is different from earlier Aurora MySQL versions. Instead of choosing between the InnoDB and MyISAM storage engines for such temporary tables, now you choose between the TempTable and InnoDB storage engines.

With the TempTable storage engine, you can make an additional choice for how to handle certain data. The data affected overflows the memory pool that holds all the internal temporary tables for the DB instance.

Those choices can influence the performance for queries that generate high volumes of temporary data, for example while performing aggregations such as GROUP BY on large tables.

**Tip**
If your workload includes queries that generate internal temporary tables, confirm how your application performs with this change by running benchmarks and monitoring performance-related metrics.

In some cases, the amount of temporary data fits within the TempTable memory pool or only overflows the memory pool by a small amount. In these cases, we recommend using the TempTable setting for internal temporary tables and memory-mapped files to hold any overflow data. This setting is the default.

The TempTable storage engine is the default. TempTable uses a common memory pool for all temporary tables that use this engine, instead of a maximum memory limit per table. The size of this memory pool is specified by the temptable_max_ram parameter. It defaults to 1 GiB on DB instances with 16 or more GiB of memory, and 16 MB on DB instances with less than 16 GiB of memory. The size of the memory pool influences session-level memory consumption.

In some cases when you use the TempTable storage engine, the temporary data might exceed the size of the memory pool. If so, Aurora MySQL stores the overflow data using a secondary mechanism.

You can set the temptable_max_mmap parameter to choose whether the data overflows to memory-mapped temporary files or to InnoDB internal temporary tables on disk. The different data formats and overflow criteria of these overflow mechanisms can affect query performance. They do so by influencing the amount of data written to disk and the demand on disk storage throughput.

Aurora MySQL stores the overflow data differently depending on your choice of data overflow destination and whether the query runs on a writer or reader DB instance:

- On the writer instance, data that overflows to InnoDB internal temporary tables is stored in the Aurora cluster volume.
- On the writer instance, data that overflows to memory-mapped temporary files resides on local storage on the Aurora MySQL version 3 instance.
- On reader instances, overflow data always resides on memory-mapped temporary files on local storage. That's because read-only instances can't store any data on the Aurora cluster volume.

The configuration parameters related to internal temporary tables apply differently to the writer and reader instances in your cluster:

- On reader instances, Aurora MySQL always uses the TempTable storage engine.
- The size for temptable_max_mmap defaults to 1 GiB for both writer and reader instances, regardless of the DB instance memory size. You can adjust this value on both writer and reader instances.
- Setting temptable_max_mmap to 0 turns off the use of memory-mapped temporary files on writer instances.
- You can't set temptable_max_mmap to 0 on reader instances.
Amazon Aurora User Guide for Aurora
Aurora MySQL version 3 compatible with MySQL 8.0

Note
We don't recommend using the temptable_use_mmap parameter. It has been deprecated, and support for it is expected to be removed in a future MySQL release.

Limiting the size of internal, in-memory temporary tables

As discussed in Storage engine for internal (implicit) temporary tables (p. 783), you can control temporary table resources globally by using the temptable_max_ram and temptable_max_mmap settings.

You can also limit the size of any individual internal, in-memory temporary table by using the tmp_table_size DB parameter. This limit is intended to prevent individual queries from consuming an inordinate amount of global temporary table resources, which can affect the performance of concurrent queries that require these resources.

The tmp_table_size parameter defines the maximum size of temporary tables created by the MEMORY storage engine in Aurora MySQL version 3.

In Aurora MySQL version 3.04 and higher, tmp_table_size also defines the maximum size of temporary tables created by the TempTable storage engine when the aurora_tmptable_enable_per_table_limit DB parameter is set to ON. This behavior is disabled by default (OFF), which is the same behavior as in Aurora MySQL version 3.03 and lower versions.

- When aurora_tmptable_enable_per_table_limit is OFF, tmp_table_size isn't considered for internal, in-memory temporary tables created by the TempTable storage engine.

However, the global TempTable resources limit still applies. Aurora MySQL has the following behavior when the global TempTable resources limit is reached:

- Writer DB instances – Aurora MySQL automatically converts the in-memory temporary table to an InnoDB on-disk temporary table.
- Reader DB instances – The query ends with an error.

```error
ERROR 1114 (HY000): The table '/rdsdbdata/tmp/#sqlxx_xxx' is full
```

- When aurora_tmptable_enable_per_table_limit is ON, Aurora MySQL has the following behavior when the tmp_table_size limit is reached:

  - Writer DB instances – Aurora MySQL automatically converts the in-memory temporary table to an InnoDB on-disk temporary table.
  - Reader DB instances – The query ends with an error.

```error
ERROR 1114 (HY000): The table '/rdsdbdata/tmp/#sqlxx_xxx' is full
```

Both the global TempTable resources limit and the per-table limit apply in this case.

Note
The aurora_tmptable_enable_per_table_limit parameter has no effect when internal_tmp_mem_storage_engine is set to MEMORY. In this case, the maximum size of an in-memory temporary table is defined by the tmp_table_size or max_heap_table_size value, whichever is smaller.

The following examples show the behavior of the aurora_tmptable_enable_per_table_limit parameter for writer and reader DB instances.

Example of writer DB instance with aurora_tmptable_enable_per_table_limit set to OFF

The in-memory temporary table isn't converted to an InnoDB on-disk temporary table.
Example of writer DB instance with `aurora_tmptable_enable_per_table_limit` set to ON

The in-memory temporary table is converted to an InnoDB on-disk temporary table.
Example of reader DB instance with `aurora_tmptable_enable_per_table_limit` set to OFF

The query finishes without an error because `tmp_table_size` doesn't apply, and the global TempTable resources limit hasn't been reached.
Example of reader DB instance with `aurora_tmptable_enable_per_table_limit` set to OFF

This query reaches the global TempTable resources limit with `aurora_tmptable_enable_per_table_limit` set to OFF. The query ends with an error on reader instances.

```sql
mysql> set aurora_tmptable_enable_per_table_limit=0;
Query OK, 0 rows affected (0.00 sec)

mysql> set cte_max_recursion_depth=4294967295;
Query OK, 0 rows affected (0.01 sec)

mysql> WITH RECURSIVE cte (n) AS (SELECT 1 UNION ALL SELECT n + 1 FROM cte WHERE n < 60000000) SELECT max(n) FROM cte;
ERROR 1114 (HY000): The table '/rdsdbdata/tmp/#sqlfd_8_2' is full
```

Example of reader DB instance with `aurora_tmptable_enable_per_table_limit` set to ON

The query ends with an error when the `tmp_table_size` limit is reached.

```sql
mysql> set aurora_tmptable_enable_per_table_limit=1;
Query OK, 0 rows affected (0.00 sec)

mysql> set cte_max_recursion_depth=4294967295;
Query OK, 0 rows affected (0.00 sec)

mysql> WITH RECURSIVE cte (n) AS (SELECT 1 UNION ALL SELECT n + 1 FROM cte WHERE n < 60000000) SELECT max(n) FROM cte;
ERROR 1114 (HY000): The table '/rdsdbdata/tmp/#sqlfd_8_2' is full
```
Mitigating fullness issues for internal temporary tables on Aurora Replicas

To avoid size limitation issues for temporary tables, set the `temptable_max_ram` and `temptable_max_mmap` parameters to a combined value that can fit the requirements of your workload.

Be careful when setting the value of the `temptable_max_ram` parameter. Setting the value too high reduces the available memory on the database instance, which can cause an out-of-memory condition. Monitor the average freeable memory on the DB instance. Then determine an appropriate value for `temptable_max_ram` so that you will still have a reasonable amount of free memory left on the instance. For more information, see Freeable memory issues in Amazon Aurora (p. 2514).

It is also important to monitor the size of the local storage and the temporary table space consumption. For more information on monitoring local storage on an instance, see the AWS Knowledge Center article What is stored in Aurora MySQL-compatible local storage, and how can I troubleshoot local storage issues?

Note
This procedure doesn't work when the `aurora_tmptable_enable_per_table_limit` parameter is set to ON. For more information, see Limiting the size of internal, in-memory temporary tables (p. 785).

Example 1

You know that your temporary tables grow to a cumulative size of 20 GiB. You want to set in-memory temporary tables to 2 GiB and to grow to a maximum of 20 GiB on disk.

Set `temptable_max_ram` to 2,147,483,648 and `temptable_max_mmap` to 21,474,836,480. These values are in bytes.

These parameter settings make sure that your temporary tables can grow to a cumulative total of 22 GiB.

Example 2

Your current instance size is 16xlarge or larger. You don't know the total size of the temporary tables that you might need. You want to be able to use up to 4 GiB in memory and up to the maximum available storage size on disk.

Set `temptable_max_ram` to 4,294,967,296 and `temptable_max_mmap` to 1,099,511,627,776. These values are in bytes.

Here you're setting `temptable_max_mmap` to 1 TiB, which is less than the maximum local storage of 1.2 TiB on a 16xlarge Aurora DB instance.

On a smaller instance size, adjust the value of `temptable_max_mmap` so that it doesn't fill up the available local storage. For example, a 2xlarge instance has only 160 GiB of local storage available. Hence, we recommend setting the value to less than 160 GiB. For more information on the available local storage for DB instance sizes, see Temporary storage limits for Aurora MySQL (p. 878).

User-created (explicit) temporary tables on reader DB instances

You can create explicit temporary tables using the `TEMPORARY` keyword in your `CREATE TABLE` statement. Explicit temporary tables are supported on the writer DB instance in an Aurora DB cluster. You can also use explicit temporary tables on reader DB instances, but the tables can't enforce the use of the InnoDB storage engine.

To avoid errors while creating explicit temporary tables on Aurora MySQL reader DB instances, make sure that you run all `CREATE TEMPORARY TABLE` statements in either or both of the following ways:

- Don't specify the `ENGINE=InnoDB` clause.
- Don't set the SQL mode to `NO_ENGINE_SUBSTITUTION`.

789
Temporary table creation errors and mitigation

The error that you receive is different depending on whether you use a plain CREATE TEMPORARY TABLE statement or the variation CREATE TEMPORARY TABLE AS SELECT. The following examples show the different kinds of errors.

This temporary table behavior only applies to read-only instances. This first example confirms that's the kind of instance the session is connected to.

```sql
mysql> select @@innodb_read_only;
+--------------------+
| @@innodb_read_only |
+--------------------+
|                  1 |
+--------------------+
```

For plain CREATE TEMPORARY TABLE statements, the statement fails when the NO_ENGINE_SUBSTITUTION SQL mode is turned on. When NO_ENGINE_SUBSTITUTION is turned off (default), the appropriate engine substitution is made, and the temporary table creation succeeds.

```sql
mysql> set sql_mode = 'NO_ENGINE_SUBSTITUTION';

mysql> CREATE TEMPORARY TABLE tt2 (id int) ENGINE=InnoDB;
ERROR 3161 (HY000): Storage engine InnoDB is disabled (Table creation is disallowed).

mysql> SET sql_mode = '';

mysql> CREATE TEMPORARY TABLE tt4 (id int) ENGINE=InnoDB;
```

For CREATE TEMPORARY TABLE AS SELECT statements, the statement fails when the NO_ENGINE_SUBSTITUTION SQL mode is turned on. When NO_ENGINE_SUBSTITUTION is turned off (default), the appropriate engine substitution is made, and the temporary table creation succeeds.

```sql
mysql> set sql_mode = 'NOENGINE_SUBSTITUTION';

mysql> CREATE TEMPORARY TABLE tt1 ENGINE=InnoDB AS SELECT * FROM t1;
ERROR 3161 (HY000): Storage engine InnoDB is disabled (Table creation is disallowed).

mysql> SET sql_mode = '';

mysql> SHOW CREATE TABLE tt3;
+-------+----------------------------------------------------------+
| Table | Create Table                                             |
+-------+----------------------------------------------------------+
| tt3   | CREATE TEMPORARY TABLE `tt3` (`id` int DEFAULT NULL)    |
|       | ENGINE=MyISAM DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci |
+-------+----------------------------------------------------------+
1 row in set (0.00 sec)
```

For more information about the storage aspects and performance implications of temporary tables in Aurora MySQL version 3, see the blog post Use the TempTable storage engine on Amazon RDS for MySQL and Amazon Aurora MySQL.
Comparison of Aurora MySQL version 2 and Aurora MySQL version 3

Use the following to learn about changes to be aware of when you upgrade your Aurora MySQL version 2 cluster to version 3.

Topics
- Feature differences between Aurora MySQL version 2 and 3 (p. 791)
- Instance class support (p. 791)
- Parameter changes for Aurora MySQL version 3 (p. 792)
- Status variables (p. 792)
- Inclusive language changes for Aurora MySQL version 3 (p. 793)
- AUTO_INCREMENT values (p. 795)
- Binary log replication (p. 795)

Feature differences between Aurora MySQL version 2 and 3

The following Amazon Aurora MySQL features are supported in Aurora MySQL for MySQL 5.7, but these features aren't supported in Aurora MySQL for MySQL 8.0:

- You can't use Aurora MySQL version 3 for Aurora Serverless v1 clusters. Aurora MySQL version 3 works with Aurora Serverless v2.
- Lab mode doesn't apply to Aurora MySQL version 3. There aren't any lab mode features in Aurora MySQL version 3. Instant DDL supersedes the fast online DDL feature that was formerly available in lab mode. For an example, see Instant DDL (Aurora MySQL version 3) (p. 897).
- The query cache is removed from community MySQL 8.0 and also from Aurora MySQL version 3.
- Aurora MySQL version 3 is compatible with the community MySQL hash join feature. The Aurora-specific implementation of hash joins in Aurora MySQL version 2 isn't used. For information about using hash joins with Aurora parallel query, see Turning on hash join for parallel query clusters (p. 956) and Aurora MySQL hints (p. 1162). For general usage information about hash joins, see Hash Join Optimization in the MySQL Reference Manual.
- The mysql.lambda_async stored procedure that was deprecated in Aurora MySQL version 2 is removed in version 3. For version 3, use the asynchronous function lambda async instead.
- The default character set in Aurora MySQL version 3 is utf8mb4. In Aurora MySQL version 2, the default character set was latin1. For information about this character set, see The utf8mb4 Character Set (4-Byte UTF-8 Unicode Encoding) in the MySQL Reference Manual.

Some Aurora MySQL features are available for certain combinations of AWS Region and DB engine version. For details, see Supported features in Amazon Aurora by AWS Region and Aurora DB engine (p. 26).

Instance class support

Aurora MySQL version 3 supports a different set of instance classes from Aurora MySQL version 2:

- For larger instances, you can use the modern instance classes such as db.r5, db.r6g, and db.x2g.
- For smaller instances, you can use the modern instance classes such as db.t3 and db.t4g.

Note

We recommend using the T DB instance classes only for development and test servers, or other non-production servers. For more details on the T instance classes, see Using T instance classes for development and testing (p. 1103).
The following instance classes from Aurora MySQL version 2 aren't available for Aurora MySQL version 3:

- `db.r4`
- `db.r3`
- `db.t3.small`
- `db.t2`

Check your administration scripts for any CLI statements that create Aurora MySQL DB instances. Hardcode instance class names that aren't available for Aurora MySQL version 3. If necessary, modify the instance class names to ones that Aurora MySQL version 3 supports.

**Tip**
To check the instance classes that you can use for a specific combination of Aurora MySQL version and AWS Region, use the `describe-orderable-db-instance-options` AWS CLI command.

For full details about Aurora instance classes, see *Aurora DB instance classes (p. 84)*.

**Parameter changes for Aurora MySQL version 3**

Aurora MySQL version 3 includes new cluster-level and instance-level configuration parameters. Aurora MySQL version 3 also removes some parameters that were present in Aurora MySQL version 2. Some parameter names are changed as a result of the initiative for inclusive language. For backward compatibility, you can still retrieve the parameter values using either the old names or the new names. However, you must use the new names to specify parameter values in a custom parameter group.

In Aurora MySQL version 3, the value of the `lower_case_table_names` parameter is set permanently at the time the cluster is created. If you use a nondefault value for this option, set up your Aurora MySQL version 3 custom parameter group before upgrading. Then specify the parameter group during the create cluster or snapshot restore operation.

**Note**
With an Aurora global database based on Aurora MySQL, you can't perform an in-place upgrade from Aurora MySQL version 2 to version 3 if the `lower_case_table_names` parameter is turned on. Use the snapshot restore method instead.

In Aurora MySQL version 3, the `init_connect` and `read_only` parameters don't apply for users who have the `CONNECTION_ADMIN` privilege. This includes the Aurora master user. For more information, see *Role-based privilege model (p. 797).*

For the full list of Aurora MySQL cluster parameters, see *Cluster-level parameters (p. 1116).* The table covers all the parameters from Aurora MySQL version 2 and 3. The table includes notes showing which parameters are new in Aurora MySQL version 3 or were removed from Aurora MySQL version 3.

For the full list of Aurora MySQL instance parameters, see *Instance-level parameters (p. 1127).* The table covers all the parameters from Aurora MySQL version 2 and 3. The table includes notes showing which parameters are new in Aurora MySQL version 3 and which parameters were removed from Aurora MySQL version 3. It also includes notes showing which parameters were modifiable in earlier versions but not Aurora MySQL version 3.

For information about parameter names that changed, see *Inclusive language changes for Aurora MySQL version 3 (p. 793).*

**Status variables**

For information about status variables that aren't applicable to Aurora MySQL, see *MySQL status variables that don't apply to Aurora MySQL (p. 1150).*
Inclusive language changes for Aurora MySQL version 3

Aurora MySQL version 3 is compatible with version 8.0.23 from the MySQL community edition. Aurora MySQL version 3 also includes changes from MySQL 8.0.26 related to keywords and system schemas for inclusive language. For example, the `SHOW REPLICA STATUS` command is now preferred instead of `SHOW SLAVE STATUS`.

The following Amazon CloudWatch metrics have new names in Aurora MySQL version 3.

In Aurora MySQL version 3, only the new metric names are available. Make sure to update any alarms or other automation that relies on metric names when you upgrade to Aurora MySQL version 3.

<table>
<thead>
<tr>
<th>Old name</th>
<th>New name</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ForwardingMasterDMLLatency</code></td>
<td><code>ForwardingWriterDMLLatency</code></td>
</tr>
<tr>
<td><code>ForwardingMasterOpenSessions</code></td>
<td><code>ForwardingWriterOpenSessions</code></td>
</tr>
<tr>
<td><code>AuroraDMLRejectedMasterFull</code></td>
<td><code>AuroraDMLRejectedWriterFull</code></td>
</tr>
<tr>
<td><code>ForwardingMasterDMLThroughput</code></td>
<td><code>ForwardingWriterDMLThroughput</code></td>
</tr>
</tbody>
</table>

The following status variables have new names in Aurora MySQL version 3.

For compatibility, you can use either name in the initial Aurora MySQL version 3 release. The old status variable names are to be removed in a future release.

<table>
<thead>
<tr>
<th>Name to be removed</th>
<th>New or preferred name</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Aurora_fwd_master_dml_stmt_duration</code></td>
<td><code>Aurora_fwd_writer_dml_stmt_duration</code></td>
</tr>
<tr>
<td><code>Aurora_fwd_master_dml_stmt_count</code></td>
<td><code>Aurora_fwd_writer_dml_stmt_count</code></td>
</tr>
<tr>
<td><code>Aurora_fwd_master_select_stmt_duration</code></td>
<td><code>Aurora_fwd_writer_select_stmt_duration</code></td>
</tr>
<tr>
<td><code>Aurora_fwd_master_select_stmt_count</code></td>
<td><code>Aurora_fwd_writer_select_stmt_count</code></td>
</tr>
<tr>
<td><code>Aurora_fwd_master_errors_session_timeout</code></td>
<td><code>Aurora_fwd_writer_errors_session_timeout</code></td>
</tr>
<tr>

slave_parallel_workers | replica_parallel_workers
slave_pending_jobs_size_max | replica_pending_jobs_size_max
pseudo_slave_mode | pseudo_replica_mode

The following stored procedures have new names in Aurora MySQL version 3.

For compatibility, you can use either name in the initial Aurora MySQL version 3 release. The old procedure names are to be removed in a future release.

### Name to be removed | New or preferred name
--- | ---
mysql.rds_set_master_auto_position | mysql.rds_set_source_auto_position
mysql.rds_set_external_master | mysql.rds_set_external_source
### AUTO_INCREMENT values

In Aurora MySQL version 3, Aurora preserves the AUTO_INCREMENT value for each table when it restarts each DB instance. In Aurora MySQL version 2, the AUTO_INCREMENT value wasn't preserved after a restart.

The AUTO_INCREMENT value isn't preserved when you set up a new cluster by restoring from a snapshot, performing a point-in-time recovery, and cloning a cluster. In these cases, the AUTO_INCREMENT value is initialized to the value based on the largest column value in the table at the time the snapshot was created. This behavior is different than in RDS for MySQL 8.0, where the AUTO_INCREMENT value is preserved during these operations.

### Binary log replication

In MySQL 8.0 community edition, binary log replication is turned on by default. In Aurora MySQL version 3, binary log replication is turned off by default.

**Tip**

If your high availability requirements are fulfilled by the Aurora built-in replication features, you can leave binary log replication turned off. That way, you can avoid the performance overhead of binary log replication. You can also avoid the associated monitoring and troubleshooting that are needed to manage binary log replication.

Aurora supports binary log replication from a MySQL 5.7–compatible source to Aurora MySQL version 3. The source system can be an Aurora MySQL DB cluster, an RDS for MySQL DB instance, or an on-premises MySQL instance.

As does community MySQL, Aurora MySQL supports replication from a source running a specific version to a target running the same major version or one major version higher. For example, replication from a MySQL 5.6–compatible system to Aurora MySQL version 3 isn't supported. Replicating from Aurora MySQL version 3 to a MySQL 5.7–compatible or MySQL 5.6–compatible system isn't supported. For details about using binary log replication, see [Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication)](p. 1015).

Aurora MySQL version 3 includes improvements to binary log replication in community MySQL 8.0, such as filtered replication. For details about the community MySQL 8.0 improvements, see [How Servers Evaluate Replication Filtering Rules](in the MySQL Reference Manual).

### Multithreaded replication

With Aurora MySQL version 3, Aurora MySQL supports multithreaded replication. For usage information, see [Multithreaded binary log replication (Aurora MySQL version 3 and higher)](p. 1032).

**Note**

We still recommend not using multithreaded replication with Aurora MySQL version 2.

### Transaction compression for binary log replication

For usage information about binary log compression, see [Binary Log Transaction Compression](in the MySQL Reference Manual).
The following limitations apply to binary log compression in Aurora MySQL version 3:

- Transactions whose binary log data is larger than the maximum allowed packet size aren't compressed. This is true regardless of whether the Aurora MySQL binary log compression setting is turned on. Such transactions are replicated without being compressed.
- If you use a connector for change data capture (CDC) that doesn't support MySQL 8.0 yet, you can't use this feature. We recommend that you test any third-party connectors thoroughly with binary log compression. Also, we recommend that you do so before turning on binlog compression on systems that use binlog replication for CDC.

Comparison of Aurora MySQL version 3 and MySQL 8.0 Community Edition

You can use the following information to learn about the changes to be aware of when you convert from a different MySQL 8.0–compatible system to Aurora MySQL version 3.

In general, Aurora MySQL version 3 supports the feature set of community MySQL 8.0.23. Some new features from MySQL 8.0 community edition don't apply to Aurora MySQL. Some of those features aren't compatible with some aspect of Aurora, such as the Aurora storage architecture. Other features aren't needed because the Amazon RDS management service provides equivalent functionality. The following features in community MySQL 8.0 aren't supported or work differently in Aurora MySQL version 3.

For release notes for all Aurora MySQL version 3 releases, see Database engine updates for Amazon Aurora MySQL version 3 in the Release Notes for Aurora MySQL.

Topics
- MySQL 8.0 features not available in Aurora MySQL version 3 (p. 796)
- Role-based privilege model (p. 797)
- Authentication (p. 799)

MySQL 8.0 features not available in Aurora MySQL version 3

The following features from community MySQL 8.0 aren't available or work differently in Aurora MySQL version 3.

- Resource groups and associated SQL statements aren't supported in Aurora MySQL.
- The Aurora storage architecture means that you don't have to manually manage files and the underlying storage for your database. In particular, Aurora handles the undo tablespace differently than community MySQL does. This difference from community MySQL has the following consequences:
  - Aurora MySQL doesn't support named tablespaces.
  - The innodb_undo_log_truncate configuration setting is turned off and can't be turned on. Aurora has its own mechanism for reclaiming storage space.
  - Aurora MySQL doesn't have the CREATE UNDO TABLESPACE, ALTER UNDO TABLESPACE ... SET INACTIVE, and DROP UNDO TABLESPACE statements.
  - Aurora sets the number of undo tablespaces automatically and manages those tablespaces for you.
- TLS 1.3 is supported in Aurora MySQL version 3.04.0 and higher.
- The aurora_hot_page_contention status variable isn't available. The hot page contention feature isn't supported. For the full list of status variables not available in Aurora MySQL version 3, see Status variables (p. 792).
- You can't modify the settings of any MySQL plugins.
- The X plugin isn't supported.
Multisource replication isn't supported.

**Role-based privilege model**

With Aurora MySQL version 3, you can't modify the tables in the mysql database directly. In particular, you can't set up users by inserting into the mysql.user table. Instead, you use SQL statements to grant role-based privileges. You also can't create other kinds of objects such as stored procedures in the mysql database. You can still query the mysql tables. If you use binary log replication, changes made directly to the mysql tables on the source cluster aren't replicated to the target cluster.

In some cases, your application might use shortcuts to create users or other objects by inserting into the mysql tables. If so, change your application code to use the corresponding statements such as CREATE USER. If your application creates stored procedures or other objects in the mysql database, use a different database instead.

To export metadata for database users during the migration from an external MySQL database, you can use mysqldump command instead of mysqldump. Use the following syntax.

```
mysqldump --exclude-databases=mysql --users
```

This statement dumps all databases except for the tables in the mysql system database. It also includes CREATE USER and GRANT statements to reproduce all MySQL users in the migrated database. You can also use the pt-show-grants tool on the source system to list CREATE USER and GRANT statements to reproduce all the database users.

To simplify managing permissions for many users or applications, you can use the CREATE ROLE statement to create a role that has a set of permissions. Then you can use the GRANT and SET ROLE statements and the current_role function to assign roles to users or applications, switch the current role, and check which roles are in effect. For more information on the role-based permission system in MySQL 8.0, see Using Roles in the MySQL Reference Manual.

**Important**

We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

Aurora MySQL version 3 includes a special role that has all of the following privileges. This role is named rds_superuser_role. The primary administrative user for each cluster already has this role granted. The rds_superuser_role role includes the following privileges for all database objects:

- ALTER
- APPLICATION_PASSWORD_ADMIN
- ALTER ROUTINE
- CONNECTION_ADMIN
- CREATE
- CREATE ROLE
- CREATE ROUTINE
- CREATE TEMPORARY TABLES
- CREATE USER
- CREATE VIEW
- DELETE
- DROP
- DROP ROLE
EVENT
EXECUTE
INDEX
INSERT
LOCK TABLES
PROCESS
REFERENCES
RELOAD
REPLICATION CLIENT
REPLICATION SLAVE
ROLE_ADMIN
SET_USER_ID
SELECT
SHOW DATABASES
SHOW ROUTINE (Aurora MySQL version 3.04 and higher)
SHOW VIEW
TRIGGER
UPDATE
XA_RECOVER_ADMIN

The role definition also includes WITH GRANT OPTION so that an administrative user can grant that role to other users. In particular, the administrator must grant any privileges needed to perform binary log replication with the Aurora MySQL cluster as the target.

Tip
To see the full details of the permissions, enter the following statements.

SHOW GRANTS FOR rds_superuser_role@'%';
SHOW GRANTS FOR name_of_administrative_user_for_your_cluster@'%';

Aurora MySQL version 3 also includes roles that you can use to access other AWS services. You can set these roles as an alternative to GRANT statements. For example, you specify GRANT AWS_LAMBDA_ACCESS TO user instead of GRANT INVOKE LAMBDA ON *.* TO user. For the procedures to access other AWS services, see Integrating Amazon Aurora MySQL with other AWS services (p. 1047). Aurora MySQL version 3 includes the following roles related to accessing other AWS services:

- AWS_LAMBDA_ACCESS role, as an alternative to the INVOKE LAMBDA privilege. For usage information, Invoking a Lambda function from an Amazon Aurora MySQL DB cluster (p. 1075).
- AWS_LOAD_S3_ACCESS role, as an alternative to the LOAD FROM S3 privilege. For usage information, see Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket (p. 1059).
- AWS_SELECT_S3_ACCESS role, as an alternative to the SELECT INTO S3 privilege. For usage information, see Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket (p. 1068).
- AWS_SAGEMAKER_ACCESS role, as an alternative to the INVOKE SAGEMAKER privilege. For usage information, see Using Amazon Aurora machine learning with Aurora MySQL (p. 1086).
- AWS_COMPREHEND_ACCESS role, as an alternative to the INVOKE COMPREHEND privilege. For usage information, see Using Amazon Aurora machine learning with Aurora MySQL (p. 1086).
When you grant access by using roles in Aurora MySQL version 3, you also activate the role by using the `SET ROLE role_name` or `SET ROLE ALL` statement. The following example shows how. Substitute the appropriate role name for `AWS_SELECT_S3_ACCESS`.

```sql
# Grant role to user
mysql> GRANT AWS_SELECT_S3_ACCESS TO 'user'@'domain-or-ip-address'

# Check the current roles for your user. In this case, the AWS_SELECT_S3_ACCESS role has not been activated.
# Only the rds_superuser_role is currently in effect.
mysql> SELECT CURRENT_ROLE();
+--------------------------+
| CURRENT_ROLE()           |
+--------------------------+
| `rds_superuser_role`@`%` |
+--------------------------+
1 row in set (0.00 sec)

# Activate all roles associated with this user using SET ROLE.
# You can activate specific roles or all roles.
# In this case, the user only has 2 roles, so we specify ALL.
mysql> SET ROLE ALL;
Query OK, 0 rows affected (0.00 sec)

# Verify role is now active
mysql> SELECT CURRENT_ROLE();
+--------------------------+
| CURRENT_ROLE()           |
+--------------------------+
| `AWS_LAMBDA_ACCESS`@`%`,`rds_superuser_role`@`%` |
+--------------------------+
```

**Authentication**

In community MySQL 8.0, the default authentication plugin is `caching_sha2_password`. Aurora MySQL version 3 still uses the `mysql_native_password` plugin. You can't change the `default_authentication_plugin` setting.

**Upgrading to Aurora MySQL version 3**

For specific upgrade paths to upgrade your database from Aurora MySQL version 2 to version 3, you can use one of the following approaches:

- Perform an in-place upgrade. Follow the procedure in [How to perform an in-place upgrade](p. 1217).
- Create a snapshot of the version 2 cluster and restore the snapshot to create a new version 3 cluster. Follow the procedure in [Restoring from a DB cluster snapshot](p. 439).

**Tip**

In some cases, you might specify the option to upload database logs to CloudWatch when you upgrade. If so, examine the logs in CloudWatch to diagnose any issues that occur during the upgrade operation. The CLI examples in this section demonstrate how to do so using the `--enable-cloudwatch-logs-exports` option.

**Topics**

- [Upgrade planning for Aurora MySQL version 3](p. 800)
- [Example of upgrading from Aurora MySQL version 2 to version 3 using the snapshot restore method](p. 800)
- [Troubleshooting upgrade issues with Aurora MySQL version 3](p. 802)
Upgrade planning for Aurora MySQL version 3

To help you decide the right time and approach to upgrade, you can learn the differences between Aurora MySQL version 3 and your current Aurora and MySQL environment:

- If you are converting from RDS for MySQL 8.0 or MySQL 8.0 Community Edition, see [Comparison of Aurora MySQL version 3 and MySQL 8.0 Community Edition](p. 796).
- If you are upgrading from Aurora MySQL version 2, RDS for MySQL 5.7, or community MySQL 5.7, see [Comparison of Aurora MySQL version 2 and Aurora MySQL version 3](p. 791).
- Create new MySQL 8.0-compatible versions of any custom parameter groups. Apply any necessary custom parameter values to the new parameter groups. Consult [Parameter changes for Aurora MySQL version 3](p. 792) to learn about parameter changes.

**Note**

For most parameter settings, you can choose the custom parameter group at two points. These are when you create the cluster or associate the parameter group with the cluster later. However, if you use a nondefault setting for the lower_case_table_names parameter, you must set up the custom parameter group with this setting in advance. Then specify the parameter group when you perform the snapshot restore to create the cluster. Any change to the lower_case_table_names parameter has no effect after the cluster is created. We recommend that you use the same setting for lower_case_table_names when you upgrade from Aurora MySQL version 2 to version 3.

With an Aurora global database based on Aurora MySQL, you can't perform an in-place upgrade from Aurora MySQL version 2 to version 3 if the lower_case_table_names parameter is turned on. For more information on the methods that you can use, see [Major version upgrades](p. 1876).

- Review your Aurora MySQL version 2 database schema and object definitions for the usage of new reserved keywords introduced in MySQL 8.0 Community Edition. Do so before you upgrade. For more information, see [MySQL 8.0 New Keywords and Reserved Words](p. 800) in the MySQL documentation.

You can also find more MySQL-specific upgrade considerations and tips in [Changes in MySQL 8.0](p. 800) in the [MySQL Reference Manual](p. 800). For example, you can use the command `mysqlcheck --check-upgrade` to analyze your existing Aurora MySQL databases and identify potential upgrade issues.

**Note**

We recommend using larger DB instance classes when upgrading to Aurora MySQL version 3 using the in-place upgrade or snapshot restore technique. Examples are db.r5.24xlarge and db.r6g.16xlarge. This helps the upgrade process to complete faster by using the majority of available CPU capacity on the DB instance. You can change to the DB instance class that you want after the major version upgrade is complete.

After you finish the upgrade itself, you can follow the post-upgrade procedures in [Post-upgrade cleanup for Aurora MySQL version 3](p. 810). Finally, test your application's functionality and performance.

If you are converting from RDS from MySQL or community MySQL, follow the migration procedure explained in [Migrating data to an Amazon Aurora MySQL DB cluster](p. 836). In some cases, you might use binary log replication to synchronize your data with an Aurora MySQL version 3 cluster as part of the migration. If so, the source system must run a version that's compatible with MySQL 5.7, or a MySQL 8.0-compatible version that is 8.0.23 or lower.

**Example of upgrading from Aurora MySQL version 2 to version 3 using the snapshot restore method**

The following AWS CLI example demonstrates the steps to upgrade an Aurora MySQL version 2 cluster to Aurora MySQL version 3.
The first step is to determine the version of the cluster that you want to upgrade. The following AWS CLI command shows how. The output confirms that the original cluster is a MySQL 5.7–compatible one that's running Aurora MySQL version 2.09.2.

This cluster has at least one DB instance. For the upgrade process to work properly, this original cluster requires a writer instance.

```
$ aws rds describe-db-clusters --db-cluster-id cluster-57-upgrade-ok --query '[]*.EngineVersion' --output text
5.7.mysql_aurora.2.09.2
```

The following command shows how to check which upgrade paths are available from a specific version. In this case, the original cluster is running version `5.7.mysql_aurora.2.09.2`. The output shows that this version can be upgraded to Aurora MySQL version 3.

If the original cluster uses a version number that is too low to upgrade to Aurora MySQL version 3, the upgrade requires an additional step. First, restore the snapshot to create a new cluster that could be upgraded to Aurora MySQL version 3. Then, take a snapshot of that intermediate cluster. Finally, restore the snapshot of the intermediate cluster to create a new Aurora MySQL version 3 cluster.

```
$ aws rds describe-db-engine-versions --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.09.2 --query 'DBEngineVersions[].ValidUpgradeTarget[].EngineVersion'
[  
  "5.7.mysql_aurora.2.09.3",
  "5.7.mysql_aurora.2.10.0",
  "5.7.mysql_aurora.2.10.1",
  "5.7.mysql_aurora.2.10.2",
  "8.0.mysql_aurora.3.01.1",
  "8.0.mysql_aurora.3.02.0"
]
```

The following command creates a snapshot of the cluster to upgrade to Aurora MySQL version 3. The original cluster remains intact. You later create a new Aurora MySQL version 3 cluster from the snapshot.

```
aws rds create-db-cluster-snapshot --db-cluster-id cluster-57-upgrade-ok --db-cluster-snapshot-id cluster-57-upgrade-ok-snapshot
{
  "DBClusterSnapshotIdentifier": "cluster-57-upgrade-ok-snapshot",
  "DBClusterIdentifier": "cluster-57-upgrade-ok",
  "SnapshotCreateTime": "2021-10-06T23:20:18.087000+00:00"
}
```

The following command restores the snapshot to a new cluster that's running Aurora MySQL version 3.

```
$ aws rds restore-db-cluster-from-snapshot --snapshot-id cluster-57-upgrade-ok-snapshot --db-cluster-id cluster-80-restored --engine aurora-mysql --engine-version 8.0.mysql_aurora.3.02.0 --enable-cloudwatch-logs-exports ['"error","general","slowquery","audit']
{
  "DBClusterIdentifier": "cluster-80-restored",
  "Engine": "aurora-mysql",
  "EngineVersion": "8.0.mysql_aurora.3.02.0",
  "Status": "creating"
}
```

Restoring the snapshot sets up the storage for the cluster and establishes the database version that the cluster can use. The compute capacity of the cluster is separate from the storage. Thus, you set up any
DB instances for the cluster after the cluster itself is created. The following example creates a writer DB instance using one of the db.r5 instance classes.

**Tip**
You might have administration scripts that create DB instances using older instance classes such as db.r3, db.r4, db.t2, or db.t3. If so, modify your scripts to use one of the instance classes that are supported with Aurora MySQL version 3. For information about the instance classes that you can use with Aurora MySQL version 3, see Instance class support (p. 791).

```bash
$ aws rds create-db-instance --db-instance-identifier instance-running-version-3 --db-cluster-identifier cluster-80-restored --db-instance-class db.r5.xlarge --engine aurora-mysql
{
  "DBInstanceIdentifier": "instance-running-version-3",
  "DBClusterIdentifier": "cluster-80-restored",
  "DBInstanceClass": "db.r5.xlarge",
  "EngineVersion": "8.0.mysql_aurora.3.02.0",
  "DBInstanceStatus": "creating"
}
```

After the upgrade is finished, you can verify the Aurora-specific version number of the cluster by using the AWS CLI.

```bash
$ aws rds describe-db-clusters --db-cluster-id cluster-80-restored --query '*[*].EngineVersion' --output text
8.0.mysql_aurora.3.02.0
```

You can also verify the MySQL-specific version of the database engine by calling the version function.

```
mysql> select version();
+-----------+
| version()  |
+-----------+
| 8.0.23     |
+-----------+
```

**Troubleshooting upgrade issues with Aurora MySQL version 3**

If your upgrade to Aurora MySQL version 3 doesn't complete successfully, you can diagnose the cause of the problem. Then you can make any required changes to the original database schema or table data and run the upgrade process again.

