DB cluster made up entirely of Aurora Replicas. At least one secondary AWS Region is required, but an Aurora global database can have up to five secondary AWS Regions. The table lists the maximum Aurora DB clusters, Aurora DB instances, and Aurora Replicas allowed in an Aurora global database.

<table>
<thead>
<tr>
<th>Description</th>
<th>Primary AWS Region</th>
<th>Secondary AWS Regions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora DB clusters</td>
<td>1</td>
<td>5 (maximum)</td>
</tr>
<tr>
<td>Writer instances</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>Read-only instances (Aurora replicas), per Aurora DB cluster</td>
<td>15 (max)</td>
<td>16 (total)</td>
</tr>
<tr>
<td>Read-only instances (max allowed, given actual number of secondary Regions)</td>
<td>15 - s</td>
<td>s = total number of secondary AWS Regions</td>
</tr>
</tbody>
</table>

The Aurora DB clusters that make up an Aurora global database have the following specific requirements:

- **DB instance class requirements** – An Aurora global database requires DB instance classes that are optimized for memory-intensive applications. For information about the memory optimized DB instance classes, see [DB instance classes](#). We recommend that you use a db.r5 or higher instance class.

- **AWS Region requirements** – An Aurora global database needs a primary Aurora DB cluster in one AWS Region, and at least one secondary Aurora DB cluster in a different Region. You can create up to five secondary (read-only) Aurora DB clusters, and each must be in a different Region. In other words, no two Aurora DB clusters in an Aurora global database can be in the same AWS Region.

- **Naming requirements** – The names you choose for each of your Aurora DB clusters must be unique, across all AWS Regions. You can't use the same name for different Aurora DB clusters even though they're in different Regions.

- **Capacity requirements for Aurora Serverless v2** – For a global database with Aurora Serverless v2, the minimum capacity required for the DB cluster in the primary AWS Region is 8 ACUs.

Before you can follow the procedures in this section, you need an AWS account. Complete the setup tasks for working with Amazon Aurora. For more information, see [Setting up your environment for Amazon Aurora](#). You also need to complete other preliminary steps for creating any Aurora DB cluster. To learn more, see [Creating an Amazon Aurora DB cluster](#).

**Creating an Amazon Aurora global database**

In some cases, you might have an existing Aurora provisioned DB cluster running an Aurora database engine that's global-compatible. If so, you can add another AWS Region to it to create your Aurora global database. To do so, see [Adding an AWS Region to an Amazon Aurora global database](#).

To create an Aurora global database by using the AWS Management Console, the AWS CLI, or the RDS API, use the following steps.

**Console**

The steps for creating an Aurora global database begin by signing in to an AWS Region that supports the Aurora global database feature. For a complete list, see [Aurora global databases](#).

One of the following steps is choosing a virtual private cloud (VPC) based on Amazon VPC for your Aurora DB cluster. To use your own VPC, we recommend that you create it in advance so it's available for
you to choose. At the same time, create any related subnets, and as needed a subnet group and security group. To learn how, see Tutorial: Create an Amazon VPC for use with a DB instance.

For general information about creating an Aurora DB cluster, see Creating an Amazon Aurora DB cluster (p. 179).

**To create an Aurora global database**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Choose Create database. On the Create database page, do the following:
   - For the database creation method, choose Standard create. (Don't choose Easy create.)
   - For Engine type in the Engine options section, choose the applicable engine type, Aurora (MySQL Compatible) or Aurora (PostgreSQL Compatible).
3. Continue creating your Aurora global database by using the steps from the following procedures.

**Creating a global database using Aurora MySQL**

The following steps apply to all versions of Aurora MySQL.

**To create an Aurora global database using Aurora MySQL**

Complete the Create database page.

1. For Engine options, choose the following:
   a. Expand Show filters, and then turn on Show versions that support the global database feature.
   b. For Engine version, choose the version of Aurora MySQL that you want to use for your Aurora global database.
2. For **Templates**, choose **Production**. Or you can choose Dev/Test if appropriate for your use case. Don't use Dev/Test in production environments.

3. For **Settings**, do the following:
   
a. Enter a meaningful name for the DB cluster identifier. When you finish creating the Aurora global database, this name identifies the primary DB cluster.

   b. Enter your own password for the admin user account for the DB instance, or have Aurora generate one for you. If you choose to autogenerate a password, you get an option to copy the password.
4. For **DB instance class**, choose `db.r5.large` or another memory optimized DB instance class. We recommend that you use a `db.r5` or higher instance class.

5. For **Availability & durability**, we recommend that you choose to have Aurora create an Aurora Replica in a different Availability Zone (AZ) for you. If you don't create an Aurora Replica now, you need to do it later.
6. For **Connectivity**, choose the virtual private cloud (VPC) based on Amazon VPC that defines the virtual networking environment for this DB instance. You can choose the defaults to simplify this task.

7. Complete the **Database authentication** settings. To simplify the process, you can choose **Password authentication** now and set up AWS Identity and Access Management (IAM) later.

8. For **Additional configuration**, do the following:
   a. Enter a name for **Initial database name** to create the primary Aurora DB instance for this cluster. This is the writer node for the Aurora primary DB cluster.
      Leave the defaults selected for the DB cluster parameter group and DB parameter group, unless you have your own custom parameter groups that you want to use.
   b. Clear the **Enable backtrack** check box if it's selected. Aurora global databases don't support backtracking. Otherwise, accept the other default settings for **Additional configuration**.

9. Choose **Create database**.

   It can take several minutes for Aurora to complete the process of creating the Aurora DB instance, its Aurora Replica, and the Aurora DB cluster. You can tell when the Aurora DB cluster is ready to use as the primary DB cluster in an Aurora global database by its status. When that's so, its status and that of the writer and replica node is **Available**, as shown following.

When your primary DB cluster is available, create the Aurora global database by adding a secondary cluster to it. To do this, follow the steps in **Adding an AWS Region to an Amazon Aurora global database** (p. 1817).

**Creating a global database using Aurora PostgreSQL**

**To create an Aurora global database using Aurora PostgreSQL**

Complete the **Create database** page.

1. For **Engine options**, choose the following:
   a. Expand **Show filters**, and then turn on **Show versions that support the global database feature**.
b. For **Engine version**, choose the version of Aurora PostgreSQL that you want to use for your Aurora global database.

```
<table>
<thead>
<tr>
<th>Engine type</th>
<th>Info</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora (MySQL Compatible)</td>
<td>![Image]</td>
</tr>
<tr>
<td>Aurora (PostgreSQL Compatible)</td>
<td>![Image]</td>
</tr>
<tr>
<td>MySQL</td>
<td>![Image]</td>
</tr>
<tr>
<td>MariaDB</td>
<td>![Image]</td>
</tr>
<tr>
<td>PostgreSQL</td>
<td>![Image]</td>
</tr>
<tr>
<td>Oracle</td>
<td>![Image]</td>
</tr>
<tr>
<td>Microsoft SQL Server</td>
<td>![Image]</td>
</tr>
</tbody>
</table>
```

2. For **Templates**, choose **Production**. Or you can choose Dev/Test if appropriate. Don't use Dev/Test in production environments.

3. For **Settings**, do the following:

   a. Enter a meaningful name for the DB cluster identifier. When you finish creating the Aurora global database, this name identifies the primary DB cluster.

   b. Enter your own password for the default admin account for the DB cluster, or have Aurora generate one for you. If you choose Auto generate a password, you get an option to copy the password.
4. For **DB instance class**, choose `db.r5.large` or another memory optimized DB instance class. We recommend that you use a `db.r5` or higher instance class.

5. For **Availability & durability**, we recommend that you choose to have Aurora create an Aurora Replica in a different AZ for you. If you don't create an Aurora Replica now, you need to do it later.
6. For **Connectivity**, choose the virtual private cloud (VPC) based on Amazon VPC that defines the virtual networking environment for this DB instance. You can choose the defaults to simplify this task.

7. (Optional) Complete the **Database authentication** settings. Password authentication is always enabled. To simplify the process, you can skip this section and set up IAM or password and Kerberos authentication later.

8. For **Additional configuration**, do the following:

   a. Enter a name for **Initial database name** to create the primary Aurora DB instance for this cluster. This is the writer node for the Aurora primary DB cluster.

      Leave the defaults selected for the DB cluster parameter group and DB parameter group, unless you have your own custom parameter groups that you want to use.

   b. Accept all other default settings for **Additional configuration**, such as Encryption, Log exports, and so on.

9. Choose **Create database**.

It can take several minutes for Aurora to complete the process of creating the Aurora DB instance, its Aurora Replica, and the Aurora DB cluster. When the cluster is ready to use, the Aurora DB cluster and its writer and replica nodes display **Available** status. This becomes the primary DB cluster of your Aurora global database, after you add a secondary.

When your primary DB cluster is available, create one or more secondary clusters by following the steps in *Adding an AWS Region to an Amazon Aurora global database* (p. 1817).

**AWS CLI**

The AWS CLI commands in the procedures following accomplish the following tasks:

1. Create an Aurora global database, giving it a name and specifying the Aurora database engine type that you plan to use.

2. Create an Aurora DB cluster for the Aurora global database.

3. Create the Aurora DB instance for the cluster. This is the primary Aurora DB cluster for the global database.

4. Create a second DB instance for Aurora DB cluster. This is a reader to complete the Aurora DB cluster.

5. Create a second Aurora DB cluster in another Region and then add it to your Aurora global database, by following the steps in *Adding an AWS Region to an Amazon Aurora global database* (p. 1817).
Follow the procedure for your Aurora database engine.

Creating a global database using Aurora MySQL

To create an Aurora global database using Aurora MySQL

1. Use the `create-global-cluster` CLI command, passing the name of the AWS Region, Aurora database engine, and version.

   For Linux, macOS, or Unix:

   ```bash
   aws rds create-global-cluster --region primary_region \
   --global-cluster-identifier global_database_id \
   --engine aurora-mysql \
   --engine-version version # optional
   ```

   For Windows:

   ```bash
   aws rds create-global-cluster ^
   --global-cluster-identifier global_database_id ^
   --engine aurora-mysql ^
   --engine-version version # optional
   ```

   This creates an "empty" Aurora global database, with just a name (identifier) and Aurora database engine. It can take a few minutes for the Aurora global database to be available. Before going to the next step, use the `describe-global-clusters` CLI command to see if it's available.

   ```bash
   aws rds describe-global-clusters --region primary_region --global-cluster-identifier global_database_id
   ```

   When the Aurora global database is available, you can create its primary Aurora DB cluster.

2. To create a primary Aurora DB cluster, use the `create-db-cluster` CLI command. Include the name of your Aurora global database by using the `--global-cluster-identifier` parameter.

   For Linux, macOS, or Unix:

   ```bash
   aws rds create-db-cluster \
   --region primary_region \
   --db-cluster-identifier primary_db_cluster_id \
   --master-username userid \
   --master-user-password password \
   --engine aurora-mysql \
   --engine-version version \
   --global-cluster-identifier global_database_id
   ```

   For Windows:

   ```bash
   aws rds create-db-cluster ^
   --region primary_region ^
   --db-cluster-identifier primary_db_cluster_id ^
   --master-username userid ^
   --master-user-password password ^
   --engine aurora-mysql ^
   --engine-version version ^
   --global-cluster-identifier global_database_id
   ```
Amazon Aurora User Guide for Aurora
Creating a Aurora global database

Use the `describe-db-clusters` AWS CLI command to confirm that the Aurora DB cluster is ready. To single out a specific Aurora DB cluster, use `--db-cluster-identifier` parameter. Or you can leave out the Aurora DB cluster name in the command to get details about all your Aurora DB clusters in the given Region.

```bash
aws rds describe-db-clusters --region primary_region --db-cluster-identifier primary_db_cluster_id
```

When the response shows "Status": "available" for the cluster, it's ready to use.

3. Create the DB instance for your primary Aurora DB cluster. To do so, use the `create-db-instance` CLI command. Give the command your Aurora DB cluster's name, and specify the configuration details for the instance. You don't need to pass the `--master-username` and `--master-user-password` parameters in the command, because it gets those from the Aurora DB cluster.

For the `--db-instance-class`, you can use only those from the memory optimized classes, such as `db.r5.large`. We recommend that you use a `db.r5` or higher instance class. For information about these classes, see [DB instance classes](#).

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance --db-cluster-identifier primary_db_cluster_id --db-instance-class instance_class --db-instance-identifier db_instance_id --engine aurora-mysql --region primary_region
```

For Windows:

```bash
aws rds create-db-instance ^
   --db-cluster-identifier primary_db_cluster_id ^
   --db-instance-class instance_class ^
   --db-instance-identifier db_instance_id ^
   --engine aurora-mysql ^
   --region primary_region
```

The `create-db-instance` operation might take some time to complete. Check the status to see if the Aurora DB instance is available before continuing.

```bash
aws rds describe-db-clusters --db-cluster-identifier primary_db_cluster_id
```

When the command returns a status of "available," you can create another Aurora DB instance for your primary DB cluster. This is the reader instance (the Aurora Replica) for the Aurora DB cluster.

4. To create another Aurora DB instance for the cluster, use the `create-db-instance` CLI command.

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance \
   --db-cluster-identifier primary_db_cluster_id \
   --db-instance-class instance_class \
   --db-instance-identifier replica_db_instance_id \
   --engine aurora-mysql
```
Creating an Aurora global database

For Windows:

```bash
aws rds create-db-instance
   --db-cluster-identifier primary_db_cluster_id
   --db-instance-class instance_class
   --db-instance-identifier replica_db_instance_id
   --engine aurora-mysql
```

When the DB instance is available, replication begins from the writer node to the replica. Before continuing, check that the DB instance is available with the `describe-db-instances` CLI command.

At this point, you have an Aurora global database with its primary Aurora DB cluster containing a writer DB instance and an Aurora Replica. You can now add a read-only Aurora DB cluster in a different Region to complete your Aurora global database. To do so, follow the steps in Adding an AWS Region to an Amazon Aurora global database (p. 1817).

Creating a global database using Aurora PostgreSQL

When you create Aurora objects for an Aurora global database by using the following commands, it can take a few minutes for each to become available. We recommend that after completing any given command, you check the specific Aurora object's status to make sure that the status is available.

To do so, use the `describe-global-clusters` CLI command.

```bash
aws rds describe-global-clusters
   --region primary_region
   --global-cluster-identifier global_database_id
```

To create an Aurora global database using Aurora PostgreSQL

1. Use the `create-global-cluster` CLI command.

   For Linux, macOS, or Unix:

   ```bash
   aws rds create-global-cluster
       --region primary_region
       --global-cluster-identifier global_database_id
       --engine aurora-postgresql
       --engine-version version # optional
   ```

   For Windows:

   ```bash
   aws rds create-global-cluster
       --global-cluster-identifier global_database_id
       --engine aurora-postgresql
       --engine-version version # optional
   ```

   When the Aurora global database is available, you can create its primary Aurora DB cluster.

2. To create a primary Aurora DB cluster, use the `create-db-cluster` CLI command. Include the name of your Aurora global database by using the `--global-cluster-identifier` parameter.

   For Linux, macOS, or Unix:

   ```bash
   aws rds create-db-cluster
       --region primary_region
       --db-cluster-identifier primary_db_cluster_id
       --master-username userid
   ```
Creating an Aurora global database

```
--master-user-password password \
--engine aurora-postgresql \
--engine-version version \ 
--global-cluster-identifier global_database_id
```

For Windows:

```
aws rds create-db-cluster ^
  --region primary_region ^
  --db-cluster-identifier primary_db_cluster_id ^
  --master-username userid ^
  --master-user-password password ^
  --engine aurora-postgresql ^
  --engine-version version ^
  --global-cluster-identifier global_database_id
```

Check that the Aurora DB cluster is ready. When the response from the following command shows "Status": "available" for the Aurora DB cluster, you can continue.

```
aws rds describe-db-clusters --region primary_region --db-cluster-identifier primary_db_cluster_id
```

3. Create the DB instance for your primary Aurora DB cluster. To do so, use the `create-db-instance` CLI command.

Pass the name of your Aurora DB cluster with the `--db-cluster-identifier` parameter.

You don't need to pass the `--master-username` and `--master-user-password` parameters in the command, because it gets those from the Aurora DB cluster.

For the `--db-instance-class`, you can use only those from the memory optimized classes, such as db.r5.large. We recommend that you use a db.r5 or higher instance class. For information about these classes, see DB instance classes.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
  --db-cluster-identifier primary_db_cluster_id \
  --db-instance-class instance_class \
  --db-instance-identifier db_instance_id \
  --engine aurora-postgresql \
  --engine-version version \
  --region primary_region
```

For Windows:

```
aws rds create-db-instance ^
  --db-cluster-identifier primary_db_cluster_id ^
  --db-instance-class instance_class ^
  --db-instance-identifier db_instance_id ^
  --engine aurora-postgresql ^
  --engine-version version ^
  --region primary_region
```

4. Check the status of the Aurora DB instance before continuing.

```
aws rds describe-db-clusters --db-cluster-identifier primary_db_cluster_id
```
If the response shows that Aurora DB instance status is "available," you can create another Aurora DB instance for your primary DB cluster.

5. To create an Aurora Replica for Aurora DB cluster, use the `create-db-instance` CLI command.

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance \
  --db-cluster-identifier primary_db_cluster_id \
  --db-instance-class instance_class \
  --db-instance-identifier replica_db_instance_id \
  --engine aurora-postgresql
```

For Windows:

```bash
aws rds create-db-instance ^
  --db-cluster-identifier primary_db_cluster_id ^
  --db-instance-class instance_class ^
  --db-instance-identifier replica_db_instance_id ^
  --engine aurora-postgresql
```

When the DB instance is available, replication begins from the writer node to the replica. Before continuing, check that the DB instance is available with the `describe-db-instances` CLI command.

Your Aurora global database exists, but it has only its primary Region with an Aurora DB cluster made up of a writer DB instance and an Aurora Replica. You can now add a read-only Aurora DB cluster in a different Region to complete your Aurora global database. To do so, follow the steps in [Adding an AWS Region to an Amazon Aurora global database](p. 1817).

### RDS API

To create an Aurora global database with the RDS API, run the `CreateGlobalCluster` operation.

---

### Adding an AWS Region to an Amazon Aurora global database

An Aurora global database needs at least one secondary Aurora DB cluster in a different AWS Region than the primary Aurora DB cluster. You can attach up to five secondary DB clusters to your Aurora global database. For each secondary DB cluster that you add to your Aurora global database, reduce the number of Aurora Replicas allowed to the primary DB cluster by one.

For example, if your Aurora global database has 5 secondary Regions, your primary DB cluster can have only 10 (rather than 15) Aurora Replicas. For more information, see [Configuration requirements of an Amazon Aurora global database](p. 1804).

The number of Aurora Replicas (reader instances) in the primary DB cluster determines the number of secondary DB clusters you can add. The total number of reader instances in the primary DB cluster plus the number of secondary clusters can't exceed 15. For example, if you have 14 reader instances in the primary DB cluster and 1 secondary cluster, you can't add another secondary cluster to the global database.

**Note**

For Aurora MySQL version 3, when you create a secondary cluster, make sure that the value of `lower_case_table_names` matches the value in the primary cluster. This setting is a database parameter that affects how the server handles identifier case sensitivity. For more information about database parameters, see [Working with parameter groups](p. 212).
We recommend that when you create a secondary cluster, you use the same DB engine version for the primary and secondary. If necessary, upgrade the primary to be the same version as the secondary. For more information, see Patch level compatibility for managed cross-Region switchovers and failovers (p. 1877).

**Console**

**To add an AWS Region to an Aurora global database**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane of the AWS Management Console, choose Databases.
3. Choose the Aurora global database that needs a secondary Aurora DB cluster. Ensure that the primary Aurora DB cluster is Available.
4. For Actions, choose Add region.

5. On the Add a region page, choose the secondary AWS Region.

You can't choose an AWS Region that already has a secondary Aurora DB cluster for the same Aurora global database. Also, it can't be the same Region as the primary Aurora DB cluster.
6. Complete the remaining fields for the secondary Aurora cluster in the new AWS Region. These are the same configuration options as for any Aurora DB cluster instance, except for the following option for Aurora MySQL–based Aurora global databases only:

- Enable read replica write forwarding – This optional setting lets your Aurora global database's secondary DB clusters forward write operations to the primary cluster. For more information, see Using write forwarding in an Amazon Aurora global database (p. 1831).

7. Choose Add region.

After you finish adding the Region to your Aurora global database, you can see it in the list of Databases in the AWS Management Console as shown in the screenshot.
AWS CLI

To add a secondary AWS Region to an Aurora global database

1. Use the `create-db-cluster` CLI command with the name (`--global-cluster-identifier`) of your Aurora global database. For other parameters, do the following:
2. For `--region`, choose a different AWS Region than that of your Aurora primary Region.
3. Choose specific values for the `--engine` and `--engine-version` parameters. These values are the same as those for the primary Aurora DB cluster in your Aurora global database.
4. For an encrypted cluster, specify your primary AWS Region as the `--source-region` for encryption.

The following example creates a new Aurora DB cluster and attaches it to an Aurora global database as a read-only secondary Aurora DB cluster. In the last step, an Aurora DB instance is added to the new Aurora DB cluster.

For Linux, macOS, or Unix:

```bash
aws rds --region secondary_region
create-db-cluster
  --db-cluster-identifier secondary_cluster_id
  --global-cluster-identifier global_database_id
  --engine aurora-mysql|aurora-postgresql
  --engine-version version
aws rds --region secondary_region
create-db-instance
  --db-instance-class instance_class
  --db-cluster-identifier secondary_cluster_id
  --db-instance-identifier db_instance_id
  --engine aurora-mysql|aurora-postgresql
```

For Windows:

```bash
aws rds --region secondary_region
create-db-cluster
  --db-cluster-identifier secondary_cluster_id
  --global-cluster-identifier global_database_id
  --engine aurora-mysql|aurora-postgresql
```
Creating a headless Aurora DB cluster in a secondary Region

Although an Aurora global database requires at least one secondary Aurora DB cluster in a different AWS Region than the primary, you can use a headless configuration for the secondary cluster. A headless secondary Aurora DB cluster is one without a DB instance. This type of configuration can lower expenses for an Aurora global database. In an Aurora DB cluster, compute and storage are decoupled. Without the DB instance, you're not charged for compute, only for storage. If it's set up correctly, a headless secondary's storage volume is kept in-sync with the primary Aurora DB cluster.

You add the secondary cluster as you normally do when creating an Aurora global database. However, after the primary Aurora DB cluster begins replication to the secondary, you delete the Aurora read-only DB instance from the secondary Aurora DB cluster. This secondary cluster is now considered “headless” because it no longer has a DB instance. Yet, the storage volume is kept in sync with the primary Aurora DB cluster.

**Warning**

With Aurora PostgreSQL, to create a headless cluster in a secondary AWS Region, use the AWS CLI or RDS API to add the secondary AWS Region. Skip the step to create the reader DB instance for the secondary cluster. Currently, creating a headless cluster isn't supported in the RDS Console. For the CLI and API procedures to use, see [Adding an AWS Region to an Amazon Aurora global database](p. 1817).

If your global database is using an engine version lower than 13.4, 12.8, or 11.13, creating a reader DB instance in a secondary Region and subsequently deleting it could lead to an Aurora PostgreSQL vacuum issue on the primary Region's writer DB instance. If you encounter this issue, restart the primary Region's writer DB instance after you delete the secondary Region's reader DB instance.

**To add a headless secondary Aurora DB cluster to your Aurora global database**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane of the AWS Management Console, choose Databases.
3. Choose the Aurora global database that needs a secondary Aurora DB cluster. Ensure that the primary Aurora DB cluster is Available.
4. For Actions, choose Add region.
5. On the Add a region page, choose the secondary AWS Region.

You can't choose an AWS Region that already has a secondary Aurora DB cluster for the same Aurora global database. Also, it can't be the same Region as the primary Aurora DB cluster.
6. Complete the remaining fields for the secondary Aurora cluster in the new AWS Region. These are the same configuration options as for any Aurora DB cluster instance.

For an Aurora MySQL–based Aurora global database, disregard the **Enable read replica write forwarding** option. This option has no function after you delete the reader instance.

7. Choose **Add region**. After you finish adding the Region to your Aurora global database, you can see it in the list of **Databases** in the AWS Management Console as shown in the screenshot.

8. Check the status of the secondary Aurora DB cluster and its reader instance before continuing, by using the AWS Management Console or the AWS CLI. For example:

```
$ aws rds describe-db-clusters --db-cluster-identifier secondary-cluster-id --query ' []*.Status' --output text
```

It can take several minutes for the status of a newly added secondary Aurora DB cluster to change from **creating** to **available**. When the Aurora DB cluster is available, you can delete the reader instance.

9. Select the reader instance in the secondary Aurora DB cluster, and then choose **Delete**.

After deleting the reader instance, the secondary cluster remains part of the Aurora global database. It has no instance associated with it, as shown following.
You can use this headless secondary Aurora DB cluster to manually recover your Amazon Aurora global database from an unplanned outage in the primary AWS Region (p. 1855) if such an outage occurs.

Using a snapshot for your Amazon Aurora global database

You can restore a snapshot of an Aurora DB cluster or from an Amazon RDS DB instance to use as the starting point for your Aurora global database. You restore the snapshot and create a new Aurora provisioned DB cluster at the same time. You then add another AWS Region to the restored DB cluster, thus turning it into an Aurora global database. Any Aurora DB cluster that you create using a snapshot in this way becomes the primary cluster of your Aurora global database.

The snapshot that you use can be from a provisioned or from a serverless Aurora DB cluster.

During the restore process, choose the same DB engine type as the snapshot. For example, suppose that you want to restore a snapshot that was made from an Aurora Serverless DB cluster running Aurora PostgreSQL. In this case, you create an Aurora PostgreSQL DB cluster using that same Aurora DB engine and version.

The restored DB cluster assumes the role of primary cluster for the Aurora global database when you add an AWS Region to it. All data contained in this primary cluster is replicated to any secondary clusters that you add to your Aurora global database.
Managing an Amazon Aurora global database

You perform most management operations on the individual clusters that make up an Aurora global database. When you choose Group related resources on the Databases page in the console, you see the primary cluster and secondary clusters grouped under the associated global database. To find the AWS Regions where a global database's DB clusters are running, its Aurora DB engine and version, and its identifier, use its Configuration tab.

The cross-Region database failover processes are available to Aurora global databases only, not for a single Aurora DB cluster. To learn more, see Using switchover or failover in an Amazon Aurora global database (p. 1854).

To recover an Aurora global database from an unplanned outage in its primary Region, see Recovering an Amazon Aurora global database from an unplanned outage (p. 1855).

- Modifying parameters for an Aurora global database (p. 1826)
Modifying an Amazon Aurora global database

The Databases page in the AWS Management Console lists all your Aurora global databases, showing the primary cluster and secondary clusters for each one. The Aurora global database has its own configuration settings. Specifically, it has AWS Regions associated with its primary and secondary clusters, as shown in the screenshot following.

![Aurora Global Database Screenshot](image)

When you make changes to the Aurora global database, you have a chance to cancel changes, as shown in the following screenshot.
When you choose Continue, you confirm the changes.

Modifying parameters for an Aurora global database

You can configure the Aurora DB cluster parameter groups independently for each Aurora cluster within the Aurora global database. Most parameters work the same as for other kinds of Aurora clusters. We recommend that you keep settings consistent among all the clusters in a global database. Doing this helps to avoid unexpected behavior changes if you promote a secondary cluster to be the primary.

For example, use the same settings for time zones and character sets to avoid inconsistent behavior if a different cluster takes over as the primary cluster.

The aurora_enable_repl_bin_log_filtering and aurora_enable_replica_log_compression configuration settings have no effect.

Removing a cluster from an Amazon Aurora global database

You can remove Aurora DB clusters from your Aurora global database for several different reasons. For example, you might want to remove an Aurora DB cluster from an Aurora global database if the primary cluster becomes degraded or isolated. It then becomes a standalone provisioned Aurora DB cluster that could be used to create a new Aurora global database. To learn more, see Recovering an Amazon Aurora global database from an unplanned outage (p. 1855).

You also might want to remove Aurora DB clusters because you want to delete an Aurora global database that you no longer need. You can’t delete the Aurora global database until after you remove (detach) all associated Aurora DB clusters, leaving the primary for last. For more information, see Deleting an Amazon Aurora global database (p. 1829).
When an Aurora DB cluster is detached from the Aurora global database, it’s no longer synchronized with the primary. It becomes a standalone provisioned Aurora DB cluster with full read/write capabilities.

You can remove Aurora DB clusters from your Aurora global database using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To remove an Aurora cluster from an Aurora global database**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Choose the cluster on the Databases page.
3. For Actions, choose Remove from Global.

You see a prompt to confirm that you want to detach the secondary from the Aurora global database.

4. Choose Remove and promote to remove the cluster from the global database.

The Aurora DB cluster is no longer serving as a secondary in the Aurora global database, and is no longer synchronized with the primary DB cluster. It is a standalone Aurora DB cluster with full read/write capability.
After you remove or delete all secondary clusters, then you can remove the primary cluster the same way. You can't detach (remove) the primary Aurora DB cluster from an Aurora global database until after you remove all secondary clusters.

The Aurora global database might remain in the Databases list, with zero Regions and AZs. You can delete if you no longer want to use this Aurora global database. For more information, see Deleting an Amazon Aurora global database (p. 1829).

AWS CLI

To remove an Aurora cluster from an Aurora global database, run the remove-from-global-cluster CLI command with the following parameters:

- --global-cluster-identifier – The name (identifier) of your Aurora global database.
- --db-cluster-identifier – The name of each Aurora DB cluster to remove from the Aurora global database. Remove all secondary Aurora DB clusters before removing the primary.

The following examples first remove a secondary cluster and then the primary cluster from an Aurora global database.

For Linux, macOS, or Unix:

```
aws rds --region secondary_region \
    remove-from-global-cluster \
    --db-cluster-identifier secondary_cluster_ARN \
    --global-cluster-identifier global_database_id
aws rds --region primary_region \
    remove-from-global-cluster \
    --db-cluster-identifier primary_cluster_ARN \
    --global-cluster-identifier global_database_id
```

Repeat the remove-from-global-cluster --db-cluster-identifier secondary_cluster_ARN command for each secondary AWS Region in your Aurora global database.

For Windows:

```
aws rds --region secondary_region ^
    remove-from-global-cluster ^
    --db-cluster-identifier secondary_cluster_ARN ^
    --global-cluster-identifier global_database_id
aws rds --region primary_region ^
    remove-from-global-cluster ^
    --db-cluster-identifier primary_cluster_ARN ^
    --global-cluster-identifier global_database_id
```
Repeat the `remove-from-global-cluster --db-cluster-identifier secondary_cluster_ARN` command for each secondary AWS Region in your Aurora global database.

**RDS API**

To remove an Aurora cluster from an Aurora global database with the RDS API, run the `RemoveFromGlobalCluster` action.

## Deleting an Amazon Aurora global database

Because an Aurora global database typically holds business-critical data, you can't delete the global database and its associated clusters in a single step. To delete an Aurora global database, do the following:

- Remove all secondary DB clusters from the Aurora global database. Each cluster becomes a standalone Aurora DB cluster. To learn how, see [Removing a cluster from an Amazon Aurora global database](p. 1826).
- From each standalone Aurora DB cluster, delete all Aurora Replicas.
- Remove the primary DB cluster from the Aurora global database. This becomes a standalone Aurora DB cluster.
- From the Aurora primary DB cluster, first delete all Aurora Replicas, then delete the writer DB instance.

Deleting the writer instance from the newly standalone Aurora DB cluster also typically removes the Aurora DB cluster and the Aurora global database.

For more general information, see [Deleting a DB instance from an Aurora DB cluster (p. 380)](p. 380).

To delete an Aurora global database, you can use the AWS Management Console, the AWS CLI, or the RDS API.

### Console

#### To delete an Aurora global database

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Choose **Databases** and find the Aurora global database you want to delete in the listing.
3. Confirm that all clusters are removed from the Aurora global database. The Aurora global database should show 0 Regions and AZs and a size of 0 clusters.

   If the Aurora global database contains any Aurora DB clusters, you can't delete it. If necessary, detach the primary and secondary Aurora DB clusters from the Aurora global database. For more information, see [Removing a cluster from an Amazon Aurora global database (p. 1826)](p. 1826).
4. Choose your Aurora global database in the list, and then choose **Delete** from the **Actions** menu.
Connecting to an Aurora global database

How you connect to an Aurora global database depends on whether you need to write to the database or read from the database:

- For read-only requests or queries, you connect to the reader endpoint for the Aurora cluster in your AWS Region.
- To run data manipulation language (DML) or data definition language (DDL) statements, you connect to the cluster endpoint for the primary cluster. This endpoint might be in a different AWS Region than your application.

When you view an Aurora global database in the console, you can see all the general-purpose endpoints associated with all of its clusters. The following screenshot shows an example. There is a single cluster endpoint associated with the primary cluster that you use for write operations. The primary cluster and each secondary cluster has a reader endpoint that you use for read-only queries. To minimize latency, choose whichever reader endpoint is in your AWS Region or the AWS Region closest to you. The following shows an Aurora MySQL example.
Using write forwarding in an Amazon Aurora global database

You can reduce the number of endpoints that you need to manage for applications running on your Aurora global database, by using write forwarding. With write forwarding enabled, secondary clusters in an Aurora global database forward SQL statements that perform write operations to the primary cluster. The primary cluster updates the source and then propagates resulting changes back to all secondary AWS Regions.

The write forwarding configuration saves you from implementing your own mechanism to send write operations from a secondary AWS Region to the primary Region. Aurora handles the cross-Region networking setup. Aurora also transmits all necessary session and transactional context for each statement. The data is always changed first on the primary cluster and then replicated to the secondary clusters in the Aurora global database. This way, the primary cluster is the source of truth and always has an up-to-date copy of all your data.

- Enabling write forwarding in Aurora MySQL (p. 1832)
- Checking if a secondary cluster has write forwarding enabled in Aurora MySQL (p. 1834)
Region and version availability of write forwarding in Aurora MySQL

Write forwarding is supported with Aurora MySQL 2.08.1 and higher versions, in every Region where Aurora MySQL-based global databases are available.

For information on version and Region availability of Aurora MySQL global databases, see [Aurora global databases with Aurora MySQL](p. 33).

Enabling write forwarding in Aurora MySQL

By default, write forwarding isn't enabled when you add a secondary cluster to an Aurora global database.

To enable write forwarding using the AWS Management Console, select the **Turn on global write forwarding** check box under **Read replica write forwarding** when you add a Region for a global database. For an existing secondary cluster, modify the cluster to **Turn on global write forwarding**. To turn off write forwarding, clear the **Turn on global write forwarding** check box when adding the Region or modifying the secondary cluster.

To enable write forwarding using the AWS CLI, use the `--enable-global-write-forwarding` option. This option works when you create a new secondary cluster using the `create-db-cluster` command. It also works when you modify an existing secondary cluster using the `modify-db-cluster` command. It requires that the global database uses an Aurora version that supports write forwarding. You can turn write forwarding off by using the `--no-enable-global-write-forwarding` option with these same CLI commands.

To enable write forwarding using the Amazon RDS API, set the `EnableGlobalWriteForwarding` parameter to `true`. This parameter works when you create a new secondary cluster using the `CreateDBCluster` operation. It also works when you modify an existing secondary cluster using the `ModifyDBCluster` operation. It requires that the global database uses an Aurora version that supports write forwarding. You can turn write forwarding off by setting the `EnableGlobalWriteForwarding` parameter to `false`.

**Note**

For a database session to use write forwarding, specify a setting for the `aurora_replica_read_consistency` configuration parameter. Do this in every session that uses the write forwarding feature. For information about this parameter, see [Isolation and consistency for write forwarding in Aurora MySQL](p. 1836). The RDS Proxy feature doesn't support the `SESSION` value for the `aurora_replica_read_consistency` variable. Setting this value can cause unexpected behavior.

The following CLI examples show how you can set up an Aurora global database with write forwarding enabled or disabled. The highlighted items represent the commands and options that are important to specify and keep consistent when setting up the infrastructure for an Aurora global database.

The following example creates an Aurora global database, a primary cluster, and a secondary cluster with write forwarding enabled. Substitute your own choices for the user name, password, and primary and secondary AWS Regions.
# Create overall global database.
aws rds create-global-cluster --global-cluster-identifier write-forwarding-test \
    --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
    --region us-east-1

# Create primary cluster, in the same AWS Region as the global database.
aws rds create-db-cluster --global-cluster-identifier write-forwarding-test \
    --db-cluster-identifier write-forwarding-test-cluster-1 \
    --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
    --master-username user_name --master-user-password password \
    --region us-east-1

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-1 \
    --db-instance-identifier write-forwarding-test-cluster-1-instance-1 \
    --db-instance-class db.r5.large \
    --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
    --region us-east-1

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-1 \
    --db-instance-identifier write-forwarding-test-cluster-1-instance-2 \
    --db-instance-class db.r5.large \
    --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
    --region us-east-1

# Create secondary cluster, in a different AWS Region than the global database, 
# with write forwarding enabled.
aws rds create-db-cluster --global-cluster-identifier write-forwarding-test \
    --db-cluster-identifier write-forwarding-test-cluster-2 \
    --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
    --region us-east-2 \
    --enable-global-write-forwarding

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-2 \
    --db-instance-identifier write-forwarding-test-cluster-2-instance-1 \
    --db-instance-class db.r5.large \
    --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
    --region us-east-2

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-2 \
    --db-instance-identifier write-forwarding-test-cluster-2-instance-2 \
    --db-instance-class db.r5.large \
    --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
    --region us-east-2

# Create secondary cluster, in a different AWS Region than the global database, 
# without write forwarding enabled.
aws rds create-db-cluster --global-cluster-identifier write-forwarding-test \
    --db-cluster-identifier write-forwarding-test-cluster-2 \
    --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
    --region us-west-1

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-2 \
    --db-instance-identifier write-forwarding-test-cluster-2-instance-1 \
    --db-instance-class db.r5.large \
    --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
    --region us-west-1

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-2 \
    --db-instance-identifier write-forwarding-test-cluster-2-instance-2 \
    --db-instance-class db.r5.large \
    --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
    --region us-west-1

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-2 \
    --db-instance-identifier write-forwarding-test-cluster-2-instance-2 \
    --db-instance-class db.r5.large \

The following example continues from the previous one. It creates a secondary cluster without write forwarding enabled, then enables write forwarding. After this example finishes, all secondary clusters in the global database have write forwarding enabled.

# Create secondary cluster, in a different AWS Region than the global database, 
# without write forwarding enabled.
aws rds create-db-cluster --global-cluster-identifier write-forwarding-test \
    --db-cluster-identifier write-forwarding-test-cluster-2 \
    --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
    --region us-west-1

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-2 \
    --db-instance-identifier write-forwarding-test-cluster-2-instance-1 \
    --db-instance-class db.r5.large \
    --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
    --region us-west-1

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-2 \
    --db-instance-identifier write-forwarding-test-cluster-2-instance-2 \
    --db-instance-class db.r5.large \
    --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
    --region us-west-1

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-2 \
    --db-instance-identifier write-forwarding-test-cluster-2-instance-2 \
    --db-instance-class db.r5.large \

Checking if a secondary cluster has write forwarding enabled in Aurora MySQL

To determine whether you can use write forwarding from a secondary cluster, you can check whether the cluster has the attribute "GlobalWriteForwardingStatus": "enabled".

In the AWS Management Console, on the Configuration tab of the details page for the cluster, you see the status Enabled for Global read replica write forwarding.

To see the status of the global write forwarding setting for all of your clusters, run the following AWS CLI command.

A secondary cluster shows the value "enabled" or "disabled" to indicate if write forwarding is turned on or off. A value of null indicates that write forwarding isn't available for that cluster. Either the cluster isn't part of a global database, or is the primary cluster instead of a secondary cluster. The value can also be "enabling" or "disabling" if write forwarding is in the process of being turned on or off.

Example

```
aws rds describe-db-clusters \
--query '*[
{DBClusterIdentifier:DBClusterIdentifier,GlobalWriteForwardingStatus:GlobalWriteForwardingStatus}]
]
{ "GlobalWriteForwardingStatus": "enabled",
 "DBClusterIdentifier": "aurora-write-forwarding-test-replica-1"
 },
 { "GlobalWriteForwardingStatus": "disabled",
 "DBClusterIdentifier": "aurora-write-forwarding-test-replica-2"
 },
 { "GlobalWriteForwardingStatus": null,
 "DBClusterIdentifier": "non-global-cluster"
 }
]
```

To find all secondary clusters that have global write forwarding enabled, run the following command. This command also returns the cluster's reader endpoint. You use the secondary cluster's reader endpoint when you use write forwarding from the secondary to the primary in your Aurora global database.

Example

```
aws rds describe-db-clusters --query 'DBClusters[
{DBClusterIdentifier:DBClusterIdentifier,GlobalWriteForwardingStatus:GlobalWriteForwardingStatus,ReaderEndpoint:ReaderEndpoint} | [GlobalWriteForwardingStatus == 'enabled']]
[
 { "GlobalWriteForwardingStatus": "enabled",
 "ReaderEndpoint": "aurora-write-forwarding-test-replica-1.cluster-ro-cnpexample.us-west-2.rds.amazonaws.com",
 "DBClusterIdentifier": "aurora-write-forwarding-test-replica-1"
 }
]
Application and SQL compatibility with write forwarding in Aurora MySQL

You can use the following kinds of SQL statements with write forwarding:

- Data manipulation language (DML) statements, such as INSERT, DELETE, and UPDATE. There are some restrictions on the properties of these statements that you can use with write forwarding, as described following.
- SELECT ... LOCK IN SHARE MODE and SELECT FOR UPDATE statements.
- PREPARE and EXECUTE statements.

Certain statements aren't allowed or can produce stale results when you use them in a global database with write forwarding. Thus, the EnableGlobalWriteForwarding setting is turned off by default for secondary clusters. Before turning it on, check to make sure that your application code isn't affected by any of these restrictions.

The following restrictions apply to the SQL statements you use with write forwarding. In some cases, you can use the statements on secondary clusters with write forwarding enabled at the cluster level. This approach works if write forwarding isn't turned on within the session by the aurora_replica_read_consistency configuration parameter. Trying to use a statement when it's not allowed because of write forwarding causes an error message with the following format.

```
ERROR 1235 (42000): This version of MySQL doesn't yet support 'operation with write forwarding'.
```

**Data definition language (DDL)**

Connect to the primary cluster to run DDL statements. You can't run them from reader DB instances.

**Updating a permanent table using data from a temporary table**

You can use temporary tables on secondary clusters with write forwarding enabled. However, you can't use a DML statement to modify a permanent table if the statement refers to a temporary table. For example, you can't use an INSERT ... SELECT statement that takes the data from a temporary table. The temporary table exists on the secondary cluster and isn't available when the statement runs on the primary cluster.

**XA transactions**

You can't use the following statements on a secondary cluster when write forwarding is turned on within the session. You can use these statements on secondary clusters that don't have write forwarding enabled, or within sessions where the aurora_replica_read_consistency setting is empty. Before turning on write forwarding within a session, check if your code uses these statements.

```
XA {START|BEGIN} xid [JOIN|RESUME]
XA END xid [SUSPEND [FOR MIGRATE]]
XA PREPARE xid
XA COMMIT xid [ONE PHASE]
XA ROLLBACK xid
XA RECOVER [CONVERT XID]
```

**LOAD statements for permanent tables**

You can't use the following statements on a secondary cluster with write forwarding enabled.
LOAD DATA INFILE 'data.txt' INTO TABLE t1;
LOAD XML LOCAL INFILE 'test.xml' INTO TABLE t1;

You can load data into a temporary table on a secondary cluster. However, make sure that you run any LOAD statements that refer to permanent tables only on the primary cluster.

**Plugin statements**

You can't use the following statements on a secondary cluster with write forwarding enabled.

```sql
INSTALL PLUGIN example SONAME 'ha_example.so';
UNINSTALL PLUGIN example;
```

**SAVEPOINT statements**

You can't use the following statements on a secondary cluster when write forwarding is turned on within the session. You can use these statements on secondary clusters that don't have write forwarding enabled, or within sessions where the `aurora_replica_read_consistency` setting is blank. Check if your code uses these statements before turning on write forwarding within a session.

```sql
SAVEPOINT t1_save;
ROLLBACK TO SAVEPOINT t1_save;
RELEASE SAVEPOINT t1_save;
```

**Isolation and consistency for write forwarding in Aurora MySQL**

In sessions that use write forwarding, you can only use the REPEATABLE_READ isolation level. Although you can also use the READ COMMITTED isolation level with read-only clusters in secondary AWS Regions, that isolation level doesn't work with write forwarding. For information about the REPEATABLE_READ and READ COMMITTED isolation levels, see Aurora MySQL isolation levels (p. 1158).

You can control the degree of read consistency on a secondary cluster. The read consistency level determines how much waiting the secondary cluster does before each read operation to ensure that some or all changes are replicated from the primary cluster. You can adjust the read consistency level to ensure that all forwarded write operations from your session are visible in the secondary cluster before any subsequent queries. You can also use this setting to ensure that queries on the secondary cluster always see the most current updates from the primary cluster. This is so even for those submitted by other sessions or other clusters. To specify this type of behavior for your application, you choose a value for the session-level parameter `aurora_replica_read_consistency`.

**Important**

Always set the `aurora_replica_read_consistency` parameter for any session for which you want to forward writes. If you don't, Aurora doesn't enable write forwarding for that session. This parameter has an empty value by default, so choose a specific value when you use this parameter. The `aurora_replica_read_consistency` parameter has an effect only on secondary clusters that have write forwarding enabled.

For Aurora MySQL version 2 and version 3 lower than 3.04, use `aurora_replica_read_consistency` as a session variable. For Aurora MySQL version 3.04 and higher, you can use `aurora_replica_read_consistency` as either a session variable or as a DB cluster parameter.

For the `aurora_replica_read_consistency` parameter, you can specify the values EVENTUAL, SESSION, and GLOBAL.

As you increase the consistency level, your application spends more time waiting for changes to be propagated between AWS Regions. You can choose the balance between fast response time and ensuring that changes made in other locations are fully available before your queries run.
With the read consistency set to EVENTUAL, queries in a secondary AWS Region that uses write forwarding might see data that is slightly stale due to replication lag. Results of write operations in the same session aren’t visible until the write operation is performed on the primary Region and replicated to the current Region. The query doesn’t wait for the updated results to be available. Thus, it might retrieve the older data or the updated data, depending on the timing of the statements and the amount of replication lag.

With the read consistency set to SESSION, all queries in a secondary AWS Region that uses write forwarding see the results of all changes made in that session. The changes are visible regardless of whether the transaction is committed. If necessary, the query waits for the results of forwarded write operations to be replicated to the current Region. It doesn’t wait for updated results from write operations performed in other Regions or in other sessions within the current Region.

With the read consistency set to GLOBAL, a session in a secondary AWS Region sees changes made by that session. It also sees all committed changes from both the primary AWS Region and other secondary AWS Regions. Each query might wait for a period that varies depending on the amount of session lag. The query proceeds when the secondary cluster is up-to-date with all committed data from the primary cluster, as of the time that the query began.

For more information about all the parameters involved with write forwarding, see Configuration parameters for write forwarding in Aurora MySQL (p. 1839).

Examples of using write forwarding

These examples use aurora_replica_read_consistency as a session variable. For Aurora MySQL version 3.04 and higher, you can use aurora_replica_read_consistency as either a session variable or as a DB cluster parameter.

In the following example, the primary cluster is in the US East (N. Virginia) Region. The secondary cluster is in the US East (Ohio) Region. The example shows the effects of running INSERT statements followed by SELECT statements. Depending on the value of the aurora_replica_read_consistency setting, the results might differ depending on the timing of the statements. To achieve higher consistency, you might wait briefly before issuing the SELECT statement. Or Aurora can automatically wait until the results finish replicating before proceeding with SELECT.

In this example, there is a read consistency setting of eventual. Running an INSERT statement immediately followed by a SELECT statement still returns the value of COUNT(*). This value reflects the number of rows before the new row is inserted. Running the SELECT again a short time later returns the updated row count. The SELECT statements don't wait.

```sql
mysql> set aurora_replica_read_consistency = 'eventual';
mysql> select count(*) from t1;
+----------+
<table>
<thead>
<tr>
<th>count(*)</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
</tr>
</tbody>
</table>
+----------+
1 row in set (0.00 sec)
mysql> insert into t1 values (6); select count(*) from t1;
+----------+
<table>
<thead>
<tr>
<th>count(*)</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
</tr>
</tbody>
</table>
+----------+
1 row in set (0.00 sec)
mysql> select count(*) from t1;
+----------+
<table>
<thead>
<tr>
<th>count(*)</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
</tr>
</tbody>
</table>
+----------+
```
With a read consistency setting of `session`, a SELECT statement immediately after an INSERT waits until the changes from the INSERT statement are visible. Subsequent SELECT statements don't wait.

```
mysql> set aurora_replica_read_consistency = 'session';
mysql> select count(*) from t1;
+----------+
| count(*) |
+----------+
|       6   |
+----------+
1 row in set (0.01 sec)
mysql> insert into t1 values (6); select count(*) from t1; select count(*) from t1;
Query OK, 1 row affected (0.08 sec)
+----------+
| count(*) |
+----------+
|       7   |
+----------+
1 row in set (0.37 sec)
+----------+
| count(*) |
+----------+
|       7   |
+----------+
1 row in set (0.00 sec)
```

With the read consistency setting still set to `session`, introducing a brief wait after performing an INSERT statement makes the updated row count available by the time the next SELECT statement runs.

```
mysql> insert into t1 values (6); select sleep(2); select count(*) from t1;
Query OK, 1 row affected (0.07 sec)
+----------+
| sleep(2) |
+----------+
|        0   |
+----------+
1 row in set (2.01 sec)
+----------+
| count(*) |
+----------+
|        8   |
+----------+
1 row in set (0.00 sec)
```

With a read consistency setting of `global`, each SELECT statement waits to ensure that all data changes as of the start time of the statement are visible before performing the query. The amount of waiting for each SELECT statement varies, depending on the amount of replication lag between the primary and secondary clusters.