If the upgrade process to Aurora MySQL version 3 fails, the problem is detected while creating and then upgrading the writer instance for the restored snapshot. Aurora leaves behind the original 5.7-compatible writer instance. That way, you can examine the log from the preliminary checks that Aurora runs before performing the upgrade. The following examples start with a 5.7-compatible database that requires some changes before it can be upgraded to Aurora MySQL version 3. The examples demonstrate how the first attempted upgrade doesn't succeed and how to examine the log file. They also show how to fix the problems and run a successful upgrade.

First, we create a new MySQL 5.7-compatible cluster named problematic-57-80-upgrade. As the name suggests, this cluster contains at least one schema object that causes a problem during an upgrade to a MySQL 8.0-compatible version.

```bash
$ aws rds create-db-cluster --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.10.0 --db-cluster-identifier problematic-57-80-upgrade --master-username my_username --manage-master-user-password
```
In the cluster that we intend to upgrade, we introduce a problematic table. Creating a FULLTEXT index and then dropping the index leaves behind some metadata that causes a problem during the upgrade. This example specifies the `--manage-master-user-password` option to generate the master user password and manage it in Secrets Manager. For more information, see Password management with Amazon Aurora and AWS Secrets Manager (p. 2371). Alternatively, you can use the `--master-password` option to specify and manage the password yourself.

This example attempts to perform the upgrade procedure. We take a snapshot of the original cluster and wait for snapshot creation to complete. Then we restore the snapshot, specifying the MySQL 8.0-compatible version number. We also create the writer instance for the cluster. That is the point where the upgrade processing actually happens. Then we wait for the writer instance to become available. That's the point where the upgrade process is finished, whether it succeeded or failed.

**Tip**
If you restore the snapshot using the AWS Management Console, Aurora creates the writer instance automatically and upgrades it to the requested engine version.
Now we examine the newly created cluster and associated instance to verify if the upgrade succeeded. The cluster and instance are still running a MySQL 5.7-compatible version. That means that the upgrade failed. When an upgrade fails, Aurora only leaves the writer instance behind so that you can examine any log files. You can't restart the upgrade process with that newly created cluster. After you correct the problem by making changes in your original cluster, you must run the upgrade steps again: make a new snapshot of the original cluster and restore it to another MySQL 8.0-compatible cluster.

To get a summary of what happened during the upgrade process, we get a listing of events for the newly created writer instance. In this example, we list the events over the last 600 minutes to cover the whole time interval of the upgrade process. The events in the listing aren't necessarily in chronological order. The highlighted event shows the problem that confirms the cluster couldn't be upgraded.

```bash
aws rds describe-events
```
To diagnose the exact cause of the problem, examine the database logs for the newly created writer instance. When an upgrade to an 8.0-compatible version fails, the instance contains a log file with the file name upgrade-prechecks.log. This example shows how to detect the presence of that log and then download it to a local file for examination.

```bash
$ aws rds describe-db-log-files --db-instance-identifier instance-attempt-1 \
--query '*[].LogFileName' --output text
error/mysql-error-running.log
error/mysql-error-running.log.2021-12-03.20
error/mysql-error-running.log.2021-12-03.21
error/mysql-error.log
external/mysql-external.log
upgrade-prechecks.log

$ aws rds download-db-log-file-portion --db-instance-identifier instance-attempt-1 \
--log-file-name upgrade-prechecks.log --starting-token 0 \
--output text upgrade_prechecks.log
```

The upgrade-prechecks.log file is in JSON format. We download it using the --output text option to avoid encoding JSON output within another JSON wrapper. For Aurora MySQL version 3 upgrades, this log always includes certain informational and warning messages. It only includes error messages if the upgrade fails. If the upgrade succeeds, the log file isn't produced at all. The following excerpts show the kinds of entries you can expect to find.
$ cat upgrade-prechecks.log
{
  "serverAddress": "/tmp%2Fmysql.sock",
  "serverVersion": "5.7.12",
  "targetVersion": "8.0.23",
  "auroraServerVersion": "2.10.0",
  "auroraTargetVersion": "3.02.0",
  "outfilePath": "/rdsdbdata/tmp/PreChecker.log",
  "checksPerformed": [
      If "detectedProblems" is empty, the upgrade didn't encounter any occurrences of that type of problem. You can ignore those entries.
      
      {
        "id": "oldTemporalCheck",
        "title": "Usage of old temporal type",
        "status": "OK",
        "detectedProblems": []
      },

      Checks for removed variables or changed default values aren't performed automatically. Aurora uses the parameter group mechanism instead of a physical configuration file. You always receive some messages with this CONFIGURATION_ERROR status, whether or not the variable changes have any effect on your database. You can consult the MySQL documentation for details about these changes.

      {
        "id": "removedSysLogVars",
        "title": "Removed system variables for error logging to the system log configuration",
        "status": "CONFIGURATION_ERROR",
        "description": "To run this check requires full path to MySQL server configuration file to be specified at 'configPath' key of options dictionary",
      },

      This warning about obsolete date and time data types occurs if the SQL_MODE setting in your parameter group is left at the default value. Your database might or might not contain columns with the affected types.

      {
        "id": "zeroDatesCheck",
        "title": "Zero Date, Datetime, and Timestamp values",
        "status": "OK",
        "description": "Warning: By default zero date/datetime/timestamp values are no longer allowed in MySQL, as of 5.7.8 NO_ZERO_IN_DATE and NO_ZERO_DATE are included in SQL_MODE by default. These modes should be used with strict mode as they will be merged with strict mode in a future release. If you do not include these modes in your SQL_MODE setting, you are able to insert date/datetime/timestamp values that contain zeros. It is strongly advised to replace zero values with valid ones, as they may not work correctly in the future.",
        "documentationLink": "https://lefred.be/content/mysql-8-0-and-wrong-dates/",
        "detectedProblems": [
          {
            "level": "Warning",
            "dbObject": "global.sql_mode",
            "description": "does not contain either NO_ZERO_DATE or NO_ZERO_IN_DATE which allows insertion of zero dates"
          }
        ]
      }
    ]
  ]
When the `detectedProblems` field contains entries with a `level` value of `Error`, that means that the upgrade can't succeed until you correct those issues.

```
{
   "id": "getDanglingFulltextIndex",
   "title": "Tables with dangling FULLTEXT index reference",
   "status": "OK",
   "description": "Error: The following tables contain dangling FULLTEXT index which is not supported. It is recommended to rebuild the table before upgrade.",
   "detectedProblems": [
      {
         "level": "Error",
         "dbObject": "problematic_upgrade.dangling_fulltext_index",
         "description": "Table 'problematic_upgrade.dangling_fulltext_index' contains dangling FULLTEXT index. Kindly recreate the table before upgrade."
      }
   ],
}
```

**Tip**

To summarize all of those errors and display the associated object and description fields, you can run the command `grep -A 2 ""level": "Error""` on the contents of the `upgrade-prechecks.log` file. Doing so displays each error line and the two lines after it. These contain the name of the corresponding database object and guidance about how to correct the problem.

```
$ cat upgrade-prechecks.log | grep -A 2 ""level": "Error"
"level": "Error",
"dbObject": "problematic_upgrade.dangling_fulltext_index",
"description": "Table 'problematic_upgrade.dangling_fulltext_index' contains dangling FULLTEXT index. Kindly recreate the table before upgrade."
```

This `defaultAuthenticationPlugin` check always displays this warning message for Aurora MySQL version 3 upgrades. That's because Aurora MySQL version 3 uses the `mysql_native_password` plugin instead of `caching_sha2_password`. You don't need to take any action for this warning.

```
{
   "id": "defaultAuthenticationPlugin",
   "title": "New default authentication plugin considerations",
   "description": "Warning: The new default authentication plugin 'caching_sha2_password' offers more secure password hashing than previously used 'mysql_native_password' (and consequent improved client connection ..."
}
```

The end of the `upgrade-prechecks.log` file summarizes how many checks encountered each type of minor or severe problem. A nonzero `errorCount` indicates that the upgrade failed.

```
],
"errorCount": 1,
"warningCount": 2,
"noticeCount": 0,
"Summary": "1 errors were found. Please correct these issues before upgrading to avoid compatibility issues."
```
The next sequence of examples demonstrates how to fix this particular issue and run the upgrade process again. This time, the upgrade succeeds.

First, we go back to the original cluster. Then we run OPTIMIZE TABLE tbl_name [, tbl_name] ... on the tables causing the following error:

Table `tbl_name` contains dangling FULLTEXT index. Kindly recreate the table before upgrade.

$ mysql -u my_username -p -h problematic-57-80-upgrade.cluster-example123.us-east-1.rds.amazonaws.com
mysql> show databases;
+---------------------+
| Database            |
+---------------------+
| information_schema  |
| mysql               |
| performance_schema  |
| problematic_upgrade |
| sys                 |
+---------------------+
5 rows in set (0.00 sec)
mysql> use problematic_upgrade;
mysql>
mysql> show tables;
+-------------------------------+
| Tables_in_problematic_upgrade |
+-------------------------------+
| dangling_fulltext_index       |
+-------------------------------+
1 row in set (0.00 sec)
mysql> OPTIMIZE TABLE dangling_fulltext_index;
Query OK, 0 rows affected (0.05 sec)

For more information, see Optimizing InnoDB Full-Text Indexes and OPTIMIZE TABLE Statement in the MySQL documentation.

As an alternative solution you could create a new table with the same structure and contents as the one with faulty metadata. In practice, you would probably rename this table back to the original table name after the upgrade.

$ mysql -u my_username -p -h problematic-57-80-upgrade.cluster-example123.us-east-1.rds.amazonaws.com
mysql> show databases;
+---------------------+
| Database            |
+---------------------+
| information_schema  |
| mysql               |
| performance_schema  |
| problematic_upgrade |
| sys                 |
+---------------------+
5 rows in set (0.00 sec)
mysql> use problematic_upgrade;
mysql>
mysql> show tables;
+-------------------------------+
| Tables_in_problematic_upgrade |
+-------------------------------+
| dangling_fulltext_index       |
+-------------------------------+
808
Now we go through the same process as before. We create a snapshot from the original cluster and restore the snapshot to a new MySQL 8.0-compatible cluster. Then we create a writer instance to complete the upgrade process.

```
$ aws rds create-db-cluster-snapshot --db-cluster-id problematic-57-80-upgrade \
--db-cluster-snapshot-id problematic-57-80-upgrade-snapshot-2 \
  "DBClusterSnapshotIdentifier": "problematic-57-80-upgrade-snapshot-2", 
  "DBClusterIdentifier": "problematic-57-80-upgrade", 
  "Engine": "aurora-mysql", 
  "EngineVersion": "5.7.mysql_aurora.2.10.0"
}

$ aws rds wait db-cluster-snapshot-available \
--db-cluster-snapshot-id problematic-57-80-upgrade-snapshot-2

$ aws rds restore-db-cluster-from-snapshot \
--snapshot-id problematic-57-80-upgrade-snapshot-2 \
--db-cluster-id cluster-80-attempt-2 --engine aurora-mysql \
--enable-cloudwatch-logs-exports '["error","general","slowquery","audit"]' \
  "DBClusterIdentifier": "cluster-80-attempt-2", 
  "Engine": "aurora-mysql", 
  "EngineVersion": "8.0.mysql_aurora.3.02.0", 
  "Status": "creating"
}

$ aws rds create-db-instance --db-instance-identifier instance-attempt-2 \
--db-cluster-identifier cluster-80-attempt-2 \
--db-instance-class db.r5.xlarge --engine aurora-mysql \
  "DBInstanceIdentifier": "instance-attempt-2", 
  "DBClusterIdentifier": "cluster-80-attempt-2", 
  "DBInstanceClass": "db.r5.xlarge", 
  "EngineVersion": "8.0.mysql_aurora.3.02.0", 
  "DBInstanceStatus": "creating"
}

$ aws rds wait db-instance-available \
--db-instance-identifier instance-attempt-2

This time, checking the version after the upgrade completes confirms that the version number changed to reflect Aurora MySQL version 3. We can connect to the database and confirm the MySQL engine
version is an 8.0-compatible one. We confirm that the upgraded cluster contains the fixed version of the table that caused the original upgrade problem.

```sql
$ aws rds describe-db-clusters \
--db-cluster-identifier cluster-80-attempt-2 \
--query '*.EngineVersion' --output text
8.0.mysql_aurora.3.02.0

**Post-upgrade cleanup for Aurora MySQL version 3**

After you finish upgrading any Aurora MySQL version 2 clusters to Aurora MySQL version 3, you can perform these other cleanup actions:

- Create new MySQL 8.0–compatible versions of any custom parameter groups. Apply any necessary custom parameter values to the new parameter groups.
- Update any CloudWatch alarms, setup scripts, and so on to use the new names for any metrics whose names were affected by inclusive language changes. For a list of such metrics, see Inclusive language changes for Aurora MySQL version 3 (p. 793).
- Update any AWS CloudFormation templates to use the new names for any configuration parameters whose names were affected by inclusive language changes. For a list of such parameters, see Inclusive language changes for Aurora MySQL version 3 (p. 793).
Spatial indexes

After upgrading to Aurora MySQL version 3, check if you need to drop or recreate objects and indexes related to spatial indexes. Before MySQL 8.0, Aurora could optimize spatial queries using indexes that didn't contain a spatial resource identifier (SRID). Aurora MySQL version 3 only uses spatial indexes containing SRIDs. During an upgrade, Aurora automatically drops any spatial indexes without SRIDs and prints warning messages in the database log. If you observe such warning messages, create new spatial indexes with SRIDs after the upgrade. For more information about changes to spatial functions and data types in MySQL 8.0, see Changes in MySQL 8.0 in the MySQL Reference Manual.

Aurora MySQL version 2 compatible with MySQL 5.7

This topic describes the differences between Aurora MySQL version 2 and MySQL 5.7 Community Edition.

Features not supported in Aurora MySQL version 2

The following features are supported in MySQL 5.7, but are currently not supported in Aurora MySQL version 2:

- CREATE TABLESPACE SQL statement
- Group replication plugin
- Increased page size
- InnoDB buffer pool loading at startup
- InnoDB full-text parser plugin
- Multisource replication
- Online buffer pool resizing
- Password validation plugin – You can install the plugin, but it isn't supported. You can't customize the plugin.
- Query rewrite plugins
- Replication filtering
- X Protocol

For more information about these features, see the MySQL 5.7 documentation.

Temporary tablespace behavior in Aurora MySQL version 2

In MySQL 5.7, the temporary tablespace is autoextending and increases in size as necessary to accommodate on-disk temporary tables. When temporary tables are dropped, freed space can be reused for new temporary tables, but the temporary tablespace remains at the extended size and doesn't shrink. The temporary tablespace is dropped and re-created when engine is restarted.

In Aurora MySQL version 2, the following behavior applies:

- For new Aurora MySQL DB clusters created with version 2.10 and higher, the temporary tablespace is removed and re-created when you restart the database. This allows the dynamic resizing feature to reclaim the storage space.
- For existing Aurora MySQL DB clusters upgraded to:
  - Version 2.10 or higher – The temporary tablespace is removed and re-created when you restart the database. This allows the dynamic resizing feature to reclaim the storage space.
  - Version 2.09 – Temporary table space isn't removed when you restart the database.

You can check the size of the temporary tablespace on your Aurora MySQL version 2 DB cluster by using the following query:
SELECT
    FILE_NAME,
    TABLESPACE_NAME,
    ROUND((TOTAL_EXTENTS * EXTENT_SIZE) / 1024 / 1024 / 1024, 4) AS SIZE
FROM
    INFORMATION_SCHEMA.FILES
WHERE
    TABLESPACE_NAME = 'innodb_temporary';

For more information, see The Temporary Tablespace in the MySQL documentation.

Storage engine for on-disk temporary tables

Aurora MySQL version 2 uses different storage engines for on-disk internal temporary tables depending on the role of the instance.

- On the writer instance, on-disk temporary tables use the InnoDB storage engine by default. They're stored in the temporary tablespace in the Aurora cluster volume.

  You can change this behavior on the writer instance by modifying the value for the DB parameter internal_tmp_disk_storage_engine. For more information, see Instance-level parameters (p. 1127).

- On reader instances, on-disk temporary tables use the MyISAM storage engine, which uses local storage. That's because read-only instances can't store any data on the Aurora cluster volume.
Security with Amazon Aurora MySQL

Security for Amazon Aurora MySQL is managed at three levels:

- To control who can perform Amazon RDS management actions on Aurora MySQL DB clusters and DB instances, you use AWS Identity and Access Management (IAM). When you connect to AWS using IAM credentials, your AWS account must have IAM policies that grant the permissions required to perform Amazon RDS management operations. For more information, see Identity and access management for Amazon Aurora (p. 2400).

  If you are using IAM to access the Amazon RDS console, make sure to first sign in to the AWS Management Console with your IAM user credentials. Then go to the Amazon RDS console at https://console.aws.amazon.com/rds/.

- Make sure to create Aurora MySQL DB clusters in a virtual public cloud (VPC) based on the Amazon VPC service. To control which devices and Amazon EC2 instances can open connections to the endpoint and port of the DB instance for Aurora MySQL DB clusters in a VPC, use a VPC security group. You can make these endpoint and port connections by using Transport Layer Security (TLS). In addition, firewall rules at your company can control whether devices running at your company can open connections to a DB instance. For more information on VPCs, see Amazon VPC VPCs and Amazon Aurora (p. 2478).

  The supported VPC tenancy depends on the DB instance class used by your Aurora MySQL DB clusters. With default VPC tenancy, the VPC runs on shared hardware. With dedicated VPC tenancy, the VPC runs on a dedicated hardware instance. The burstable performance DB instance classes support default VPC tenancy only. The burstable performance DB instance classes include the db.t2, db.t3, and db.t4g DB instance classes. All other Aurora MySQL DB instance classes support both default and dedicated VPC tenancy.

    Note
    We recommend using the T DB instance classes only for development and test servers, or other non-production servers. For more details on the T instance classes, see Using T instance classes for development and testing (p. 1105).

  For more information about instance classes, see Aurora DB instance classes (p. 84). For more information about default and dedicated VPC tenancy, see Dedicated instances in the Amazon Elastic Compute Cloud User Guide.

- To authenticate login and permissions for an Amazon Aurora MySQL DB cluster, you can take either of the following approaches, or a combination of them:

  - You can take the same approach as with a standalone instance of MySQL.

    Commands such as CREATE USER, RENAME USER, GRANT, REVOKE, and SET PASSWORD work just as they do in on-premises databases, as does directly modifying database schema tables. For more information, see Access control and account management in the MySQL documentation.

  - You can also use IAM database authentication.

    With IAM database authentication, you authenticate to your DB cluster by using an IAM user or IAM role and an authentication token. An authentication token is a unique value that is generated using the Signature Version 4 signing process. By using IAM database authentication, you can use the same credentials to control access to your AWS resources and your databases. For more information, see IAM database authentication (p. 2432).

    Note
    For more information, see Security in Amazon Aurora (p. 2367).
Master user privileges with Amazon Aurora MySQL

When you create an Amazon Aurora MySQL DB instance, the master user has the default privileges listed in Master user account privileges (p. 2474).

To provide management services for each DB cluster, the admin and rdsadmin users are created when the DB cluster is created. Attempting to drop, rename, change the password, or change privileges for the rdsadmin account results in an error.

In Aurora MySQL version 2 DB clusters, the admin and rdsadmin users are created when the DB cluster is created. In Aurora MySQL version 3 DB clusters, the admin, rdsadmin, and rds_superuser_role users are created.

Important
We strongly recommend that you do not use the master user directly in your applications.
Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

For management of the Aurora MySQL DB cluster, the standard kill and kill_query commands have been restricted. Instead, use the Amazon RDS commands rds_kill and rds_kill_query to terminate user sessions or queries on Aurora MySQL DB instances.

Note
Encryption of a database instance and snapshots is not supported for the China (Ningxia) region.

Using TLS with Aurora MySQL DB clusters

Amazon Aurora MySQL DB clusters support Transport Layer Security (TLS) connections from applications using the same process and public key as RDS for MySQL DB instances.

Amazon RDS creates an TLS certificate and installs the certificate on the DB instance when Amazon RDS provisions the instance. These certificates are signed by a certificate authority. The TLS certificate includes the DB instance endpoint as the Common Name (CN) for the TLS certificate to guard against spoofing attacks. As a result, you can only use the DB cluster endpoint to connect to a DB cluster using TLS if your client supports Subject Alternative Names (SAN). Otherwise, you must use the instance endpoint of a writer instance.

For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 2385).

We recommend the AWS JDBC Driver for MySQL as a client that supports SAN with TLS. For more information about the AWS JDBC Driver for MySQL and complete instructions for using it, see the AWS JDBC Driver for MySQL GitHub repository.

Topics
- Requiring a TLS connection to an Aurora MySQL DB cluster (p. 814)
- TLS versions for Aurora MySQL (p. 815)
- Configuring cipher suites for connections to Aurora MySQL DB clusters (p. 816)
- Encrypting connections to an Aurora MySQL DB cluster (p. 818)

Requiring a TLS connection to an Aurora MySQL DB cluster

You can require that all user connections to your Aurora MySQL DB cluster use TLS by using the require_secure_transport DB cluster parameter. By default, the require_secure_transport
parameter is set to OFF. You can set the require_secure_transport parameter to ON to require TLS for connections to your DB cluster.

You can set the require_secure_transport parameter value by updating the DB cluster parameter group for your DB cluster. You don’t need to reboot your DB cluster for the change to take effect. For more information on parameter groups, see Working with parameter groups (p. 212).

Note
The require_secure_transport parameter is available for Aurora MySQL version 2 and 3. You can set this parameter in a custom DB cluster parameter group. The parameter isn’t available in DB instance parameter groups.

When the require_secure_transport parameter is set to ON for a DB cluster, a database client can connect to it if it can establish an encrypted connection. Otherwise, an error message similar to the following is returned to the client:

MySQL Error 3159 (HY000): Connections using insecure transport are prohibited while --require_secure_transport=ON.

**TLS versions for Aurora MySQL**

Aurora MySQL supports Transport Layer Security (TLS) versions 1.0, 1.1, 1.2, and 1.3. Starting in Aurora MySQL version 3.04.0 and higher, you can use the TLS 1.3 protocol to secure your connections. The following table shows the TLS support for Aurora MySQL versions.

<table>
<thead>
<tr>
<th>Aurora MySQL version</th>
<th>TLS 1.0</th>
<th>TLS 1.1</th>
<th>TLS 1.2</th>
<th>TLS 1.3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL version 3</td>
<td>Supported (all versions below 3.04.0)</td>
<td>Supported (all versions below 3.04.0)</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>Aurora MySQL version 2</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
<td>Unsupported</td>
</tr>
</tbody>
</table>

**Important**
If you are using custom parameter groups for your Aurora MySQL clusters with version 2 and versions lower than 3.04.0, we recommend using TLS 1.2 because TLS 1.0 and 1.1 are less secure. The community edition of MySQL 8.0.26 and Aurora MySQL 3.03 and its minor versions deprecated support for TLS versions 1.1 and 1.0.

The community edition of MySQL 8.0.28 and compatible Aurora MySQL versions 3.04.0 and higher do not support TLS 1.1 and TLS 1.0. If you are using Aurora MySQL versions 3.04.0 and higher, do not set the TLS protocol to 1.0 and 1.1 in your custom parameter group.

For Aurora MySQL versions 3.04.0 and higher, the default setting is TLS 1.3 and TLS 1.2.

You can use the tls_version DB cluster parameter to indicate the permitted protocol versions. Similar client parameters exist for most client tools or database drivers. Some older clients might not support newer TLS versions. By default, the DB cluster attempts to use the highest TLS protocol version allowed by both the server and client configuration.

Set the tls_version DB cluster parameter to one of the following values:

- TLSv1.3
- TLSv1.2
- TLSv1.1
• TLSv1

You can also set the `tls_version` parameter as a string of comma-separated list. If you want to use both TLS 1.2 and TLS 1.0 protocols, the `tls_version` parameter must include all protocols from the lowest to the highest protocol. In this case, `tls_version` is set as:

```
tls_version=TLSv1,TLSv1.1,TLSv1.2
```

For information about modifying parameters in a DB cluster parameter group, see [Modifying parameters in a DB cluster parameter group](p. 219). If you use the AWS CLI to modify the `tls_version` DB cluster parameter, the `ApplyMethod` must be set to `pending-reboot`. When the application method is `pending-reboot`, changes to parameters are applied after you stop and restart the DB clusters associated with the parameter group.

### Configuring cipher suites for connections to Aurora MySQL DB clusters

By using configurable cipher suites, you can have more control over the security of your database connections. You can specify a list of cipher suites that you want to allow to secure client TLS connections to your database. With configurable cipher suites, you can control the connection encryption that your database server accepts. Doing this prevents the use of insecure or deprecated ciphers.

Configurable cipher suites are supported in Aurora MySQL version 3 and Aurora MySQL version 2. To specify the list of permissible TLS 1.2, TLS 1.1, TLS 1.0 ciphers for encrypting connections, modify the `ssl_cipher` cluster parameter. Set the `ssl_cipher` parameter in a cluster parameter group using the AWS Management Console, the AWS CLI, or the RDS API.

Set the `ssl_cipher` parameter to a string of comma-separated cipher values for your TLS version. For the client application, you can specify the ciphers to use for encrypted connections by using the `--ssl-cipher` option when connecting to the database. For more about connecting to your database, see [Connecting to an Amazon Aurora MySQL DB cluster](p. 204).

Starting in Aurora MySQL version 3.04.0 and higher, you can specify TLS 1.3 cipher suites. To specify the permissible TLS 1.3 cipher suites, modify the `tls_ciphersuites` parameter in your parameter group. TLS 1.3 has reduced the number of available cipher suites due to changes in the naming convention that removes the key exchange mechanism and certificate used. Set the `tls_ciphersuites` to a string of comma-separated cipher values for TLS 1.3.

The following table shows the supported ciphers along with the TLS encryption protocol and valid Aurora MySQL engine versions for each cipher.

<table>
<thead>
<tr>
<th>Cipher</th>
<th>Encryption protocol</th>
<th>Supported Aurora MySQL versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>DHE-RSA-AES128-SHA</td>
<td>TLS 1.0</td>
<td>3.01.0 and higher, all below 2.11.0</td>
</tr>
<tr>
<td>DHE-RSA-AES128-SHA256</td>
<td>TLS 1.0</td>
<td>3.01.0 and higher, all below 2.11.0</td>
</tr>
<tr>
<td>DHE-RSA-AES128-GCM-SHA256</td>
<td>TLS 1.2</td>
<td>3.01.0 and higher, all below 2.11.0</td>
</tr>
<tr>
<td>DHE-RSA-AES256-SHA</td>
<td>TLS 1.0</td>
<td>3.03.0 and lower, all below 2.11.0</td>
</tr>
<tr>
<td>DHE-RSA-AES256-SHA256</td>
<td>TLS 1.0</td>
<td>3.01.0 and higher, all below 2.11.0</td>
</tr>
<tr>
<td>DHE-RSA-AES256-GCM-SHA384</td>
<td>TLS 1.2</td>
<td>3.01.0 and higher, all below 2.11.0</td>
</tr>
<tr>
<td>ECDHE-RSA-AES128-SHA</td>
<td>TLS 1.0</td>
<td>3.01.0 and higher, 2.09.3 and higher, 2.10.2 and higher</td>
</tr>
</tbody>
</table>
### Using TLS with Aurora MySQL DB clusters

<table>
<thead>
<tr>
<th>Cipher</th>
<th>Encryption protocol</th>
<th>Supported Aurora MySQL versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>ECDHE-RSA-AES128-SHA256</td>
<td>TLS 1.2</td>
<td>3.01.0 and higher, 2.09.3 and higher, 2.10.2 and higher</td>
</tr>
<tr>
<td>ECDHE-RSA-AES128-GCM-SHA256</td>
<td>TLS 1.2</td>
<td>3.01.0 and higher, 2.09.3 and higher, 2.10.2 and higher</td>
</tr>
<tr>
<td>ECDHE-RSA-AES256-SHA</td>
<td>TLS 1.0</td>
<td>3.01.0 and higher, 2.09.3 and higher, 2.10.2 and higher</td>
</tr>
<tr>
<td>ECDHE-RSA-AES256-SHA384</td>
<td>TLS 1.2</td>
<td>3.01.0 and higher, 2.09.3 and higher, 2.10.2 and higher</td>
</tr>
<tr>
<td>ECDHE-RSA-AES256-GCM-SHA384</td>
<td>TLS 1.2</td>
<td>3.01.0 and higher, 2.09.3 and higher, 2.10.2 and higher</td>
</tr>
<tr>
<td>TLS_AES_128_GCM_SHA256</td>
<td>TLS 1.3</td>
<td>3.04.0 and higher</td>
</tr>
<tr>
<td>TLS_AES_256_GCM_SHA384</td>
<td>TLS 1.3</td>
<td>3.04.0 and higher</td>
</tr>
<tr>
<td>TLS_CHACHA20_POLY1305_SHA256</td>
<td>TLS 1.3</td>
<td>3.04.0 and higher</td>
</tr>
</tbody>
</table>

**Note**

DHE-RSA ciphers are only supported by Aurora MySQL versions before 2.11.0. Versions 2.11.0 and higher support only ECDHE ciphers.

For information about modifying parameters in a DB cluster parameter group, see Modifying parameters in a DB cluster parameter group (p. 219). If you use the CLI to modify the ssl_cipher DB cluster parameter, make sure to set the ApplyMethod to pending-reboot. When the application method is pending-reboot, changes to parameters are applied after you stop and restart the DB clusters associated with the parameter group.

You can also use the describe-engine-default-cluster-parameters CLI command to determine which cipher suites are currently supported for a specific parameter group family. The following example shows how to get the allowed values for the ssl_cipher cluster parameter for Aurora MySQL version 2.

```
aws rds describe-engine-default-cluster-parameters --db-parameter-group-family aurora-mysql5.7
```

...some output truncated...

```json
{
  "ParameterName": "ssl_cipher",
  "Description": "The list of permissible ciphers for connection encryption.",
  "Source": "system",
  "ApplyType": "static",
  "DataType": "list",
  "IsModifiable": true,
  "SupportedEngineModes": ["provisioned"]
}
```
For more information about ciphers, see the `ssl_cipher` variable in the MySQL documentation. For more information about cipher suite formats, see the `openssl-ciphers list format` and `openssl-ciphers string format` documentation on the OpenSSL website.

**Encrypting connections to an Aurora MySQL DB cluster**

To encrypt connections using the default `mysql` client, launch the `mysql` client using the `--ssl-ca` parameter to reference the public key, for example:

For MySQL 5.7 and 8.0:

```sql
mysql -h myinstance.123456789012.rds-us-east-1.amazonaws.com --ssl-ca=full_path_to_CA_certificate --ssl-mode=VERIFY_IDENTITY
```

For MySQL 5.6:

```sql
mysql -h myinstance.123456789012.rds-us-east-1.amazonaws.com --ssl-ca=full_path_to_CA_certificate --ssl-verify-server-cert
```

Replace `full_path_to_CA_certificate` with the full path to your Certificate Authority (CA) certificate. For information about downloading a certificate, see *Using SSL/TLS to encrypt a connection to a DB cluster* (p. 2385).

You can require TLS connections for specific users accounts. For example, you can use one of the following statements, depending on your MySQL version, to require TLS connections on the user account `encrypted_user`.

For MySQL 5.7 and 8.0:

```sql
ALTER USER 'encrypted_user'@'%' REQUIRE SSL;
```

For MySQL 5.6:

```sql
GRANT USAGE ON *.* TO 'encrypted_user'@'%' REQUIRE SSL;
```

When you use an RDS Proxy, you connect to the proxy endpoint instead of the usual cluster endpoint. You can make SSL/TLS required or optional for connections to the proxy, in the same way as for connections directly to the Aurora DB cluster. For information about using RDS Proxy, see *Using Amazon RDS Proxy for Aurora* (p. 1879).

**Note**

For more information on TLS connections with MySQL, see the MySQL documentation.
As of January 13, 2023, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your Aurora DB clusters using Transport Layer Security (TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use TLS to connect to your DB clusters. If they do, you can further check whether those applications require certificate verification to connect.

**Note**
Some applications are configured to connect to Aurora MySQL DB clusters only if they can successfully verify the certificate on the server. For such applications, you must update your client application trust stores to include the new CA certificates.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB clusters. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate (p. 2391). For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 2385). For information about using TLS with Aurora MySQL DB clusters, see Using TLS with Aurora MySQL DB clusters (p. 814).
Determining whether a client requires certificate verification to connect

You can check whether JDBC clients and MySQL clients require certificate verification to connect.

**JDBC**

The following example with MySQL Connector/J 8.0 shows one way to check an application's JDBC connection properties to determine whether successful connections require a valid certificate. For more information on all of the JDBC connection options for MySQL, see [Configuration properties](#) in the MySQL documentation.

When using the MySQL Connector/J 8.0, an TLS connection requires verification against the server CA certificate if your connection properties have `sslMode` set to `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```java
Properties properties = new Properties();
properties.setProperty("sslMode", "VERIFY_IDENTITY");
properties.put("user", DB_USER);
properties.put("password", DB_PASSWORD);
```

**Note**

If you use either the MySQL Java Connector v5.1.38 or later, or the MySQL Java Connector v8.0.9 or later to connect to your databases, even if you haven't explicitly configured your applications to use TLS when connecting to your databases, these client drivers default to using TLS. In addition, when using TLS, they perform partial certificate verification and fail to connect if the database server certificate is expired.

**MySQL**

The following examples with the MySQL Client show two ways to check a script's MySQL connection to determine whether successful connections require a valid certificate. For more information on all of the connection options with the MySQL Client, see [Client-side configuration for encrypted connections](#) in the MySQL documentation.

When using the MySQL 5.7 or MySQL 8.0 Client, an TLS connection requires verification against the server CA certificate if for the `--ssl-mode` option you specify `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem --ssl-mode=VERIFY_CA
```

When using the MySQL 5.6 Client, an SSL connection requires verification against the server CA certificate if you specify the `--ssl-verify-server-cert` option, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem --ssl-verify-server-cert
```
Updating your application trust store

For information about updating the trust store for MySQL applications, see Installing SSL certificates in the MySQL documentation.

**Note**
When you update the trust store, you can retain older certificates in addition to adding the new certificates.

Updating your application trust store for JDBC

You can update the trust store for applications that use JDBC for TLS connections.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 2385).

For sample scripts that import certificates, see Sample script for importing certificates into your trust store (p. 2397).

If you are using the mysql JDBC driver in an application, set the following properties in the application.

```java
System.setProperty("javax.net.ssl.trustStore", "certs");
System.setProperty("javax.net.ssl.trustStorePassword", "password");
```

**Note**
Specify a password other than the prompt shown here as a security best practice.

When you start the application, set the following properties.

```bash
java -Djavax.net.ssl.trustStore=\!/path_to_truststore/MyTruststore.jks
-Djavax.net.ssl.trustStorePassword=\!my_truststore_password
com.companyName.MyApplication
```

Example Java code for establishing TLS connections

The following code example shows how to set up the SSL connection that validates the server certificate using JDBC.

```java
public class MySQLSSLTest {
    private static final String DB_USER = "user name";
    private static final String DB_PASSWORD = "password";
    // This key store has only the prod root ca.
    private static final String KEY_STORE_FILE_PATH = "file-path-to-keystore";
    private static final String KEY_STORE_PASS = "keystore-password";

    public static void test(String[] args) throws Exception {
        Class.forName("com.mysql.jdbc.Driver");

        System.setProperty("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
        System.setProperty("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);

        Properties properties = new Properties();
        properties.setProperty("sslMode", "VERIFY_IDENTITY");
        properties.put("user", DB_USER);
        properties.put("password", DB_PASSWORD);

        Connection connection = DriverManager.getConnection("jdbc:mysql://jagdeeps-ssl-test.cn162e2e7kwh.us-east-1.rds.amazonaws.com:3306", properties);
```
Important
After you have determined that your database connections use TLS and have updated your application trust store, you can update your database to use the rds-ca-rsa2048-g1 certificates. For instructions, see step 3 in Updating your CA certificate by modifying your DB instance (p. 2391).
Using Kerberos authentication for Aurora MySQL

You can use Kerberos authentication to authenticate users when they connect to your Aurora MySQL DB cluster. To do so, configure your DB cluster to use AWS Directory Service for Microsoft Active Directory for Kerberos authentication. AWS Directory Service for Microsoft Active Directory is also called AWS Managed Microsoft AD. It's a feature available with AWS Directory Service. To learn more, see What is AWS Directory Service? in the AWS Directory Service Administration Guide.

To start, create an AWS Managed Microsoft AD directory to store user credentials. Then, provide the Active Directory's domain and other information to your Aurora MySQL DB cluster. When users authenticate with the Aurora MySQL DB cluster, authentication requests are forwarded to the AWS Managed Microsoft AD directory.

Keeping all of your credentials in the same directory can save you time and effort. With this approach, you have a centralized location for storing and managing credentials for multiple DB clusters. Using a directory can also improve your overall security profile.

In addition, you can access credentials from your own on-premises Microsoft Active Directory. To do so, create a trusting domain relationship so that the AWS Managed Microsoft AD directory trusts your on-premises Microsoft Active Directory. In this way, your users can access your Aurora MySQL DB clusters with the same Windows single sign-on (SSO) experience as when they access workloads in your on-premises network.

A database can use Kerberos, AWS Identity and Access Management (IAM), or both Kerberos and IAM authentication. However, because Kerberos and IAM authentication provide different authentication methods, a specific user can log in to a database using only one or the other authentication method, but not both. For more information about IAM authentication, see IAM database authentication (p. 2432).

Contents
• Overview of Kerberos authentication for Aurora MySQL DB clusters (p. 824)
• Limitations of Kerberos authentication for Aurora MySQL (p. 824)
• Setting up Kerberos authentication for Aurora MySQL DB clusters (p. 825)
  • Step 1: Create a directory using AWS Managed Microsoft AD (p. 825)
  • Step 2: (Optional) Create a trust for an on-premises Active Directory (p. 827)
  • Step 3: Create an IAM role for use by Amazon Aurora (p. 828)
  • Step 4: Create and configure users (p. 829)
  • Step 5: Create or modify an Aurora MySQL DB cluster (p. 829)
  • Step 6: Create Aurora MySQL users that use Kerberos authentication (p. 830)
    • Modifying an existing Aurora MySQL login (p. 831)

  • Understanding domain membership (p. 835)
Overview of Kerberos authentication for Aurora MySQL DB clusters

To set up Kerberos authentication for an Aurora MySQL DB cluster, complete the following general steps. These steps are described in more detail later.

1. Use AWS Managed Microsoft AD to create an AWS Managed Microsoft AD directory. You can use the AWS Management Console, the AWS CLI, or the AWS Directory Service to create the directory. For detailed instructions, see Create your AWS Managed Microsoft AD directory in the AWS Directory Service Administration Guide.

2. Create an AWS Identity and Access Management (IAM) role that uses the managed IAM policy AmazonRDSDirectoryServiceAccess. The role allows Amazon Aurora to make calls to your directory.

   For the role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further action. For more information, see Activating and deactivating AWS STS in an AWS Region in the IAM User Guide.

3. Create and configure users in the AWS Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users in your Active Directory, see Manage users and groups in AWS managed Microsoft AD in the AWS Directory Service Administration Guide.

4. Create or modify an Aurora MySQL DB cluster. If you use either the CLI or RDS API in the create request, specify a domain identifier with the Domain parameter. Use the d-* identifier that was generated when you created your directory and the name of the IAM role that you created.

   If you modify an existing Aurora MySQL DB cluster to use Kerberos authentication, set the domain and IAM role parameters for the DB cluster. Locate the DB cluster in the same VPC as the domain directory.

5. Use the Amazon RDS primary user credentials to connect to the Aurora MySQL DB cluster. Create the database user in Aurora MySQL by using the instructions in Step 6: Create Aurora MySQL users that use Kerberos authentication (p. 830).

   Users that you create this way can log in to the Aurora MySQL DB cluster using Kerberos authentication. For more information, see Connecting to Aurora MySQL with Kerberos authentication (p. 832).

To use Kerberos authentication with an on-premises or self-hosted Microsoft Active Directory, create a forest trust. A forest trust is a trust relationship between two groups of domains. The trust can be one-way or two-way. For more information about setting up forest trusts using AWS Directory Service, see When to create a trust relationship in the AWS Directory Service Administration Guide.

Limitations of Kerberos authentication for Aurora MySQL

The following limitations apply to Kerberos authentication for Aurora MySQL:

- Kerberos authentication is supported for Aurora MySQL version 3.03 and higher.

For information about AWS Region support, see Kerberos authentication with Aurora MySQL (p. 37).

- To use Kerberos authentication with Aurora MySQL, your MySQL client or connector must use version 8.0.26 or higher on Unix platforms, 8.0.27 or higher on Windows. Otherwise, the client-side authentication_kerberos_client plugin isn't available and you can't authenticate.
Setting up Kerberos authentication for Aurora MySQL

Setting up Kerberos authentication for Aurora MySQL DB clusters

Use AWS Managed Microsoft AD to set up Kerberos authentication for an Aurora MySQL DB cluster. To set up Kerberos authentication, take the following steps.

Topics

- Step 1: Create a directory using AWS Managed Microsoft AD (p. 825)
- Step 2: (Optional) Create a trust for an on-premises Active Directory (p. 827)
- Step 3: Create an IAM role for use by Amazon Aurora (p. 828)
- Step 4: Create and configure users (p. 829)
- Step 5: Create or modify an Aurora MySQL DB cluster (p. 829)
- Step 6: Create Aurora MySQL users that use Kerberos authentication (p. 830)
- Step 7: Configure a MySQL client (p. 831)
- Step 8: (Optional) Configure case-insensitive username comparison (p. 832)

Step 1: Create a directory using AWS Managed Microsoft AD

AWS Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and Domain Name System (DNS) servers on your behalf. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:
• Sets up an Active Directory within the VPC.
• Creates a directory administrator account with the username Admin and the specified password. You use this account to manage your directory.

  Note
  Be sure to save this password. AWS Directory Service doesn't store it. You can reset it, but you can't retrieve it.

• Creates a security group for the directory controllers.

When you launch an AWS Managed Microsoft AD, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU has the NetBIOS name that you entered when you created your directory. It is located in the domain root, which is owned and managed by AWS.

The Admin account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU, including:

• Create, update, or delete users
• Add resources to your domain, such as file or print servers, and then assign permissions for those resources to users in your OU
• Create additional OUs and containers
• Delegate authority
• Restore deleted objects from the Active Directory Recycle Bin
• Run AD and DNS Windows PowerShell modules on the Active Directory Web Service

The Admin account also has rights to perform the following domain-wide activities:

• Manage DNS configurations (add, remove, or update records, zones, and forwarders)
• View DNS event logs
• View security event logs

To create a directory with AWS Managed Microsoft AD

2. In the navigation pane, choose Directories and choose Set up Directory.
3. Choose AWS Managed Microsoft AD. AWS Managed Microsoft AD is the only option that you can currently use with Amazon RDS.
4. Enter the following information:

  Directory DNS name
  The fully qualified name for the directory, such as corp.example.com.

  Directory NetBIOS name
  The short name for the directory, such as CORP.

  Directory description
  (Optional) A description for the directory.

  Admin password
  The password for the directory administrator. The directory creation process creates an administrator account with the username Admin and this password.
The directory administrator password and can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:
- Lowercase letters (a–z)
- Uppercase letters (A–Z)
- Numbers (0–9)
- Non-alphanumeric characters (~!#$%^&*_-+=`|(){}[]:;"'<>,.?/)

Confirm password

The administrator password re-entered.

5. Choose Next.

6. Enter the following information in the Networking section and then choose Next:

VPC

The VPC for the directory. Create the Aurora MySQL DB cluster in this same VPC.

Subnets

Subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Review the directory information and make any necessary changes. When the information is correct, choose Create directory.

It takes several minutes to create the directory. When it has been successfully created, the Status value changes to Active.

To see information about your directory, choose the directory name in the directory listing. Note the Directory ID value because you need this value when you create or modify your Aurora MySQL DB cluster.

Step 2: (Optional) Create a trust for an on-premises Active Directory

If you don’t plan to use your own on-premises Microsoft Active Directory, skip to Step 3: Create an IAM role for use by Amazon Aurora (p. 828).

To use Kerberos authentication with your on-premises Active Directory, you need to create a trusting domain relationship using a forest trust between your on-premises Microsoft Active Directory and the AWS Managed Microsoft AD directory (created in Step 1: Create a directory using AWS Managed Microsoft AD (p. 825)). The trust can be one-way, where the AWS Managed Microsoft AD directory trusts the on-premises Microsoft Active Directory. The trust can also be two-way, where both Active Directories trust each other. For more information about setting up trusts using AWS Directory Service, see When to create a trust relationship in the AWS Directory Service Administration Guide.

Note

If you use an on-premises Microsoft Active Directory:

- Windows clients must connect using the domain name of the AWS Directory Service in the endpoint rather than rds.amazonaws.com. For more information, see Connecting to Aurora MySQL with Kerberos authentication (p. 832).
- Windows clients can’t connect using Aurora custom endpoints. To learn more, see Amazon Aurora connection management (p. 62).
- For global databases (p. 1800):
  - Windows clients can connect using instance endpoints or cluster endpoints in the primary AWS Region of the global database only.
• Windows clients can't connect using cluster endpoints in secondary AWS Regions.

Make sure that your on-premises Microsoft Active Directory domain name includes a DNS suffix routing that corresponds to the newly created trust relationship. The following screenshot shows an example.

Step 3: Create an IAM role for use by Amazon Aurora

For Amazon Aurora to call AWS Directory Service for you, you need an AWS Identity and Access Management (IAM) role that uses the managed IAM policy AmazonRDSDirectoryServiceAccess. This role allows Aurora to make calls to the AWS Directory Service.

When you create a DB cluster using the AWS Management Console, and you have the iam:CreateRole permission, the console creates this role automatically. In this case, the role name is rds-directoryservice-kerberos-access-role. Otherwise, you must create the IAM role manually.

When you create this IAM role, choose Directory Service, and attach the AWS managed policy AmazonRDSDirectoryServiceAccess to it.

For more information about creating IAM roles for a service, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

Optionally, you can create policies with the required permissions instead of using the managed IAM policy AmazonRDSDirectoryServiceAccess. In this case, the IAM role must have the following IAM trust policy.

```json

{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "",  
            "Effect": "Allow",  
            "Principal": {  
                "Service": [  
                    "directoryservice.rds.amazonaws.com",  
                    "rds.amazonaws.com"  
                ]  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]
}

```

The role must also have the following IAM role policy.
Step 4: Create and configure users

You can create users with the Active Directory Users and Computers tool. This tool is part of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. Users represent individual people or entities that have access to your directory.

To create users in an AWS Directory Service directory, you use an on-premises or Amazon EC2 instance based on Microsoft Windows that is joined to your AWS Directory Service directory. You must be logged in to the instance as a user that has privileges to create users. For more information, see Manage users and groups in AWS Managed Microsoft AD in the AWS Directory Service Administration Guide.

Step 5: Create or modify an Aurora MySQL DB cluster

Create or modify an Aurora MySQL DB cluster for use with your directory. You can use the console, AWS CLI, or RDS API to associate a DB cluster with a directory. You can do this task in one of the following ways:

- Create a new Aurora MySQL DB cluster using the console, the create-db-cluster CLI command, or the CreateDBCluster RDS API operation.
  
  For instructions, see Creating an Amazon Aurora DB cluster (p. 179).
- Modify an existing Aurora MySQL DB cluster using the console, the modify-db-cluster CLI command, or the ModifyDBCluster RDS API operation.
  
  For instructions, see Modifying an Amazon Aurora DB cluster (p. 269).
- Restore an Aurora MySQL DB cluster from a DB snapshot using the console, the restore-db-cluster-from-snapshot CLI command, or the RestoreDBClusterFromSnapshot RDS API operation.
  
  For instructions, see Restoring from a DB cluster snapshot (p. 439).
- Restore an Aurora MySQL DB cluster to a point-in-time using the console, the restore-db-cluster-to-point-in-time CLI command, or the RestoreDBClusterToPointInTime RDS API operation.
  
  For instructions, see Restoring a DB cluster to a specified time (p. 490).

Kerberos authentication is only supported for Aurora MySQL DB clusters in a VPC. The DB cluster can be in the same VPC as the directory, or in a different VPC. The DB cluster's VPC must have a VPC security group that allows outbound communication to your directory.
Console

When you use the console to create, modify, or restore a DB cluster, choose **Kerberos authentication** in the **Database authentication** section. Choose **Browse Directory** and then select the directory, or choose **Create a new directory**.

AWS CLI

When you use the AWS CLI or RDS API, associate a DB cluster with a directory. The following parameters are required for the DB cluster to use the domain directory you created:

- For the **--domain** parameter, use the domain identifier ("d-*" identifier) generated when you created the directory.
- For the **--domain-iam-role-name** parameter, use the role you created that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

For example, the following CLI command modifies a DB cluster to use a directory.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster --db-cluster-identifier mydbcluster --domain d-ID --domain-iam-role-name role-name
```

For Windows:

```bash
aws rds modify-db-cluster --db-cluster-identifier mydbcluster --domain d-ID --domain-iam-role-name role-name
```

**Important**

If you modify a DB cluster to turn on Kerberos authentication, reboot the reader DB instances after making the change.

Step 6: Create Aurora MySQL users that use Kerberos authentication

The DB cluster is joined to the AWS Managed Microsoft AD domain. Thus, you can create Aurora MySQL users from the Active Directory users in your domain. Database permissions are managed through standard Aurora MySQL permissions that are granted to and revoked from these users.

You can allow an Active Directory user to authenticate with Aurora MySQL. To do this, first use the Amazon RDS primary user credentials to connect to the Aurora MySQL DB cluster as with any other DB cluster. After you're logged in, create an externally authenticated user with Kerberos authentication in Aurora MySQL as shown here:

```sql
CREATE USER user_name@'host_name' IDENTIFIED WITH 'authentication_kerberos' BY 'realm_name';
```

- Replace `user_name` with the username. Users (both humans and applications) from your domain can now connect to the DB cluster from a domain-joined client machine using Kerberos authentication.
- Replace `host_name` with the hostname. You can use % as a wild card. You can also use specific IP addresses for the hostname.
• Replace `realm_name` with the directory realm name of the domain. The realm name is usually the same as the DNS domain name in uppercase letters, such as CORP.EXAMPLE.COM. A realm is a group of systems that use the same Kerberos Key Distribution Center.

The following example creates a database user with the name Admin that authenticates against the Active Directory with the realm name MYSQL.LOCAL.

```
CREATE USER Admin@'%' IDENTIFIED WITH 'authentication_kerberos' BY 'MYSQL.LOCAL';
```

### Modifying an existing Aurora MySQL login

You can also modify an existing Aurora MySQL login to use Kerberos authentication by using the following syntax:

```
ALTER USER user_name IDENTIFIED WITH 'authentication_kerberos' BY 'realm_name';
```

### Step 7: Configure a MySQL client

To configure a MySQL client, take the following steps:

1. Create a `krb5.conf` file (or equivalent) to point to the domain.
2. Verify that traffic can flow between the client host and AWS Directory Service. Use a network utility such as Netcat, for the following:
   - Verify traffic over DNS for port 53.
   - Verify traffic over TCP/UDP for port 53 and for Kerberos, which includes ports 88 and 464 for AWS Directory Service.
3. Verify that traffic can flow between the client host and the DB instance over the database port. For example, use `mysql` to connect and access the database.

The following is sample `krb5.conf` content for AWS Managed Microsoft AD.

```
[libdefaults]
default_realm = EXAMPLE.COM
[realms]
EXAMPLE.COM = {
  kdc = example.com
  admin_server = example.com
}
[domain_realm]
.example.com = EXAMPLE.COM
eexample.com = EXAMPLE.COM
```

The following is sample `krb5.conf` content for an on-premises Microsoft Active Directory.

```
[libdefaults]
default_realm = EXAMPLE.COM
[realms]
EXAMPLE.COM = {
  kdc = example.com
  admin_server = example.com
}
ONPREM.COM = {
  kdc = onprem.com
  admin_server = onprem.com
}
[domain_realm]
```
Step 8: (Optional) Configure case-insensitive username comparison

By default, the character case of the MySQL database username must match that of the Active Directory login. However, you can now use case-insensitive username comparison with the `authentication_kerberos` plugin. To do so, you set the `authentication_kerberos_caseins_cmp` DB cluster parameter to `true`.

To use case-insensitive username comparison

1. Create a custom DB cluster parameter group. Follow the procedures in Creating a DB cluster parameter group (p. 216).
2. Edit the new parameter group to set the value of `authentication_kerberos_caseins_cmp` to `true`. Follow the procedures in Modifying parameters in a DB cluster parameter group (p. 219).
3. Associate the DB cluster parameter group with your Aurora MySQL DB cluster. Follow the procedures in Associating a DB cluster parameter group with a DB cluster (p. 218).
4. Reboot the DB cluster.

Connecting to Aurora MySQL with Kerberos authentication

To avoid errors, use a MySQL client with version 8.0.26 or higher on Unix platforms, 8.0.27 or higher on Windows.

Using the Aurora MySQL Kerberos login to connect to the DB cluster

To connect to Aurora MySQL with Kerberos authentication, you log in as a database user that you created using the instructions in Step 6: Create Aurora MySQL users that use Kerberos authentication (p. 830).

At a command prompt, connect to one of the endpoints associated with your Aurora MySQL DB cluster. When you're prompted for the password, enter the Kerberos password associated with that username.

When you authenticate with Kerberos, a ticket-granting ticket (TGT) is generated if one doesn't already exist. The `authentication_kerberos` plugin uses the TGT to get a service ticket, which is then presented to the Aurora MySQL database server.

You can use the MySQL client to connect to Aurora MySQL with Kerberos authentication using either Windows or Unix.

Unix

You can connect by using either one of the following methods:

- Obtain the TGT manually. In this case, you don't need to supply the password to the MySQL client.
- Supply the password for the Active Directory login directly to the MySQL client.
The client-side plugin is supported on Unix platforms for MySQL client versions 8.0.26 and higher.

**To connect by obtaining the TGT manually**

1. At the command line interface, use the following command to obtain the TGT.

   ```bash
   kinit user_name
   ```

2. Use the following `mysql` command to log in to the DB instance endpoint of your DB cluster.

   ```bash
   mysql -h DB_instance_endpoint -P 3306 -u user_name -p
   ```

   **Note**
   
   Authentication can fail if the keytab is rotated on the DB instance. In this case, obtain a new TGT by rerunning `kinit`.

**To connect directly**

1. At the command line interface, use the following `mysql` command to log in to the DB instance endpoint of your DB cluster.

   ```bash
   mysql -h DB_instance_endpoint -P 3306 -u user_name -p
   ```

2. Enter the password for the Active Directory user.

**Windows**

On Windows, authentication is usually done at login time, so you don't need to obtain the TGT manually to connect to the Aurora MySQL DB cluster. The case of the database username must match the character case of the user in the Active Directory. For example, if the user in the Active Directory appears as `Admin`, the database username must be `Admin`.

The client-side plugin is supported on Windows for MySQL client versions 8.0.27 and higher.

**To connect directly**

- At the command line interface, use the following `mysql` command to log in to the DB instance endpoint of your DB cluster.

  ```bash
  mysql -h DB_instance_endpoint -P 3306 -u user_name
  ```

**Kerberos authentication with Aurora global databases**

Kerberos authentication for Aurora MySQL is supported for Aurora global databases. To authenticate users on the secondary DB cluster using the Active Directory of the primary DB cluster, replicate the Active Directory to the secondary AWS Region. You turn on Kerberos authentication on the secondary cluster using the same domain ID as for the primary cluster. AWS Managed Microsoft AD replication is supported only with the Enterprise version of Active Directory. For more information, see Multi-Region replication in the AWS Directory Service Administration Guide.

**Migrating from RDS for MySQL to Aurora MySQL**

After you migrate from RDS for MySQL with Kerberos authentication enabled to Aurora MySQL, modify users created with the `auth_pam` plugin to use the `authentication_kerberos` plugin. For example:
ALTER USER user_name IDENTIFIED WITH 'authentication_kerberos' BY 'realm_name';

Preventing ticket caching

If a valid TGT doesn't exist when the MySQL client application starts, the application can obtain and cache the TGT. If you want to prevent the TGT from being cached, set a configuration parameter in the /etc/krb5.conf file.

**Note**
This configuration only applies to client hosts running Unix, not Windows.

**To prevent TGT caching**

- Add an [appdefaults] section to /etc/krb5.conf as follows:

  ```
  [appdefaults]
  mysql = {
    destroy_tickets = true
  }
  ```

Logging for Kerberos authentication

The AUTHENTICATION_KERBEROS_CLIENT_LOG environment variable sets the logging level for Kerberos authentication. You can use the logs for client-side debugging.

The permitted values are 1–5. Log messages are written to the standard error output. The following table describes each logging level.

<table>
<thead>
<tr>
<th>Logging level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 or not set</td>
<td>No logging</td>
</tr>
<tr>
<td>2</td>
<td>Error messages</td>
</tr>
<tr>
<td>3</td>
<td>Error and warning messages</td>
</tr>
<tr>
<td>4</td>
<td>Error, warning, and information messages</td>
</tr>
<tr>
<td>5</td>
<td>Error, warning, information, and debug messages</td>
</tr>
</tbody>
</table>

Managing a DB cluster in a domain

You can use the AWS CLI or the RDS API to manage your DB cluster and its relationship with your managed Active Directory. For example, you can associate an Active Directory for Kerberos authentication and disassociate an Active Directory to turn off Kerberos authentication. You can also move a DB cluster to be externally authenticated by one Active Directory to another.

For example, using the Amazon RDS API, you can do the following:

- To reattempt turning on Kerberos authentication for a failed membership, use the ModifyDBInstance API operation and specify the current membership's directory ID.
- To update the IAM role name for membership, use the ModifyDBInstance API operation and specify the current membership's directory ID and the new IAM role.
To turn off Kerberos authentication on a DB cluster, use the `ModifyDBInstance` API operation and specify `none` as the domain parameter.

To move a DB cluster from one domain to another, use the `ModifyDBInstance` API operation and specify the domain identifier of the new domain as the domain parameter.

To list membership for each DB cluster, use the `DescribeDBInstances` API operation.

**Understanding domain membership**

After you create or modify your DB cluster, it becomes a member of the domain. You can view the status of the domain membership for the DB cluster by running the `describe-db-clusters` CLI command. The status of the DB cluster can be one of the following:

- **kerberos-enabled** – The DB cluster has Kerberos authentication turned on.
- **enabling-kerberos** – AWS is in the process of turning on Kerberos authentication on this DB cluster.
- **pending-enable-kerberos** – Turning on Kerberos authentication is pending on this DB cluster.
- **pending-maintenance-enable-kerberos** – AWS will attempt to turn on Kerberos authentication on the DB cluster during the next scheduled maintenance window.
- **pending-disable-kerberos** – Turning off Kerberos authentication is pending on this DB cluster.
- **pending-maintenance-disable-kerberos** – AWS will attempt to turn off Kerberos authentication on the DB cluster during the next scheduled maintenance window.
- **enable-kerberos-failed** – A configuration problem has prevented AWS from turning on Kerberos authentication on the DB cluster. Check and fix your configuration before reissuing the DB cluster modify command.
- **disabling-kerberos** – AWS is in the process of turning off Kerberos authentication on this DB cluster.

A request to turn on Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. For example, suppose that you create a DB cluster or modify an existing DB cluster and the attempt to turn on Kerberos authentication fails. In this case, reissue the modify command or modify the newly created DB cluster to join the domain.
Migrating data to an Amazon Aurora MySQL DB cluster

You have several options for migrating data from your existing database to an Amazon Aurora MySQL DB cluster. Your migration options also depend on the database that you are migrating from and the size of the data that you are migrating.

There are two different types of migration: physical and logical. Physical migration means that physical copies of database files are used to migrate the database. Logical migration means that the migration is accomplished by applying logical database changes, such as inserts, updates, and deletes.

Physical migration has the following advantages:

- Physical migration is faster than logical migration, especially for large databases.
- Database performance does not suffer when a backup is taken for physical migration.
- Physical migration can migrate everything in the source database, including complex database components.

Physical migration has the following limitations:

- The `innodb_page_size` parameter must be set to its default value (16KB).
- The `innodb_data_file_path` parameter must be configured with only one data file that uses the default data file name "ibdata1:12M:autoextend". Databases with two data files, or with a data file with a different name, can't be migrated using this method.

  The following are examples of file names that are not allowed:
  "innodb_data_file_path=ibdata1:50M; ibdata2:50M:autoextend" and "innodb_data_file_path=ibdata01:50M:autoextend".

- The `innodb_log_files_in_group` parameter must be set to its default value (2).

Logical migration has the following advantages:

- You can migrate subsets of the database, such as specific tables or parts of a table.
- The data can be migrated regardless of the physical storage structure.

Logical migration has the following limitations:

- Logical migration is usually slower than physical migration.
- Complex database components can slow down the logical migration process. In some cases, complex database components can even block logical migration.
The following table describes your options and the type of migration for each option.

<table>
<thead>
<tr>
<th>Migrating from</th>
<th>Migration type</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>An RDS for MySQL DB instance</td>
<td>Physical</td>
<td>You can migrate from an RDS for MySQL DB instance by first creating an Aurora MySQL read replica of a MySQL DB instance. When the replica lag between the MySQL DB instance and the Aurora MySQL read replica is 0, you can direct your client applications to read from the Aurora read replica and then stop replication to make the Aurora MySQL read replica a standalone Aurora MySQL DB cluster for reading and writing. For details, see [Migrating data from an RDS for MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica](p. 865).</td>
</tr>
<tr>
<td>An RDS for MySQL DB snapshot</td>
<td>Physical</td>
<td>You can migrate data directly from an RDS for MySQL DB snapshot to an Amazon Aurora MySQL DB cluster. For details, see [Migrating an RDS for MySQL snapshot to Aurora](p. 858).</td>

<tr>
<td>A MySQL database external to Amazon RDS</td>
<td>Logical</td>
<td>You can create a dump of your data using the mysqldump utility, and then import that data into an existing Amazon Aurora MySQL DB cluster. For details, see [Logical migration from MySQL to Amazon Aurora MySQL by using mysqldump](p. 857).</td>
</tr>
<tr>
<td>A MySQL database external to Amazon RDS</td>
<td>Physical</td>
<td>You can copy the backup files from your database to an Amazon Simple Storage Service (Amazon S3) bucket, and then restore an Amazon Aurora MySQL DB cluster from those files. This option can be considerably faster than migrating data using mysqldump. For details, see [Physical migration from MySQL by using Percona XtraBackup and Amazon S3](p. 839).</td>
</tr>
<tr>
<td>A MySQL database external to Amazon RDS</td>
<td>Logical</td>
<td>You can save data from your database as text files and copy those files to an Amazon S3 bucket. You can then load that data into an existing Aurora MySQL DB cluster using the LOAD DATA FROM S3 MySQL command. For more information, see [Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket](p. 1059).</td>
</tr>
<tr>
<td>A database that isn't MySQL-compatible</td>
<td>Logical</td>
<td>You can use AWS Database Migration Service (AWS DMS) to migrate data from a database that isn't MySQL-compatible. For</td>
</tr>
<tr>
<td>Migrating from</td>
<td>Migration type</td>
<td>Solution</td>
</tr>
<tr>
<td>---------------</td>
<td>----------------</td>
<td>----------</td>
</tr>
</tbody>
</table>

**Note**
If you're migrating a MySQL database external to Amazon RDS, the migration options described in the table are supported only if your database supports the InnoDB or MyISAM tablespaces. If the MySQL database you're migrating to Aurora MySQL uses memcached, remove memcached before migrating it.
You can't migrate to Aurora MySQL version 3.05 and higher from some older MySQL 8.0 versions, including 8.0.11, 8.0.13, and 8.0.15. We recommend that you upgrade to MySQL version 8.0.28 before migrating.
Migrating data from an external MySQL database to an Amazon Aurora MySQL DB cluster

If your database supports the InnoDB or MyISAM tablespaces, you have these options for migrating your data to an Amazon Aurora MySQL DB cluster:

- You can create a dump of your data using the mysqldump utility, and then import that data into an existing Amazon Aurora MySQL DB cluster. For more information, see Logical migration from MySQL to Amazon Aurora MySQL by using mysqldump (p. 857).
- You can copy the full and incremental backup files from your database to an Amazon S3 bucket, and then restore to an Amazon Aurora MySQL DB cluster from those files. This option can be considerably faster than migrating data using mysqldump. For more information, see Physical migration from MySQL by using Percona XtraBackup and Amazon S3 (p. 839).

Topics
- Physical migration from MySQL by using Percona XtraBackup and Amazon S3 (p. 839)
- Logical migration from MySQL to Amazon Aurora MySQL by using mysqldump (p. 857)

Physical migration from MySQL by using Percona XtraBackup and Amazon S3

You can copy the full and incremental backup files from your source MySQL version 5.7 or 8.0 database to an Amazon S3 bucket. Then you can restore to an Amazon Aurora MySQL DB cluster with the same major DB engine version from those files.

This option can be considerably faster than migrating data using mysqldump, because using mysqldump replays all of the commands to recreate the schema and data from your source database in your new Aurora MySQL DB cluster. By copying your source MySQL data files, Aurora MySQL can immediately use those files as the data for an Aurora MySQL DB cluster.

You can also minimize downtime by using binary log replication during the migration process. If you use binary log replication, the external MySQL database remains open to transactions while the data is being migrated to the Aurora MySQL DB cluster. After the Aurora MySQL DB cluster has been created, you use binary log replication to synchronize the Aurora MySQL DB cluster with the transactions that happened after the backup. When the Aurora MySQL DB cluster is caught up with the MySQL database, you finish the migration by completely switching to the Aurora MySQL DB cluster for new transactions. For more information, see Synchronizing the Amazon Aurora MySQL DB cluster with the MySQL database using replication (p. 849).

  - Configuring your external MySQL database and your Aurora MySQL DB cluster for encrypted replication (p. 849)
  - Synchronizing the Amazon Aurora MySQL DB cluster with the external MySQL database (p. 850)

• **Reducing the time for physical migration to Amazon Aurora MySQL (p. 854)**
  - Unsupported table types (p. 854)
  - User accounts with unsupported privileges (p. 855)
  - Dynamic privileges in Aurora MySQL version 3 (p. 855)
  - Stored objects with 'rdsadmin'@'localhost' as the definer (p. 856)

**Limitations and considerations**

The following limitations and considerations apply to restoring to an Amazon Aurora MySQL DB cluster from an Amazon S3 bucket:

• You can migrate your data only to a new DB cluster, not an existing DB cluster.

• You must use Percona XtraBackup to back up your data to S3. For more information, see Installing Percona XtraBackup (p. 841).

• The Amazon S3 bucket and the Aurora MySQL DB cluster must be in the same AWS Region.

• You can't restore from the following:
  - A DB cluster snapshot export to Amazon S3. You also can't migrate data from a DB cluster snapshot export to your S3 bucket.
  - An encrypted source database, but you can encrypt the data being migrated. You can also leave the data unencrypted during the migration process.
  - A MySQL 5.5 or 5.6 database

• You can't restore to an Aurora Serverless DB cluster.

• Backward migration isn't supported for either major versions or minor versions. For example, you can't migrate from MySQL version 8.0 to Aurora MySQL version 2 (compatible with MySQL 5.7), and you can't migrate from MySQL version 8.0.32 to Aurora MySQL version 3.0.3, which is compatible with MySQL community version 8.0.26.

• You can't migrate to Aurora MySQL version 3.05 and higher from some older MySQL 8.0 versions, including 8.0.11, 8.0.13, and 8.0.15. We recommend that you upgrade to MySQL version 8.0.28 before migrating.

• Importing from Amazon S3 isn't supported on the db.t2.micro DB instance class. However, you can restore to a different DB instance class, and change the DB instance class later. For more information about DB instance classes, see Aurora DB instance classes (p. 84).

• Amazon S3 limits the size of a file uploaded to an S3 bucket to 5 TB. If a backup file exceeds 5 TB, then you must split the backup file into smaller files.

• Amazon RDS limits the number of files uploaded to an S3 bucket to 1 million. If the backup data for your database, including all full and incremental backups, exceeds 1 million files, use a Gzip (.gz), tar (.tar.gz), or Percona xbstream (.xbstream) file to store full and incremental backup files in the S3 bucket. Percona XtraBackup 8.0 only supports Percona xbstream for compression.

• To provide management services for each DB cluster, the rdsadmin user is created when the DB cluster is created. As this is a reserved user in RDS, the following limitations apply:
  - Functions, procedures, views, events, and triggers with the 'rdsadmin'@'localhost' definer aren't imported. For more information, see Stored objects with 'rdsadmin'@'localhost' as the definer (p. 856) and Master user privileges with Amazon Aurora MySQL (p. 814).
• When the Aurora MySQL DB cluster is created, a master user is created with the maximum privileges supported. While restoring from backup, any unsupported privileges assigned to users being imported are removed automatically during import.

To identify users that might be affected by this, see User accounts with unsupported privileges (p. 855). For more information on supported privileges in Aurora MySQL, see Role-based privilege model (p. 797).

• For Aurora MySQL version 3, dynamic privileges aren't imported. Aurora-supported dynamic privileges can be imported after migration. For more information, see Dynamic privileges in Aurora MySQL version 3 (p. 855).

• User-created tables in the mysql schema aren't migrated.

• The innodb_data_file_path parameter must be configured with only one data file that uses the default data file name ibdata1:12M:autoextend. Databases with two data files, or with a data file with a different name, can't be migrated using this method.

The following are examples of file names that aren't allowed:
innodb_data_file_path=ibdata1:50M, ibdata2:50M:autoextend, and
innodb_data_file_path=ibdata01:50M:autoextend.

• You can't migrate from a source database that has tables defined outside of the default MySQL data directory.

• The maximum supported size for uncompressed backups using this method is currently limited to 64 TiB. For compressed backups, this limit goes lower to account for the uncompression space requirements. In such cases, the maximum supported backup size would be (64 TiB – compressed backup size).

• Aurora MySQL doesn't support the importing of MySQL and other external components and plugins.

• Aurora MySQL doesn't restore everything from your database. We recommend that you save the database schema and values for the following items from your source MySQL database, then add them to your restored Aurora MySQL DB cluster after it has been created:
  • User accounts
  • Functions
  • Stored procedures
  • Time zone information. Time zone information is loaded from the local operating system of your Aurora MySQL DB cluster. For more information, see Local time zone for Amazon Aurora DB clusters (p. 21).

Before you begin

Before you can copy your data to an Amazon S3 bucket and restore to a DB cluster from those files, you must do the following:

• Install Percona XtraBackup on your local server.
• Permit Aurora MySQL to access your Amazon S3 bucket on your behalf.

Installing Percona XtraBackup

Amazon Aurora can restore a DB cluster from files that were created using Percona XtraBackup. You can install Percona XtraBackup from Software Downloads - Percona.

For MySQL 5.7 migration, use Percona XtraBackup 2.4.

For MySQL 8.0 migration, use Percona XtraBackup 8.0. Make sure that the Percona XtraBackup version is compatible with the engine version of your source database.
## Required permissions

To migrate your MySQL data to an Amazon Aurora MySQL DB cluster, several permissions are required:

- The user that is requesting that Aurora create a new cluster from an Amazon S3 bucket must have permission to list the buckets for your AWS account. You grant the user this permission using an AWS Identity and Access Management (IAM) policy.
- Aurora requires permission to act on your behalf to access the Amazon S3 bucket where you store the files used to create your Amazon Aurora MySQL DB cluster. You grant Aurora the required permissions using an IAM service role.
- The user making the request must also have permission to list the IAM roles for your AWS account.
- If the user making the request is to create the IAM service role or request that Aurora create the IAM service role (by using the console), then the user must have permission to create an IAM role for your AWS account.
- If you plan to encrypt the data during the migration process, update the IAM policy of the user who will perform the migration to grant RDS access to the AWS KMS keys used for encrypting the backups. For instructions, see [Creating an IAM policy to access AWS KMS resources (p. 1053)](link).

For example, the following IAM policy grants a user the minimum required permissions to use the console to list IAM roles, create an IAM role, list the Amazon S3 buckets for your account, and list the KMS keys.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "iam:ListRoles",
            "iam:CreateRole",
            "iam:CreatePolicy",
            "iam:AttachRolePolicy",
            "s3:ListBucket",
            "kms:ListKeys"
         ],
         "Resource": "*"
      }
   ]
}
```

Additionally, for a user to associate an IAM role with an Amazon S3 bucket, the IAM user must have the `iam:PassRole` permission for that IAM role. This permission allows an administrator to restrict which IAM roles a user can associate with Amazon S3 buckets.

For example, the following IAM policy allows a user to associate the role named `S3Access` with an Amazon S3 bucket.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "AllowS3AccessRole",
         "Effect": "Allow",
         "Action": "iam:PassRole",
         "Resource": "arn:aws:iam::123456789012:role/S3Access"
      }
   ]
}
```
Creating the IAM service role

You can have the AWS Management Console create a role for you by choosing the **Create a New Role** option (shown later in this topic). If you select this option and specify a name for the new role, then Aurora creates the IAM service role required for Aurora to access your Amazon S3 bucket with the name that you supply.

As an alternative, you can manually create the role using the following procedure.

**To create an IAM role for Aurora to access Amazon S3**

1. Complete the steps in [Creating an IAM policy to access Amazon S3 resources](p. 1048).
2. Complete the steps in [Creating an IAM role to allow Amazon Aurora to access AWS services](p. 1053).
3. Complete the steps in [Associating an IAM role with an Amazon Aurora MySQL DB cluster](p. 1054).

Backing up files to be restored as an Amazon Aurora MySQL DB cluster

You can create a full backup of your MySQL database files using Percona XtraBackup and upload the backup files to an Amazon S3 bucket. Alternatively, if you already use Percona XtraBackup to back up your MySQL database files, you can upload your existing full and incremental backup directories and files to an Amazon S3 bucket.

**Topics**

- [Creating a full backup with Percona XtraBackup](p. 843)
- [Using incremental backups with Percona XtraBackup](p. 844)
- [Backup considerations](p. 844)

Creating a full backup with Percona XtraBackup

To create a full backup of your MySQL database files that can be restored from Amazon S3 to create an Aurora MySQL DB cluster, use the Percona XtraBackup utility (xtrabackup) to back up your database.