```
mysql> set aurora_replica_read_consistency = 'global';
mysql> select count(*) from t1;
+----------+
| count(*) |
+----------+
|        8   |
+----------+
1 row in set (0.75 sec)
mysql> select count(*) from t1;
+----------+
| count(*) |
+----------+
1 row in set (0.00 sec)
```
Running multipart statements with write forwarding in Aurora MySQL

A DML statement might consist of multiple parts, such as a `INSERT ... SELECT` statement or a `DELETE ... WHERE` statement. In this case, the entire statement is forwarded to the primary cluster and run there.

Transactions with write forwarding in Aurora MySQL

Whether the transaction is forwarded to the primary cluster depends on the access mode of the transaction. You can specify the access mode for the transaction by using the `SET TRANSACTION` statement or the `START TRANSACTION` statement. You can also specify the transaction access mode by changing the value of the Aurora MySQL session variable `tx_read_only`. You can only change this session value while you're connected to a secondary cluster that has write forwarding enabled.

If a long-running transaction doesn't issue any statement for a substantial period of time, it might exceed the idle timeout period. This period has a default of one minute. You can increase it up to one day. A transaction that exceeds the idle timeout is canceled by the primary cluster. The next subsequent statement you submit receives a timeout error. Then Aurora rolls back the transaction.

This type of error can occur in other cases when write forwarding becomes unavailable. For example, Aurora cancels any transactions that use write forwarding if you restart the primary cluster or if you turn off the write forwarding configuration setting.

Configuration parameters for write forwarding in Aurora MySQL

The Aurora cluster parameter groups include settings for the write forwarding feature. Because these are cluster parameters, all DB instances in each cluster have the same values for these variables. Details about these parameters are summarized in the following table, with usage notes after the table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Type</th>
<th>Default value</th>
<th>Valid values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>aurora_fwd_master_idle_timeout</code></td>
<td>Global</td>
<td>unsigned int</td>
<td>60</td>
<td>1–86,400</td>
</tr>
<tr>
<td>(Aurora MySQL version 2)</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>aurora_fwd_master_max_connections</code></td>
<td>Global</td>
<td>unsigned long</td>
<td>10</td>
<td>0–90</td>
</tr>
<tr>
<td>(Aurora MySQL version 2)</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>aurora_fwd_writer_idle_timeout</code></td>
<td>Global</td>
<td>unsigned int</td>
<td>60</td>
<td>1–86,400</td>
</tr>
<tr>
<td>(Aurora MySQL version 3)</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>aurora_fwd_writer_max_connections</code></td>
<td>Global</td>
<td>unsigned long</td>
<td>10</td>
<td>0–90</td>
</tr>
<tr>
<td>(Aurora MySQL version 3)</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
To control incoming write requests from secondary clusters, use these settings on the primary cluster:

- **aurora_fwd_master_idle_timeout, aurora_fwd_writer_idle_timeout**: The number of seconds the primary cluster waits for activity on a connection that's forwarded from a secondary cluster before closing it. If the session remains idle beyond this period, Aurora cancels the session.

- **aurora_fwd_master_max_connections_pct, aurora_fwd_writer_max_connections_pct**: The upper limit on database connections that can be used on a writer DB instance to handle queries forwarded from readers. It's expressed as a percentage of the max_connections setting for the writer DB instance in the primary cluster. For example, if max_connections is 800 and aurora_fwd_master_max_connections_pct or aurora_fwd_writer_max_connections_pct is 10, then the writer allows a maximum of 80 simultaneous forwarded sessions. These connections come from the same connection pool managed by the max_connections setting.

This setting applies only on the primary cluster, when one or more secondary clusters have write forwarding enabled. If you decrease the value, existing connections aren't affected. Aurora takes the new value of the setting into account when attempting to create a new connection from a secondary cluster. The default value is 10, representing 10% of the max_connections value. If you enable query forwarding on any of the secondary clusters, this setting must have a nonzero value for write operations from secondary clusters to succeed. If the value is zero, the write operations receive the error code ER_CON_COUNT_ERROR with the message Not enough connections on writer to handle your request.

The **aurora_replica_read_consistency** parameter is a session-level parameter that enables write forwarding. You use it in each session. You can specify EVENTUAL, SESSION, or GLOBAL for read consistency level. To learn more about consistency levels, see [Isolation and consistency for write forwarding in Aurora MySQL](p. 1836). The following rules apply to this parameter:

- This is a session-level parameter. The default value is " (empty).
- Write forwarding is available in a session only if aurora_replica_read_consistency is set to EVENTUAL or SESSION or GLOBAL. This parameter is relevant only in reader instances of secondary clusters that have write forwarding enabled and that are in an Aurora global database.
- You can't set this variable (when empty) or unset (when already set) inside a multistatement transaction. However, you can change it from one valid value (EVENTUAL, SESSION, or GLOBAL) to another valid value (EVENTUAL, SESSION, or GLOBAL) during such a transaction.
- The variable can't be SET when write forwarding isn't enabled on the secondary cluster.
- Setting the session variable on a primary cluster doesn't have any effect. If you try to modify this variable on a primary cluster, you receive an error.

**Amazon CloudWatch metrics for write forwarding in Aurora MySQL**

The following Amazon CloudWatch metrics and Aurora MySQL status variables apply to the primary cluster when you use write forwarding on one or more secondary clusters. These metrics are all measured on the writer DB instance in the primary cluster.
<table>
<thead>
<tr>
<th>CloudWatch metric</th>
<th>Aurora MySQL status variable</th>

Region and version availability of write forwarding in Aurora PostgreSQL

Write forwarding is supported with Aurora PostgreSQL version 15.4 and higher minor versions, and version 14.9 and higher minor versions. Write forwarding is available in every Region where Aurora PostgreSQL-based global databases are available.

For more information on version and Region availability of Aurora PostgreSQL global databases, see Aurora global databases with Aurora PostgreSQL (p. 34).

Enabling write forwarding in Aurora PostgreSQL

By default, write forwarding isn't enabled when you add a secondary cluster to an Aurora global database. You can enable write forwarding for your secondary DB cluster while you're creating it or anytime after you create it. If needed, you can disable it later. Enabling or disabling write forwarding doesn't cause downtime or a reboot.

Console

In the console, you can enable or disable write forwarding when you create or modify a secondary DB cluster.

Enabling or disabling write forwarding when creating a secondary DB cluster

When you create a new secondary DB cluster, you enable write forwarding by selecting the Turn on global write forwarding check box under Read replica write forwarding. Or clear the check box to disable it. To create a secondary DB cluster, follow the instructions for your DB engine in Creating an Amazon Aurora DB cluster (p. 179).

The following screenshot shows the Read replica write forwarding section with the Turn on global write forwarding check box selected.

![Read replica write forwarding](image)

Enabling or disabling write forwarding when modifying a secondary DB cluster

In the console, you can modify a secondary DB cluster to enable or disable write forwarding.

To enable or disable write forwarding for a secondary DB cluster by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Databases.
3. Choose the secondary DB cluster, and choose Modify.
4. In the Read replica write forwarding section, check or clear the Turn on global write forwarding check box.
5. Choose Continue.
6. For Schedule modifications, choose Apply immediately. If you choose Apply during the next scheduled maintenance window, Aurora ignores this setting and turns on write forwarding immediately.
7. Choose Modify cluster.

AWS CLI

To enable write forwarding by using the AWS CLI, use the --enable-global-write-forwarding option. This option works when you create a new secondary cluster using the create-db-cluster command. It also works when you modify an existing secondary cluster using the modify-db-cluster command. It requires that the global database uses an Aurora version that supports write forwarding. You can disable write forwarding by using the --no-enable-global-write-forwarding option with these same CLI commands.
The following procedures describe how to enable or disable write forwarding for a secondary DB cluster in your global cluster by using the AWS CLI.

To enable or disable write forwarding for an existing secondary DB cluster

- Call the `modify-db-cluster` AWS CLI command and supply the following values:
  - `--db-cluster-identifier` - The name of the DB cluster.
  - `--enable-global-write-forwarding` to turn on or `--no-enable-global-write-forwarding` to turn off.

The following example enables write forwarding for DB cluster `sample-secondary-db-cluster`.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster
   --db-cluster-identifier sample-secondary-db-cluster
   --enable-global-write-forwarding
```

For Windows:

```bash
aws rds modify-db-cluster
   --db-cluster-identifier sample-secondary-db-cluster
   --enable-global-write-forwarding
```

RDS API

To enable write forwarding using the Amazon RDS API, set the `EnableGlobalWriteForwarding` parameter to `true`. This parameter works when you create a new secondary cluster using the `CreateDBCluster` operation. It also works when you modify an existing secondary cluster using the `ModifyDBCluster` operation. It requires that the global database uses an Aurora version that supports write forwarding. You can disable write forwarding by setting the `EnableGlobalWriteForwarding` parameter to `false`.

Checking if a secondary cluster has write forwarding enabled in Aurora PostgreSQL

To determine whether you can use write forwarding from a secondary cluster, you can check whether the cluster has the attribute "GlobalWriteForwardingStatus": "enabled".

In the AWS Management Console, you see Read replica write forwarding on the Configuration tab of the details page for the cluster. To see the status of the global write forwarding setting for all of your clusters, run the following AWS CLI command.

A secondary cluster shows the value "enabled" or "disabled" to indicate if write forwarding is turned on or off. A value of null indicates that write forwarding isn't available for that cluster. Either the cluster isn't part of a global database, or is the primary cluster instead of a secondary cluster. The value can also be "enabling" or "disabling" if write forwarding is in the process of being turned on or off.

Example

```bash
aws rds describe-db-clusters --query '.[0].
   {DBClusterIdentifier:DBClusterIdentifier,
   GlobalWriteForwardingStatus:GlobalWriteForwardingStatus})'
```

1846
To find all secondary clusters that have global write forwarding enabled, run the following command. This command also returns the cluster's reader endpoint. You use the secondary cluster's reader endpoint when you use write forwarding from the secondary to the primary in your Aurora global database.

**Example**

```bash
aws rds describe-db-clusters --query 'DBClusters[].{DBClusterIdentifier:DBClusterIdentifier,GlobalWriteForwardingStatus:GlobalWriteForwardingStatus,ReaderEndpoint:ReaderEndpoint}|[?GlobalWriteForwardingStatus == `enabled`]
```

**Application and SQL compatibility with write forwarding in Aurora PostgreSQL**

Certain statements aren't allowed or can produce stale results when you use them in a global database with write forwarding. Thus, the EnableGlobalWriteForwarding setting is turned off by default for secondary clusters. Before turning it on, check to make sure that your application code isn't affected by any of these restrictions.

You can use the following kinds of SQL statements with write forwarding:

- Data manipulation language (DML) statements, such as INSERT, DELETE, and UPDATE
- `SELECT FOR { UPDATE | NO KEY UPDATE | SHARE | KEY SHARE }` statements
- PREPARE and EXECUTE statements
- EXPLAIN statements with the statements in this list

The following kinds of SQL statements aren't supported with write forwarding:

- Data definition language (DDL) statements
- ANALYZE
- CLUSTER
- COPY
- Cursors – Cursors aren't supported, so make sure to close them before using write forwarding.
- GRANT|REVOKE|REASSIGN OWNED|SECURITY LABEL
- LOCK
Isolation and consistency for write forwarding in Aurora PostgreSQL

In sessions that use write forwarding, you can use the REPEATABLE READ and READ COMMITTED isolation levels. However, the SERIALIZABLE isolation level isn't supported.

You can control the degree of read consistency on a secondary cluster. The read consistency level determines how much waiting the secondary cluster does before each read operation to ensure that some or all changes are replicated from the primary cluster. You can adjust the read consistency level to ensure that all forwarded write operations from your session are visible in the secondary cluster before any subsequent queries. You can also use this setting to ensure that queries on the secondary cluster always see the most current updates from the primary cluster. This is so even for those submitted by other sessions or other clusters. To specify this type of behavior for your application, you choose the appropriate value for the session-level parameter apg_write_forward.consistency_mode. The apg_write_forward.consistency_mode parameter has an effect only on secondary clusters that have write forwarding enabled.

Note
For the apg_write_forward.consistency_mode parameter, you can specify the value SESSION, EVENTUAL, GLOBAL, or OFF. By default, the value is set to SESSION. Setting the value to OFF disables write forwarding in the session.

As you increase the consistency level, your application spends more time waiting for changes to be propagated between AWS Regions. You can choose the balance between fast response time and ensuring that changes made in other locations are fully available before your queries run.

With each available consistency mode setting, the effect is as follows:

- **SESSION** – All queries in a secondary AWS Region that uses write forwarding see the results of all changes made in that session. The changes are visible regardless of whether the transaction is committed. If necessary, the query waits for the results of forwarded write operations to be replicated to the current Region. It doesn't wait for updated results from write operations performed in other Regions or in other sessions within the current Region.

- **EVENTUAL** – Queries in a secondary AWS Region that uses write forwarding might see data that is slightly stale due to replication lag. Results of write operations in the same session aren't visible until the write operation is performed on the primary Region and replicated to the current Region. The query doesn't wait for the updated results to be available. Thus, it might retrieve the older data or the updated data, depending on the timing of the statements and the amount of replication lag.

- **GLOBAL** – A session in a secondary AWS Region sees changes made by that session. It also sees all committed changes from both the primary AWS Region and other secondary AWS Regions. Each query might wait for a period that varies depending on the amount of session lag. The query proceeds when the secondary cluster is up-to-date with all committed data from the primary cluster, as of the time that the query began.

- **OFF** – Write forwarding is disabled in the session.

For more information about all the parameters involved with write forwarding, see Configuration parameters for write forwarding in Aurora PostgreSQL (p. 1849).
Running multipart statements with write forwarding in Aurora PostgreSQL

A DML statement might consist of multiple parts, such as a INSERT ... SELECT statement or a DELETE ... WHERE statement. In this case, the entire statement is forwarded to the primary cluster and run there.

Configuration parameters for write forwarding in Aurora PostgreSQL

The Aurora cluster parameter groups include settings for the write forwarding feature. Because these are cluster parameters, all DB instances in each cluster have the same values for these variables. Details about these parameters are summarized in the following table, with usage notes after the table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Type</th>
<th>Default value</th>
<th>Valid values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apg_write_forward.connect_timeout</td>
<td>Session</td>
<td>seconds</td>
<td>30</td>
<td>0–2147483647</td>
</tr>
<tr>
<td>apg_write_forward.consistency_mode</td>
<td>Session</td>
<td>enum</td>
<td>Session</td>
<td>SESSION, EVENTUAL, GLOBAL, OFF</td>
</tr>
<tr>
<td>apg_write_forward.idle_in_transaction</td>
<td>Session</td>
<td>milliseconds</td>
<td>86400000</td>
<td>0–2147483647</td>
</tr>
<tr>
<td>apg_write_forward.idle_session_timeout</td>
<td>Session</td>
<td>milliseconds</td>
<td>300000</td>
<td>0–2147483647</td>
</tr>
<tr>
<td>apg_write_forward.max_forwarding_connections_percent</td>
<td>Global</td>
<td>int</td>
<td>25</td>
<td>1–100</td>
</tr>
</tbody>
</table>

The `apg_write_forward.max_forwarding_connections_percent` parameter is the upper limit on database connection slots that can be used to handle queries forwarded from readers. It is expressed as a percentage of the `max_connections` setting for the writer DB instance in the primary cluster. For example, if `max_connections` is 800 and `apg_write_forward.max_forwarding_connections_percent` is 10, then the writer allows a maximum of 80 simultaneous forwarded sessions. These connections come from the same connection pool managed by the `max_connections` setting. This setting applies only on the primary cluster when at least one secondary clusters has write forwarding enabled.

Use the following settings on the secondary cluster:

- `apg_write_forward.consistency_mode` – A session-level parameter that controls the degree of read consistency on the secondary cluster. Valid values are SESSION, EVENTUAL, GLOBAL, or OFF. By default, the value is set to SESSION. Setting the value to OFF disables write forwarding in the session. To learn more about consistency levels, see Isolation and consistency for write forwarding in Aurora PostgreSQL (p. 1848). This parameter is relevant only in reader instances of secondary clusters that have write forwarding enabled and that are in an Aurora global database.
- `apg_write_forward.connect_timeout` – The maximum number of seconds the secondary cluster waits when establishing a connection to the primary cluster before giving up. A value of 0 means to wait indefinitely.
- `apg_write_forward.idle_in_transaction_session_timeout` – The number of milliseconds the primary cluster waits for activity on a connection that's forwarded from a secondary cluster that
has an open transaction before closing it. If the session remains idle in transaction beyond this period, Aurora terminates the session. A value of 0 disables the timeout.

- `apg_write_forward.idle_session_timeout` – The number of milliseconds the primary cluster waits for activity on a connection that's forwarded from a secondary cluster before closing it. If the session remains idle beyond this period, Aurora terminates the session. A value of 0 disables the timeout.

### Amazon CloudWatch metrics for write forwarding in Aurora PostgreSQL

The following Amazon CloudWatch metrics apply to the primary cluster when you use write forwarding on one or more secondary clusters. These metrics are all measured on the writer DB instance in the primary cluster.

<table>
<thead>
<tr>
<th>CloudWatch Metric</th>
<th>Units and description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AuroraForwardingWriterDMLThroughput</td>
<td>Count (per second). Number of forwarded DML statements processed each second by this writer DB instance.</td>
</tr>
<tr>
<td>AuroraForwardingWriterOpenSessions</td>
<td>Count. Number of open sessions on this writer DB instance processing forwarded queries.</td>
</tr>
<tr>
<td>AuroraForwardingWriterTotalSessions</td>
<td>Count. Total number of forwarded sessions on this writer DB instance.</td>
</tr>
</tbody>
</table>

The following CloudWatch metrics apply to each secondary cluster. These metrics are measured on each reader DB instance in a secondary cluster with write forwarding enabled.

<table>
<thead>
<tr>
<th>CloudWatch Metric</th>
<th>Unit and description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AuroraForwardingReplicaCommitThroughput</td>
<td>Count (per second). Number of commits in sessions forwarded by this replica each second.</td>
</tr>
<tr>
<td>AuroraForwardingReplicaDMLLatency</td>
<td>Milliseconds. Average response time in milliseconds of forwarded DMLs on replica.</td>
</tr>
<tr>
<td>AuroraForwardingReplicaDMLThroughput</td>
<td>Count (per second). Number of forwarded DML statements processed on this replica each second.</td>
</tr>
<tr>
<td>AuroraForwardingReplicaErrorSessionsLimit</td>
<td>Count. Number of sessions rejected by the primary cluster because the limit for max connections or max write forward connections was reached.</td>
</tr>
<tr>
<td>AuroraForwardingReplicaOpenSessions</td>
<td>Count. The number of sessions that are using write forwarding on a replica instance.</td>
</tr>
<tr>
<td>AuroraForwardingReplicaReadWaitLatency</td>
<td>Milliseconds. Average wait time in milliseconds that the replica waits to be consistent with the LSN of the primary cluster. The degree to which the reader DB instance waits depends on the <code>apg_write_forward.consistency_mode</code> setting. For information about this setting, see the section called “Configuration parameters for write forwarding in Aurora PostgreSQL” (p. 1849).</td>
</tr>
</tbody>
</table>
Amazon Aurora User Guide for Aurora
Using write forwarding in Aurora PostgreSQL

Wait events for write forwarding in Aurora PostgreSQL

Amazon Aurora generates the following wait events when you use write forwarding with Aurora PostgreSQL.

Topics
- IPC:AuroraWriteForwardConnect (p. 1851)
- IPC:AuroraWriteForwardConsistencyPoint (p. 1851)
- IPC:AuroraWriteForwardExecute (p. 1852)
- IPC:AuroraWriteForwardGetGlobalConsistencyPoint (p. 1852)
- IPC:AuroraWriteForwardXactAbort (p. 1853)
- IPC:AuroraWriteForwardXactCommit (p. 1853)
- IPC:AuroraWriteForwardXactStart (p. 1853)

IPC:AuroraWriteForwardConnect

The IPC:AuroraWriteForwardConnect event occurs when a backend process on the secondary DB cluster is waiting for a connection to the writer node of the primary DB cluster to be opened.

Likely causes of increased waits

This event increases as the number of connection attempts from a secondary Region's reader node to the writer node of the primary DB cluster increases.

Actions

Reduce the number of simultaneous connections from a secondary node to the primary Region's writer node.

IPC:AuroraWriteForwardConsistencyPoint

The IPC:AuroraWriteForwardConsistencyPoint event describes how long a query from a node on the secondary DB cluster will wait for the results of forwarded write operations to be replicated to the current Region. This event is only generated if the session-level parameter apg_write_forward.consistency_mode is set to one of the following:

- SESSION – queries on a secondary node wait for the results of all changes made in that session.
- GLOBAL – queries on a secondary node wait for the results of changes made by that session, plus all committed changes from both the primary Region and other secondary Regions in the global cluster.

For more information about the apg_write_forward.consistency_mode parameter settings, see the section called "Configuration parameters for write forwarding in Aurora PostgreSQL" (p. 1849).

Likely causes of increased waits

Common causes for longer wait times include the following:

- Increased replica lag, as measured by the Amazon CloudWatch ReplicaLag metric. For more information about this metric, see Monitoring Aurora PostgreSQL replication (p. 1506).
- Increased load on the primary Region's writer node or on the secondary node.

Actions
Change your consistency mode, depending on your application's requirements.

**IPC:AuroraWriteForwardExecute**

The **IPC:AuroraWriteForwardExecute** event occurs when a backend process on the secondary DB cluster is waiting for a forwarded query to complete and obtain results from the writer node of the primary DB cluster.

**Likely causes of increased waits**

Common causes for increased waits include the following:

- Fetching a large number of rows from the primary Region's writer node.
- Increased network latency between the secondary node and primary Region's writer node increases the time it takes the secondary node to receive data from the writer node.
- Increased load on the secondary node can delay transmission of the query request from the secondary node to the primary Region's writer node.
- Increased load on the primary Region's writer node can delay transmission of data from the writer node to the secondary node.

**Actions**

We recommend different actions depending on the causes of your wait event.

- Optimize queries to retrieve only necessary data.
- Optimize data manipulation language (DML) operations to only modify necessary data.
- If the secondary node or primary Region's writer node is constrained by CPU or network bandwidth, consider changing it to an instance type with more CPU capacity or more network bandwidth.

**IPC:AuroraWriteForwardGetGlobalConsistencyPoint**

The **IPC:AuroraWriteForwardGetGlobalConsistencyPoint** event occurs when a backend process on the secondary DB cluster that's using the GLOBAL consistency mode is waiting to obtain the global consistency point from the writer node before executing a query.

**Likely causes of increased waits**

Common causes for increased waits include the following:

- Increased network latency between the secondary node and primary Region's writer node increases the time it takes the secondary node to receive data from the writer node.
- Increased load on the secondary node can delay transmission of the query request from the secondary node to the primary Region's writer node.
- Increased load on the primary Region's writer node can delay transmission of data from the writer node to the secondary node.

**Actions**

We recommend different actions depending on the causes of your wait event.

- Change your consistency mode, depending on your application's requirements.
- If the secondary node or primary Region's writer node is constrained by CPU or network bandwidth, consider changing it to an instance type with more CPU capacity or more network bandwidth.
IPC:AuroraWriteForwardXactAbort

The IPC:AuroraWriteForwardXactAbort event occurs when a backend process on the secondary DB cluster is waiting for the result of a remote cleanup query. Cleanup queries are issued to return the process to the appropriate state after a write-forwarded transaction is aborted. Amazon Aurora performs them either because an error was found or because an user issued an explicit ABORT command or cancelled a running query.

Likely causes of increased waits

Common causes for increased waits include the following:

- Increased network latency between the secondary node and primary Region's writer node increases the time it takes the secondary node to receive data from the writer node.
- Increased load on the secondary node can delay transmission of the cleanup query request from the secondary node to the primary Region's writer node.
- Increased load on the primary Region's writer node can delay transmission of data from the writer node to the secondary node.

Actions

We recommend different actions depending on the causes of your wait event.

- Investigate the cause of the aborted transaction.
- If the secondary node or primary Region's writer node is constrained by CPU or network bandwidth, consider changing it to an instance type with more CPU capacity or more network bandwidth.

IPC:AuroraWriteForwardXactCommit

The IPC:AuroraWriteForwardXactCommit event occurs when a backend process on the secondary DB cluster is waiting for the result of a forwarded commit transaction command.

Likely causes of increased waits

Common causes for increased waits include the following:

- Increased network latency between the secondary node and primary Region's writer node increases the time it takes the secondary node to receive data from the writer node.
- Increased load on the secondary node can delay transmission of the query request from the secondary node to the primary Region's writer node.
- Increased load on the primary Region's writer node can delay transmission of data from the writer node to the secondary node.

Actions

If the secondary node or primary Region's writer node is constrained by CPU or network bandwidth, consider changing it to an instance type with more CPU capacity or more network bandwidth.

IPC:AuroraWriteForwardXactStart

The IPC:AuroraWriteForwardXactStart event occurs when a backend process on the secondary DB cluster is waiting for the result of a forwarded start transaction command.

Likely causes of increased waits
Common causes for increased waits include the following:

- Increased network latency between the secondary node and primary Region's writer node increases the time it takes the secondary node to receive data from the writer node.
- Increased load on the secondary node can delay transmission of the query request from the secondary node to the primary Region's writer node.
- Increased load on the primary Region's writer node can delay transmission of data from the writer node to the secondary node.

**Actions**

If the secondary node or primary Region's writer node is constrained by CPU or network bandwidth, consider changing it to an instance type with more CPU capacity or more network bandwidth.

### Using switchover or failover in an Amazon Aurora global database

An Aurora global database provides more business continuity and disaster recovery (BCDR) protection than the standard high availability (p. 102) provided by an Aurora DB cluster in a single AWS Region. By using an Aurora global database, you can plan for and recover from true Regional disasters or complete service-level outages quickly. Recovery from disaster is typically driven by the following two business objectives:

- **Recovery time objective (RTO)** – The time it takes a system to return to a working state after a disaster or service outage. In other words, RTO measures downtime. For an Aurora global database, RTO can be in the order of minutes.
- **Recovery point objective (RPO)** – The amount of data that can be lost (measured in time) after a disaster or service outage. This data loss is usually due to asynchronous replication lag. For an Aurora global database, RPO is typically measured in seconds. With an Aurora PostgreSQL–based global database, you can use the `rds.global_db_rpo` parameter to set and track the upper bound on RPO, but doing so might affect transaction processing on the primary cluster's writer node. For more information, see Managing RPOs for Aurora PostgreSQL–based global databases (p. 1865).

Switching over or failing over an Aurora global database involves promoting a DB cluster in one of your global database's secondary Regions to be the primary DB cluster. The term "regional outage" is often used to describe a variety of failure scenarios. A worst case scenario could be a wide-spread outage from a catastrophic event that affects hundreds of square miles. However, most outages are much more localized, affecting only a small subset of cloud services or customer systems. Consider the full scope of the outage to make sure cross-Region failover is the proper solution and to choose the appropriate failover method for the situation. Whether you should use the failover or switchover approach depends on the specific outage scenario:

- **Failover** – Use this approach to recover from an unplanned outage. With this approach, you perform a cross-Region failover to one of the secondary DB clusters in your Aurora global database. The RPO for this approach is typically a non-zero value measured in seconds. The amount of data loss depends on the Aurora global database replication lag across the AWS Regions at the time of the failure. To learn more, see Recovering an Amazon Aurora global database from an unplanned outage (p. 1855).
- **Switchover** – This operation was previously called "managed planned failover." Use this approach for controlled scenarios, such as operational maintenance and other planned operational procedures. Because this feature synchronizes secondary DB clusters with the primary before making any other changes, RPO is 0 (no data loss). To learn more, see Performing switchovers for Amazon Aurora global databases (p. 1861).
Note
If you want to switch over or fail over to a headless secondary Aurora DB cluster, you need to first add a DB instance to it. For more information about headless DB clusters, see Creating a headless Aurora DB cluster in a secondary Region (p. 1821).

Topics
- Recovering an Amazon Aurora global database from an unplanned outage (p. 1855)
- Performing switchovers for Amazon Aurora global databases (p. 1861)
- Managing RPOs for Aurora PostgreSQL–based global databases (p. 1865)

Recovering an Amazon Aurora global database from an unplanned outage

On very rare occasions, your Aurora global database might experience an unexpected outage in its primary AWS Region. If this happens, your primary Aurora DB cluster and its writer node aren't available, and the replication between the primary and secondary DB clusters stops. To minimize both downtime (RTO) and data loss (RPO), you can work quickly to perform a cross-Region failover.

There are two methods for failing over in a disaster recovery situation:

- Managed failover – This method is recommended for disaster recovery. When you use this method, Aurora automatically adds back the old primary Region to the global database as a secondary Region when it becomes available again. Thus, the original topology of your global cluster is maintained. To learn how to use this method, see Performing managed failovers for Aurora global databases (p. 1855).
- Manual failover – This alternative method can be used when managed failover isn't an option, for example, when your primary and secondary Regions are running incompatible engine versions. To learn how to use this method, see Performing manual failovers for Aurora global databases (p. 1860).

Important
Both failover methods can result in a loss of write transaction data that wasn't replicated to the chosen secondary before the failover event occurred. However, the recovery process that promotes a DB instance on the chosen secondary DB cluster to be the primary writer DB instance guarantees that the data is in a transactionally consistent state.

Performing managed failovers for Aurora global databases

This approach is intended for business continuity in the event of a true Regional disaster or complete service-level outage.

During a managed failover, your primary cluster is failed over to your choice of secondary Region while your Aurora global database's existing replication topology is maintained. The chosen secondary cluster promotes one of its read-only nodes to full writer status. This step allows the cluster to assume the role of primary cluster. Your database is unavailable for a short time while this cluster is assuming its new role. Data that wasn't replicated from the old primary to the chosen secondary cluster is missing when this secondary becomes the new primary.

Note
You can only perform a managed cross-Region database failover on an Aurora global database if the primary and secondary DB clusters have the same major, minor, and patch level engine versions. However, the patch levels can be different, depending on the minor engine version. For more information, see Patch level compatibility for managed cross-Region switchovers and failovers (p. 1877). If your engine versions are incompatible, you can perform the failover manually by following the steps in Performing manual failovers for Aurora global databases (p. 1860).
To minimize data loss, we recommend that you do the following before using this feature:

- Take applications offline to prevent writes from being sent to the primary cluster of Aurora global database.
- Check lag times for all secondary Aurora DB clusters in the Aurora global database. Choosing the secondary Region with the least replication lag can minimize data loss with the current failed primary Region. For all Aurora PostgreSQL-based global databases and for Aurora MySQL-based global databases starting with engine versions 3.04.0 and higher, or 2.12.0 and higher, use Amazon CloudWatch to view the `AuroraGlobalDBRPOPLag` metric for all secondary DB clusters. For lower minor versions of Aurora MySQL-based global databases, view the `AuroraGlobalDBReplicationLag` metric instead. These metrics show you how far behind (in milliseconds) replication to a secondary cluster is to the primary DB cluster.

For more information about CloudWatch metrics for Aurora, see Cluster-level metrics for Amazon Aurora (p. 638).

During a managed failover, the chosen secondary DB cluster is promoted to its new role as primary. However, it doesn't inherit the various configuration options of the primary DB cluster. A mismatch in configuration can lead to performance issues, workload incompatibilities, and other anomalous behavior. To avoid such issues, we recommend that you resolve differences between your Aurora global database clusters for the following:

- **Configure Aurora DB cluster parameter group for the new primary, if necessary** – You can configure your Aurora DB cluster parameter groups independently for each Aurora cluster in your Aurora global database. Therefore, when you promote a secondary DB cluster to take over the primary role, the parameter group from the secondary might be configured differently than for the primary. If so, modify the promoted secondary DB cluster's parameter group to conform to your primary cluster's settings. To learn how, see Modifying parameters for an Aurora global database (p. 1826).

- **Configure monitoring tools and options, such as Amazon CloudWatch Events and alarms** – Configure the promoted DB cluster with the same logging ability, alarms, and so on as needed for the global database. As with parameter groups, configuration for these features isn't inherited from the primary during the failover process. Some CloudWatch metrics, such as replication lag, are only available for secondary Regions. Thus, a failover changes how to view those metrics and set alarms on them, and could require changes to any predefined dashboards. For more information about Aurora DB clusters and monitoring, see Overview of monitoring Amazon Aurora.

- **Configure integrations with other AWS services** – If your Aurora global database integrates with AWS services, such as AWS Secrets Manager, AWS Identity and Access Management, Amazon S3, and AWS Lambda, you need to make sure these are configured as needed. For more information about integrating Aurora global databases with IAM, Amazon S3 and Lambda, see Using Amazon Aurora global databases with other AWS services (p. 1875). To learn more about Secrets Manager, see How to automate replication of secrets in AWS Secrets Manager across AWS Regions.

Typically, the chosen secondary cluster assumes the primary role within a few minutes. As soon as the new primary Region's writer node is available, you can connect your applications to it and resume your workloads. After Aurora promotes the new primary cluster, it automatically rebuilds all additional secondary Region clusters.

Because Aurora global databases use asynchronous replication, the replication lag in each secondary Region can vary. Aurora rebuilds these secondary Regions to have the exact same point-in-time data as the new primary Region cluster. The duration of the complete rebuilding task can take a few minutes to several hours, depending on the size of the storage volume and the distance between the Regions. When the secondary Region clusters finish rebuilding from the new primary Region, they become available for read access.

As soon as the new primary writer is promoted and available, the new primary Region's cluster can handle read and write operations for the Aurora global database. Make sure to change the endpoint for
your application to use the new endpoint. If you accepted the provided names when you created the Aurora global database, you can change the endpoint by removing the -ro from the promoted cluster's endpoint string in your application.

For example, the secondary cluster's endpoint my-global.cluster-ro-aaaaaabbbbbbb.us-west-1.rds.amazonaws.com becomes my-global.cluster-aaaaaabbbbbbb.us-west-1.rds.amazonaws.com when that cluster is promoted to primary.

If you are using RDS Proxy, make sure to redirect your application's write operations to the appropriate read/write endpoint of the proxy that's associated with the new primary cluster. This proxy endpoint might be the default endpoint or a custom read/write endpoint. For more information see How RDS Proxy endpoints work with global databases (p. 1936).

To restore the global database cluster's original topology, Aurora monitors the availability of the old primary Region. As soon as that Region is healthy and available again, Aurora automatically adds it back to the global cluster as a secondary Region. Before creating the new storage volume in the old primary Region, Aurora tries to take a snapshot of the old storage volume at the point of failure. It does this so that you can use it to recover any of the missing data. If this operation is successful, Aurora places this snapshot named "rds:unplanned-global-failover-name-of-old-primary-DB-cluster-timestamp" in the snapshot section of the AWS Management Console. You can also see this snapshot listed in the information returned by the DescribeDBClusterSnapshots API operation.

**Note**
The snapshot of the old storage volume is a system snapshot that's subject to the backup retention period configured on the old primary cluster. To preserve this snapshot outside of the retention period, you can copy it to save it as a manual snapshot. To learn more about copying snapshots, including pricing, see Copying a DB cluster snapshot (p. 442).

After the original topology is restored, you can fail back your global database to the original primary Region by performing a switchover operation when it makes the most sense for your business and workload. To do so, follow the steps in Performing switchovers for Amazon Aurora global databases (p. 1861).

You can fail over your Aurora global database using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To perform the managed failover on your Aurora global database**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Databases and find the Aurora global database you want to fail over.
3. Choose **Switch over or fail over global database** from the **Actions** menu.
4. Choose **Failover (allow data loss)**.

![Switch over or fail over global database demo-global-db](image)

---

**Switch over or fail over global database demo-global-db**

Promote a secondary DB cluster to be the new primary DB cluster for your global database by choosing the applicable operation and the target DB cluster.

- **Switchover**
  Switch the roles of your primary and chosen secondary DB cluster. Use this operation on a healthy global cluster for planned events, such as Regional rotation or failing back to the old primary after a failover. This change might take several minutes to complete. No data loss should occur, but you can't write to your global database during this time. Learn more [here](link).

- **Failover (allow data loss)**
  Fail over the primary DB cluster to the specified secondary DB cluster to respond to unplanned events, such as a Regional disaster in the primary Region. This operation can result in data loss of any uncommitted work and committed transactions that were not replicated to the secondary cluster. Learn more [here](link).

**New primary cluster**

Choose an active cluster in one of your secondary AWS Regions to be the new primary cluster.

Choose an option

To confirm failover (allow data loss), enter **confirm**.

confirm

---

5. For **New primary cluster**, choose an active cluster in one of your secondary AWS Regions to be the new primary cluster.

6. Enter **confirm**, and then choose **Confirm**.

When the failover completes, you can see the Aurora DB clusters and their current state in the **Databases** list, as shown in the following image.
AWS CLI

To perform the managed failover on an Aurora global database

Use the `failover-global-cluster` CLI command to fail over your Aurora global database. With the command, pass values for the following parameters.

- `--region` – Specify the AWS Region where the secondary DB cluster that you want to be the new primary for the Aurora global database is running.
- `--global-cluster-identifier` – Specify the name of your Aurora global database.
- `--target-db-cluster-identifier` – Specify the Amazon Resource Name (ARN) of the Aurora DB cluster that you want to promote to be the new primary for the Aurora global database.
- `--allow-data-loss` – Explicitly make this a failover operation instead of a switchover operation. A failover operation can result in some data loss if the asynchronous replication components haven’t completed sending all replicated data to the secondary Region.

For Linux, macOS, or Unix:

```bash
aws rds --region region_of_selected_secondary \
  failover-global-cluster --global-cluster-identifier global_database_id \
  --target-db-cluster-identifier arn_of_secondary_to_promote \
  --allow-data-loss
```

For Windows:

```bash
aws rds --region region_of_selected_secondary ^
  failover-global-cluster --global-cluster-identifier global_database_id ^
  --target-db-cluster-identifier arn_of_secondary_to_promote ^
  --allow-data-loss
```

RDS API

To fail over an Aurora global database, run the `FailoverGlobalCluster` API operation.
Performing manual failovers for Aurora global databases

In some scenarios, you might not be able to use the managed failover process. One example is if your primary and secondary DB clusters aren't running compatible engine versions. In this case, you can follow this manual process to fail over your global database to your target secondary Region.

Tip
We recommend that you understand this process before using it. Have a plan ready to quickly proceed at the first sign of a Region-wide issue. You can be ready to identify the secondary Region with the least replication lag by using Amazon CloudWatch regularly to track lag times for the secondary clusters. Make sure to test your plan to check that your procedures are complete and accurate, and that staff are trained to perform a disaster recovery failover before it really happens.

To manually fail over to a secondary cluster after an unplanned outage in the primary Region

1. Stop issuing DML statements and other write operations to the primary Aurora DB cluster in the AWS Region with the outage.

2. Identify an Aurora DB cluster from a secondary AWS Region to use as a new primary DB cluster. If you have two or more secondary AWS Regions in your Aurora global database, choose the secondary cluster that has the least replication lag.

3. Detach your chosen secondary DB cluster from the Aurora global database.

Removing a secondary DB cluster from an Aurora global database immediately stops the replication from the primary to this secondary and promotes it to a standalone provisioned Aurora DB cluster with full read/write capabilities. Any other secondary Aurora DB clusters associated with the primary cluster in the Region with the outage are still available and can accept calls from your application. They also consume resources. Because you're recreating the Aurora global database, remove the other secondary DB clusters before creating the new Aurora global database in the following steps. Doing this avoids data inconsistencies among the DB clusters in the Aurora global database (split-brain issues).

For detailed steps for detaching, see Removing a cluster from an Amazon Aurora global database (p. 1826).

4. Reconfigure your application to send all write operations to this now standalone Aurora DB cluster using its new endpoint. If you accepted the provided names when you created the Aurora global database, you can change the endpoint by removing the -ro from the cluster's endpoint string in your application.

For example, the secondary cluster's endpoint my-global.cluster-ro-aaaaabbbbbb.us-west-1.rds.amazonaws.com becomes my-global.cluster-aaaaabbbbbb.us-west-1.rds.amazonaws.com when that cluster is detached from the Aurora global database.

This Aurora DB cluster becomes the primary cluster of a new Aurora global database when you start adding Regions to it in the next step.

If you are using RDS Proxy, make sure to redirect your application's write operations to the appropriate read/write endpoint of the proxy that's associated with the new primary cluster. This proxy endpoint might be the default endpoint or a custom read/write endpoint. For more information see How RDS Proxy endpoints work with global databases (p. 1936).

5. Add an AWS Region to the DB cluster. When you do this, the replication process from primary to secondary begins. For detailed steps to add a Region, see Adding an AWS Region to an Amazon Aurora global database (p. 1817).

6. Add more AWS Regions as needed to recreate the topology needed to support your application.
Make sure that application writes are sent to the correct Aurora DB cluster before, during, and after making these changes. Doing this avoids data inconsistencies among the DB clusters in the Aurora global database (split-brain issues).

If you reconfigured in response to an outage in an AWS Region, you can make that AWS Region the primary again after the outage is resolved. To do so, you add the old AWS Region to your new global database, and then use the switchover process to switch its role. Your Aurora global database must use a version of Aurora PostgreSQL or Aurora MySQL that supports switchovers. For more information, see Performing switchovers for Amazon Aurora global databases (p. 1861).

Performing switchovers for Amazon Aurora global databases

**Note**
Switchovers were previously called "managed planned failovers."

By using switchovers, you can change the Region of your primary cluster on a routine basis. This approach is intended for controlled scenarios, such as operational maintenance and other planned operational procedures.

There are three common use cases for using switchovers.

- For "regional rotation" requirements imposed on specific industries. For example, financial service regulations might want tier-0 systems to switch to a different Region for several months to ensure that disaster recovery procedures are regularly exercised.
- For multi-Region "follow-the-sun" applications. For example, a business might want to provide lower latency writes in different Regions based on business hours across different time zones.
- As a zero-data-loss method to fail back to the original primary Region after a failover.

**Note**
Switchovers are designed to be used on a healthy Aurora global database. To recover from an unplanned outage, follow the appropriate procedure in Recovering an Amazon Aurora global database from an unplanned outage (p. 1855).

To perform a switchover, your target secondary DB cluster must be running the exact same engine version as the primary, including the patch level, depending on the engine version. For more information, see Patch level compatibility for managed cross-Region switchovers and failovers (p. 1877). Before you begin the switchover, check the engine versions in your global cluster to make sure that they support managed cross-Region switchover, and upgrade them if needed.

During a switchover, Aurora switches over your primary cluster to your chosen secondary Region while it maintains your global database's existing replication topology. Before it starts the switchover process, Aurora waits for all secondary Region clusters to be fully synchronized with the primary Region cluster. Then, the DB cluster in the primary Region becomes read-only and the chosen secondary cluster promotes one of its read-only nodes to full writer status. Promoting this node to a writer allows that secondary cluster to assume the role of primary cluster. Because all secondary clusters were synchronized with the primary at the beginning of the process, the new primary continues operations for the Aurora global database without losing any data. Your database is unavailable for a short time while the primary and selected secondary clusters are assuming their new roles.

To optimize application availability, we recommend that you do the following before using this feature:

- Perform this operation during nonpeak hours or at another time when writes to the primary DB cluster are minimal.
- Take applications offline to prevent writes from being sent to the primary cluster of Aurora global database.
• Check lag times for all secondary Aurora DB clusters in the Aurora global database. For all Aurora PostgreSQL-based global databases and for Aurora MySQL-based global databases starting with engine versions 3.04.0 and higher or 2.12.0 and higher, use Amazon CloudWatch to view the AuroraGlobalDBRPLag metric for all secondary DB clusters. For lower minor versions of Aurora MySQL-based global databases, view the AuroraGlobalDBReplicationLag metric instead. These metrics show you how far behind (in milliseconds) replication to a secondary cluster is to the primary DB cluster. This value is directly proportional to the time it takes for Aurora to complete the switchover. Therefore, the larger the lag value, the longer the switchover will take.

For more information about CloudWatch metrics for Aurora, see Cluster-level metrics for Amazon Aurora (p. 638).

During a switchover, the chosen secondary DB cluster is promoted to its new role as primary. However, it doesn't inherit the various configuration options of the primary DB cluster. A mismatch in configuration can lead to performance issues, workload incompatibilities, and other anomalous behavior. To avoid such issues, we recommend that you resolve differences between your Aurora global database clusters for the following:

• **Configure Aurora DB cluster parameter group for the new primary, if necessary** – You can configure your Aurora DB cluster parameter groups independently for each Aurora cluster in your Aurora global database. That means that when you promote a secondary DB cluster to take over the primary role, the parameter group from the secondary might be configured differently than for the primary. If so, modify the promoted secondary DB cluster's parameter group to conform to your primary cluster's settings. To learn how, see Modifying parameters for an Aurora global database (p. 1826).

• **Configure monitoring tools and options, such as Amazon CloudWatch Events and alarms** – Configure the promoted DB cluster with the same logging ability, alarms, and so on as needed for the global database. As with parameter groups, configuration for these features isn't inherited from the primary during the switchover process. Some CloudWatch metrics, such as replication lag, are only available for secondary Regions. Thus, a switchover changes how to view those metrics and set alarms on them, and could require changes to any predefined dashboards. For more information about Aurora DB clusters and monitoring, see Overview of monitoring Amazon Aurora.

• **Configure integrations with other AWS services** – If your Aurora global database integrates with AWS services, such as AWS Secrets Manager, AWS Identity and Access Management, Amazon S3, and AWS Lambda, make sure to configure your integrations with these services as needed. For more information about integrating Aurora global databases with IAM, Amazon S3 and Lambda, see Using Amazon Aurora global databases with other AWS services (p. 1875). To learn more about Secrets Manager, see How to automate replication of secrets in AWS Secrets Manager across AWS Regions.

**Note**

Typically, the role switchover can take up to several minutes. However, building additional secondary clusters can take a few minutes to several hours, depending on the size of your database and the physical distance between the Regions.

When the switchover process completes, the promoted Aurora DB cluster can handle write operations for the Aurora global database. Make sure to change the endpoint for your application to use the new endpoint. If you accepted the provided names when you created the Aurora global database, you can change the endpoint by removing the `-ro` from the promoted cluster's endpoint string in your application.

For example, the secondary cluster's endpoint `my-global.cluster-ro-aaaaaabbbbbb.us-west-1.rds.amazonaws.com` becomes `my-global.cluster-aaaaaabbbbbb.us-west-1.rds.amazonaws.com` when that cluster is promoted to primary.

If you are using RDS Proxy, make sure to redirect your application's write operations to the appropriate read/write endpoint of the proxy that's associated with the new primary cluster. This proxy endpoint
might be the default endpoint or a custom read/write endpoint. For more information see How RDS Proxy endpoints work with global databases (p. 1936).

You can switch over your Aurora global database using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To perform the switchover on your Aurora global database**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Choose **Databases** and find the Aurora global database you want to switch over.
3. Choose **Switch over or fail over global database** from the **Actions** menu.

4. Choose **Switchover**.
5. For **New primary cluster**, choose an active cluster in one of your secondary AWS Regions to be the new primary cluster.

6. Choose **Confirm**.

When the switchover completes, you can see the Aurora DB clusters and their current roles in the **Databases** list, as shown in the following image.
AWS CLI

To perform the switchover on an Aurora global database

Use the `switchover-global-cluster` CLI command to switch over your Aurora global database. With the command, pass values for the following parameters.

- `--region` – Specify the AWS Region where the primary DB cluster of the Aurora global database is running.
- `--global-cluster-identifier` – Specify the name of your Aurora global database.
- `--target-db-cluster-identifier` – Specify the Amazon Resource Name (ARN) of the Aurora DB cluster that you want to promote to be the primary for the Aurora global database.

For Linux, macOS, or Unix:

```bash
aws rds --region region_of_primary \
  switchover-global-cluster --global-cluster-identifier global_database_id \
  --target-db-cluster-identifier arn_of_secondary_to_promote
```

For Windows:

```bash
aws rds --region region_of_primary ^ \
  switchover-global-cluster --global-cluster-identifier global_database_id ^ \
  --target-db-cluster-identifier arn_of_secondary_to_promote
```

RDS API

To switch over an Aurora global database, run the `SwitchoverGlobalCluster` API operation.

Managing RPOs for Aurora PostgreSQL–based global databases

With an Aurora PostgreSQL–based global database, you can manage the recovery point objective (RPO) for your Aurora global database by using the `rds.global_db_rpo` parameter. RPO represents the maximum amount of data that can be lost in the event of an outage.
When you set an RPO for your Aurora PostgreSQL–based global database, Aurora monitors the RPO lag time of all secondary clusters to make sure that at least one secondary cluster stays within the target RPO window. RPO lag time is another time-based metric.

The RPO is used when your database resumes operations in a new AWS Region after a failover. Aurora evaluates RPO and RPO lag times to commit (or block) transactions on the primary as follows:

- Commits the transaction if at least one secondary DB cluster has an RPO lag time less than the RPO.
- Blocks the transaction if all secondary DB clusters have RPO lag times that are larger than the RPO. It also logs the event to the PostgreSQL log file and emits "wait" events that show the blocked sessions.

In other words, if all secondary clusters are behind the target RPO, Aurora pauses transactions on the primary cluster until at least one of the secondary clusters catches up. Paused transactions are resumed and committed as soon as the lag time of at least one secondary DB cluster becomes less than the RPO. The result is that no transactions can commit until the RPO is met.

The rds.global_db_rpo parameter is dynamic. If you decide that you don't want all write transactions to stall until the lag decreases sufficiently, you can reset it quickly. In this case, Aurora recognizes and implements the change after a short delay.

**Important**

In a global database with only two Regions, we recommend keeping the rds.global_db_rpo parameter's default value in the secondary Region's parameter group. Otherwise, failing over to this Region due to a loss of the primary Region could cause Aurora to pause transactions. Instead, wait until Aurora completes rebuilding the cluster in the old failed Region before changing this parameter to enforce a maximum RPO.

If you set this parameter as outlined in the following, you can then also monitor the metrics that it generates. You can do so by using psql or another tool to query the Aurora global database's primary DB cluster and obtain detailed information about your Aurora PostgreSQL–based global database's operations. To learn how, see [Monitoring Aurora PostgreSQL-based global databases](p. 1873).

**Topics**

- Setting the recovery point objective (p. 1866)
- Viewing the recovery point objective (p. 1867)
- Disabling the recovery point objective (p. 1868)

**Setting the recovery point objective**

The rds.global_db_rpo parameter controls the RPO setting for a PostgreSQL database. This parameter is supported by Aurora PostgreSQL. Valid values for rds.global_db_rpo range from 20 seconds to 2,147,483,647 seconds (68 years). Choose a realistic value to meet your business need and use case. For example, you might want to allow up to 10 minutes for your RPO, in which case you set the value to 600.

You can set this value for your Aurora PostgreSQL–based global database by using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To set the RPO**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Choose the primary cluster of your Aurora global database and open the Configuration tab to find its DB cluster parameter group. For example, the default parameter group for a primary DB cluster running Aurora PostgreSQL 11.7 is default.aurora-postgresql11.
Parameter groups can't be edited directly. Instead, you do the following:

- Create a custom DB cluster parameter group using the appropriate default parameter group as the starting point. For example, create a custom DB cluster parameter group based on the default.aurora-postgresql11.
- On your custom DB parameter group, set the value of the `rds.global_db_rpo` parameter to meet your use case. Valid values range from 20 seconds up to the maximum integer value of 2,147,483,647 (68 years).
- Apply the modified DB cluster parameter group to your Aurora DB cluster.

For more information, see Modifying parameters in a DB cluster parameter group (p. 219).

**AWS CLI**

To set the `rds.global_db_rpo` parameter, use the `modify-db-cluster-parameter-group` CLI command. In the command, specify the name of your primary cluster's parameter group and values for RPO parameter.

The following example sets the RPO to 600 seconds (10 minutes) for the primary DB cluster's parameter group named `my_custom_global_parameter_group`.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group
   --db-cluster-parameter-group-name my_custom_global_parameter_group
   --parameters "ParameterName=rds.global_db_rpo,ParameterValue=600,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-cluster-parameter-group ^
   --db-cluster-parameter-group-name my_custom_global_parameter_group ^
   --parameters "ParameterName=rds.global_db_rpo,ParameterValue=600,ApplyMethod=immediate"
```

**RDS API**

To modify the `rds.global_db_rpo` parameter, use the Amazon RDS ModifyDBClusterParameterGroup API operation.

**Viewing the recovery point objective**

The recovery point objective (RPO) of a global database is stored in the `rds.global_db_rpo` parameter for each DB cluster. You can connect to the endpoint for the secondary cluster you want to view and use `psql` to query the instance for this value.

```
db-name=> show rds.global_db_rpo;
```

If this parameter isn't set, the query returns the following:

```
  rds.global_db_rpo
  -------------------
  -1
  (1 row)
```

This next response is from a secondary DB cluster that has 1 minute RPO setting.
You can also use the CLI to get values for find out if `rds.global_db_rpo` is active on any of the Aurora DB clusters by using the CLI to get values of all user parameters for the cluster.

For Linux, macOS, or Unix:

```bash
aws rds describe-db-cluster-parameters --db-cluster-parameter-group-name lab-test-apg-global --source user
```

For Windows:

```bash
aws rds describe-db-cluster-parameters --db-cluster-parameter-group-name lab-test-apg-global --source user
```

The command returns output similar to the following for all user parameters that aren’t default-engine or system DB cluster parameters.

```json
{
   "Parameters": [
       {
           "ParameterName": "rds.global_db_rpo",
           "ParameterValue": "60",
           "Description": "(s) Recovery point objective threshold, in seconds, that blocks user commits when it is violated."
       },
       {
           "ParameterName": "rds.global_db_rpo",
           "ParameterValue": "60",
           "Description": "(s) Recovery point objective threshold, in seconds, that blocks user commits when it is violated."
       },
       {
           "ParameterName": "rds.global_db_rpo",
           "ParameterValue": "60",
           "Description": "(s) Recovery point objective threshold, in seconds, that blocks user commits when it is violated."
       }
   ]
}
```

To learn more about viewing parameters of the cluster parameter group, see [Viewing parameter values for a DB cluster parameter group](#).

## Disabling the recovery point objective

To disable the RPO, reset the `rds.global_db_rpo` parameter. You can reset parameters using the AWS Management Console, the AWS CLI, or the RDS API.

### Console

**To disable the RPO**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.

1868
3. In the list, choose your primary DB cluster parameter group.
4. Choose Edit parameters.
5. Choose the box next to the rds.global_db_rpo parameter.
6. Choose Reset.
7. When the screen shows Reset parameters in DB parameter group, choose Reset parameters.

For more information on how to reset a parameter with the console, see Modifying parameters in a DB cluster parameter group (p. 219).

AWS CLI

To reset the rds.global_db_rpo parameter, use the reset-db-cluster-parameter-group command.

For Linux, macOS, or Unix:

```bash
aws rds reset-db-cluster-parameter-group \
  --db-cluster-parameter-group-name global_db_cluster_parameter_group \
  --parameters "ParameterName=rds.global_db_rpo,ApplyMethod=immediate"
```

For Windows:

```bash
aws rds reset-db-cluster-parameter-group ^
  --db-cluster-parameter-group-name global_db_cluster_parameter_group ^
  --parameters "ParameterName=rds.global_db_rpo,ApplyMethod=immediate"
```

RDS API

To reset the rds.global_db_rpo parameter, use the Amazon RDS API ResetDBClusterParameterGroup operation.

Monitoring an Amazon Aurora global database

When you create the Aurora DB clusters that make up your Aurora global database, you can choose many options that let you monitor your DB cluster's performance. These options include the following:

- Amazon RDS Performance Insights – Enables performance schema in the underlying Aurora database engine. To learn more about Performance Insights and Aurora global databases, see Monitoring an Amazon Aurora global database with Amazon RDS Performance Insights (p. 1870).
- Enhanced monitoring – Generates metrics for process or thread utilization on the CPU. To learn about enhanced monitoring, see Monitoring OS metrics with Enhanced Monitoring (p. 631).
- Amazon CloudWatch Logs – Publishes specified log types to CloudWatch Logs. Error logs are published by default, but you can choose other logs specific to your Aurora database engine.
  - For Aurora MySQL–based Aurora DB clusters, you can export the audit log, general log, and slow query log.
  - For Aurora PostgreSQL–based Aurora DB clusters, you can export the PostgreSQL log.
- For Aurora MySQL–based global databases, you can query specific information_schema tables to check the status of your Aurora global database and its instances. To learn how, see Monitoring Aurora MySQL-based global databases (p. 1871).
- For Aurora PostgreSQL–based global databases, you can use specific functions to check the status of your Aurora global database and its instances. To learn how, see Monitoring Aurora PostgreSQL-based global databases (p. 1873).
The following screenshot shows some of the options available on the Monitoring tab of a primary Aurora DB cluster in an Aurora global database.

For more information, see [Monitoring metrics in an Amazon Aurora cluster](p. 509).

**Monitoring an Amazon Aurora global database with Amazon RDS Performance Insights**

You can use Amazon RDS Performance Insights for your Aurora global databases. You enable this feature individually, for each Aurora DB cluster in your Aurora global database. To do so, you choose **Enable Performance Insights** in the Additional configuration section of the Create database page. Or you can modify your Aurora DB clusters to use this feature after they are up and running. You can enable or turn off Performance Insights for each cluster that's part of your Aurora global database.

The reports created by Performance Insights apply to each cluster in the global database. When you add a new secondary AWS Region to an Aurora global database that's already using Performance Insights, be sure that you enable Performance Insights in the newly added cluster. It doesn't inherit the Performance Insights setting from the existing global database.

You can switch AWS Regions while viewing the Performance Insights page for a DB instance that's attached to a global database. However, you might not see performance information immediately after switching AWS Regions. Although the DB instances might have identical names in each AWS Region, the associated Performance Insights URL is different for each DB instance. After switching AWS Regions, choose the name of the DB instance again in the Performance Insights navigation pane.

For DB instances associated with a global database, the factors affecting performance might be different in each AWS Region. For example, the DB instances in each AWS Region might have different capacity.

To learn more about using Performance Insights, see [Monitoring DB load with Performance Insights on Amazon Aurora](p. 559).
Monitoring Aurora global databases with Database Activity Streams

By using the Database Activity Streams feature, you can monitor and set alarms for auditing activity in the DB clusters in your global database. You start a database activity stream on each DB cluster separately. Each cluster delivers audit data to its own Kinesis stream within its own AWS Region. For more information, see Monitoring Amazon Aurora with Database Activity Streams (p. 746).

Monitoring Aurora MySQL-based global databases

To view the status of an Aurora MySQL-based global database, query the information_schema.aurora_global_db_status (p. 1196) and information_schema.aurora_global_db_instance_status (p. 1195) tables.

Note
The information_schema.aurora_global_db_status and information_schema.aurora_global_db_instance_status tables are only available with Aurora MySQL version 3.04.0 and higher global databases.

To monitor an Aurora MySQL-based global database

1. Connect to the global database primary cluster endpoint using a MySQL client. For more information about how to connect, see Connecting to an Amazon Aurora global database (p. 1830).
2. Query the information_schema.aurora_global_db_status table in a mysql command to list the primary and secondary volumes. This query returns the lag times of the global database secondary DB clusters, as in the following example.

   ```
   mysql> select * from information_schema.aurora_global_db_status;
   +-----------+---------------------+--------------------------------+------------------------+------------------------+
<table>
<thead>
<tr>
<th>AWS_REGION</th>
<th>HIGHEST_LSN_WRITTEN</th>
<th>DURABILITY_LAG_IN_MILLISECONDS</th>
<th>RPO_LAG_IN_MILLISECONDS</th>
<th>LAST_LAG_CALCULATION_TIMESTAMP</th>
<th>OLDEST_READ_VIEW_TRX_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>us-east-1</td>
<td>183537946</td>
<td></td>
<td>0</td>
<td>1970-01-01 00:00:00.000000</td>
<td>0</td>
</tr>
<tr>
<td>us-west-2</td>
<td>183537944</td>
<td>428</td>
<td>428</td>
<td>2023-02-18 01:26:41.925000</td>
<td>20806982</td>
</tr>
</tbody>
</table>
   (2 rows)
   ```

   The output includes a row for each DB cluster of the global database containing the following columns:

   - **AWS_REGION** – The AWS Region that this DB cluster is in. For tables listing AWS Regions by engine, see Regions and Availability Zones.
   - **HIGHEST_LSN_WRITTEN** – The highest log sequence number (LSN) currently written on this DB cluster.
     
     A log sequence number (LSN) is a unique sequential number that identifies a record in the database transaction log. LSNs are ordered such that a larger LSN represents a later transaction.
   - **DURABILITY_LAG_IN_MILLISECONDS** – The difference in the timestamp values between the HIGHEST_LSN_WRITTEN on a secondary DB cluster and the HIGHEST_LSN_WRITTEN on the primary DB cluster. This value is always 0 on the primary DB cluster of the Aurora global database.
   - **RPO_LAG_IN_MILLISECONDS** – The recovery point objective (RPO) lag. The RPO lag is the time it takes for the most recent user transaction COMMIT to be stored on a secondary DB cluster after
it's been stored on the primary DB cluster of the Aurora global database. This value is always 0 on the primary DB cluster of the Aurora global database.

In simple terms, this metric calculates the recovery point objective for each Aurora MySQL DB cluster in the Aurora global database, that is, how much data might be lost if there were an outage. As with lag, RPO is measured in time.

- **LAST_LAG_CALCULATION_TIMESTAMP** – The timestamp that specifies when values were last calculated for DURABILITY_LAG_IN_MILLISECONDS and RPO_LAG_IN_MILLISECONDS. A time value such as 1970-01-01 00:00:00+00 means this is the primary DB cluster.
- **OLDEST_READ_VIEW_TRX_ID** – The ID of the oldest transaction that the writer DB instance can purge to.

3. Query the information_schema.aurora_global_db_instance_status table to list all secondary DB instances for both the primary DB cluster and the secondary DB clusters.

```sql
mysql> select * from information_schema.aurora_global_db_instance_status;
```

<table>
<thead>
<tr>
<th>SERVER_ID</th>
<th>SESSION_ID</th>
<th>AWS_REGION</th>
<th>DURABLE_LSN</th>
<th>HIGHEST_LSN_RECEIVED</th>
<th>OLDEST_READ_VIEW_TRX_ID</th>
<th>OLDEST_READ_VIEW_LSN</th>
</tr>
</thead>
<tbody>
<tr>
<td>ams-gdb-primary-i2</td>
<td>MASTER_SESSION_ID</td>
<td>us-east-1</td>
<td>183537698</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>ams-gdb-secondary-i1</td>
<td>cc43165b-bdc6-4651-abbf-4f74f08bf931</td>
<td>us-west-2</td>
<td>183537689</td>
<td>183537692</td>
<td>20806928</td>
<td>183537682</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>ams-gdb-secondary-i2</td>
<td>53303ff0-70b5-411f-bc86-28d7a53f8c19</td>
<td>us-west-2</td>
<td>183537689</td>
<td>183537692</td>
<td>20806928</td>
<td>183537682</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>ams-gdb-primary-i1</td>
<td>5af1e20f-43db-421f-9f0d-2b92774c7d02</td>
<td>us-east-1</td>
<td>183537697</td>
<td>183537698</td>
<td>20806930</td>
<td>183537691</td>
</tr>
</tbody>
</table>

(4 rows)

The output includes a row for each DB instance of the global database containing the following columns:

- **SERVER_ID** – The server identifier for the DB instance.
- **SESSION_ID** – A unique identifier for the current session. A value of MASTER_SESSION_ID identifies the Writer (primary) DB instance.
- **AWS_REGION** – The AWS Region that this DB instance is in. For tables listing AWS Regions by engine, see Regions and Availability Zones.
- **DURABLE_LSN** – The LSN made durable in storage.
- **HIGHEST_LSN_RECEIVED** – The highest LSN received by the DB instance from the writer DB instance.
- **OLDEST_READ_VIEW_TRX_ID** – The ID of the oldest transaction that the writer DB instance can purge to.
- **OLDEST_READ_VIEW_LSN** – The oldest LSN used by the DB instance to read from storage.
- **VISIBILITY_LAG_IN_MSEC** – For readers in the primary DB cluster, how far this DB instance is lagging behind the writer DB instance in milliseconds. For readers in a secondary DB cluster, how far this DB instance is lagging behind the secondary volume in milliseconds.
To see how these values change over time, consider the following transaction block where a table insert takes an hour.

```sql
mysql> BEGIN;
mysql> INSERT INTO table1 SELECT Large_Data_That_Takes_1_Hr_To_Insert;
mysql> COMMIT;
```

In some cases, there might be a network disconnect between the primary DB cluster and the secondary DB cluster after the `BEGIN` statement. If so, the secondary DB cluster's `DURABILITY_LAG_IN_MILLISECONDS` value starts increasing. At the end of the `INSERT` statement, the `DURABILITY_LAG_IN_MILLISECONDS` value is 1 hour. However, the `RPO_LAG_IN_MILLISECONDS` value is 0 because all the user data committed between the primary DB cluster and secondary DB cluster are still the same. As soon as the `COMMIT` statement completes, the `RPO_LAG_IN_MILLISECONDS` value increases.

### Monitoring Aurora PostgreSQL-based global databases

To view the status of an Aurora PostgreSQL-based global database, use the `aurora_global_db_status` and `aurora_global_db_instance_status` functions.

**Note**

Only Aurora PostgreSQL supports the `aurora_global_db_status` and `aurora_global_db_instance_status` functions.

#### To monitor an Aurora PostgreSQL-based global database

1. Connect to the global database primary cluster endpoint using a PostgreSQL utility such as `psql`. For more information about how to connect, see [Connecting to an Amazon Aurora global database](p. 1830).
2. Use the `aurora_global_db_status` function in a `psql` command to list the primary and secondary volumes. This shows the lag times of the global database secondary DB clusters.

```sql
postgres=> select * from aurora_global_db_status();
```

<table>
<thead>
<tr>
<th>aws_region</th>
<th>highest_lsn_written</th>
<th>durability_lag_in_msec</th>
<th>rpo_lag_in_msec</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>us-east-1</td>
<td>93763984222</td>
<td>-1</td>
<td>-1</td>
</tr>
<tr>
<td>1970-01-01</td>
<td>00:00:00+00</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>us-west-2</td>
<td>93763984222</td>
<td>900</td>
<td>1090</td>
</tr>
<tr>
<td>2020-05-12</td>
<td>22:49:14.328+00</td>
<td>2</td>
<td>3315479243</td>
</tr>
</tbody>
</table>
(2 rows)

The output includes a row for each DB cluster of the global database containing the following columns:

- **aws_region** – The AWS Region that this DB cluster is in. For tables listing AWS Regions by engine, see [Regions and Availability Zones](p. 1830).
- **highest_lsn_written** – The highest log sequence number (LSN) currently written on this DB cluster.

A **log sequence number (LSN)** is a unique sequential number that identifies a record in the database transaction log. LSNs are ordered such that a larger LSN represents a later transaction.
• **durability_lag_in_msec** – The timestamp difference between the highest log sequence number written on a secondary DB cluster (highest_lsn_written) and the highest_lsn_written on the primary DB cluster.

• **rpo_lag_in_msec** – The recovery point objective (RPO) lag. This lag is the time difference between the most recent user transaction commit stored on a secondary DB cluster and the most recent user transaction commit stored on the primary DB cluster.

• **last_calculation_time** – The timestamp when values were last calculated for durability_lag_in_msec and rpo_lag_in_msec.

• **feedback_epoch** – The epoch a secondary DB cluster uses when it generates hot standby information.

**Hot standby** is when a DB cluster can connect and query while the server is in recovery or standby mode. Hot standby feedback is information about the DB cluster when it's in hot standby. For more information, see [Hot standby](#) in the PostgreSQL documentation.

• **feedback_xmin** – The minimum (oldest) active transaction ID used by a secondary DB cluster.

3. Use the `aurora_global_db_instance_status` function to list all secondary DB instances for both the primary DB cluster and secondary DB clusters.

```
pagres=> select * from aurora_global_db_instance_status();
```

<table>
<thead>
<tr>
<th>server_id</th>
<th>aws_region</th>
<th>durable_lsn</th>
<th>highest_lsn_rcvd</th>
<th>feedback_epoch</th>
<th>feedback_xmin</th>
<th>oldest_read_view_lsn</th>
<th>visibility_lag_in_msec</th>
</tr>
</thead>
<tbody>
<tr>
<td>apg-global-db-rpo-mammothrw-elephantro-1-n1</td>
<td>us-east-1</td>
<td>93763985102</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>apg-global-db-rpo-mammothrw-elephantro-1-n2</td>
<td>us-east-1</td>
<td>93763985099</td>
<td>93763985102</td>
<td>2</td>
<td>3315479243</td>
<td>93763985095</td>
<td></td>
</tr>
<tr>
<td>apg-global-db-rpo-elephantro-mammothrw-n1</td>
<td>us-west-2</td>
<td>93763985095</td>
<td>93763985099</td>
<td>2</td>
<td>3315479243</td>
<td>1017</td>
<td></td>
</tr>
</tbody>
</table>

The output includes a row for each DB instance of the global database containing the following columns:

• **server_id** – The server identifier for the DB instance.

• **session_id** – A unique identifier for the current session.

• **aws_region** – The AWS Region that this DB instance is in. For tables listing AWS Regions by engine, see [Regions and Availability Zones](#).

• **durable_lsn** – The LSN made durable in storage.

• **highest_lsn_rcvd** – The highest LSN received by the DB instance from the writer DB instance.

• **feedback_epoch** – The epoch the DB instance uses when it generates hot standby information.

**Hot standby** is when a DB instance can connect and query while the server is in recovery or standby mode. Hot standby feedback is information about the DB instance when it's in hot standby. For more information, see the PostgreSQL documentation on [Hot standby](#).

• **feedback_xmin** – The minimum (oldest) active transaction ID used by the DB instance.

• **oldest_read_view_lsn** – The oldest LSN used by the DB instance to read from storage.

• **visibility_lag_in_msec** – How far this DB instance is lagging behind the writer DB instance.
To see how these values change over time, consider the following transaction block where a table insert takes an hour.

```
psql> BEGIN;
psql> INSERT INTO table1 SELECT Large_Data_That_Takes_1_Hr_To_Insert;
psql> COMMIT;
```

In some cases, there might be a network disconnect between the primary DB cluster and the secondary DB cluster after the BEGIN statement. If so, the secondary DB cluster's `durability_lag_in_msec` value starts increasing. At the end of the INSERT statement, the `durability_lag_in_msec` value is 1 hour. However, the `rpo_lag_in_msec` value is 0 because all the user data committed between the primary DB cluster and secondary DB cluster are still the same. As soon as the COMMIT statement completes, the `rpo_lag_in_msec` value increases.

Using Amazon Aurora global databases with other AWS services

You can use your Aurora global databases with other AWS services, such as Amazon S3 and AWS Lambda. Doing so requires that all Aurora DB clusters in your global database have the same privileges, external functions, and so on in the respective AWS Regions. Because a read-only Aurora secondary DB cluster in an Aurora global database can be promoted to the role of primary, we recommend that you set up write privileges ahead of time, on all Aurora DB clusters for any services you plan to use with your Aurora global database.

The following procedures summarize the actions to take for each AWS service.

**To invoke AWS Lambda functions from an Aurora global database**

1. For all the Aurora clusters that make up the Aurora global database, perform the procedures in [Invoking a Lambda function from an Amazon Aurora MySQL DB cluster](p. 1075).
2. For each cluster in the Aurora global database, set the (ARN) of the new IAM (IAM) role.
3. To permit database users in an Aurora global database to invoke Lambda functions, associate the role that you created in [Creating an IAM role to allow Amazon Aurora to access AWS services](p. 1053) with each cluster in the Aurora global database.
4. Configure each cluster in the Aurora global database to allow outbound connections to Lambda. For instructions, see [Enabling network communication from Amazon Aurora MySQL to other AWS services](p. 1058).

**To load data from Amazon S3**

1. For all the Aurora clusters that make up the Aurora global database, perform the procedures in [Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket](p. 1059).
2. For each Aurora cluster in the global database, set either the `aurora_load_from_s3_role` or `aws_default_s3_role` DB cluster parameter to the Amazon Resource Name (ARN) of the new IAM role. If an IAM role isn't specified for `aurora_load_from_s3_role`, Aurora uses the IAM role specified in `aws_default_s3_role`.
3. To permit database users in an Aurora global database to access S3, associate the role that you created in [Creating an IAM role to allow Amazon Aurora to access AWS services](p. 1053) with each Aurora cluster in the global database.
4. Configure each Aurora cluster in the global database to allow outbound connections to S3. For instructions, see [Enabling network communication from Amazon Aurora MySQL to other AWS services](p. 1058).
To save queried data to Amazon S3

1. For all the Aurora clusters that make up the Aurora global database, perform the procedures in Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket (p. 1068).

2. For each Aurora cluster in the global database, set either the aurora_select_into_s3_role or aws_default_s3_role DB cluster parameter to the Amazon Resource Name (ARN) of the new IAM role. If an IAM role isn't specified for aurora_select_into_s3_role, Aurora uses the IAM role specified in aws_default_s3_role.

3. To permit database users in an Aurora global database to access S3, associate the role that you created in Creating an IAM role to allow Amazon Aurora to access AWS services (p. 1053) with each Aurora cluster in the global database.

4. Configure each Aurora cluster in the global database to allow outbound connections to S3. For instructions, see Enabling network communication from Amazon Aurora MySQL to other AWS services (p. 1058).

Upgrading an Amazon Aurora global database

Upgrading an Aurora global database follows the same procedures as upgrading Aurora DB clusters. However, following are some important differences to take note of before you start the process.

We recommend that you upgrade the primary and secondary DB clusters to the same version. You can only perform a managed cross-Region database failover on an Aurora global database if the primary and secondary DB clusters have the same major, minor, and patch level engine versions. However, the patch levels can be different, depending on the minor engine version. For more information, see Patch level compatibility for managed cross-Region switchovers and failovers (p. 1877).

Major version upgrades

When you perform a major version upgrade of an Amazon Aurora global database, you upgrade the global database cluster instead the individual clusters that it contains.

To learn how to upgrade an Aurora PostgreSQL global database to a higher major version, see Major upgrades for global databases (p. 1792).

Note
With an Aurora global database based on Aurora PostgreSQL, you can't perform a major version upgrade of the Aurora DB engine if the recovery point objective (RPO) feature is turned on. For information about the RPO feature, see Managing RPOs for Aurora PostgreSQL-based global databases (p. 1865).

To learn how to upgrade an Aurora MySQL global database to a higher major version, see In-place major upgrades for global databases (p. 1220).

Note
With an Aurora global database based on Aurora MySQL, you can't perform an in-place upgrade from Aurora MySQL version 2 to version 3 if the lower_case_table_names parameter is turned on.

To perform a major version upgrade to Aurora MySQL version 3 when using lower_case_table_names, use the following process:

1. Remove all secondary Regions from the global cluster. Follow the steps in Removing a cluster from an Amazon Aurora global database (p. 1826).

2. Upgrade the engine version of the primary Region to Aurora MySQL version 3. Follow the steps in How to perform an in-place upgrade (p. 1217).
3. Add secondary Regions to the global cluster. Follow the steps in Adding an AWS Region to an Amazon Aurora global database (p. 1817).

You can also use the snapshot restore method instead. For more information, see Restoring from a DB cluster snapshot (p. 439).

**Minor version upgrades**

For a minor upgrade on an Aurora global database, you upgrade all of the secondary clusters before you upgrade the primary cluster.

To learn how to upgrade an Aurora PostgreSQL global database to a higher minor version, see How to perform minor version upgrades and apply patches (p. 1794). To learn how to upgrade an Aurora MySQL global database to a higher minor version, see Upgrading Aurora MySQL by modifying the engine version (p. 1209).

Before you perform the upgrade, review the following considerations:

- Upgrading the minor version of a secondary cluster doesn’t affect availability or usage of the primary cluster in any way.
- A secondary cluster must have at least one DB instance to perform a minor upgrade.
- If you upgrade an Aurora MySQL global database to version 2.11.*, you must upgrade your primary and secondary DB clusters to the exact same version, including the patch level.
- To support managed cross-Region switchovers or failovers, you must upgrade your primary and secondary DB clusters to the exact same version, including the patch level, depending on the engine version. For more information, see Patch level compatibility for managed cross-Region switchovers and failovers (p. 1877).

**Patch level compatibility for managed cross-Region switchovers and failovers**

When you upgrade your Aurora global database to one of the following minor engine versions, you can perform managed cross-Region switchovers or failovers even if the patch levels of your primary and secondary DB clusters don’t match. For minor engine versions lower than the ones on this list, you must upgrade your primary and secondary DB clusters to the same major, minor, and patch levels to perform managed cross-Region switchovers or failovers. Make sure to review the version information and the notes in the following table.

**Note**

For manual cross-Region failovers, you can perform the failover process as long as the target secondary DB cluster is running the same major and minor engine version as the primary DB cluster. In this case, the patch levels don’t need to match.

<table>
<thead>

Using Amazon RDS Proxy for Aurora

By using Amazon RDS Proxy, you can allow your applications to pool and share database connections to improve their ability to scale. RDS Proxy makes applications more resilient to database failures by automatically connecting to a standby DB instance while preserving application connections. By using RDS Proxy, you can also enforce AWS Identity and Access Management (IAM) authentication for databases, and securely store credentials in AWS Secrets Manager.

Using RDS Proxy, you can handle unpredictable surges in database traffic. Otherwise, these surges might cause issues due to oversubscribing connections or creating new connections at a fast rate. RDS Proxy establishes a database connection pool and reuses connections in this pool. This approach avoids the memory and CPU overhead of opening a new database connection each time. To protect the database against oversubscription, you can control the number of database connections that are created.

RDS Proxy queues or throttles application connections that can't be served immediately from the pool of connections. Although latencies might increase, your application can continue to scale without abruptly failing or overwhelming the database. If connection requests exceed the limits you specify, RDS Proxy rejects application connections (that is, it sheds load). At the same time, it maintains predictable performance for the load that can be served with the available capacity.

You can reduce the overhead to process credentials and establish a secure connection for each new connection. RDS Proxy can handle some of that work on behalf of the database.

RDS Proxy is fully compatible with the engine versions that it supports. You can enable RDS Proxy for most applications with no code changes. For a list of supported engine versions, see Amazon RDS Proxy (p. 49).

Region and version availability

For information about database engine version support and availability of RDS Proxy in a given AWS Region, see Amazon RDS Proxy (p. 49).

Quotas and limitations for RDS Proxy

The following quotas and limitations apply to RDS Proxy:
You can have up to 20 proxies for each AWS account ID. If your application requires more proxies, you can request additional proxies by opening a ticket with the AWS Support organization.

Each proxy can have up to 200 associated Secrets Manager secrets. Thus, each proxy can connect to with up to 200 different user accounts at any given time.

You can create, view, modify, and delete up to 20 endpoints for each proxy. These endpoints are in addition to the default endpoint that's automatically created for each proxy.

In an Aurora cluster, all of the connections using the default proxy endpoint are handled by the Aurora writer instance. To perform load balancing for read-intensive workloads, you can create a read-only endpoint for a proxy. That endpoint passes connections to the reader endpoint of the cluster. That way, your proxy connections can take advantage of Aurora read scalability. For more information, see Overview of proxy endpoints (p. 1912).

You can use RDS Proxy with Aurora Serverless v2 clusters, but not with Aurora Serverless v1 clusters.

Your RDS Proxy must be in the same virtual private cloud (VPC) as the database. The proxy can't be publicly accessible, although the database can be. For example, if you're prototyping on a local host, you can't connect to your RDS Proxy unless you set up dedicated networking. This is the case because your local host is outside of the proxy's VPC.

Note
For Aurora DB clusters, you can turn on cross-VPC access. To do this, create an additional endpoint for a proxy and specify a different VPC, subnets, and security groups with that endpoint. For more information, see Accessing Aurora databases across VPCs (p. 1915).

You can't use RDS Proxy with a VPC that has its tenancy set to dedicated.

If you use RDS Proxy with an Aurora DB cluster that has IAM authentication enabled, check user authentication. Users who connect through a proxy must authenticate through sign-in credentials. For details about Secrets Manager and IAM support in RDS Proxy, see Setting up database credentials in AWS Secrets Manager and Setting up AWS Identity and Access Management (IAM) policies (p. 1890).

You can't use RDS Proxy with custom DNS when using SSL hostname validation.

Each proxy can be associated with a single target DB cluster. However, you can associate multiple proxies with the same DB cluster.

Any statement with a text size greater than 16 KB causes the proxy to pin the session to the current connection.

Certain Regions have Availability-Zone (AZ) restrictions to consider while creating your proxy. US East (N. Virginia) Region does not support RDS Proxy in the use1-az3 Availability Zone. US West (N. California) Region does not support RDS Proxy in the usw1-az2 Availability Zone. When selecting subnets while creating your proxy, make sure that you don't select subnets in the Availability Zones mentioned above.

For additional limitations for each DB engine, see the following sections:

- Additional limitations for Aurora MySQL (p. 1880)
- Additional limitations for Aurora PostgreSQL (p. 1881)

### Additional limitations for Aurora MySQL

The following additional limitations apply to RDS Proxy with Aurora MySQL databases:

- RDS Proxy doesn't support the MySQL sha256_password and caching_sha2_password authentication plugins. These plugins implement SHA-256 hashing for user account passwords.
- Currently, all proxies listen on port 3306 for MySQL. The proxies still connect to your database using the port that you specified in the database settings.
- You can't use RDS Proxy with self-managed MySQL databases in EC2 instances.
• You can’t use RDS Proxy with an RDS for MySQL DB instance that has the read_only parameter in its DB parameter group set to 1.
• RDS Proxy doesn’t support MySQL compressed mode. For example, it doesn’t support the compression used by the --compress or -C options of the mysql command.
• Database connections processing a GET DIAGNOSTIC command might return inaccurate information when RDS Proxy reuses the same database connection to run another query. This can happen when RDS Proxy multiplexes database connections.
• Some SQL statements and functions such as SET LOCAL can change the connection state without causing pinning. For the most current pinning behavior, see Avoiding pinning (p. 1908).

Important
For proxies associated with MySQL databases, don’t set the configuration parameter sql_auto_is_null to true or a nonzero value in the initialization query. Doing so might cause incorrect application behavior.

Additional limitations for Aurora PostgreSQL

The following additional limitations apply to RDS Proxy with Aurora PostgreSQL databases:

• RDS Proxy doesn’t support session pinning filters for PostgreSQL.
• Currently, all proxies listen on port 5432 for PostgreSQL.
• For PostgreSQL, RDS Proxy doesn’t currently support canceling a query from a client by issuing a CancelRequest. This is the case, for example, when you cancel a long-running query in an interactive psql session by using Ctrl+C.
• The results of the PostgreSQL function lastval aren’t always accurate. As a work-around, use the INSERT statement with the RETURNING clause.
• RDS Proxy currently doesn’t support streaming replication mode.

Important
For existing proxies with PostgreSQL databases, if you modify the database authentication to use SCRAM only, the proxy becomes unavailable for up to 60 seconds. To avoid the issue, do one of the following:

• Ensure that the database allows both SCRAM and MD5 authentication.
• To use only SCRAM authentication, create a new proxy, migrate your application traffic to the new proxy, then delete the proxy previously associated with the database.

Planning where to use RDS Proxy

You can determine which of your DB instances, clusters, and applications might benefit the most from using RDS Proxy. To do so, consider these factors:

• Any DB cluster that encounters “too many connections” errors is a good candidate for associating with a proxy. This is often characterized by a high value of the ConnectionAttempts CloudWatch metric. The proxy enables applications to open many client connections, while the proxy manages a smaller number of long-lived connections to the DB cluster.
• For DB clusters that use smaller AWS instance classes, such as T2 or T3, using a proxy can help avoid out-of-memory conditions. It can also help reduce the CPU overhead for establishing connections. These conditions can occur when dealing with large numbers of connections.
• You can monitor certain Amazon CloudWatch metrics to determine whether a DB cluster is approaching certain types of limit. These limits are for the number of connections and the memory...
associated with connection management. You can also monitor certain CloudWatch metrics to
determine whether a DB cluster is handling many short-lived connections. Opening and closing such
connections can impose performance overhead on your database. For information about the metrics to
monitor, see Monitoring RDS Proxy metrics with Amazon CloudWatch (p. 1921).

- AWS Lambda functions can also be good candidates for using a proxy. These functions make frequent
  short database connections that benefit from connection pooling offered by RDS Proxy. You can take
  advantage of any IAM authentication you already have for Lambda functions, instead of managing
database credentials in your Lambda application code.

- Applications that typically open and close large numbers of database connections and don't have
  built-in connection pooling mechanisms are good candidates for using a proxy.

- Applications that keep a large number of connections open for long periods are typically good
  candidates for using a proxy. Applications in industries such as software as a service (SaaS) or
  ecommerce often minimize the latency for database requests by leaving connections open. With RDS
  Proxy, an application can keep more connections open than it can when connecting directly to the DB
  cluster.

- You might not have adopted IAM authentication and Secrets Manager due to the complexity of setting
  up such authentication for all DB clusters. If so, you can leave the existing authentication methods in
  place and delegate the authentication to a proxy. The proxy can enforce the authentication policies
  for client connections for particular applications. You can take advantage of any IAM authentication
  you already have for Lambda functions, instead of managing database credentials in your Lambda
  application code.

- RDS Proxy can help make applications more resilient and transparent to database failures. RDS Proxy
  bypasses Domain Name System (DNS) caches to reduce failover times by up to 66% for Aurora Multi-
  AZ databases. RDS Proxy also automatically routes traffic to a new database instance while preserving
  application connections. This makes failovers more transparent for applications.

RDS Proxy concepts and terminology

You can simplify connection management for your Amazon Aurora DB clusters by using RDS Proxy.

RDS Proxy handles the network traffic between the client application and the database. It does so in an
active way first by understanding the database protocol. It then adjusts its behavior based on the SQL
operations from your application and the result sets from the database.

RDS Proxy reduces the memory and CPU overhead for connection management on your database.
The database needs less memory and CPU resources when applications open many simultaneous
connections. It also doesn't require logic in your applications to close and reopen connections that stay
idle for a long time. Similarly, it requires less application logic to reestablish connections in case of a
database problem.

The infrastructure for RDS Proxy is highly available and deployed over multiple Availability Zones (AZs).
The computation, memory, and storage for RDS Proxy are independent of your Aurora DB cluster. This
separation helps lower overhead on your database servers, so that they can devote their resources to
serving database workloads. The RDS Proxy compute resources are serverless, automatically scaling
based on your database workload.

Topics
- Overview of RDS Proxy concepts (p. 1883)
- Connection pooling (p. 1883)
- RDS Proxy security (p. 1884)
- Failover (p. 1885)
- Transactions (p. 1886)
Overview of RDS Proxy concepts

RDS Proxy handles the infrastructure to perform connection pooling and the other features described in the sections that follow. You see the proxies represented in the RDS console on the Proxies page.

Each proxy handles connections to a single Aurora DB cluster. The proxy automatically determines the current writer instance for Aurora provisioned clusters.

The connections that a proxy keeps open and available for your database application to use make up the connection pool.

By default, RDS Proxy can reuse a connection after each transaction in your session. This transaction-level reuse is called multiplexing. When RDS Proxy temporarily removes a connection from the connection pool to reuse it, that operation is called borrowing the connection. When it's safe to do so, RDS Proxy returns that connection to the connection pool.

In some cases, RDS Proxy can't be sure that it's safe to reuse a database connection outside of the current session. In these cases, it keeps the session on the same connection until the session ends. This fallback behavior is called pinning.

A proxy has a default endpoint. You connect to this endpoint when you work with an Amazon Aurora DB cluster. You do so instead of connecting to the read/write endpoint that connects directly to the cluster. The special-purpose endpoints for an Aurora cluster remain available for you to use. For Aurora DB clusters, you can also create additional read/write and read-only endpoints. For more information, see Overview of proxy endpoints (p. 1912).

For example, you can still connect to the cluster endpoint for read/write connections without connection pooling. You can still connect to the reader endpoint for load-balanced read-only connections. You can still connect to the instance endpoints for diagnosis and troubleshooting of specific DB instances within a cluster. If you use other AWS services such as AWS Lambda to connect to RDS databases, change their connection settings to use the proxy endpoint. For example, you specify the proxy endpoint to allow Lambda functions to access your database while taking advantage of RDS Proxy functionality.

Each proxy contains a target group. This target group embodies the Aurora DB cluster that the proxy can connect to. For an Aurora cluster, by default the target group is associated with all the DB instances in that cluster. That way, the proxy can connect to whichever Aurora DB instance is promoted to be the writer instance in the cluster. The Aurora DB cluster associated with a proxy are called the targets of that proxy. For convenience, when you create a proxy through the console, RDS Proxy also creates the corresponding target group and registers the associated targets automatically.

An engine family is a related set of database engines that use the same DB protocol. You choose the engine family for each proxy that you create.

Connection pooling

Each proxy performs connection pooling for the writer instance of its associated Aurora DB. Connection pooling is an optimization that reduces the overhead associated with opening and closing connections and with keeping many connections open simultaneously. This overhead includes memory needed to handle each new connection. It also involves CPU overhead to close each connection and open a new one. Examples include Transport Layer Security/Secure Sockets Layer (TLS/SSL) handshaking, authentication, negotiating capabilities, and so on. Connection pooling simplifies your application logic. You don't need to write application code to minimize the number of simultaneous open connections.

Each proxy also performs connection multiplexing, also known as connection reuse. With multiplexing, RDS Proxy performs all the operations for a transaction using one underlying database connection. RDS then can use a different connection for the next transaction. You can open many simultaneous connections to the proxy, and the proxy keeps a smaller number of connections open to the DB instance.
or cluster. Doing so further minimizes the memory overhead for connections on the database server. This technique also reduces the chance of “too many connections” errors.

**RDS Proxy security**

RDS Proxy uses the existing RDS security mechanisms such as TLS/SSL and AWS Identity and Access Management (IAM). For general information about those security features, see *Security in Amazon Aurora* (p. 2367). Also, make sure to familiarize yourself with how Aurora work with authentication, authorization, and other areas of security.

RDS Proxy can act as an additional layer of security between client applications and the underlying database. For example, you can connect to the proxy using TLS 1.2, even if the underlying DB instance supports an older version of TLS. You can connect to the proxy using an IAM role. This is so even if the proxy connects to the database using the native user and password authentication method. By using this technique, you can enforce strong authentication requirements for database applications without a costly migration effort for the DB instances themselves.

You store the database credentials used by RDS Proxy in AWS Secrets Manager. Each database user for the Aurora DB cluster accessed by a proxy must have a corresponding secret in Secrets Manager. You can also set up IAM authentication for users of RDS Proxy. By doing so, you can enforce IAM authentication for database access even if the databases use native password authentication. We recommend using these security features instead of embedding database credentials in your application code.

**Using TLS/SSL with RDS Proxy**

You can connect to RDS Proxy using the TLS/SSL protocol.

*Note*

RDS Proxy uses certificates from the AWS Certificate Manager (ACM). If you are using RDS Proxy, you don’t need to download Amazon RDS certificates or update applications that use RDS Proxy connections.

To enforce TLS for all connections between the proxy and your database, you can specify a setting `Require Transport Layer Security` when you create or modify a proxy.

RDS Proxy can also ensure that your session uses TLS/SSL between your client and the RDS Proxy endpoint. To have RDS Proxy do so, specify the requirement on the client side. SSL session variables are not set for SSL connections to a database using RDS Proxy.

- For Aurora MySQL, specify the requirement on the client side with the `--ssl-mode` parameter when you run the `mysql` command.
- For and Aurora PostgreSQL, specify `sslmode=require` as part of the `conninfo` string when you run the `psql` command.

RDS Proxy supports TLS protocol version 1.0, 1.1, and 1.2. You can connect to the proxy using a higher version of TLS than you use in the underlying database.

By default, client programs establish an encrypted connection with RDS Proxy, with further control available through the `--ssl-mode` option. From the client side, RDS Proxy supports all SSL modes.

For the client, the SSL modes are the following:

**PREFERRED**

SSL is the first choice, but it isn’t required.

**DISABLED**

No SSL is allowed.
REQUIRED

Enforce SSL.

VERIFY_CA

Enforce SSL and verify the certificate authority (CA).

VERIFY_IDENTITY

Enforce SSL and verify the CA and CA hostname.

When using a client with --ssl-mode VERIFY_CA or VERIFY_IDENTITY, specify the --ssl-ca option pointing to a CA in .pem format. For the .pem file to use, download all root CA PEMs from Amazon Trust Services and place them into a single .pem file.

RDS Proxy uses wildcard certificates, which apply to both a domain and its subdomains. If you use the mysql client to connect with SSL mode VERIFY_IDENTITY, currently you must use the MySQL 8.0-compatible mysql command.

Failover

Failover is a high-availability feature that replaces a database instance with another one when the original instance becomes unavailable. A failover might happen because of a problem with a database instance. It might also be part of normal maintenance procedures, such as during a database upgrade. Failover applies to Aurora DB clusters with one or more reader instances in addition to the writer instance.

Connecting through a proxy makes your application more resilient to database failovers. When the original DB instance becomes unavailable, RDS Proxy connects to the standby database without dropping idle application connections. Doing so helps to speed up and simplify the failover process. The result is faster failover that's less disruptive to your application than a typical reboot or database problem.

Without RDS Proxy, a failover involves a brief outage. During the outage, you can't perform write operations on that database. Any existing database connections are disrupted, and your application must reopen them. The database becomes available for new connections and write operations when a read-only DB instance is promoted in place of one that's unavailable.

During DB failovers, RDS Proxy continues to accept connections at the same IP address and automatically directs connections to the new primary DB instance. Clients connecting through RDS Proxy are not susceptible to the following:

- Domain Name System (DNS) propagation delays on failover.
- Local DNS caching.
- Connection timeouts.
- Uncertainty about which DB instance is the current writer.
- Waiting for a query response from a former writer that became unavailable without closing connections.

For applications that maintain their own connection pool, going through RDS Proxy means that most connections stay alive during failovers or other disruptions. Only connections that are in the middle of a transaction or SQL statement are canceled. RDS Proxy immediately accepts new connections. When the database writer is unavailable, RDS Proxy queues up incoming requests.

For applications that don't maintain their own connection pools, RDS Proxy offers faster connection rates and more open connections. It offloads the expensive overhead of frequent reconnects from the
database. It does so by reusing database connections maintained in the RDS Proxy connection pool. This approach is particularly important for TLS connections, where setup costs are significant.

**Transactions**

All the statements within a single transaction always use the same underlying database connection. The connection becomes available for use by a different session when the transaction ends. Using the transaction as the unit of granularity has the following consequences:

- Connection reuse can happen after each individual statement when the Aurora MySQL autocommit setting is turned on.
- Conversely, when the autocommit setting is turned off, the first statement you issue in a session begins a new transaction. For example, suppose that you enter a sequence of SELECT, INSERT, UPDATE, and other data manipulation language (DML) statements. In this case, connection reuse doesn't happen until you issue a COMMIT, ROLLBACK, or otherwise end the transaction.
- Entering a data definition language (DDL) statement causes the transaction to end after that statement completes.

RDS Proxy detects when a transaction ends through the network protocol used by the database client application. Transaction detection doesn't rely on keywords such as COMMIT or ROLLBACK appearing in the text of the SQL statement.

In some cases, RDS Proxy might detect a database request that makes it impractical to move your session to a different connection. In these cases, it turns off multiplexing for that connection the remainder of your session. The same rule applies if RDS Proxy can’t be certain that multiplexing is practical for the session. This operation is called pinning. For ways to detect and minimize pinning, see Avoiding pinning (p. 1908).

**Getting started with RDS Proxy**

In the following sections, you can find how to set up RDS Proxy. You can also find how to set related security options. These control who can access each proxy and how each proxy connects to DB instances.

**Topics**

- [Setting up network prerequisites](p. 1886)
- [Setting up database credentials in AWS Secrets Manager](p. 1889)
- [Setting up AWS Identity and Access Management (IAM) policies](p. 1890)
- [Creating an RDS Proxy](p. 1892)
- [Viewing an RDS Proxy](p. 1896)
- [Connecting to a database through RDS Proxy](p. 1897)

**Setting up network prerequisites**

Using RDS Proxy requires you to have a common virtual private cloud (VPC) between your Aurora DB cluster and RDS Proxy. This VPC should have a minimum of two subnets that are in different Availability Zones. Your account can either own these subnets or share them with other accounts. For information about VPC sharing, see [Work with shared VPCs](p. 1892). Your client application resources such as Amazon EC2, Lambda, or Amazon ECS can be in the same VPC as the proxy. Or they can be in a separate VPC from the proxy. If you successfully connected to any Aurora DB clusters, you already have the required network resources.
Getting information about your subnets

If you're just getting started with RDS or Aurora, you can learn the basics of connecting to a database by following the procedures in Setting up your environment for Amazon Aurora (p. 119). You can also follow the tutorial in Getting started with Amazon Aurora (p. 124).

The following Linux example shows AWS CLI commands that examine the VPCs and subnets owned by your AWS account. In particular, you pass subnet IDs as parameters when you create a proxy using the CLI.

```
aws ec2 describe-vpcs
aws ec2 describe-internet-gateways
aws ec2 describe-subnets --query '*[].[VpcId,SubnetId]' --output text | sort
```

The following Linux example shows AWS CLI commands to determine the subnet IDs corresponding to a specific Aurora DB cluster.

For an Aurora cluster, first you find the ID for one of the associated DB instances. You can extract the subnet IDs used by that DB instance. To do so, examine the nested fields within the DBSubnetGroup and Subnets attributes in the describe output for the DB instance. You specify some or all of those subnet IDs when setting up a proxy for that database server.

```
$ # Find the ID of any DB instance in the cluster.
$ aws rds describe-db-clusters --db-cluster-identifier my_cluster_id --query '*[].[DBClusterMembers][0][0][*].DBInstanceIdentifier' --output text
my_instance_id
instance_id_2
instance_id_3
```

After finding the DB instance identifier, examine the associated VPC to find its subnets. The following Linux example shows how.

```
...