For example, the following command creates a backup of a MySQL database and stores the files in the /on-premises/s3-restore/backup folder.

```
xtrabackup --backup --user=<myuser> --password=<password> --target-dir=/on-premises/s3-restore/backup
```

If you want to compress your backup into a single file (which can be split, if needed), you can use the --stream option to save your backup in one of the following formats:

- Gzip (.gz)
- tar (.tar)
- Percona xbstream (.xbstream)

The following command creates a backup of your MySQL database split into multiple Gzip files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=tar --streamdir=/on-premises/s3-restore/backup | gzip -d --bytes=500MB
```
The following command creates a backup of your MySQL database split into multiple tar files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=\n--target-dir=/on-premises/s3-restore/backup | split -d --bytes=500MB \n- /on-premises/s3-restore/backup.tar
```

The following command creates a backup of your MySQL database split into multiple xbstream files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=xbstream \n--target-dir=/on-premises/s3-restore/backup | split -d --bytes=500MB \n- /on-premises/s3-restore/backup.xbstream
```

**Note**

If you see the following error, it might be caused by mixing file formats in your command:

```
ERROR:/bin/tar: This does not look like a tar archive
```

Once you have backed up your MySQL database using the Percona XtraBackup utility, you can copy your backup directories and files to an Amazon S3 bucket.

For information on creating and uploading a file to an Amazon S3 bucket, see [Getting started with Amazon Simple Storage Service](https://docs.aws.amazon.com/AmazonS3/latest/userguide/getting-started.html) in the [Amazon S3 Getting Started Guide](https://docs.aws.amazon.com/AmazonS3/latest/userguide/getting-started.html).

**Using incremental backups with Percona XtraBackup**

Amazon Aurora MySQL supports both full and incremental backups created using Percona XtraBackup. If you already use Percona XtraBackup to perform full and incremental backups of your MySQL database files, you don't need to create a full backup and upload the backup files to Amazon S3. Instead, you can save a significant amount of time by copying your existing backup directories and files for your full and incremental backups to an Amazon S3 bucket. For more information, see [Create an incremental backup](https://www.percona.com/doc/Percona_XtraBackup/index.html) on the Percona website.

When copying your existing full and incremental backup files to an Amazon S3 bucket, you must recursively copy the contents of the base directory. Those contents include the full backup and also all incremental backup directories and files. This copy must preserve the directory structure in the Amazon S3 bucket. Aurora iterates through all files and directories. Aurora uses the `xtrabackup-checkpoints` file included with each incremental backup to identify the base directory and to order incremental backups by log sequence number (LSN) range.

For information on creating and uploading a file to an Amazon S3 bucket, see [Getting started with Amazon Simple Storage Service](https://docs.aws.amazon.com/AmazonS3/latest/userguide/getting-started.html) in the [Amazon S3 Getting Started Guide](https://docs.aws.amazon.com/AmazonS3/latest/userguide/getting-started.html).

**Backup considerations**

Aurora doesn't support partial backups created using Percona XtraBackup. You can't use the following options to create a partial backup when you back up the source files for your database: `--tables`, `--tables-exclude`, `--tables-file`, `--databases`, `--databases-exclude`, or `--databases-file`.

For more information about backing up your database with Percona XtraBackup, see [Percona XtraBackup - Documentation](https://www.percona.com/doc/Percona_XtraBackup/index.html) and [Work with binary logs](https://www.percona.com/doc/mysql-server/5.7/troubleshooting/working-with-binary-logs.html) on the Percona website.

Aurora supports incremental backups created using Percona XtraBackup. For more information, see [Create an incremental backup](https://www.percona.com/doc/Percona_XtraBackup/index.html) on the Percona website.
Aurora consumes your backup files based on the file name. Be sure to name your backup files with the appropriate file extension based on the file format—for example, .xbstream for files stored using the Percona xbstream format.

Aurora consumes your backup files in alphabetical order and also in natural number order. Always use the split option when you issue the xtrabackup command to ensure that your backup files are written and named in the proper order.

Amazon S3 limits the size of a file uploaded to an Amazon S3 bucket to 5 TB. If the backup data for your database exceeds 5 TB, use the split command to split the backup files into multiple files that are each less than 5 TB.

Aurora limits the number of source files uploaded to an Amazon S3 bucket to 1 million files. In some cases, backup data for your database, including all full and incremental backups, can come to a large number of files. In these cases, use a tarball (.tar.gz) file to store full and incremental backup files in the Amazon S3 bucket.

When you upload a file to an Amazon S3 bucket, you can use server-side encryption to encrypt the data. You can then restore an Amazon Aurora MySQL DB cluster from those encrypted files. Amazon Aurora MySQL can restore a DB cluster with files encrypted using the following types of server-side encryption:

- Server-side encryption with Amazon S3–managed keys (SSE-S3) – Each object is encrypted with a unique key employing strong multifactor encryption.
- Server-side encryption with AWS KMS–managed keys (SSE-KMS) – Similar to SSE-S3, but you have the option to create and manage encryption keys yourself, and also other differences.

For information about using server-side encryption when uploading files to an Amazon S3 bucket, see Protecting data using server-side encryption in the Amazon S3 Developer Guide.

**Restoring an Amazon Aurora MySQL DB cluster from an Amazon S3 bucket**

You can restore your backup files from your Amazon S3 bucket to create a new Amazon Aurora MySQL DB cluster by using the Amazon RDS console.

**To restore an Amazon Aurora MySQL DB cluster from files on an Amazon S3 bucket**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the top right corner of the Amazon RDS console, choose the AWS Region in which to create your DB cluster. Choose the same AWS Region as the Amazon S3 bucket that contains your database backup.
3. In the navigation pane, choose Databases, and then choose Restore from S3.
4. Choose Restore from S3.

The Create database by restoring from S3 page appears.
5. Under **S3 destination**:
   a. Choose the **S3 bucket** that contains the backup files.
   b. (Optional) For **S3 folder path prefix**, enter a file path prefix for the files stored in your Amazon S3 bucket.
If you don't specify a prefix, then RDS creates your DB instance using all of the files and folders in the root folder of the S3 bucket. If you do specify a prefix, then RDS creates your DB instance using the files and folders in the S3 bucket where the path for the file begins with the specified prefix.

For example, suppose that you store your backup files on S3 in a subfolder named backups, and you have multiple sets of backup files, each in its own directory (gzip_backup1, gzip_backup2, and so on). In this case, you specify a prefix of backups/gzip_backup1 to restore from the files in the gzip_backup1 folder.

6. Under Engine options:
   a. For Engine type, choose Amazon Aurora.
   b. For Version, choose the Aurora MySQL engine version for your restored DB instance.

7. For IAM role, you can choose an existing IAM role.

8. (Optional) You can also have a new IAM role created for you by choosing Create a new role. If so:
   a. Enter the IAM role name.
   b. Choose whether to Allow access to KMS key:
      • If you didn't encrypt the backup files, choose No.
      • If you encrypted the backup files with AES-256 (SSE-S3) when you uploaded them to Amazon S3, choose No. In this case, the data is decrypted automatically.
      • If you encrypted the backup files with AWS KMS (SSE-KMS) server-side encryption when you uploaded them to Amazon S3, choose Yes. Next, choose the correct KMS key for AWS KMS key.

      The AWS Management Console creates an IAM policy that enables Aurora to decrypt the data.

      For more information, see Protecting data using server-side encryption in the Amazon S3 Developer Guide.

9. Choose settings for your DB cluster, such as the DB cluster storage configuration, DB instance class, DB cluster identifier, and login credentials. For information about each setting, see Settings for Aurora DB clusters (p. 190).

10. Customize additional settings for your Aurora MySQL DB cluster as needed.

11. Choose Create database to launch your Aurora DB instance.

On the Amazon RDS console, the new DB instance appears in the list of DB instances. The DB instance has a status of creating until the DB instance is created and ready for use. When the state changes to available, you can connect to the primary instance for your DB cluster. Depending on the DB instance class and store allocated, it can take several minutes for the new instance to be available.

To view the newly created cluster, choose the Databases view in the Amazon RDS console and choose the DB cluster. For more information, see Viewing an Amazon Aurora DB cluster (p. 515).
Note the port and the writer endpoint of the DB cluster. Use the writer endpoint and port of the DB cluster in your JDBC and ODBC connection strings for any application that performs write or read operations.
Synchronizing the Amazon Aurora MySQL DB cluster with the MySQL database using replication

To achieve little or no downtime during the migration, you can replicate transactions that were committed on your MySQL database to your Aurora MySQL DB cluster. Replication enables the DB cluster to catch up with the transactions on the MySQL database that happened during the migration. When the DB cluster is completely caught up, you can stop the replication and finish the migration to Aurora MySQL.

Topics
- Configuring your external MySQL database and your Aurora MySQL DB cluster for encrypted replication (p. 849)
- Synchronizing the Amazon Aurora MySQL DB cluster with the external MySQL database (p. 850)

Configuring your external MySQL database and your Aurora MySQL DB cluster for encrypted replication

To replicate data securely, you can use encrypted replication.

**Note**
If you don't need to use encrypted replication, you can skip these steps and move on to the instructions in *Synchronizing the Amazon Aurora MySQL DB cluster with the external MySQL database* (p. 850).

The following are prerequisites for using encrypted replication:

- Secure Sockets Layer (SSL) must be enabled on the external MySQL primary database.
- A client key and client certificate must be prepared for the Aurora MySQL DB cluster.

During encrypted replication, the Aurora MySQL DB cluster acts a client to the MySQL database server. The certificates and keys for the Aurora MySQL client are in files in .pem format.

**To configure your external MySQL database and your Aurora MySQL DB cluster for encrypted replication**

1. Ensure that you are prepared for encrypted replication:
   - If you don't have SSL enabled on the external MySQL primary database and don't have a client key and client certificate prepared, enable SSL on the MySQL database server and generate the required client key and client certificate.
   - If SSL is enabled on the external primary, supply a client key and certificate for the Aurora MySQL DB cluster. If you don't have these, generate a new key and certificate for the Aurora MySQL DB cluster. To sign the client certificate, you must have the certificate authority key that you used to configure SSL on the external MySQL primary database.

For more information, see [*Creating SSL certificates and keys using openssl*](https://dev.mysql.com/doc/ssl/en/openssl.html) in the MySQL documentation.

You need the certificate authority certificate, the client key, and the client certificate.

2. Connect to the Aurora MySQL DB cluster as the primary user using SSL.

   For information about connecting to an Aurora MySQL DB cluster with SSL, see [*Using TLS with Aurora MySQL DB clusters* (p. 814)].

3. Run the *mysqlrds_import_binlog_ssl_material* (p. 1176) stored procedure to import the SSL information into the Aurora MySQL DB cluster.
For the `ssl_material_value` parameter, insert the information from the .pem format files for the Aurora MySQL DB cluster in the correct JSON payload.

The following example imports SSL information into an Aurora MySQL DB cluster. In .pem format files, the body code typically is longer than the body code shown in the example.

```sql
call mysql.rds_import_binlog_ssl_material(
    'ssl_ca': '-----BEGIN CERTIFICATE-----

');
```

For more information, see `mysql.rds_import_binlog_ssl_material` (p. 1176) and `Using TLS with Aurora MySQL DB clusters` (p. 814).

**Note**

After running the procedure, the secrets are stored in files. To erase the files later, you can run the `mysql.rds_remove_binlog_ssl_material` (p. 1181) stored procedure.

### Synchronizing the Amazon Aurora MySQL DB cluster with the external MySQL database

You can synchronize your Amazon Aurora MySQL DB cluster with the MySQL database using replication.

**To synchronize your Amazon Aurora MySQL DB cluster with the MySQL database using replication**

1. Ensure that the `/etc/my.cnf` file contains the correct entries for the external MySQL database.

   If encrypted replication is not required, ensure that the external MySQL database is started with binary logs (binlogs) enabled and SSL disabled. The following are the relevant entries in the `/etc/my.cnf` file for unencrypted data.

   ```
   log-bin=mysql-bin
   server-id=2133421
   innodb_flush_log_at_trx_commit=1
   sync_binlog=1
   ```

   If encrypted replication is required, ensure that the external MySQL database is started with SSL and binlogs enabled. The entries in the `/etc/my.cnf` file include the .pem file locations for the MySQL database server.

   ```
   log-bin=mysql-bin
   server-id=2133421
   ```

850
innodb_flush_log_at_trx_commit=1
sync_binlog=1

# Setup SSL.
ssl-ca=/home/sslcerts/ca.pem
ssl-cert=/home/sslcerts/server-cert.pem
ssl-key=/home/sslcerts/server-key.pem

You can verify that SSL is enabled with the following command.

```
mysql> show variables like 'have_ssl';
```

Your output should be similar the following.

```
+~-~-~-~-~-~-~-~-~-~-~-~-~-~--+~-~-~-~-~-~--+
| Variable_name | Value |
+~-~-~-~-~-~-~-~-~-~-~-~-~-~--+~-~-~-~-~-~--+
| have_ssl      | YES   |
+~-~-~-~-~-~-~-~-~-~-~-~-~-~--+~-~-~-~-~-~--+
1 row in set (0.00 sec)
```

2. Determine the starting binary log position for replication. You specify the position to start replication in a later step.

**Using the AWS Management Console**

a. Sign in to the AWS Management Console and open the Amazon RDS console at `https://console.aws.amazon.com/rds/`.

b. In the navigation pane, choose **Events**.

c. In the **Events** list, note the position in the **Recovered from Binary log filename** event.

```
Identifier   Type          Event                                         
------------- ------ ------------- __________________________________________
testing      Instances  DB instance created                            
testing      Instances  Binlog position from crash recovery is OFF.000001 532   
testing-duster DB clusters  Recovered from Binary log filename 'mysqld-bin.000001'
```

**Using the AWS CLI**

You can also get the binlog file name and position by using the `describe-events` AWS CLI command. The following shows an example `describe-events` command.

```
PROMPT> aws rds describe-events
```

In the output, identify the event that shows the binlog position.
3. While connected to the external MySQL database, create a user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following is an example.

```sql
mysql> CREATE USER '<user_name>'@'<domain_name>' IDENTIFIED BY '<password>';
```

The user requires the REPLICATION CLIENT and REPLICATION SLAVE privileges. Grant these privileges to the user.

```sql
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO '<user_name>'@'<domain_name>';
```

If you need to use encrypted replication, require SSL connections for the replication user. For example, you can use the following statement to require SSL connections on the user account <user_name>.

```sql
GRANT USAGE ON *.* TO '<user_name>'@'<domain_name>' REQUIRE SSL;
```

**Note**

If REQUIRE_SSL is not included, the replication connection might silently fall back to an unencrypted connection.

4. In the Amazon RDS console, add the IP address of the server that hosts the external MySQL database to the VPC security group for the Aurora MySQL DB cluster. For more information on modifying a VPC security group, see [Security groups for your VPC](https://docs.aws.amazon.com/AmazonVirtualPrivateCloudUserGuide) in the Amazon Virtual Private Cloud User Guide.

You might also need to configure your local network to permit connections from the IP address of your Aurora MySQL DB cluster, so that it can communicate with your external MySQL database. To find the IP address of the Aurora MySQL DB cluster, use the host command.

```sql
host <db_cluster_endpoint>
```

The host name is the DNS name from the Aurora MySQL DB cluster endpoint.

5. Enable binary log replication by running the `mysql.rds_reset_external_master` (Aurora MySQL version 2) or `mysql.rds_reset_external_source` (Aurora MySQL version 3) stored procedure. This stored procedure has the following syntax.

```sql
CALL mysql.rds_set_external_master (
    host_name,
    host_port,
    replication_user_name,
    replication_user_password,
    mysql_binary_log_file_name,
    mysql_binary_log_file_location,
    ssl_encryption
);
```

```sql
CALL mysql.rds_set_external_source (
    host_name,
    host_port,
    replication_user_name,
    replication_user_password,
    mysql_binary_log_file_name,
    mysql_binary_log_file_location
);
```
For information about the parameters, see `mysql.rds_reset_external_master` (Aurora MySQL version 2) (p. 1181) and `mysql.rds_reset_external_source` (Aurora MySQL version 3) (p. 1182).

For `mysql_binary_log_file_name` and `mysql_binary_log_file_location`, use the position in the Recovered from Binary log filename event you noted earlier.

If the data in the Aurora MySQL DB cluster is not encrypted, the `ssl_encryption` parameter must be set to 0. If the data is encrypted, the `ssl_encryption` parameter must be set to 1.

The following example runs the procedure for an Aurora MySQL DB cluster that has encrypted data.

```sql
CALL mysql.rds_set_external_master(
    'Externaldb.some.com',
    3306,
    'repl_user'@'mydomain.com',
    'password',
    'mysql-bin.000010',
    120,
    1);

CALL mysql.rds_set_external_source(
    'Externaldb.some.com',
    3306,
    'repl_user'@'mydomain.com',
    'password',
    'mysql-bin.000010',
    120,
    1);
```

This stored procedure sets the parameters that the Aurora MySQL DB cluster uses for connecting to the external MySQL database and reading its binary log. If the data is encrypted, it also downloads the SSL certificate authority certificate, client certificate, and client key to the local disk.

6. Start binary log replication by running the `mysql.rds_start_replication` (p. 1193) stored procedure.

```sql
CALL mysql.rds_start_replication;
```

7. Monitor how far the Aurora MySQL DB cluster is behind the MySQL replication primary database. To do so, connect to the Aurora MySQL DB cluster and run the following command.

Aurora MySQL version 2:
SHOW SLAVE STATUS;

Aurora MySQL version 3:
SHOW REPLICA STATUS;

In the command output, the Seconds Behind Master field shows how far the Aurora MySQL DB cluster is behind the MySQL primary. When this value is 0 (zero), the Aurora MySQL DB cluster has caught up to the primary, and you can move on to the next step to stop replication.

8. Connect to the MySQL replication primary database and stop replication. To do so, run the `mysql.rds_stop_replication` (p. 1195) stored procedure.
CALL mysql.rds_stop_replication;

Reducing the time for physical migration to Amazon Aurora MySQL

You can make the following database modifications to speed up the process of migrating a database to Amazon Aurora MySQL.

**Important**

Make sure to perform these updates on a copy of a production database, rather than on a production database. You can then back up the copy and restore it to your Aurora MySQL DB cluster to avoid any service interruptions on your production database.

Unsupported table types

Aurora MySQL supports only the InnoDB engine for database tables. If you have MyISAM tables in your database, then those tables must be converted before migrating to Aurora MySQL. The conversion process requires additional space for the MyISAM to InnoDB conversion during the migration procedure.

To reduce your chances of running out of space or to speed up the migration process, convert all of your MyISAM tables to InnoDB tables before migrating them. The size of the resulting InnoDB table is equivalent to the size required by Aurora MySQL for that table. To convert a MyISAM table to InnoDB, run the following command:

```sql
ALTER TABLE schema.table_name engine=innodb, algorithm=copy;
```

Aurora MySQL doesn't support compressed tables or pages, that is, tables created with ROW_FORMAT=COMpressed or COMPRESSION = {"zlib","lz4"}.

To reduce your chances of running out of space or to speed up the migration process, expand your compressed tables by setting ROW_FORMAT to DEFAULT, COMPACT, DYNAMIC, or REDUNDANT. For compressed pages, set COMPRESSION="none".

You can use the following SQL script on your existing MySQL DB instance to list the tables in your database that are MyISAM tables or compressed tables.

```sql
-- This script examines a MySQL database for conditions that block
-- migrating the database into Aurora MySQL.
-- It must be run from an account that has read permission for the
-- INFORMATION_SCHEMA database.
-- Verify that this is a supported version of MySQL.
select msg as `==> Checking current version of MySQL.`
from
  (select
   'This script should be run on MySQL version 5.6 or higher. ' +
   'Earlier versions are not supported.' as msg,
   cast(substring_index(version(), '.', 1) as unsigned) * 100 +
   cast(substring_index(substring_index(version(), '.', 2), '.', -1)
   as unsigned)
  as major_minor
) as T
where major_minor <> 506;

-- List MyISAM and compressed tables. Include the table size.
```
select concat(TABLE_SCHEMA, '.', TABLE_NAME) as `MyISAM or Compressed Tables`,
    round(((data_length + index_length) / 1024 / 1024), 2) "Approx size (MB)"
from INFORMATION_SCHEMA.TABLES
where
    ENGINE <> 'InnoDB'
    and
    ( -- User tables
        TABLE_SCHEMA not in ('mysql', 'performance_schema',
                             'information_schema')
        or
        -- Non-standard system tables
        TABLE_SCHEMA = 'mysql' and TABLE_NAME not in
        ( 'columns_priv', 'db', 'event', 'func', 'general_log',
          'help_category', 'help_keyword', 'help_relation',
          'help_topic', 'host', 'ndb_binlog_index', 'plugin',
          'proc', 'procs_priv', 'proxies_priv', 'servers', 'slow_log',
          'tables_priv', 'time_zone', 'time_zone_leap_second',
          'time_zone_name', 'time_zone_transition',
          'time_zone_transition_type', 'user'
        )
    )
    or
    ( -- Compressed tables
        ROW_FORMAT = 'Compressed'
    );

User accounts with unsupported privileges

User accounts with privileges that aren't supported by Aurora MySQL are imported without the unsupported privileges. For the list of supported privileges, see Role-based privilege model (p. 797).

You can run the following SQL query on your source database to list the user accounts that have unsupported privileges.

```sql
SELECT user, host
FROM mysql.user
WHERE Shutdown_priv = 'y'
    OR File_priv = 'y'
    OR Super_priv = 'y'
    OR Create_tablespace_priv = 'y';
```

Dynamic privileges in Aurora MySQL version 3

Dynamic privileges aren't imported. Aurora MySQL version 3 supports the following dynamic privileges.

'APPLICATION_PASSWORD_ADMIN',
'CONNECTION_ADMIN',
'REPLICATION_APPLIER',
'ROLE_ADMIN',
'SESSION_VARIABLES_ADMIN',
'SET_USER_ID',
'XA_RECOVER_ADMIN'
The following example script grants the supported dynamic privileges to the user accounts in the Aurora MySQL DB cluster.

```
-- This script finds the user accounts that have Aurora MySQL supported dynamic privileges
-- and grants them to corresponding user accounts in the Aurora MySQL DB cluster.

/home/ec2-user/opt/mysql/8.0.26/bin/mysql -username -pxxxxx -P8026 -h127.0.0.1 -BNe
"SELECT
  CONCAT('GRANT ', GRANTS, ' ON *.* TO ', GRANTEE ,';') AS grant_statement
FROM (select GRANTEE, group_concat(privilege_type) AS GRANTS FROM
  information_schema.user_privileges
  WHERE privilege_type IN ('APPLICATION_PASSWORD_ADMIN',
                           'CONNECTION_ADMIN',
                           'REPLICATION_APPLIER',
                           'ROLE_ADMIN',
                           'SESSION_VARIABLES_ADMIN',
                           'SET_USER_ID',
                           'XA_RECOVER_ADMIN')
  AND GRANTEE NOT IN ('mysql.session@localhost',
                       'mysql.infoschema@localhost',
                       'mysql.sys@localhost') GROUP BY GRANTEE)
AS PRIVGRANTS; " | /home/ec2-user/opt/mysql/8.0.26/bin/mysql -u master_username -p master_password -h DB_cluster_endpoint
```

**Stored objects with 'rdsadmin'@'localhost' as the definer**

Functions, procedures, views, events, and triggers with 'rdsadmin'@'localhost' as the definer aren't imported.

You can use the following SQL script on your source MySQL database to list the stored objects that have the unsupported definer.

```
-- This SQL query lists routines with 'rdsadmin'@'localhost' as the definer.
SELECT
  ROUTINE_SCHEMA,
  ROUTINE_NAME
FROM
  information_schema.routines
WHERE
  definer = 'rdsadmin@localhost';

-- This SQL query lists triggers with 'rdsadmin'@'localhost' as the definer.
SELECT
  TRIGGER_SCHEMA,
  TRIGGER_NAME,
  DEFINER
FROM
  information_schema.triggers
WHERE
  DEFINER = 'rdsadmin@localhost';

-- This SQL query lists events with 'rdsadmin'@'localhost' as the definer.
SELECT
  EVENT_SCHEMA,
  EVENT_NAME
FROM
  information_schema.events
WHERE
  DEFINER = 'rdsadmin@localhost';
```
Logical migration from MySQL to Amazon Aurora MySQL by using mysqldump

Because Amazon Aurora MySQL is a MySQL-compatible database, you can use the mysqldump utility to copy data from your MySQL or MariaDB database to an existing Aurora MySQL DB cluster.

For a discussion of how to do so with MySQL databases that are very large, see Importing data to a MySQL or MariaDB DB instance with reduced downtime. For MySQL databases that have smaller amounts of data, see Importing data from a MySQL or MariaDB DB to a MySQL or MariaDB DB instance.
Migrating data from an RDS for MySQL DB instance to an Amazon Aurora MySQL DB cluster

You can migrate (copy) data to an Amazon Aurora MySQL DB cluster from an RDS for MySQL DB instance.

Topics
- Migrating an RDS for MySQL snapshot to Aurora (p. 858)
- Migrating data from an RDS for MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica (p. 865)

Note
Because Amazon Aurora MySQL is compatible with MySQL, you can migrate data from your MySQL database by setting up replication between your MySQL database and an Amazon Aurora MySQL DB cluster. For more information, see Replication with Amazon Aurora (p. 104).

Migrating an RDS for MySQL snapshot to Aurora

You can migrate a DB snapshot of an RDS for MySQL DB instance to create an Aurora MySQL DB cluster. The new Aurora MySQL DB cluster is populated with the data from the original RDS for MySQL DB instance. The DB snapshot must have been made from an Amazon RDS DB instance running a MySQL version that's compatible with Aurora MySQL.

You can migrate either a manual or automated DB snapshot. After the DB cluster is created, you can then create optional Aurora Replicas.

Note
You can also migrate an RDS for MySQL DB instance to an Aurora MySQL DB cluster by creating an Aurora read replica of your source RDS for MySQL DB instance. For more information, see Migrating data from an RDS for MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica (p. 865).

You can't migrate to Aurora MySQL version 3.05 and higher from some older MySQL 8.0 versions, including 8.0.11, 8.0.13, and 8.0.15. We recommend that you upgrade to MySQL version 8.0.28 before migrating.

The general steps you must take are as follows:

1. Determine the amount of space to provision for your Aurora MySQL DB cluster. For more information, see How much space do I need? (p. 858)
2. Use the console to create the snapshot in the AWS Region where the Amazon RDS MySQL instance is located. For information about creating a DB snapshot, see Creating a DB snapshot.
3. If the DB snapshot is not in the same AWS Region as your DB cluster, use the Amazon RDS console to copy the DB snapshot to that AWS Region. For information about copying a DB snapshot, see Copying a DB snapshot.
4. Use the console to migrate the DB snapshot and create an Aurora MySQL DB cluster with the same databases as the original MySQL DB instance.

Warning
Amazon RDS limits each AWS account to one snapshot copy into each AWS Region at a time.

How much space do I need?

When you migrate a snapshot of a MySQL DB instance into an Aurora MySQL DB cluster, Aurora uses an Amazon Elastic Block Store (Amazon EBS) volume to format the data from the snapshot before migrating it. In some cases, additional space is needed to format the data for migration.
Tables that are not MyISAM tables and are not compressed can be up to 16 TB in size. If you have MyISAM tables, then Aurora must use additional space in the volume to convert the tables to be compatible with Aurora MySQL. If you have compressed tables, then Aurora must use additional space in the volume to expand these tables before storing them on the Aurora cluster volume. Because of this additional space requirement, you should ensure that none of the MyISAM and compressed tables being migrated from your MySQL DB instance exceeds 8 TB in size.

Reducing the amount of space required to migrate data into Amazon Aurora MySQL

You might want to modify your database schema prior to migrating it into Amazon Aurora. Such modification can be helpful in the following cases:

- You want to speed up the migration process.
- You are unsure of how much space you need to provision.
- You have attempted to migrate your data and the migration has failed due to a lack of provisioned space.

You can make the following changes to improve the process of migrating a database into Amazon Aurora.

**Important**

Be sure to perform these updates on a new DB instance restored from a snapshot of a production database, rather than on a production instance. You can then migrate the data from the snapshot of your new DB instance into your Aurora DB cluster to avoid any service interruptions on your production database.

<table>
<thead>
<tr>
<th>Table type</th>
<th>Limitation or guideline</th>
</tr>
</thead>
<tbody>
<tr>
<td>MyISAM tables</td>
<td>Aurora MySQL supports InnoDB tables only. If you have MyISAM tables in your database, then those tables must be converted before being migrated into Aurora MySQL. The conversion process requires additional space for the MyISAM to InnoDB conversion during the migration procedure. To reduce your chances of running out of space or to speed up the migration process, convert all of your MyISAM tables to InnoDB tables before migrating them. The size of the resulting InnoDB table is equivalent to the size required by Aurora MySQL for that table. To convert a MyISAM table to InnoDB, run the following command: alter table <code>&lt;schema&gt;</code>.<code>&lt;table_name&gt;</code> engine=innodb, algorithm=copy;</td>
</tr>
<tr>
<td>Compressed tables</td>
<td>Aurora MySQL doesn’t support compressed tables (that is, tables created with ROW_FORMAT=COMPRESSED). To reduce your chances of running out of space or to speed up the migration process, expand your compressed tables by setting ROW_FORMAT to DEFAULT, COMPACT, DYNAMIC, or REDUNDANT. For more information, see InnoDB row formats in the MySQL documentation.</td>
</tr>
</tbody>
</table>

You can use the following SQL script on your existing MySQL DB instance to list the tables in your database that are MyISAM tables or compressed tables.
This script examines a MySQL database for conditions that block migrating the database into Amazon Aurora.

It needs to be run from an account that has read permission for the INFORMATION_SCHEMA database.

Verify that this is a supported version of MySQL.

```sql
select msg as '==> Checking current version of MySQL.'
from
(
    select 'This script should be run on MySQL version 5.6 or higher. ' + 'Earlier versions are not supported.' as msg,
        cast(substring_index(version(), '.', 1) as unsigned) * 100 +
        cast(substring_index(substring_index(version(), '.', 2), '.', -1) as unsigned)
    as major_minor
) as T
where major_minor <> 506;
```

List MyISAM and compressed tables. Include the table size.

```sql
select concat(TABLE_SCHEMA, '.', TABLE_NAME) as '==> MyISAM or Compressed Tables',
    round(((data_length + index_length) / 1024 / 1024), 2) "Approx size (MB)"
from INFORMATION_SCHEMA.TABLES
where ENGINE <> 'InnoDB'
and
    ( -- User tables
        TABLE_SCHEMA not in ('mysql', 'performance_schema',
                             'information_schema')
    or
    -- Non-standard system tables
    ) TABLE_SCHEMA = 'mysql' and TABLE_NAME not in
    (
        'columns_priv', 'db', 'event', 'func', 'general_log',
        'help_category', 'help_keyword', 'help_relation',
        'help_topic', 'host', 'ndb_binlog_index', 'plugin',
        'proc', 'procs_priv', 'proxies_priv', 'servers', 'slow_log',
        'tables_priv', 'time_zone', 'time_zone_leap_second',
        'time_zone_name', 'time_zone_transition',
        'time_zone_transition_type', 'user'
    )
) or
or
    ( -- Compressed tables
        ROW_FORMAT = 'Compressed'
    );
```

The script produces output similar to the output in the following example. The example shows two tables that must be converted from MyISAM to InnoDB. The output also includes the approximate size of each table in megabytes (MB).

<table>
<thead>
<tr>
<th>==&gt; MyISAM or Compressed Tables</th>
<th>Approx size (MB)</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.name_table</td>
<td>2102.25</td>
</tr>
<tr>
<td>test.my_table</td>
<td>65.25</td>
</tr>
</tbody>
</table>

860
Migrating an RDS for MySQL DB snapshot to an Aurora MySQL DB cluster

You can migrate a DB snapshot of an RDS for MySQL DB instance to create an Aurora MySQL DB cluster using the AWS Management Console or the AWS CLI. The new Aurora MySQL DB cluster is populated with the data from the original RDS for MySQL DB instance. For information about creating a DB snapshot, see [Creating a DB snapshot](#).

If the DB snapshot is not in the AWS Region where you want to locate your data, copy the DB snapshot to that AWS Region. For information about copying a DB snapshot, see [Copying a DB snapshot](#).

### Console

When you migrate the DB snapshot by using the AWS Management Console, the console takes the actions necessary to create both the DB cluster and the primary instance.

You can also choose for your new Aurora MySQL DB cluster to be encrypted at rest using an AWS KMS key.

#### To migrate a MySQL DB snapshot by using the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Either start the migration from the MySQL DB instance or from the snapshot:
   - **To start the migration from the DB instance:**
     1. In the navigation pane, choose **Databases**, and then select the MySQL DB instance.
     2. For **Actions**, choose **Migrate latest snapshot**.
   - **To start the migration from the snapshot:**
     1. Choose **Snapshots**.
     2. On the **Snapshots** page, choose the snapshot that you want to migrate into an Aurora MySQL DB cluster.
     3. Choose **Snapshot Actions**, and then choose **Migrate Snapshot**.

   The **Migrate Database** page appears.
3. Set the following values on the **Migrate Database** page:
   - **Migrate to DB Engine**: Select `aurora`.
   - **DB Engine Version**: Select the DB engine version for the Aurora MySQL DB cluster.
   - **DB Instance Class**: Select a DB instance class that has the required storage and capacity for your database, for example `db.r3.large`. Aurora cluster volumes automatically grow as the amount of data in your database increases. An Aurora cluster volume can grow to a maximum size of 128 tebibytes (TiB). So you only need to select a DB instance class that meets your current storage requirements. For more information, see [Overview of Amazon Aurora storage](#).
   - **DB Instance Identifier**: Type a name for the DB cluster that is unique for your account in the AWS Region you selected. This identifier is used in the endpoint addresses for the instances in your DB cluster. You might choose to add some intelligence to the name, such as including the AWS Region and DB engine you selected, for example `aurora-cluster1`.

   The DB instance identifier has the following constraints:
• It must contain from 1 to 63 alphanumeric characters or hyphens.
• Its first character must be a letter.
• It cannot end with a hyphen or contain two consecutive hyphens.
• It must be unique for all DB instances per AWS account, per AWS Region.

• **Virtual Private Cloud (VPC):** If you have an existing VPC, then you can use that VPC with your Aurora MySQL DB cluster by selecting your VPC identifier, for example `vpc-a464d1c1`. For information on creating a VPC, see [Tutorial: Create a VPC for use with a DB cluster (IPv4 only)](p. 2494).

Otherwise, you can choose to have Aurora create a VPC for you by selecting **Create a new VPC**.

• **DB subnet group:** If you have an existing subnet group, then you can use that subnet group with your Aurora MySQL DB cluster by selecting your subnet group identifier, for example `gs-subnet-group1`. Otherwise, you can choose to have Aurora create a subnet group for you by selecting **Create a new subnet group**.

• **Public accessibility:** Select **No** to specify that instances in your DB cluster can only be accessed by resources inside of your VPC. Select **Yes** to specify that instances in your DB cluster can be accessed by resources on the public network. The default is **Yes**.

  **Note**
  Your production DB cluster might not need to be in a public subnet, because only your application servers require access to your DB cluster. If your DB cluster doesn't need to be in a public subnet, set **Publicly Accessible to No**.

• **Availability Zone:** Select the Availability Zone to host the primary instance for your Aurora MySQL DB cluster. To have Aurora select an Availability Zone for you, select **No Preference**.

• **Database Port:** Type the default port to be used when connecting to instances in the Aurora MySQL DB cluster. The default is 3306.

  **Note**
  You might be behind a corporate firewall that doesn't allow access to default ports such as the MySQL default port, 3306. In this case, provide a port value that your corporate firewall allows. Remember that port value later when you connect to the Aurora MySQL DB cluster.

• **Encryption:** Choose **Enable Encryption** for your new Aurora MySQL DB cluster to be encrypted at rest. If you choose **Enable Encryption**, you must choose a KMS key as the **AWS KMS key** value.

  If your DB snapshot isn't encrypted, specify an encryption key to have your DB cluster encrypted at rest.

  If your DB snapshot is encrypted, specify an encryption key to have your DB cluster encrypted at rest using the specified encryption key. You can specify the encryption key used by the DB snapshot or a different key. You can't create an unencrypted DB cluster from an encrypted DB snapshot.

• **Auto Minor Version Upgrade:** This setting doesn't apply to Aurora MySQL DB clusters.

For more information about engine updates for Aurora MySQL, see [Database engine updates for Amazon Aurora MySQL](p. 1200).

4. Choose **Migrate** to migrate your DB snapshot.

5. Choose **Instances**, and then choose the arrow icon to show the DB cluster details and monitor the progress of the migration. On the details page, you can find the cluster endpoint used to connect to the primary instance of the DB cluster. For more information on connecting to an Aurora MySQL DB cluster, see [Connecting to an Amazon Aurora DB cluster](p. 204).
AWS CLI

You can create an Aurora DB cluster from a DB snapshot of an RDS for MySQL DB instance by using the `restore-db-cluster-from-snapshot` command with the following parameters:

- `--db-cluster-identifier` – The name of the DB cluster to create.
- `--engine aurora-mysql` – For a MySQL 5.7–compatible or 8.0–compatible DB cluster.
- `--kms-key-id` – The AWS KMS key to optionally encrypt the DB cluster with, depending on whether your DB snapshot is encrypted.
  - If your DB snapshot isn't encrypted, specify an encryption key to have your DB cluster encrypted at rest. Otherwise, your DB cluster isn't encrypted.
  - If your DB snapshot is encrypted, specify an encryption key to have your DB cluster encrypted at rest using the specified encryption key. Otherwise, your DB cluster is encrypted at rest using the encryption key for the DB snapshot.

  **Note**
  You can't create an unencrypted DB cluster from an encrypted DB snapshot.

- `--snapshot-identifier` – The Amazon Resource Name (ARN) of the DB snapshot to migrate. For more information about Amazon RDS ARNs, see Amazon Relational Database Service (Amazon RDS).

When you migrate the DB snapshot by using the `RestoreDBClusterFromSnapshot` command, the command creates both the DB cluster and the primary instance.

In this example, you create a MySQL 5.7–compatible DB cluster named `mydbcluster` from a DB snapshot with an ARN set to `mydbsnapshotARN`.

For Linux, macOS, or Unix:

```bash
aws rds restore-db-cluster-from-snapshot
  --db-cluster-identifier mydbcluster
  --snapshot-identifier mydbsnapshotARN
  --engine aurora-mysql
```

For Windows:

```bash
aws rds restore-db-cluster-from-snapshot ^
  --db-cluster-identifier mydbcluster ^
  --snapshot-identifier mydbsnapshotARN ^
  --engine aurora-mysql
```

In this example, you create a MySQL 5.7–compatible DB cluster named `mydbcluster` from a DB snapshot with an ARN set to `mydbsnapshotARN`.

For Linux, macOS, or Unix:

```bash
aws rds restore-db-cluster-from-snapshot
  --db-cluster-identifier mydbcluster
  --snapshot-identifier mydbsnapshotARN
  --engine aurora-mysql
```

For Windows:

```bash
aws rds restore-db-cluster-from-snapshot ^
  --db-cluster-identifier mydbcluster ^
  --snapshot-identifier mydbsnapshotARN ^
  --engine aurora-mysql
```
Migrating data from an RDS for MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica

Aurora uses the MySQL DB engines' binary log replication functionality to create a special type of DB cluster called an Aurora read replica for a source RDS for MySQL DB instance. Updates made to the source RDS for MySQL DB instance are asynchronously replicated to the Aurora read replica.

We recommend using this functionality to migrate from a RDS for MySQL DB instance to an Aurora MySQL DB cluster by creating an Aurora read replica of your source RDS for MySQL DB instance. When the replica lag between the RDS for MySQL DB instance and the Aurora read replica is 0, you can direct your client applications to the Aurora read replica and then stop replication to make the Aurora read replica a standalone Aurora MySQL DB cluster. Be prepared for migration to take a while, roughly several hours per terabyte (TiB) of data.

For a list of regions where Aurora is available, see Amazon Aurora in the AWS General Reference.

When you create an Aurora read replica of an RDS for MySQL DB instance, Amazon RDS creates a DB snapshot of your source RDS for MySQL DB instance (private to Amazon RDS, and incurring no charges). Amazon RDS then migrates the data from the DB snapshot to the Aurora read replica. After the data from the DB snapshot has been migrated to the new Aurora MySQL DB cluster, Amazon RDS starts replication between your RDS for MySQL DB instance and the Aurora MySQL DB cluster. If your RDS for MySQL DB instance contains tables that use storage engines other than InnoDB, or that use compressed row format, you can speed up the process of creating an Aurora read replica by altering those tables to use the InnoDB storage engine and dynamic row format before you create your Aurora read replica. For more information about the process of copying a MySQL DB snapshot to an Aurora MySQL DB cluster, see Migrating data from an RDS for MySQL DB instance to an Amazon Aurora MySQL DB cluster (p. 858).

You can have only one Aurora read replica for an RDS for MySQL DB instance.

**Note**
Replication issues can arise due to feature differences between Aurora MySQL and the MySQL database engine version of your RDS for MySQL DB instance that is the replication primary. If you encounter an error, you can find help in the Amazon RDS community forum or by contacting AWS Support.
You can't create an Aurora read replica if your RDS for MySQL DB instance is already the source for a cross-Region read replica.
You can't migrate to Aurora MySQL version 3.05 and higher from some older RDS for MySQL 8.0 versions, including 8.0.11, 8.0.13, and 8.0.15. We recommend that you upgrade to RDS for MySQL version 8.0.28 before migrating.

For more information on MySQL read replicas, see Working with read replicas of MariaDB, MySQL, and PostgreSQL DB instances.

Creating an Aurora read replica

You can create an Aurora read replica for an RDS for MySQL DB instance by using the console, the AWS CLI, or the RDS API.

**Console**

To create an Aurora read replica from a source RDS for MySQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the MySQL DB instance that you want to use as the source for your Aurora read replica.
4. For **Actions**, choose **Create Aurora read replica**.
5. Choose the DB cluster specifications you want to use for the Aurora read replica, as described in the following table.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DB instance class</strong></td>
<td>Choose a DB instance class that defines the processing and memory requirements for the primary instance in the DB cluster. For more information about DB instance class options, see [Aurora DB instance classes](p. 84).</td>
</tr>
<tr>
<td><strong>Multi-AZ deployment</strong></td>
<td>Choose <strong>Create Replica in Different Zone</strong> to create a standby replica of the new DB cluster in another Availability Zone in the target AWS Region for failover support. For more information about multiple Availability Zones, see [Regions and Availability Zones](p. 16).</td>
</tr>
<tr>
<td><strong>DB instance identifier</strong></td>
<td>Type a name for the primary instance in your Aurora read replica DB cluster. This identifier is used in the endpoint address for the primary instance of the new DB cluster.</td>
</tr>
<tr>
<td></td>
<td>The DB instance identifier has the following constraints:</td>
</tr>
<tr>
<td></td>
<td>• It must contain from 1 to 63 alphanumeric characters or hyphens.</td>
</tr>
<tr>
<td></td>
<td>• Its first character must be a letter.</td>
</tr>
<tr>
<td></td>
<td>• It cannot end with a hyphen or contain two consecutive hyphens.</td>
</tr>
<tr>
<td></td>
<td>• It must be unique for all DB instances for each AWS account, for each AWS Region.</td>
</tr>
<tr>
<td></td>
<td>Because the Aurora read replica DB cluster is created from a snapshot of the source DB instance, the master user name and master password for the Aurora read replica are the same as the master user name and master password for the source DB instance.</td>
</tr>
<tr>
<td><strong>Virtual Private Cloud (VPC)</strong></td>
<td>Select the VPC to host the DB cluster. Select <strong>Create new VPC</strong> to have Aurora create a VPC for you. For more information, see [DB cluster prerequisites](p. 179).</td>
</tr>
<tr>
<td><strong>DB subnet group</strong></td>
<td>Select the DB subnet group to use for the DB cluster. Select <strong>Create new DB subnet group</strong> to have Aurora create a DB subnet group for you. For more information, see [DB cluster prerequisites](p. 179).</td>
</tr>
<tr>
<td><strong>Public accessibility</strong></td>
<td>Select Yes to give the DB cluster a public IP address; otherwise, select No. The instances in your DB cluster can be a mix of both public and private DB instances. For more information about hiding instances from public access, see [Hiding a DB cluster in a VPC from the internet](p. 2484).</td>
</tr>
<tr>
<td><strong>Availability zone</strong></td>
<td>Determine if you want to specify a particular Availability Zone. For more information about Availability Zones, see [Regions and Availability Zones](p. 16).</td>
</tr>
</tbody>
</table>
## Migrating from a MySQL DB instance to Aurora MySQL

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>VPC security group (firewall)</strong></td>
<td>Select <a href="#">Create new VPC security group</a> to have Aurora create a VPC security group for you. Select <a href="#">Select existing VPC security groups</a> to specify one or more VPC security groups to secure network access to the DB cluster. </thead>
<tbody>
<tr>
<td>Enhanced Monitoring</td>
<td>Choose <strong>Enable enhanced monitoring</strong> to enable gathering metrics in real time for the operating system that your DB cluster runs on. For more information, see [Monitoring OS metrics with Enhanced Monitoring](p. 631).</td>
</tr>
<tr>
<td>Monitoring Role</td>
<td>Only available if <strong>Enhanced Monitoring</strong> is set to <strong>Enable enhanced monitoring</strong>. Choose the IAM role that you created to permit Aurora to communicate with Amazon CloudWatch Logs for you, or choose <strong>Default</strong> to have Aurora create a role for you named <code>rds-monitoring-role</code>. For more information, see [Monitoring OS metrics with Enhanced Monitoring](p. 631).</td>
</tr>
<tr>
<td>Granularity</td>
<td>Only available if <strong>Enhanced Monitoring</strong> is set to <strong>Enable enhanced monitoring</strong>. Set the interval, in seconds, between when metrics are collected for your DB cluster.</td>
</tr>
<tr>
<td>Auto minor version upgrade</td>
<td>This setting doesn't apply to Aurora MySQL DB clusters. For more information about engine updates for Aurora MySQL, see [Database engine updates for Amazon Aurora MySQL](p. 1200).</td>
</tr>
<tr>
<td>Maintenance window</td>
<td>Select <strong>Select window</strong> and specify the weekly time range during which system maintenance can occur. Or, select <strong>No preference</strong> for Aurora to assign a period randomly.</td>
</tr>
</tbody>
</table>

6. Choose **Create read replica**.

**AWS CLI**

To create an Aurora read replica from a source RDS for MySQL DB instance, use the `create-db-cluster` and `create-db-instance` AWS CLI commands to create a new Aurora MySQL DB cluster. When you call the `create-db-cluster` command, include the `--replication-source-identifier` parameter to identify the Amazon Resource Name (ARN) for the source MySQL DB instance. For more information about Amazon RDS ARNs, see [Amazon Relational Database Service (Amazon RDS)].

Don't specify the master username, master password, or database name as the Aurora read replica uses the same master username, master password, and database name as the source MySQL DB instance.

For Linux, macOS, or Unix:

```bash
```

For Windows:

```bash
```

If you use the console to create an Aurora read replica, then Aurora automatically creates the primary instance for your DB cluster Aurora read replica. If you use the AWS CLI to create an Aurora read replica,
you must explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster.

You can create a primary instance for your DB cluster by using the `create-db-instance` AWS CLI command with the following parameters:

- `--db-cluster-identifier` The name of your DB cluster.
- `--db-instance-class` The name of the DB instance class to use for your primary instance.
- `--db-instance-identifier` The name of your primary instance.
- `--engine aurora`

In this example, you create a primary instance named `myreadreplicainstance` for the DB cluster named `myreadreplicacluster`, using the DB instance class specified in `myinstanceclass`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance \
  --db-cluster-identifier myreadreplicacluster \
  --db-instance-class myinstanceclass \
  --db-instance-identifier myreadreplicainstance \
  --engine aurora
```

For Windows:

```bash
aws rds create-db-instance ^
  --db-cluster-identifier myreadreplicacluster ^
  --db-instance-class myinstanceclass ^
  --db-instance-identifier myreadreplicainstance ^
  --engine aurora
```

**RDS API**

To create an Aurora read replica from a source RDS for MySQL DB instance, use the `CreateDBCluster` and `CreateDBInstance` Amazon RDS API commands to create a new Aurora DB cluster and primary instance. Do not specify the master username, master password, or database name as the Aurora read replica uses the same master username, master password, and database name as the source RDS for MySQL DB instance.

You can create a new Aurora DB cluster for an Aurora read replica from a source RDS for MySQL DB instance by using the `CreateDBCluster` Amazon RDS API command with the following parameters:

- `DBClusterIdentifier` The name of the DB cluster to create.
- `DBSubnetGroupName` The name of the DB subnet group to associate with this DB cluster.
Amazon Aurora User Guide for Aurora
Migrating from a MySQL DB instance to Aurora MySQL

- Engine=aurora
- KmsKeyId

The AWS KMS key to optionally encrypt the DB cluster with, depending on whether your MySQL DB instance is encrypted.

- If your MySQL DB instance isn't encrypted, specify an encryption key to have your DB cluster encrypted at rest. Otherwise, your DB cluster is encrypted at rest using the default encryption key for your account.
- If your MySQL DB instance is encrypted, specify an encryption key to have your DB cluster encrypted at rest using the specified encryption key. Otherwise, your DB cluster is encrypted at rest using the encryption key for the MySQL DB instance.

Note
You can't create an unencrypted DB cluster from an encrypted MySQL DB instance.

- ReplicationSourceIdentifier

The Amazon Resource Name (ARN) for the source MySQL DB instance. For more information about Amazon RDS ARNs, see Amazon Relational Database Service (Amazon RDS).

- VpcSecurityGroupIds

The list of EC2 VPC security groups to associate with this DB cluster.

In this example, you create a DB cluster named myreadreplicaccluster from a source MySQL DB instance with an ARN set to mysqlprimaryARN, associated with a DB subnet group named mysubnetgroup and a VPC security group named mysecuritygroup.

Example

https://rds.us-east-1.amazonaws.com/
?Action=CreateDBCluster
&DBClusterIdentifier=myreadreplicaccluster
&DBSubnetGroupName=mysubnetgroup
&Engine=aurora
&ReplicationSourceIdentifier=mysqlprimaryARN
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Version=2014-10-31
&VpcSecurityGroupIds=mysecuritygroup

If you use the console to create an Aurora read replica, then Aurora automatically creates the primary instance for your DB cluster Aurora read replica. If you use the AWS CLI to create an Aurora read replica, you must explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster.

You can create a primary instance for your DB cluster by using the CreateDBInstance Amazon RDS API command with the following parameters:

- DBClusterIdentifier

  The name of your DB cluster.

- DBInstanceClass

  The name of the DB instance class to use for your primary instance.
• **DBInstanceIdentifier**
  
  The name of your primary instance.

• **Engine=aurora**

In this example, you create a primary instance named `myreadreplicainstance` for the DB cluster named `myreadreplicaccluster`, using the DB instance class specified in `myinstanceclass`.

**Example**

```plaintext
https://rds.us-east-1.amazonaws.com/
?Action=CreateDBInstance
&DBClusterIdentifier=myreadreplicaccluster
&DBInstanceClass=myinstanceclass
&DBInstanceIdentifier=myreadreplicainstance
&Engine=aurora
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Version=2014-09-01
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20140424/us-east-1/rds/aws4_request
&X-Amz-Date=20140424T194844Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=bee4aabc750bf7dad0cd9e22b952bd6089d91e2a16592c2293e532eeab8bc77
```

**Viewing an Aurora read replica**

You can view the MySQL to Aurora MySQL replication relationships for your Aurora MySQL DB clusters by using the AWS Management Console or the AWS CLI.

**Console**

**To view the primary MySQL DB instance for an Aurora read replica**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the DB cluster for the Aurora read replica to display its details. The primary MySQL DB instance information is in the **Replication source** field.
AWS CLI

To view the MySQL to Aurora MySQL replication relationships for your Aurora MySQL DB clusters by using the AWS CLI, use the `describe-db-clusters` and `describe-db-instances` commands.

To determine which MySQL DB instance is the primary, use the `describe-db-clusters` and specify the cluster identifier of the Aurora read replica for the `--db-cluster-identifier` option. Refer to the `ReplicationSourceIdentifier` element in the output for the ARN of the DB instance that is the replication primary.

To determine which DB cluster is the Aurora read replica, use the `describe-db-instances` and specify the instance identifier of the MySQL DB instance for the `--db-instance-identifier` option. Refer to the `ReadReplicaDBClusterIdentifiers` element in the output for the DB cluster identifier of the Aurora read replica.

**Example**

For Linux, macOS, or Unix:
Promoting an Aurora read replica

After migration completes, you can promote the Aurora read replica to a stand-alone DB cluster using the AWS Management Console or AWS CLI.

Then you can direct your client applications to the endpoint for the Aurora read replica. For more information on the Aurora endpoints, see Amazon Aurora connection management (p. 62). Promotion should complete fairly quickly, and you can read from and write to the Aurora read replica during promotion. However, you can't delete the primary MySQL DB instance or unlink the DB Instance and the Aurora read replica during this time.

Before you promote your Aurora read replica, stop any transactions from being written to the source MySQL DB instance, and then wait for the replica lag on the Aurora read replica to reach 0. You can view the replica lag for an Aurora read replica by calling the SHOW SLAVE STATUS (Aurora MySQL version 2) or SHOW REPLICA STATUS (Aurora MySQL version 3) command on your Aurora read replica. Check the Seconds behind master value.

You can start writing to the Aurora read replica after write transactions to the primary have stopped and replica lag is 0. If you write to the Aurora read replica before this and you modify tables that are also being modified on the MySQL primary, you risk breaking replication to Aurora. If this happens, you must delete and recreate your Aurora read replica.

**Console**

**To promote an Aurora read replica to an Aurora DB cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB cluster for the Aurora read replica.
4. For Actions, choose Promote.
5. Choose Promote read replica.

After you promote, confirm that the promotion has completed by using the following procedure.

**To confirm that the Aurora read replica was promoted**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Events.
3. On the **Events** page, verify that there is a Promoted Read Replica cluster to a stand-alone database cluster event for the cluster that you promoted.

After promotion is complete, the primary MySQL DB instance and the Aurora read replica are unlinked, and you can safely delete the DB instance if you want.

**AWS CLI**

To promote an Aurora read replica to a stand-alone DB cluster, use the `promote-read-replica-db-cluster` AWS CLI command.

**Example**

For Linux, macOS, or Unix:

```
aws rds promote-read-replica-db-cluster \
    --db-cluster-identifier myreadreplicacluster
```

For Windows:

```
aws rds promote-read-replica-db-cluster ^
    --db-cluster-identifier myreadreplicacluster
```
Managing Amazon Aurora MySQL

The following sections discuss managing an Amazon Aurora MySQL DB cluster.

**Topics**

- Managing performance and scaling for Amazon Aurora MySQL (p. 875)
- Backtracking an Aurora DB cluster (p. 880)
- Testing Amazon Aurora MySQL using fault injection queries (p. 894)
- Altering tables in Amazon Aurora using Fast DDL (p. 897)
- Displaying volume status for an Aurora MySQL DB cluster (p. 902)

**Managing performance and scaling for Amazon Aurora MySQL**

**Scaling Aurora MySQL DB instances**

You can scale Aurora MySQL DB instances in two ways, instance scaling and read scaling. For more information about read scaling, see Read scaling (p. 301).

You can scale your Aurora MySQL DB cluster by modifying the DB instance class for each DB instance in the DB cluster. Aurora MySQL supports several DB instance classes optimized for Aurora. Don't use db.t2 or db.t3 instance classes for larger Aurora clusters of size greater than 40 TB. For the specifications of the DB instance classes supported by Aurora MySQL, see Aurora DB instance classes (p. 84).

**Note**

We recommend using the T DB instance classes only for development and test servers, or other non-production servers. For more details on the T instance classes, see Using T instance classes for development and testing (p. 1103).

**Maximum connections to an Aurora MySQL DB instance**

The maximum number of connections allowed to an Aurora MySQL DB instance is determined by the `max_connections` parameter in the instance-level parameter group for the DB instance.

The following table lists the resulting default value of `max_connections` for each DB instance class available to Aurora MySQL. You can increase the maximum number of connections to your Aurora MySQL DB instance by scaling the instance up to a DB instance class with more memory, or by setting a larger value for the `max_connections` parameter in the DB parameter group for your instance, up to 16,000.

**Tip**

If your applications frequently open and close connections, or keep a large number of long-lived connections open, we recommend that you use Amazon RDS Proxy. RDS Proxy is a fully managed, highly available database proxy that uses connection pooling to share database connections securely and efficiently. To learn more about RDS Proxy, see Using Amazon RDS Proxy for Aurora (p. 1879).

For details about how Aurora Serverless v2 instances handle this parameter, see Maximum connections for Aurora Serverless v2 (p. 2016).

If you create a new parameter group to customize your own default for the connection limit, you'll see that the default connection limit is derived using a formula based on the `DBInstanceClassMemory` value. As shown in the preceding table, the formula produces connection limits that increase by 1000 as the memory doubles between progressively larger R3, R4, and R5 instances, and by 45 for different memory sizes of T2 and T3 instances.

See [Specifying DB parameters](p. 237) for more details on how `DBInstanceClassMemory` is calculated.

Aurora MySQL and RDS for MySQL DB instances have different amounts of memory overhead. Therefore, the `max_connections` value can be different for Aurora MySQL and RDS for MySQL DB instances that use the same instance class. The values in the table only apply to Aurora MySQL DB instances.

**Note**
The much lower connectivity limits for T2 and T3 instances are because with Aurora, those instance classes are intended only for development and test scenarios, not for production workloads.

The default connection limits are tuned for systems that use the default values for other major memory consumers, such as the buffer pool and query cache. If you change those other settings for your cluster,
consider adjusting the connection limit to account for the increase or decrease in available memory on
the DB instances.

**Temporary storage limits for Aurora MySQL**

Aurora MySQL stores tables and indexes in the Aurora storage subsystem. Aurora MySQL uses separate
temporary storage for nonpersistent temporary files. Aurora MySQL uses local storage for storing
error logs, general logs, slow query logs, audit logs, and non-InnoDB temporary tables. Local storage
also includes files that are used for such purposes as sorting large datasets during query processing
or for index build operations. It does not include InnoDB temporary tables. For more information,
see the article [What is stored in Aurora MySQL-Compatible local storage, and how can I troubleshoot
local storage issues?](https://aws.amazon.com/premierreliability). For more information on temporary tables
in version 3, see [New
For more information on temporary tables

These local storage volumes are backed by Amazon Elastic Block Store and can be extended by using
a larger DB instance class. For more information about storage, see [Amazon Aurora storage and

**Note**

You might see storage-optimization events when scaling DB instances, for example, from
db.r5.2xlarge to db.r5.4xlarge.

The following table shows the maximum amount of temporary storage available for each Aurora MySQL
DB instance class. For more information on DB instance class support for Aurora, see [Aurora DB instance
classes (p. 84)](https://aws.amazon.com/premierreliability).

</table>

**Important**

These values represent the theoretical maximum amount of free storage on each DB instance. The actual local storage available to you might be lower. Aurora uses some local storage for its management processes, and the DB instance uses some local storage even before you load data.
any data. You can monitor the temporary storage available for a specific DB instance with the FreeLocalStorage CloudWatch metric, described in Amazon CloudWatch metrics for Amazon Aurora (p. 638). You can check the amount of free storage at the present time. You can also chart the amount of free storage over time. Monitoring the free storage over time helps you to determine whether the value is increasing or decreasing, or to find the minimum, maximum, or average values.

(This doesn’t apply to Aurora Serverless v2.)

Backtracking an Aurora DB cluster

With Amazon Aurora MySQL-Compatible Edition, you can backtrack a DB cluster to a specific time, without restoring data from a backup.

Overview of backtracking

Backtracking "rewinds" the DB cluster to the time you specify. Backtracking is not a replacement for backing up your DB cluster so that you can restore it to a point in time. However, backtracking provides the following advantages over traditional backup and restore:

• You can easily undo mistakes. If you mistakenly perform a destructive action, such as a DELETE without a WHERE clause, you can backtrack the DB cluster to a time before the destructive action with minimal interruption of service.
• You can backtrack a DB cluster quickly. Restoring a DB cluster to a point in time launches a new DB cluster and restores it from backup data or a DB cluster snapshot, which can take hours. Backtracking a DB cluster doesn’t require a new DB cluster and rewinds the DB cluster in minutes.
• You can explore earlier data changes. You can repeatedly backtrack a DB cluster back and forth in time to help determine when a particular data change occurred. For example, you can backtrack a DB cluster three hours and then backtrack forward in time one hour. In this case, the backtrack time is two hours before the original time.

Note
For information about restoring a DB cluster to a point in time, see Overview of backing up and restoring an Aurora DB cluster (p. 427).

Backtrack window

With backtracking, there is a target backtrack window and an actual backtrack window:

• The target backtrack window is the amount of time you want to be able to backtrack your DB cluster. When you enable backtracking, you specify a target backtrack window. For example, you might specify a target backtrack window of 24 hours if you want to be able to backtrack the DB cluster one day.
• The actual backtrack window is the actual amount of time you can backtrack your DB cluster, which can be smaller than the target backtrack window. The actual backtrack window is based on your workload and the storage available for storing information about database changes, called change records.

As you make updates to your Aurora DB cluster with backtracking enabled, you generate change records. Aurora retains change records for the target backtrack window, and you pay an hourly rate for storing them. Both the target backtrack window and the workload on your DB cluster determine the number of change records you store. The workload is the number of changes you make to your DB cluster in a given amount of time. If your workload is heavy, you store more change records in your backtrack window than you do if your workload is light.

You can think of your target backtrack window as the goal for the maximum amount of time you want to be able to backtrack your DB cluster. In most cases, you can backtrack the maximum amount of time that you specified. However, in some cases, the DB cluster can’t store enough change records to backtrack the
maximum amount of time, and your actual backtrack window is smaller than your target. Typically, the actual backtrack window is smaller than the target when you have extremely heavy workload on your DB cluster. When your actual backtrack window is smaller than your target, we send you a notification.

When backtracking is enabled for a DB cluster, and you delete a table stored in the DB cluster, Aurora keeps that table in the backtrack change records. It does this so that you can revert back to a time before you deleted the table. If you don't have enough space in your backtrack window to store the table, the table might be removed from the backtrack change records eventually.

**Backtracking time**

Aurora always backtracks to a time that is consistent for the DB cluster. Doing so eliminates the possibility of uncommitted transactions when the backtrack is complete. When you specify a time for a backtrack, Aurora automatically chooses the nearest possible consistent time. This approach means that the completed backtrack might not exactly match the time you specify, but you can determine the exact time for a backtrack by using the `describe-db-cluster-backtracks` AWS CLI command. For more information, see [Retrieving existing backtracks](p.893).

**Backtracking limitations**

The following limitations apply to backtracking:

- Backtracking is only available for DB clusters that were created with the Backtrack feature enabled. You can enable the Backtrack feature when you create a new DB cluster or restore a snapshot of a DB cluster. For DB clusters that were created with the Backtrack feature enabled, you can create a clone DB cluster with the Backtrack feature enabled. Currently, you can't perform backtracking on DB clusters that were created with the Backtrack feature disabled.

- The limit for a backtrack window is 72 hours.

- Backtracking affects the entire DB cluster. For example, you can't selectively backtrack a single table or a single data update.

- Backtracking isn't supported with binary log (binlog) replication. Cross-Region replication must be disabled before you can configure or use backtracking.

- You can't backtrack a database clone to a time before that database clone was created. However, you can use the original database to backtrack to a time before the clone was created. For more information about database cloning, see [Cloning a volume for an Amazon Aurora DB cluster](p.303).

- Backtracking causes a brief DB instance disruption. You must stop or pause your applications before starting a backtrack operation to ensure that there are no new read or write requests. During the backtrack operation, Aurora pauses the database, closes any open connections, and drops any uncommitted reads and writes. It then waits for the backtrack operation to complete.

- You can't restore a cross-Region snapshot of a backtrack-enabled cluster in an AWS Region that doesn't support backtracking.

- If you perform an in-place upgrade for a backtrack-enabled cluster from Aurora MySQL version 2 to version 3, you can't backtrack to a point in time before the upgrade happened.

**Region and version availability**

Backtrack is not available for Aurora PostgreSQL.

Following are the supported engines and Region availability for Backtrack with Aurora MySQL.

Upgrade considerations for backtrack-enabled clusters

You can upgrade a backtrack-enabled DB cluster from Aurora MySQL version 2 to version 3, because all minor versions of Aurora MySQL version 3 are supported for Backtrack.

Configuring backtracking

To use the Backtrack feature, you must enable backtracking and specify a target backtrack window. Otherwise, backtracking is disabled.

For the target backtrack window, specify the amount of time that you want to be able to rewind your database using Backtrack. Aurora tries to retain enough change records to support that window of time.

Console

You can use the console to configure backtracking when you create a new DB cluster. You can also modify a DB cluster to change the backtrack window for a backtrack-enabled cluster. If you turn off backtracking entirely for a cluster by setting the backtrack window to 0, you can't enable backtrack again for that cluster.

Topics

- Configuring backtracking with the console when creating a DB cluster (p. 883)
- Configuring backtrack with the console when modifying a DB cluster (p. 884)

Configuring backtracking with the console when creating a DB cluster

When you create a new Aurora MySQL DB cluster, backtracking is configured when you choose Enable Backtrack and specify a Target Backtrack window value that is greater than zero in the Backtrack section.

To create a DB cluster, follow the instructions in Creating an Amazon Aurora DB cluster (p. 179). The following image shows the Backtrack section.

<table>
<thead>
<tr>
<th>Region</th>
<th>Aurora MySQL version 3</th>
<th>Aurora MySQL version 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS GovCloud (US-West)</td>
<td>–</td>
<td>–</td>
</tr>
</tbody>
</table>
When you create a new DB cluster, Aurora has no data for the DB cluster's workload. So it can't estimate a cost specifically for the new DB cluster. Instead, the console presents a typical user cost for the specified target backtrack window based on a typical workload. The typical cost is meant to provide a general reference for the cost of the Backtrack feature.

**Important**

Your actual cost might not match the typical cost, because your actual cost is based on your DB cluster's workload.

Configuring backtrack with the console when modifying a DB cluster

You can modify backtracking for a DB cluster using the console.

**Note**

Currently, you can modify backtracking only for a DB cluster that has the Backtrack feature enabled. The Backtrack section doesn't appear for a DB cluster that was created with the Backtrack feature disabled or if the Backtrack feature has been disabled for the DB cluster.

**To modify backtracking for a DB cluster using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Choose Databases.
3. Choose the cluster that you want to modify, and choose Modify.
4. For Target Backtrack window, modify the amount of time that you want to be able to backtrack. The limit is 72 hours.
The console shows the estimated cost for the amount of time you specified based on the DB cluster's past workload:

- If backtracking was disabled on the DB cluster, the cost estimate is based on the VolumeWriteIOPS metric for the DB cluster in Amazon CloudWatch.
- If backtracking was enabled previously on the DB cluster, the cost estimate is based on the BacktrackChangeRecordsCreationRate metric for the DB cluster in Amazon CloudWatch.

5. Choose **Continue**.

6. For **Scheduling of Modifications**, choose one of the following:
   - **Apply during the next scheduled maintenance window** – Wait to apply the Target Backtrack window modification until the next maintenance window.
   - **Apply immediately** – Apply the Target Backtrack window modification as soon as possible.

7. Choose **Modify cluster**.

**AWS CLI**

When you create a new Aurora MySQL DB cluster using the `create-db-cluster` AWS CLI command, backtracking is configured when you specify a `--backtrack-window` value that is greater than zero. The `--backtrack-window` value specifies the target backtrack window. For more information, see [Creating an Amazon Aurora DB cluster](p. 179).

You can also specify the `--backtrack-window` value using the following AWS CLI commands:

- `modify-db-cluster`
- `restore-db-cluster-from-s3`
- `restore-db-cluster-from-snapshot`
- `restore-db-cluster-to-point-in-time`

The following procedure describes how to modify the target backtrack window for a DB cluster using the AWS CLI.
To modify the target backtrack window for a DB cluster using the AWS CLI

- Call the `modify-db-cluster` AWS CLI command and supply the following values:
  - `--db-cluster-identifier` – The name of the DB cluster.
  - `--backtrack-window` – The maximum number of seconds that you want to be able to backtrack the DB cluster.

The following example sets the target backtrack window for `sample-cluster` to one day (86,400 seconds).

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
    --db-cluster-identifier sample-cluster \
    --backtrack-window 86400
```

For Windows:

```
aws rds modify-db-cluster ^
    --db-cluster-identifier sample-cluster ^
    --backtrack-window 86400
```

**Note**
Currently, you can enable backtracking only for a DB cluster that was created with the Backtrack feature enabled.

**RDS API**

When you create a new Aurora MySQL DB cluster using the `CreateDBCluster` Amazon RDS API operation, backtracking is configured when you specify a `BacktrackWindow` value that is greater than zero. The `BacktrackWindow` value specifies the target backtrack window for the DB cluster specified in the `DBClusterIdentifier` value. For more information, see [Creating an Amazon Aurora DB cluster](p. 179).

You can also specify the `BacktrackWindow` value using the following API operations:

- `ModifyDBCluster`
- `RestoreDBClusterFromS3`
- `RestoreDBClusterFromSnapshot`
- `RestoreDBClusterToPointInTime`

**Note**
Currently, you can enable backtracking only for a DB cluster that was created with the Backtrack feature enabled.

**Performing a backtrack**

You can backtrack a DB cluster to a specified backtrack time stamp. If the backtrack time stamp isn't earlier than the earliest possible backtrack time, and isn't in the future, the DB cluster is backtracked to that time stamp.
Otherwise, an error typically occurs. Also, if you try to backtrack a DB cluster for which binary logging is enabled, an error typically occurs unless you've chosen to force the backtrack to occur. Forcing a backtrack to occur can interfere with other operations that use binary logging.

**Important**
Backtracking doesn't generate binlog entries for the changes that it makes. If you have binary logging enabled for the DB cluster, backtracking might not be compatible with your binlog implementation.

**Note**
For database clones, you can't backtrack the DB cluster earlier than the date and time when the clone was created. For more information about database cloning, see Cloning a volume for an Amazon Aurora DB cluster (p. 303).

**Console**
The following procedure describes how to perform a backtrack operation for a DB cluster using the console.

**To perform a backtrack operation using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Instances**.
3. Choose the primary instance for the DB cluster that you want to backtrack.
4. For **Actions**, choose **Backtrack DB cluster**.
5. On the **Backtrack DB cluster** page, enter the backtrack time stamp to backtrack the DB cluster to.

   ![Backtrack DB cluster](image)

6. Choose **Backtrack DB cluster**.

**AWS CLI**
The following procedure describes how to backtrack a DB cluster using the AWS CLI.

**To backtrack a DB cluster using the AWS CLI**

- Call the **backtrack-db-cluster** AWS CLI command and supply the following values:
• `--db-cluster-identifier` – The name of the DB cluster.
• `--backtrack-to` – The backtrack time stamp to backtrack the DB cluster to, specified in ISO 8601 format.

The following example backtracks the DB cluster sample-cluster to March 19, 2018, at 10 a.m.

For Linux, macOS, or Unix:

```
aws rds backtrack-db-cluster
   --db-cluster-identifier sample-cluster
   --backtrack-to 2018-03-19T10:00:00+00:00
```

For Windows:

```
aws rds backtrack-db-cluster ^
   --db-cluster-identifier sample-cluster ^
   --backtrack-to 2018-03-19T10:00:00+00:00
```

**RDS API**

To backtrack a DB cluster using the Amazon RDS API, use the `BacktrackDBCluster` operation. This operation backtracks the DB cluster specified in the `DBClusterIdentifier` value to the specified time.

**Monitoring backtracking**

You can view backtracking information and monitor backtracking metrics for a DB cluster.

**Console**

**To view backtracking information and monitor backtracking metrics using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Databases**.
3. Choose the DB cluster name to open information about it.
   
The backtrack information is in the **Backtrack** section.
When backtracking is enabled, the following information is available:

- **Target window** – The current amount of time specified for the target backtrack window. The target is the maximum amount of time that you can backtrack if there is sufficient storage.
- **Actual window** – The actual amount of time you can backtrack, which can be smaller than the target backtrack window. The actual backtrack window is based on your workload and the storage available for retaining backtrack change records.
- **Earliest backtrack time** – The earliest possible backtrack time for the DB cluster. You can't backtrack the DB cluster to a time before the displayed time.

4. Do the following to view backtracking metrics for the DB cluster:
   a. In the navigation pane, choose **Instances**.
   b. Choose the name of the primary instance for the DB cluster to display its details.
   c. In the **CloudWatch** section, type **Backtrack** into the **CloudWatch** box to show only the Backtrack metrics.

The following metrics are displayed:
• **Backtrack Change Records Creation Rate (Count)** – This metric shows the number of backtrack change records created over five minutes for your DB cluster. You can use this metric to estimate the backtrack cost for your target backtrack window.

• **[Billed] Backtrack Change Records Stored (Count)** – This metric shows the actual number of backtrack change records used by your DB cluster.

• **Backtrack Window Actual (Minutes)** – This metric shows whether there is a difference between the target backtrack window and the actual backtrack window. For example, if your target backtrack window is 2 hours (120 minutes), and this metric shows that the actual backtrack window is 100 minutes, then the actual backtrack window is smaller than the target.

• **Backtrack Window Alert (Count)** – This metric shows how often the actual backtrack window is smaller than the target backtrack window for a given period of time.

**Note**
The following metrics might lag behind the current time:

• **Backtrack Change Records Creation Rate (Count)**

• **[Billed] Backtrack Change Records Stored (Count)**

---

**AWS CLI**

The following procedure describes how to view backtrack information for a DB cluster using the AWS CLI.

**To view backtrack information for a DB cluster using the AWS CLI**

- Call the [describe-db-clusters](https://docs.aws.amazon.com/cli/latest/reference/rds/describe-db-clusters.html) AWS CLI command and supply the following values:
  - `--db-cluster-identifier` – The name of the DB cluster.

The following example lists backtrack information for `sample-cluster`.

For Linux, macOS, or Unix:

```bash
aws rds describe-db-clusters \  --db-cluster-identifier sample-cluster
```

For Windows:

```bash
aws rds describe-db-clusters ^  --db-cluster-identifier sample-cluster
```

**RDS API**

To view backtrack information for a DB cluster using the Amazon RDS API, use the [DescribeDBClusters](https://docs.aws.amazon.com/AmazonRDS/latest/APIReference/API_DescribeDBClusters.html) operation. This operation returns backtrack information for the DB cluster specified in the `DBClusterIdentifier` value.
Subscribing to a backtrack event with the console

The following procedure describes how to subscribe to a backtrack event using the console. The event sends you an email or text notification when your actual backtrack window is smaller than your target backtrack window.

To view backtrack information using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Event subscriptions.
3. Choose Create event subscription.
4. In the Name box, type a name for the event subscription, and ensure that Yes is selected for Enabled.
5. In the Target section, choose New email topic.
6. For Topic name, type a name for the topic, and for With these recipients, enter the email addresses or phone numbers to receive the notifications.
7. In the Source section, choose Instances for Source type.
8. For Instances to include, choose Select specific instances, and choose your DB instance.
9. For Event categories to include, choose Select specific event categories, and choose backtrack.

Your page should look similar to the following page.
Create event subscription

- select event categories
10. Choose Create.

Retrieving existing backtracks

You can retrieve information about existing backtracks for a DB cluster. This information includes the unique identifier of the backtrack, the date and time backtracked to and from, the date and time the backtrack was requested, and the current status of the backtrack.

Note
Currently, you can't retrieve existing backtracks using the console.

AWS CLI

The following procedure describes how to retrieve existing backtracks for a DB cluster using the AWS CLI.

To retrieve existing backtracks using the AWS CLI

- Call the describe-db-cluster-backtracks AWS CLI command and supply the following values:
  - `--db-cluster-identifier` – The name of the DB cluster.

The following example retrieves existing backtracks for sample-cluster.

For Linux, macOS, or Unix:

```bash
aws rds describe-db-cluster-backtracks
  --db-cluster-identifier sample-cluster
```

For Windows:

```bash
aws rds describe-db-cluster-backtracks ^
  --db-cluster-identifier sample-cluster
```

RDS API

To retrieve information about the backtracks for a DB cluster using the Amazon RDS API, use the DescribeDBClusterBacktracks operation. This operation returns information about backtracks for the DB cluster specified in the DBClusterIdentifier value.

Disabling backtracking for a DB cluster

You can disable the Backtrack feature for a DB cluster.

Console

You can disable backtracking for a DB cluster using the console. After you turn off backtracking entirely for a cluster, you can't enable it again for that cluster.

To disable the Backtrack feature for a DB cluster using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Databases.
3. Choose the cluster you want to modify, and choose Modify.
4. In the **Backtrack** section, choose **Disable Backtrack**.
5. Choose **Continue**.
6. For **Scheduling of Modifications**, choose one of the following:
   - **Apply during the next scheduled maintenance window** – Wait to apply the modification until the next maintenance window.
   - **Apply immediately** – Apply the modification as soon as possible.
7. Choose **Modify Cluster**.

**AWS CLI**

You can disable the Backtrack feature for a DB cluster using the AWS CLI by setting the target backtrack window to 0 (zero). After you turn off backtracking entirely for a cluster, you can't enable it again for that cluster.

**To modify the target backtrack window for a DB cluster using the AWS CLI**

- Call the `modify-db-cluster` AWS CLI command and supply the following values:
  - `--db-cluster-identifier` – The name of the DB cluster.
  - `--backtrack-window` – specify 0 to turn off backtracking.

The following example disables the Backtrack feature for the `sample-cluster` by setting `--backtrack-window` to 0.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster \
  --db-cluster-identifier sample-cluster \
  --backtrack-window 0
```

For Windows:

```bash
aws rds modify-db-cluster ^
  --db-cluster-identifier sample-cluster ^
  --backtrack-window 0
```

**RDS API**

To disable the Backtrack feature for a DB cluster using the Amazon RDS API, use the `ModifyDBCluster` operation. Set the `BacktrackWindow` value to 0 (zero), and specify the DB cluster in the `DBClusterIdentifier` value. After you turn off backtracking entirely for a cluster, you can't enable it again for that cluster.

**Testing Amazon Aurora MySQL using fault injection queries**

You can test the fault tolerance of your Aurora MySQL DB cluster by using fault injection queries. Fault injection queries are issued as SQL commands to an Amazon Aurora instance. They let you schedule a simulated occurrence of one of the following events:
• A crash of a writer or reader DB instance
• A failure of an Aurora Replica
• A disk failure
• Disk congestion

When a fault injection query specifies a crash, it forces a crash of the Aurora MySQL DB instance. The other fault injection queries result in simulations of failure events, but don't cause the event to occur. When you submit a fault injection query, you also specify an amount of time for the failure event simulation to occur for.

You can submit a fault injection query to one of your Aurora Replica instances by connecting to the endpoint for the Aurora Replica. For more information, see Amazon Aurora connection management (p. 62).

Running fault injection queries requires all of the master user privileges. For more information, see Master user account privileges (p. 2474).

Testing an instance crash

You can force a crash of an Amazon Aurora instance using the ALTER SYSTEM CRASH fault injection query.

For this fault injection query, a failover will not occur. If you want to test a failover, then you can choose the Failover instance action for your DB cluster in the RDS console, or use the failover-db-cluster AWS CLI command or the FailoverDBCluster RDS API operation.

Syntax

ALTER SYSTEM CRASH [ INSTANCE | DISPATCHER | NODE ];

Options

This fault injection query takes one of the following crash types:

• INSTANCE — A crash of the MySQL-compatible database for the Amazon Aurora instance is simulated.
• DISPATCHER — A crash of the dispatcher on the writer instance for the Aurora DB cluster is simulated. The dispatcher writes updates to the cluster volume for an Amazon Aurora DB cluster.
• NODE — A crash of both the MySQL-compatible database and the dispatcher for the Amazon Aurora instance is simulated. For this fault injection simulation, the cache is also deleted.

The default crash type is INSTANCE.

Testing an Aurora replica failure

You can simulate the failure of an Aurora Replica using the ALTER SYSTEM SIMULATE READ REPLICA FAILURE fault injection query.

An Aurora Replica failure blocks all requests from the writer instance to an Aurora Replica or all Aurora Replicas in the DB cluster for a specified time interval. When the time interval completes, the affected Aurora Replicas will be automatically synced up with master instance.

Syntax

ALTER SYSTEM SIMULATE percentage_of_failure PERCENT READ REPLICA FAILURE
[ TO ALL | TO "replica name" ]
FOR INTERVAL quantity { YEAR | QUARTER | MONTH | WEEK | DAY | HOUR | MINUTE | SECOND };

Options

This fault injection query takes the following parameters:

- **percentage_of_failure** — The percentage of requests to block during the failure event. This value can be a double between 0 and 100. If you specify 0, then no requests are blocked. If you specify 100, then all requests are blocked.

- **Failure type** — The type of failure to simulate. Specify TO ALL to simulate failures for all Aurora Replicas in the DB cluster. Specify TO and the name of the Aurora Replica to simulate a failure of a single Aurora Replica. The default failure type is TO ALL.

- **quantity** — The amount of time for which to simulate the Aurora Replica failure. The interval is an amount followed by a time unit. The simulation will occur for that amount of the specified unit. For example, 20 MINUTE will result in the simulation running for 20 minutes.

**Note**
Take care when specifying the time interval for your Aurora Replica failure event. If you specify too long of a time interval, and your writer instance writes a large amount of data during the failure event, then your Aurora DB cluster might assume that your Aurora Replica has crashed and replace it.

Testing a disk failure

You can simulate a disk failure for an Aurora DB cluster using the ALTER SYSTEM SIMULATE DISK FAILURE fault injection query.