$ # From the DB instance, trace through the DBSubnetGroup and Subnets to find the subnet IDs.
$ aws rds describe-db-instances --db-instance-identifier my_instance_id --query '*[].[DBSubnetGroup][0][0][Subnets][0][*].SubnetIdentifier' --output text
subnet_id_1
subnet_id_2
subnet_id_3
...
```

```
$ # From the DB instance, find the VPC.
$ aws rds describe-db-instances --db-instance-identifier my_instance_id --query '*[].[DBSubnetGroup][0][0].VpcId' --output text
my_vpc_id

$ aws ec2 describe-subnets --filters Name=vpc-id,Values=my_vpc_id --query '*[].[SubnetId]' --output text
```

---

1887
Planning for IP address capacity

An RDS Proxy automatically adjusts its capacity as needed based on the size and number of DB instances registered with it. Certain operations might also require additional proxy capacity. Some examples are increasing the size of a registered database or internal RDS Proxy maintenance operations. During these operations, your proxy might need more IP addresses to provision the extra capacity. These additional addresses allow your proxy to scale without affecting your workload. A lack of free IP addresses in your subnets prevents a proxy from scaling up. This can lead to higher query latencies or client connection failures. RDS notifies you through event RDS-EVENT-0243 when there aren't enough free IP addresses in your subnets. For information about this event, see Working with RDS Proxy events (p. 1925).

Following are the recommended minimum number of IP addresses to leave free in your subnets for your proxy based on DB instance class sizes.

<table>
<thead>
<tr>
<th>DB instance class</th>
<th>Minimum free IP addresses</th>
</tr>
</thead>
<tbody>
<tr>
<td>db.*.xlarge or smaller</td>
<td>10</td>
</tr>
<tr>
<td>db.*.2xlarge</td>
<td>15</td>
</tr>
<tr>
<td>db.*.4xlarge</td>
<td>25</td>
</tr>
<tr>
<td>db.*.8xlarge</td>
<td>45</td>
</tr>
<tr>
<td>db.*.12xlarge</td>
<td>60</td>
</tr>
<tr>
<td>db.*.16xlarge</td>
<td>75</td>
</tr>
<tr>
<td>db.*.24xlarge</td>
<td>110</td>
</tr>
</tbody>
</table>

These numbers of recommended IP addresses are estimates for a proxy with only the default endpoint. A proxy with additional endpoints or read replicas might need more free IP addresses. For each additional endpoint, we recommend that you reserve three more IP addresses. For each read replica, we recommend that you reserve additional IP addresses as specified in the table based on that read replica's size.

**Note**
RDS Proxy never uses more than 215 IP addresses in a VPC.

For example, suppose that you want to estimate the required IP addresses for a proxy that's associated with an Aurora DB cluster.

In this case, assume the following:

- Your Aurora DB cluster has 1 writer instance of size db.r5.8xlarge and 1 reader instance of size db.r5.2xlarge.
- The proxy that's attached to this DB cluster has the default endpoint and 1 custom endpoint with the read-only role.

In this case, the proxy needs approximately 63 free IP addresses (45 for the writer instance, 15 for reader instance, and 3 for the additional custom endpoint).
Setting up database credentials in AWS Secrets Manager

For each proxy that you create, you first use the Secrets Manager service to store sets of user name and password credentials. You create a separate Secrets Manager secret for each database user account that the proxy connects to on the Aurora DB cluster.

In Secrets Manager, you create these secrets with values for the username and password fields. Doing so allows the proxy to connect to the corresponding database users on a Aurora DB cluster that you associate with the proxy. To do this, you can use the setting Credentials for other database, Credentials for RDS database, or Other type of secrets. Fill in the appropriate values for the User name and Password fields, and placeholder values for any other required fields. The proxy ignores other fields such as Host and Port if they're present in the secret. Those details are automatically supplied by the proxy.

You can also choose Other type of secrets. In this case, you create the secret with keys named username and password.

Because the secrets used by your proxy aren't tied to a specific database server, you can reuse a secret across multiple proxies. To do so, use the same credentials across multiple database servers. For example, you might use the same credentials across a group of development and test servers.

To connect through the proxy as a specific user, make sure that the password associated with a secret matches the database password for that user. If there's a mismatch, you can update the associated secret in Secrets Manager. In this case, you can still connect to other accounts where the secret credentials and the database passwords do match.

When you create a proxy through the AWS CLI or RDS API, you specify the Amazon Resource Names (ARNs) of the corresponding secrets. You do so for all the DB user accounts that the proxy can access. In the AWS Management Console, you choose the secrets by their descriptive names.

For instructions about creating secrets in Secrets Manager, see the Creating a secret page in the Secrets Manager documentation. Use one of the following techniques:

- Use Secrets Manager in the console.
- To use the CLI to create a Secrets Manager secret for use with RDS Proxy, use a command such as the following.

```bash
aws secretsmanager create-secret
--name "secret_name"
--description "secret_description"
--region region_name
--secret-string '{"username":"db_user","password":"db_user_password"}'
```

For example, the following commands create Secrets Manager secrets for two database users, one named admin and the other named app-user.

```bash
aws secretsmanager create-secret
--name admin_secret_name --description "db admin user"
--secret-string '{"username":"admin","password":"choose_your_own_password"}'
aws secretsmanager create-secret
--name proxy_secret_name --description "application user"
--secret-string '{"username":"app-user","password":"choose_your_own_password"}'
```

To see the secrets owned by your AWS account, use a command such as the following.
Setting up IAM policies

When you create a proxy using the CLI, you pass the Amazon Resource Names (ARNs) of one or more secrets to the `--auth` parameter. The following Linux example shows how to prepare a report with only the name and ARN of each secret owned by your AWS account. This example uses the `--output table` parameter that is available in AWS CLI version 2. If you are using AWS CLI version 1, use `--output text` instead.

/aws secretsmanager list-secrets

To verify that you stored the correct credentials and in the right format in a secret, use a command such as the following. Substitute the short name or the ARN of the secret for `your_secret_name`.

/aws secretsmanager get-secret-value --secret-id your_secret_name

The output should include a line displaying a JSON-encoded value like the following.

"SecretString": "{"username":"your_username","password":"your_password"},

Setting up AWS Identity and Access Management (IAM) policies

After you create the secrets in Secrets Manager, you create an IAM policy that can access those secrets. For general information about using IAM, see Identity and access management for Amazon Aurora (p. 2400).

Tip

The following procedure applies if you use the IAM console. If you use the AWS Management Console for RDS, RDS can create the IAM policy for you automatically. In that case, you can skip the following procedure.

To create an IAM policy that accesses your Secrets Manager secrets for use with your proxy

1. Sign in to the IAM console. Follow the Create role process, as described in Creating IAM roles, choosing Create a role to delegate permissions to an AWS service.

   Choose AWS service for the Trusted entity type. Under Use case, select RDS from Use cases for other AWS services dropdown. Select RDS - Add Role to Database.

2. For the new role, perform the Add inline policy step. Use the same general procedures as in Editing IAM policies. Paste the following JSON into the JSON text box. Substitute your own account ID. Substitute your AWS Region for us-east-2. Substitute the Amazon Resource Names (ARNs) for the secrets that you created, see Specifying KMS keys in IAM policy statements. For the kms:Decrypt action, substitute the ARN of the default AWS KMS key or your own KMS key. Which one you use depends on which one you used to encrypt the Secrets Manager secrets.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": "secretsmanager:GetSecretValue",
            "Resource": [
                "arn:aws:secretsmanager:us-east-2:account_id:secret:secret_name_1",
```
Amazon Aurora User Guide for Aurora
Setting up IAM policies

3. Edit the trust policy for this IAM role. Paste the following JSON into the JSON text box.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

The following commands perform the same operation through the AWS CLI.

```
PREFIX=my_identifier

aws iam create-role --role-name my_role_name
  --assume-role-policy-document '{"Version":"2012-10-17","Statement":
  [{"Effect":"Allow","Principal":{"Service":
     ["rds.amazonaws.com"],"Action":"sts:AssumeRole"}]}'}

aws iam put-role-policy --role-name my_role_name
  --policy-name $PREFIX-secret-reader-policy --policy-document
  '{"Version":"2012-10-17","Statement": [{"Effect":"Allow","Principal":{"Service":
     ["rds.amazonaws.com"],"Action":"sts:AssumeRole"}]}'}

aws kms create-key --description "$PREFIX-test-key" --policy '{
  "Id": "$PREFIX-kms-policy",
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Enable IAM User Permissions",
      "Effect": "Allow",
      "Principal": {"AWS": "arn:aws:iam::account_id:root"},
      "Action": "kms:*", "Resource": "*"
    },
    {
      "Sid": "Allow access for Key Administrators",
      "Effect": "Allow",
      "Principal": {
```
Creating an RDS Proxy

To manage connections for a DB cluster, you can create a proxy. You can associate a proxy with an Aurora MySQL or Aurora PostgreSQL DB cluster.

AWS Management Console

To create a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Proxies.
3. Choose Create proxy.
4. Choose all the settings for your proxy.

For Proxy configuration, provide information for the following:

- **Engine family**: This setting determines which database network protocol the proxy recognizes when it interprets network traffic to and from the database. For Aurora MySQL, choose MariaDB and MySQL. For Aurora PostgreSQL, choose PostgreSQL.

- **Proxy identifier**: Specify a name of your choosing, unique within your AWS account ID and current AWS Region.

- **Idle client connection timeout**: Choose a time period that a client connection can be idle before the proxy can close it. The default is 1,800 seconds (30 minutes). A client connection is considered idle when the application doesn’t submit a new request within the specified time after the previous request completed. The underlying database connection stays open and is returned to the connection pool. Thus, it's available to be reused for new client connections.
Consider lowering the idle client connection timeout if you want the proxy to proactively remove stale connections. If your workload is spiking, consider raising the idle client connection timeout to save the cost of establishing connections.

For **Target group configuration**, provide information for the following:

- **Database**. Choose one Aurora DB cluster to access through this proxy. The list only includes DB instances and clusters with compatible database engines, engine versions, and other settings. If the list is empty, create a new DB instance or cluster that's compatible with RDS Proxy. To do so, follow the procedure in [Creating an Amazon Aurora DB cluster](p. 179). Then try creating the proxy again.

- **Connection pool maximum connections**. Specify a value from 1 through 100. This setting represents the percentage of the `max_connections` value that RDS Proxy can use for its connections. If you only intend to use one proxy with this DB instance or cluster, you can set this value to 100. For details about how RDS Proxy uses this setting, see [MaxConnectionsPercent](p. 1906).

- **Session pinning filters**. (Optional) This option allows you to force RDS Proxy to not pin for certain types of detected session states. This circumvents the default safety measures for multiplexing database connections across client connections. Currently, the setting isn't supported for PostgreSQL and the only choice is `EXCLUDE_VARIABLE_SETS`.

Enabling this setting can cause variables of one connection to impact other connections. This can cause errors or correctness issues if your queries depend on session variable values set outside of the current transaction. Consider using this option after verifying it is safe for your applications to share database connections across client connections.

The following patterns can be considered safe:

- SET statements where there is no change to the effective session variable value, i.e., there is no change to the session variable.
- You change the session variable value and execute a statement in the same transaction.

For more information, see [Avoiding pinning](p. 1908).

- **Connection borrow timeout**. In some cases, you might expect the proxy to sometimes use all available database connections. In such cases, you can specify how long the proxy waits for a database connection to become available before returning a timeout error. You can specify a period up to a maximum of five minutes. This setting only applies when the proxy has the maximum number of connections open and all connections are already in use.

- **Initialization query**. (Optional) You can specify one or more SQL statements for the proxy to run when opening each new database connection. The setting is typically used with SET statements to make sure that each connection has identical settings such as time zone and character set. For multiple statements, use semicolons as the separator. You can also include multiple variables in a single SET statement, such as `SET x=1, y=2`.

For **Authentication**, provide information for the following:

- **IAM role**. Choose an IAM role that has permission to access the Secrets Manager secrets that you chose earlier. You can also choose for the AWS Management Console to create a new IAM role for you and use that.

- **Secrets Manager secrets**. Choose at least one Secrets Manager secret that contains database user credentials for the Aurora DB cluster to access with this proxy.

- **Client authentication type**. Choose the type of authentication the proxy uses for connections from clients. Your choice applies to all Secrets Manager secrets that you associate with this proxy.
If you need to specify a different client authentication type for each secret, create your proxy by using the AWS CLI or the API instead.

- **IAM authentication.** Choose whether to require or disallow IAM authentication for connections to your proxy. Your choice applies to all Secrets Manager secrets that you associate with this proxy. If you need to specify a different IAM authentication for each secret, create your proxy by using the AWS CLI or the API instead.

For **Connectivity**, provide information for the following:

- **Require Transport Layer Security.** Choose this setting if you want the proxy to enforce TLS/SSL for all client connections. For an encrypted or unencrypted connection to a proxy, the proxy uses the same encryption setting when it makes a connection to the underlying database.

- **Subnets.** This field is prepopulated with all the subnets associated with your VPC. You can remove any subnets that you don't need for this proxy. You must leave at least two subnets.

Provide additional connectivity configuration:

- **VPC security group.** Choose an existing VPC security group. You can also choose for the AWS Management Console to create a new security group for you and use that. You must configure the **Inbound rules** to allow your applications to access the proxy. You must also configure the **Outbound rules** to allow traffic from your DB targets.

  **Note**
  This security group must allow connections from the proxy to the database. The same security group is used for ingress from your applications to the proxy, and for egress from the proxy to the database. For example, suppose that you use the same security group for your database and your proxy. In this case, make sure that you specify that resources in that security group can communicate with other resources in the same security group. When using a shared VPC, you can’t use the default security group for the VPC, or one that belongs to another account. Choose a security group that belongs to your account. If one doesn’t exist, create one. For more information about this limitation, see **Work with shared VPCs.**

(Optional) Provide advanced configuration:

- **Enable enhanced logging.** You can enable this setting to troubleshoot proxy compatibility or performance issues.

  When this setting is enabled, RDS Proxy includes detailed information about SQL statements in its logs. This information helps you to debug issues involving SQL behavior or the performance and scalability of the proxy connections. The debug information includes the text of SQL statements that you submit through the proxy. Thus, only enable this setting when needed for debugging. Also, only enable it when you have security measures in place to safeguard any sensitive information that appears in the logs.

  To minimize overhead associated with your proxy, RDS Proxy automatically turns this setting off 24 hours after you enable it. Enable it temporarily to troubleshoot a specific issue.

5. Choose **Create Proxy**.

**AWS CLI**

To create a proxy by using the AWS CLI, call the `create-db-proxy` command with the following required parameters:

- `--db-proxy-name`
• `--engine-family`
• `--role-arn`
• `--auth`
• `--vpc-subnet-ids`

The `--engine-family` value is case-sensitive.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-proxy
  --db-proxy-name proxy_name
  --engine-family { MYSQL | POSTGRESQL | SQLSERVER } \
  --auth ProxyAuthenticationConfig_JSON_string \
  --role-arn iam_role \
  --vpc-subnet-ids space_separated_list \
  [--vpc-security-group-ids space_separated_list] \
  [--require-tls | --no-require-tls] \
  [--idle-client-timeout value] \
  [--debug-logging | --no-debug-logging] \
  [--tags comma_separated_list]
```

For Windows:

```bash
aws rds create-db-proxy ^
  --db-proxy-name proxy_name ^
  --engine-family { MYSQL | POSTGRESQL | SQLSERVER } ^
  --auth ProxyAuthenticationConfig_JSON_string ^
  --role-arn iam_role ^
  --vpc-subnet-ids space_separated_list ^
  [--vpc-security-group-ids space_separated_list] ^
  [--require-tls | --no-require-tls] ^
  [--idle-client-timeout value] ^
  [--debug-logging | --no-debug-logging] ^
  [--tags comma_separated_list]
```

The following is an example of the JSON value for the `--auth` option. This example applies a different client authentication type to each secret.

```json
[
  {
    "Description": "proxy description 1",
    "AuthScheme": "SECRETS",
    "IAMAuth": "DISABLED",
    "ClientPasswordAuthType": "POSTGRES_SCRAM_SHA_256"
  },
  {
    "Description": "proxy description 2",
    "AuthScheme": "SECRETS",
    "IAMAuth": "DISABLED",
    "ClientPasswordAuthType": "POSTGRES_MD5"
  }
]
```
Tip
If you don't already know the subnet IDs to use for the --vpc-subnet-ids parameter, see Setting up network prerequisites (p. 1886) for examples of how to find them.

Note
The security group must allow access to the database the proxy connects to. The same security group is used for ingress from your applications to the proxy, and for egress from the proxy to the database. For example, suppose that you use the same security group for your database and your proxy. In this case, make sure that you specify that resources in that security group can communicate with other resources in the same security group.
When using a shared VPC, you can't use the default security group for the VPC, or one that belongs to another account. Choose a security group that belongs to your account. If one doesn't exist, create one. For more information about this limitation, see Work with shared VPCs.

To create the required information and associations for the proxy, you also use the register-db-proxy-targets command. Specify the target group name default. RDS Proxy automatically creates a target group with this name when you create each proxy.

RDS API
To create an RDS proxy, call the Amazon RDS API operation CreateDBProxy. You pass a parameter with the AuthConfig data structure.

RDS Proxy automatically creates a target group named default when you create each proxy. You associate an Aurora DB cluster with the target group by calling the function RegisterDBProxyTargets.

Viewing an RDS Proxy
After you create one or more RDS proxies, you can view them all. Doing so makes it possible to examine their configuration details and choose which ones to modify, delete, and so on.

Any database applications that use the proxy require the proxy endpoint to use in the connection string.

AWS Management Console
To view your proxy
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you created the RDS Proxy.
3. In the navigation pane, choose **Proxies**.
4. Choose the name of an RDS proxy to display its details.
5. On the details page, the **Target groups** section shows how the proxy is associated with a specific Aurora DB cluster. You can follow the link to the **default** target group page to see more details about the association between the proxy and the database. This page is where you see settings that you specified when creating the proxy. These include maximum connection percentage, connection borrow timeout, engine family, and session pinning filters.

**CLI**

To view your proxy using the CLI, use the `describe-db-proxies` command. By default, it displays all proxies owned by your AWS account. To see details for a single proxy, specify its name with the `-d db-proxy-name` parameter.

```bash
aws rds describe-db-proxies [--db-proxy-name proxy_name]
```

To view the other information associated with the proxy, use the following commands.

```bash
aws rds describe-db-proxy-target-groups --db-proxy-name proxy_name
aws rds describe-db-proxy-targets --db-proxy-name proxy_name
```

Use the following sequence of commands to see more detail about the things that are associated with the proxy:

1. To get a list of proxies, run `describe-db-proxies`.
2. To show connection parameters such as the maximum percentage of connections that the proxy can use, run `describe-db-proxy-target-groups` `--db-proxy-name`. Use the name of the proxy as the parameter value.
3. To see the details of the Aurora DB cluster associated with the returned target group, run `describe-db-proxy-targets`.

**RDS API**

To view your proxies using the RDS API, use the **DescribeDBProxies** operation. It returns values of the **DBProxy** data type.

To see details of the connection settings for the proxy, use the proxy identifiers from this return value with the **DescribeDBProxyTargetGroups** operation. It returns values of the **DBProxyTargetGroup** data type.

To see the RDS instance or Aurora DB cluster associated with the proxy, use the **DescribeDBProxyTargets** operation. It returns values of the **DBProxyTarget** data type.

**Connecting to a database through RDS Proxy**

You connect to an Aurora DB cluster or cluster that uses Aurora Serverless v2 through a proxy in generally the same way as you connect directly to the database. The main difference is that you specify the proxy endpoint instead of the cluster endpoint. By default all proxy connections have read/write capability and use the writer instance. If you normally use the reader endpoint for read-only connections, you can create an additional read-only endpoint for the proxy. You can use that endpoint the same way. For more information, see **Overview of proxy endpoints** (p. 1912).
Connecting to a proxy using native authentication

Use the following basic steps to connect to a proxy using native authentication:

1. Find the proxy endpoint. In the AWS Management Console, you can find the endpoint on the details page for the corresponding proxy. With the AWS CLI, you can use the `describe-db-proxies` command. The following example shows how.

   ```bash
   # Add --output text to get output as a simple tab-separated list.
   $ aws rds describe-db-proxies --query '*[*].{DBProxyName:DBProxyName,Endpoint:Endpoint}[
   [  
     {  "Endpoint": "the-proxy.proxy-demo.us-east-1.rds.amazonaws.com",  
         "DBProxyName": "the-proxy"  
     },  
     {  "Endpoint": "the-proxy-other-secret.proxy-demo.us-east-1.rds.amazonaws.com",  
         "DBProxyName": "the-proxy-other-secret"  
     },  
     {  "Endpoint": "the-proxy-rds-secret.proxy-demo.us-east-1.rds.amazonaws.com",  
         "DBProxyName": "the-proxy-rds-secret"  
     },  
     {  "Endpoint": "the-proxy-t3.proxy-demo.us-east-1.rds.amazonaws.com",  
         "DBProxyName": "the-proxy-t3"  
     }  
   ]  
   ]
   ``

2. Specify that endpoint as the host parameter in the connection string for your client application. For example, specify the proxy endpoint as the value for the `mysql -h` option or `psql -h` option.

3. Supply the same database user name and password as you usually do.

Connecting to a proxy using IAM authentication

When you use IAM authentication with RDS Proxy, set up your database users to authenticate with regular user names and passwords. The IAM authentication applies to RDS Proxy retrieving the user name and password credentials from Secrets Manager. The connection from RDS Proxy to the underlying database doesn't go through IAM.

To connect to RDS Proxy using IAM authentication, use the same general connection procedure as for IAM authentication with an Aurora DB cluster. For general information about using IAM, see Security in Amazon Aurora (p. 2367).

The major differences in IAM usage for RDS Proxy include the following:

- You don't configure each individual database user with an authorization plugin. The database users still have regular user names and passwords within the database. You set up Secrets Manager secrets containing these user names and passwords, and authorize RDS Proxy to retrieve the credentials from Secrets Manager.
The IAM authentication applies to the connection between your client program and the proxy. The proxy then authenticates to the database using the user name and password credentials retrieved from Secrets Manager.

- Instead of the instance, cluster, or reader endpoint, you specify the proxy endpoint. For details about the proxy endpoint, see Connecting to your DB cluster using IAM authentication (p. 2440).
- In the direct database IAM authentication case, you selectively choose database users and configure them to be identified with a special authentication plugin. You can then connect to those users using IAM authentication.

In the proxy use case, you provide the proxy with Secrets that contain some user's user name and password (native authentication). You then connect to the proxy using IAM authentication. Here, you do this by generating an authentication token with the proxy endpoint, not the database endpoint. You also use a user name that matches one of the user names for the secrets that you provided.

- Make sure that you use Transport Layer Security (TLS)/Secure Sockets Layer (SSL) when connecting to a proxy using IAM authentication.

You can grant a specific user access to the proxy by modifying the IAM policy. An example follows.

```
```

**Considerations for connecting to a proxy with PostgreSQL**

For PostgreSQL, when a client starts a connection to a PostgreSQL database, it sends a startup message. This message includes pairs of parameter name and value strings. For details, see the StartupMessage in PostgreSQL message formats in the PostgreSQL documentation.

When connecting through an RDS proxy, the startup message can include the following currently recognized parameters:

- user
- database
- replication

The startup message can also include the following additional runtime parameters:

- application_name
- client_encoding
- DateStyle
- TimeZone
- extra_float_digits

For more information about PostgreSQL messaging, see the Frontend/Backend protocol in the PostgreSQL documentation.

For PostgreSQL, if you use JDBC we recommend the following to avoid pinning:

- Set the JDBC connection parameter assumeMinServerVersion to at least 9.0 to avoid pinning. Doing this prevents the JDBC driver from performing an extra round trip during connection startup when it runs SET extra_float_digits = 3.
- Set the JDBC connection parameter ApplicationName to any/your-application-name to avoid pinning. Doing this prevents the JDBC driver from performing an extra round trip during
connection startup when it runs `SET application_name = "PostgreSQL JDBC Driver"`. Note the JDBC parameter is `ApplicationName` but the PostgreSQL `StartupMessage` parameter is `application_name`.

For more information, see Avoiding pinning (p. 1908). For more information about connecting using JDBC, see Connecting to the database in the PostgreSQL documentation.

## Managing an RDS Proxy

Following, you can find an explanation of how to manage RDS Proxy operation and configuration. These procedures help your application make the most efficient use of database connections and achieve maximum connection reuse. The more that you can take advantage of connection reuse, the more CPU and memory overhead that you can save. This in turn reduces latency for your application and enables the database to devote more of its resources to processing application requests.

### Topics

- Modifying an RDS Proxy (p. 1900)
- Adding a new database user (p. 1904)
- Changing the password for a database user (p. 1905)
- Client and database connections (p. 1905)
- Configuring connection settings (p. 1905)
- Avoiding pinning (p. 1908)
- Deleting an RDS Proxy (p. 1911)

## Modifying an RDS Proxy

You can change specific settings associated with a proxy after you create the proxy. You do so by modifying the proxy itself, its associated target group, or both. Each proxy has an associated target group.

### AWS Management Console

**Important**

The values in the **Client authentication type** and **IAM authentication** fields apply to all Secrets Manager secrets that are associated with this proxy. To specify different values for each secret, modify your proxy by using the AWS CLI or the API instead.

**To modify the settings for a proxy**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Proxies**.
3. In the list of proxies, choose the proxy whose settings you want to modify or go to its details page.
4. For **Actions**, choose **Modify**.
5. Enter or choose the properties to modify. You can modify the following:
   - **Proxy identifier** – Rename the proxy by entering a new identifier.
   - **Idle client connection timeout** – Enter a time period for the idle client connection timeout.
   - **IAM role** – Change the IAM role used to retrieve the secrets from Secrets Manager.
• **Secrets Manager secrets** – Add or remove Secrets Manager secrets. These secrets correspond to database user names and passwords.

• **Client authentication type** – (PostgreSQL only) Change the type of authentication for client connections to the proxy.

• **IAM authentication** – Require or disallow IAM authentication for connections to the proxy.

• **Require Transport Layer Security** – Turn the requirement for Transport layer Security (TLS) on or off.

• **VPC security group** – Add or remove VPC security groups for the proxy to use.

• **Enable enhanced logging** – Enable or disable enhanced logging.

6. Choose **Modify**.

If you didn’t find the settings listed that you want to change, use the following procedure to update the target group for the proxy. The target group associated with a proxy controls the settings related to the physical database connections. Each proxy has one associated target group named `default`, which is created automatically along with the proxy.

You can only modify the target group from the proxy details page, not from the list on the **Proxies** page.

### To modify the settings for a proxy target group

1. On the **Proxies** page, go to the details page for a proxy.

2. For **Target groups**, choose the `default` link. Currently, all proxies have a single target group named `default`.

3. On the details page for the `default` target group, choose **Modify**.

4. Choose new settings for the properties that you can modify:

   • **Database** – Choose a different Aurora cluster.

   • **Connection pool maximum connections** – Adjust what percentage of the maximum available connections the proxy can use.

   • **Session pinning filters** – (Optional) Choose a session pinning filter. Doing this can help reduce performance issues due to insufficient transaction-level reuse for connections. Using this setting requires understanding of application behavior and the circumstances under which RDS Proxy pins a session to a database connection. Currently, the setting isn’t supported for PostgreSQL and the only choice is `EXCLUDE_VARIABLE_SETS`.

   • **Connection borrow timeout** – Adjust the connection borrow timeout interval. This setting applies when the maximum number of connections is already being used for the proxy. The setting determines how long the proxy waits for a connection to become available before returning a timeout error.

   • **Initialization query** – (Optional) Add an initialization query, or modify the current one. You can specify one or more SQL statements for the proxy to run when opening each new database connection. The setting is typically used with `SET` statements to make sure that each connection has identical settings such as time zone and character set. For multiple statements, use semicolons as the separator. You can also include multiple variables in a single `SET` statement, such as `SET x=1, y=2`.

   You can’t change certain properties, such as the target group identifier and the database engine.

5. Choose **Modify target group**.

### AWS CLI

To modify a proxy using the AWS CLI, use the commands **modify-db-proxy**, **modify-db-proxy-target-group**, **deregister-db-proxy-targets**, and **register-db-proxy-targets**.
With the `modify-db-proxy` command, you can change properties such as the following:

- The set of Secrets Manager secrets used by the proxy.
- Whether TLS is required.
- The idle client timeout.
- Whether to log additional information from SQL statements for debugging.
- The IAM role used to retrieve Secrets Manager secrets.
- The security groups used by the proxy.

The following example shows how to rename an existing proxy.

```
aws rds modify-db-proxy --db-proxy-name the-proxy --new-db-proxy-name the_new_name
```

To modify connection-related settings or rename the target group, use the `modify-db-proxy-target-group` command. Currently, all proxies have a single target group named `default`. When working with this target group, you specify the name of the proxy and `default` for the name of the target group.

The following example shows how to first check the `MaxIdleConnectionsPercent` setting for a proxy and then change it, using the target group.

```
aws rds describe-db-proxy-target-groups --db-proxy-name the-proxy
{
    "TargetGroups": [
    {
        "Status": "available",
        "UpdatedDate": "2019-11-30T16:49:30.342Z",
        "ConnectionPoolConfig": {

```
With the deregister-db-proxy-targets and register-db-proxy-targets commands, you change which Aurora DB clusters the proxy is associated with through its target group. Currently, each proxy can connect to one Aurora DB cluster. The target group tracks the connection details for all the DB instances in an Aurora cluster.

The following example starts with a proxy that is associated with an Aurora MySQL cluster named cluster-56-2020-02-25-1399. The example shows how to change the proxy so that it can connect to a different cluster named provisioned-cluster.

When you work with an Aurora DB cluster, you specify the --db-cluster-identifier option.

The following example modifies an Aurora MySQL proxy. An Aurora PostgreSQL proxy has port 5432.

```
aws rds describe-db-proxy-targets --db-proxy-name the-proxy
{
  "Targets": [
    {
      "Endpoint": "instance-9814.demo.us-east-1.rds.amazonaws.com",
      "Type": "RDS_INSTANCE",
      "Port": 3306,
      "RdsResourceId": "instance-9814"
    },
    {
      "Endpoint": "instance-8898.demo.us-east-1.rds.amazonaws.com",
      "Type": "RDS_INSTANCE",
      "Port": 3306,
      "RdsResourceId": "instance-8898"
    },
    {
      "Endpoint": "instance-1018.demo.us-east-1.rds.amazonaws.com",
      "Type": "RDS_INSTANCE",
      "Port": 3306,
      "RdsResourceId": "instance-1018"
    },
    {
      "Type": "TRACKED_CLUSTER",
      "Port": 0,
      "RdsResourceId": "cluster-56-2020-02-25-1399"
    },
    {
      "Endpoint": "instance-4330.demo.us-east-1.rds.amazonaws.com",
      "Type": "RDS_INSTANCE",
      "Port": 3306,
      "RdsResourceId": "instance-4330"
    }
  ]
}
aws rds deregister-db-proxy-targets --db-proxy-name the-proxy --db-cluster-identifier cluster-56-2020-02-25-1399
aws rds describe-db-proxy-targets --db-proxy-name the-proxy
{
  "Targets": []
}
aws rds register-db-proxy-targets --db-proxy-name the-proxy --db-cluster-identifier provisioned-cluster
```
Adding a database user

In some cases, you might add a new database user to an RDS DB instance or cluster Aurora cluster that's associated with a proxy. If so, add or repurpose a Secrets Manager secret to store the credentials for that user. To do this, choose one of the following options:

1. Create a new Secrets Manager secret, using the procedure described in Setting up database credentials in AWS Secrets Manager (p. 1889).
2. Update the IAM role to give RDS Proxy access to the new Secrets Manager secret. To do so, update the resources section of the IAM role policy.
3. Modify the RDS Proxy to add the new Secrets Manager secret under Secrets Manager secrets.
4. If the new user takes the place of an existing one, update the credentials stored in the proxy’s Secrets Manager secret for the existing user.

If you have run the following command for your PostgreSQL databases:

```sql
REVOKE CONNECT ON DATABASE postgres FROM PUBLIC;
```

Grant the rdsproxyadmin user the CONNECT privilege so the user can monitor connections on the target database.

```sql
GRANT CONNECT ON DATABASE postgres TO rdsproxyadmin;
```

You can also allow other target database users to perform health checks by changing rdsproxyadmin to the database user in the command above.

### Changing the password for a database user

In some cases, you might change the password for a database user in an RDS DB instance Aurora cluster that’s associated with a proxy. If so, update the corresponding Secrets Manager secret with the new password.

### Client and database connections

Connections from your application to RDS Proxy are known as client connections. Connections from a proxy to the database are database connections. When using RDS Proxy, client connections terminate at the proxy while database connections are managed within RDS Proxy.

Application side connection pooling can provide the benefit of reducing recurring connection establishment between your application and RDS Proxy.

Consider the following configuration aspects before implementing an application side connection pool:

- **Client connection max life**: RDS Proxy enforces a max life of client connections of 24 hours. This value is not configurable. Configure your pool with a max connection life less than 24 hours to avoid unexpected client connection drops.
- **Client connection idle timeout**: RDS Proxy enforces a max idle time for client connections. Configure your pool with an idle connection timeout of a value lower than your client connection idle timeout setting for RDS Proxy to avoid unexpected connection drops.

The maximum number of client connections configured in your application side connection pool does not have to be limited to the `max_connections` setting for RDS Proxy.

Client connection pooling results in longer client connection life. If your connections experience pinning, then pooling client connections might reduce multiplexing efficiency. Client connections that are pinned but idle in the application side connection pool continue to hold on to a database connection and prevent the database connection to be reused by other client connections. Review your proxy logs to check if your connections experience pinning.

### Configuring connection settings

To adjust RDS Proxy’s connection pooling, you can modify the following settings:
IdleClientTimeout

You can specify how long a client connection can be idle before the proxy can close it. The default is 1,800 seconds (30 minutes).

A client connection is considered idle when the application doesn't submit a new request within the specified time after the previous request completed. The underlying database connection stays open and is returned to the connection pool. Thus, it's available to be reused for new client connections. If you want the proxy to proactively remove stale connections, consider lowering the idle client connection timeout. If your workload establishes frequent connections with the proxy, consider raising the idle client connection timeout to save the cost of establishing connections.

This setting is represented by the Idle client connection timeout field in the RDS console and the IdleClientTimeout setting in the AWS CLI and the API. To learn how to change the value of the Idle client connection timeout field in the RDS console, see AWS Management Console (p. 1900). To learn how to change the value of the IdleClientTimeout setting, see the CLI command modify-db-proxy or the API operation ModifyDBProxy.

MaxConnectionsPercent

You can limit the number of connections that an RDS Proxy can establish with the target database. You specify the limit as a percentage of the maximum connections available for your database. This setting is represented by the Connection pool maximum connections field in the RDS console and the MaxConnectionsPercent setting in the AWS CLI and the API.

The MaxConnectionsPercent value is expressed as a percentage of the max_connections setting for the Aurora DB cluster used by the target group. The proxy doesn't create all of these connections in advance. This setting reserves the right for the proxy to establish these connections as the workload needs them.

For example, for a registered database target with max_connections set to 1000, and MaxConnectionsPercent set to 95, RDS Proxy sets 950 connections as the upper limit for concurrent connections to that database target.

A common side-effect of your workload reaching the maximum number of allowed database connections is an increase in overall query latency, along with an increase in the DatabaseConnectionsBorrowLatency metric. You can monitor currently used and total allowed database connections by comparing the DatabaseConnections and MaxDatabaseConnectionsAllowed metrics.

When setting this parameter, note the following best practices:

- Allow sufficient connection headroom for changes in workload pattern. It is recommended to set the parameter at least 30% above your maximum recent monitored usage. As RDS Proxy redistributes database connection quotas across multiple nodes, internal capacity changes might require at least 30% headroom for additional connections to avoid increased borrow latencies.
- RDS Proxy reserves a certain number of connections for active monitoring to support fast failover, traffic routing and internal operations. The MaxDatabaseConnectionsAllowed metric does not include these reserved connections. It represents the number of connections available to serve the workload, and can be lower than the value derived from the MaxConnectionsPercent setting.
Minimal recommended MaxConnectionsPercent values

- db.t3.small: 100
- db.t3.medium: 55
- db.t3.large: 35
- db.r3.large or above: 20

If multiple target instances are registered with RDS Proxy like an Aurora cluster with reader nodes, set the minimum value based on the smallest registered instance.

To learn how to change the value of the Connection pool maximum connections field in the RDS console, see AWS Management Console (p. 1900). To learn how to change the value of the MaxConnectionsPercent setting, see the CLI command modify-db-proxy-target-group or the API operation ModifyDBProxyTargetGroup.

Important
If the DB cluster is part of a global database with write forwarding turned on, reduce your proxy's MaxConnectionsPercent value by the quota that's allotted for write forwarding. The write forwarding quota is set in the DB cluster parameter aurora_fwd_writer_max_connections_pct. For information about write forwarding, see Using write forwarding in an Amazon Aurora global database (p. 1831).

For information on database connection limits, see Maximum connections to an Aurora MySQL DB instance and Maximum connections to an Aurora PostgreSQL DB instance.

MaxIdleConnectionsPercent

You can control the number of idle database connections that RDS Proxy can keep in the connection pool. RDS Proxy considers a database connection in its pool to be idle when there's been no activity on the connection for five minutes.

You specify the limit as a percentage of the maximum connections available for your database. The default value is 50 percent of MaxConnectionsPercent, and the upper limit is the value of MaxConnectionsPercent. With a high value, the proxy leaves a high percentage of idle database connections open. With a low value, the proxy closes a high percentage of idle database connections. If your workloads are unpredictable, consider setting a high value for MaxIdleConnectionsPercent. Doing so means that RDS Proxy can accommodate surges in activity without opening a lot of new database connections.

This setting is represented by the MaxIdleConnectionsPercent setting of DBProxyTargetGroup in the AWS CLI and the API. To learn how to change the value of the MaxIdleConnectionsPercent setting, see the CLI command modify-db-proxy-target-group or the API operation ModifyDBProxyTargetGroup.

For information on database connection limits, see Maximum connections to an Aurora MySQL DB instance and Maximum connections to an Aurora PostgreSQL DB instance.

ConnectionBorrowTimeout

You can choose how long RDS Proxy waits for a database connection in the connection pool to become available for use before returning a timeout error. The default is 120 seconds. This setting applies when the number of connections is at the maximum, and so no connections are available in the connection pool. It also applies if no appropriate database instance is available to handle the request because, for example, a failover operation is in process. Using this setting, you can set the best wait period for your application without having to change the query timeout in your application code.
Avoiding pinning

Multiplexing is more efficient when database requests don't rely on state information from previous requests. In that case, RDS Proxy can reuse a connection at the conclusion of each transaction. Examples of such state information include most variables and configuration parameters that you can change through SET or SELECT statements. SQL transactions on a client connection can multiplex between underlying database connections by default.

Your connections to the proxy can enter a state known as pinning. When a connection is pinned, each later transaction uses the same underlying database connection until the session ends. Other client connections also can't reuse that database connection until the session ends. The session ends when the client connection is dropped.

RDS Proxy automatically pins a client connection to a specific DB connection when it detects a session state change that isn't appropriate for other sessions. Pinning reduces the effectiveness of connection reuse. If all or almost all of your connections experience pinning, consider modifying your application code or workload to reduce the conditions that cause the pinning.

For example, suppose that your application changes a session variable or configuration parameter. In this case, later statements can rely on the new variable or parameter to be in effect. Thus, when RDS Proxy processes requests to change session variables or configuration settings, it pins that session to the DB connection. That way, the session state remains in effect for all later transactions in the same session.

For some database engines, this rule doesn't apply to all parameters that you can set. RDS Proxy tracks certain statements and variables. Thus RDS Proxy doesn't pin the session when you modify them. In this case, RDS Proxy only reuses the connection for other sessions that have the same values for those settings. For the lists of tracked statements and variables for Aurora MySQL, see What RDS Proxy tracks for Aurora MySQL databases (p. 1908).

What RDS Proxy tracks for Aurora MySQL databases

Following are the MySQL statements that RDS Proxy tracks:

- DROP DATABASE
- DROP SCHEMA
- USE

Following are the MySQL variables that RDS Proxy tracks:

- AUTOCOMMIT
- AUTO_INCREMENT_INCREMENT
- CHARACTER_SET (or CHAR_SET)
- CHARACTER_SET_CLIENT
- CHARACTER_SET_DATABASE
- CHARACTER_SET_FILESYSTEM
- CHARACTER_SET_CONNECTION
Minimizing pinning

Performance tuning for RDS Proxy involves trying to maximize transaction-level connection reuse (multiplexing) by minimizing pinning.

In some cases, RDS Proxy can't be sure that it's safe to reuse a database connection outside of the current session. In these cases, it keeps the session on the same connection until the session ends. This fallback behavior is called pinning.

You can minimize pinning by doing the following:

- Avoid unnecessary database requests that might cause pinning.
- Set variables and configuration settings consistently across all connections. That way, later sessions are more likely to reuse connections that have those particular settings.

However, for PostgreSQL setting a variable leads to session pinning.

- For a MySQL engine family database, apply a session pinning filter to the proxy. You can exempt certain kinds of operations from pinning the session if you know that doing so doesn't affect the correct operation of your application.
- See how frequently pinning occurs by monitoring the Amazon CloudWatch metric DatabaseConnectionsCurrentlySessionPinned. For information about this and other CloudWatch metrics, see Monitoring RDS Proxy metrics with Amazon CloudWatch (p. 1921).
- If you use SET statements to perform identical initialization for each client connection, you can do so while preserving transaction-level multiplexing. In this case, you move the statements that set up the initial session state into the initialization query used by a proxy. This property is a string containing one or more SQL statements, separated by semicolons.

For example, you can define an initialization query for a proxy that sets certain configuration parameters. Then, RDS Proxy applies those settings whenever it sets up a new connection for that proxy. You can remove the corresponding SET statements from your application code, so that they don't interfere with transaction-level multiplexing.

For metrics about how often pinning occurs for a proxy, see Monitoring RDS Proxy metrics with Amazon CloudWatch (p. 1921).
Conditions that cause pinning for all engine families

The proxy pins the session to the current connection in the following situations where multiplexing might cause unexpected behavior:

- Any statement with a text size greater than 16 KB causes the proxy to pin the session.

Conditions that cause pinning for Aurora MySQL

For MySQL, the following interactions also cause pinning:

- Explicit table lock statements `LOCK TABLE`, `LOCK TABLES`, or `FLUSH TABLES WITH READ LOCK` cause the proxy to pin the session.
- Creating named locks by using `GET_LOCK` causes the proxy to pin the session.
- Setting a user variable or a system variable (with some exceptions) causes the proxy to pin the session. If this situation reduces your connection reuse too much, you can choose for `SET` operations not to cause pinning. For information about how to do so by setting the session pinning filters property, see Creating an RDS Proxy (p. 1892) and Modifying an RDS Proxy (p. 1900).
- RDS Proxy does not pin connections when you use `SET LOCAL`.
- Creating a temporary table causes the proxy to pin the session. That way, the contents of the temporary table are preserved throughout the session regardless of transaction boundaries.
- Calling the functions `ROW_COUNT`, `FOUND_ROWS`, and `LAST_INSERT_ID` sometimes causes pinning.

The exact circumstances where these functions cause pinning might differ among Aurora MySQL versions that are compatible with MySQL 5.7.
- Prepared statements cause the proxy to pin the session. This rule applies whether the prepared statement uses SQL text or the binary protocol.

Calling stored procedures and stored functions doesn't cause pinning. RDS Proxy doesn't detect any session state changes resulting from such calls. Therefore, make sure that your application doesn't change session state inside stored routines and rely on that session state to persist across transactions. For example, if a stored procedure creates a temporary table that is intended to persist across transactions, that application currently isn't compatible with RDS Proxy.

If you have expert knowledge about your application behavior, you can skip the pinning behavior for certain application statements. To do so, choose the Session pinning filters option when creating the proxy. Currently, you can opt out of session pinning for setting session variables and configuration settings.

Conditions that cause pinning for Aurora PostgreSQL

For PostgreSQL, the following interactions also cause pinning:

- Using `SET` commands
- Using `PREPARE`, `DISCARD`, `DEALLOCATE`, or `EXECUTE` commands to manage prepared statements
- Creating temporary sequences, tables, or views
- Declaring cursors
- Discarding the session state
- Listening on a notification channel
- Loading a library module such as `auto_explain`
- Manipulating sequences using functions such as `nextval` and `setval`
• Interacting with locks using functions such as `pg_advisory_lock` and `pg_try_advisory_lock`
• Setting a parameter, or resetting a parameter to its default

Deleting an RDS Proxy

You can delete a proxy if you no longer need it. You might delete a proxy because the application that was using it is no longer relevant. Or you might delete a proxy if you take the DB instance or cluster associated with it out of service.

AWS Management Console

To delete a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at `https://console.aws.amazon.com/rds/`.
2. In the navigation pane, choose Proxies.
3. Choose the proxy to delete from the list.

AWS CLI

To delete a DB proxy, use the AWS CLI command `delete-db-proxy`. To remove related associations, also use the `deregister-db-proxy-targets` command.

```bash
aws rds delete-db-proxy --name proxy_name
```

```bash
aws rds deregister-db-proxy-targets
  --db-proxy-name proxy_name
  [--target-group-name target_group_name] # or
  [--target-ids comma_separated_list] # or
  [--db-instance-identifiers instance_id]
  [--db-cluster-identifiers cluster_id]
```

RDS API

To delete a DB proxy, call the Amazon RDS API function `DeleteDBProxy`. To delete related items and associations, you also call the functions `DeleteDBProxyTargetGroup` and `DeregisterDBProxyTargets`.

Working with Amazon RDS Proxy endpoints

Learn about endpoints for RDS Proxy and how to use them. By using endpoints, you can take advantage of the following capabilities:

• You can use multiple endpoints with a proxy to monitor and troubleshoot connections from different applications independently.
• You can use reader endpoints with Aurora DB clusters to improve read scalability and high availability for your query-intensive applications.
• You can use a cross-VPC endpoint to allow access to databases in one VPC from resources such as Amazon EC2 instances in a different VPC.
Overview of proxy endpoints

Working with RDS Proxy endpoints involves the same kinds of procedures as with Aurora DB cluster and reader endpoints. If you aren't familiar with Aurora endpoints, find more information in Amazon Aurora connection management.

By default, the endpoint that you connect to when you use RDS Proxy with an Aurora cluster has read/write capability. As a result, this endpoint sends all requests to the writer instance of the cluster. All of those connections count against the max_connections value for the writer instance. If your proxy is associated with an Aurora DB cluster, you can create additional read/write or read-only endpoints for that proxy.

You can use a read-only endpoint with your proxy for read-only queries. You do this the same way that you use the reader endpoint for an Aurora provisioned cluster. Doing so helps you to take advantage of the read scalability of an Aurora cluster with one or more reader DB instances. You can run more simultaneous queries and make more simultaneous connections by using a read-only endpoint and adding more reader DB instances to your Aurora cluster as needed.

Tip
When you create a proxy for an Aurora cluster using the AWS Management Console, you can have RDS Proxy automatically create a reader endpoint. For information about the benefits of a reader endpoint, see Using reader endpoints with Aurora clusters.

For a proxy endpoint that you create, you can also associate the endpoint with a different virtual private cloud (VPC) than the proxy itself uses. By doing so, you can connect to the proxy from a different VPC, for example a VPC used by a different application within your organization.

For information about limits associated with proxy endpoints, see Limitations for proxy endpoints.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name you specified for a user-defined endpoint. Or it can be the special name default for read/write requests using the default endpoint of a proxy.

Each proxy endpoint has its own set of CloudWatch metrics. You can monitor the metrics for all endpoints of a proxy. You can also monitor metrics for a specific endpoint, or for all the read/write or read-only endpoints of a proxy. For more information, see Monitoring RDS Proxy metrics with Amazon CloudWatch.

A proxy endpoint uses the same authentication mechanism as its associated proxy. RDS Proxy automatically sets up permissions and authorizations for the user-defined endpoint, consistent with the properties of the associated proxy.

To learn how proxy endpoints work for DB clusters in an Aurora global database, see How RDS Proxy endpoints work with global databases.
Using reader endpoints with Aurora clusters

You can create and connect to read-only endpoints called reader endpoints when you use RDS Proxy with Aurora clusters. These reader endpoints help to improve the read scalability of your query-intensive applications. Reader endpoints also help to improve the availability of your connections if a reader DB instance in your cluster becomes unavailable.

**Note**
When you specify that a new endpoint is read-only, RDS Proxy requires that the Aurora cluster has one or more reader DB instances. In some cases, you might change the target of the proxy to an Aurora cluster containing only a single writer or a multi-writer Aurora cluster. If you do, any requests to the reader endpoint fail with an error. Requests also fail if the target of the proxy is an RDS instance instead of an Aurora cluster.

If an Aurora cluster has reader instances but those instances aren't available, RDS Proxy waits to send the request instead of returning an error immediately. If no reader instance becomes available within the connection borrow timeout period, the request fails with an error.

**How reader endpoints help application availability**

In some cases, one or more reader instances in your cluster might become unavailable. If so, connections that use a reader endpoint of a DB proxy can recover more quickly than ones that use the Aurora reader endpoint. RDS Proxy routes connections to only the available reader instances in the cluster. There isn't a delay due to DNS caching when an instance becomes unavailable.

If the connection is multiplexed, RDS Proxy directs subsequent queries to a different reader DB instance without any interruption to your application. During the automatic switchover to a new reader instance, RDS Proxy checks the replication lag of the old and new reader instances. RDS Proxy makes sure that the new reader instance is up to date with the same changes as the previous reader instance. That way, your application never sees stale data when RDS Proxy switches from one reader DB instance to another.

If the connection is pinned, the next query on the connection returns an error. However, your application can immediately reconnect to the same endpoint. RDS Proxy routes the connection to a different reader DB instance that's in available state. When you manually reconnect, RDS Proxy doesn't check the replication lag between the old and new reader instances.

If your Aurora cluster doesn't have any available reader instances, RDS Proxy checks whether this condition is temporary or permanent. The behavior in each case is as follows:

- Suppose that your cluster has one or more reader DB instances, but none of them are in the Available state. For example, all reader instances might be rebooting or encountering problems. In that case, attempts to connect to a reader endpoint wait for a reader instance to become available. If no reader instance becomes available within the connection borrow timeout period, the connection attempt fails. If a reader instance does become available, the connection attempt succeeds.
- Suppose that your cluster has no reader DB instances. In that case, RDS Proxy returns an error immediately if you try to connect to a reader endpoint. To resolve this problem, add one or more reader instances to your cluster before you connect to the reader endpoint.

**How reader endpoints help query scalability**

Reader endpoints for a proxy help with Aurora query scalability in the following ways:

- As you add reader instances to your Aurora cluster, RDS Proxy can route new connections to any reader endpoints to the different reader instances. That way, queries performed using one reader endpoint connection don't slow down queries performed using another reader endpoint connection. The queries run on separate DB instances. Each DB instance has its own compute resources, buffer cache, and so on.
• Where practical, RDS Proxy uses the same reader DB instance for all the queries issue using a particular reader endpoint connection. That way, a set of related queries on the same tables can take advantage of caching, plan optimization, and so on, on a particular DB instance.