During a disk failure simulation, the Aurora DB cluster randomly marks disk segments as faulting. Requests to those segments will be blocked for the duration of the simulation.

Syntax

ALTER SYSTEM SIMULATE percentage_of_failure PERCENT DISK FAILURE
[ IN DISK index | NODE index ]
FOR INTERVAL quantity { YEAR | QUARTER | MONTH | WEEK | DAY | HOUR | MINUTE | SECOND };

Options

This fault injection query takes the following parameters:

- **percentage_of_failure** — The percentage of the disk to mark as faulting during the failure event. This value can be a double between 0 and 100. If you specify 0, then none of the disk is marked as faulting. If you specify 100, then the entire disk is marked as faulting.

- **DISK index** — A specific logical block of data to simulate the failure event for. If you exceed the range of available logical blocks of data, you will receive an error that tells you the maximum index value that you can specify. For more information, see Displaying volume status for an Aurora MySQL DB cluster (p. 902).

- **NODE index** — A specific storage node to simulate the failure event for. If you exceed the range of available storage nodes, you will receive an error that tells you the maximum index value that you can specify. For more information, see Displaying volume status for an Aurora MySQL DB cluster (p. 902).

- **quantity** — The amount of time for which to simulate the disk failure. The interval is an amount followed by a time unit. The simulation will occur for that amount of the specified unit. For example, 20 MINUTE will result in the simulation running for 20 minutes.
Testing disk congestion

You can simulate a disk failure for an Aurora DB cluster using the ALTER SYSTEM SIMULATE DISK CONGESTION fault injection query.

During a disk congestion simulation, the Aurora DB cluster randomly marks disk segments as congested. Requests to those segments will be delayed between the specified minimum and maximum delay time for the duration of the simulation.

Syntax

```
ALTER SYSTEM SIMULATE percentage_of_failure PERCENT DISK CONGESTION
   BETWEEN minimum AND maximum MILLISECONDS
   [ IN DISK index | NODE index ]
   FOR INTERVAL quantity { YEAR | QUARTER | MONTH | WEEK | DAY | HOUR | MINUTE | SECOND };
```

Options

This fault injection query takes the following parameters:

- **percentage_of_failure** — The percentage of the disk to mark as congested during the failure event. This value can be a double between 0 and 100. If you specify 0, then none of the disk is marked as congested. If you specify 100, then the entire disk is marked as congested.

- **DISK index Or NODE index** — A specific disk or node to simulate the failure event for. If you exceed the range of indexes for the disk or node, you will receive an error that tells you the maximum index value that you can specify.

- **minimum And maximum** — The minimum and maximum amount of congestion delay, in milliseconds. Disk segments marked as congested will be delayed for a random amount of time within the range of the minimum and maximum amount of milliseconds for the duration of the simulation.

- **quantity** — The amount of time for which to simulate the disk congestion. The interval is an amount followed by a time unit. The simulation will occur for that amount of the specified time unit. For example, 20 MINUTE will result in the simulation running for 20 minutes.

Altering tables in Amazon Aurora using Fast DDL

Amazon Aurora includes optimizations to run an ALTER TABLE operation in place, nearly instantaneously. The operation completes without requiring the table to be copied and without having a material impact on other DML statements. Because the operation doesn’t consume temporary storage for a table copy, it makes DDL statements practical even for large tables on small instance classes.

Aurora MySQL version 3 is compatible with the MySQL 8.0 feature called instant DDL. Aurora MySQL version 2 uses a different implementation called Fast DDL.

Topics

- Instant DDL (Aurora MySQL version 3) (p. 897)
- Fast DDL (Aurora MySQL version 2) (p. 899)

Instant DDL (Aurora MySQL version 3)

The optimization performed by Aurora MySQL version 3 to improve the efficiency of some DDL operations is called instant DDL.
Aurora MySQL version 3 is compatible with the instant DDL from community MySQL 8.0. You perform an instant DDL operation by using the clause ALGORITHM=INSTANT with the ALTER TABLE statement. For syntax and usage details about instant DDL, see ALTER TABLE and Online DDL Operations in the MySQL documentation.

The following examples demonstrate the instant DDL feature. The ALTER TABLE statements add columns and change default column values. The examples include both regular and virtual columns, and both regular and partitioned tables. At each step, you can see the results by issuing SHOW CREATE TABLE and DESCRIBE statements.

```sql
mysql> CREATE TABLE t1 (a INT, b INT, KEY(b)) PARTITION BY KEY(b) PARTITIONS 6;
Query OK, 0 rows affected (0.02 sec)

mysql> ALTER TABLE t1 RENAME TO t2, ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> ALTER TABLE t2 ALTER COLUMN b SET DEFAULT 100, ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.00 sec)

mysql> ALTER TABLE t2 ALTER COLUMN b DROP DEFAULT, ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> ALTER TABLE t2 ADD COLUMN c ENUM('a', 'b', 'c'), ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> ALTER TABLE t2 MODIFY COLUMN c ENUM('a', 'b', 'c', 'd', 'e'), ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> ALTER TABLE t2 ADD COLUMN (d INT GENERATED ALWAYS AS (a + 1) VIRTUAL), ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.02 sec)

mysql> ALTER TABLE t2 ALTER COLUMN a SET DEFAULT 20,
   ->   ALTER COLUMN b SET DEFAULT 200, ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t3 (a INT, b INT) PARTITION BY LIST(a)(
   ->   PARTITION mypart1 VALUES IN (1,3,5),
   ->   PARTITION MyPart2 VALUES IN (2,4,6)
   -> );
Query OK, 0 rows affected (0.03 sec)

mysql> ALTER TABLE t3 ALTER COLUMN a SET DEFAULT 20, ALTER COLUMN b SET DEFAULT 200,
   ->   ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t4 (a INT, b INT) PARTITION BY RANGE(a)
   ->   (PARTITION p0 VALUES LESS THAN(100), PARTITION p1 VALUES LESS THAN(1000),
   ->   PARTITION p2 VALUES LESS THAN MAXVALUE);
Query OK, 0 rows affected (0.05 sec)

mysql> ALTER TABLE t4 ALTER COLUMN a SET DEFAULT 20,
   ->   ALTER COLUMN b SET DEFAULT 200, ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

/* Sub-partitioning example */
mysql> CREATE TABLE ts (id INT, purchased DATE, a INT, b INT)
   ->   PARTITION BY RANGE( YEAR(purchased) )
   ->   SUBPARTITION BY HASH( TO_DAYS(purchased) )
   ->   SUBPARTITIONS 2 {
   ->       PARTITION p0 VALUES LESS THAN (1990),
   ->       PARTITION p1 VALUES LESS THAN (2000),
   ->       PARTITION p2 VALUES LESS THAN MAXVALUE
   ->   );
Fast DDL (Aurora MySQL version 2)

In MySQL, many data definition language (DDL) operations have a significant performance impact. For example, suppose that you use an ALTER TABLE operation to add a column to a table. Depending on the algorithm specified for the operation, this operation can involve the following:

- Creating a full copy of the table
- Creating a temporary table to process concurrent data manipulation language (DML) operations
- Rebuilding all indexes for the table
- Applying table locks while applying concurrent DML changes
- Slowing concurrent DML throughput

The optimization performed by Aurora MySQL version 2 to improve the efficiency of some DDL operations is called Fast DDL.

In Aurora MySQL version 3, Aurora uses the MySQL 8.0 feature called instant DDL. Aurora MySQL version 2 uses a different implementation called Fast DDL.

**Important**
Currently, Aurora lab mode must be enabled to use Fast DDL for Aurora MySQL. We don't recommend using Fast DDL for production DB clusters. For information about enabling Aurora lab mode, see Amazon Aurora MySQL lab mode (p. 1101).

Fast DDL limitations

Currently, Fast DDL has the following limitations:

- Fast DDL only supports adding nullable columns, without default values, to the end of an existing table.
- Fast DDL doesn't work for partitioned tables.
- Fast DDL doesn't work for InnoDB tables that use the REDUNDANT row format.
- Fast DDL doesn't work for tables with full-text search indexes.
- If the maximum possible record size for the DDL operation is too large, Fast DDL is not used. A record size is too large if it is greater than half the page size. The maximum size of a record is computed by adding the maximum sizes of all columns. For variable sized columns, according to InnoDB standards, extern bytes are not included for computation.

Fast DDL syntax

```
ALTER TABLE `tbl_name` ADD COLUMN `col_name` column_definition
```

This statement takes the following options:

- `tbl_name` — The name of the table to be modified.
- `col_name` — The name of the column to be added.
Fast DDL examples

The following examples demonstrate the speedup from Fast DDL operations. The first SQL example runs ALTER TABLE statements on a large table without using Fast DDL. This operation takes substantial time. A CLI example shows how to enable Fast DDL for the cluster. Then another SQL example runs the same ALTER TABLE statements on an identical table. With Fast DDL enabled, the operation is very fast.

This example uses the ORDERS table from the TPC-H benchmark, containing 150 million rows. This cluster intentionally uses a relatively small instance class, to demonstrate how long ALTER TABLE statements can take when you can't use Fast DDL. The example creates a clone of the original table containing identical data. Checking the aurora_lab_mode setting confirms that the cluster can't use Fast DDL, because lab mode isn't enabled. Then ALTER TABLE ADD COLUMN statements take substantial time to add new columns at the end of the table.

```
mysql> create table orders_regular_ddl like orders;
Query OK, 0 rows affected (0.06 sec)

mysql> insert into orders_regular_ddl select * from orders;
Query OK, 150000000 rows affected (1 hour 1 min 25.46 sec)

mysql> select @@aurora_lab_mode;
+-------------------+
<table>
<thead>
<tr>
<th>@@aurora_lab_mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
+-------------------+

mysql> ALTER TABLE orders_regular_ddl ADD COLUMN o_refunded boolean;
Query OK, 0 rows affected (40 min 31.41 sec)

mysql> ALTER TABLE orders_regular_ddl ADD COLUMN o_coverletter varchar(512);
Query OK, 0 rows affected (40 min 44.45 sec)
```

This example does the same preparation of a large table as the previous example. However, you can't simply enable lab mode within an interactive SQL session. That setting must be enabled in a custom parameter group. Doing so requires switching out of the mysql session and running some AWS CLI commands or using the AWS Management Console.

```
mysql> create table orders_fast_ddl like orders;
Query OK, 0 rows affected (0.02 sec)

mysql> insert into orders_fast_ddl select * from orders;
Query OK, 150000000 rows affected (58 min 3.25 sec)

mysql> set aurora_lab_mode=1;
ERROR 1238 (HY000): Variable 'aurora_lab_mode' is a read only variable

Enabling lab mode for the cluster requires some work with a parameter group. This AWS CLI example uses a cluster parameter group, to ensure that all DB instances in the cluster use the same value for the lab mode setting.

```
$ aws rds create-db-cluster-parameter-group

```
The following example shows the remaining steps after the parameter group change takes effect. It tests the `aurora_lab_mode` setting to make sure that the cluster can use Fast DDL. Then it runs `ALTER TABLE` statements to add columns to the end of another large table. This time, the statements finish very quickly.

```sql
mysql> select @@aurora_lab_mode;
+-------------------+
| @@aurora_lab_mode |
+-------------------+
|                 1 |
+-------------------+
mysql> ALTER TABLE orders_fast_ddl ADD COLUMN o_refunded boolean;
Query OK, 0 rows affected (1.51 sec)
mysql> ALTER TABLE orders_fast_ddl ADD COLUMN o_coverletter varchar(512);
Query OK, 0 rows affected (0.40 sec)
```
Displaying volume status for an Aurora MySQL DB cluster

In Amazon Aurora, a DB cluster volume consists of a collection of logical blocks. Each of these represents 10 gigabytes of allocated storage. These blocks are called protection groups.

The data in each protection group is replicated across six physical storage devices, called storage nodes. These storage nodes are allocated across three Availability Zones (AZs) in the AWS Region where the DB cluster resides. In turn, each storage node contains one or more logical blocks of data for the DB cluster volume. For more information about protection groups and storage nodes, see Introducing the Aurora storage engine on the AWS Database Blog.

You can simulate the failure of an entire storage node, or a single logical block of data within a storage node. To do so, you use the ALTER SYSTEM SIMULATE DISK FAILURE fault injection statement. For the statement, you specify the index value of a specific logical block of data or storage node. However, if you specify an index value greater than the number of logical blocks of data or storage nodes used by the DB cluster volume, the statement returns an error. For more information about fault injection queries, see Testing Amazon Aurora MySQL using fault injection queries (p. 894).

You can avoid that error by using the SHOW VOLUME STATUS statement. The statement returns two server status variables, Disks and Nodes. These variables represent the total number of logical blocks of data and storage nodes, respectively, for the DB cluster volume.

Syntax

SHOW VOLUME STATUS

Example

The following example illustrates a typical SHOW VOLUME STATUS result.

```
mysql> SHOW VOLUME STATUS;
+-----------------+-------+
| Variable_name   | Value |
| Disks           | 96    |
| Nodes           | 74    |
+-----------------+-------+
```
Tuning Aurora MySQL

Wait events and thread states are important tuning tools for Aurora MySQL. If you can find out why sessions are waiting for resources and what they are doing, you are better able to reduce bottlenecks. You can use the information in this section to find possible causes and corrective actions.

Amazon DevOps Guru for RDS can proactively determine whether your Aurora MySQL databases are experiencing problematic conditions that might cause bigger problems later. Amazon DevOps Guru for RDS publishes an explanation and recommendations for corrective actions in a proactive insight. This section contains insights for common problems.

**Important**
The wait events and thread states in this section are specific to Aurora MySQL. Use the information in this section to tune only Amazon Aurora, not Amazon RDS for MySQL. Some wait events in this section have no analogs in the open source versions of these database engines. Other wait events have the same names as events in open source engines, but behave differently. For example, Amazon Aurora storage works different from open source storage, so storage-related wait events indicate different resource conditions.

**Topics**
- Essential concepts for Aurora MySQL tuning (p. 903)
- Tuning Aurora MySQL with wait events (p. 905)
- Tuning Aurora MySQL with thread states (p. 939)
- Tuning Aurora MySQL with Amazon DevOps Guru proactive insights (p. 944)

Essential concepts for Aurora MySQL tuning

Before you tune your Aurora MySQL database, make sure to learn what wait events and thread states are and why they occur. Also review the basic memory and disk architecture of Aurora MySQL when using the InnoDB storage engine. For a helpful architecture diagram, see the [MySQL Reference Manual](https://dev.mysql.com/doc/refman/8.0/en/).

**Topics**
- Aurora MySQL wait events (p. 903)
- Aurora MySQL thread states (p. 904)
- Aurora MySQL memory (p. 904)
- Aurora MySQL processes (p. 904)

Aurora MySQL wait events

A *wait event* indicates a resource for which a session is waiting. For example, the wait event `io/socket/sql/client_connection` indicates that a thread is in the process of handling a new connection. Typical resources that a session waits for include the following:

- Single-threaded access to a buffer, for example, when a session is attempting to modify a buffer
- A row that is currently locked by another session
- A data file read
- A log file write

For example, to satisfy a query, the session might perform a full table scan. If the data isn't already in memory, the session waits for the disk I/O to complete. When the buffers are read into memory, the session might need to wait because other sessions are accessing the same buffers. The database records the waits by using a predefined wait event. These events are grouped into categories.
A wait event doesn't by itself show a performance problem. For example, if requested data isn't in memory, reading data from disk is necessary. If one session locks a row for an update, another session waits for the row to be unlocked so that it can update it. A commit requires waiting for the write to a log file to complete. Waits are integral to the normal functioning of a database.

Large numbers of wait events typically show a performance problem. In such cases, you can use wait event data to determine where sessions are spending time. For example, if a report that typically runs in minutes now runs for hours, you can identify the wait events that contribute the most to total wait time. If you can determine the causes of the top wait events, you can sometimes make changes that improve performance. For example, if your session is waiting on a row that has been locked by another session, you can end the locking session.

**Aurora MySQL thread states**

A general thread state is a State value that is associated with general query processing. For example, the thread state sending data indicates that a thread is reading and filtering rows for a query to determine the correct result set.

You can use thread states to tune Aurora MySQL in a similar fashion to how you use wait events. For example, frequent occurrences of sending data usually indicate that a query isn't using an index. For more information about thread states, see General Thread States in the MySQL Reference Manual.

When you use Performance Insights, one of the following conditions is true:

- Performance Schema is turned on – Aurora MySQL shows wait events rather than the thread state.
- Performance Schema isn't turned on – Aurora MySQL shows the thread state.

We recommend that you configure the Performance Schema for automatic management. The Performance Schema provides additional insights and better tools to investigate potential performance problems. For more information, see Turning on the Performance Schema for Performance Insights on Aurora MySQL (p. 568).

**Aurora MySQL memory**

In Aurora MySQL, the most important memory areas are the buffer pool and log buffer.

**Topics**

- Buffer pool (p. 904)

**Buffer pool**

The buffer pool is the shared memory area where Aurora MySQL caches table and index data. Queries can access frequently used data directly from memory without reading from disk.

The buffer pool is structured as a linked list of pages. A page can hold multiple rows. Aurora MySQL uses a least recently used (LRU) algorithm to age pages out of the pool.

For more information, see Buffer Pool in the MySQL Reference Manual.

**Aurora MySQL processes**

Aurora MySQL uses a process model that is very different from Aurora PostgreSQL.

**Topics**

- MySQL server (mysqld) (p. 905)
- Threads (p. 905)
- Thread pool (p. 905)
MySQL server (mysqld)

The MySQL server is a single operating-system process named mysqld. The MySQL server doesn't spawn additional processes. Thus, an Aurora MySQL database uses mysqld to perform most of its work.

When the MySQL server starts, it listens for network connections from MySQL clients. When a client connects to the database, mysqld opens a thread.

Threads

Connection manager threads associate each client connection with a dedicated thread. This thread manages authentication, runs statements, and returns results to the client. Connection manager creates new threads when necessary.

The thread cache is the set of available threads. When a connection ends, MySQL returns the thread to the thread cache if the cache isn't full. The thread_cache_size system variable determines the thread cache size.

Thread pool

The thread pool consists of a number of thread groups. Each group manages a set of client connections. When a client connects to the database, the thread pool assigns the connections to thread groups in round-robin fashion. The thread pool separates connections and threads. There is no fixed relationship between connections and the threads that run statements received from those connections.

Tuning Aurora MySQL with wait events

The following table summarizes the Aurora MySQL wait events that most commonly indicate performance problems. The following wait events are a subset of the list in Aurora MySQL wait events (p. 1151).

<table>
<thead>
<tr>
<th>Wait event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cpu (p. 906)</td>
<td>This event occurs when a thread is active in CPU or is waiting for CPU.</td>
</tr>
<tr>
<td>io/aurora_redo_log_flush (p. 909)</td>
<td>This event occurs when a session is writing persistent data to Aurora storage.</td>
</tr>
<tr>
<td>io/aurora_respond_to_client (p. 912)</td>
<td>This event occurs when a thread is waiting to return a result set to a client.</td>
</tr>
<tr>
<td>io/socket/sql/client_connection (p. 914)</td>
<td>This event occurs when a thread is in the process of handling a new connection.</td>
</tr>
<tr>
<td>io/table/sql/handler (p. 916)</td>
<td>This event occurs when work has been delegated to a storage engine.</td>
</tr>
<tr>
<td>synch/cond/innodb/row_lock_wait (p. 919)</td>
<td>This event occurs when one session has locked a row for an update, and another session tries to update the same row.</td>
</tr>
<tr>
<td>synch/cond/innodb/row_lock_wait_cond (p. 921)</td>
<td>This event occurs when one session has locked a row for an update, and another session tries to update the same row.</td>
</tr>
<tr>
<td>synch/cond/mysys/my_thread_var::suspend (p. 923)</td>
<td>This event occurs when threads are suspended because they are waiting on a condition.</td>
</tr>
</tbody>
</table>
### Wait event

<table>
<thead>
<tr>
<th>Wait event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>synch/cond/sql/MDL_context::COND_wait_status (p. 924)</code></td>
<td>This event occurs when there are threads waiting on a table metadata lock.</td>
</tr>
<tr>
<td><code>synch/mutex/innodb/aurora_lock_thread_slot_futex (p. 928)</code></td>
<td>This event occurs when one session has locked a row for an update, and another session tries to update the same row.</td>
</tr>
<tr>
<td><code>synch/mutex/innodb/buf_pool_mutex (p. 930)</code></td>
<td>This event occurs when a thread has acquired a lock on the InnoDB buffer pool to access a page in memory.</td>
</tr>
<tr>
<td><code>synch/mutex/innodb/fil_system_mutex (p. 932)</code></td>
<td>This event occurs when a session is waiting to access the tablespace memory cache.</td>
</tr>
<tr>
<td><code>synch/mutex/innodb/trx_sys_mutex (p. 935)</code></td>
<td>This event occurs when there is high database activity with a large number of transactions.</td>
</tr>
<tr>
<td><code>synch/sxlock/innodb/hash_table_locks (p. 936)</code></td>
<td>This event occurs when pages not found in the buffer pool must be read from a file.</td>
</tr>
</tbody>
</table>

### CPU

The CPU wait event occurs when a thread is active in CPU or is waiting for CPU.

**Topics**

- Supported engine versions (p. 906)
- Context (p. 906)
- Likely causes of increased waits (p. 907)
- Actions (p. 907)

### Supported engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2

### Context

For every vCPU, a connection can run work on this CPU. In some situations, the number of active connections that are ready to run is higher than the number of vCPUs. This imbalance results in connections waiting for CPU resources. If the number of active connections stays consistently higher than the number of vCPUs, then your instance experiences CPU contention. The contention causes the CPU wait event to occur.

**Note**

The Performance Insights metric for CPU is DBLoadCPU. The value for DBLoadCPU can differ from the value for the CloudWatch metric CPUUtilization. The latter metric is collected from the HyperVisor for a database instance.

Performance Insights OS metrics provide detailed information about CPU utilization. For example, you can display the following metrics:

- `os.cpuUtilization.nice.avg`
- `os.cpuUtilization.total.avg`
• `os.cpuUtilization.wait.avg`
• `os.cpuUtilization.idle.avg`

Performance Insights reports the CPU usage by the database engine as `os.cpuUtilization.nice.avg`.

**Likely causes of increased waits**

When this event occurs more than normal, possibly indicating a performance problem, typical causes include the following:

- Analytic queries
- Highly concurrent transactions
- Long-running transactions
- A sudden increase in the number of connections, known as a *login storm*
- An increase in context switching

**Actions**

If the CPU wait event dominates database activity, it doesn't necessarily indicate a performance problem. Respond to this event only when performance degrades.

Depending on the cause of the increase in CPU utilization, consider the following strategies:

- Increase the CPU capacity of the host. This approach typically gives only temporary relief.
- Identify top queries for potential optimization.
- Redirect some read-only workload to reader nodes, if applicable.

**Topics**

- [Identify the sessions or queries that are causing the problem (p. 907)]
- [Analyze and optimize the high CPU workload (p. 908)]

**Identify the sessions or queries that are causing the problem**

To find the sessions and queries, look at the **Top SQL** table in Performance Insights for the SQL statements that have the highest CPU load. For more information, see [Analyzing metrics with the Performance Insights dashboard (p. 576)]

Typically, one or two SQL statements consume the majority of CPU cycles. Concentrate your efforts on these statements. Suppose that your DB instance has 2 vCPUs with a DB load of 3.1 average active sessions (AAS), all in the CPU state. In this case, your instance is CPU bound. Consider the following strategies:

- Upgrade to a larger instance class with more vCPUs.
- Tune your queries to have lower CPU load.

In this example, the top SQL queries have a DB load of 1.5 AAS, all in the CPU state. Another SQL statement has a load of 0.1 in the CPU state. In this example, if you stopped the lowest-load SQL statement, you don't significantly reduce database load. However, if you optimize the two high-load queries to be twice as efficient, you eliminate the CPU bottleneck. If you reduce the CPU load of 1.5 AAS by 50 percent, the AAS for each statement decreases to 0.75. The total DB load spent on CPU is now 1.6 AAS. This value is below the maximum vCPU line of 2.0.
For a useful overview of troubleshooting using Performance Insights, see the blog post Analyze Amazon Aurora MySQL Workloads with Performance Insights. Also see the AWS Support article How can I troubleshoot and resolve high CPU utilization on my Amazon RDS for MySQL instances?

Analyze and optimize the high CPU workload

After you identify the query or queries increasing CPU usage, you can either optimize them or end the connection. The following example shows how to end a connection.

```
CALL mysql.rds_kill(processID);
```

For more information, see mysql.rds_kill (p. 1168).

If you end a session, the action might trigger a long rollback.

Follow the guidelines for optimizing queries

To optimize queries, consider the following guidelines:

- Run the EXPLAIN statement.
  
  This command shows the individual steps involved in running a query. For more information, see Optimizing Queries with EXPLAIN in the MySQL documentation.

- Run the SHOW PROFILE statement.
  
  Use this statement to review profile details that can indicate resource usage for statements that are run during the current session. For more information, see SHOW PROFILE Statement in the MySQL documentation.

- Run the ANALYZE TABLE statement.
  
  Use this statement to refresh the index statistics for the tables accessed by the high-CPU consuming query. By analyzing the statement, you can help the optimizer choose an appropriate execution plan. For more information, see ANALYZE TABLE Statement in the MySQL documentation.

Follow the guidelines for improving CPU usage

To improve CPU usage in a database instance, follow these guidelines:

- Ensure that all queries are using proper indexes.

- Find out whether you can use Aurora parallel queries. You can use this technique to reduce CPU usage on the head node by pushing down function processing, row filtering, and column projection for the WHERE clause.

- Find out whether the number of SQL executions per second meets the expected thresholds.

- Find out whether index maintenance or new index creation takes up CPU cycles needed by your production workload. Schedule maintenance activities outside of peak activity times.

- Find out whether you can use partitioning to help reduce the query data set. For more information, see the blog post How to plan and optimize Amazon Aurora with MySQL compatibility for consolidated workloads.

Check for connection storms

If the DBLoadCPU metric is not very high, but the CPUUtilization metric is high, the cause of the high CPU utilization lies outside of the database engine. A classic example is a connection storm.

Check whether the following conditions are true:
• There is an increase in both the Performance Insights CPUUtilization metric and the Amazon CloudWatch DatabaseConnections metric.
• The number of threads in the CPU is greater than the number of vCPUs.

If the preceding conditions are true, consider decreasing the number of database connections. For example, you can use a connection pool such as RDS Proxy. To learn the best practices for effective connection management and scaling, see the whitepaper Amazon Aurora MySQL DBA Handbook for Connection Management.

**io/aurora_redo_log_flush**

The `io/aurora_redo_log_flush` event occurs when a session is writing persistent data to Amazon Aurora storage.

**Topics**

- Supported engine versions (p. 909)
- Context (p. 909)
- Likely causes of increased waits (p. 909)
- Actions (p. 910)

**Supported engine versions**

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2

**Context**

The `io/aurora_redo_log_flush` event is for a write input/output (I/O) operation in Aurora MySQL.

** Likely causes of increased waits**

For data persistence, commits require a durable write to stable storage. If the database is doing too many commits, there is a wait event on the write I/O operation, the `io/aurora_redo_log_flush` wait event.

In the following examples, 50,000 records are inserted into an Aurora MySQL DB cluster using the db.r5.xlarge DB instance class:

- In the first example, each session inserts 10,000 records row by row. By default, if a data manipulation language (DML) command isn’t within a transaction, Aurora MySQL uses implicit commits. Autocommit is turned on. This means that for each row insertion there is a commit. Performance Insights shows that the connections spend most of their time waiting on the `io/aurora_redo_log_flush` wait event.
This is caused by the simple insert statements used.

![Image](https://via.placeholder.com/150)

The 50,000 records take 3.5 minutes to be inserted.

- In the second example, inserts are made in 1,000 batches, that is each connection performs 10 commits instead of 10,000. Performance Insights shows that the connections don't spend most of their time on the `io/aurora_redo_log_flush` wait event.

![Image](https://via.placeholder.com/150)

The 50,000 records take 4 seconds to be inserted.

**Actions**

We recommend different actions depending on the causes of your wait event.

**Identify the problematic sessions and queries**

If your DB instance is experiencing a bottleneck, your first task is to find the sessions and queries that cause it. For a useful AWS Database Blog post, see [Analyze Amazon Aurora MySQL Workloads with Performance Insights](https://aws.amazon.com/blogs/database/analyze-amazon-aurora-mysql-workloads-with-performance-insights/).

**To identify sessions and queries causing a bottleneck**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Performance Insights.
3. Choose your DB instance.
4. In Database load, choose Slice by wait.
5. At the bottom of the page, choose Top SQL.

    The queries at the top of the list are causing the highest load on the database.

**Group your write operations**

The following examples trigger the `io/aurora_redo_log_flush` wait event. (Autocommit is turned on.)

```
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
....
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
```
To reduce the time spent waiting on the **io/aurora_redo_log_flush** wait event, group your write operations logically into a single commit to reduce persistent calls to storage.

### Turn off autocommit

Turn off autocommit before making large changes that aren't within a transaction, as shown in the following example.

```
SET SESSION AUTOCOMMIT=OFF;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1=xx;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1=xx;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1=xx;
....
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1=xx;
```

---

```
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
....
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
```

---

```
-- Other DML statements here
COMMIT;
```

```
SET SESSION AUTOCOMMIT=ON;
```

### Use transactions

You can use transactions, as shown in the following example.

```
BEGIN
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
....
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
```

---

```
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
....
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
```

---

```
-- Other DML statements here
END
```

### Use batches

You can make changes in batches, as shown in the following example. However, using batches that are too large can cause performance issues, especially in read replicas or when doing point-in-time recovery (PITR).

```
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx'),('xxxx','xxxxx'),...,('xxxx','xxxxx'),('xxxx','xxxxx');
```

---

```
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1 BETWEEN xx AND xxx;
```
**io/aurora_respond_to_client**

The `io/aurora_respond_to_client` event occurs when a thread is waiting to return a result set to a client.

**Topics**
- Supported engine versions (p. 912)
- Context (p. 912)
- Likely causes of increased waits (p. 912)
- Actions (p. 912)

**Supported engine versions**

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2

In versions before version 2.07.7, 2.09.3, and 2.10.2, this wait event erroneously includes idle time.

**Context**

The event `io/aurora_respond_to_client` indicates that a thread is waiting to return a result set to a client.

The query processing is complete, and the results are being returned back to the application client. However, because there isn't enough network bandwidth on the DB cluster, a thread is waiting to return the result set.

**Likely causes of increased waits**

When the `io/aurora_respond_to_client` event appears more than normal, possibly indicating a performance problem, typical causes include the following:

- **DB instance class insufficient for the workload**
  
  The DB instance class used by the DB cluster doesn't have the necessary network bandwidth to process the workload efficiently.

- **Large result sets**
  
  There was an increase in size of the result set being returned, because the query returns higher numbers of rows. The larger result set consumes more network bandwidth.

- **Increased load on the client**
  
  There might be CPU pressure, memory pressure, or network saturation on the client. An increase in load on the client delays the reception of data from the Aurora MySQL DB cluster.

- **Increased network latency**
  
  There might be increased network latency between the Aurora MySQL DB cluster and client. Higher network latency increases the time required for the client to receive the data.

**Actions**

We recommend different actions depending on the causes of your wait event.
Identify the sessions and queries causing the events

You can use Performance Insights to show queries blocked by the `io/aurora_respond_to_client` wait event. Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn't optimal, then examine where the database is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.

To find SQL queries that are responsible for high load

1. Sign in to the AWS Management Console and open the Amazon RDS console at `https://console.aws.amazon.com/rds/`.
2. In the navigation pane, choose Performance Insights.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.
4. In the Database load chart, choose Slice by wait.
5. At the bottom of the page, choose Top SQL.

   The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

Scale the DB instance class

Check for the increase in the value of the Amazon CloudWatch metrics related to network throughput, such as `NetworkReceiveThroughput` and `NetworkTransmitThroughput`. If the DB instance class network bandwidth is being reached, you can scale the DB instance class used by the DB cluster by modifying the DB cluster. A DB instance class with larger network bandwidth returns data to clients more efficiently.

For information about monitoring Amazon CloudWatch metrics, see [Viewing metrics in the Amazon RDS console](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/CHAP_Monitoring.html). For information about DB instance classes, see [Aurora DB instance classes](https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUserGuide/AuroraDB_Instance_Classes.html). For information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster](https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUserGuide/CHAP_MonitoringAutoScaling.html).

Check workload for unexpected results

Check the workload on the DB cluster and make sure that it isn't producing unexpected results. For example, there might be queries that are returning a higher number of rows than expected. In this case, you can use Performance Insights counter metrics such as `Innodb_rows_read`. For more information, see [Performance Insights counter metrics](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/CHAP_PerformanceInsights.html).

Distribute workload with reader instances

You can distribute read-only workload with Aurora replicas. You can scale horizontally by adding more Aurora replicas. Doing so can result in an increase in the throttling limits for network bandwidth. For more information, see [Amazon Aurora DB clusters](https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUserGuide/CHAP_AmazonAuroraDBClusters.html).
Use the SQL_BUFFER_RESULT modifier

You can add the SQL_BUFFER_RESULT modifier to SELECT statements to force the result into a temporary table before they are returned to the client. This modifier can help with performance issues when InnoDB locks aren't being freed because queries are in the io/aurora_respond_to_client wait state. For more information, see SELECT Statement in the MySQL documentation.

io/socket/sql/client_connection

The io/socket/sql/client_connection event occurs when a thread is in the process of handling a new connection.

Topics

- Supported engine versions (p. 914)
- Context (p. 914)
- Likely causes of increased waits (p. 914)
- Actions (p. 914)

Supported engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2

Context

The event io/socket/sql/client_connection indicates that mysqld is busy creating threads to handle incoming new client connections. In this scenario, the processing of servicing new client connection requests slows down while connections wait for the thread to be assigned. For more information, see MySQL server (mysqld) (p. 905).

Likely causes of increased waits

When this event appears more than normal, possibly indicating a performance problem, typical causes include the following:

- There is a sudden increase in new user connections from the application to your Amazon RDS instance.
- Your DB instance can't process new connections because the network, CPU, or memory is being throttled.

Actions

If io/socket/sql/client_connection dominates database activity, it doesn't necessarily indicate a performance problem. In a database that isn't idle, a wait event is always on top. Act only when performance degrades. We recommend different actions depending on the causes of your wait event.

Topics

- Identify the problematic sessions and queries (p. 915)
- Follow best practices for connection management (p. 915)
- Scale up your instance if resources are being throttled (p. 915)
- Check the top hosts and top users (p. 915)
- Query the performance_schema tables (p. 916)
- Check the thread states of your queries (p. 916)
Audit your requests and queries (p. 916)
Pool your database connections (p. 916)

Identify the problematic sessions and queries

If your DB instance is experiencing a bottleneck, your first task is to find the sessions and queries that cause it. For a useful blog post, see Analyze Amazon Aurora MySQL Workloads with Performance Insights.

To identify sessions and queries causing a bottleneck

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Performance Insights.
3. Choose your DB instance.
4. In Database load, choose Slice by wait.
5. At the bottom of the page, choose Top SQL.

The queries at the top of the list are causing the highest load on the database.

Follow best practices for connection management

To manage your connections, consider the following strategies:

• Use connection pooling.

You can gradually increase the number of connections as required. For more information, see the whitepaper Amazon Aurora MySQL Database Administrator’s Handbook.

• Use a reader node to redistribute read-only traffic.

For more information, see Aurora Replicas (p. 104) and Amazon Aurora connection management (p. 62).

Scale up your instance if resources are being throttled

Look for examples of throttling in the following resources:

• CPU

Check your Amazon CloudWatch metrics for high CPU usage.

• Network

Check for an increase in the value of the CloudWatch metrics network receive throughput and network transmit throughput. If your instance has reached the network bandwidth limit for your instance class, consider scaling up your RDS instance to a higher instance class type. For more information, see Aurora DB instance classes (p. 84).

• Freeable memory

Check for a drop in the CloudWatch metric FreeableMemory. Also, consider turning on Enhanced Monitoring. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 631).

Check the top hosts and top users

Use Performance Insights to check the top hosts and top users. For more information, see Analyzing metrics with the Performance Insights dashboard (p. 576).
Query the performance_schema tables

To get an accurate count of the current and total connections, query the performance_schema tables. With this technique, you identify the source user or host that is responsible for creating a high number of connections. For example, query the performance_schema tables as follows.

```
SELECT * FROM performance_schema.accounts;
SELECT * FROM performance_schema.users;
SELECT * FROM performance_schema.hosts;
```

Check the thread states of your queries

If your performance issue is ongoing, check the thread states of your queries. In the mysql client, issue the following command.

```
show processlist;
```

Audit your requests and queries

To check the nature of the requests and queries from user accounts, use Aurora MySQL Advanced Auditing. To learn how to turn on auditing, see Using Advanced Auditing with an Amazon Aurora MySQL DB cluster (p. 980).

Pool your database connections

Consider using Amazon RDS Proxy for connection management. By using RDS Proxy, you can allow your applications to pool and share database connections to improve their ability to scale. RDS Proxy makes applications more resilient to database failures by automatically connecting to a standby DB instance while preserving application connections. For more information, see Using Amazon RDS Proxy for Aurora (p. 1879).

io/table/sql/handler

The io/table/sql/handler event occurs when work has been delegated to a storage engine.

Topics

- Supported engine versions (p. 916)
- Context (p. 916)
- Likely causes of increased waits (p. 917)
- Actions (p. 917)

Supported engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL version 3: 3.01.0 and 3.01.1
- Aurora MySQL version 2

Context

The event io/table indicates a wait for access to a table. This event occurs regardless of whether the data is cached in the buffer pool or accessed on disk. The io/table/sql/handler event indicates an increase in workload activity.
A handler is a routine specialized in a certain type of data or focused on certain special tasks. For example, an event handler receives and digests events and signals from the operating system or from a user interface. A memory handler performs tasks related to memory. A file input handler is a function that receives file input and performs special tasks on the data, according to context.

Views such as `performance_schema.events_waits_current` often show `io/table/sql/handler` when the actual wait is a nested wait event such as a lock. When the actual wait isn't `io/table/sql/handler`, Performance Insights reports the nested wait event. When Performance Insights reports `io/table/sql/handler`, it represents the actual I/O wait and not a hidden nested wait event. For more information, see Performance Schema Atom and Molecule Events in the MySQL Reference Manual.

**Note**
However, in Aurora MySQL versions 3.01.0 and 3.01.1, `synch/mutex/innodb/aurora_lock_thread_slot_futex` (p. 928) is reported as `io/table/sql/handler`.

The `io/table/sql/handler` event often appears in top wait events with I/O waits such as `io/aurora_redo_log_flush` and `io/file/innodb/innodb_data_file`.

**Likely causes of increased waits**

In Performance Insights, sudden spikes in the `io/table/sql/handler` event indicate an increase in workload activity. Increased activity means increased I/O.

Performance Insights filters the nesting event IDs and doesn't report a `io/table/sql/handler` wait when the underlying nested event is a lock wait. For example, if the root cause event is `synch/mutex/innodb/aurora_lock_thread_slot_futex` (p. 928), Performance Insights displays this wait in top wait events and not `io/table/sql/handler`.

In views such as `performance_schema.events_waits_current`, waits for `io/table/sql/handler` often appear when the actual wait is a nested wait event such as a lock. When the actual wait differs from `io/table/sql/handler`, Performance Insights looks up the nested wait and reports the actual wait instead of `io/table/sql/handler`. When Performance Insights reports `io/table/sql/handler`, the real wait is `io/table/sql/handler` and not a hidden nested wait event. For more information, see Performance Schema Atom and Molecule Events in the MySQL 5.7 Reference Manual.

**Note**
However, in Aurora MySQL versions 3.01.0 and 3.01.1, `synch/mutex/innodb/aurora_lock_thread_slot_futex` (p. 928) is reported as `io/table/sql/handler`.

**Actions**

If this wait event dominates database activity, it doesn't necessarily indicate a performance problem. A wait event is always on top when the database is active. You need to act only when performance degrades.

We recommend different actions depending on the other wait events that you see.

**Topics**

- Identify the sessions and queries causing the events (p. 917)
- Check for a correlation with Performance Insights counter metrics (p. 918)
- Check for other correlated wait events (p. 919)

**Identify the sessions and queries causing the events**

Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance is isn't optimal, then examine where the database
is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.

**To find SQL queries that are responsible for high load**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Performance Insights.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.
4. In the Database load chart, choose Slice by wait.
5. At the bottom of the page, choose Top SQL.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the blog post [Analyze Amazon Aurora MySQL Workloads with Performance Insights](https://aws.amazon.com/blogs/database/analyze-amazon-aurora-mysql-workloads-performance-insights/).

**Check for a correlation with Performance Insights counter metrics**

Check for Performance Insights counter metrics such as Innodb_rows_changed. If counter metrics are correlated with io/table/sql/handler, follow these steps:

1. In Performance Insights, look for the SQL statements accounting for the io/table/sql/handler top wait event. If possible, optimize this statement so that it returns fewer rows.

By default, rows are sorted by descending total wait time. Tables with the most contention appear first. The output indicates whether time is spent on reads, writes, fetches, inserts, updates, or deletes. The following example was run on an Aurora MySQL 2.09.1 instance.

```sql
mysql> select * from sys.schema_table_statistics limit 1
+--------------------------+--------------------------+--------------------------+--------------------------+--------------------------+--------------------------+--------------------------+--------------------------+--------------------------+--------------------------+--------------------------+--------------------------+--------------------------+--------------------------+--------------------------+--------------------------+--------------------------+
| table_schema             | table_name               | total_latency            | rows_fetched             | fetch_latency            | rows_inserted            | insert_latency           | rows_updated             | update_latency           | rows_deleted             | delete_latency           | io_read_requests          | io_read                    | io_read_latency           | io_write_requests         | io_write                    | io_write_latency           |
|--------------------------|--------------------------|--------------------------|--------------------------|--------------------------|--------------------------|--------------------------|--------------------------|--------------------------|--------------------------|--------------------------|--------------------------|--------------------------|--------------------------|--------------------------|--------------------------|
| read_only_db             | sbtest41                 | 54.11 m                  | 6001557                  | 39.14 m                  | 14833                    | 5.78 m                   | 30470                    | 5.39 m                   | 14833                    | 3.81 m                   | NULL                     | NULL                     | NULL                     | NULL                     | NULL                     |
+--------------------------+--------------------------+--------------------------+--------------------------+--------------------------+--------------------------+--------------------------+--------------------------+--------------------------+--------------------------+--------------------------+--------------------------+--------------------------+--------------------------+--------------------------+--------------------------+
1 row in set (0.11 sec)
```
Check for other correlated wait events

If synch/sxlock/innodb/btr_search_latch and io/table/sql/handler contribute most to the DB load anomaly together, check whether the innodb_adaptive_hash_index variable is turned on. If it is, consider increasing the innodb_adaptive_hash_index_parts parameter value.

If the Adaptive Hash Index is turned off, consider turning it on. To learn more about the MySQL Adaptive Hash Index, see the following resources:

- The article Is Adaptive Hash Index in InnoDB right for my workload? on the Percona website
- Adaptive Hash Index in the MySQL Reference Manual
- The article Contention in MySQL InnoDB: Useful Info From the Semaphores Section on the Percona website

Note
The Adaptive Hash Index isn't supported on Aurora reader DB instances.

In some cases, performance might be poor on a reader instance when synch/sxlock/innodb/btr_search_latch and io/table/sql/handler are dominant. If so, consider redirecting the workload temporarily to the writer DB instance and turning on the Adaptive Hash Index.

**synch/cond/innodb/row_lock_wait**

The synch/cond/innodb/row_lock_wait event occurs when one session has locked a row for an update, and another session tries to update the same row. For more information, see InnoDB locking in the MySQL Reference.

**Supported engine versions**

This wait event information is supported for the following engine versions:

- Aurora MySQL version 3: 3.02.0, 3.02.1, 3.02.2

**Likely causes of increased waits**

Multiple data manipulation language (DML) statements are accessing the same row or rows simultaneously.

**Actions**

We recommend different actions depending on the other wait events that you see.

**Topics**

- Find and respond to the SQL statements responsible for this wait event (p. 919)
- Find and respond to the blocking session (p. 920)

**Find and respond to the SQL statements responsible for this wait event**

Use Performance Insights to identify the SQL statements responsible for this wait event. Consider the following strategies:

- If row locks are a persistent problem, consider rewriting the application to use optimistic locking.
- Use multirow statements.
- Spread the workload over different database objects. You can do this through partitioning.
• Check the value of the `innodb_lock_wait_timeout` parameter. It controls how long transactions wait before generating a timeout error.

For a useful overview of troubleshooting using Performance Insights, see the blog post [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).

**Find and respond to the blocking session**

Determine whether the blocking session is idle or active. Also, find out whether the session comes from an application or an active user.

To identify the session holding the lock, you can run `SHOW ENGINE INNODB STATUS`. The following example shows sample output.

```
mysql> SHOW ENGINE INNODB STATUS;
---TRANSACTION 1688153, ACTIVE 82 sec starting index read
mysql tables in use 1, locked 1
LOCK WAIT 2 lock struct(s), heap size 1136, 2 row lock(s)
MySQL thread id 4244, OS thread handle 70569524330224, query id 4020834 172.31.14.179
reinvent executing
select id1 from test.t1 where id1=1 for update
------- TRX HAS BEEN WAITING 24 SEC FOR THIS LOCK TO BE GRANTED:
RECORD LOCKS space id 11 page no 4 n bits 72 index GEN_CLUST_INDEX of table test.t1 trx id
1688153 lock_mode X waiting
Record lock, heap no 2 PHYSICAL RECORD: n_fields 5; compact format; info bits 0
```

Or you can use the following query to extract details on current locks.

```
mysql> SELECT p1.id waiting_thread,
p1.user waiting_user,
p1.host waiting_host,
it1.trx_query waiting_query,
ilw.requesting_engine_transaction_id waiting_transaction,
il.lock_mode blocking_mode,
il.lock_type blocking_type,
ilw.blocking_engine_transaction_id blocking_transaction,
CASE it.trx_state
    WHEN 'LOCK WAIT'
    THEN it.trx_state
    ELSE p.state end blocker_state,
    concat(il.object_schema,'.', il.object_name) as locked_table,
it.trx_mysql_thread_id blocker_thread,
p.user blocker_user,
p.host blocker_host
FROM performance_schema.data_lock_waits ilw
JOIN performance_schema.data_locks il
ON ilw.blocking_engine_lock_id = il.engine_lock_id
AND ilw.blocking_engine_transaction_id = il.engine_transaction_id
JOIN information_schema.innodb_trx it
ON ilw.blocking_engine_transaction_id = it.trx_id
AND it.engine_lock_id = il.engine_lock_id
JOIN information_schema.innodb_trx p
ON it.trx_mysql_thread_id = p.id
JOIN information_schema.innodb_trx it1
ON ilw.requesting_engine_transaction_id = it1.trx_id
JOIN information_schema.processlist pl
ON it1.trx_mysql_thread_id = pl.id
G

*************************** 1. row ***************************
waiting_thread: 4244
waiting_user: reinvent
waiting_host: 123.456.789.012:18158
waiting_query: select id1 from test.t1 where id1=1 for update
waiting_transaction: 1688153
```
When you identify the session, your options include the following:

- Contact the application owner or the user.
- If the blocking session is idle, consider ending the blocking session. This action might trigger a long rollback. To learn how to end a session, see Ending a session or query (p. 1168).

For more information about identifying blocking transactions, see Using InnoDB Transaction and Locking Information in the MySQL Reference Manual.

**synch/cond/innodb/row_lock_wait_cond**

The `synch/cond/innodb/row_lock_wait_cond` event occurs when one session has locked a row for an update, and another session tries to update the same row. For more information, see InnoDB locking in the MySQL Reference.

**Supported engine versions**

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2

**Likely causes of increased waits**

Multiple data manipulation language (DML) statements are accessing the same row or rows simultaneously.

**Actions**

We recommend different actions depending on the other wait events that you see.

**Topics**

- Find and respond to the SQL statements responsible for this wait event (p. 921)
- Find and respond to the blocking session (p. 922)

**Find and respond to the SQL statements responsible for this wait event**

Use Performance Insights to identify the SQL statements responsible for this wait event. Consider the following strategies:

- If row locks are a persistent problem, consider rewriting the application to use optimistic locking.
- Use multirow statements.
- Spread the workload over different database objects. You can do this through partitioning.
- Check the value of the `innodb_lock_wait_timeout` parameter. It controls how long transactions wait before generating a timeout error.
For a useful overview of troubleshooting using Performance Insights, see the blog post [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).

**Find and respond to the blocking session**

Determine whether the blocking session is idle or active. Also, find out whether the session comes from an application or an active user.

To identify the session holding the lock, you can run `SHOW ENGINE INNODB STATUS`. The following example shows sample output.

```sql
mysql> SHOW ENGINE INNODB STATUS;
---TRANSACTION 2771110, ACTIVE 112 sec starting index read
mysql tables in use 1, locked 1
LOCK WAIT 2 lock struct(s), heap size 1136, 1 row lock(s)
MySQL thread id 24, OS thread handle 70369573642160, query id 13271336 172.31.14.179
reinvent Sending data
------- TRX HAS BEEN WAITING 43 SEC FOR THIS LOCK TO BE GRANTED:
RECORD LOCKS space id 11 page no 3 n bits 0 index GEN_CLUST_INDEX of table test.t1 trx id
2771110 lock_mode X waiting
Record lock, heap no 2 PHYSICAL RECORD: n_fields 5; compact format; info bits 0
```

Or you can use the following query to extract details on current locks.

```sql
mysql> SELECT p1.id waiting_thread,
    -> p1.user waiting_user,
    -> p1.host waiting_host,
    -> it1.trx_query waiting_query,
    -> ilw.requesting_trx_id waiting_transaction,
    -> ilw.blocking_lock_id blocking_lock,
    -> il.lock_mode blocking_mode,
    -> il.lock_type blocking_type,
    -> ilw.blocking_trx_id blocking_transaction,
    -> CASE it.trx_state
    -> WHEN 'LOCK WAIT'
    -> THEN it.trx_state
    -> ELSE p.state
    -> END blocker_state,
    -> il.lock_table locked_table,
    -> it.trx_mysql_thread_id blocker_thread,
    -> p.user blocker_user,
    -> p.host blocker_host
    -> FROM information_schema.innodb_lock_waits ilw
    -> JOIN information_schema.innodb_locks il
    -> ON ilw.blocking_lock_id = il.lock_id
    -> AND ilw.blocking_trx_id = il.lock_trx_id
    -> JOIN information_schema.innodb_trx it
    -> ON ilw.blocking_trx_id = it.trx_id
    -> JOIN information_schema.processlist p
    -> ON it.trx.mysql_thread_id = p.id
    -> JOIN information_schema.innodb_trx it1
    -> ON ilw.requesting_trx_id = it1.trx_id
    -> JOIN information_schema.processlist pl
    -> ON it1.trx.mysql_thread_id = pl.id

*************************** 1. row ***************************

When you identify the session, your options include the following:

- Contact the application owner or the user.
- If the blocking session is idle, consider ending the blocking session. This action might trigger a long rollback. To learn how to end a session, see Ending a session or query (p. 1168).

For more information about identifying blocking transactions, see Using InnoDB Transaction and Locking Information in the MySQL Reference Manual.

**synch/cond/mysys/my_thread_var::suspend**

The `synch/cond/mysys/my_thread_var::suspend` wait event indicates that threads are suspended because they are waiting on a condition.

**Topics**

- Supported engine versions (p. 923)
- Context (p. 923)
- Likely causes of increased waits (p. 923)
- Actions (p. 924)

**Supported engine versions**

This wait event information is supported for the following versions:

- Aurora MySQL version 2

**Context**

The event `synch/cond/mysys/my_thread_var::suspend` indicates that threads are suspended because they are waiting on a condition. For example, this wait event occurs when threads are waiting for a table-level lock. In this case, we recommend that you investigate your workload to determine which threads might be acquiring table locks on your DB instance.

**Likely causes of increased waits**

When the `synch/cond/mysys/my_thread_var::suspend` event appears more than normal, possibly indicating a performance problem, typical causes include the following:

**Thread waiting on a table-level lock**

One or more threads are waiting on a table-level lock. In this case, the thread state is Waiting for table level lock.

**Data being sent to the mysqldump client**

One or more threads are waiting because you are using mysqldump, and the result is being sent to the mysqldump client. In this case, the thread state is: Writing to net.
Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Avoid locking tables (p. 924)
- Make sure that backup tools don't lock tables (p. 924)
- Long-running sessions that lock tables (p. 924)
- Non-InnoDB temporary table (p. 924)

Avoid locking tables

Make sure that the application is not explicitly locking the tables using the LOCK TABLE statement. You can check the statements run by applications using Advanced Auditing. For more information, see Using Advanced Auditing with an Amazon Aurora MySQL DB cluster (p. 980).

Make sure that backup tools don't lock tables

If you are using a backup tool, make sure that it isn't locking tables. For example, if you are using mysqldump, use the --single-transaction option so that it doesn't lock tables.

Long-running sessions that lock tables

There might be long-running sessions that have explicitly locked tables. Run the following SQL statement to check for such sessions.

```sql
SELECT p.id as session_id, p.user, p.host, p.db, p.command, p.time, p.state,
SUBSTRING(p.info, 1, 50) AS INFO,
t.trx_started, unix_timestamp(now()) - unix_timestamp(t.trx_started) as trx_age_seconds,
t.trx_rows_modified, t.trx_isolation_level
FROM information_schema.processlist p
LEFT JOIN information_schema.innodb_trx t
ON p.id = t.trx_mysql_thread_id;
```

When you identify the session, your options include the following:

- Contact the application owner or the user.
- If the blocking session is idle, consider ending the blocking session. This action might trigger a long rollback. To learn how to end a session, see Ending a session or query (p. 1168).

For more information about identifying blocking transactions, see Using InnoDB Transaction and Locking Information in the MySQL documentation.

Non-InnoDB temporary table

If you are using a non-InnoDB temporary table, then the database doesn't use row-level locking, which can result in table locks. MyISAM and MEMORY tables are examples of a non-InnoDB temporary table. If you are using a non-InnoDB temporary table, consider switching to an InnoDB memory table.

synch/cond/sql/MDL_context::COND_wait_status

The synch/cond/sql/MDL_context::COND_wait_status event occurs when there are threads waiting on a table metadata lock.
Supported engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL versions 2 and 3

Context

The event synch/cond/sql/MDL_context::COND_wait_status indicates that there are threads waiting on a table metadata lock. In some cases, one session holds a metadata lock on a table and another session tries to get the same lock on the same table. In such a case, the second session waits on the synch/cond/sql/MDL_context::COND_wait_status wait event.

MySQL uses metadata locking to manage concurrent access to database objects and to ensure data consistency. Metadata locking applies to tables, schemas, scheduled events, tablespaces, and user locks acquired with the get_lock function, and stored programs. Stored programs include procedures, functions, and triggers. For more information, see [Metadata locking](https://dev.mysql.com/doc/refman/8.0/en/metadata-locking.html) in the MySQL documentation.

The MySQL process list shows this session in the state waiting for metadata lock. In Performance Insights, if Performance_schema is turned on, the event synch/cond/sql/MDL_context::COND_wait_status appears.

The default timeout for a query waiting on a metadata lock is based on the value of the lock_wait_timeout parameter, which defaults to 31,536,000 seconds (365 days).

For more details on different InnoDB locks and the types of locks that can cause conflicts, see [InnoDB Locking](https://dev.mysql.com/doc/refman/8.0/en/innodb-locking.html) in the MySQL documentation.

Likely causes of increased waits

When the synch/cond/sql/MDL_context::COND_wait_status event appears more than normal, possibly indicating a performance problem, typical causes include the following:

**Long-running transactions**

One or more transactions are modifying a large amount of data and holding locks on tables for a very long time.

**Idle transactions**

One or more transactions remain open for a long time, without being committed or rolled back.

**DDL statements on large tables**

One or more data definition statements (DDL) statements, such as ALTER TABLE commands, were run on very large tables.

**Explicit table locks**

There are explicit locks on tables that aren't being released in a timely manner. For example, an application might run LOCK TABLE statements improperly.
Actions

We recommend different actions depending on the causes of your wait event and on the version of the Aurora MySQL DB cluster.

Topics

- Identify the sessions and queries causing the events (p. 926)
- Check for past events (p. 926)
- Run queries on Aurora MySQL version 2 (p. 927)
- Respond to the blocking session (p. 928)

Identify the sessions and queries causing the events

You can use Performance Insights to show queries blocked by the synch/cond/sql/MDL_context::COND_wait_status wait event. However, to identify the blocking session, query metadata tables from performance_schema and information_schema on the DB cluster.

Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn't optimal, then examine where the database is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.

To find SQL queries that are responsible for high load

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Performance Insights.
3. Choose a DB instance. The Performance Insights dashboard for that DB instance appears.
4. In the Database load chart, choose Slice by wait.
5. At the bottom of the page, choose Top SQL.

   The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the AWS Database Blog post Analyze Amazon Aurora MySQL Workloads with Performance Insights.

Check for past events

You can gain insight into this wait event to check for past occurrences of it. To do so, complete the following actions:

- Check the data manipulation language (DML) and DDL throughput and latency to see if there were any changes in workload.

  You can use Performance Insights to find queries waiting on this event at the time of the issue. Also, you can view the digest of the queries run near the time of issue.

- If audit logs or general logs are turned on for the DB cluster, you can check for all queries run on the objects (schema.table) involved in the waiting transaction. You can also check for the queries that completed running before the transaction.

The information available to troubleshoot past events is limited. Performing these checks doesn't show which object is waiting for information. However, you can identify tables with heavy load at the time of
the event and the set of frequently operated rows causing conflict at the time of issue. You can then use this information to reproduce the issue in a test environment and provide insights about its cause.

Run queries on Aurora MySQL version 2

In Aurora MySQL version 2, you can identify the blocked session directly by querying `performance_schema` tables or `sys` schema views. An example can illustrate how to query tables to identify blocking queries and sessions.

In the following process list output, the connection ID 89 is waiting on a metadata lock, and it's running a `TRUNCATE TABLE` command. In a query on the `performance_schema` tables or `sys` schema views, the output shows that the blocking session is 76.

1 row in set (0.00 sec)

**Respond to the blocking session**

When you identify the session, your options include the following:

- Contact the application owner or the user.
- If the blocking session is idle, consider ending the blocking session. This action might trigger a long rollback. To learn how to end a session, see [Ending a session or query](p. 1168).

For more information about identifying blocking transactions, see [Using InnoDB Transaction and Locking Information](the MySQL documentation).

**synch/mutex/innodb/aurora_lock_thread_slot_futex**

The `synch/mutex/innodb/aurora_lock_thread_slot_futex` event occurs when one session has locked a row for an update, and another session tries to update the same row. For more information, see [InnoDB locking](in the MySQL Reference).

**Supported engine versions**

This wait event information is supported for the following engine versions:
• Aurora MySQL version 2

Note
In Aurora MySQL versions 3.01.0 and 3.01.1, this wait event is reported as `io/table/sql/handler` (p. 916).

Likely causes of increased waits
Multiple data manipulation language (DML) statements are accessing the same row or rows simultaneously.

Actions
We recommend different actions depending on the other wait events that you see.

Topics
• Find and respond to the SQL statements responsible for this wait event (p. 929)
• Find and respond to the blocking session (p. 929)

Find and respond to the SQL statements responsible for this wait event
Use Performance Insights to identify the SQL statements responsible for this wait event. Consider the following strategies:

• If row locks are a persistent problem, consider rewriting the application to use optimistic locking.
• Use multirow statements.
• Spread the workload over different database objects. You can do this through partitioning.
• Check the value of the `innodb_lock_wait_timeout` parameter. It controls how long transactions wait before generating a timeout error.

For a useful overview of troubleshooting using Performance Insights, see the blog post Analyze Amazon Aurora MySQL Workloads with Performance Insights.

Find and respond to the blocking session
Determine whether the blocking session is idle or active. Also, find out whether the session comes from an application or an active user.

To identify the session holding the lock, you can run `SHOW ENGINE INNODB STATUS`. The following example shows sample output.

```sql
mysql> SHOW ENGINE INNODB STATUS;
```

```
---TRANSACTION 302631452, ACTIVE 2 sec starting index read
mysql tables in use 1, locked 1
LOCK WAIT 2 lock struct(s), heap size 376, 1 row lock(s)
MySQL thread id 80109, OS thread handle 0x2ae915060700, query id 938819 10.0.4.12 reinvent
  updating
  UPDATE sbtest1 SET k=k+1 WHERE id=503
  ------ TRX HAS BEEN WAITING 2 SEC FOR THIS LOCK TO BE GRANTED:
  RECORD LOCKS space id 148 page no 11 n bits 30 index `PRIMARY` of table `sysbench2`.`sbtest1` trx id 302631452 lock_mode X locks rec but not gap waiting
  Record lock, heap no 30 PHYSICAL RECORD: n_fields 6; compact format; info bits 0
```

Or you can use the following query to extract details on current locks.

```sql
mysql> SELECT p1.id waiting_thread,
```
pl.user waiting_user,  
pl.host waiting_host,  
it1.trx_query waiting_query,  
ilw.requesting_trx_id waiting_transaction,  
ilw.blocking_lock_id blocking_lock,  
il.lock_mode blocking_mode,  
il.lock_type blocking_type,  
ilw.blocking_trx_id blocking_transaction,  
CASE it.trx_state  
WHEN 'LOCK WAIT'  
THEN it.trx_state  
ELSE p.state  
END blocker_state,  
il.lock_table locked_table,  
it.trx_mysql_thread_id blocker_thread,  
p.user blocker_user,  
p.host blocker_host 
FROM information_schema.innodb_lock_waits ilw  
JOIN information_schema.innodb_locks il  
ON ilw.blocking_lock_id = il.lock_id  
AND ilw.blocking_trx_id = il.lock_trx_id  
JOIN information_schema.innodb_trx it  
ON ilw.blocking_trx_id = it.trx_id  
JOIN information_schema.processlist p  
ON it.trx_mysql_thread_id = p.id  
JOIN information_schema.innodb_trx it1  
ON ilw.requesting_trx_id = it1.trx_id  
JOIN information_schema.processlist pl  
ON it1.trx_mysql_thread_id = pl.id\G

*************************** 1. row ***************************
waiting_thread: 3561959471
waiting_user: reinvent
waiting_host: 123.456.789.012:20485
waiting_query: select id1 from test.t1 where id1=1 for update
waiting_transaction: 312337314
blocking_lock: 312337287:261:3:2
blocking_mode: X
blocking_type: RECORD
blocking_transaction: 312337287
blocker_state: User sleep
locked_table: `test`.`t1`

blocker_user: reinvent
blocker_host: 123.456.789.012:17746
1 row in set (0.04 sec)

When you identify the session, your options include the following:

- Contact the application owner or the user.
- If the blocking session is idle, consider ending the blocking session. This action might trigger a long rollback. To learn how to end a session, see Ending a session or query (p. 1168).

For more information about identifying blocking transactions, see Using InnoDB Transaction and Locking Information in the MySQL Reference Manual.

**synch/mutex/innodb/buf_pool_mutex**

The synch/mutex/innodb/buf_pool_mutex event occurs when a thread has acquired a lock on the InnoDB buffer pool to access a page in memory.

**Topics**
• Relevant engine versions (p. 931)
• Context (p. 931)
• Likely causes of increased waits (p. 931)
• Actions (p. 931)

Relevant engine versions
This wait event information is supported for the following engine versions:
• Aurora MySQL version 2

Context
The buf_pool_mutex is a single mutex that protects the control data structures of the buffer pool.
For more information, see Monitoring InnoDB Mutex Waits Using Performance Schema in the MySQL documentation.

Likely causes of increased waits
This is a workload-specific wait event. Common causes for synch/mutex/innodb/buf_pool_mutex to appear among the top wait events include the following:
• The buffer pool size isn't large enough to hold the working set of data.
• The workload is more specific to certain pages from a specific table in the database, leading to contention in the buffer pool.

Actions
We recommend different actions depending on the causes of your wait event.

Identify the sessions and queries causing the events
Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn't optimal, then examine where the database is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.

To view the Top SQL chart in the AWS Management Console
1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Performance Insights.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.
4. In the Database load chart, choose Slice by wait.
5. Underneath the Database load chart, choose Top SQL.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the blog post Analyze Amazon Aurora MySQL Workloads with Performance Insights.

Use Performance Insights
This event is related to workload. You can use Performance Insights to do the following:
• Identify when wait events start, and whether there's any change in the workload around that time from the application logs or related sources.

• Identify the SQL statements responsible for this wait event. Examine the execution plan of the queries to make sure that these queries are optimized and using appropriate indexes.

  If the top queries responsible for the wait event are related to the same database object or table, then consider partitioning that object or table.

Create Aurora Replicas

You can create Aurora Replicas to serve read-only traffic. You can also use Aurora Auto Scaling to handle surges in read traffic. Make sure to run scheduled read-only tasks and logical backups on Aurora Replicas.

For more information, see Using Amazon Aurora Auto Scaling with Aurora Replicas (p. 328).

Examine the buffer pool size

Check whether the buffer pool size is sufficient for the workload by looking at the metric `innodb_buffer_pool_wait_free`. If the value of this metric is high and increasing continuously, that indicates that the size of the buffer pool isn't sufficient to handle the workload. If `innodb_buffer_pool_size` has been set properly, the value of `innodb_buffer_pool_wait_free` should be small. For more information, see `innodb_buffer_pool_wait_free` in the MySQL documentation.

Increase the buffer pool size if the DB instance has enough memory for session buffers and operating-system tasks. If it doesn't, change the DB instance to a larger DB instance class to get additional memory that can be allocated to the buffer pool.

  Note
  Aurora MySQL automatically adjusts the value of `innodb_buffer_pool_instances` based on the configured `innodb_buffer_pool_size`.

Monitor the global status history

By monitoring the change rates of status variables, you can detect locking or memory issues on your DB instance. Turn on Global Status History (GoSH) if it isn't already turned on. For more information on GoSH, see Managing the global status history.

You can also create custom Amazon CloudWatch metrics to monitor status variables. For more information, see Publishing custom metrics.

synch/mutex/innodb/fil_system_mutex

The `synch/mutex/innodb/fil_system_mutex` event occurs when a session is waiting to access the tablespace memory cache.

Topics

• Supported engine versions (p. 932)
• Context (p. 933)
• Likely causes of increased waits (p. 933)
• Actions (p. 933)

Supported engine versions

This wait event information is supported for the following engine versions:

• Aurora MySQL version 2
Context

InnoDB uses tablespaces to manage the storage area for tables and log files. The *tablespace memory cache* is a global memory structure that maintains information about tablespaces. MySQL uses synch/mutex/innodb/fil_system_mutex waits to control concurrent access to the tablespace memory cache.

The event synch/mutex/innodb/fil_system_mutex indicates that there is currently more than one operation that needs to retrieve and manipulate information in the tablespace memory cache for the same tablespace.

Likely causes of increased waits

When the synch/mutex/innodb/fil_system_mutex event appears more than normal, possibly indicating a performance problem, this typically occurs when all of the following conditions are present:

- An increase in concurrent data manipulation language (DML) operations that update or delete data in the same table.
- The tablespace for this table is very large and has a lot of data pages.
- The fill factor for these data pages is low.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Identify the sessions and queries causing the events (p. 933)
- Reorganize large tables during off-peak hours (p. 935)

Identify the sessions and queries causing the events

Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn't optimal, examine where the database is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.

To find SQL queries that are responsible for high load

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Performance Insights.
3. Choose a DB instance. The Performance Insights dashboard appears for that DB instance.
4. In the Database load chart, choose Slice by wait.
5. At the bottom of the page, choose Top SQL.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the blog post Analyze Amazon Aurora MySQL Workloads with Performance Insights.

Another way to find out which queries are causing high numbers of synch/mutex/innodb/fil_system_mutex waits is to check performance_schema, as in the following example.
### Table: Performance Schema Event Waits

The following SQL query is used to retrieve information about wait events in the performance schema.

```sql
mysql> select * from performance_schema.events_waits_current where EVENT_NAME='wait/synch/mutex/innodb/fil_system_mutex'
G
```

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
Reorganize large tables during off-peak hours

Reorganize large tables that you identify as the source of high numbers of synch/mutex/innodb/fil_system_mutex wait events during a maintenance window outside of production hours. Doing so ensures that the internal tablespaces map cleanup doesn't occur when quick access to the table is critical. For information about reorganizing tables, see OPTIMIZE TABLE Statement in the MySQL Reference.

synch/mutex/innodb/trx_sys_mutex

The synch/mutex/innodb/trx_sys_mutex event occurs when there is high database activity with a large number of transactions.

Topics

- Relevant engine versions (p. 935)
- Context (p. 935)
- Likely causes of increased waits (p. 935)
- Actions (p. 936)

Relevant engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL versions 2 and 3

Context

Internally, the InnoDB database engine uses the repeatable read isolation level with snapshots to provide read consistency. This gives you a point-in-time view of the database at the time the snapshot was created.

In InnoDB, all changes are applied to the database as soon as they arrive, regardless of whether they're committed. This approach means that without multiversion concurrency control (MVCC), all users connected to the database see all of the changes and the latest rows. Therefore, InnoDB requires a way to track the changes to understand what to roll back when necessary.

To do this, InnoDB uses a transaction system (trx_sys) to track snapshots. The transaction system does the following:

- Tracks the transaction ID for each row in the undo logs.
- Uses an internal InnoDB structure called ReadView that helps to identify which transaction IDs are visible for a snapshot.

Likely causes of increased waits

Any database operation that requires the consistent and controlled handling (creating, reading, updating, and deleting) of transactions IDs generates a call from trx_sys to the mutex.

These calls happen inside three functions:

- trx_sys_mutex_enter – Creates the mutex.
- trx_sys_mutex_exit – Releases the mutex.
- trx_sys_mutex_own – Tests whether the mutex is owned.
The InnoDB Performance Schema instrumentation tracks all `trx_sys` mutex calls. Tracking includes, but isn't limited to, management of `trx_sys` on database startup or shutdown, rollback operations, undo cleanups, row read access, and buffer pool loads. High database activity with a large number of transactions results in `synch/mutex/innodb/trx_sys_mutex` appearing among the top wait events.

For more information, see Monitoring InnoDB Mutex Waits Using Performance Schema in the MySQL documentation.

**Actions**

We recommend different actions depending on the causes of your wait event.

**Identify the sessions and queries causing the events**

Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn't optimal, then examine where the database is spending the most time. Look at the wait events that contribute to the highest load. Find out whether you can optimize the database and application to reduce those events.

**To view the Top SQL chart in the AWS Management Console**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.
4. In the **Database load** chart, choose **Slice by wait**.
5. Under the **Database load** chart, choose **Top SQL**.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

**Examine other wait events**

Examine the other wait events associated with the `synch/mutex/innodb/trx_sys_mutex` wait event. Doing this can provide more information about the nature of the workload. A large number of transactions might reduce throughput, but the workload might also make this necessary.

For more information on how to optimize transactions, see Optimizing InnoDB Transaction Management in the MySQL documentation.

**synch/sxlock/innodb/hash_table_locks**

The `synch/sxlock/innodb/hash_table_locks` event occurs when pages not found in the buffer pool must be read from a file.

**Topics**

- Supported engine versions (p. 936)
- Context (p. 937)
- Likely causes of increased waits (p. 937)
- Actions (p. 937)

**Supported engine versions**

This wait event information is supported for the following versions:
Aurora MySQL version 2

Context

The event `synch/sxlock/innodb/hash_table_locks` indicates that a workload is frequently accessing data that isn't stored in the buffer pool. This wait event is associated with new page additions and old data evictions from the buffer pool. The data stored in the buffer pool aged and new data must be cached, so the aged pages are evicted to allow caching of the new pages. MySQL uses a least recently used (LRU) algorithm to evict pages from the buffer pool. The workload is trying to access data that hasn't been loaded into the buffer pool or data that has been evicted from the buffer pool.

This wait event occurs when the workload must access the data in files on disk or when blocks are freed from or added to the buffer pool's LRU list. These operations wait to obtain a shared excluded lock (SX-lock). This SX-lock is used for the synchronization over the hash table, which is a table in memory designed to improve buffer pool access performance.

For more information, see Buffer Pool in the MySQL documentation.

Likely causes of increased waits

When the `synch/sxlock/innodb/hash_table_locks` wait event appears more than normal, possibly indicating a performance problem, typical causes include the following:

An undersized buffer pool

The size of the buffer pool is too small to keep all of the frequently accessed pages in memory.

Heavy workload

The workload is causing frequent evictions and data pages reloads in the buffer cache.

Errors reading the pages

There are errors reading pages in the buffer pool, which might indicate data corruption.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Increase the size of the buffer pool (p. 937)
- Improve data access patterns (p. 937)
- Reduce or avoid full-table scans (p. 938)
- Check the error logs for page corruption (p. 938)

Increase the size of the buffer pool

Make sure that the buffer pool is appropriately sized for the workload. To do so, you can check the buffer pool cache hit rate. Typically, if the value drops below 95 percent, consider increasing the buffer pool size. A larger buffer pool can keep frequently accessed pages in memory longer. To increase the size of the buffer pool, modify the value of the `innodb_buffer_pool_size` parameter. The default value of this parameter is based on the DB instance class size. For more information, see Best practices for Amazon Aurora MySQL database configuration.

Improve data access patterns

Check the queries affected by this wait and their execution plans. Consider improving data access patterns. For example, if you are using `mysqli_result::fetch_array`, you can try increasing the array fetch size.
You can use Performance Insights to show queries and sessions that might be causing the synch/sxlock/innodb/hash_table_locks wait event.

To find SQL queries that are responsible for high load

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Performance Insights.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.
4. In the Database load chart, choose Slice by wait.
5. At the bottom of the page, choose Top SQL.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the AWS Database Blog post Analyze Amazon Aurora MySQL Workloads with Performance Insights.

Reduce or avoid full-table scans

Monitor your workload to see if it's running full-table scans, and, if it is, reduce or avoid them. For example, you can monitor status variables such as Handler_read_rnd_next. For more information, see Server Status Variables in the MySQL documentation.

Check the error logs for page corruption

You can check the mysql-error.log for corruption-related messages that were detected near the time of the issue. Messages that you can work with to resolve the issue are in the error log. You might need to recreate objects that were reported as corrupted.
Tuning Aurora MySQL with thread states

The following table summarizes the most common general thread states for Aurora MySQL.

<table>
<thead>
<tr>
<th>General thread state</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>??? (p. 939)</td>
<td>This thread state indicates that a thread is processing a SELECT statement that requires the use of an internal temporary table to sort the data.</td>
</tr>
<tr>
<td>??? (p. 941)</td>
<td>This thread state indicates that a thread is reading and filtering rows for a query to determine the correct result set.</td>
</tr>
</tbody>
</table>

creating sort index

The creating sort index thread state indicates that a thread is processing a SELECT statement that requires the use of an internal temporary table to sort the data.

Topics
- Supported engine versions (p. 939)
- Context (p. 939)
- Likely causes of increased waits (p. 939)
- Actions (p. 939)

Supported engine versions

This thread state information is supported for the following versions:

- Aurora MySQL version 2 up to 2.09.2

Context

The creating sort index state appears when a query with an ORDER BY or GROUP BY clause can't use an existing index to perform the operation. In this case, MySQL needs to perform a more expensive filesort operation. This operation is typically performed in memory if the result set isn't too large. Otherwise, it involves creating a file on disk.

Likely causes of increased waits

The appearance of creating sort index doesn't by itself indicate a problem. If performance is poor, and you see frequent instances of creating sort index, the most likely cause is slow queries with ORDER BY or GROUP BY operators.

Actions

The general guideline is to find queries with ORDER BY or GROUP BY clauses that are associated with the increases in the creating sort index state. Then see whether adding an index or increasing the sort buffer size solves the problem.

Topics
- Turn on the Performance Schema if it isn't turned on (p. 940)
- Identify the problem queries (p. 940)
• **Examine the explain plans for filesort usage (p. 940)**

• **Increase the sort buffer size (p. 941)**

**Turn on the Performance Schema if it isn’t turned on**

Performance Insights reports thread states only if Performance Schema instruments aren’t turned on. When Performance Schema instruments are turned on, Performance Insights reports wait events instead. Performance Schema instruments provide additional insights and better tools when you investigate potential performance problems. Therefore, we recommend that you turn on the Performance Schema. For more information, see [Turning on the Performance Schema for Performance Insights on Aurora MySQL (p. 568)](Turning%20on%20the%20Performance%20Schema%20for%20Performance%20Insights%20on%20Aurora%20MySQL).

**Identify the problem queries**

To identify current queries that are causing increases in the creating sort index state, run show processlist and see if any of the queries have ORDER BY or GROUP BY. Optionally, run explain for connection N, where N is the process list ID of the query with filesort.

To identify past queries that are causing these increases, turn on the slow query log and find the queries with ORDER BY. Run EXPLAIN on the slow queries and look for "using filesort." For more information, see [Examine the explain plans for filesort usage (p. 940)](Examine%20the%20explain%20plans%20for%20filesort%20usage).

**Examine the explain plans for filesort usage**

Identify the statements with ORDER BY or GROUP BY clauses that result in the creating sort index state.

The following example shows how to run explain on a query. The Extra column shows that this query uses filesort.

```sql
mysql> explain select * from mytable order by c1 limit 10\G
*************************** 1. row ***************************
  id: 1
  select_type: SIMPLE
  table: mytable
  partitions: NULL
  type: ALL
  possible_keys: NULL
  key: NULL
  key_len: NULL
  ref: NULL
  rows: 2866548
  filtered: 100.00
  Extra: Using filesort
1 row in set, 1 warning (0.01 sec)
```

The following example shows the result of running EXPLAIN on the same query after an index is created on column c1.