• If a reader DB instance becomes unavailable, the effect on your application depends on whether the session is multiplexed or pinned. If the session is multiplexed, RDS Proxy routes any subsequent queries to a different reader DB instance without any action on your part. If the session is pinned, your application gets an error and must reconnect. You can reconnect to the reader endpoint immediately and RDS Proxy routes the connection to an available reader DB instance. For more information about multiplexing and pinning for proxy sessions, see Overview of RDS Proxy concepts (p. 1883).

• The more reader DB instances that you have in the cluster, the more simultaneous connections you can make using reader endpoints. For example, suppose that your cluster has four reader DB instances, each configured to support 200 simultaneous connections. Suppose also that your proxy is configured to use 50% of the maximum connections. Here, the maximum number of connections that you can make through the reader endpoints in the proxy is 100 (50% of 200) for reader 1. It’s also 100 for reader 2, and so on, for a total of 400. If you double the number of cluster reader DB instances to eight, then the maximum number of connections through the reader endpoints also doubles, to 800.

Examples of using reader endpoints

The following Linux example shows how you can confirm that you’re connected to an Aurora MySQL cluster through a reader endpoint. The innodb_read_only configuration setting is enabled. Attempts to perform write operations such as CREATE DATABASE statements fail with an error. And you can confirm that you’re connected to a reader DB instance by checking the DB instance name using the aurora_server_id variable.

Tip
Don’t rely only on checking the DB instance name to determine whether the connection is read/write or read-only. Remember that DB instances in an Aurora cluster can change roles between writer and reader when failovers happen.

```
$ mysql -h endpoint-demo-reader.endpoint.proxy-demo.us-east-1.rds.amazonaws.com -u admin -p...
...
mysql> select @@innodb_read_only;
+--------------------+
<table>
<thead>
<tr>
<th>@@innodb_read_only</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
+--------------------+
mysql> create database shouldnt_work;
ERROR 1290 (HY000): The MySQL server is running with the --read-only option so it cannot execute this statement

mysql> select @@aurora_server_id;
+---------------------------------------+
<table>
<thead>
<tr>
<th>@@aurora_server_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>proxy-reader-endpoint-demo-instance-3</td>
</tr>
</tbody>
</table>
+---------------------------------------+
```

The following example shows how your connection to a proxy reader endpoint can keep working even when the reader DB instance is deleted. In this example, the Aurora cluster has two reader instances, instance-5507 and instance-7448. The connection to the reader endpoint begins using one of the reader instances. During the example, this reader instance is deleted by a delete-db-instance command. RDS Proxy switches to a different reader instance for subsequent queries.

```
$ mysql -h reader-demo.endpoint.proxy-demo.us-east-1.rds.amazonaws.com
-u my_user -p
```
Accessing Aurora databases across VPCs

By default, the components of your Aurora technology stack are all in the same Amazon VPC. For example, suppose that an application running on an Amazon EC2 instance connects to an Aurora DB cluster. In this case, the application server and database must both be within the same VPC.

With RDS Proxy, you can set up access to an Aurora DB cluster in one VPC from resources such as EC2 instances in another VPC. For example, your organization might have multiple applications that access the same database resources. Each application might be in its own VPC.

To enable cross-VC access, you create a new endpoint for the proxy. The proxy itself resides in the same VPC as the Aurora DB cluster. However, the cross-VC endpoint resides in the other VPC, along with the other resources such as the EC2 instances. The cross-VC endpoint is associated with subnets and security groups from the same VPC as the EC2 and other resources. These associations let you connect to the endpoint from the applications that otherwise can't access the database due to the VPC restrictions.
The following steps explain how to create and access a cross-VPC endpoint through RDS Proxy:

1. Create two VPCs, or choose two VPCs that you already use for Aurora work. Each VPC should have its own associated network resources such as an Internet gateway, route tables, subnets, and security groups. If you only have one VPC, you can consult Getting started with Amazon Aurora (p. 124) for the steps to set up another VPC to use Aurora successfully. You can also examine your existing VPC in the Amazon EC2 console to see what kinds of resources to connect together.

2. Create a DB proxy associated with the Aurora DB cluster that you want to connect to. Follow the procedure in Creating an RDS Proxy (p. 1892).

3. On the Details page for your proxy in the RDS console, under the Proxy endpoints section, choose Create endpoint. Follow the procedure in Creating a proxy endpoint (p. 1916).

4. Choose whether to make the cross-VPC endpoint read/write or read-only.

5. Instead of accepting the default of the same VPC as the Aurora DB cluster, choose a different VPC. This VPC must be in the same AWS Region as the VPC where the proxy resides.

6. Now instead of accepting the defaults for subnets and security groups from the same VPC as the Aurora DB cluster, make new selections. Make these based on the subnets and security groups from the VPC that you chose.

7. You don't need to change any of the settings for the Secrets Manager secrets. The same credentials work for all endpoints for your proxy, regardless of which VPC each endpoint is in.

8. Wait for the new endpoint to reach the Available state.

9. Make a note of the full endpoint name. This is the value ending in Region_name.rds.amazonaws.com that you supply as part of the connection string for your database application.

10. Access the new endpoint from a resource in the same VPC as the endpoint. A simple way to test this process is to create a new EC2 instance in this VPC. Then you can log into the EC2 instance and run the mysql or psql commands to connect by using the endpoint value in your connection string.

**Creating a proxy endpoint**

**Console**

**To create a proxy endpoint**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose Proxies.

3. Click the name of the proxy that you want to create a new endpoint for.

   The details page for that proxy appears.

4. In the Proxy endpoints section, choose Create proxy endpoint.

   The Create proxy endpoint window appears.

5. For Proxy endpoint name, enter a descriptive name of your choice.

6. For Target role, choose whether to make the endpoint read/write or read-only.

   Connections that use a read/write endpoint can perform any kind of operation: data definition language (DDL) statements, data manipulation language (DML) statements, and queries. These endpoints always connect to the primary instance of the Aurora cluster. You can use read/write endpoints for general database operations when you only use a single endpoint in your application. You can also use read/write endpoints for administrative operations, online transaction processing (OLTP) applications, and extract-transform-load (ETL) jobs.
Connections that use a read-only endpoint can only perform queries. When there are multiple reader instances in the Aurora cluster, RDS Proxy can use a different reader instance for each connection to the endpoint. That way, a query-intensive application can take advantage of Aurora's clustering capability. You can add more query capacity to the cluster by adding more reader DB instances. These read-only connections don't impose any overhead on the primary instance of the cluster. That way, your reporting and analysis queries don't slow down the write operations of your OLTP applications.

7. For **Virtual Private Cloud (VPC)**, choose the default to access the endpoint from the same EC2 instances or other resources that normally use to access the proxy or its associated database. To set up cross-VPC access for this proxy, choose a VPC other than the default. For more information about cross-VPC access, see [Accessing Aurora databases across VPCs](p. 1915).

8. For **Subnets**, RDS Proxy fills in the same subnets as the associated proxy by default. To restrict access to the endpoint so only a portion of the VPC’s address range can connect to it, remove one or more subnets.

9. For **VPC security group**, you can choose an existing security group or create a new one. RDS Proxy fills in the same security group or groups as the associated proxy by default. If the inbound and outbound rules for the proxy are appropriate for this endpoint, you can keep the default choice.

   If you choose to create a new security group, specify a name for the security group on this page. Then edit the security group settings from the EC2 console afterward.

10. Choose **Create proxy endpoint**.

**AWS CLI**

To create a proxy endpoint, use the AWS CLI `create-db-proxy-endpoint` command.

Include the following required parameters:

- `--db-proxy-name value`
- `--db-proxy-endpoint-name value`
- `--vpc-subnet-ids list_of_ids`. Separate the subnet IDs with spaces. You don't specify the ID of the VPC itself.

You can also include the following optional parameters:

- `--target-role { READ_WRITE | READ_ONLY }`. This parameter defaults to READ_WRITE. The READ_ONLY value affects only Aurora provisioned clusters that contain one or more reader DB instances. When the proxy is associated with an Aurora cluster that only contains a writer DB instance, you can't specify READ_ONLY. For more information about the intended use of read-only endpoints with Aurora clusters, see [Using reader endpoints with Aurora clusters](p. 1913).
- `--vpc-security-group-ids value`. Separate the security group IDs with spaces. If you omit this parameter, RDS Proxy uses the default security group for the VPC. RDS Proxy determines the VPC based on the subnet IDs that you specify for the `--vpc-subnet-ids` parameter.

**Example**

The following example creates a proxy endpoint named `my-endpoint`.

For Linux, macOS, or Unix:

```bash
aws rds create-db-proxy-endpoint \
    --db-proxy-name my-proxy \
```
Amazon Aurora User Guide for Aurora
Viewing proxy endpoints

For Windows:

```bash
aws rds create-db-proxy-endpoint ^
--db-proxy-name my-proxy ^
--db-proxy-endpoint-name my-endpoint ^
--vpc-subnet-ids subnet_id_1 subnet_id_2 subnet_id_3 ... ^
--target-role READ_ONLY ^
--vpc-security-group-ids security_group_id
```

RDS API

To create a proxy endpoint, use the RDS API [CreateDBProxyEndpoint](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/seqdb-db-proxy-create.html) action.

**Viewing proxy endpoints**

**Console**

**To view the details for a proxy endpoint**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Proxies**.
3. In the list, choose the proxy whose endpoint you want to view. Click the proxy name to view its details page.
4. In the **Proxy endpoints** section, choose the endpoint that you want to view. Click its name to view the details page.
5. Examine the parameters whose values you're interested in. You can check properties such as the following:
   - Whether the endpoint is read/write or read-only.
   - The endpoint address that you use in a database connection string.
   - The VPC, subnets, and security groups associated with the endpoint.

**AWS CLI**

To view one or more DB proxy endpoints, use the AWS CLI [describe-db-proxy-endpoints](https://docs.aws.amazon.com/cli/latest/reference/rds/describe-db-proxy-endpoints.html) command.

You can include the following optional parameters:

- `--db-proxy-endpoint-name`  
- `--db-proxy-name`

The following example describes the `my-endpoint` proxy endpoint.

**Example**

For Linux, macOS, or Unix:
**Modifying a proxy endpoint**

### Console

**To modify one or more proxy endpoints**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose *Proxies*.
3. In the list, choose the proxy whose endpoint you want to modify. Click the proxy name to view its details page.
4. In the *Proxy endpoints* section, choose the endpoint that you want to modify. You can select it in the list, or click its name to view the details page.
5. On the proxy details page, under the *Proxy endpoints* section, choose *Edit*. Or on the proxy endpoint details page, for *Actions*, choose *Edit*.
6. Change the values of the parameters that you want to modify.
7. Choose *Save changes*.

### AWS CLI

To modify a DB proxy endpoint, use the AWS CLI `modify-db-proxy-endpoint` command with the following required parameters:

- `--db-proxy-endpoint-name`

Specify changes to the endpoint properties by using one or more of the following parameters:

- `--new-db-proxy-endpoint-name`
- `--vpc-security-group-ids`. Separate the security group IDs with spaces.

The following example renames the *my-endpoint* proxy endpoint to *new-endpoint-name*.

**Example**

For Linux, macOS, or Unix:

```
aws rds modify-db-proxy-endpoint \
    --new-db-proxy-endpoint-name new-endpoint-name
```
Deleting a proxy endpoint

You can delete an endpoint for your proxy using the console as described following.

**Note**
You can't delete the default endpoint that RDS Proxy automatically creates for each proxy. When you delete a proxy, RDS Proxy automatically deletes all the associated endpoints.

**Console**

To delete a proxy endpoint using the AWS Management Console

1. In the navigation pane, choose **Proxies**.
2. In the list, choose the proxy whose endpoint you want to delete. Click the proxy name to view its details page.
3. In the **Proxy endpoints** section, choose the endpoint that you want to delete. You can select one or more endpoints in the list, or click the name of a single endpoint to view the details page.
4. On the proxy details page, under the **Proxy endpoints** section, choose **Delete**. Or on the proxy endpoint details page, for **Actions**, choose **Delete**.

**AWS CLI**

To delete a proxy endpoint, run the `delete-db-proxy-endpoint` command with the following required parameters:

- `--db-proxy-endpoint-name` 

The following command deletes the proxy endpoint named `my-endpoint`.

For Linux, macOS, or Unix:

```bash
aws rds delete-db-proxy-endpoint \ 
--db-proxy-endpoint-name my-endpoint
```

For Windows:

```bash
aws rds delete-db-proxy-endpoint ^ 
--db-proxy-endpoint-name my-endpoint
```
RDS API

To delete a proxy endpoint with the RDS API, run the `DeleteDBProxyEndpoint` operation. Specify the name of the proxy endpoint for the `DBProxyEndpointName` parameter.

Limitations for proxy endpoints

Each proxy has a default endpoint that you can modify but not create or delete.

The maximum number of user-defined endpoints for a proxy is 20. Thus, a proxy can have up to 21 endpoints: the default endpoint, plus 20 that you create.

When you associate additional endpoints with a proxy, RDS Proxy automatically determines which DB instances in your cluster to use for each endpoint. You can't choose specific instances the way that you can with Aurora custom endpoints.

Reader endpoints aren't available for Aurora multi-writer clusters.

Monitoring RDS Proxy metrics with Amazon CloudWatch

You can monitor RDS Proxy by using Amazon CloudWatch. CloudWatch collects and processes raw data from the proxies into readable, near-real-time metrics. To find these metrics in the CloudWatch console, choose Metrics, then choose RDS, and choose Per-Proxy Metrics. For more information, see Using Amazon CloudWatch metrics in the Amazon CloudWatch User Guide.

**Note**

RDS publishes these metrics for each underlying Amazon EC2 instance associated with a proxy. A single proxy might be served by more than one EC2 instance. Use CloudWatch statistics to aggregate the values for a proxy across all the associated instances. Some of these metrics might not be visible until after the first successful connection by a proxy.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name you specified for a user-defined endpoint, or the special name default for read/write requests using the default endpoint of a proxy.

All RDS Proxy metrics are in the group `proxy`.

Each proxy endpoint has its own CloudWatch metrics. You can monitor the usage of each proxy endpoint independently. For more information about proxy endpoints, see Working with Amazon RDS Proxy endpoints (p. 1911).

You can aggregate the values for each metric using one of the following dimension sets. For example, by using the `ProxyName` dimension set, you can analyze all the traffic for a particular proxy. By using the other dimension sets, you can split the metrics in different ways. You can split the metrics based on the different endpoints or target databases of each proxy, or the read/write and read-only traffic to each database.

- Dimension set 1: `ProxyName`
- Dimension set 2: `ProxyName`, `EndpointName`
- Dimension set 3: `ProxyName`, `TargetGroup`, `Target`
- Dimension set 4: ProxyName, TargetGroup, TargetRole

<table>

</tbody>
</table>
### Working with RDS Proxy events

You can find logs of RDS Proxy activity under CloudWatch in the AWS Management Console. Each proxy has an entry in the **Log groups** page.

**Important**
These logs are intended for human consumption for troubleshooting purposes and not for programmatic access. The format and content of the logs is subject to change. In particular, older logs don’t contain any prefixes indicating the endpoint for each request. In newer logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name that you specified for a user-defined endpoint, or the special name `default` for requests using the default endpoint of a proxy.

### Working with RDS Proxy events

An *event* indicates a change in an environment. This can be an AWS environment or a service or application from a software as a service (SaaS) partner. Or it can be one of your own custom applications or services. For example, Amazon Aurora generates an event when you create or modify an RDS Proxy. Amazon Aurora delivers events to CloudWatch Events and Amazon EventBridge in near-real time.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
<th>Valid period</th>
<th>CloudWatch dimension set</th>
</tr>
</thead>
<tbody>
<tr>
<td>QueryRequests</td>
<td>The number of queries received. A query including multiple statements is counted as one query. The most useful statistic for this metric is <em>Sum</em>.</td>
<td>1 minute and above</td>
<td>Dimension set 1 (p. 1921), Dimension set 2 (p. 1921)</td>
</tr>
<tr>
<td>QueryRequestsNoTLS</td>
<td>The number of queries received from non-TLS connections. A query including multiple statements is counted as one query. The most useful statistic for this metric is <em>Sum</em>.</td>
<td>1 minute and above</td>
<td>Dimension set 1 (p. 1921), Dimension set 2 (p. 1921)</td>

</tr>
</tbody>
</table>
Following, you can find a list of RDS Proxy events that you can subscribe to and an example of an RDS Proxy event.

For more information about working with events, see the following:

- For instructions on how to view events by using the AWS Management Console, AWS CLI, or RDS API, see Viewing Amazon RDS events (p. 687).
- To learn how to configure Amazon Aurora to send events to EventBridge, see Creating a rule that triggers on an Amazon Aurora event (p. 706).

## RDS Proxy events

The following table shows the event category and a list of events when an RDS Proxy is the source type.

<table>
<thead>
<tr>
<th>Category</th>

RDS Proxy command-line examples

To see how combinations of connection commands and SQL statements interact with RDS Proxy, look at the following examples.

**Examples**

- [Preserving Connections to a MySQL Database Across a Failover](#)
- [Adjusting the max_connections Setting for an Aurora DB Cluster](#)
Example Preserving connections to a MySQL database across a failover

This MySQL example demonstrates how open connections continue working during a failover. An example is when you reboot a database or it becomes unavailable due to a problem. This example uses a proxy named the-proxy and an Aurora DB cluster with DB instances instance-8898 and instance-9814. When you run the failover-db-cluster command from the Linux command line, the writer instance that the proxy is connected to changes to a different DB instance. You can see that the DB instance associated with the proxy changes while the connection remains open.

```sql
$ mysql -h the-proxy.proxy-demo.us-east-1.rds.amazonaws.com -u admin_user -p
Enter password: ...
mysql> select @@aurora_server_id;
+--------------------+
| @@aurora_server_id |
| instance-9814      |
+--------------------+
1 row in set (0.01 sec)
mysql>
mysql -h the-proxy.proxy-demo.us-east-1.rds.amazonaws.com -u admin_user -p
$ aws rds failover-db-cluster --db-cluster-identifier cluster-56-2019-11-14-1399
$ # After a short time, the console shows that the failover operation is complete.
$ # Now instance-8898 is the writer.
$ fg
mysql -h the-proxy.proxy-demo.us-east-1.rds.amazonaws.com -u admin_user -p
mysql> select @@aurora_server_id;
+--------------------+
| @@aurora_server_id |
| instance-8898      |
+--------------------+
1 row in set (0.01 sec)
mysql>
mysql -h the-proxy.proxy-demo.us-east-1.rds.amazonaws.com -u admin_user -p
$ aws rds failover-db-cluster --db-cluster-identifier cluster-56-2019-11-14-1399
$ # After a short time, the console shows that the failover operation is complete.
$ # Now instance-9814 is the writer again.
$ fg
mysql -h the-proxy.proxy-demo.us-east-1.rds.amazonaws.com -u admin_user -p
mysql> select @@aurora_server_id;
+--------------------+
| @@aurora_server_id |
| instance-9814      |
+--------------------+
1 row in set (0.01 sec)
mysql> select @aurora_server_id;
+--------------------+
| @aurora_server_id   |
| ip-10-1-3-178       |
+--------------------+
1 row in set (0.02 sec)
```

1928
Example  Adjusting the max_connections setting for an Aurora DB cluster

This example demonstrates how you can adjust the max_connections setting for an Aurora MySQL DB cluster. To do so, you create your own DB cluster parameter group based on the default parameter settings for clusters that are compatible with MySQL 5.7. You specify a value for the max_connections setting, overriding the formula that sets the default value. You associate the DB cluster parameter group with your DB cluster.

```
export REGION=us-east-1
export CLUSTER_PARAM_GROUP=rds-proxy-mysql-57-max-connections-demo
export CLUSTER_NAME=rds-proxy-mysql-57
aws rds create-db-parameter-group --region $REGION \
  --db-parameter-group-family aurora-mysql5.7 \
  --db-parameter-group-name $CLUSTER_PARAM_GROUP \
  --description "Aurora MySQL 5.7 cluster parameter group for RDS Proxy demo."

aws rds modify-db-cluster --region $REGION \
  --db-cluster-identifier $CLUSTER_NAME \
  --db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP

echo "New cluster param group is assigned to cluster:"
aws rds describe-db-clusters --region $REGION \
  --db-cluster-identifier $CLUSTER_NAME \
  --query '*[].{DBClusterParameterGroup:DBClusterParameterGroup}'

echo "Current value for max_connections:"
aws rds describe-db-cluster-parameters --region $REGION \
  --db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP \
  --query '*[].{ParameterName:ParameterName,ParameterValue:ParameterValue}' \
  --output text | grep '^max_connections'

echo -n "Enter number for max_connections setting: 
read answer
aws rds modify-db-cluster-parameter-group --region $REGION --db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP \
  --parameters "ParameterName=max_connections,ParameterValue=$answer,ApplyMethod=immediate"

echo "Updated value for max_connections:"
aws rds describe-db-cluster-parameters --region $REGION \
  --db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP \
  --query '*[].{ParameterName:ParameterName,ParameterValue:ParameterValue}' \
  --output text | grep '^max_connections'
```

Troubleshooting for RDS Proxy

Following, you can find troubleshooting ideas for some common RDS Proxy issues and information on CloudWatch logs for RDS Proxy.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name that you specified for a user-defined endpoint. Or it can be the special name default for read/write requests using the default endpoint of a proxy. For more information about proxy endpoints, see [Working with Amazon RDS Proxy endpoints](p. 1911).

Topics
- [Verifying connectivity for a proxy](p. 1930)
- [Common issues and solutions](p. 1931)
### Verifying connectivity for a proxy

You can use the following commands to verify that all components of the connection mechanism can communicate with the other components.

Examine the proxy itself using the `describe-db-proxies` command. Also examine the associated target group using the `describe-db-proxy-target-groups` command. Check that the details of the targets match the RDS DB instance/Aurora cluster that you intend to associate with the proxy. Use commands such as the following.

```
aws rds describe-db-proxies --db-proxy-name $DB_PROXY_NAME
aws rds describe-db-proxy-target-groups --db-proxy-name $DB_PROXY_NAME
```

To confirm that the proxy can connect to the underlying database, examine the targets specified in the target groups using the `describe-db-proxy-targets` command. Use a command such as the following.

```
aws rds describe-db-proxy-targets --db-proxy-name $DB_PROXY_NAME
```

The output of the `describe-db-proxy-targets` command includes a `TargetHealth` field. You can examine the fields `State`, `Reason`, and `Description` inside `TargetHealth` to check if the proxy can communicate with the underlying DB instance.

- A `State` value of `AVAILABLE` indicates that the proxy can connect to the DB instance.
- A `State` value of `UNAVAILABLE` indicates a temporary or permanent connection problem. In this case, examine the `Reason` and `Description` fields. For example, if `Reason` has a value of `PENDING_PROXY_CAPACITY`, try connecting again after the proxy finishes its scaling operation. If `Reason` has a value of `UNREACHABLE`, `CONNECTION_FAILED`, or `AUTH_FAILURE`, use the explanation from the `Description` field to help you diagnose the issue.
- The `State` field might have a value of `REGISTERING` for a brief time before changing to `AVAILABLE` or `UNAVAILABLE`.

If the following Netcat command (nc) is successful, you can access the proxy endpoint from the EC2 instance or other system where you're logged in. This command reports failure if you're not in the same VPC as the proxy and the associated database. You might be able to log directly in to the database without being in the same VPC. However, you can't log into the proxy unless you're in the same VPC.

```
nc -zx MySQL_proxy_endpoint 3306
nc -zx PostgreSQL_proxy_endpoint 5432
```

You can use the following commands to make sure that your EC2 instance has the required properties. In particular, the VPC for the EC2 instance must be the same as the VPC for the RDS DB instance Aurora cluster that the proxy connects to.

```
aws ec2 describe-instances --instance-ids your_ec2_instance_id
```

Examine the Secrets Manager secrets used for the proxy.

```
aws secretsmanager list-secrets
aws secretsmanager get-secret-value --secret-id your_secret_id
```

Make sure that the `SecretString` field displayed by `get-secret-value` is encoded as a JSON string that includes `username` and `password` fields. The following example shows the format of the `SecretString` field.
Common issues and solutions

For possible causes and solutions to some common problems that you might encounter using RDS Proxy, see the following.

After running `aws rds describe-db-proxy-targets`, if the TargetHealth description states Proxy does not have any registered credentials, verify the following:

- There are credentials registered for the user to access the proxy.
- The IAM role to access the proxy secret from Secrets Manager is valid.
- The DB proxy is using an authentication method.

You might encounter the following RDS events while creating or connecting to a DB proxy.

<table>
<thead>
<tr>
<th>Category</th>
<th>RDS event ID</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>failure</td>
<td>RDS-EVENT-0243</td>
<td>RDS couldn't provision capacity for the proxy because there aren't enough IP addresses available in your subnets. To fix the issue, make sure that your subnets have the minimum number of unused IP addresses. To determine the recommended number for your instance class, see Planning for IP address capacity (p. 1888).</td>
</tr>
<tr>
<td>failure</td>
<td>RDS-EVENT-0275</td>
<td>RDS throttled some connections to DB proxy (RDS Proxy).</td>
</tr>
</tbody>
</table>

You might encounter the following issues while creating a new proxy or connecting to a proxy.

<table>
<thead>
<tr>
<th>Error</th>
<th>Causes or workarounds</th>
</tr>
</thead>
<tbody>
<tr>
<td>403: The security token included in the request is invalid</td>
<td>Select an existing IAM role instead of choosing to create a new one.</td>
</tr>
</tbody>

Using RDS Proxy with AWS CloudFormation

You can use RDS Proxy with AWS CloudFormation. Doing so helps you to create groups of related resources. Such a group can include a proxy that can connect to a newly created Aurora DB cluster. RDS Proxy support in AWS CloudFormation involves two new registry types: DBProxy and DBProxyTargetGroup.

The following listing shows a sample AWS CloudFormation template for RDS Proxy.

```yaml
Resources:
  DBProxy:
    Type: AWS::RDS::DBProxy
    Properties:
      DBProxyName: CanaryProxy
      EngineFamily: MYSQL
      RoleArn:
        Fn::ImportValue: SecretReaderRoleArn
      Auth:
        - {AuthScheme: SECRETS, SecretArn: !ImportValue ProxySecret, IAMAuth: DISABLED}
      VpcSubnetIds:
        Fn::Split: [",", "Fn::ImportValue": SubnetIds]
  ProxyTargetGroup:
    Type: AWS::RDS::DBProxyTargetGroup
    Properties:
      DBProxyName: CanaryProxy
      TargetGroupName: default
      DBInstanceIdentifiers:
```

Using RDS Proxy with AWS CloudFormation

<table>
<thead>
<tr>
<th>Error</th>
<th>Cause</th>
<th>Solution</th>
</tr>
</thead>
</table>
| Timed-out waiting to acquire database connection. | The proxy timed-out waiting to acquire a database connection. Some possible reasons include the following:  
• The proxy can't establish a database connection because the maximum connections have been reached.  
• The proxy can't establish a database connection because the database is unavailable. | Possible solutions are the following:  
• Check the target of the RDS DB instance Aurora cluster status to see if it's unavailable.  
• Check if there are long-running transactions and/or queries being executed. They can use database connections from the connection pool for a long time. |
| Request returned an error: `database_error`. | The database connection established from the proxy returned an error. | The solution depends on the specific database error. One example is: Request returned an error: database "your-database-name" does not exist. This means that the specified database name doesn't exist on the database server. Or it means that the user name used as a database name (if a database name isn't specified) doesn't exist on the server. |
Using RDS Proxy with Aurora global databases

An Aurora global database is a single database that spans multiple AWS Regions, allowing for low-latency global reads and disaster recovery from any Region-wide outage. It provides built-in fault tolerance for your deployment because the DB instance relies not on a single AWS Region, but upon multiple Regions and different Availability Zones. For more information, see Using Amazon Aurora global databases (p. 1800).

You can use RDS Proxy with any DB cluster in an Aurora global database. Before you begin to use these features together, make sure that you familiarize yourself with the following information.

**Important**

If the DB cluster is part of a global database with write forwarding turned on, reduce your proxy's MaxConnectionsPercent value by the quota that's allotted for write forwarding. The write forwarding quota is set in the DB cluster parameter aurora_fwd_writer_max_connections_pct. For information about write forwarding, see Using write forwarding in an Amazon Aurora global database (p. 1831).

**Limitations for RDS Proxy with global databases**

When the Aurora DB cluster has write forwarding turned on, RDS Proxy doesn't support the SESSION value for the aurora_replica_read_consistency variable. Setting this value can cause unexpected behavior.

**How RDS Proxy endpoints work with global databases**

When you understand how RDS Proxy endpoints work with global databases, you can better manage your applications that use Aurora databases with both of these features.

For a proxy with a global database's primary cluster as the registered target, the proxy endpoints work the same way as with any Aurora DB cluster. The proxy's read/write endpoints send all requests to the writer instance of the cluster. The proxy's read-only endpoints send all requests to the reader instances. If a reader becomes unavailable while a connection is open, RDS Proxy redirects subsequent queries on the connection to another reader instance. For a proxy with a secondary cluster as the registered target, requests that are sent to the proxy's read-only endpoints are also sent to the reader instances. Because the cluster has no writer instances, requests that are sent to read/write endpoints fail with the error "The target group doesn't have any associated read/write instances".

Global database switchover and failover operations both involve a role switch between the primary and one of the secondary DB clusters. When the selected secondary cluster becomes the new primary, one of its reader instances is promoted to a writer. This DB instance is now the new writer instance for the global cluster. Make sure to redirect your application's write operations to the appropriate read/write endpoint of the proxy that's associated with the new primary cluster. This proxy endpoint might be the default endpoint or a custom read/write endpoint.
RDS Proxy queues all requests through read/write endpoints and sends them to the writer instance of the new primary cluster as soon as it's available. It does so regardless of whether the switchover or failover operation has completed. During switchover or failover, the default endpoint of the proxy for the old primary cluster still accepts write operations. However, as soon as that cluster becomes a secondary cluster, all of the write operations fail. To learn how and when to perform specific global switchover or failover tasks, see the following topics:

- Global database switchover – Performing switchovers for Amazon Aurora global databases (p. 1861)
- Global database failover – Recovering an Amazon Aurora global database from an unplanned outage (p. 1855)
Working with Aurora zero-ETL integrations with Amazon Redshift

An Aurora zero-ETL integration with Amazon Redshift enables near real-time analytics and machine learning (ML) using Amazon Redshift on petabytes of transactional data from Aurora. It's a fully managed solution for making transactional data available in Amazon Redshift after it is written to an Aurora DB cluster. Extract, transform, and load (ETL) is the process of combining data from multiple sources into a large, central repository.

A zero-ETL integration makes the data in your Aurora DB cluster available in Amazon Redshift within minutes of the data updates being written. Once that data is in Amazon Redshift, you can power your analytics, ML, and AI workloads using the built-in capabilities of Amazon Redshift, such as machine learning, materialized views, data sharing, federated access to multiple data stores and data lakes, and integrations with Amazon SageMaker, Amazon QuickSight, and other AWS services.

To create a zero-ETL integration, you specify an Aurora DB cluster as the source, and an Amazon Redshift data warehouse as the target. The integration replicates data from the source database into the target data warehouse.

The following diagram illustrates this functionality:

The integration monitors the health of the data pipeline and recovers from issues when possible. You can create integrations from multiple Aurora DB clusters into a single Amazon Redshift namespace, enabling you to derive insights across multiple applications.

For information about pricing for zero-ETL integrations, see Amazon Aurora pricing and Amazon Redshift pricing.

Topics
- **Benefits** (p. 1939)
- **Key concepts** (p. 1939)
- **Limitations** (p. 1939)
- **Quotas** (p. 1940)
- **Supported Regions** (p. 1941)
- **Getting started with Aurora zero-ETL integrations with Amazon Redshift** (p. 1941)
- **Creating Aurora zero-ETL integrations with Amazon Redshift** (p. 1947)
Benefits

Aurora zero-ETL integrations with Amazon Redshift have the following benefits:

- Help you derive holistic insights from multiple data sources.
- Eliminate the need to build and maintain complex data pipelines that perform extract, transform, and load (ETL) operations. Zero-ETL integrations remove the challenges that come with building and managing pipelines by provisioning and managing them for you.
- Reduce operational burden and cost, and let you focus on improving your applications.
- Let you leverage Amazon Redshift’s analytics and ML capabilities to derive insights from transactional and other data, to respond effectively to critical, time-sensitive events.

Key concepts

As you get started with zero-ETL integrations, consider the following concepts:

Integration

A fully managed data pipeline that automatically replicates transactional data and schemas from an Aurora DB cluster to an Amazon Redshift data warehouse.

Source database

The Aurora DB cluster where data is replicated from. You can specify a cluster that uses provisioned DB instances or Aurora Serverless v2 DB instances as the source. Multiple source databases can write to the same target. There are some restrictions on settings for the source database, which are outlined in the section called “Limitations” (p. 1939).

Target data warehouse

The Amazon Redshift data warehouse where the data is replicated to. There are two types of data warehouse: a provisioned cluster data warehouse and a serverless data warehouse. A provisioned cluster data warehouse is a collection of computing resources called nodes, which are organized into a group called a cluster. A serverless data warehouse is comprised of a workgroup that stores compute resources, and a namespace that houses the database objects and users. Both data warehouses run an Amazon Redshift engine and contain one or more databases.

For more information, see Data warehouse system architecture in the Amazon Redshift Developer Guide.

Limitations

The following limitations apply to Aurora zero-ETL integrations with Amazon Redshift.

General limitations

- The source DB cluster must be in the same Region as the target Amazon Redshift data warehouse.
• You can’t modify an integration after you create it. If you need to change certain settings, such as the integration name, you must delete and recreate the integration.

• You can’t rename a DB cluster or any of its instances if it has existing integrations.

• You can’t delete a DB cluster that has existing integrations. You must delete all associated integrations first.

• If you stop the source DB cluster, the last few transactions might not be replicated to the target data warehouse until you resume the cluster.

• Zero-ETL integrations don’t currently support data filtering.

• If your cluster is the source of a blue/green deployment, the blue and green environments can’t have existing zero-ETL integrations during switchover. You must delete the integration first and switch over, then recreate it.

• If your source cluster is the primary DB cluster in an Aurora global database and it fails over to one of its secondary clusters, the integration becomes inactive. You must delete and recreate the integration.

• When you initially create an integration, or when a table is being resynchronized, data seeding from the source to the target can take 20-25 minutes or more depending on the size of the source database. This delay can lead to increased replica lag when tables are resynchronized.

• Some data types aren’t supported. For a list of supported data types, see the section called “Data type differences” (p. 1953).

• ALTER TABLE partition operations will cause your table to resynchronize in order to reload data from Aurora to Amazon Redshift. The table will be unavailable for querying while it’s resynchronizing.

• Foreign key references with predefined table updates aren’t supported. Specifically, ON DELETE and ON UPDATE rules aren’t supported with CASCADE, SET NULL, and SET DEFAULT actions. Attempting to create or update a table with such references to another table will put the table into a failed state.

• XA transaction aren’t supported.

• Object identifiers (including database name, table name, column names, and others) can contain only alphanumeric characters, numbers, $, and _ (underscore).

### Aurora MySQL limitations

• Your source DB cluster must be running Aurora MySQL version 3.05.0 (compatible with MySQL 8.0.32) or higher. Aurora PostgreSQL is not currently supported.

• Zero-ETL integrations rely on MySQL binary logging (binlog) to capture ongoing data changes. We recommend that you do not use binlog-based data filtering, as it can cause data inconsistencies between the source and target databases.

• Aurora MySQL system tables, temporary tables, and views aren’t replicated to Amazon Redshift.

• Zero-ETL integrations are supported only for databases configured to use the InnoDB storage engine.

### Amazon Redshift limitations

For a list of Amazon Redshift limitations related to zero-ETL integrations, see Consideration in the Amazon Redshift Management Guide.

### Quotas

Your account has the following quotas related to Aurora zero-ETL integrations with Amazon Redshift. Each quota is per-Region unless otherwise specified.
Name | Default | Description
--- | --- | ---
Integrations | 100 | The total number of integrations within an AWS account.
Integrations per target data warehouse | 25 | The number of integrations sending data to a single target Amazon Redshift data warehouse.
Integrations per source cluster | 5 | The number of integrations sending data from a single source database.

In addition, Amazon Redshift places certain limits on the number of tables allowed in each DB instance or cluster node. For more information, see [Quotas and limits in Amazon Redshift](https://docs.aws.amazon.com/redshift/latest/guide/quotas-limits.html) in the *Amazon Redshift Management Guide*.

### Supported Regions

Aurora zero-ETL integrations with Amazon Redshift are available in a subset of AWS Regions. For a list of supported Regions, see the section called "Zero-ETL integrations" (p. 48).

### Getting started with Aurora zero-ETL integrations with Amazon Redshift

Before you create a zero-ETL integration with Amazon Redshift, configure your Aurora DB cluster and your Amazon Redshift data warehouse with the required parameters and permissions. During setup, you'll complete the following steps:

1. [Create a custom DB cluster parameter group](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-parameter-groups-create-copy.html) (p. 1941)
2. [Create a source DB cluster](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-create-cluster.html) (p. 1942)
3. [Create a target Amazon Redshift data warehouse](https://docs.aws.amazon.com/redshift/latest/guide/cluster-create.html) (p. 1942)

After you complete these tasks, continue to the section called "Creating zero-ETL integrations" (p. 1947).

**Tip**

If the source DB cluster and target Amazon Redshift data warehouse that you intend to use are in the same AWS account, you can have RDS complete these setup steps for you while you're creating the integration, rather than completing them manually. To immediately start creating an integration, see the section called "Creating zero-ETL integrations" (p. 1947).

You can use the AWS SDKs to automate the setup process for you. For more information, see the section called "Set up an integration using the AWS SDKs" (p. 1943).

### Step 1: Create a custom DB cluster parameter group

Aurora zero-ETL integrations with Amazon Redshift require specific values for the DB cluster parameters that control binary logging (binlog). Specifically, they require *enhanced binlog* (`aurora_enhanced_binlog`), which reduces the compute performance overhead caused by turning on binlog. For more information, see the section called "Setting up enhanced binlog" (p. 1037).
To configure binary logging, you must first create a custom DB cluster parameter group, and then associate it with the source DB cluster.

Create a custom Aurora MySQL DB cluster parameter group with the following settings:

- `aurora_enhanced_binlog=1`
- `binlog_backup=0`
- `binlog_format=ROW`
- `binlog_replication_globaldb=0`
- `binlog_row_image=full`
- `binlog_row_metadata=full`

In addition, make sure that the `binlog_transaction_compression` parameter is not set to ON, and that the `binlog_row_value_options` parameter is not set to `PARTIAL_JSON`.

For instructions to create a parameter group, see the section called "Working with DB cluster parameter groups" (p. 214).

**Step 2: Create a source DB cluster**

After you create a custom DB cluster parameter group, create an Aurora MySQL DB cluster. This cluster will be the source of data replication to Amazon Redshift. The cluster must be running Aurora MySQL version 3.05.0 (compatible with MySQL 8.0.32) or higher. For instructions to create a DB cluster, see the section called "Creating a DB cluster" (p. 179).

Under **Additional configuration** change the default **DB cluster parameter group** to the custom parameter group that you created in the previous step.

**Note**
If you associate the parameter group with the DB cluster after the cluster is already created, you must reboot the primary DB instance in the cluster to apply the changes before you can create a zero-ETL integration. For instructions, see the section called "Rebooting an Aurora DB cluster or instance" (p. 358).

**Step 3: Create a target Amazon Redshift data warehouse**

After you create your source DB cluster, you must create and configure a target data warehouse in Amazon Redshift. The data warehouse must meet the following requirements:

- Using an RA3 node type (ra3.16xlarge, ra3.4xlarge, or ra3.xlplus) with at least two nodes, or Redshift Serverless
- Encrypted (if using a provisioned cluster). For more information, see Amazon Redshift database encryption.

For instructions to create a data warehouse, see Creating a cluster for provisioned clusters, or Creating a workgroup with a namespace for Redshift Serverless.

**Enable case sensitivity on the data warehouse**

For the integration to be successful, the case sensitivity parameter (`enable_case_sensitive_identifier`) must be enabled for the data warehouse. By default, case sensitivity is disabled on all provisioned clusters and Redshift Serverless workgroups.
To enable case sensitivity, perform the following steps depending on your data warehouse type:

- **Provisioned cluster** – To enable case sensitivity on a provisioned cluster, create a custom parameter group with the `enable_case_sensitive_identifier` parameter enabled. Then, associate the parameter group with the cluster. For instructions, see [Managing parameter groups using the console](#) or [Configuring parameter values using the AWS CLI](#).

  **Note**
  Remember to reboot the cluster after you associate the custom parameter group with it.

- **Serverless workgroup** – To enable case sensitivity on a Redshift Serverless workgroup, you must use the AWS CLI. The Amazon Redshift console doesn't currently support modifying Redshift Serverless parameter values. Use the `update-workgroup` command and specify `--config-parameters parameterKey=enable_case_sensitive_identifier,parameterValue=true`.

  You don't need to reboot a workgroup after you modify its parameter values.

**Configure authorization for the data warehouse**

After you create a data warehouse, you must configure the source Aurora DB cluster as an authorized integration source. For instructions, see [Configure authorization for your Amazon Redshift data warehouse](#).

**Set up an integration using the AWS SDKs**

Rather than setting up each resource manually, you can run the following Python script to automatically set up the required resources for you. The code example uses the AWS SDK for Python (Boto3) to create a source Aurora MySQL DB cluster and target Amazon Redshift data warehouse, each with the required parameter values. It then waits for the clusters to be available before creating a zero-ETL integration between them. You can comment out different functions depending on which resources you need to set up.

To install the required dependencies, run the following commands:

```
pip install boto3
pip time
```

Within the script, optionally modify the names of the source, target, and parameter groups. The final function creates an integration named `my-integration` after the resources are set up.

**Python code example**

```python
import boto3
import time

# Build the client using the default credential configuration.
# You can use the CLI and run 'aws configure' to set access key, secret
# key, and default region.

rds = boto3.client('rds')
redshift = boto3.client('redshift')
sts = boto3.client('sts')

source_cluster_name = 'my-source-cluster'  # A name for the source cluster
source_param_group_name = 'my-source-param-group'  # A name for the source parameter group

target_cluster_name = 'my-target-cluster'  # A name for the target cluster
target_param_group_name = 'my-target-param-group'  # A name for the target parameter group
```

1943
def create_source_cluster(*args):
    
    response = rds.create_db_cluster_parameter_group(
        DBClusterParameterGroupName=source_param_group_name,
        DBParameterGroupFamily='aurora-mysql8.0',
        Description='For Aurora MySQL zero-ETL integrations'
    )
    print('Created source parameter group: ' + response['DBClusterParameterGroup']['DBClusterParameterGroupName'])

    response = rds.modify_db_cluster_parameter_group(
        DBClusterParameterGroupName=source_param_group_name,
        Parameters=[
            {
                'ParameterName': 'aurora_enhanced_binlog',
                'ParameterValue': '1',
                'ApplyMethod': 'pending-reboot'
            },
            {
                'ParameterName': 'binlog_backup',
                'ParameterValue': '0',
                'ApplyMethod': 'pending-reboot'
            },
            {
                'ParameterName': 'binlog_format',
                'ParameterValue': 'ROW',
                'ApplyMethod': 'pending-reboot'
            },
            {
                'ParameterName': 'binlog_replication_globaldb',
                'ParameterValue': '0',
                'ApplyMethod': 'pending-reboot'
            },
            {
                'ParameterName': 'binlog_row_image',
                'ParameterValue': 'full',
                'ApplyMethod': 'pending-reboot'
            },
            {
                'ParameterName': 'binlog_row_metadata',
                'ParameterValue': 'full',
                'ApplyMethod': 'pending-reboot'
            }
        ]
    )
    print('Modified source parameter group: ' + response['DBClusterParameterGroupName'])

    response = rds.create_db_cluster(
        DBClusterIdentifier=source_cluster_name,
        DBClusterParameterGroupName=source_param_group_name,
        Engine='aurora-mysql',
        EngineVersion='8.0.mysql_aurora.3.05.0',
        DatabaseName='myauroradb',
        MasterUsername='username',
        MasterUserPassword='Password01**'
    )
    print('Creating source cluster: ' + response['DBCluster']['DBClusterIdentifier'])

    source_arn = (response['DBCluster']['DBClusterArn'])
    create_target_cluster(target_cluster_name, source_arn, target_param_group_name)

    response = rds.create_db_instance(
        DBInstanceClass='db.r6g.2xlarge',
        DBClusterIdentifier=source_cluster_name,
        DBInstanceIdentifier=source_cluster_name + '-instance',
        DBParameterGroupArn=source_param_group_arn,
        Engine='aurora-mysql',
        EngineVersion='8.0.mysql_aurora.3.05.0',
        MasterUsername='username',
        MasterUserPassword='Password01**'
    )
    print('Creating source instance: ' + response['DBInstance']['DBInstanceArn'])

    source_arn = (response['DBInstance']['DBInstanceArn'])
    create_target_instance(target_instance_name, source_arn, target_instance_arn)
def create_target_cluster(target_cluster_name, source_arn, target_param_group_name):
    
    Engine='aurora-mysql'
    return(response)

    def create_target_cluster(target_cluster_name, source_arn, target_param_group_name):
        
        response = redshift.create_cluster()
        print('Created target parameter group: ' + response['ClusterParameterGroup']['ParameterGroupName'])
        response = redshift.modify_cluster_parameter_group()
        print('Modified target parameter group: ' + response['ParameterGroupName'])
        response = redshift.create_cluster()
        print('Creating target cluster: ' + response['Cluster']['ClusterIdentifier'])
        # Retrieve the target cluster ARN
        response = redshift.describe_clusters()
        target_arn = response['Clusters'][0]['ClusterNamespaceArn']
        # Retrieve the current user's account ID
        response = sts.get_caller_identity()
        account_id = response['Account']
        # Create a resource policy specifying cluster ARN and account ID
        response = redshift.put_resource_policy()
        Policy='''
        {"Version": "2012-10-17",
        "Statement":[
            {
                "Effect": "Allow",
                "Principal":{
                    "Service": "redshift.amazonaws.com"},
                "Action": ["redshift:AuthorizeInboundIntegration"],
                "Condition":{
                    "StringEquals":{
                        "aws:SourceArn": "%s"}}
            },
            {
                "Effect": "Allow",
                "Principal":{
                    "Service": "redshift.amazonaws.com"},
                "Action": ["redshift:AuthorizeInboundIntegration"],
                "Condition":{
                    "StringEquals":{
                        "aws:SourceArn": "%s"}
            }
        }
    )
}
With a source Aurora DB cluster and an Amazon Redshift target data warehouse, you can now create a zero-ETL integration and replicate data. For instructions, see the section called "Creating zero-ETL integrations" (p. 1947).
Creating Aurora zero-ETL integrations with Amazon Redshift

When you create an Aurora zero-ETL integration, you specify the source Aurora DB cluster and the target Amazon Redshift data warehouse. You can also customize encryption settings and add tags. Aurora creates an integration between the source DB cluster and its target. Once the integration is active, any data that you insert into the source DB cluster will be replicated into the configured Amazon Redshift target.

Topics
- Prerequisites (p. 1947)
- Required permissions (p. 1947)
- Creating zero-ETL integrations (p. 1949)
- Next steps (p. 1951)

Prerequisites

Before you create a zero-ETL integration, you must create a source DB cluster and a target Amazon Redshift data warehouse. You also must allow replication into the data warehouse by adding the DB cluster as an authorized integration source.

For instructions to complete each of these steps, see the section called "Getting started with zero-ETL integrations" (p. 1941).

Required permissions

Certain IAM permissions are required to create a zero-ETL integration. At minimum, you need permissions to perform the following actions:

- Create zero-ETL integrations for the source Aurora DB cluster.
- View and delete all zero-ETL integrations.
- Create inbound integrations into the target data warehouse. You don't need this permission if the same account owns the Amazon Redshift data warehouse and this account is an authorized principal for that data warehouse. For information about adding authorized principals, see Configure authorization for your Amazon Redshift data warehouse.

The following sample policy demonstrates the least privilege permissions required to create and manage integrations. Note that if you have broader permissions, such as rds:* or the AdministratorAccess policy, these permissions encompass the least privilege permissions in the sample policy.

Note

Redshift Amazon Resource Names (ARNs) have the following format. Note the use of a forward slash (/) rather than a colon (:) before the serverless namespace UUID.

- Provisioned cluster – arn:aws:redshift:{region}:{account-id}:namespace:namespace-uuid
- Serverless – arn:aws:redshift-serverless:{region}:{account-id}:namespace/namespace-uuid
Sample policy

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds:CreateIntegration"
      ],
      "Resource": [
        "arn:aws:rds:{region}:{account-id}:cluster:source-db",
        "arn:aws:rds:{region}:{account-id}:integration:*"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "rds:DescribeIntegrations"
      ],
      "Resource": ["**"]
    },
    {
      "Effect": "Allow",
      "Action": [
        "rds:DeleteIntegration"
      ],
      "Resource": [
        "arn:aws:rds:{region}:{account-id}:integration:*"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "redshift:CreateInboundIntegration"
      ],
      "Resource": [
        "arn:aws:redshift:{region}:{account-id}:namespace:namespace-uuid"
      ]
    }
  ]
}
```

Choosing a target data warehouse in a different account

If you plan to specify a target Amazon Redshift data warehouse that's in another AWS account, you must create a role that allows users in the current account to access resources in the target account. For more information, see [Providing access to an IAM user in another AWS account that you own](#).

The role must have the following permissions, which allow the user to view available Amazon Redshift provisioned clusters and Redshift Serverless namespaces in the target account.

Required permissions and trust policy

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "redshift:DescribeClusters",
        "redshift-serverless:ListNamespaces"
      ],
      "Resource": ["**"]
    }
  ]
}
```
The role must have the following trust policy, which specifies the target account ID.

```json
{
  "Version":"2012-10-17",
  "Statement":[
    {
      "Effect":"Allow",
      "Principal":{
        "AWS": "arn:aws:iam::external-account-id:root"
      },
      "Action":"sts:AssumeRole"
    }
  ]
}
```

For instructions to create the role, see Creating a role using custom trust policies.

## Creating zero-ETL integrations

You can create a zero-ETL integration with Amazon Redshift using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

### To create a zero-ETL integration

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the left navigation pane, choose **Zero-ETL integrations**.
3. Choose **Create zero-ETL integration**.
4. For **Integration identifier**, enter a name for the integration. The name can have up to 63 alphanumeric characters and can include hyphens.
5. Choose **Next**.
6. For **Source**, select the Aurora DB cluster where the data will originate from. The cluster must be running Aurora MySQL version 3.05.0 (compatible with MySQL 8.0.32) or higher. **Note**

   RDS notifies you if the DB cluster parameters aren't configured correctly. If you receive this message, you can either choose **Fix it for me**, or configure them manually. For instructions to fix them manually, see the section called "Step 1: Create a custom DB cluster parameter group" (p. 1941).

   Modifying DB cluster parameters requires a reboot. Before you can create the integration, the reboot must be complete and the new parameter values must be successfully applied to the cluster.

7. Once your source DB cluster is successfully configured, choose **Next**.
8. For **Target**, do the following:

   1. (Optional) To use a different AWS account for the Amazon Redshift target, choose **Specify a different account**. Then, enter the ARN of an IAM role with permissions to display your data.
warehouses. For instructions to create the IAM role, see the section called “Choosing a target data warehouse in a different account” (p. 1948).

2. For Amazon Redshift data warehouse, select the target for replicated data from the source DB cluster. You can choose a provisioned Amazon Redshift cluster or a Redshift Serverless namespace as the target.

   **Note**
   RDS notifies you if the resource policy or case sensitivity settings for the specified data warehouse aren't configured correctly. If you receive this message, you can either choose Fix it for me, or configure them manually. For instructions to fix them manually, see Turn on case sensitivity for your data warehouse and Configure authorization for your data warehouse in the Amazon Redshift Management Guide.
   Modifying case sensitivity for a provisioned Redshift cluster requires a reboot. Before you can create the integration, the reboot must be complete and the new parameter value must be successfully applied to the cluster.
   If your selected source and target are in different AWS accounts, then Amazon RDS cannot fix these settings for you. You must navigate to the other account and fix them manually in Amazon Redshift.

9. Once your target data warehouse is configured correctly, choose Next.

10. (Optional) For Tags, add one or more tags to the integration. For more information, see Tagging Amazon RDS resources.

11. For Encryption, specify how you want your integration to be encrypted. By default, RDS encrypts all integrations with an AWS owned key. To choose a customer managed key instead, enable Customize encryption settings and choose a KMS key to use for encryption. For more information, see Encrypting Amazon Aurora resources.

   **Note**
   If you specify a custom KMS key, the key policy must allow the kms:CreateGrant action for the Amazon Redshift service principal (redshift.amazonaws.com). For more information, see Creating a key policy in the AWS Key Management Service Developer Guide.

   Optionally, add an encryption context. For more information, see Encryption context in the AWS Key Management Service Developer Guide.

12. Choose Next.

13. Review your integration settings and choose Create zero-ETL integration. It takes approximately 30 minutes for the integration to be active.

   If creation fails, see the section called “I can't create a zero-ETL integration” (p. 1958) for troubleshooting steps.

The integration has a status of Creating while it's being created, and the target Amazon Redshift data warehouse has a status of Modifying. During this time, you can't query the data warehouse or make any configuration changes on it.

When the integration is successfully created, the status of the integration and the target Amazon Redshift data warehouse both change to Active.

**AWS CLI**

To create a zero-ETL integration using the AWS CLI, use the create-integration command with the following options:

- **--integration-name** – Specify a name for the integration.
- **--source-arn** – Specify the ARN of the Aurora DB cluster that will be the source for the integration.
• --target-arn – Specify the ARN of the Amazon Redshift data warehouse that will be the target for the integration.

Example

For Linux, macOS, or Unix:

```bash
aws rds create-integration \
  --integration-name my-integration \
  --source-arn arn:aws:rds:{region}:{account-id}:my-cluster \
  --target-arn arn:aws:redshift:{region}:{account-id}:namespace:namespace-uuid
```

For Windows:

```bash
aws rds create-integration ^
  --integration-name my-integration ^
  --source-arn arn:aws:rds:{region}:{account-id}:my-cluster ^
  --target-arn arn:aws:redshift:{region}:{account-id}:namespace:namespace-uuid
```

**RDS API**

To create a zero-ETL integration by using the Amazon RDS API, use the `CreateIntegration` operation with the following parameters:

- **IntegrationName** – Specify a name for the integration.
- **SourceArn** – Specify the ARN of the Aurora DB cluster that will be the source for the integration.
- **TargetArn** – Specify the ARN of the Amazon Redshift data warehouse that will be the target for the integration.

**Next steps**

After you successfully create a zero-ETL integration, you must create a destination database within your target Amazon Redshift cluster or workgroup. Then, you can start adding data to the source Aurora DB cluster and querying it in Amazon Redshift. For instructions, see [Creating destination databases in Amazon Redshift](#).

### Adding data to a source Aurora DB cluster and querying it in Amazon Redshift

To finish creating a zero-ETL integration that replicates data from Amazon Aurora into Amazon Redshift, you must create a destination database in Amazon Redshift.

First, connect to your Amazon Redshift cluster or workgroup and create a database with a reference to your integration identifier. Then, you can add data to your source Aurora DB cluster and see it replicated in Amazon Redshift.

**Topics**

- [Create a destination database in Amazon Redshift (p. 1952)](#)
- [Add data to the source DB cluster (p. 1952)](#)
- [Query your data in Amazon Redshift (p. 1952)](#)
- [Data type differences between Aurora and Amazon Redshift databases (p. 1953)](#)
Create a destination database in Amazon Redshift

Before you can start replicating data into Amazon Redshift, after you create an integration, you must create a destination database in your target data warehouse. This destination database must include a reference to the integration identifier. You can use the Amazon Redshift console or the Query editor v2 to create the database.

For instructions to create a destination database, see Create a destination database in Amazon Redshift.

Add data to the source DB cluster

Add some data to the Aurora DB cluster that you want to replicate into your Amazon Redshift data warehouse.

Note
There are differences between data types in Amazon Aurora and Amazon Redshift. For a table of data type mappings, see the section called “Data type differences” (p. 1953).

First, connect to the source DB cluster using the MySQL client of your choice. For instructions, see the section called “Connecting to Aurora MySQL” (p. 204).

Then, create a table and insert a row of sample data. The following example uses the MySQL Workbench utility.

```
CREATE DATABASE my_db;
USE my_db;
CREATE TABLE books_table (ID int NOT NULL, Title VARCHAR(50) NOT NULL, Author VARCHAR(50) NOT NULL, Copyright INT NOT NULL, Genre VARCHAR(50) NOT NULL, PRIMARY KEY (ID));
INSERT INTO books_table VALUES (1, 'The Shining', 'Stephen King', 1977, 'Supernatural fiction');
```

Important
Make sure that the table has a primary key. Otherwise, it can't be replicated to the target data warehouse.

Query your data in Amazon Redshift

After you add data to the Aurora DB cluster, it's immediately replicated into Amazon Redshift and ready to be queried.

Note
Amazon Redshift accepts only UTF-8 characters, so it might not honor the collation defined in the source database. The sorting and comparison rules might be different, which can ultimately change the query results.

To query the replicated data

1. Navigate to the Amazon Redshift console and choose Query editor v2 from the left navigation pane.
2. Connect to your cluster or workgroup and choose your destination database (which you created from the integration) from the dropdown menu (destination_database in this example). For instructions to create a destination database, see Create a destination database in Amazon Redshift.
3. Run the following command to select all data from the schema and table that you created in the source Aurora DB cluster:
Data type differences between Aurora and Amazon Redshift databases

The following table shows the mapping of an Aurora MySQL data type to a corresponding Amazon Redshift data type. Amazon Aurora currently supports only these data types for zero-ETL integrations.

If a table in your source DB cluster includes an unsupported data type, the table goes out of sync and isn't consumable by the Amazon Redshift target. Streaming from the source to the target continues, but the table with the unsupported data type isn't available. To fix the table and make it available in Amazon Redshift, you must manually revert the breaking change and then refresh the integration by running `ALTER DATABASE...INTEGRATION REFRESH`.

Viewing and monitoring Aurora zero-ETL integrations with Amazon Redshift

You can view the details of an Amazon Aurora zero-ETL integration to see its configuration information and current status. You can also monitor the status of your integration by querying specific system views in Amazon Redshift. In addition, Amazon Redshift publishes certain integration-related metrics to Amazon CloudWatch, which you can view within the Amazon Redshift console.

Topics
- Viewing integrations (p. 1955)
- Monitoring integrations using system tables (p. 1957)
- Monitoring integrations with Amazon EventBridge (p. 1957)

Viewing integrations

You can view Aurora zero-ETL integrations with Amazon Redshift using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To view the details of a zero-ETL integration

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. From the left navigation pane, choose Zero-ETL integrations.
3. Select an integration to view more details about it, such as its source DB cluster and target data warehouse.
An integration can have the following statuses:

- **Creating** – The integration is being created.
- **Active** – The integration is sending transactional data to the target data warehouse.
- **Syncing** – The integration has encountered a recoverable error and is reseeding data. Affected tables aren’t available for querying in Amazon Redshift until they finish resyncing.
- **Needs Attention** – The integration encountered an event or error that requires manual intervention to resolve it. To fix the issue, follow the instructions in the error message on the integration details page.
- **Failed** – The integration encountered an unrecoverable event or error that can’t be fixed. You must delete and recreate the integration.
- **Deleting** – The integration is being deleted.

### AWS CLI

To view all zero-ETL integrations in the current account using the AWS CLI, use the `describe-integrations` command and specify the `--integration-identifier` option.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds describe-integrations \
  --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374
```

For Windows:

```bash
aws rds describe-integrations ^
  --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374
```

### RDS API

To view zero-ETL integration using the Amazon RDS API, use the `DescribeIntegrations` operation with the `IntegrationIdentifier` parameter.
Monitoring integrations using system tables

Amazon Redshift has system tables and views that contain information about how the system is functioning. You can query these system tables and views the same way that you would query any other database table. For more information about system tables and views in Amazon Redshift, see System tables reference in the Amazon Redshift Database Developer Guide.

You can query the following system views and tables to get information about your Aurora zero-ETL integrations with Amazon Redshift:

- **SVV_INTEGRATION** – Provides configuration details for your integrations.
- **SVV_INTEGRATION_TABLE_STATE** – Describes the state of each table within an integration.
- **SYS_INTEGRATION_TABLE_STATE_CHANGE** – Displays table state change logs for an integration.
- **SYS_INTEGRATION_ACTIVITY** – Provides information about completed integration runs.

All integration-related Amazon CloudWatch metrics originate from Amazon Redshift. For more information, see Monitoring zero-ETL integrations in the Amazon Redshift Management Guide. Currently, Amazon Aurora doesn't publish any integration metrics to CloudWatch.

Monitoring integrations with Amazon EventBridge

Amazon Redshift sends integration-related events to Amazon EventBridge. For a list of events and their corresponding event IDs, see Zero-ETL integration event notifications with Amazon EventBridge in the Amazon Redshift Management Guide.

Deleting Aurora zero-ETL integrations with Amazon Redshift

When you delete a zero-ETL integration, Amazon Aurora removes it from the source Aurora DB cluster. Your transactional data isn't deleted from Amazon Aurora or Amazon Redshift, but Aurora doesn't send new data to Amazon Redshift.

You can only delete an integration when it has a status of Active, Failed, Syncing, or Needs Attention.

You can delete zero-ETL integration using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

To delete a zero-ETL integration

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. From the left navigation pane, choose Zero-ETL integrations.
3. Select the zero-ETL integration that you want to delete.
4. Choose Actions, Delete, and confirm deletion.

**AWS CLI**

To delete a zero-ETL integration, use the delete-integration command and specify the --integration-identifier option.
Example

For Linux, macOS, or Unix:

```bash
aws rds delete-integration \
  --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374
```

For Windows:

```bash
aws rds delete-integration ^
  --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374
```

RDS API

To delete a zero-ETL integration using the Amazon RDS API, use the `DeleteIntegration` operation with the `IntegrationIdentifier` parameter.

Troubleshooting Aurora zero-ETL integrations with Amazon Redshift

You can check the state of a zero-ETL integration by querying the `SVV_INTEGRATION` system table in Amazon Redshift. If the `state` column has a value of `ErrorState`, it means something's wrong. For more information, see the section called "Monitoring using system tables" (p. 1957).

Use the following information to troubleshoot common issues with Aurora zero-ETL integrations with Amazon Redshift.

Topics

- I can't create a zero-ETL integration (p. 1958)
- My integration is in a perpetual state of Syncing (p. 1959)
- One or more of my Amazon Redshift tables requires a resync (p. 1959)

I can't create a zero-ETL integration

If you can't create a zero-ETL integration, make sure that the following are correct for your source DB cluster:

- Your source DB cluster is running Aurora MySQL version 3.05.0 (compatible with MySQL 8.0.32) or higher. To validate the engine version, choose the `Configuration` tab for the DB cluster and check the `Engine version`.
- You correctly configured DB cluster parameters. If the required parameters are set incorrectly or not associated with the cluster, creation fails. See the section called “Step 1: Create a custom DB cluster parameter group” (p. 1941).

In addition, make sure the following are correct for your target data warehouse:

- Case sensitivity is enabled. See `Turn on case sensitivity for your data warehouse`.
- You added the correct authorized principal and integration source. For instructions, see `Configure authorization for your Amazon Redshift data warehouse`.

1958
My integration is in a perpetual state of Syncing

Your integration might consistently show a status of Syncing if you change the value of one of the required DB cluster parameters.

To fix this issue, check the values of the parameters in the parameter group associated with the source DB cluster, and make sure that they match the required values. For more information, see the section called "Step 1: Create a custom DB cluster parameter group" (p. 1941).

If you modify any parameters, make sure to reboot the DB cluster to apply the changes.

One or more of my Amazon Redshift tables requires a resync

Running certain commands on your source DB cluster might require your tables to be resynchronized. In these cases, the SVV_INTEGRATION_TABLE_STATE system view shows a table_state of ResyncRequired, which means that the integration must completely reload data for that specific table from MySQL to Amazon Redshift.

When the table starts to resynchronize, it enters a state of Syncing. You don't need to take any manual action to resynchronize a table. While table data is resynchronizing, you might not be able to access it in Amazon Redshift.

The following are some example operations that can put a table into a ResyncRequired state, and possible alternatives to consider.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Example</th>
<th>Alternative</th>
</tr>
</thead>
<tbody>
<tr>
<td>Adding a column into a specific position</td>
<td>ALTER TABLE <code>table_name</code> ADD COLUMN <code>column_name</code> INTEGER NOT NULL first;</td>
<td>Amazon Redshift doesn't support adding columns into specific positions using <code>first</code> or <code>after</code> keywords. If the order of columns in the target table isn't critical, add the column to the end of the table using a simpler command: ALTER TABLE <code>table_name</code> ADD COLUMN <code>column_name</code> column_type;</td>
</tr>
<tr>
<td>Adding a timestamp</td>
<td>ALTER TABLE <code>table_name</code> CURRENT_TIMESTAMP</td>
<td>The CURRENT_TIMESTAMP</td>
</tr>
<tr>
<td>Operation</td>
<td>Example</td>
<td>Alternative</td>
</tr>
<tr>
<td>-----------------------------------------------</td>
<td>-------------------------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>column with the default CURRENT_TIMESTAMP</td>
<td><code>ADD COLUMN column_name TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP;</code></td>
<td>value for existing table rows is calculated by Aurora MySQL and can't be simulated in Amazon Redshift without full table data resynchronization. If possible, switch the default value to a literal constant like 2023-01-01 00:00:15 to avoid latency in table availability.</td>
</tr>
<tr>
<td>Performing multiple column operations within a single command</td>
<td><code>ALTER TABLE table_name ADD COLUMN column_1, RENAME COLUMN column_2 TO column_3;</code></td>
<td>Consider splitting the command into two separate operations, ADD and RENAME, which won't require resynchronization.</td>
</tr>
</tbody>
</table>
Using Aurora Serverless v2

Aurora Serverless v2 is an on-demand, autoscaling configuration for Amazon Aurora. Aurora Serverless v2 helps to automate the processes of monitoring the workload and adjusting the capacity for your databases. Capacity is adjusted automatically based on application demand. You're charged only for the resources that your DB clusters consume. Thus, Aurora Serverless v2 can help you to stay within budget and avoid paying for computer resources that you don't use.

This type of automation is especially valuable for multitenant databases, distributed databases, development and test systems, and other environments with highly variable and unpredictable workloads.

Aurora Serverless v2 use cases

Aurora Serverless v2 supports many types of database workloads. These range from development and testing environments, to websites and applications that have unpredictable workloads, to the most demanding, business-critical applications that require high scale and availability.

Aurora Serverless v2 is especially useful for the following use cases:

- **Variable workloads** – You're running workloads that have sudden and unpredictable increases in activity. An example is a traffic site that sees a surge of activity when it starts raining. Another is an e-commerce site with increased traffic when you offer sales or special promotions. With Aurora Serverless v2, your database automatically scales capacity to meet the needs of the application's peak load and scales back down when the surge of activity is over. With Aurora Serverless v2, you no longer need to provision for peak or average capacity. You can specify an upper capacity limit to handle the worst-case situation, and that capacity isn't used unless it's needed.

The granularity of scaling in Aurora Serverless v2 helps you to match capacity closely to your database's needs. For a provisioned cluster, scaling up requires adding a whole new DB instance. For an Aurora Serverless v1 cluster, scaling up requires doubling the number of Aurora capacity units (ACUs) for the cluster, such as from 16 to 32 or 32 to 64. In contrast, Aurora Serverless v2 can add half an ACU when only a little more capacity is needed. It can add 0.5, 1, 1.5, 2, or additional half-ACUs based on the additional capacity needed to handle an increase in workload. And it can remove 0.5, 1, 1.5, 2, or additional half-ACUs when the workload decreases and that capacity is no longer needed.
- **Multi-tenant applications** – With Aurora Serverless v2, you don't have to individually manage database capacity for each application in your fleet. Aurora Serverless v2 manages individual database capacity for you.

You can create a cluster for each tenant. That way, you can use features such as cloning, snapshot restore, and Aurora global databases to enhance high availability and disaster recovery as appropriate for each tenant.

Each tenant might have specific busy and idle periods depending on the time of day, time of year, promotional events, and so on. Each cluster can have a wide capacity range. That way, clusters with low activity incur minimal DB instance charges. Any cluster can quickly scale up to handle periods of high activity.

- **New applications** – You're deploying a new application and you're unsure about the DB instance size you need. By using Aurora Serverless v2, you can set up a cluster with one or many DB instances and have the database autoscale to the capacity requirements of your application.

- **Mixed-use applications** – Suppose that you have an online transaction processing (OLTP) application, but you periodically experience spikes in query traffic. By specifying promotion tiers for the Aurora Serverless v2 DB instances in a cluster, you can configure your cluster so that the reader DB instances can scale independently of the writer DB instance to handle the additional load. When the usage spike subsides, the reader DB instances scale back down to match the capacity of the writer DB instance.

- **Capacity planning** – Suppose that you usually adjust your database capacity, or verify the optimal database capacity for your workload, by modifying the DB instance classes of all the DB instances in a cluster. With Aurora Serverless v2, you can avoid this administrative overhead. You can determine the appropriate minimum and maximum capacity by running the workload and checking how much the DB instances actually scale.

You can modify existing DB instances from provisioned to Aurora Serverless v2 or from Aurora Serverless v2 to provisioned. You don't need to create a new cluster or a new DB instance in such cases.

With an Aurora global database, you might not need as much capacity for the secondary clusters as in the primary cluster. You can use Aurora Serverless v2 DB instances in the secondary clusters. That way, the cluster capacity can scale up if a secondary region is promoted and takes over your application's workload.

- **Development and testing** – In addition to running your most demanding applications, you can also use Aurora Serverless v2 for development and testing environments. With Aurora Serverless v2, you can create DB instances with a low minimum capacity instead of using burstable db.t* DB instance classes. You can set the maximum capacity high enough that those DB instances can still run substantial workloads without running low on memory. When the database isn't in use, all of the DB instances scale down to avoid unnecessary charges.

  **Tip**
  
  To make it convenient to use Aurora Serverless v2 in development and test environments, the AWS Management Console provides the Easy create shortcut when you create a new cluster. If you choose the Dev/Test option, Aurora creates a cluster with an Aurora Serverless v2 DB instance and a capacity range that's typical for a development and test system.

### Using Aurora Serverless v2 for existing provisioned workloads

Suppose that you already have an Aurora application running on a provisioned cluster. You can check how the application would work with Aurora Serverless v2 by adding one or more Aurora Serverless v2 DB instances to the existing cluster as reader DB instances. You can check how often the reader DB instances scale up and down. You can use the Aurora failover mechanism to promote an Aurora Serverless v2 DB instance to be the writer and check how it handles the read/write workload. That way, you can switch over with minimal downtime and without changing the endpoint that your client
Advantages of Aurora Serverless v2

Aurora Serverless v2 is intended for variable or "spiky" workloads. With such unpredictable workloads, you might have difficulty planning when to change your database capacity. You might also have trouble making capacity changes quickly enough using the familiar mechanisms such as adding DB instances or changing DB instance classes. Aurora Serverless v2 provides the following advantages to help with such use cases:

- **Simpler capacity management than provisioned** – Aurora Serverless v2 reduces the effort for planning DB instance sizes and resizing DB instances as the workload changes. It also reduces the effort for maintaining consistent capacity for all the DB instances in a cluster.

- **Faster and easier scaling during periods of high activity** – Aurora Serverless v2 scales compute and memory capacity as needed, with no disruption to client transactions or your overall workload. The ability to use reader DB instances with Aurora Serverless v2 helps you to take advantage of horizontal scaling in addition to vertical scaling. The ability to use Aurora global databases means that you can spread your Aurora Serverless v2 read workload across multiple AWS Regions. This capability is more convenient than the scaling mechanisms for provisioned clusters. It's also faster and more granular than the scaling capabilities in Aurora Serverless v1.

- **Cost-effective during periods of low activity** – Aurora Serverless v2 helps you to avoid overprovisioning your DB instances. Aurora Serverless v2 adds resources in granular increments when DB instances scale up. You pay only for the database resources that you consume. Aurora Serverless v2 resource usage is measured on a per-second basis. That way, when a DB instance scales down, the reduced resource usage is registered right away.

- **Greater feature parity with provisioned** – You can use many Aurora features with Aurora Serverless v2 that aren't available for Aurora Serverless v1. For example, with Aurora Serverless v2 you can use reader DB instances, global databases, AWS Identity and Access Management (IAM) database authentication, and Performance Insights. You can also use many more configuration parameters than with Aurora Serverless v1.

In particular, with Aurora Serverless v2 you can take advantage of the following features from provisioned clusters:

- **Reader DB instances** – Aurora Serverless v2 can take advantage of reader DB instances to scale horizontally. When a cluster contains one or more reader DB instances, the cluster can fail over immediately in case of problems with the writer DB instance. This is a capability that isn't available with Aurora Serverless v1.

- **Multi-AZ clusters** – You can distribute the Aurora Serverless v2 DB instances of a cluster across multiple Availability Zones (AZs). Setting up a Multi-AZ cluster helps to ensure business continuity even in the rare case of issues that affect an entire AZ. This is a capability that isn't available with Aurora Serverless v1.

- **Global databases** – You can use Aurora Serverless v2 in combination with Aurora global databases to create additional read-only copies of your cluster in other AWS Regions for disaster recovery purposes.

- **RDS Proxy** – You can use Amazon RDS Proxy to allow your applications to pool and share database connections to improve their ability to scale.

- **Faster, more granular, less disruptive scaling than Aurora Serverless v1** – Aurora Serverless v2 can scale up and down faster. Scaling can change capacity by as little as 0.5 ACUs, instead of doubling or halving the number of ACUs. Scaling typically happens with no pause in processing at all. Scaling doesn't involve an event that you have to be aware of, as with Aurora Serverless v1. Scaling can happen while SQL statements are running and transactions are open, without the need to wait for a quiet point.
How Aurora Serverless v2 works

The following overview describes how Aurora Serverless v2 works.

Topics
- Aurora Serverless v2 overview (p. 1964)
- Configurations for Aurora clusters (p. 1965)
- Aurora Serverless v2 capacity (p. 1965)
- Aurora Serverless v2 scaling (p. 1966)
- Aurora Serverless v2 and high availability (p. 1968)
- Aurora Serverless v2 and storage (p. 1968)
- Configuration parameters for Aurora clusters (p. 1968)

Aurora Serverless v2 overview

Amazon Aurora Serverless v2 is suitable for the most demanding, highly variable workloads. For example, your database usage might be heavy for a short period of time, followed by long periods of light activity or no activity at all. Some examples are retail, gaming, or sports websites with periodic promotional events, and databases that produce reports when needed. Others are development and testing environments, and new applications where usage might ramp up quickly. For cases such as these and many others, configuring capacity correctly in advance isn't always possible with the provisioned model. It can also result in higher costs if you overprovision and have capacity that you don't use.

In contrast, Aurora provisioned clusters are suitable for steady workloads. With provisioned clusters, you choose a DB instance class that has a predefined amount of memory, CPU power, I/O bandwidth, and so on. If your workload changes, you manually modify the instance class of your writer and readers. The provisioned model works well when you can adjust capacity in advance of expected consumption patterns and it's acceptable to have brief outages while you change the instance class of the writer and readers in your cluster.

Aurora Serverless v2 is architected from the ground up to support serverless DB clusters that are instantly scalable. Aurora Serverless v2 is engineered to provide the same degree of security and isolation as with provisioned writers and readers. These aspects are crucial in multitenant serverless cloud environments. The dynamic scaling mechanism has very little overhead so that it can respond quickly to changes in the database workload. It's also powerful enough to meet dramatic increases in processing demand.

By using Aurora Serverless v2, you can create an Aurora DB cluster without being locked into a specific database capacity for each writer and reader. You specify the minimum and maximum capacity range. Aurora scales each Aurora Serverless v2 writer or reader in the cluster within that capacity range. By using a Multi-AZ cluster where each writer or reader can scale dynamically, you can take advantage of dynamic scaling and high availability.

Aurora Serverless v2 scales the database resources automatically based on your minimum and maximum capacity specifications. Scaling is fast because most scaling events operations keep the writer or reader on the same host. In the rare cases that an Aurora Serverless v2 writer or reader is moved from one host to another, Aurora Serverless v2 manages the connections automatically. You don't need to change your database client application code or your database connection strings.

With Aurora Serverless v2, as with provisioned clusters, storage capacity and compute capacity are separate. When we refer to Aurora Serverless v2 capacity and scaling, it's always compute capacity that's increasing or decreasing. Thus, your cluster can contain many terabytes of data even when the CPU and memory capacity scale down to low levels.
Instead of provisioning and managing database servers, you specify database capacity. For details about Aurora Serverless v2 capacity, see [Aurora Serverless v2 capacity](p. 1965). The actual capacity of each Aurora Serverless v2 writer or reader varies over time, depending on your workload. For details about that mechanism, see [Aurora Serverless v2 scaling](p. 1966).

**Important**

With Aurora Serverless v1, your cluster has a single measure of compute capacity that can scale between the minimum and maximum capacity values. With Aurora Serverless v2, your cluster can contain readers in addition to the writer. Each Aurora Serverless v2 writer and reader can scale between the minimum and maximum capacity values. Thus, the total capacity of your Aurora Serverless v2 cluster depends on both the capacity range that you define for your DB cluster and the number of writers and readers in the cluster. At any specific time, you are only charged for the Aurora Serverless v2 capacity that is being actively used in your Aurora DB cluster.

### Configurations for Aurora clusters

For each of your Aurora DB clusters, you can choose any combination of Aurora Serverless v2 capacity, provisioned capacity, or both.

You can set up a cluster that contains both Aurora Serverless v2 and provisioned capacity, called a *mixed-configuration cluster*. For example, suppose that you need more read/write capacity than is available for an Aurora Serverless v2 writer. In this case, you can set up the cluster with a very large provisioned writer. In that case, you can still use Aurora Serverless v2 for the readers. Or suppose that the write workload for your cluster varies but the read workload is steady. In this case, you can set up your cluster with an Aurora Serverless v2 writer and one or more provisioned readers.

You can also set up a DB cluster where all the capacity is managed by Aurora Serverless v2. To do this, you can create a new cluster and use Aurora Serverless v2 from the start. Or you can replace all the provisioned capacity in an existing cluster with Aurora Serverless v2. For example, some of the upgrade paths from older engine versions require starting with a provisioned writer and replacing it with a Aurora Serverless v2 writer. For the procedures to create a new DB cluster with Aurora Serverless v2 or to switch an existing DB cluster to Aurora Serverless v2, see [Creating a cluster that uses Aurora Serverless v2](p. 1984) and [Switching from a provisioned cluster to Aurora Serverless v2](p. 1973).

If you don’t use Aurora Serverless v2 at all in a DB cluster, all the writers and readers in the DB cluster are *provisioned*. This is the oldest and most common kind of DB cluster that most users are familiar with. In fact, before Aurora Serverless, there wasn’t a special name for this kind of Aurora DB cluster. Provisioned capacity is constant. The charges are relatively easy to forecast. However, you have to predict in advance how much capacity you need. In some cases, your predictions might be inaccurate or your capacity needs might change. In these cases, your DB cluster can become underprovisioned (slower than you want) or overprovisioned (more expensive than you want).

### Aurora Serverless v2 capacity

The unit of measure for Aurora Serverless v2 is the *Aurora capacity unit (ACU)*. Aurora Serverless v2 capacity isn’t tied to the DB instance classes that you use for provisioned clusters.

Each ACU is a combination of approximately 2 gibibytes (GiB) of memory, corresponding CPU, and networking. You specify the database capacity range using this unit of measure. The `ServerlessDatabaseCapacity` and `ACUUtilization` metrics help you to determine how much capacity your database is actually using and where that capacity falls within the specified range.

At any moment in time, each Aurora Serverless v2 DB writer or reader has a *capacity*. The capacity is represented as a floating-point number representing ACUs. The capacity increases or decreases whenever the writer or reader scales. This value is measured every second. For each DB cluster where you intend to use Aurora Serverless v2, you define a *capacity range*: the minimum and maximum capacity values that
each Aurora Serverless v2 writer or reader can scale between. The capacity range is the same for each Aurora Serverless v2 writer or reader in a DB cluster. Each Aurora Serverless v2 writer or reader has its own capacity, falling somewhere in that range.

The largest Aurora Serverless v2 capacity that you can define is 128 ACUs. For all the considerations when choosing the maximum capacity value, see Choosing the maximum Aurora Serverless v2 capacity setting for a cluster (p. 2006).

The smallest Aurora Serverless v2 capacity that you can define is 0.5 ACUs. You can specify a higher number if it’s less than or equal to the maximum capacity value. Setting the minimum capacity to a small number lets lightly loaded DB clusters consume minimal compute resources. At the same time, they stay ready to accept connections immediately and scale up when they become busy.

We recommend setting the minimum to a value that allows each DB writer or reader to hold the working set of the application in the buffer pool. That way, the contents of the buffer pool aren’t discarded during idle periods. For all the considerations when choosing the minimum capacity value, see Choosing the minimum Aurora Serverless v2 capacity setting for a cluster (p. 2005).

Depending on how you configure the readers in a Multi-AZ DB cluster, their capacities can be tied to the capacity of the writer or independently. For details about how to do that, see Aurora Serverless v2 scaling (p. 1966).

Monitoring Aurora Serverless v2 involves measuring the capacity values for the writer and readers in your DB cluster over time. If your database doesn’t scale down to the minimum capacity, you can take actions such as adjusting the minimum and optimizing your database application. If your database consistently reaches its maximum capacity, you can take actions such as increasing the maximum. You can also optimize your database application and spread the query load across more readers.

The charges for Aurora Serverless v2 capacity are measured in terms of ACU-hours. For information about how Aurora Serverless v2 charges are calculated, see the Aurora pricing page.

Suppose that the total number of writers and readers in your cluster is N. In that case, the cluster consumes approximately $n \times \text{minimum ACUs}$ when you aren’t running any database operations. Aurora itself might run monitoring or maintenance operations that cause some small amount of load. That cluster consumes no more than $n \times \text{maximum ACUs}$ when the database is running at full capacity.

For more details about choosing appropriate minimum and maximum ACU values, see Choosing the Aurora Serverless v2 capacity range for an Aurora cluster (p. 2005). The minimum and maximum ACU values that you specify also affect the way some of the Aurora configuration parameters work for Aurora Serverless v2. For details about the interaction between the capacity range and configuration parameters, see Working with parameter groups for Aurora Serverless v2 (p. 2014).

**Aurora Serverless v2 scaling**

For each Aurora Serverless v2 writer or reader, Aurora continuously tracks utilization of resources such as CPU, memory, and network. These measurements collectively are called the load. The load includes the database operations performed by your application. It also includes background processing for the database server and Aurora administrative tasks. When capacity is constrained by any of these, Aurora Serverless v2 scales up. Aurora Serverless v2 also scales up when it detects performance issues that it can resolve by doing so. You can monitor resource utilization and how it affects Aurora Serverless v2 scaling by using the procedures in Important Amazon CloudWatch metrics for Aurora Serverless v2 (p. 2018) and Monitoring Aurora Serverless v2 performance with Performance Insights (p. 2021).

The load can vary across the writer and readers in your DB cluster. The writer handles all data definition language (DDL) statements, such as CREATE TABLE, ALTER TABLE, and DROP TABLE. The writer also handles all data manipulation language (DML) statements, such as INSERT and UPDATE. Readers can process read-only statements, such as SELECT queries.
Scaling is the operation that increases or decreases Aurora Serverless v2 capacity for your database. With Aurora Serverless v2, each writer and reader has its own current capacity value, measured in ACUs. Aurora Serverless v2 scales a writer or reader up to a higher capacity when its current capacity is too low to handle the load. It scales the writer or reader down to a lower capacity when its current capacity is higher than needed.

Unlike Aurora Serverless v1, which scales by doubling the capacity each time the DB cluster reaches a threshold, Aurora Serverless v2 can increase capacity incrementally. When your workload demand begins to reach the current database capacity of a writer or reader, Aurora Serverless v2 increases the number of ACUs for that writer or reader. Aurora Serverless v2 scales capacity in the increments required to provide the best performance for the resources consumed. Scaling happens in increments as small as 0.5 ACUs. The larger the current capacity, the larger the scaling increment and thus the faster scaling can happen.

Because Aurora Serverless v2 scaling is so frequent, granular, and nondisruptive, it doesn't cause discrete events in the AWS Management Console the way that Aurora Serverless v1 does. Instead, you can measure the Amazon CloudWatch metrics such as **ServerlessDatabaseCapacity** and **ACUUtilization** and track their minimum, maximum, and average values over time. To learn more about Aurora metrics, see [Monitoring metrics in an Amazon Aurora cluster (p. 509)](). For tips about monitoring Aurora Serverless v2, see [Important Amazon CloudWatch metrics for Aurora Serverless v2 (p. 2018)]() .

You can choose to make a reader scale at the same time as the associated writer, or independently from the writer. You do so by specifying the promotion tier for that reader.

- Readers in promotion tiers 0 and 1 scale at the same time as the writer. That scaling behavior makes readers in priority tiers 0 and 1 ideal for availability. That's because they are always sized to the right capacity to take over the workload from the writer in case of failover.
- Readers in promotion tiers 2–15 scale independently from the writer. Each reader remains within the minimum and maximum ACU values that you specified for your cluster. When a reader scales independently of the associated writer DB, it can become idle and scale down while the writer continues to process a high volume of transactions. It's still available as a failover target, if no other readers are available in lower promotion tiers. However, if it's promoted to be the writer, it might need to scale up to handle the full workload of the writer.

For details about promotion tiers, see [Choosing the promotion tier for an Aurora Serverless v2 reader (p. 1999)]() .

The notions of scaling points and associated timeout periods from Aurora Serverless v1 don't apply in Aurora Serverless v2. Aurora Serverless v2 scaling can happen while database connections are open, while SQL transactions are in process, while tables are locked, and while temporary tables are in use. Aurora Serverless v2 doesn't wait for a quiet point to begin scaling. Scaling doesn't disrupt any database operations that are underway.

If your workload requires more read capacity than is available with a single writer and a single reader, you can add multiple Aurora Serverless v2 readers to the cluster. Each Aurora Serverless v2 reader can scale within the range of minimum and maximum capacity values that you specified for your DB cluster. You can use the cluster's reader endpoint to direct read-only sessions to the readers and reduce the load on the writer.

Whether Aurora Serverless v2 performs scaling, and how fast scaling occurs once it starts, also depends on the minimum and maximum ACU settings for the cluster. In addition, it depends on whether a reader is configured to scale along with the writer or independently from it. For details about the factors that affect Aurora Serverless v2 scaling, see [Performance and scaling for Aurora Serverless v2 (p. 2004)]().

**Note**
Currently, Aurora Serverless v2 writers and readers don't scale all the way down to zero ACUs. Idle Aurora Serverless v2 writers and readers can scale down to the minimum ACU value that you specified for the cluster.
That behavior is different than Aurora Serverless v1, which can pause after a period of idleness, but then takes some time to resume when you open a new connection. When your DB cluster with Aurora Serverless v2 capacity isn't needed for some time, you can stop and start clusters as with provisioned DB clusters. For details about stopping and starting clusters, see Stopping and starting an Amazon Aurora DB cluster (p. 249).

Aurora Serverless v2 and high availability

The way to establish high availability for an Aurora DB cluster is to make it a Multi-AZ DB cluster. A Multi-AZ Aurora DB cluster has compute capacity available at all times in more than one Availability Zone (AZ). That configuration keeps your database up and running even in case of a significant outage. Aurora performs an automatic failover in case of an issue that affects the writer or even the entire AZ. With Aurora Serverless v2, you can choose for the standby compute capacity to scale up and down along with the capacity of the writer. That way, the compute capacity in the second AZ is ready to take over the current workload at any time. At the same time, the compute capacity in all AZs can scale down when the database is idle. For details about how Aurora works with AWS Regions and Availability Zones, see High availability for Aurora DB instances (p. 102).

The Aurora Serverless v2 Multi-AZ capability uses readers in addition to the writer. Support for readers is new for Aurora Serverless v2 compared to Aurora Serverless v1. You can add up to 15 Aurora Serverless v2 readers spread across 3 AZs to an Aurora DB cluster.

For business-critical applications that must remain available even in case of an issue that affects your entire cluster or the whole AWS Region, you can set up an Aurora global database. You can use Aurora Serverless v2 capacity in the secondary clusters so they're ready to take over during disaster recovery. They can also scale down when the database isn't busy. For details about Aurora global databases, see Using Amazon Aurora global databases (p. 1800).

Aurora Serverless v2 works like provisioned for failover and other high availability features. For more information, see High availability for Amazon Aurora (p. 102).

Suppose that you want to ensure maximum availability for your Aurora Serverless v2 cluster. You can create a reader in addition to the writer. If you assign the reader to promotion tier 0 or 1, whatever scaling happens for the writer also happens for the reader. That way, a reader with identical capacity is always ready to take over for the writer in case of a failover.

Suppose that you want to run quarterly reports for your business at the same time as your cluster continues to process transactions. If you add an Aurora Serverless v2 reader to the cluster and assign it to a promotion tier from 2 through 15, you can connect directly to that reader to run the reports. Depending on how memory-intensive and CPU-intensive the reporting queries are, that reader can scale up to accommodate the workload. It can then scale down again when the reports are finished.

Aurora Serverless v2 and storage

The storage for each Aurora DB cluster consists of six copies of all your data, spread across three AZs. This built-in data replication applies regardless of whether your DB cluster includes any readers in addition to the writer. That way, your data is safe, even from issues that affect the compute capacity of the cluster.

Aurora Serverless v2 storage has the same reliability and durability characteristics as described in Amazon Aurora storage and reliability (p. 97). That's because the storage for Aurora DB clusters works the same whether the compute capacity uses Aurora Serverless v2 or provisioned.

Configuration parameters for Aurora clusters

You can adjust all the same cluster and database configuration parameters for clusters with Aurora Serverless v2 capacity as for provisioned DB clusters. However, some capacity-related parameters are
handled differently for Aurora Serverless v2. In a mixed-configuration cluster, the parameter values that you specify for those capacity-related parameters still apply to any provisioned writers and readers.

Almost all of the parameters work the same way for Aurora Serverless v2 writers and readers as for provisioned ones. The exceptions are some parameters that Aurora automatically adjusts during scaling, and some parameters that Aurora keeps at fixed values that depend on the maximum capacity setting.

For example, the amount of memory reserved for the buffer cache increases as a writer or reader scales up, and decreases as it scales down. That way, memory can be released when your database isn't busy. Conversely, Aurora automatically sets the maximum number of connections to a value that's appropriate based on the maximum capacity setting. That way, active connections aren't dropped if the load drops and Aurora Serverless v2 scales down. For information about how Aurora Serverless v2 handles specific parameters, see Working with parameter groups for Aurora Serverless v2 (p. 2014).

Requirements for Aurora Serverless v2

When you create a cluster where you intend to use Aurora Serverless v2 DB instances, pay attention to the following requirements.

Topics
- Region and version availability (p. 1969)
- Clusters that use Aurora Serverless v2 must have a capacity range specified (p. 1969)
- Some provisioned features aren't supported in Aurora Serverless v2 (p. 1970)
- Some Aurora Serverless v2 aspects are different from Aurora Serverless v1 (p. 1970)

Region and version availability

Feature availability and support varies across specific versions of each Aurora database engine, and across AWS Regions. For more information on version and Region availability with Aurora and Aurora Serverless v2, see Aurora Serverless v2 (p. 53).

The following example shows the AWS CLI commands to confirm the exact DB engine values you can use with Aurora Serverless v2 for a specific AWS Region. The --db-instance-class parameter for Aurora Serverless v2 is always db.serverless. The --engine parameter can be aurora-mysql or aurora-postgresql. Substitute the appropriate --region and --engine values to confirm the --engine-version values that you can use. If the command doesn't produce any output, Aurora Serverless v2 isn't available for that combination of AWS Region and DB engine.

```
aws rds describe-orderable-db-instance-options --engine aurora-mysql --db-instance-class db.serverless \  --region my_region --query 'OrderableDBInstanceOptions[].[EngineVersion]' --output text
aws rds describe-orderable-db-instance-options --engine aurora-postgresql --db-instance-class db.serverless \  --region my_region --query 'OrderableDBInstanceOptions[].[EngineVersion]' --output text
```

Clusters that use Aurora Serverless v2 must have a capacity range specified

An Aurora cluster must have a ServerlessV2ScalingConfiguration attribute before you can add any DB instances that use the db.serverless DB instance class. This attribute specifies the capacity range. Aurora Serverless v2 capacity ranges from a minimum of 0.5 Aurora capacity units (ACU) through
128 ACUs, in increments of 0.5 ACU. Each ACU provides the equivalent of approximately 2 gibibytes (GiB) of RAM and associated CPU and networking. For details about how Aurora Serverless v2 uses the capacity range settings, see How Aurora Serverless v2 works (p. 1964).

You can specify the minimum and maximum ACU values in the AWS Management Console when you create a cluster and associated Aurora Serverless v2 DB instance. You can also specify the --serverless-v2-scaling-configuration option in the AWS CLI. Or you can specify the ServerlessV2ScalingConfiguration parameter with the Amazon RDS API. You can specify this attribute when you create a cluster or modify an existing cluster. For the procedures to set the capacity range, see Setting the Aurora Serverless v2 capacity range for a cluster (p. 1988). For a detailed discussion of how to pick minimum and maximum capacity values and how those settings affect some database parameters, see Choosing the Aurora Serverless v2 capacity range for an Aurora cluster (p. 2005).

Some provisioned features aren't supported in Aurora Serverless v2

The following features from Aurora provisioned DB instances currently aren't available for Amazon Aurora Serverless v2:

- Database activity streams (DAS).
- Cluster cache management for Aurora PostgreSQL. The apg__ccm_enabled configuration parameter doesn't apply to Aurora Serverless v2 DB instances.

Some Aurora features work with Aurora Serverless v2, but might cause issues if your capacity range is lower than needed for the memory requirements for those features with your specific workload. In that case, your database might not perform as well as usual, or might encounter out-of-memory errors. For recommendations about setting the appropriate capacity range, see Choosing the Aurora Serverless v2 capacity range for an Aurora cluster (p. 2005). For troubleshooting information if your database encounters out-of-memory errors due to a misconfigured capacity range, see Avoiding out-of-memory errors (p. 2017).

Aurora Auto Scaling isn't supported. This type of scaling adds new readers to handle additional read-intensive workload, based on CPU utilization. However, scaling based on CPU utilization isn't meaningful for Aurora Serverless v2. As an alternative, you can create Aurora Serverless v2 reader DB instances in advance and leave them scaled down to low capacity. That's a faster and less disruptive way to scale a cluster's read capacity than adding new DB instances dynamically.

Some Aurora Serverless v2 aspects are different from Aurora Serverless v1

If you are an Aurora Serverless v1 user and this is your first time using Aurora Serverless v2, consult differences between Aurora Serverless v2 and Aurora Serverless v1 requirements (p. 1978) to understand how requirements are different between Aurora Serverless v1 and Aurora Serverless v2.

Getting started with Aurora Serverless v2

To convert an existing DB cluster to use Aurora Serverless v2, you can do the following:

- Upgrade from a provisioned Aurora DB cluster.
- Upgrade from an Aurora Serverless v1 cluster.
- Migrate from an on-premises database to an Aurora Serverless v2 cluster.
When your upgraded cluster is running the appropriate engine version as listed in Requirements for Aurora Serverless v2 (p. 1969), you can begin adding Aurora Serverless v2 DB instances to it. The first DB instance that you add to the upgraded cluster must be a provisioned DB instance. Then you can switch over the processing for the write workload, the read workload, or both to the Aurora Serverless v2 DB instances.

  - Aurora PostgreSQL–compatible DB clusters (p. 1983)
- Migrating from an on-premises database to Aurora Serverless v2 (p. 1984)

Note

These topics describe how to convert an existing DB cluster. For information on creating a new Aurora Serverless v2 DB cluster, see Creating a cluster that uses Aurora Serverless v2 (p. 1984).

Upgrading or switching existing clusters to use Aurora Serverless v2

If your provisioned cluster has an engine version that supports Aurora Serverless v2, switching to Aurora Serverless v2 doesn't require an upgrade. In that case, you can add Aurora Serverless v2 DB instances to your original cluster. You can switch the cluster to use all Aurora Serverless v2 DB instances. You can also use a combination of Aurora Serverless v2 and provisioned DB instances in the same DB cluster. For the Aurora engine versions that support Aurora Serverless v2, see Aurora Serverless v2 (p. 53).

If you're running a lower engine version that doesn't support Aurora Serverless v2, you take these general steps:

1. Upgrade the cluster.
2. Create a provisioned writer DB instance for the upgraded cluster.
3. Modify the cluster to use Aurora Serverless v2 DB instances.

Such an upgrade might involve one or more snapshot restore operations. When doing an upgrade across multiple major engine versions, you perform an intermediate upgrade for every major version between the original and final clusters.

Important

When you perform a major version upgrade to an Aurora Serverless v2-compatible version by using snapshot restore or cloning, the first DB instance that you add to the new cluster must be a provisioned DB instance. This addition starts the final stage of the upgrade process.
Until that final stage happens, the cluster doesn't have the infrastructure that's required for Aurora Serverless v2 support. Thus, these upgraded clusters always start with a provisioned writer DB instance. Then you can convert or fail over the provisioned DB instance to an Aurora Serverless v2 one.

Upgrading from Aurora Serverless v1 to Aurora Serverless v2 involves creating a provisioned cluster as an intermediate step. Then you perform the same upgrade steps as when you start with a provisioned cluster.

**Upgrade paths for MySQL-compatible clusters to use Aurora Serverless v2**

If your original cluster is running Aurora MySQL, choose the appropriate procedure depending on the engine version and engine mode of your cluster.

<table>
<thead>
<tr>
<th>If your original Aurora MySQL cluster is this</th>
<th>Do this to switch to Aurora Serverless v2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Provisioned cluster running Aurora MySQL version 3, compatible with MySQL 8.0</td>
<td>This is the final stage for all conversions from existing Aurora MySQL clusters. If necessary, perform a minor version upgrade to version 3.02.0 or higher. Use a provisioned DB instance for the writer DB instance. Add one Aurora Serverless v2 reader DB instance. Perform a failover to make that the writer DB instance. (Optional) Convert other provisioned DB instances in the cluster to Aurora Serverless v2. Or add new Aurora Serverless v2 DB instances and remove the provisioned DB instances. For the full procedure and examples, see [Switching from a provisioned cluster to Aurora Serverless v2](p. 1973).</td>
</tr>
<tr>
<td>Provisioned cluster running Aurora MySQL version 2, compatible with MySQL 5.7</td>

## Switching from a provisioned cluster to Aurora Serverless v2

To switch a provisioned cluster to use Aurora Serverless v2, follow these steps:
1. Check if the provisioned cluster needs to be upgraded to be used with Aurora Serverless v2 DB instances. For the Aurora versions that are compatible with Aurora Serverless v2, see [Requirements for Aurora Serverless v2](p. 1969).

   If the provisioned cluster is running an engine version that isn't available for Aurora Serverless v2, upgrade the engine version of the cluster:
   
   - If you have a MySQL 5.7–compatible provisioned cluster, follow the upgrade instructions for Aurora MySQL version 3. Use the procedures in [Upgrading to Aurora MySQL version 3](p. 799).
   - If you have a PostgreSQL-compatible provisioned cluster running PostgreSQL version 11 or 12, follow the upgrade instructions for Aurora PostgreSQL version 13. Use the procedures in [How to perform a major version upgrade](p. 1786).

2. Configure any other cluster properties to match the Aurora Serverless v2 requirements from [Requirements for Aurora Serverless v2](p. 1969).

3. Configure the scaling configuration for the cluster. Follow the procedure in [Setting the Aurora Serverless v2 capacity range for a cluster](p. 1988).

4. Add one or more Aurora Serverless v2 DB instances to the cluster. Follow the general procedure in [Adding Aurora Replicas to a DB cluster](p. 293). For each new DB instance, specify the special DB instance class name `Serverless` in the AWS Management Console, or `db.serverless` in the AWS CLI or Amazon RDS API.

   In some cases, you might already have one or more provisioned reader DB instances in the cluster. If so, you can convert one of the readers to an Aurora Serverless v2 DB instance instead of creating a new DB instance. To do so, follow the procedure in [Converting a provisioned writer or reader to Aurora Serverless v2](p. 1996).

5. Perform a failover operation to make one of the Aurora Serverless v2 DB instances the writer DB instance for the cluster.

6. (Optional) Convert any provisioned DB instances to Aurora Serverless v2, or remove them from the cluster. Follow the general procedure in [Converting a provisioned writer or reader to Aurora Serverless v2](p. 1996) or [Deleting a DB instance from an Aurora DB cluster](p. 380).

   **Tip**
   Removing the provisioned DB instances isn't mandatory. You can set up a cluster containing both Aurora Serverless v2 and provisioned DB instances. However, until you are familiar with the performance and scaling characteristics of Aurora Serverless v2 DB instances, we recommend that you configure your clusters with DB instances all of the same type.

The following AWS CLI example shows the switchover process using a provisioned cluster that's running Aurora MySQL version 3.02.0. The cluster is named mysql-80. The cluster starts with two provisioned DB instances named `provisioned-instance-1` and `provisioned-instance-2`, a writer and a reader. They both use the `db.r6g.large` DB instance class.