```sql
mysql> alter table mytable add index (c1);

mysql> explain select * from mytable order by c1 limit 10\G
*************************** 1. row ***************************
  id: 1
  select_type: SIMPLE
  table: mytable
  partitions: NULL
  type: index
  possible_keys: NULL
  key: c1
```

---

940
For information on using indexes for sort order optimization, see ORDER BY Optimization in the MySQL documentation.

Increase the sort buffer size

To see whether a specific query required a filesort process that created a file on disk, check the sort_merge_passes variable value after running the query. The following shows an example.

```sql
mysql> show session status like 'sort_merge_passes';
+-------------------+-------+
| Variable_name     | Value |
+-------------------+-------+
| Sort_merge_passes | 0     |
+-------------------+-------+
1 row in set (0.01 sec)
```

--- run query:
```
mysql> select * from mytable order by u limit 10;
```

--- run status again:
```
mysql> show session status like 'sort_merge_passes';
+-------------------+-------+
| Variable_name     | Value |
+-------------------+-------+
| Sort_merge_passes | 0     |
+-------------------+-------+
1 row in set (0.01 sec)
```

If the value of sort_merge_passes is high, consider increasing the sort buffer size. Apply the increase at the session level, because increasing it globally can significantly increase the amount of RAM MySQL uses. The following example shows how to change the sort buffer size before running a query.

```sql
mysql> set session sort_buffer_size=10*1024*1024;
Query OK, 0 rows affected (0.00 sec)
```

sending data

The sending data thread state indicates that a thread is reading and filtering rows for a query to determine the correct result set. The name is misleading because it implies the state is transferring data, not collecting and preparing data to be sent later.

Topics
- Supported engine versions (p. 941)
- Context (p. 942)
- Likely causes of increased waits (p. 942)
- Actions (p. 942)

Supported engine versions

This thread state information is supported for the following versions:
• Aurora MySQL version 2 up to 2.09.2

Context

Many thread states are short-lasting. Operations occurring during sending data tend to perform large numbers of disk or cache reads. Therefore, sending data is often the longest-running state over the lifetime of a given query. This state appears when Aurora MySQL is doing the following:

• Reading and processing rows for a SELECT statement
• Performing a large number of reads from either disk or memory
• Completing a full read of all data from a specific query
• Reading data from a table, an index, or the work of a stored procedure
• Sorting, grouping, or ordering data

After the sending data state finishes preparing the data, the thread state writing to net indicates the return of data to the client. Typically, writing to net is captured only when the result set is very large or severe network latency is slowing the transfer.

Likely causes of increased waits

The appearance of sending data doesn't by itself indicate a problem. If performance is poor, and you see frequent instances of sending data, the most likely causes are as follows.

Topics
• Inefficient query (p. 942)
• Suboptimal server configuration (p. 942)

Inefficient query

In most cases, what's responsible for this state is a query that isn't using an appropriate index to find the result set of a specific query. For example, consider a query reading a 10 million record table for all orders placed in California, where the state column isn't indexed or is poorly indexed. In the latter case, the index might exist, but the optimizer ignores it because of low cardinality.

Suboptimal server configuration

If several queries appear in the sending data state, the database server might be configured poorly. Specifically, the server might have the following issues:

• The database server doesn't have enough computing capacity: disk I/O, disk type and speed, CPU, or number of CPUs.
• The server is starved for allocated resources, such as the InnoDB buffer pool for InnoDB tables or the key buffer for MyIsam tables.
• Per-thread memory settings such as sort_buffer, read_buffer, and join_buffer consume more RAM than required, starving the physical server for memory resources.

Actions

The general guideline is to find queries that return large numbers of rows by checking the Performance Schema. If logging queries that don't use indexes is turned on, you can also examine the results from the slow logs.

Topics
• Turn on the Performance Schema if it isn't turned on (p. 943)

Turn on the Performance Schema if it isn't turned on

Performance Insights reports thread states only if Performance Schema instruments aren't turned on. When Performance Schema instruments are turned on, Performance Insights reports wait events instead. Performance Schema instruments provide additional insights and better tools when you investigate potential performance problems. Therefore, we recommend that you turn on the Performance Schema. For more information, see Turning on the Performance Schema for Performance Insights on Aurora MySQL (p. 568).

Examine memory settings

Examine the memory settings for the primary buffer pools. Make sure that these pools are appropriately sized for the workload. If your database uses multiple buffer pool instances, make sure that they aren't divided into many small buffer pools. Threads can only use one buffer pool at a time.

Make sure that the following memory settings used for each thread are properly sized:

• read_buffer
• read_rnd_buffer
• sort_buffer
• join_buffer
• binlog_cache

Unless you have a specific reason to modify the settings, use the default values.

Examine the explain plans for index usage

For queries in the sending data thread state, examine the plan to determine whether appropriate indexes are used. If a query isn't using a useful index, consider adding hints like USE INDEX or FORCE INDEX. Hints can greatly increase or decrease the time it takes to run a query, so use care before adding them.

Check the volume of data returned

Check the tables that are being queried and the amount of data that they contain. Can any of this data be archived? In many cases, the cause of poor query execution times isn't the result of the query plan, but the volume of data to be processed. Many developers are very efficient in adding data to a database but seldom consider dataset life cycle in the design and development phases.

Look for queries that perform well in low-volume databases but perform poorly in your current system. Sometimes developers who design specific queries might not realize that these queries are returning 350,000 rows. The developers might have developed the queries in a lower-volume environment with smaller datasets than production environments have.

Check for concurrency issues

Check whether multiple queries of the same type are running at the same time. Some forms of queries run efficiently when they run alone. However, if similar forms of query run together, or in high volume,
they can cause concurrency issues. Often, these issues are caused when the database uses temp tables to render results. A restrictive transaction isolation level can also cause concurrency issues.

If tables are read and written to concurrently, the database might be using locks. To help identify periods of poor performance, examine the use of databases through large-scale batch processes. To see recent locks and rollbacks, examine the output of the `SHOW ENGINE INNODB STATUS` command.

**Check the structure of your queries**

Check whether captured queries from these states use subqueries. This type of query often leads to poor performance because the database compiles the results internally and then substitutes them back into the query to render data. This process is an extra step for the database. In many cases, this step can cause poor performance in a highly concurrent loading condition.

Also check whether your queries use large numbers of `ORDER BY` and `GROUP BY` clauses. In such operations, often the database must first form the entire dataset in memory. Then it must order or group it in a specific manner before returning it to the client.

**Tuning Aurora MySQL with Amazon DevOps Guru proactive insights**

DevOps Guru proactive insights detect known problematic conditions on your Aurora MySQL DB clusters before they occur. DevOps Guru can do the following:

- Prevent many common database issues by cross-checking your database configuration against common recommended settings.
- Alert you to critical issues in your fleet that, if left unchecked, can lead to larger problems later.
- Alert you to newly discovered problems.

Every proactive insight contains an analysis of the cause of the problem and recommendations for corrective actions.

- [Database is creating temporary tables on disk](#)

**The InnoDB history list length increased significantly**

Starting on `date`, your history list for row changes increased significantly, up to `length` on `db-instance`. This increase affects query and database shutdown performance.

**Topics**

- [Supported engine versions](#)
- [Context](#)
- [Likely causes for this issue](#)
- [Actions](#)
- [Relevant metrics](#)

**Supported engine versions**

This insight information is supported for all versions of Aurora MySQL.
Context

The InnoDB transaction system maintains multiversion concurrency control (MVCC). When a row is modified, the pre-modification version of the data being modified is stored as an undo record in an undo log. Every undo record has a reference to its previous redo record, forming a linked list.

The InnoDB history list is a global list of the undo logs for committed transactions. MySQL uses the history list to purge records and log pages when transactions no longer require the history. The history list length is the total number of undo logs that contain modifications in the history list. Each log contains one or more modifications. If the InnoDB history list length grows too large, indicating a large number of old row versions, queries and database shutdowns become slower.

Likely causes for this issue

Typical causes of a long history list include the following:

- Long-running transactions, either read or write
- A heavy write load

Actions

We recommend different actions depending on the causes of your insight.

Topics

- Don't begin any operation involving a database shutdown until the InnoDB history list decreases (p. 945)
- Identify and end long-running transactions (p. 945)
- Identify the top hosts and top users by using Performance Insights. (p. 946)

Don't begin any operation involving a database shutdown until the InnoDB history list decreases

Because a long InnoDB history list slows database shutdowns, reduce the list size before initiating operations involving a database shutdown. These operations include major version database upgrades.

Identify and end long-running transactions

You can find long-running transactions by querying information_schema.innodb_trx.

To identify and end long-running transactions

1. In your SQL client, run the following query:

   ```sql
   SELECT a.trx_id, 
   a.trx_state, 
   a.trx_started, 
   TIMESTAMPDIFF(SECOND,a.trx_started, now()) as "Seconds Transaction Has Been Open", 
   a.trx_rows_modified, 
   b.USER, 
   b.host, 
   b.db, 
   b.command, 
   b.time, 
   b.state 
FROM information_schema.innodb_trx a, 
information_schema.processlist b 
WHERE a.trx_mysql_thread_id=b.id
   ```
2. End each long-running transaction with a COMMIT or ROLLBACK command.

Identify the top hosts and top users by using Performance Insights.

Optimize transactions so that large numbers of modified rows are immediately committed.

Relevant metrics

The following metrics are related to this insight:

- `trx_rseg_history_len`

  For more information, see InnoDB INFORMATION_SCHEMA Metrics Table in the MySQL 5.7 Reference Manual.

Database is creating temporary tables on disk

Your recent on-disk temporary table usage increased significantly, up to `percentage`. The database is creating around `number` temporary tables per second. This might impact performance and increase disk operations on `db-instance`.

Topics

- Supported engine versions (p. 946)
- Context (p. 946)
- Likely causes for this issue (p. 946)
- Actions (p. 946)
- Relevant metrics (p. 947)

Supported engine versions

This insight information is supported for all versions of Aurora MySQL.

Context

Sometimes it's necessary for the MySQL server to create an internal temporary table while processing a query. Aurora MySQL can hold an internal temporary table in memory, where it can be processed by the TempTable or MEMORY storage engine, or stored on disk by InnoDB. For more information, see Internal Temporary Table Use in MySQL in the MySQL Reference Manual.

Likely causes for this issue

An increase in on-disk temporary tables indicates the use of complex queries. If the configured memory is insufficient to store temporary tables in memory, Aurora MySQL creates the tables on disk. This can impact performance and increase disk operations.

Actions

We recommend different actions depending on the causes of your insight.

- For Aurora MySQL version 3, we recommend that you use the TempTable storage engine.
- Optimize your queries to return less data by selecting only necessary columns.
If you turn on the Performance Schema with all statement instruments enabled and timed, you can query SYS.statements_with_temp_tables to retrieve the list of queries that use temporary tables. For more information, see Prerequisites for Using the sys Schema in the MySQL documentation.

- Consider indexing columns that are involved in sorting and grouping operations.
- Rewrite your queries to avoid BLOB and TEXT columns. These columns always use disk.
- Tune the following database parameters: tmp_table_size and max_heap_table_size.

The default values for these parameters is 16 MiB. When using the MEMORY storage engine for in-memory temporary tables, their maximum size is defined by the tmp_table_size or max_heap_table_size value, whichever is smaller. When this maximum size is reached, MySQL automatically converts the in-memory internal temporary table to an InnoDB on-disk internal temporary table. For more information, see Use the TempTable storage engine on Amazon RDS for MySQL and Amazon Aurora MySQL.

**Note**

When explicitly creating MEMORY tables with CREATE TABLE, only the max_heap_table_size variable determines how large a table can grow. There is also no conversion to an on-disk format.

**Relevant metrics**

The following Performance Insights metrics are related to this insight:

- Created_tmp_disk_tables
- Created_tmp_tables

For more information, see Created_tmp_disk_tables in the MySQL documentation.
Working with parallel query for Amazon Aurora MySQL

This topic describes the parallel query performance optimization for Amazon Aurora MySQL-Compatible Edition. This feature uses a special processing path for certain data-intensive queries, taking advantage of the Aurora shared storage architecture. Parallel query works best with Aurora MySQL DB clusters that have tables with millions of rows and analytic queries that take minutes or hours to complete.

Overview of parallel query for Aurora MySQL

Aurora MySQL parallel query is an optimization that parallelizes some of the I/O and computation involved in processing data-intensive queries. The work that is parallelized includes retrieving rows from storage, extracting column values, and determining which rows match the conditions in the WHERE clause and join clauses. This data-intensive work is delegated (in database optimization terms, pushed down) to multiple nodes in the Aurora distributed storage layer. Without parallel query, each query brings all the scanned data to a single node within the Aurora MySQL cluster (the head node) and performs all the query processing there.

**Tip**
The PostgreSQL database engine also has a feature called "parallel query." That feature is unrelated to Aurora parallel query.

When the parallel query feature is turned on, the Aurora MySQL engine automatically determines when queries can benefit, without requiring SQL changes such as hints or table attributes. In the following sections, you can find an explanation of when parallel query is applied to a query. You can also find how to make sure that parallel query is applied where it provides the most benefit.

**Note**
The parallel query optimization provides the most benefit for long-running queries that take minutes or hours to complete. Aurora MySQL generally doesn't perform parallel query optimization for inexpensive queries. It also generally doesn't perform parallel query optimization if another optimization technique makes more sense, such as query caching, buffer pool caching, or index lookups. If you find that parallel query isn't being used when you expect it, see [Verifying which statements use parallel query](p. 959).

**Benefits**
With parallel query, you can run data-intensive analytic queries on Aurora MySQL tables. In many cases, you can get an order-of-magnitude performance improvement over the traditional division of labor for query processing.

Benefits of parallel query include the following:

- Improved I/O performance, due to parallelizing physical read requests across multiple storage nodes.
• Reduced network traffic. Aurora doesn't transmit entire data pages from storage nodes to the head node and then filter out unnecessary rows and columns afterward. Instead, Aurora transmits compact tuples containing only the column values needed for the result set.
• Reduced CPU usage on the head node, due to pushing down function processing, row filtering, and column projection for the WHERE clause.
• Reduced memory pressure on the buffer pool. The pages processed by the parallel query aren't added to the buffer pool. This approach reduces the chance of a data-intensive scan evicting frequently used data from the buffer pool.
• Potentially reduced data duplication in your extract, transform, load (ETL) pipeline, by making it practical to perform long-running analytic queries on existing data.

Architecture

The parallel query feature uses the major architectural principles of Aurora MySQL: decoupling the database engine from the storage subsystem, and reducing network traffic by streamlining communication protocols. Aurora MySQL uses these techniques to speed up write-intensive operations such as redo log processing. Parallel query applies the same principles to read operations.

Note
The architecture of Aurora MySQL parallel query differs from that of similarly named features in other database systems. Aurora MySQL parallel query doesn't involve symmetric multiprocessing (SMP) and so doesn't depend on the CPU capacity of the database server. The parallel processing happens in the storage layer, independent of the Aurora MySQL server that serves as the query coordinator.

By default, without parallel query, the processing for an Aurora query involves transmitting raw data to a single node within the Aurora cluster (the head node). Aurora then performs all further processing for that query in a single thread on that single node. With parallel query, much of this I/O-intensive and CPU-intensive work is delegated to nodes in the storage layer. Only the compact rows of the result set are transmitted back to the head node, with rows already filtered, and column values already extracted and transformed. The performance benefit comes from the reduction in network traffic, reduction in CPU usage on the head node, and parallelizing the I/O across the storage nodes. The amount of parallel I/O, filtering, and projection is independent of the number of DB instances in the Aurora cluster that runs the query.

Prerequisites

To use all features of parallel query requires an Aurora MySQL DB cluster that's running version 2.09 or higher. If you already have a cluster that you want to use with parallel query, you can upgrade it to a compatible version and turn on parallel query afterward. In that case, make sure to follow the upgrade procedure in Upgrade considerations for parallel query (p. 957) because the configuration setting names and default values are different in these newer versions.

The DB instances in your cluster must use the db.r* instance classes.

Make sure that hash join optimization is turned on for your cluster. To learn how, see Turning on hash join for parallel query clusters (p. 956).

To customize parameters such as aurora_parallel_query and aurora_disable_hash_join, you must have a custom parameter group that you use with your cluster. You can specify these parameters individually for each DB instance by using a DB parameter group. However, we recommend that you specify them in a DB cluster parameter group. That way, all DB instances in your cluster inherit the same settings for these parameters.

Limitations

The following limitations apply to the parallel query feature:
• Parallel query isn't supported with the Aurora I/O-Optimized DB cluster storage configuration.

• You can't use parallel query with the db.t2 or db.t3 instance classes. This limitation applies even if you request parallel query using the `aurora_pq_force` session variable.

• Parallel query doesn't apply to tables using the `COMPRESSED` or `REDUNDANT` row formats. Use the `COMPACT` or `DYNAMIC` row formats for tables you plan to use with parallel query.

• Aurora uses a cost-based algorithm to determine whether to use the parallel query mechanism for each SQL statement. Using certain SQL constructs in a statement can prevent parallel query or make parallel query unlikely for that statement. For information about compatibility of SQL constructs with parallel query, see `How parallel query works with SQL constructs` (p. 965).

• Each Aurora DB instance can run only a certain number of parallel query sessions at one time. If a query has multiple parts that use parallel query, such as subqueries, joins, or UNION operators, those phases run in sequence. The statement only counts as a single parallel query session at any one time. You can monitor the number of active sessions using the `parallel query status variables` (p. 962). You can check the limit on concurrent sessions for a given DB instance by querying the status variable `Aurora_pq_max_concurrent_requests`.

• Parallel query is available in all AWS Regions that Aurora supports. For most AWS Regions, the minimum required Aurora MySQL version to use parallel query is 2.09.

• Parallel query is designed to improve the performance of data-intensive queries. It isn't designed for lightweight queries.

• We recommend that you use reader nodes for SELECT statements, especially data-intensive ones.

I/O costs with parallel query

If your Aurora MySQL cluster uses parallel query, you might see an increase in `VolumeReadIOPS` values. Parallel queries don't use the buffer pool. Thus, although the queries are fast, this optimized processing can result in an increase in read operations and associated charges.

Parallel query I/O costs for your query are metered at the storage layer, and will be the same or larger with parallel query turned on. Your benefit is the improvement in query performance. There are two reasons for potentially higher I/O costs with parallel query:

• Even if some of the data in a table is in the buffer pool, parallel query requires all data to be scanned at the storage layer, incurring I/O costs.

• Running a parallel query doesn't warm up the buffer pool. As a result, consecutive runs of the same parallel query incur the full I/O cost.

Planning for a parallel query cluster

Planning for a DB cluster that has parallel query turned on requires making some choices. These include performing setup steps (either creating or restoring a full Aurora MySQL cluster) and deciding how broadly to turn on parallel query across your DB cluster.

Consider the following as part of planning:

• If you use Aurora MySQL that's compatible with MySQL 5.7, you must choose Aurora MySQL 2.09 or higher. In this case, you always create a provisioned cluster. Then you turn on parallel query using the `aurora_parallel_query` parameter.

If you have an existing Aurora MySQL cluster that's running version 2.09 or higher, you don't have to create a new cluster to use parallel query. You can associate your cluster, or specific DB instances in the cluster, with a parameter group that has the `aurora_parallel_query` parameter turned on. By doing so, you can reduce the time and effort to set up the relevant data to use with parallel query.
• Plan for any large tables that you need to reorganize so that you can use parallel query when accessing them. You might need to create new versions of some large tables where parallel query is useful. For example, you might need to remove full-text search indexes. For details, see Creating schema objects to take advantage of parallel query (p. 958).

Checking Aurora MySQL version compatibility for parallel query

To check which Aurora MySQL versions are compatible with parallel query clusters, use the describe-db-engine-versions AWS CLI command and check the value of the SupportsParallelQuery field. The following code example shows how to check which combinations are available for parallel query clusters in a specified AWS Region. Make sure to specify the full --query parameter string on a single line.

```bash
aws rds describe-db-engine-versions --region us-east-1 --engine aurora-mysql --query '*[]|[?SupportsParallelQuery == `true`].[EngineVersion]' --output text
```

The preceding commands produce output similar to the following. The output might vary depending on which Aurora MySQL versions are available in the specified AWS Region.

```
5.7.mysql_aurora.2.11.1
8.0.mysql_aurora.3.01.0
8.0.mysql_aurora.3.01.1
8.0.mysql_aurora.3.02.0
8.0.mysql_aurora.3.02.1
8.0.mysql_aurora.3.02.2
8.0.mysql_aurora.3.03.0
```

After you start using parallel query with a cluster, you can monitor performance and remove obstacles to parallel query usage. For those instructions, see Performance tuning for parallel query (p. 958).

Creating a DB cluster that works with parallel query

To create an Aurora MySQL cluster with parallel query, add new instances to it, or perform other administrative operations, you use the same AWS Management Console and AWS CLI techniques that you do with other Aurora MySQL clusters. You can create a new cluster to work with parallel query. You can also create a DB cluster to work with parallel query by restoring from a snapshot of a MySQL-compatible Aurora DB cluster. If you aren’t familiar with the process for creating a new Aurora MySQL cluster, you can find background information and prerequisites in Creating an Amazon Aurora DB cluster (p. 179).

When you choose an Aurora MySQL engine version, we recommend that you choose the latest one available. Currently, Aurora MySQL versions 2.09 and higher support parallel query. You have more flexibility to turn parallel query on and off, or use parallel query with existing clusters, if you use Aurora MySQL 2.09 and higher.

Whether you create a new cluster or restore from a snapshot, you use the same techniques to add new DB instances that you do with other Aurora MySQL clusters.

Creating a parallel query cluster using the console

You can create a new parallel query cluster with the console as described following.

To create a parallel query cluster with the AWS Management Console

1. Follow the general AWS Management Console procedure in Creating an Amazon Aurora DB cluster (p. 179).
2. On the Select engine screen, choose Aurora MySQL.
For **Engine version**, choose Aurora MySQL 2.09 or higher. With these versions, you have the fewest limitations on parallel query usage. Those versions also have the most flexibility to turn parallel query on or off at any time.

If it isn't practical to use a recent Aurora MySQL version for this cluster, choose **Show versions that support the parallel query feature**. Doing so filters the **Version** menu to show only the specific Aurora MySQL versions that are compatible with parallel query.

3. For **Additional configuration**, choose a parameter group that you created for **DB cluster parameter group**. Using such a custom parameter group is required for Aurora MySQL 2.09 and higher. In your DB cluster parameter group, specify the parameter settings `aurora_parallel_query=ON` and `aurora_disable_hash_join=OFF`. Doing so turns on parallel query for the cluster, and turns on the hash join optimization that works in combination with parallel query.

**To verify that a new cluster can use parallel query**

1. Create a cluster using the preceding technique.
2. (For Aurora MySQL version 2 or 3) Check that the `aurora_parallel_query` configuration setting is true.

```bash
mysql> select @@aurora_parallel_query;
+-------------------------+
<table>
<thead>
<tr>
<th>@@aurora_parallel_query</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
+-------------------------+
```

3. (For Aurora MySQL version 2) Check that the `aurora_disable_hash_join` setting is false.

```bash
mysql> select @@aurora_disable_hash_join;
+----------------------------+
<table>
<thead>
<tr>
<th>@@aurora_disable_hash_join</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
+----------------------------+
```

4. With some large tables and data-intensive queries, check the query plans to confirm that some of your queries are using the parallel query optimization. To do so, follow the procedure in [Verifying which statements use parallel query](p. 959).

**Creating a parallel query cluster using the CLI**

You can create a new parallel query cluster with the CLI as described following.

**To create a parallel query cluster with the AWS CLI**

1. (Optional) Check which Aurora MySQL versions are compatible with parallel query clusters. To do so, use the `describe-db-engine-versions` command and check the value of the `SupportsParallelQuery` field. For an example, see [Checking Aurora MySQL version compatibility for parallel query](p. 952).

2. (Optional) Create a custom DB cluster parameter group with the settings `aurora_parallel_query=ON` and `aurora_disable_hash_join=OFF`. Use commands such as the following.

   ```bash
   aws rds create-db-cluster-parameter-group --db-parameter-group-family aurora-mysql5.7 --db-cluster-parameter-group-name pq-enabled-57-compatible
   ```
aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name pq-enabled-57-compatible
  --parameters
    ParameterName=aurora_parallel_query,ParameterValue=ON,ApplyMethod=pending-reboot
aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name pq-enabled-57-compatible
  --parameters
    ParameterName=aurora_disable_hash_join,ParameterValue=OFF,ApplyMethod=pending-reboot

If you perform this step, specify the option --db-cluster-parameter-group-name my_cluster_parameter_group in the subsequent create-db-cluster statement. Substitute the name of your own parameter group. If you omit this step, you create the parameter group and associate it with the cluster later, as described in Turning parallel query on and off (p. 955).

3. Follow the general AWS CLI procedure in Creating an Amazon Aurora DB cluster (p. 179).

4. Specify the following set of options:
   - For the --engine option, use aurora-mysql. These values produce parallel query clusters that are compatible with MySQL 5.7 or 8.0.
   - For the --db-cluster-parameter-group-name option, specify the name of a DB cluster parameter group that you created and specified the parameter value aurora_parallel_query=ON. If you omit this option, you can create the cluster with a default parameter group and later modify it to use such a custom parameter group.
   - For the --engine-version option, use an Aurora MySQL version that's compatible with parallel query. Use the procedure from Planning for a parallel query cluster (p. 951) to get a list of versions if necessary. Use at least version 2.09.0. These versions and all higher ones contain substantial enhancements to parallel query.

The following code example shows how. Substitute your own value for each of the environment variables such as $CLUSTER_ID. This example also specifies the --manage-master-user-password option to generate the master user password and manage it in Secrets Manager. For more information, see Password management with Amazon Aurora and AWS Secrets Manager (p. 2371). Alternatively, you can use the --master-password option to specify and manage the password yourself.

aws rds create-db-cluster --db-cluster-identifier $CLUSTER_ID
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1
  --master-username $MASTER_USER_ID --manage-master-user-password
  --db-cluster-parameter-group-name $CUSTOM_CLUSTER_PARAM_GROUP
aws rds create-db-instance --db-instance-identifier ${INSTANCE_ID}-1
  --engine same_value_as_in_create_cluster_command
  --db-cluster-identifier $CLUSTER_ID --db-instance-class $INSTANCE_CLASS

5. Verify that a cluster you created or restored has the parallel query feature available.

Check that the aurora_parallel_query configuration setting exists. If this setting has the value 1, parallel query is ready for you to use. If this setting has the value 0, set it to 1 before you can use parallel query. Either way, the cluster is capable of performing parallel queries.

mysql> select @aurora_parallel_query;
+------------------------+
| @aurora_parallel_query|
+------------------------+
| 1                      |
+------------------------+
To restore a snapshot to a parallel query cluster with the AWS CLI

1. Check which Aurora MySQL versions are compatible with parallel query clusters. To do so, use the `describe-db-engine-versions` command and check the value of the `SupportsParallelQuery` field. For an example, see Checking Aurora MySQL version compatibility for parallel query (p. 952). Decide which version to use for the restored cluster. Choose Aurora MySQL 2.0.9.0 or higher for a MySQL 5.7-compatible cluster.

2. Locate an Aurora MySQL-compatible cluster snapshot.

3. Follow the general AWS CLI procedure in Restoring from a DB cluster snapshot (p. 439).

   ```
   aws rds restore-db-cluster-from-snapshot \
   --db-cluster-identifier mynewdbcluster \
   --snapshot-identifier mydbclustersnapshot \
   --engine aurora-mysql
   ```

4. Verify that a cluster you created or restored has the parallel query feature available. Use the same verification procedure as in Creating a parallel query cluster using the CLI (p. 953).

Turning parallel query on and off

When parallel query is turned on, Aurora MySQL determines whether to use it at runtime for each query. In the case of joins, unions, subqueries, and so on, Aurora MySQL determines whether to use parallel query at runtime for each query block. For details, see Verifying which statements use parallel query (p. 959) and How parallel query works with SQL constructs (p. 965).

You can turn on and turn off parallel query dynamically at both the global and session level for a DB instance by using the `aurora_parallel_query` option. You can change the `aurora_parallel_query` setting in your DB cluster group to turn parallel query on or off by default.

```
mysql> select @@aurora_parallel_query;
+------------------------+
| @@aurora_parallel_query|
+------------------------+
|                      1 |
+------------------------+
```

To toggle the `aurora_parallel_query` parameter at the session level, use the standard methods to change a client configuration setting. For example, you can do so through the `mysql` command line or within a JDBC or ODBC application. The command on the standard MySQL client is `set session aurora_parallel_query = {'ON'/'OFF'}`. You can also add the session-level parameter to the JDBC configuration or within your application code to turn on or turn off parallel query dynamically.

You can permanently change the setting for the `aurora_parallel_query` parameter, either for a specific DB instance or for your whole cluster. If you specify the parameter value in a DB parameter group, that value only applies to specific DB instance in your cluster. If you specify the parameter value in a DB cluster parameter group, all DB instances in the cluster inherit the same setting. To toggle the `aurora_parallel_query` parameter, use the techniques for working with parameter groups, as described in Working with parameter groups (p. 212). Follow these steps:

1. Create a custom cluster parameter group (recommended) or a custom DB parameter group.

2. In this parameter group, update `parallel_query` to the value that you want.

3. Depending on whether you created a DB cluster parameter group or a DB parameter group, attach the parameter group to your Aurora cluster or to the specific DB instances where you plan to use the parallel query feature.
Tip
Because `aurora_parallel_query` is a dynamic parameter, it doesn't require a cluster restart after changing this setting. However, any connections that were using parallel query before toggling the option will continue to do so until the connection is closed, or the instance is rebooted.

You can modify the parallel query parameter by using the `ModifyDBClusterParameterGroup` or `ModifyDBParameterGroup` API operation or the AWS Management Console.

Turning on hash join for parallel query clusters

Parallel query is typically used for the kinds of resource-intensive queries that benefit from the hash join optimization. Thus, it's helpful to make sure that hash joins are turned on for clusters where you plan to use parallel query. For information about how to use hash joins effectively, see Optimizing large Aurora MySQL join queries with hash joins (p. 1106).

Turning on and turning off parallel query using the console

You can turn on or turn off parallel query at the DB instance level or the DB cluster level by working with parameter groups.

To turn on or turn off parallel query for a DB cluster with the AWS Management Console

1. Create a custom parameter group, as described in Working with parameter groups (p. 212).
2. Update `aurora_parallel_query` to 1 (turned on) or 0 (turned off). For clusters where the parallel query feature is available, `aurora_parallel_query` is turned off by default.
3. If you use a custom cluster parameter group, attach it to the Aurora DB cluster where you plan to use the parallel query feature. If you use a custom DB parameter group, attach it to one or more DB instances in the cluster. We recommend using a cluster parameter group. Doing so makes sure that all DB instances in the cluster have the same settings for parallel query and associated features such as hash join.

Turning on and turning off parallel query using the CLI

You can modify the parallel query parameter by using the `modify-db-cluster-parameter-group` or `modify-db-parameter-group` command. Choose the appropriate command depending on whether you specify the value of `aurora_parallel_query` through a DB cluster parameter group or a DB parameter group.

To turn on or turn off parallel query for a DB cluster with the CLI

- Modify the parallel query parameter by using the `modify-db-cluster-parameter-group` command. Use a command such as the following. Substitute the appropriate name for your own custom parameter group. Substitute either ON or OFF for the `ParameterValue` portion of the `--parameters` option.

```
$ aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name cluster_param_group_name \
   --parameters ParameterName=aurora_parallel_query,ParameterValue=ON,ApplyMethod=pending-reboot 
{
   "DBClusterParameterGroupName": "cluster_param_group_name"
}
```
You can also turn on or turn off parallel query at the session level, for example through the mysql command line or within a JDBC or ODBC application. To do so, use the standard methods to change a client configuration setting. For example, the command on the standard MySQL client is set session aurora_parallel_query = {'ON'/'OFF'} for Aurora MySQL.

You can also add the session-level parameter to the JDBC configuration or within your application code to turn on or turn off parallel query dynamically.

Overriding the parallel query optimizer

You can use the aurora_pq_force session variable to override the parallel query optimizer and request parallel query for every query. We recommend that you do this only for testing purposes. The following example shows how to use aurora_pq_force in a session.

```sql
set SESSION aurora_parallel_query = ON;
set SESSION aurora_pq_force = ON;
```

To turn off the override, do the following:

```sql
set SESSION aurora_pq_force = OFF;
```

Upgrade considerations for parallel query

Depending on the original and destination versions when you upgrade a parallel query cluster, you might find enhancements in the types of queries that parallel query can optimize. You might also find that you don't need to specify a special engine mode parameter for parallel query. The following sections explain the considerations when you upgrade a cluster that has parallel query turned on.

Upgrading parallel query clusters to Aurora MySQL version 3

Several SQL statements, clauses, and data types have new or improved parallel query support starting in Aurora MySQL version 3. When you upgrade from a release that's earlier than version 3, check whether additional queries can benefit from parallel query optimizations. For information about these parallel query enhancements, see Column data types (p. 969), Partitioned tables (p. 969), and Aggregate functions, GROUP BY clauses, and HAVING clauses (p. 970).

If you're upgrading a parallel query cluster from Aurora MySQL 2.08 or lower, also learn about changes in how to turn on parallel query. To do so, read Upgrading to Aurora MySQL 2.09 and higher (p. 957).

In Aurora MySQL version 3, hash join optimization is turned on by default. The aurora_disable_hash_join configuration option from earlier versions isn't used.

Upgrading to Aurora MySQL 2.09 and higher

In Aurora MySQL version 2.09 and higher, parallel query works for provisioned clusters and doesn't require the parallelquery engine mode parameter. Thus, you don't need to create a new cluster or restore from an existing snapshot to use parallel query with these versions. You can use the upgrade procedures described in Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1209) to upgrade your cluster to such a version. You can upgrade an older cluster regardless of whether it was a parallel query cluster or a provisioned cluster. To reduce the number of choices in the Engine version menu, you can choose Show versions that support the parallel query feature to filter the entries in that menu. Then choose Aurora MySQL 2.09 or higher.
After you upgrade an earlier parallel query cluster to Aurora MySQL 2.09 or higher, you turn on parallel query in the upgraded cluster. Parallel query is turned off by default in these versions, and the procedure for enabling it is different. The hash join optimization is also turned off by default and must be turned on separately. Thus, make sure that you turn on these settings again after the upgrade. For instructions on doing so, see Turning parallel query on and off (p. 955) and Turning on hash join for parallel query clusters (p. 956).

In particular, you turn on parallel query by using the configuration parameters aurora_parallel_query=ON and aurora_disable_hash_join=OFF instead of aurora_pq_supported and aurora_pq. The aurora_pq_supported and aurora_pq parameters are deprecated in the newer Aurora MySQL versions.

In the upgraded cluster, the EngineMode attribute has the value provisioned instead of parallelquery. To check whether parallel query is available for a specified engine version, now you check the value of the SupportsParallelQuery field in the output of the describe-db-engine-versions AWS CLI command. In earlier Aurora MySQL versions, you checked for the presence of parallelquery in the SupportedEngineModes list.

After you upgrade to Aurora MySQL version 2.09 or higher, you can take advantage of the following features. These features aren't available to parallel query clusters running older Aurora MySQL versions.

- Performance Insights. For more information, see Monitoring DB load with Performance Insights on Amazon Aurora (p. 559).
- Backtracking. For more information, see Backtracking an Aurora DB cluster (p. 880).
- Stopping and starting the cluster. For more information, see Stopping and starting an Amazon Aurora DB cluster (p. 249).

Performance tuning for parallel query

To manage the performance of a workload with parallel query, make sure that parallel query is used for the queries where this optimization helps the most.

To do so, you can do the following:

- Make sure that your biggest tables are compatible with parallel query. You might change table properties or recreate some tables so that queries for those tables can take advantage of the parallel query optimization. To learn how, see Creating schema objects to take advantage of parallel query (p. 958).
- Monitor which queries use parallel query. To learn how, see Monitoring parallel query (p. 962).
- Verify that parallel query is being used for the most data-intensive and long-running queries, and with the right level of concurrency for your workload. To learn how, see Verifying which statements use parallel query (p. 959).
- Fine-tune your SQL code to turn on parallel query to apply to the queries that you expect. To learn how, see How parallel query works with SQL constructs (p. 965).

Creating schema objects to take advantage of parallel query

Before you create or modify tables that you plan to use for parallel query, make sure to familiarize yourself with the requirements described in Prerequisites (p. 950) and Limitations (p. 950).

Because parallel query requires tables to use the ROW_FORMAT=Compact or ROW_FORMAT=Dynamic setting, check your Aurora configuration settings for any changes to the INNODB_FILE_FORMAT
configuration option. Issue the \texttt{SHOW TABLE STATUS} statement to confirm the row format for all the
tables in a database.

Before changing your schema to turn on parallel query to work with more tables, make sure to test. Your
tests should confirm if parallel query results in a net increase in performance for those tables. Also, make
sure that the schema requirements for parallel query are otherwise compatible with your goals.

For example, before switching from \texttt{ROW\_FORMAT=Compressed} to \texttt{ROW\_FORMAT=Compact} or
\texttt{ROW\_FORMAT=Dynamic}, test the performance of workloads for the original and new tables. Also,
consider other potential effects such as increased data volume.

\textbf{Verifying which statements use parallel query}

In typical operation, you don't need to perform any special actions to take advantage of parallel query.
After a query meets the essential requirements for parallel query, the query optimizer automatically
decides whether to use parallel query for each specific query.

If you run experiments in a development or test environment, you might find that parallel query isn't
used because your tables are too small in number of rows or overall data volume. The data for the table
might also be entirely in the buffer pool, especially for tables that you created recently to perform
experiments.

As you monitor or tune cluster performance, make sure to decide whether parallel query is being used
in the appropriate contexts. You might adjust the database schema, settings, SQL queries, or even the
cluster topology and application connection settings to take advantage of this feature.

To check if a query is using parallel query, check the query plan (also known as the "explain plan") by
running the \texttt{EXPLAIN} statement. For examples of how SQL statements, clauses, and expressions affect
\texttt{EXPLAIN} output for parallel query, see How parallel query works with SQL constructs (p. 965).

The following example demonstrates the difference between a traditional query plan and a parallel
query plan. This explain plan is from Query 3 from the TPC-H benchmark. Many of the sample queries
throughout this section use the tables from the TPC-H dataset. You can get the table definitions, queries,
and the \texttt{dbgen} program that generates sample data from the \texttt{TPC-h website}.

```sql
EXPLAIN SELECT l_orderkey,
    sum(l_extendedprice * (1 - l_discount)) AS revenue,
    o_orderdate,
    o_shippriority
FROM customer,
    orders,
    lineitem
WHERE c_mktsegment = 'AUTOMOBILE'
AND c_custkey = o_custkey
AND l_orderkey = o_orderkey
AND o_orderdate < date '1995-03-13'
AND l_shipdate > date '1995-03-13'
GROUP BY l_orderkey,
    o_orderdate,
    o_shippriority
ORDER BY revenue DESC,
    o_orderdate LIMIT 10;
```

By default, the query might have a plan like the following. If you don't see hash join used in the query
plan, make sure that optimization is turned on first.

```
+----+-------------+----------+------------+------+---------------+------+---------+------+
| id | select_type | table    | partitions | type | possible_keys | key  | key_len | ref  |
| rows| filtered    | Extra    | Extra      | Extra |
```