```
$ aws rds describe-db-clusters --db-cluster-identifier mysql-80 \
  --query '*[][DBClusterIdentifier, DBClusterMembers[*][DBInstanceIdentifier, IsClusterWriter]]' --output text
mysql-80
provisioned-instance-2     False
provisioned-instance-1     True

$ aws rds describe-db-instances --db-instance-identifier provisioned-instance-1 \
  --output text --query '[][DBInstanceIdentifier, DBInstanceClass]' db.r6g.large
provisioned-instance-1

$ aws rds describe-db-instances --db-instance-identifier provisioned-instance-2 \
  --output text --query '[][DBInstanceIdentifier, DBInstanceClass]' db.r6g.large
provisioned-instance-2
```
We create a table with some data. That way, we can confirm that the data and operation of the cluster are the same before and after the switchover.

```
mysql> create database serverless_v2_demo;
mysql> create table serverless_v2_demo.demo (s varchar(128));
mysql> insert into serverless_v2_demo.demo values ('This cluster started with a provisioned writer.');
Query OK, 1 row affected (0.02 sec)
```

First, we add a capacity range to the cluster. Otherwise, we get an error when adding any Aurora Serverless v2 DB instances to the cluster. If we use the AWS Management Console for this procedure, that step is automatic when we add the first Aurora Serverless v2 DB instance.

```
$ aws rds create-db-instance --db-instance-identifier serverless-v2-instance-1 --db-cluster-identifier mysql-80 --db-instance-class db.serverless --engine aurora-mysql

An error occurred (InvalidDBClusterStateFault) when calling the CreateDBInstance operation: Set the Serverless v2 scaling configuration on the parent DB cluster before creating a Serverless v2 DB instance.

$ # The blank ServerlessV2ScalingConfiguration attribute confirms that the cluster doesn't have a capacity range set yet.
$ aws rds describe-db-clusters --db-cluster-identifier mysql-80 --query 'DBClusters[*].ServerlessV2ScalingConfiguration'

[]

$ aws rds modify-db-cluster --db-cluster-identifier mysql-80 --serverless-v2-scaling-configuration MinCapacity=0.5,MaxCapacity=16
{
    "DBClusterIdentifier": "mysql-80",
    "ServerlessV2ScalingConfiguration": {
        "MinCapacity": 0.5,
        "MaxCapacity": 16
    }
}
```

We create two Aurora Serverless v2 readers to take the place of the original DB instances. We do so by specifying the db.serverless DB instance class for the new DB instances.

```
$ aws rds create-db-instance --db-instance-identifier serverless-v2-instance-1 --db-cluster-identifier mysql-80 --db-instance-class db.serverless --engine aurora-mysql
{
    "DBInstanceIdentifier": "serverless-v2-instance-1",
    "DBClusterIdentifier": "mysql-80",
    "DBInstanceClass": "db.serverless",
    "DBInstanceStatus": "creating"
}

$ aws rds create-db-instance --db-instance-identifier serverless-v2-instance-2 --db-cluster-identifier mysql-80 --db-instance-class db.serverless --engine aurora-mysql
{
    "DBInstanceIdentifier": "serverless-v2-instance-2",
    "DBClusterIdentifier": "mysql-80",
    "DBInstanceClass": "db.serverless",
    "DBInstanceStatus": "creating"
}

$ # Wait for both DB instances to finish being created before proceeding.
$ aws rds wait db-instance-available --db-instance-identifier serverless-v2-instance-1 &&
aws rds wait db-instance-available --db-instance-identifier serverless-v2-instance-2
```

1975
We perform a failover to make one of the Aurora Serverless v2 DB instances the new writer for the cluster.

```
$ aws rds failover-db-cluster --db-cluster-identifier mysql-80
   --target-db-instance-identifier serverless-v2-instance-1
{
   "DBClusterIdentifier": "mysql-80",
   "DBClusterMembers": [
   {
     "DBInstanceIdentifier": "serverless-v2-instance-1",
     "IsClusterWriter": false,
     "DBClusterParameterGroupStatus": "in-sync",
     "PromotionTier": 1
   },
   {
     "DBInstanceIdentifier": "serverless-v2-instance-2",
     "IsClusterWriter": false,
     "DBClusterParameterGroupStatus": "in-sync",
     "PromotionTier": 1
   },
   {
     "DBInstanceIdentifier": "provisioned-instance-2",
     "IsClusterWriter": false,
     "DBClusterParameterGroupStatus": "in-sync",
     "PromotionTier": 1
   },
   {
     "DBInstanceIdentifier": "provisioned-instance-1",
     "IsClusterWriter": true,
     "DBClusterParameterGroupStatus": "in-sync",
     "PromotionTier": 1
   }
   ],
   "Status": "available"
}
```

It takes a few seconds for that change to take effect. At that point, we have an Aurora Serverless v2 writer and an Aurora Serverless v2 reader. Thus, we don't need either of the original provisioned DB instances.

```
$ aws rds describe-db-clusters --db-cluster-identifier mysql-80
   --query '*'[DBClusterIdentifier, DBClusterMembers[*][DBInstanceIdentifier, IsClusterWriter]]
   --output text
mysql-80
serverless-v2-instance-1        True
serverless-v2-instance-2        False
provisioned-instance-2          False
provisioned-instance-1          False
```

The last step in the switchover procedure is to delete both of the provisioned DB instances.

```
$ aws rds delete-db-instance --db-instance-identifier provisioned-instance-2
   --skip-final-snapshot
{
   "DBInstanceIdentifier": "provisioned-instance-2",
   "DBInstanceStatus": "deleting",
   "Engine": "aurora-mysql",
   "EngineVersion": "8.0.mysql_aurora.3.02.0",
   "DBInstanceClass": "db.r6g.large"
}
```
As a final check, we confirm that the original table is accessible and writeable from the Aurora Serverless v2 writer DB instance.

```sql
mysql> select * from serverless_v2_demo.demo;
+---------------------------------------------------+
| s                                                 |
+---------------------------------------------------+
This cluster started with a provisioned writer. 1 row in set (0.00 sec)

mysql> insert into serverless_v2_demo.demo values ('And it finished with a Serverless v2 writer.');
Query OK, 1 row affected (0.01 sec)

mysql> select * from serverless_v2_demo.demo;
+---------------------------------------------------+
| s                                                 |
+---------------------------------------------------+
| This cluster started with a provisioned writer.   |
| And it finished with a Serverless v2 writer.      |
+---------------------------------------------------+
2 rows in set (0.01 sec)
```

We also connect to the Aurora Serverless v2 reader DB instance and confirm that the newly written data is available there too.

```sql
mysql> select * from serverless_v2_demo.demo;
+---------------------------------------------------+
| s                                                 |
+---------------------------------------------------+
| This cluster started with a provisioned writer.   |
| And it finished with a Serverless v2 writer.      |
+---------------------------------------------------+
2 rows in set (0.01 sec)
```

## Comparison of Aurora Serverless v2 and Aurora Serverless v1

If you are already using Aurora Serverless v1, you can learn the major differences between Aurora Serverless v1 and Aurora Serverless v2. The architectural differences, such as support for reader DB instances, open up new types of use cases.

You can use the following tables to help understand the most important differences between Aurora Serverless v2 and Aurora Serverless v1.

**Topics**
- [Comparison of Aurora Serverless v2 and Aurora Serverless v1 requirements](#)
- [Comparison of Aurora Serverless v2 and Aurora Serverless v1 scaling and availability](#)
The following table summarizes the different requirements to run your database using Aurora Serverless v2 or Aurora Serverless v1. Aurora Serverless v2 offers higher versions of the Aurora MySQL and Aurora PostgreSQL DB engines than Aurora Serverless v1 does.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Aurora Serverless v2 requirement</th>
<th>Aurora Serverless v1 requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB engines</td>
<td>Aurora MySQL, Aurora PostgreSQL</td>
<td>Aurora MySQL, Aurora PostgreSQL</td>
</tr>
<tr>
<td>Supported Aurora MySQL versions</td>

<td>Restore snapshot of provisioned cluster to create new Aurora Serverless v1 cluster.</td>
</tr>
<tr>
<td></td>
<td>• Add one or more Aurora Serverless v2 reader DB instances to an existing provisioned cluster. To use Aurora Serverless v2 for the writer, perform a failover to one of the Aurora Serverless v2 DB instances. For the entire cluster to use Aurora Serverless v2 DB instances, remove any provisioned writer DB instances after promoting the Aurora Serverless v2 DB instance to the writer.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Create a new cluster with the appropriate DB engine and engine version. Use any of the standard methods. For example, restore a cluster snapshot or create a clone</td>
<td></td>
</tr>
</tbody>
</table>
### Comparison of Aurora Serverless v2 and Aurora Serverless v1 scaling and availability

The following table summarizes differences between Aurora Serverless v2 and Aurora Serverless v1 for scalability and availability.

Aurora Serverless v2 scaling is more responsive, more granular, and less disruptive than the scaling in Aurora Serverless v1. Aurora Serverless v2 can scale both by changing the size of the DB instance and by adding more DB instances to the DB cluster. It can also scale by adding clusters in other AWS Regions to an Aurora global database. In contrast, Aurora Serverless v1 only scales by increasing or decreasing the capacity of the writer. All the compute for an Aurora Serverless v1 cluster runs in a single Availability Zone and a single AWS Region.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Aurora Serverless v2 requirement</th>
<th>Aurora Serverless v1 requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>of an existing cluster. Choose Aurora Serverless v2 for some or all of the DB instances in the new cluster. If you create the new cluster through cloning, you can't upgrade the engine version at the same time. Make sure that the original cluster is already running an engine version that's compatible with Aurora Serverless v2.</td>
<td>Not applicable</td>

Comparison of Aurora Serverless v2 and Aurora Serverless v1 feature support

The following table summarizes these:

- Features that are available in Aurora Serverless v2 but not Aurora Serverless v1
- Features that work differently between Aurora Serverless v1 and Aurora Serverless v2
- Features that aren't currently available in Aurora Serverless v2

Aurora Serverless v2 includes many features from provisioned clusters that aren't available for Aurora Serverless v1.

### Adapting Aurora Serverless v1 use cases to Aurora Serverless v2

Depending on your use case for Aurora Serverless v1, you might adapt that approach to take advantage of Aurora Serverless v2 features as follows.

Suppose that you have an Aurora Serverless v1 cluster that is lightly loaded and your priority is maintaining continuous availability while minimizing costs. With Aurora Serverless v2, you can configure a smaller minimum ACU setting of 0.5, compared with a minimum of 1 ACU for Aurora Serverless v1. You can increase availability by creating a Multi-AZ configuration, with the reader DB instance also having a minimum of 0.5 ACUs.

Suppose that you have an Aurora Serverless v1 cluster that you use in a development and test scenario. In this case, cost is also a high priority but the cluster doesn't need to be available at all times. Currently, Aurora Serverless v2 doesn't automatically pause when the cluster is completely idle. Instead, you
can manually stop the cluster when it's not needed, and start it when it's time for the next test or development cycle.

Suppose that you have an Aurora Serverless v1 cluster with a heavy workload. An equivalent cluster using Aurora Serverless v2 can scale with more granularity. For example, Aurora Serverless v1 scales by doubling the capacity, for example from 64 to 128 ACUs. In contrast, your Aurora Serverless v2 DB instance can scale to a value somewhere between those numbers.

Suppose that your workload requires a higher total capacity than is available in Aurora Serverless v1. You can use multiple Aurora Serverless v2 reader DB instances to offload the read-intensive parts of the workload from the writer DB instance. You can also divide the read-intensive workload among multiple reader DB instances.

For a write-intensive workload, you might configure the cluster with a large provisioned DB instance as the writer. You might do so alongside one or more Aurora Serverless v2 reader DB instances.

### Upgrading from an Aurora Serverless v1 cluster to Aurora Serverless v2

The process of upgrading a DB cluster from Aurora Serverless v1 to Aurora Serverless v2 has multiple steps. That's because you can't convert directly from Aurora Serverless v1 to Aurora Serverless v2. There's always an intermediate step that involves converting the Aurora Serverless v1 DB cluster to a provisioned cluster.

#### Aurora MySQL–compatible DB clusters

**To upgrade an Aurora Serverless v1 cluster running Aurora MySQL version 2 (MySQL 5.7–compatible)**

1. Convert the Aurora Serverless v1 DB cluster to a provisioned Aurora MySQL version 2 cluster. Follow the procedure in [Converting from Aurora Serverless v1 to provisioned](p. 2054).

2. Upgrade the provisioned Aurora MySQL version 2 cluster to a version of Aurora MySQL version 3 that's compatible with Aurora Serverless v2, for example, 3.02.0. Follow the procedure in [How to perform an in-place upgrade](p. 1217).

   For compatible versions, see [Aurora Serverless v2](p. 53).

3. Modify the writer DB instance of the provisioned DB cluster to use the Serverless v2 (db.serverless) DB instance class.

   For details, see [Converting a provisioned writer or reader to Aurora Serverless v2](p. 1996).

#### Aurora PostgreSQL–compatible DB clusters

**To upgrade an Aurora Serverless v1 cluster running Aurora PostgreSQL version 11**

1. Upgrade the Aurora Serverless v1 cluster to an Aurora PostgreSQL version 13 version that's compatible with Aurora Serverless v2, for example, 13.9. Follow the procedure in [Upgrading the major version](p. 2053).

   For compatible versions, see [Aurora Serverless v2](p. 53).

2. Convert the Aurora Serverless v1 DB cluster to a provisioned Aurora PostgreSQL cluster. Follow the procedure in [Converting from Aurora Serverless v1 to provisioned](p. 2054).

3. Modify the writer DB instance of the provisioned DB cluster to use the Serverless v2 (db.serverless) DB instance class.
To upgrade an Aurora Serverless v1 cluster running Aurora PostgreSQL version 13

1. Convert the Aurora Serverless v1 DB cluster to a provisioned Aurora PostgreSQL cluster. Follow the procedure in Converting from Aurora Serverless v1 to provisioned (p. 2054).
2. Modify the writer DB instance of the provisioned DB cluster to use the Serverless v2 (db.serverless) DB instance class.

For details, see Converting a provisioned writer or reader to Aurora Serverless v2 (p. 1996).

Migrating from an on-premises database to Aurora Serverless v2

You can migrate your on-premises databases to Aurora Serverless v2, just as with provisioned Aurora MySQL and Aurora PostgreSQL.

- For MySQL databases, you can use the mysqldump command. For more information, see Importing data to a MySQL or MariaDB DB instance with reduced downtime.
- For PostgreSQL databases, you can use the pg_dump and pg_restore commands. For more information, see the blog post Best practices for migrating PostgreSQL databases to Amazon RDS and Amazon Aurora.

Creating a cluster that uses Aurora Serverless v2

To create an Aurora cluster where you can add Aurora Serverless v2 DB instances, you follow the same procedure as in Creating an Amazon Aurora DB cluster (p. 179). With Aurora Serverless v2, your clusters are interchangeable with provisioned clusters. You can have clusters where some DB instances use Aurora Serverless v2 and some DB instances are provisioned.

If you intend to use Aurora Serverless v2 DB instances in a cluster, make sure that the cluster's initial settings meet the requirements that are listed in Requirements for Aurora Serverless v2 (p. 1969). Specify the following settings to make sure that you can add Aurora Serverless v2 DB instances to the cluster:

AWS Region

Create the cluster in an AWS Region where Aurora Serverless v2 DB instances are available. For details about available Regions, see Aurora Serverless v2 (p. 53).

DB engine version

Choose an engine version that's compatible with Aurora Serverless v2. For information about the Aurora Serverless v2 version requirements, see Requirements for Aurora Serverless v2 (p. 1969). On the Create database page in the AWS Management Console, you can choose the filter setting Show versions that support Serverless v2. You can also see the applicable versions in the Info panel on the Create database page.

DB instance class

If you create a cluster using the AWS Management Console, you choose the DB instance class for the writer DB instance at the same time. Choose the Serverless DB instance class. When you choose that
DB instance class, you also specify the capacity range for the writer DB instance. That same capacity range applies to all other Aurora Serverless v2 DB instances that you add to that cluster. If you don't see the Serverless choice for the DB instance class, make sure that you chose a DB engine version that's compatible with Aurora Serverless v2.

When you use the AWS CLI or the Amazon RDS API, the parameter that you specify for the DB instance class parameter is `db.serverless`.

**capacity range**

Fill in the minimum and maximum Aurora capacity unit (ACU) values that apply to all the DB instances in the cluster. This option is available on both the Create cluster and Add reader console pages when you choose Serverless for the DB instance class.

If you don't see the minimum and maximum ACU boxes, make sure that you chose the Serverless DB instance class for the writer DB instance.

**Tip**

A simple way to set up a new cluster where you can use Aurora Serverless v2 is to choose the Easy create setting on the console Create database page. With that setting, you only make a single other choice: whether the cluster is intended for development and test use or for production. Both of those options set up a cluster with an Aurora Serverless v2 writer DB instance.

If you initially create the cluster with a provisioned DB instance, you don't specify the minimum and maximum ACUs. In that case you can modify the cluster afterward to add that setting. You can also add an Aurora Serverless v2 reader DB instance to the cluster. You specify the capacity range as part of that process.

Until you specify the capacity range for your cluster, you can't add any Aurora Serverless v2 DB instances to the cluster using the AWS CLI or RDS API. If you try to add a Aurora Serverless v2 DB instance, you get an error. In the AWS CLI or the RDS API procedures, the capacity range is represented by the `ServerlessV2ScalingConfiguration` attribute.

For clusters containing more than one reader DB instance, the failover priority of each Aurora Serverless v2 reader DB instance plays an important part in how that DB instance scales up and down. You can't specify the priority when you initially create the cluster. Keep this property in mind when you add a second or later reader DB instance to your cluster. For more information, see [Choosing the promotion tier for an Aurora Serverless v2 reader](p. 1999).

**Console**

**To create a cluster with an Aurora Serverless v2 writer**

1. Sign in using the AWS Management Console and open the Amazon RDS console.
2. Choose Create Database. On the page that appears, choose the following options:
   - For **Engine type**, choose Aurora (MySQL Compatible) or Aurora (PostgreSQL Compatible).
   - For **Version**, choose one of the compatible versions from Aurora Serverless v2 (p. 53). To see the available versions, choose the filter Show versions that support Serverless v2.
3. For **Capacity settings**, you can accept the default range. Or you can choose other values for minimum and maximum capacity units. You can choose from 0.5 ACUs minimum through 128 ACUs maximum, in increments of 0.5 ACU.

For more information about Aurora Serverless v2 capacity units, see Aurora Serverless v2 capacity (p. 1965) and Performance and scaling for Aurora Serverless v2 (p. 2004).
4. Choose any other cluster settings, as described in Creating an Amazon Aurora DB cluster (p. 179).

5. Choose **Create database** to create your Aurora cluster with an Aurora Serverless v2 DB instance as the writer instance, also known as the primary DB instance.

### CLI

To create a DB cluster that's compatible with Aurora Serverless v2 DB instances using the AWS CLI, you follow the CLI procedure in Creating an Amazon Aurora DB cluster (p. 179). Include the following parameters in your `create-db-cluster` command:

- `--region AWS_Region_where_Aurora_Serverless_v2_instances_are_available`
- `--engine-version serverless_v2_compatible_engine_version`
- `--serverless-v2-scaling-configuration MinCapacity=minimum_capacity,MaxCapacity=maximum_capacity`

The following example shows the creation of an Aurora Serverless v2 DB cluster.

```bash
aws rds create-db-cluster \
--db-cluster-identifier my-serverless-v2-cluster \
--region eu-central-1 \
--engine aurora-mysql \
--engine-version 8.0.mysql_aurora.3.02.0 \
--serverless-v2-scaling-configuration MinCapacity=1,MaxCapacity=4 \
--master-username myuser \
--manage-master-user-password \
--backup-retention 1
```

**Note**

When you create an Aurora Serverless v2 DB cluster using the AWS CLI, the engine mode appears in the output as provisioned rather than serverless. The serverless engine mode refers to Aurora Serverless v1.

This example specifies the `--manage-master-user-password` option to generate the master user password and manage it in Secrets Manager. For more information, see Password management with Amazon Aurora and AWS Secrets Manager (p. 2371). Alternatively, you can use the `--master-password` option to specify and manage the password yourself.

For information about the Aurora Serverless v2 version requirements, see Requirements for Aurora Serverless v2 (p. 1969). For information about the allowed numbers for the capacity range and what those numbers represent, see Aurora Serverless v2 capacity (p. 1965) and Performance and scaling for Aurora Serverless v2 (p. 2004).

To verify whether an existing cluster has the capacity settings specified, check the output of the `describe-db-clusters` command for the `ServerlessV2ScalingConfiguration` attribute. That attribute looks similar to the following.

```json
"ServerlessV2ScalingConfiguration": {
  "MinCapacity": 1.5,
  "MaxCapacity": 24.0
}
```
Tip
If you don't specify the minimum and maximum ACUs when you create the cluster, you can use the `modify-db-cluster` command afterward to add that setting. Until you do, you can't add any Aurora Serverless v2 DB instances to the cluster. If you try to add a `db.serverless` DB instance, you get an error.

API
To create a DB cluster that's compatible with Aurora Serverless v2 DB instances using the RDS API, you follow the API procedure in Creating an Amazon Aurora DB cluster (p. 179). Choose the following settings. Make sure that your `CreateDBCluster` operation includes the following parameters:

```
EngineVersion serverless_v2_compatible_engine_version
ServerlessV2ScalingConfiguration with MinCapacity=minimum_capacity and MaxCapacity=maximum_capacity
```

For information about the Aurora Serverless v2 version requirements, see Requirements for Aurora Serverless v2 (p. 1969). For information about the allowed numbers for the capacity range and what those numbers represent, see Aurora Serverless v2 capacity (p. 1965) and Performance and scaling for Aurora Serverless v2 (p. 2004).

To check if an existing cluster has the capacity settings specified, check the output of the `DescribeDBClusters` operation for the `ServerlessV2ScalingConfiguration` attribute. That attribute looks similar to the following.

```
"ServerlessV2ScalingConfiguration": {
  "MinCapacity": 1.5,
  "MaxCapacity": 24.0
}
```

Tip
If you don't specify the minimum and maximum ACUs when you create the cluster, you can use the `ModifyDBCluster` operation afterward to add that setting. Until you do, you can't add any Aurora Serverless v2 DB instances to the cluster. If you try to add a `db.serverless` DB instance, you get an error.

Managing Aurora Serverless v2

With Aurora Serverless v2, your clusters are interchangeable with provisioned clusters. The Aurora Serverless v2 properties apply to one or more DB instances within a cluster. Thus, the procedures for creating clusters, modifying clusters, creating and restoring snapshots, and so on, are basically the same as for other kinds of Aurora clusters. For general procedures for managing Aurora clusters and DB instances, see Managing an Amazon Aurora DB cluster (p. 248).

Following, you can learn about management considerations for clusters that contain Aurora Serverless v2 DB instances.

Topics
- Setting the Aurora Serverless v2 capacity range for a cluster (p. 1988)
- Checking the capacity range for Aurora Serverless v2 (p. 1991)
- Creating an Aurora Serverless v2 writer (p. 1993)
- Adding an Aurora Serverless v2 reader (p. 1995)
- Converting a provisioned writer or reader to Aurora Serverless v2 (p. 1996)
- Converting an Aurora Serverless v2 writer or reader to provisioned (p. 1998)
Setting the Aurora Serverless v2 capacity range for a cluster

To modify configuration parameters or other settings for clusters containing Aurora Serverless v2 DB instances, or the DB instances themselves, follow the same general procedures as for provisioned clusters. For details, see [Modifying an Amazon Aurora DB cluster](p. 269).

The most important setting that's unique to Aurora Serverless v2 is the capacity range. After you set the minimum and maximum Aurora capacity unit (ACU) values for an Aurora cluster, you don't need to actively adjust the capacity of the Aurora Serverless v2 DB instances in the cluster. Aurora does that for you. This setting is managed at the cluster level. The same minimum and maximum ACU values apply to each Aurora Serverless v2 DB instance in the cluster.

You can set the following specific values:

- **Minimum ACUs** – The Aurora Serverless v2 DB instance can reduce capacity down to this number of ACUs.
- **Maximum ACUs** – The Aurora Serverless v2 DB instance can increase capacity up to this number of ACUs.

**Note**
When you modify the capacity range for an Aurora Serverless v2 DB cluster, the change takes place immediately, regardless of whether you choose to apply it immediately or during the next scheduled maintenance window.

For details about the effects of the capacity range and how to monitor and fine-tune it, see [Important Amazon CloudWatch metrics for Aurora Serverless v2](p. 2018) and [Performance and scaling for Aurora Serverless v2](p. 2004). Your goal is to make sure that the maximum capacity for the cluster is high enough to handle spikes in workload, and the minimum is low enough to minimize costs when the cluster isn't busy.

Suppose that you determine based on your monitoring that the ACU range for the cluster should be higher, lower, wider, or narrower. You can set the capacity of an Aurora cluster to a specific range of ACUs with the AWS Management Console, the AWS CLI, or the Amazon RDS API. This capacity range applies to every Aurora Serverless v2 DB instance in the cluster.

For example, suppose that your cluster has a capacity range of 1–16 ACUs and contains two Aurora Serverless v2 DB instances. Then the cluster as a whole consumes somewhere between 2 ACUs (when idle) and 32 ACUs (when fully utilized). If you change the capacity range from 8 to 20.5 ACUs, now the cluster consumes 16 ACUs when idle, and up to 41 ACUs when fully utilized.

Aurora automatically sets certain parameters for Aurora Serverless v2 DB instances to values that depend on the maximum ACU value in the capacity range. For the list of such parameters, see [Maximum connections for Aurora Serverless v2](p. 2016). For static parameters that rely on this type of calculation, the value is evaluated again when you reboot the DB instance. Thus, you can update the value of such parameters by rebooting the DB instance after changing the capacity range. To check whether you need to reboot your DB instance to pick up such parameter changes, check the `ParameterApplyStatus` attribute of the DB instance. A value of `pending-reboot` indicates that rebooting will apply changes to some parameter values.
Console

You can set the capacity range of a cluster that contains Aurora Serverless v2 DB instances with the AWS Management Console.

When you use the console, you set the capacity range for the cluster at the time that you add the first Aurora Serverless v2 DB instance to that cluster. You might do so when you choose the Serverless v2 DB instance class for the writer DB instance when you create the cluster. Or you might do so when you choose the Serverless DB instance class when you add an Aurora Serverless v2 reader DB instance to the cluster. Or you might do so when you convert an existing provisioned DB instance in the cluster to the Serverless DB instance class. For the full versions of those procedures, see Creating an Aurora Serverless v2 writer (p. 1993), Adding an Aurora Serverless v2 reader (p. 1995), and Converting a provisioned writer or reader to Aurora Serverless v2 (p. 1996).

Whatever capacity range that you set at the cluster level applies to all Aurora Serverless v2 DB instances in your cluster. The following image shows a cluster with multiple Aurora Serverless v2 reader DB instances. Each has an identical capacity range of 2–64 ACUs.

To modify the capacity range of an Aurora Serverless v2 cluster

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the cluster containing your Aurora Serverless v2 DB instances from the list. The cluster must already contain at least one Aurora Serverless v2 DB instance. Otherwise, Aurora doesn't show the Capacity range section.
4. For Actions, choose Modify.
5. In the Capacity range section, choose the following:
   a. Enter a value for Minimum ACUs. The console shows the allowed range of values. You can choose from 0.5 ACUs minimum to 128 ACUs maximum, in increments of 0.5 ACU.
   b. Enter a value for Maximum ACUs. This value must be greater than or equal to Minimum ACUs. The console shows the allowed range of values. The following screenshot shows that choice.
6. Choose **Continue**. The **Summary of modifications** page appears.
7. Choose **Apply immediately**.

   The capacity modification takes place immediately, regardless of whether you choose to apply it immediately or during the next scheduled maintenance window.

8. Choose **Modify cluster** to accept the summary of modifications. You can also choose **Back** to modify your changes or **Cancel** to discard your changes.

**AWS CLI**

To set the capacity of a cluster where you intend to use Aurora Serverless v2 DB instances using the AWS CLI, run the `modify-db-cluster` AWS CLI command. Specify the `--serverless-v2-scaling-configuration` option. The cluster might already contain one or more Aurora Serverless v2 DB instances, or you can add the DB instances later. Valid values for the MinCapacity and MaxCapacity fields include the following:

- 0.5, 1, 1.5, 2, and so on, in steps of 0.5, up to a maximum of 128.

In this example, you set the ACU range of an Aurora DB cluster named `sample-cluster` to a minimum of 48.5 and a maximum of 64.

```
aws rds modify-db-cluster --db-cluster-identifier sample-cluster \
--serverless-v2-scaling-configuration MinCapacity=48.5,MaxCapacity=64
```

The capacity modification takes place immediately, regardless of whether you choose to apply it immediately or during the next scheduled maintenance window.

After doing so, you can add Aurora Serverless v2 DB instances to the cluster and each new DB instance can scale between 48.5 and 64 ACUs. The new capacity range also applies to any Aurora Serverless v2 DB instances.
instances that were already in the cluster. The DB instances scale up or down if necessary to fall within
the new capacity range.

For additional examples of setting the capacity range using the CLI, see Choosing the Aurora Serverless
v2 capacity range for an Aurora cluster (p. 2005).

To modify the scaling configuration of an Aurora Serverless DB cluster using the AWS CLI, run the
modify-db-cluster AWS CLI command. Specify the --serverless-v2-scaling-configuration option to configure the minimum capacity and maximum capacity. Valid capacity values include the following:

- Aurora MySQL: 0.5, 1, 1.5, 2, and so on, in increments of 0.5 ACUs up to a maximum of 128.
- Aurora PostgreSQL: 0.5, 1, 1.5, 2, and so on, in increments of 0.5 ACUs up to a maximum of 128.

In the following example, you modify the scaling configuration of an Aurora Serverless v2 DB instance
named sample-instance that's part of a cluster named sample-cluster.

For Linux, macOS, or Unix:

```sh
aws rds modify-db-cluster --db-cluster-identifier sample-cluster --serverless-v2-scaling-configuration MinCapacity=8,MaxCapacity=64
```

For Windows:

```sh
aws rds modify-db-cluster --db-cluster-identifier sample-cluster --serverless-v2-scaling-configuration MinCapacity=8,MaxCapacity=64
```

**RDS API**

You can set the capacity of an Aurora DB instance with the ModifyDBCluster API operation. Specify
the ServerlessV2ScalingConfiguration parameter. Valid values for the MinCapacity and
MaxCapacity fields include the following:

- 0.5, 1, 1.5, 2, and so on, in steps of 0.5, up to a maximum of 128.

You can modify the scaling configuration of a cluster containing Aurora Serverless v2 DB instances with
the ModifyDBCluster API operation. Specify the ServerlessV2ScalingConfiguration parameter to
configure the minimum capacity and the maximum capacity. Valid capacity values include the following:

- Aurora MySQL: 0.5, 1, 1.5, 2, and so on, in increments of 0.5 ACUs up to a maximum of 128.
- Aurora PostgreSQL: 0.5, 1, 1.5, 2, and so on, in increments of 0.5 ACUs up to a maximum of 128.

The capacity modification takes place immediately, regardless of whether you choose to apply it
immediately or during the next scheduled maintenance window.

**Checking the capacity range for Aurora Serverless v2**

The procedure to check the capacity range for your Aurora Serverless v2 cluster requires that you first
set a capacity range. If you haven't done so, follow the procedure in Setting the Aurora Serverless v2
capacity range for a cluster (p. 1988).

Whatever capacity range you set at the cluster level applies to all Aurora Serverless v2 DB instances in
your cluster. The following image shows a cluster with multiple Aurora Serverless v2 DB instances. Each
has an identical capacity range.
You can also view the details page for any Aurora Serverless v2 DB instance in the cluster. DB instances' capacity range appears on the **Configuration** tab.

You can also see the current capacity range for the cluster on the **Modify** page for the cluster. The following image shows how. At that point, you can change the capacity range. For all the ways that you can set or change the capacity range, see [Setting the Aurora Serverless v2 capacity range for a cluster](p. 1988).
Creating an Aurora Serverless v2 writer

Console

When you create a cluster using the AWS Management Console, you specify the properties of the writer DB instance at the same time. To make the writer DB instance use Aurora Serverless v2, choose the Serverless DB instance class. Then you set the capacity range for the cluster by specifying the minimum and maximum Aurora capacity unit (ACU) values. These minimum and maximum values apply to each Aurora Serverless v2 DB instance in the cluster.
If you don't create an Aurora Serverless v2 DB instance when you first create the cluster, you can add one or more Aurora Serverless v2 DB instances later. To do so, follow the procedures in Adding an Aurora Serverless v2 reader (p. 1995) and Converting a provisioned writer or reader to Aurora Serverless v2 (p. 1996). You specify the capacity range at the time that you add the first Aurora Serverless v2 DB instance to the cluster. You can change the capacity range later by following the procedure in Setting the Aurora Serverless v2 capacity range for a cluster (p. 1988).

**CLI**

When you create a Aurora Serverless v2 DB cluster using the AWS CLI, you explicitly add the writer DB instance using the `create-db-instance` command. Include the following parameter:

- `--db-instance-class db.serverless`

The following example shows the creation of an Aurora Serverless v2 writer DB instance.

```
aws rds create-db-instance \
  --db-cluster-identifier my-serverless-v2-cluster \
  --db-instance-identifier my-serverless-v2-instance \
  --db-instance-class db.serverless \
  --engine aurora-mysql
```
Adding an Aurora Serverless v2 reader

To add an Aurora Serverless v2 reader DB instance to your cluster, you follow the same general procedure as in Adding Aurora Replicas to a DB cluster (p. 293). Choose the Serverless v2 instance class for the new DB instance.

If the reader DB instance is the first Aurora Serverless v2 DB instance in the cluster, you also choose the capacity range. The following image shows the controls that you use to specify the minimum and maximum Aurora capacity units (ACUs). This setting applies to this reader DB instance and to any other Aurora Serverless v2 DB instances that you add to the cluster. Each Aurora Serverless v2 DB instance can scale between the minimum and maximum ACU values.

![Instance configuration](image)

If you already added any Aurora Serverless v2 DB instances to the cluster, adding another Aurora Serverless v2 reader DB instance shows you the current capacity range. The following image shows those read-only controls.
If you want to change the capacity range for the cluster, follow the procedure in Setting the Aurora Serverless v2 capacity range for a cluster (p. 1988).

For clusters containing more than one reader DB instance, the failover priority of each Aurora Serverless v2 reader DB instance plays an important part in how that DB instance scales up and down. You can't specify the priority when you initially create the cluster. Keep this property in mind when you add a second reader or later DB instance to your cluster. For more information, see Choosing the promotion tier for an Aurora Serverless v2 reader (p. 1999).

For other ways that you can see the current capacity range for a cluster, see Checking the capacity range for Aurora Serverless v2 (p. 1991).

Converting a provisioned writer or reader to Aurora Serverless v2

You can convert a provisioned DB instance to use Aurora Serverless v2. To do so, you follow the procedure in Modifying a DB instance in a DB cluster (p. 270). The cluster must meet the requirements in Requirements for Aurora Serverless v2 (p. 1969). For example, Aurora Serverless v2 DB instances require that the cluster be running certain minimum engine versions.

Suppose that you are converting a running provisioned cluster to take advantage of Aurora Serverless v2. In that case, you can minimize downtime by converting a DB instance to Aurora Serverless v2 as the first step in the switchover process. For the full procedure, see Switching from a provisioned cluster to Aurora Serverless v2 (p. 1973).

If the DB instance that you convert is the first Aurora Serverless v2 DB instance in the cluster, you choose the capacity range for the cluster as part of the Modify operation. This capacity range applies to each Aurora Serverless v2 DB instance that you add to the cluster. The following image shows the page where you specify the minimum and maximum Aurora capacity units (ACUs).
For details about the significance of the capacity range, see [Aurora Serverless v2 capacity (p. 1965)](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-serverless-v2-capacity.html).

If the cluster already contains one or more Aurora Serverless v2 DB instances, you see the existing capacity range during the **Modify** operation. The following image shows an example of that information panel.
Converting from Aurora Serverless v2 to provisioned

If you want to change the capacity range for the cluster after you add more Aurora Serverless v2 DB instances, follow the procedure in Setting the Aurora Serverless v2 capacity range for a cluster (p. 1988).

Converting an Aurora Serverless v2 writer or reader to provisioned

You can convert an Aurora Serverless v2 DB instance to a provisioned DB instance. To do so, you follow the procedure in Modifying a DB instance in a DB cluster (p. 270). Choose a DB instance class other than Serverless.

You might convert an Aurora Serverless v2 DB instance to provisioned if it needs a larger capacity than is available with the maximum Aurora capacity units (ACUs) of an Aurora Serverless v2 DB instance. For example, the largest db.r5 and db.r6g DB instance classes have a larger memory capacity than an Aurora Serverless v2 DB instance can scale to.

**Tip**
Some of the older DB instance classes such as db.r3 and db.t2 aren’t available for the Aurora versions that you use with Aurora Serverless v2. To see which DB instance classes you can use when converting an Aurora Serverless v2 DB instance to a provisioned one, see Supported DB engines for DB instance classes (p. 86).

If you are converting the writer DB instance of your cluster from Aurora Serverless v2 to provisioned, you can follow the procedure in Switching from a provisioned cluster to Aurora Serverless v2 (p. 1973) but in reverse. Switch one of the reader DB instances in the cluster from Aurora Serverless v2 to provisioned. Then perform a failover to make that provisioned DB instance into the writer.

Any capacity range that you previously specified for the cluster remains in place, even if all Aurora Serverless v2 DB instances are removed from the cluster. If you want to change the capacity range, you can modify the cluster, as explained in Setting the Aurora Serverless v2 capacity range for a cluster (p. 1988).
Choosing the promotion tier for an Aurora Serverless v2 reader

For clusters containing multiple Aurora Serverless v2 DB instances or a mixture of provisioned and Aurora Serverless v2 DB instances, pay attention to the promotion tier setting for each Aurora Serverless v2 DB instance. This setting controls more behavior for Aurora Serverless v2 DB instances than for provisioned DB instances.

In the AWS Management Console, you specify this setting using the Failover priority choice under Additional configuration for the Create database, Modify instance, and Add reader pages. You see this property for existing DB instances in the optional Priority tier column on the Databases page. You can also see this property on the details page for a DB cluster or DB instance.

For provisioned DB instances, the choice of tier 0–15 determines only the order in which Aurora chooses which reader DB instance to promote to the writer during a failover operation. For Aurora Serverless v2 reader DB instances, the tier number also determines whether the DB instance scales up to match the capacity of the writer DB instance or scales independently based on its own workload. Aurora Serverless v2 reader DB instances in tier 0 or 1 are kept at a minimum capacity at least as high as the writer DB instance. That way, they are ready to take over from the writer DB instance in case of a failover. If the writer DB instance is a provisioned DB instance, Aurora estimates the equivalent Aurora Serverless v2 capacity. It uses that estimate as the minimum capacity for the Aurora Serverless v2 reader DB instance.

Aurora Serverless v2 reader DB instances in tiers 2–15 don't have the same constraint on their minimum capacity. When they are idle, they can scale down to the minimum Aurora capacity unit (ACU) value specified in the cluster's capacity range.

The following Linux AWS CLI example shows how to examine the promotion tiers of all the DB instances in your cluster. The final field includes a value of True for the writer DB instance and False for all the reader DB instances.

```bash
$ aws rds describe-db-clusters --db-cluster-identifier promotion-tier-demo --query 'DBClusters[*].DBClusterMembers[*].[PromotionTier,DBInstanceIdentifier,IsClusterWriter]' --output text
```

```
1   instance-192  True
1   tier-01-4840  False
10  tier-10-7425  False
15  tier-15-6694  False
```

The following Linux AWS CLI example shows how to change the promotion tier of a specific DB instance in your cluster. The commands first modify the DB instance with a new promotion tier. Then they wait for the DB instance to become available again and confirm the new promotion tier for the DB instance.

```bash
$ aws rds modify-db-instance --db-instance-identifier instance-192 --promotion-tier 0
$ aws rds wait db-instance-available --db-instance-identifier instance-192
$ aws rds describe-db-instances --db-instance-identifier instance-192 --query '*[].[PromotionTier]' --output text
```

```
0
```

For more guidance about specifying promotion tiers for different use cases, see Aurora Serverless v2 scaling (p. 1966).

Using TLS/SSL with Aurora Serverless v2

Aurora Serverless v2 can use the Transport Layer Security/Secure Sockets Layer (TLS/SSL) protocol to encrypt communications between clients and your Aurora Serverless v2 DB instances. It supports TLS/
SSL versions 1.0, 1.1, and 1.2. For general information about using TLS/SSL with Aurora, see Using TLS with Aurora MySQL DB clusters (p. 814).

To learn more about connecting to Aurora MySQL database with the MySQL client, see Connecting to a DB instance running the MySQL database engine.

Aurora Serverless v2 supports all TLS/SSL modes available to the MySQL client (mysql) and PostgreSQL client (psql), including those listed in the following table.

<table>
<thead>
<tr>
<th>Description of TLS/SSL mode</th>
<th>mysql</th>
<th>psql</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connect without using TLS/SSL.</td>
<td>DISABLED</td>
<td>disable</td>
</tr>
<tr>
<td>Try the connection using TLS/SSL first, but fall back to non-SSL if necessary.</td>
<td>PREFERRED</td>
<td>prefer (default)</td>
</tr>
<tr>
<td>Enforce using TLS/SSL.</td>
<td>REQUIRED</td>
<td>require</td>
</tr>
<tr>
<td>Enforce TLS/SSL and verify the certificate authority (CA).</td>
<td>VERIFY_CA</td>
<td>verify-ca</td>
</tr>
<tr>
<td>Enforce TLS/SSL, verify the CA, and verify the CA hostname.</td>
<td>VERIFY_IDENTITY</td>
<td>verify-full</td>
</tr>
</tbody>
</table>

Aurora Serverless v2 uses wildcard certificates. If you specify the "verify CA" or the "verify CA and CA hostname" option when using TLS/SSL, first download the Amazon root CA 1 trust store from Amazon Trust Services. After doing so, you can identify this PEM-formatted file in your client command. To do so using the PostgreSQL client, do the following.

For Linux, macOS, or Unix:

```
psql 'host=endpoint user=user sslmode=require sslrootcert=amazon-root-CA-1.pem dbname=db-name'
```

To learn more about working with the Aurora PostgreSQL database using the Postgres client, see Connecting to a DB instance running the PostgreSQL database engine.

For more information about connecting to Aurora DB clusters in general, see Connecting to an Amazon Aurora DB cluster (p. 204).

**Supported cipher suites for connections to Aurora Serverless v2 DB clusters**

By using configurable cipher suites, you can have more control over the security of your database connections. You can specify a list of cipher suites that you want to allow to secure client TLS/SSL connections to your database. With configurable cipher suites, you can control the connection encryption that your database server accepts. Doing this prevents the use of ciphers that aren't secure or that are no longer used.

Aurora Serverless v2 DB clusters that are based on Aurora MySQL support the same cipher suites as Aurora MySQL provisioned DB clusters. For information about these cipher suites, see Configuring cipher suites for connections to Aurora MySQL DB clusters (p. 816).

Aurora Serverless v2 DB clusters that are based on Aurora PostgreSQL support the same cipher suites as Aurora PostgreSQL provisioned DB clusters. For information about these cipher suites, see Configuring cipher suites for connections to Aurora PostgreSQL DB clusters (p. 1245).
Viewing Aurora Serverless v2 writers and readers

You can view the details of Aurora Serverless v2 DB instances in the same way that you do for provisioned DB instances. To do so, follow the general procedure from Viewing an Amazon Aurora DB cluster (p. 515). A cluster might contain all Aurora Serverless v2 DB instances, all provisioned DB instances, or some of each.

After you create one or more Aurora Serverless v2 DB instances, you can view which DB instances are type Serverless and which are type Instance. You can also view the minimum and maximum Aurora capacity units (ACUs) that the Aurora Serverless v2 DB instance can use. Each ACU is a combination of processing (CPU) and memory (RAM) capacity. This capacity range applies to each Aurora Serverless v2 DB instance in the cluster. For the procedure to check the capacity range of a cluster or any Aurora Serverless v2 DB instance in the cluster, see Checking the capacity range for Aurora Serverless v2 (p. 1991).

In the AWS Management Console, Aurora Serverless v2 DB instances are marked under the Size column in the Databases page. Provisioned DB instances show the name of a DB instance class such as r6g.xlarge. The Aurora Serverless DB instances show Serverless for the DB instance class, along with the DB instance's minimum and maximum capacity. For example, you might see Serverless v2 (4–64 ACUs) or Serverless v2 (1–40 ACUs).

You can find the same information on the Configuration tab for each Aurora Serverless v2 DB instance in the console. For example, you might see an Instance type section such as the following. Here, the Instance type value is Serverless v2, the Minimum capacity value is 2 ACUs (4 GiB), and the Maximum capacity value is 64 ACUs (128 GiB).

<table>
<thead>
<tr>
<th>Instance configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Instance type</td>
</tr>
<tr>
<td>Serverless v2</td>
</tr>
<tr>
<td>Minimum capacity</td>
</tr>
<tr>
<td>2 ACUs (4 GiB)</td>
</tr>
<tr>
<td>Maximum capacity</td>
</tr>
<tr>
<td>64 ACUs (128 GiB)</td>
</tr>
</tbody>
</table>

You can monitor the capacity of each Aurora Serverless v2 DB instance over time. That way, you can check the minimum, maximum, and average ACUs consumed by each DB instance. You can also check how close the DB instance came to its minimum or maximum capacity. To see such details in the AWS Management Console, examine the graphs of Amazon CloudWatch metrics on the Monitoring tab for the DB instance. For information about the metrics to watch and how to interpret them, see Important Amazon CloudWatch metrics for Aurora Serverless v2 (p. 2018).

Logging for Aurora Serverless v2

To turn on database logging, you specify the logs to enable using configuration parameters in your custom parameter group.
For Aurora MySQL, you can enable the following logs.

<table>
<thead>
<tr>
<th><strong>Aurora MySQL</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>general_log</td>
<td>Creates the general log. Set to 1 to turn on. Default is off (0).</td>
</tr>
<tr>
<td>log_queries_not_using_indexes</td>
<td>Logs any queries to the slow query log that don’t use an index. Default is off (0). Set to 1 to turn on this log.</td>
</tr>
<tr>
<td>long_query_time</td>
<td>Prevents fast-running queries from being logged in the slow query log. Can be set to a float between 0 and 31536000. Default is 0 (not active).</td>
</tr>
<tr>
<td>server_audit_events</td>
<td>The list of events to capture in the logs. Supported values are CONNECT, QUERY, QUERY_DCL, QUERY_DDL, QUERY_DML, and TABLE.</td>
</tr>
<tr>
<td>server_audit_logging</td>
<td>Set to 1 to turn on server audit logging. If you turn this on, you can specify the audit events to send to CloudWatch by listing them in the server_audit_events parameter.</td>
</tr>
<tr>
<td>slow_query_log</td>
<td>Creates a slow query log. Set to 1 to turn on the slow query log. Default is off (0).</td>
</tr>
</tbody>
</table>

For more information, see [Using Advanced Auditing with an Amazon Aurora MySQL DB cluster](p. 980).

For Aurora PostgreSQL, you can enable the following logs on your Aurora Serverless v2 DB instances.

<table>
<thead>
<tr>
<th><strong>Aurora PostgreSQL</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>log_connections</td>
<td>Logs each successful connection.</td>
</tr>
<tr>
<td>log_disconnections</td>
<td>Logs end of a session including duration.</td>
</tr>
<tr>
<td>log_lock_waits</td>
<td>Default is 0 (off). Set to 1 to log lock waits.</td>
</tr>
<tr>
<td>log_min_duration_statement</td>
<td>The minimum duration (in milliseconds) for a statement to run before it’s logged.</td>
</tr>
<tr>
<td>log_min_messages</td>
<td>Sets the message levels that are logged. Supported values are debug5, debug4, debug3, debug2, debug1, info, notice, warning, error, log, fatal, panic. To log performance data to the postgres log, set the value to debug1.</td>
</tr>
<tr>
<td>log_temp_files</td>
<td>Logs the use of temporary files that are above the specified kilobytes (kB).</td>
</tr>
<tr>
<td>log_statement</td>
<td>Controls the specific SQL statements that get logged. Supported values are none, ddl, mod, and all. Default is none.</td>
</tr>
</tbody>
</table>
Topics

- Logging with Amazon CloudWatch (p. 2003)
- Viewing Aurora Serverless v2 logs in Amazon CloudWatch (p. 2003)
- Monitoring capacity with Amazon CloudWatch (p. 2003)

Logging with Amazon CloudWatch

After you use the procedure in Logging for Aurora Serverless v2 (p. 2001) to choose which database logs to turn on, you can choose which logs to upload ("publish") to Amazon CloudWatch.

You can use Amazon CloudWatch to analyze log data, create alarms, and view metrics. By default, error logs for Aurora Serverless v2 are enabled and automatically uploaded to CloudWatch. You can also upload other logs from Aurora Serverless v2 DB instances to CloudWatch.

Then you choose which of those logs to upload to CloudWatch, by using the Log exports settings in the AWS Management Console or the --enable-cloudwatch-logs-exports option in the AWS CLI.

You can choose which of your Aurora Serverless v2 logs to upload to CloudWatch. For more information, see Using Advanced Auditing with an Amazon Aurora MySQL DB cluster (p. 980).

As with any type of Aurora DB cluster, you can't modify the default DB cluster parameter group. Instead, create your own DB cluster parameter group based on a default parameter for your DB cluster and engine type. We recommend that you create your custom DB cluster parameter group before creating your Aurora Serverless v2 DB cluster, so that it's available to choose when you create a database on the console.

Note
For Aurora Serverless v2, you can create both DB cluster and DB parameter groups. This contrasts with Aurora Serverless v1, where you can only create DB cluster parameter groups.

Viewing Aurora Serverless v2 logs in Amazon CloudWatch

After you use the procedure in Logging with Amazon CloudWatch (p. 2003) to choose which database logs to turn on, you can view the contents of the logs.

For more information on using CloudWatch with Aurora MySQL and Aurora PostgreSQL logs, see Monitoring log events in Amazon CloudWatch (p. 1086) and Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs (p. 1548).

To view logs for your Aurora Serverless v2 DB cluster

2. Choose your AWS Region.
3. Choose Log groups.
4. Choose your Aurora Serverless v2 DB cluster log from the list. The log naming pattern is as follows.

/aws/rds/cluster/cluster-name/log_type

Note
For Aurora MySQL-compatible Aurora Serverless v2 DB clusters, the error log includes buffer pool scaling events even when there are no errors.

Monitoring capacity with Amazon CloudWatch

With Aurora Serverless v2, you can use CloudWatch to monitor the capacity and utilization of all the Aurora Serverless v2 DB instances in your cluster. You can view instance-level metrics to check the
capacity of each Aurora Serverless v2 DB instance as it scales up and down. You can also compare the
capacity-related metrics to other metrics to see how changes in workloads affect resource consumption.
For example, you can compare ServerlessDatabaseCapacity to DatabaseUsedMemory,
DatabaseConnections, and DMLThroughput to assess how your DB cluster is responding during
operations. For details about the capacity-related metrics that apply to Aurora Serverless v2, see
Important Amazon CloudWatch metrics for Aurora Serverless v2 (p. 2018).

To monitor your Aurora Serverless v2 DB cluster's capacity

2. Choose Metrics. All available metrics appear as cards in the console, grouped by service name.
3. Choose RDS.
4. (Optional) Use the Search box to find the metrics that are especially important for Aurora
   Serverless v2: ServerlessDatabaseCapacity, ACUUtilization, CPUUtilization, and
   FreeableMemory.

We recommend that you set up a CloudWatch dashboard to monitor your Aurora Serverless v2
DB cluster capacity using the capacity-related metrics. To learn how, see Building dashboards with
CloudWatch.

To learn more about using Amazon CloudWatch with Amazon Aurora, see Publishing Amazon Aurora
MySQL logs to Amazon CloudWatch Logs (p. 1083).

Performance and scaling for Aurora Serverless v2

The following procedures and examples show how you can set the capacity range for Aurora Serverless
v2 clusters and their associated DB instances. You can also use procedures following to monitor how busy
your DB instances are. Then you can use your findings to determine if you need to adjust the capacity
range upward or downward.

Before you use these procedures, make sure that you are familiar with how Aurora Serverless v2 scaling
works. The scaling mechanism is different than in Aurora Serverless v1. For details, see Aurora Serverless
v2 scaling (p. 1966).

Choosing the Aurora Serverless v2 capacity range for an Aurora cluster

With Aurora Serverless v2 DB instances, you set the capacity range that applies to all the DB instances in your DB cluster at the same time that you add the first Aurora Serverless v2 DB instance to the DB cluster. For the procedure to do so, see Setting the Aurora Serverless v2 capacity range for a cluster (p. 1988).

You can also change the capacity range for an existing cluster. The following sections discuss in more detail how to choose appropriate minimum and maximum values and what happens when you make a change to the capacity range. For example, changing the capacity range can modify the default values of some configuration parameters. Applying all the parameter changes can require rebooting each Aurora Serverless v2 DB instance.

Choosing the minimum Aurora Serverless v2 capacity setting for a cluster

It's tempting to always choose 0.5 for the minimum Aurora Serverless v2 capacity setting. That value allows the DB instance to scale down the most when it's completely idle. However, depending on how you use that cluster and the other settings that you configure, a different value might be the most effective. Consider the following factors when choosing the minimum capacity setting:

- The scaling rate for an Aurora Serverless v2 DB instance depends on its current capacity. The higher the current capacity, the faster it can scale up. If you need the DB instance to quickly scale up to a very high capacity, consider setting the minimum capacity to a value where the scaling rate meets your requirement.

- If you typically modify the DB instance class of your DB instances in anticipation of especially high or low workload, you can use that experience to make a rough estimate of the equivalent Aurora Serverless v2 capacity range. To determine the memory size to use in times of low traffic, consult Hardware specifications for DB instance classes for Aurora (p. 94).

For example, suppose that you use the db.r6g.xlarge DB instance class when your cluster has a low workload. That DB instance class has 32 GiB of memory. Thus, you can specify a minimum Aurora capacity unit (ACU) setting of 16 to set up an Aurora Serverless v2 DB instance that can scale down to approximately that same capacity. That's because each ACU corresponds to approximately 2 GiB of memory. You might specify a somewhat lower value to let the DB instance scale down further in case your db.r6g.xlarge DB instance was sometimes underutilized.

- If your application works most efficiently when the DB instances have a certain amount of data in the buffer cache, consider specifying a minimum ACU setting where the memory is large enough to hold
Choosing the capacity range

the frequently accessed data. Otherwise, some data is evicted from the buffer cache when the Aurora Serverless v2 DB instances scale down to a lower memory size. Then when the DB instances scale back up, the information is read back into the buffer cache over time. If the amount of I/O to bring the data back into the buffer cache is substantial, it might be more effective to choose a higher minimum ACU value.

- If your Aurora Serverless v2 DB instances run most of the time at a particular capacity, consider specifying a minimum capacity setting that's lower than that baseline, but not too much lower. Aurora Serverless v2 DB instances can most effectively estimate how much and how fast to scale up when the current capacity isn't drastically lower than the required capacity.
- If your provisioned workload has memory requirements that are too high for small DB instance classes such as T3 or T4g, choose a minimum ACU setting that provides memory comparable to an R5 or R6g DB instance.

In particular, we recommend the following minimum capacity for use with the specified features (these recommendations are subject to change):

- Performance Insights – 2 ACUs
- Aurora global databases – 8 ACUs (applies only to the primary AWS Region)
- In some cases, your cluster might contain Aurora Serverless v2 reader DB instances that scale independently from the writer. If so, choose a minimum capacity setting that's high enough that when the writer DB instance is busy with a write-intensive workload, the reader DB instances can apply the changes from the writer without falling behind. If you observe replica lag in readers that are in promotion tiers 2–15, consider increasing the minimum capacity setting for your cluster. For details on choosing whether reader DB instances scale along with the writer or independently, see Choosing the promotion tier for an Aurora Serverless v2 reader (p. 1999).
- If you have a mixed-configuration cluster with a provisioned writer and Aurora Serverless v2 readers, the readers can't scale along with the writer. In that case, setting a low minimum capacity can result in excessive replication lag. That's because the readers might not have enough capacity to apply changes from the writer when the database is busy. When your cluster uses a provisioned writer, set the minimum capacity to a value that represents a comparable amount of memory and CPU to the writer.
- The value of the max_connections parameter for Aurora Serverless v2DB instances is based on the memory size derived from the maximum ACUs. However, when you specify a minimum capacity of 0.5 ACUs on PostgreSQL-compatible DB instances, the maximum value of max_connections is capped at 2,000.

If you intend to use the Aurora PostgreSQL cluster for a high-connection workload, consider using a minimum ACU setting of 1 or higher. For details about how Aurora Serverless v2 handles the max_connections configuration parameter, see Maximum connections for Aurora Serverless v2 (p. 2016).
- The time it takes for an Aurora Serverless v2 DB instance to scale from its minimum capacity to its maximum capacity depends on the difference between its minimum and maximum ACU values. When the current capacity of the DB instance is large, Aurora Serverless v2 scales up in larger increments than when the DB instance starts from a small capacity. Thus, if you specify a relatively large maximum capacity and the DB instance spends most of its time near that capacity, consider increasing the minimum ACU setting. That way, an idle DB instance can scale back up to maximum capacity more quickly.

Choosing the maximum Aurora Serverless v2 capacity setting for a cluster

It's tempting to always choose some high value for the maximum Aurora Serverless v2 capacity setting. A large maximum capacity allows the DB instance to scale up the most when it's running an intensive workload. A low value avoids the possibility of unexpected charges. Depending on how you use that
Choosing the capacity range

cluster and the other settings that you configure, the most effective value might be higher or lower than you originally thought. Consider the following factors when choosing the maximum capacity setting:

- The maximum capacity must be at least as high as the minimum capacity. You can set the minimum and maximum capacity to be identical. However, in that case the capacity never scales up or down. Thus, using identical values for minimum and maximum capacity isn't appropriate outside of testing situations.

- The maximum capacity must be higher than 0.5 ACUs. You can set the minimum and maximum capacity to be the same in most cases. However, you can't specify 0.5 for both the minimum and maximum. Use a value of 1 or higher for the maximum capacity.

- If you typically modify the DB instance class of your DB instances in anticipation of especially high or low workload, you can use that experience to estimate the equivalent Aurora Serverless v2 capacity range. To determine the memory size to use in times of high traffic, consult Hardware specifications for DB instance classes for Aurora (p. 94).

For example, suppose that you use the db.r6g.4xlarge DB instance class when your cluster has a high workload. That DB instance class has 128 GiB of memory. Thus, you can specify a maximum ACU setting of 64 to set up an Aurora Serverless v2 DB instance that can scale up to approximately that same capacity. That's because each ACU corresponds to approximately 2 GiB of memory. You might specify a somewhat higher value to let the DB instance scale up farther in case your db.r6g.4xlarge DB instance sometimes doesn't have enough capacity to handle the workload effectively.

- If you have a budgetary cap on your database usage, choose a value that stays within that cap even if all your Aurora Serverless v2 DB instances run at maximum capacity all the time. Remember that when you have \( n \) Aurora Serverless v2 DB instances in your cluster, the theoretical maximum Aurora Serverless v2 capacity that the cluster can consume at any moment is \( n \) times the maximum ACU setting for the cluster. (The actual amount consumed might be less, for example if some readers scale independently from the writer.)

- If you make use of Aurora Serverless v2 reader DB instances to offload some of the read-only workload from the writer DB instance, you might be able to choose a lower maximum capacity setting. You do this to reflect that each reader DB instance doesn't need to scale as high as if the cluster contains only a single DB instance.

- Suppose that you want to protect against excessive usage due to misconfigured database parameters or inefficient queries in your application. In that case, you might avoid accidental overuse by choosing a maximum capacity setting that's lower than the absolute highest that you could set.

- If spikes due to real user activity are rare but do happen, you can take those occasions into account when choosing the maximum capacity setting. If the priority is for the application to keep running with full performance and scalability, you can specify a maximum capacity setting that's higher than you observe in normal usage. If it's OK for the application to run with reduced throughput during very extreme spikes in activity, you can choose a slightly lower maximum capacity setting. Make sure that you choose a setting that still has enough memory and CPU resources to keep the application running.

- If you turn on settings in your cluster that increase the memory usage for each DB instance, take that memory into account when deciding on the maximum ACU value. Such settings include those for Performance Insights, Aurora MySQL parallel queries, Aurora MySQL performance schema, and Aurora MySQL binary log replication. Make sure that the maximum ACU value allows the Aurora Serverless v2 DB instances to scale up enough to handle the workload when those feature are being used. For information about troubleshooting problems caused by the combination of a low maximum ACU setting and Aurora features that impose memory overhead, see Avoiding out-of-memory errors (p. 2017).

Example: Change the Aurora Serverless v2 capacity range of an Aurora MySQL cluster

The following AWS CLI example shows how to update the ACU range for Aurora Serverless v2 DB instances in an existing Aurora MySQL cluster. Initially, the capacity range for the cluster is 8–32 ACUs.
Choosing the capacity range

```
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster --query 'DBClusters[*].ServerlessV2ScalingConfiguration[0]'
{
  "MinCapacity": 8.0,
  "MaxCapacity": 32.0
}
```

The DB instance is idle and scaled down to 8 ACUs. The following capacity-related settings apply to the DB instance at this point. To represent the size of the buffer pool in easily readable units, we divide it by 2 to the power of 30, yielding a measurement in gibibytes (GiB). That's because memory-related measurements for Aurora use units based on powers of 2, not powers of 10.

```
mysql> select @@max_connections;
+-------------------+
| @@max_connections |
+-------------------+
|              3000 |
+-------------------+
1 row in set (0.00 sec)

mysql> select @@innodb_buffer_pool_size;
+---------------------------+
| @@innodb_buffer_pool_size |
+---------------------------+
|                9294577664 |
+---------------------------+
1 row in set (0.00 sec)

mysql> select @@innodb_buffer_pool_size / pow(2,30) as gibibytes;
+-----------+
| gibibytes |
+-----------+
|     8.65625 |
+-----------+
1 row in set (0.00 sec)
```

Next, we change the capacity range for the cluster. After the `modify-db-cluster` command finishes, the ACU range for the cluster is 12.5–80.

```
aws rds modify-db-cluster --db-cluster-identifier serverless-v2-cluster --serverless-v2-scaling-configuration MinCapacity=12.5,MaxCapacity=80
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster --query 'DBClusters[*].ServerlessV2ScalingConfiguration[0]'
{
  "MinCapacity": 12.5,
  "MaxCapacity": 80.0
}
```

Changing the capacity range caused changes to the default values of some configuration parameters. Aurora can apply some of those new defaults immediately. However, some of the parameter changes take effect only after a reboot. The `pending-reboot` status indicates that a reboot is needed to apply some parameter changes.

**Tip**
You can reboot the DB instances yourself to apply these parameter changes. Or you can wait for Aurora to do the reboot and apply the parameter changes during your next scheduled maintenance window.

```
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster
```
Choosing the capacity range

At this point, the cluster is idle and the DB instance serverless-v2-instance-1 is consuming 12.5 ACUs. The innodb_buffer_pool_size parameter is already adjusted based on the current capacity of the DB instance. The max_connections parameter still reflects the value from the former maximum capacity. Resetting that value requires rebooting the DB instance, because max_connections is a static parameter for Aurora Serverless v2.

```
mysql> select @@max_connections;
+-------------------+
| @@max_connections |
+-------------------+
|              3000 |
+-------------------+
1 row in set (0.00 sec)

mysql> select @@innodb_buffer_pool_size;
+---------------------------+
| @@innodb_buffer_pool_size |
+---------------------------+
|           15572402176 |
+---------------------------+
1 row in set (0.00 sec)

mysql> select @@innodb_buffer_pool_size / pow(2,30) as gibibytes;
+---------------+
| gibibytes     |
+---------------+
| 14.5029296875 |
+---------------+
1 row in set (0.00 sec)
```

Now we reboot the DB instance and wait for it to become available again.

```
aws rds reboot-db-instance --db-instance-identifier serverless-v2-instance-1
{
    "DBInstanceIdentifier": "serverless-v2-instance-1",
    "DBInstanceStatus": "rebooting"
}
aws rds wait db-instance-available --db-instance-identifier serverless-v2-instance-1
```

The pending-reboot status is cleared. The value in-sync confirms that Aurora has applied all the pending parameter changes.

```
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
--query '*[].{DBClusterMembers:DBClusterMembers[*].(DBInstanceIdentifier:DBInstanceIdentifier,DBClusterParameterGroupStatus:DBClusterParameterGroupStatus)}|0]['
{
    "DBClusterMembers": [
    
    ]
}
```
Amazon Aurora User Guide for Aurora
Choosing the capacity range

The innodb_buffer_pool_size parameter has increased to its final size for an idle DB instance. The max_connections parameter has increased to reflect a value derived from the maximum ACU value. The formula that Aurora uses for max_connections causes an increase of 1,000 when the memory size doubles.

```
mysql> select @@innodb_buffer_pool_size;
+---------------------------+
| @@innodb_buffer_pool_size |
+---------------------------+
|               16139681792 |
+---------------------------+
1 row in set (0.00 sec)

mysql> select @@innodb_buffer_pool_size / pow(2,30) as gibibytes;
+-----------+
| gibibytes |
+-----------+
|  15.03125 |
+-----------+
1 row in set (0.00 sec)

mysql> select @@max_connections;
+-------------------+
| @@max_connections |
+-------------------+
|              4000 |
+-------------------+
1 row in set (0.00 sec)
```

We set the capacity range to 0.5–128 ACUs, and reboot the DB instance to apply any resulting changes to static parameters. Now the idle DB instance has a buffer cache size that’s less than 1 GiB, so we measure it in mebibytes (MiB). The max_connections value of 5000 is derived from the memory size of the maximum capacity setting.

```
mysql> select @@innodb_buffer_pool_size / pow(2,20) as mebibytes, @@max_connections;
+-----------+--------------------+
| mebibytes | @@max_connections |
+-----------+--------------------+
|       672   |              5000 |
+-----------+--------------------+
1 row in set (0.00 sec)
```

Example: Change the Aurora Serverless v2 capacity range of an Aurora PostgreSQL cluster

The following CLI examples show how to update the ACU range for Aurora Serverless v2 DB instances in an existing Aurora PostgreSQL cluster.

1. The capacity range for the cluster starts at 0.5–1 ACU.
2. Change the capacity range to 8–32 ACUs.
3. Change the capacity range to 12.5–80 ACUs.
4. Change the capacity range to 0.5–128 ACUs.
5. Return the capacity to its initial range of 0.5–1 ACU.

The following figure shows the capacity changes in Amazon CloudWatch.

The DB instance is idle and scaled down to 0.5 ACUs. The following capacity-related settings apply to the DB instance at this point.

```
postgres=> show max_connections;
max_connections
-----------------
189
(1 row)
postgres=> show shared_buffers;
shared_buffers
----------------
16384
(1 row)
```

Next, we change the capacity range for the cluster. After the `modify-db-cluster` command finishes, the ACU range for the cluster is 8.0–32.

```
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster
--query 'DBClusters[*].ServerlessV2ScalingConfiguration[0]' {
  "MinCapacity": 8.0,
  "MaxCapacity": 32.0
}
```

Changing the capacity range causes changes to the default values of some configuration parameters. Aurora can apply some of those new defaults immediately. However, some of the parameter changes take effect only after a reboot. The pending-reboot status indicates that you need a reboot to apply some parameter changes. You can reboot the DB instances yourself to apply these parameter changes. Or you can wait for Aurora to do the reboot and apply the parameter changes during your next scheduled maintenance window.

```
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster
--query '*[].{DBClusterMembers:DBClusterMembers[*].DBInstanceIdentifier:DBInstanceIdentifier,DBClusterParameterGroupStatus:DBClusterParameterGroupStatus}[0]'
{ "DBClusterMembers": [ 
  { "DBInstanceIdentifier": "serverless-v2-instance-1", "DBClusterParameterGroupStatus": "pending-reboot"
```
At this point, the cluster is idle and the DB instance `serverless-v2-instance-1` is consuming 8.0 ACUs. The `shared_buffers` parameter is already adjusted based on the current capacity of the DB instance. The `max_connections` parameter still reflects the value from the former maximum capacity. Resetting that value requires rebooting the DB instance, because `max_connections` is a static parameter for Aurora Serverless v2 (and Aurora PostgreSQL in general).

```
postgres=> show max_connections;
max_connections
-------------
189
(1 row)
```

```
postgres=> show shared_buffers;
shared_buffers
----------
1425408
(1 row)
```

We reboot the DB instance and wait for it to become available again.

```
aws rds reboot-db-instance --db-instance-identifier serverless-v2-instance-1
{
  "DBInstanceIdentifier": "serverless-v2-instance-1",
  "DBInstanceState": "rebooting"
}
aws rds wait db-instance-available --db-instance-identifier serverless-v2-instance-1
```

Now that the DB instance is rebooted, the `pending-reboot` status is cleared. The value `in-sync` confirms that Aurora has applied all the pending parameter changes.

```
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
--query '[].{DBClusterMembers:DBClusterMembers[*].
(DBInstanceIdentifier:DBInstanceIdentifier,DBClusterParameterGroupStatus:DBClusterParameterGroupStatus)}

[0]
{
  "DBClusterMembers": [
  {
    "DBInstanceIdentifier": "serverless-v2-instance-1",
    "DBClusterParameterGroupStatus": "in-sync"
  }
  ]
}
```

After rebooting, `max_connections` shows the value from the new maximum capacity.

```
postgres=> show max_connections;
max_connections
----------------
5000
(1 row)
```

```
postgres=> show shared_buffers;
shared_buffers
----------
1425408
```
Next, we change the capacity range for the cluster to 12.5–80 ACUs.

```
aws rds modify-db-cluster --db-cluster-identifier serverless-v2-cluster \
  --serverless-v2-scaling-configuration MinCapacity=12.5,MaxCapacity=80
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
  --query 'DBClusters[*].ServerlessV2ScalingConfiguration[0]' 
  {
    "MinCapacity": 12.5,
    "MaxCapacity": 80.0
  }
```

At this point, the cluster is idle and the DB instance `serverless-v2-instance-1` is consuming 12.5 ACUs. The `shared_buffers` parameter is already adjusted based on the current capacity of the DB instance. The `max_connections` value is still 5000.

```
postgres=> show max_connections;
               max_connections
-------------------------
               5000
(1 row)
postgres=> show shared_buffers;
                  shared_buffers
-------------------------
             2211840
(1 row)
```

We reboot again, but the parameter values stay the same. This is because `max_connections` has a maximum value of 5000 for an Aurora Serverless v2 DB cluster running Aurora PostgreSQL.

```
postgres=> show max_connections;
               max_connections
-------------------------
               5000
(1 row)
postgres=> show shared_buffers;
                  shared_buffers
-------------------------
             2211840
(1 row)
```

Now we set the capacity range from 0.5 to 128 ACUs. The DB cluster scales down to 10 ACUs, then to 2. We reboot the DB instance.

```
postgres=> show max_connections;
               max_connections
-------------------------
               2000
(1 row)
postgres=> show shared_buffers;
                  shared_buffers
-------------------------
              16384
(1 row)
```
The `max_connections` value for Aurora Serverless v2 DB instances is based on the memory size derived from the maximum ACUs. However, when you specify a minimum capacity of 0.5 ACUs on PostgreSQL-compatible DB instances, the maximum value of `max_connections` is capped at 2,000.

Now we return the capacity to its initial range of 0.5–1 ACU and reboot the DB instance. The `max_connections` parameter has returned to its original value.

```sql
postgres=> show max_connections;
max_connections
-----------------
  189
(1 row)
```

```sql
postgres=> show shared_buffers;
shared_buffers
-------------
 16384
(1 row)
```

---

**Working with parameter groups for Aurora Serverless v2**

When you create your Aurora Serverless v2 DB cluster, you choose a specific Aurora DB engine and an associated DB cluster parameter group. If you aren't familiar with how Aurora uses parameter groups to apply configuration settings consistently across clusters, see [Working with parameter groups](p. 212). All of those procedures for creating, modifying, applying, and other actions for parameter groups apply to Aurora Serverless v2.

The parameter group feature works generally the same between provisioned clusters and clusters containing Aurora Serverless v2 DB instances:

- The default parameter values for all DB instances in the cluster are defined by the cluster parameter group.
- You can override some parameters for specific DB instances by specifying a custom DB parameter group for those DB instances. You might do so during debugging or performance tuning for specific DB instances. For example, suppose that you have a cluster containing some Aurora Serverless v2 DB instances and some provisioned DB instances. In this case, you might specify some different parameters for the provisioned DB instances by using a custom DB parameter group.
- For Aurora Serverless v2, you can use all the parameters that have the value `provisioned` in the `SupportedEngineModes` attribute in the parameter group. In Aurora Serverless v1, you can only use the subset of parameters that have `serverless` in the `SupportedEngineModes` attribute.

**Topics**

- Default parameter values (p. 2014)
- Maximum connections for Aurora Serverless v2 (p. 2016)
- Parameters that Aurora adjusts as Aurora Serverless v2 scales up and down (p. 2016)
- Parameters that Aurora computes based on Aurora Serverless v2 maximum capacity (p. 2017)

---

**Default parameter values**

The crucial difference between provisioned DB instances and Aurora Serverless v2 DB instances is that Aurora overrides any custom parameter values for certain parameters that are related to DB instance capacity. The custom parameter values still apply to any provisioned DB instances in your
Working with parameter groups for Aurora Serverless v2

You can get a list of default values for the default parameter groups for the various Aurora DB engines by using the `describe-db-cluster-parameters` CLI command and querying the AWS Region. The following are values that you can use for the `--db-parameter-group-family` and `--db-parameter-group-name` options for engine versions that are compatible with Aurora Serverless v2.

<table>
<thead>
<tr>
<th>Database engine and version</th>
<th>Parameter group family</th>
<th>Default parameter group name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL version 3</td>
<td>aurora-mysql8.0</td>
<td>default.aurora-mysql8.0</td>
</tr>
<tr>
<td>Aurora PostgreSQL version 13.x</td>
<td>aurora-postgresql13</td>
<td>default.aurora-postgresql13</td>
</tr>
<tr>
<td>Aurora PostgreSQL version 14.x</td>
<td>aurora-postgresql14</td>
<td>default.aurora-postgresql14</td>
</tr>
<tr>
<td>Aurora PostgreSQL version 15.x</td>
<td>aurora-postgresql15</td>
<td>default.aurora-postgresql15</td>
</tr>
</tbody>
</table>

The following example gets a list of parameters from the default DB cluster group for Aurora MySQL version 3 and Aurora PostgreSQL 13. Those are the Aurora MySQL and Aurora PostgreSQL versions that you use with Aurora Serverless v2.

For Linux, macOS, or Unix:

```bash
aws rds describe-db-cluster-parameters \
   --db-cluster-parameter-group-name default.aurora-mysql8.0 \
   --query 'Parameters[*].{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} | 
       [?contains(SupportedEngineModes, 'provisioned') == 'true'] | [*].[ParameterName]' \
   --output text

aws rds describe-db-cluster-parameters \
   --db-cluster-parameter-group-name default.aurora-postgresql13 \
   --query 'Parameters[*].{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} | 
       [?contains(SupportedEngineModes, 'provisioned') == 'true'] | [*].[ParameterName]' \
   --output text
```

For Windows:

```bash
aws rds describe-db-cluster-parameters ^
   --db-cluster-parameter-group-name default.aurora-mysql8.0 ^
   --query 'Parameters[*].{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} | 
       [?contains(SupportedEngineModes, 'provisioned') == 'true'] | [*].[ParameterName]' ^
   --output text

aws rds describe-db-cluster-parameters ^
   --db-cluster-parameter-group-name default.aurora-postgresql13 ^
   --query 'Parameters[*].{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} | 
       [?contains(SupportedEngineModes, 'provisioned') == 'true'] | [*].[ParameterName]' ^
```

2015
Maximum connections for Aurora Serverless v2

For both Aurora MySQL and Aurora PostgreSQL, Aurora Serverless v2 DB instances hold the `max_connections` parameter constant so that connections aren't dropped when the DB instance scales down. The default value for this parameter is derived from a formula based on the memory size of the DB instance. For details about the formula and the default values for provisioned DB instance classes, see Maximum connections to an Aurora MySQL DB instance (p. 875) and Maximum connections to an Aurora PostgreSQL DB instance (p. 1398).

When Aurora Serverless v2 evaluates the formula, it uses the memory size based on the maximum Aurora capacity units (ACUs) for the DB instance, not the current ACU value. If you change the default value, we recommend using a variation of the formula instead of specifying a constant value. That way, Aurora Serverless v2 can use an appropriate setting based on the maximum capacity.

When you change the maximum capacity of an Aurora Serverless v2 DB cluster, you have to reboot the Aurora Serverless v2 DB instances to update the `max_connections` value. This is because `max_connections` is a static parameter for Aurora Serverless v2.

The following table shows the default values for `max_connections` for Aurora Serverless v2 based on the maximum ACU value.

<table>
<thead>
<tr>
<th>Maximum ACUs</th>
<th>Default maximum connections on Aurora MySQL</th>
<th>Default maximum connections on Aurora PostgreSQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>90</td>
<td>189</td>
</tr>
<tr>
<td>4</td>
<td>135</td>
<td>823</td>
</tr>
<tr>
<td>8</td>
<td>1,000</td>
<td>1,669</td>
</tr>
<tr>
<td>16</td>
<td>2,000</td>
<td>3,360</td>
</tr>
<tr>
<td>32</td>
<td>3,000</td>
<td>5,000</td>
</tr>
<tr>
<td>64</td>
<td>4,000</td>
<td>5,000</td>
</tr>
<tr>
<td>128</td>
<td>5,000</td>
<td>5,000</td>
</tr>
</tbody>
</table>

Note
The `max_connections` value for Aurora Serverless v2 DB instances is based on the memory size derived from the maximum ACUs. However, when you specify a minimum capacity of 0.5 ACUs on PostgreSQL-compatible DB instances, the maximum value of `max_connections` is capped at 2,000.

For specific examples showing how `max_connections` changes with the maximum ACU value, see Example: Change the Aurora Serverless v2 capacity range of an Aurora MySQL cluster (p. 2007) and Example: Change the Aurora Serverless v2 capacity range of an Aurora PostgreSQL cluster (p. 2010).

Parameters that Aurora adjusts as Aurora Serverless v2 scales up and down

During autoscaling, Aurora Serverless v2 needs to be able to change parameters for each DB instance to work best for the increased or decreased capacity. Thus, you can't override some parameters related to capacity. For some parameters that you can override, avoid hardcoding fixed values. The following considerations apply to these settings that are related to capacity.
For Aurora MySQL, Aurora Serverless v2 resizes some parameters dynamically during scaling. For the following parameters, Aurora Serverless v2 doesn't use any custom parameter values that you specify:

- `innodb_buffer_pool_size`
- `innodb_purge_threads`
- `table_definition_cache`
- `table_open_cache`

For Aurora PostgreSQL, Aurora Serverless v2 resizes the following parameter dynamically during scaling. For the following parameters, Aurora Serverless v2 doesn't use any custom parameter values that you specify:

- `shared_buffers`

For all parameters other than those listed here, Aurora Serverless v2 DB instances work the same as provisioned DB instances. The default parameter value is inherited from the cluster parameter group. You can modify the default for the whole cluster by using a custom cluster parameter group. Or you can modify the default for certain DB instances by using a custom DB parameter group. Dynamic parameters are updated immediately. Changes to static parameters only take effect after you reboot the DB instance.

**Parameters that Aurora computes based on Aurora Serverless v2 maximum capacity**

For the following parameters, Aurora PostgreSQL uses default values that are derived from the memory size based on the maximum ACU setting, the same as with `max_connections`:

- `autovacuum_max_workers`
- `autovacuum_vacuum_cost_limit`
- `autovacuum_work_mem`
- `effective_cache_size`
- `maintenance_work_mem`

**Avoiding out-of-memory errors**

If one of your Aurora Serverless v2 DB instances consistently reaches the limit of its maximum capacity, Aurora indicates this condition by setting the DB instance to a status of `incompatible-parameters`. While the DB instance has the `incompatible-parameters` status, some operations are blocked. For example, you can't upgrade the engine version.

Typically, your DB instance goes into this status when it restarts frequently due to out-of-memory errors. Aurora records an event when this type of restart happens. You can view the event by following the procedure in [Viewing Amazon RDS events](p. 687). Unusually high memory usage can happen because of overhead from turning on settings such as Performance Insights and IAM authentication. It can also come from a heavy workload on your DB instance or from managing the metadata associated with a large number of schema objects.

If the memory pressure becomes lower so that the DB instance doesn't reach its maximum capacity very often, Aurora automatically changes the DB instance status back to `available`.

To recover from this condition, you can take some or all of the following actions:

- Increase the lower limit on capacity for Aurora Serverless v2 DB instances by changing the minimum Aurora capacity unit (ACU) value for the cluster. Doing so avoids issues where an idle database scales
down to a capacity with less memory than is needed for the features that are turned on in your cluster. After changing the ACU settings for the cluster, reboot the Aurora Serverless v2 DB instance. Doing so evaluates whether Aurora can reset the status back to available.

- Increase the upper limit on capacity for Aurora Serverless v2 DB instances by changing the maximum ACU value for the cluster. Doing so avoids issues where a busy database can't scale up to a capacity with enough memory for the features that are turned on in your cluster and the database workload. After changing the ACU settings for the cluster, reboot the Aurora Serverless v2 DB instance. Doing so evaluates whether Aurora can reset the status back to available.

- Turn off configuration settings that require memory overhead. For example, suppose that you have features such as AWS Identity and Access Management (IAM), Performance Insights, or Aurora MySQL binary log replication turned on but don't use them. If so, you can turn them off. Or you can adjust the minimum and maximum capacity values for the cluster higher to account for the memory used by those features. For guidelines about choosing minimum and maximum capacity settings, see Choosing the Aurora Serverless v2 capacity range for an Aurora cluster (p. 2005).

- Reduce the workload on the DB instance. For example, you can add reader DB instances to the cluster to spread the load from read-only queries across more DB instances.

- Tune the SQL code used by your application to use fewer resources. For example, you can examine your query plans, check the slow query log, or adjust the indexes on your tables. You can also perform other traditional kinds of SQL tuning.

### Important Amazon CloudWatch metrics for Aurora Serverless v2

To get started with Amazon CloudWatch for your Aurora Serverless v2 DB instance, see Viewing Aurora Serverless v2 logs in Amazon CloudWatch (p. 2003). To learn more about how to monitor Aurora DB clusters through CloudWatch, see Monitoring log events in Amazon CloudWatch (p. 1086).

You can view your Aurora Serverless v2 DB instances in CloudWatch to monitor the capacity consumed by each DB instance with the `ServerlessDatabaseCapacity` metric. You can also monitor all of the standard Aurora CloudWatch metrics, such as DatabaseConnections and Queries. For the full list of CloudWatch metrics that you can monitor for Aurora, see Amazon CloudWatch metrics for Amazon Aurora (p. 638). The metrics are divided into cluster-level and instance-level metrics, in Cluster-level metrics for Amazon Aurora (p. 638) and Instance-level metrics for Amazon Aurora (p. 643).

The following CloudWatch instance-level metrics are important to monitor for you to understand how your Aurora Serverless v2 DB instances are scaling up and down. All of these metrics are calculated every second. That way, you can monitor the current status of your Aurora Serverless v2 DB instances. You can set alarms to notify you if any Aurora Serverless v2 DB instance approaches a threshold for metrics related to capacity. You can determine if the minimum and maximum capacity settings are appropriate, or if you need to adjust them. You can determine where to focus your efforts for optimizing the efficiency of your database.

- **ServerlessDatabaseCapacity.** As an instance-level metric, it reports the number of ACUs represented by the current DB instance capacity. As a cluster-level metric, it represents the average of the `ServerlessDatabaseCapacity` values of all the Aurora Serverless v2 DB instances in the cluster. This metric is only a cluster-level metric in Aurora Serverless v1. In Aurora Serverless v2, it's available at the DB instance level and at the cluster level.

- **ACUUtilization.** This metric is new in Aurora Serverless v2. This value is represented as a percentage. It's calculated as the value of the `ServerlessDatabaseCapacity` metric divided by the maximum ACU value of the DB cluster. Consider the following guidelines to interpret this metric and take action:
  - If this metric approaches a value of 100.0, the DB instance has scaled up as high as it can. Consider increasing the maximum ACU setting for the cluster. That way, both writer and reader DB instances can scale to a higher capacity.
Important CloudWatch metrics

- Suppose that a read-only workload causes a reader DB instance to approach an ACUUtilization of 100.0, while the writer DB instance isn't close to its maximum capacity. In that case, consider adding additional reader DB instances to the cluster. That way, you can spread the read-only part of the workload spread across more DB instances, reducing the load on each reader DB instance.

- Suppose that you are running a production application, where performance and scalability are the primary considerations. In that case, you can set the maximum ACU value for the cluster to a high number. Your goal is for the ACUUtilization metric to always be below 100.0. With a high maximum ACU value, you can be confident that there's enough room in case there are unexpected spikes in database activity. You are only charged for the database capacity that's actually consumed.

- CPUUtilization. This metric is interpreted differently in Aurora Serverless v2 than in provisioned DB instances. For Aurora Serverless v2, this value is a percentage that's calculated as the amount of CPU currently being used divided by the CPU capacity that's available under the maximum ACU value of the DB cluster. Aurora monitors this value automatically and scales up your Aurora Serverless v2 DB instance when the DB instance consistently uses a high proportion of its CPU capacity.

  If this metric approaches a value of 100.0, the DB instance has reached its maximum CPU capacity. Consider increasing the maximum ACU setting for the cluster. If this metric approaches a value of 100.0 on a reader DB instance, consider adding additional reader DB instances to the cluster. That way, you can spread the read-only part of the workload spread across more DB instances, reducing the load on each reader DB instance.

- FreeableMemory. This value represents the amount of unused memory that is available when the Aurora Serverless v2 DB instance is scaled to its maximum capacity. For every ACU that the current capacity is below the maximum capacity, this value increases by approximately 2 GiB. Thus, this metric doesn't approach zero until the DB instance is scaled up as high as it can.

  If this metric approaches a value of 0, the DB instance has scaled up as much as it can and is nearing the limit of its available memory. Consider increasing the maximum ACU setting for the cluster. If this metric approaches a value of 0 on a reader DB instance, consider adding additional reader DB instances to the cluster. That way, the read-only part of the workload can be spread across more DB instances, reducing the memory usage on each reader DB instance.

- TempStorageIops. The number of IOPS done on local storage attached to the DB instance. It includes the IOPS for both reads and writes. This metric represents a count and is measured once per second. This is a new metric for Aurora Serverless v2. For details, see Instance-level metrics for Amazon Aurora (p. 643).

  TempStorageThroughput. The amount of data transferred to and from local storage associated with the DB instance. This metric represents bytes and is measured once per second. This is a new metric for Aurora Serverless v2. For details, see Instance-level metrics for Amazon Aurora (p. 643).

Typically, most scaling up for Aurora Serverless v2 DB instances is caused by memory usage and CPU activity. The TempStorageIops and TempStorageThroughput metrics can help you to diagnose the rare cases where network activity for transfers between your DB instance and local storage devices is responsible for unexpected capacity increases. To monitor other network activity, you can use these existing metrics:

- NetworkReceiveThroughput
- NetworkThroughput
- NetworkTransmitThroughput
- StorageNetworkReceiveThroughput
- StorageNetworkThroughput
- StorageNetworkTransmitThroughput

You can have Aurora publish some or all database logs to CloudWatch. You select the logs to publish by turning on the configuration parameters such as general_log and slow_query_log in the DB
cluster parameter group (p. 2014) associated with the cluster that contains your Aurora Serverless v2 DB instances. When you turn off a log configuration parameter, publishing that log to CloudWatch stops. You can also delete the logs in CloudWatch if they are no longer needed.

How Aurora Serverless v2 metrics apply to your AWS bill

The Aurora Serverless v2 charges on your AWS bill are calculated based on the same ServerlessDatabaseCapacity metric that you can monitor. The billing mechanism can differ from the computed CloudWatch average for this metric in cases where you use Aurora Serverless v2 capacity for only part of an hour. It can also differ if system issues make the CloudWatch metric unavailable for brief periods. Thus, you might see a slightly different value of ACU-hours on your bill than if you compute the number yourself from the ServerlessDatabaseCapacity average value.

Examples of CloudWatch commands for Aurora Serverless v2 metrics

The following AWS CLI examples demonstrate how you can monitor the most important CloudWatch metrics related to Aurora Serverless v2. In each case, replace the Value= string for the --dimensions parameter with the identifier of your own Aurora Serverless v2 DB instance.

The following Linux example displays the minimum, maximum, and average capacity values for a DB instance, measured every 10 minutes over one hour. The Linux date command specifies the start and end times relative to the current date and time. The sort_by function in the --query parameter sorts the results chronologically based on the Timestamp field.

```
aws cloudwatch get-metric-statistics --metric-name "ServerlessDatabaseCapacity" \  --start-time "$(date -d '1 hour ago')" --end-time "$(date -d 'now')" --period 600 \  --namespace "AWS/RDS" --statistics Minimum Maximum Average \  --dimensions Name=DBInstanceIdentifier,Value=my_instance \  --query 'sort_by(Datapoints[*].{min:Minimum,max:Maximum,avg:Average,ts:Timestamp},&ts)' \  --output table
```

The following Linux examples demonstrate monitoring the capacity of each DB instance in a cluster. They measure the minimum, maximum, and average capacity utilization of each DB instance. The measurements are taken once each hour over a three-hour period. These examples use the ACUUtilization metric representing a percentage of the upper limit on ACUs, instead of ServerlessDatabaseCapacity representing a fixed number of ACUs. That way, you don't need to know the actual numbers for the minimum and maximum ACU values in the capacity range. You can see percentages ranging from 0 to 100.

```
aws cloudwatch get-metric-statistics --metric-name "ACUUtilization" \  --start-time "$(date -d '3 hours ago')" --end-time "$(date -d 'now')" --period 3600 \  --namespace "AWS/RDS" --statistics Minimum Maximum Average \  --dimensions Name=DBInstanceIdentifier,Value=my_writer_instance \  --query 'sort_by(Datapoints[*].{min:Minimum,max:Maximum,avg:Average,ts:Timestamp},&ts)' \  --output table
```

```
aws cloudwatch get-metric-statistics --metric-name "ACUUtilization" \  --start-time "$(date -d '3 hours ago')" --end-time "$(date -d 'now')" --period 3600 \  --namespace "AWS/RDS" --statistics Minimum Maximum Average \  --dimensions Name=DBInstanceIdentifier,Value=my_reader_instance \  --query 'sort_by(Datapoints[*].{min:Minimum,max:Maximum,avg:Average,ts:Timestamp},&ts)' \  --output table
```

The following Linux example does similar measurements as the previous ones. In this case, the measurements are for the CPUUtilization metric. The measurements are taken every 10 minutes over a 1-hour period. The numbers represent the percentage of available CPU used, based on the CPU resources available to the maximum capacity setting for the DB instance.
aws cloudwatch get-metric-statistics --metric-name "CPUUtilization" \\
--start-time "$(date -d '1 hour ago')" --end-time "$(date -d 'now')" --period 600 \\
--namespace "AWS/RDS" --statistics Minimum Maximum Average \\
--dimensions Name=DBInstanceIdentifier,Value=my_instance \\
--query 'sort_by(Datapoints[*].{min:Minimum,max:Maximum,avg:Average,ts:Timestamp},&ts)' \\
--output table

The following Linux example does similar measurements as the previous ones. In this case, the measurements are for the FreeableMemory metric. The measurements are taken every 10 minutes over a 1-hour period.

aws cloudwatch get-metric-statistics --metric-name "FreeableMemory" \\
--start-time "$(date -d '1 hour ago')" --end-time "$(date -d 'now')" --period 600 \\
--namespace "AWS/RDS" --statistics Minimum Maximum Average \\
--dimensions Name=DBInstanceIdentifier,Value=my_instance \\
--query 'sort_by(Datapoints[*].{min:Minimum,max:Maximum,avg:Average,ts:Timestamp},&ts)' \\
--output table

Monitoring Aurora Serverless v2 performance with Performance Insights

You can use Performance Insights to monitor the performance of Aurora Serverless v2 DB instances. For Performance Insights procedures, see Monitoring DB load with Performance Insights on Amazon Aurora (p. 559).

The following new Performance Insights counters apply to Aurora Serverless v2 DB instances:

• os.general.serverlessDatabaseCapacity – The current capacity of the DB instance in ACUs. The value corresponds to the ServerlessDatabaseCapacity CloudWatch metric for the DB instance.

• os.general.acuUtilization – The percentage of current capacity out of the maximum configured capacity. The value corresponds to the ACUUtilization CloudWatch metric for the DB instance.

• os.general.maxConfiguredAcu – The maximum capacity that you configured for this Aurora Serverless v2 DB instance. It's measured in ACUs.

• os.general.minConfiguredAcu – The minimum capacity that you configured for this Aurora Serverless v2 DB instance. It's measured in ACUs

For the full list of Performance Insights counters, see Performance Insights counter metrics (p. 658).

When vCPU values are shown for an Aurora Serverless v2 DB instance in Performance Insights, those values represent estimates based on the ACU value for the DB instance. At the default interval of one minute, any fractional vCPU values are rounded up to the nearest whole number. For longer intervals, the vCPU value shown is the average of the integer vCPU values for each minute.

Troubleshooting Aurora Serverless v2 capacity issues

In some cases, Aurora Serverless v2 doesn't scale down to the minimum capacity, even with no load on the database. This can happen for the following reasons:

• Certain features can increase resource usage and prevent the database from scaling down to minimum capacity. These features include the following:
  • Aurora global databases
  • Exporting CloudWatch Logs
• Enabling `pg_audit` on Aurora PostgreSQL–compatible DB clusters
• Enhanced Monitoring
• Performance Insights

For more information, see Choosing the minimum Aurora Serverless v2 capacity setting for a cluster (p. 2005).

• If a reader instance isn't scaling down to the minimum and stays at the same or higher capacity than the writer instance, then check the priority tier of the reader instance. Aurora Serverless v2 reader DB instances in tier 0 or 1 are kept at a minimum capacity at least as high as the writer DB instance. Change the priority tier of the reader to 2 or higher so that it scales up and down independently of the writer. For more information, see Choosing the promotion tier for an Aurora Serverless v2 reader (p. 1999).

• Set any database parameters that impact the size of shared memory to their default values. Setting a value higher than the default increases the shared memory requirement and prevents the database from scaling down to the minimum capacity. Examples are `max_connections` and `max_locks_per_transaction`.

  **Note**
  Updating shared memory parameters requires a database restart for the changes to take effect.

• Heavy database workloads can increase resource usage.
• Large database volumes can increase resource usage.

  Amazon Aurora uses memory and CPU resources for DB cluster management. Aurora requires more CPU and memory to manage DB clusters with larger database volumes. If your cluster’s minimum capacity is less than the minimum required for cluster management, your cluster won’t scale down to the minimum capacity.

• Background processes, such as purge, can also increase resource usage.

If the database still doesn't scale down to the minimum capacity configured, then stop and restart the database to reclaim any memory fragments that might have built up over time. Stopping and starting a database results in downtime, so we recommend doing this sparingly.
Amazon Aurora Serverless v1 (Amazon Aurora Serverless version 1) is an on-demand autoscaling configuration for Amazon Aurora. An Aurora Serverless v1 DB cluster is a DB cluster that scales compute capacity up and down based on your application's needs. This contrasts with Aurora provisioned DB clusters, for which you manually manage capacity. Aurora Serverless v1 provides a relatively simple, cost-effective option for infrequent, intermittent, or unpredictable workloads. It is cost-effective because it automatically starts up, scales compute capacity to match your application's usage, and shuts down when it's not in use.

To learn more about pricing, see Serverless Pricing under MySQL-Compatible Edition or PostgreSQL-Compatible Edition on the Amazon Aurora pricing page.

Aurora Serverless v1 clusters have the same kind of high-capacity, distributed, and highly available storage volume that is used by provisioned DB clusters.

For an Aurora Serverless v2 cluster, you can choose whether to encrypt the cluster volume.

For an Aurora Serverless v1 cluster, the cluster volume is always encrypted. You can choose the encryption key, but you can't disable encryption. That means that you can perform the same operations on an Aurora Serverless v1 that you can on encrypted snapshots. For more information, see Aurora Serverless v1 and snapshots (p. 2039).

Important
Aurora has two generations of serverless technology, Aurora Serverless v2 and Aurora Serverless v1. If your application can run on MySQL 8.0 or PostgreSQL 13, we recommend that you use Aurora Serverless v2. Aurora Serverless v2 scales more quickly and in a more granular way. Aurora Serverless v2 also has more compatibility with other Aurora features such as reader DB instances. Thus, if you're already familiar with Aurora, you don't have to learn as many new procedures or limitations to use Aurora Serverless v2 as with Aurora Serverless v1.

You can learn about Aurora Serverless v2 in Using Aurora Serverless v2 (p. 1961).
Region and version availability

Feature availability and support varies across specific versions of each Aurora database engine, and across AWS Regions. For more information on version and Region availability with Aurora and Aurora Serverless v1, see Aurora Serverless v1 (p. 56).

Advantages of Aurora Serverless v1

Aurora Serverless v1 provides the following advantages:

- **Simpler than provisioned** – Aurora Serverless v1 removes much of the complexity of managing DB instances and capacity.
- **Scalable** – Aurora Serverless v1 seamlessly scales compute and memory capacity as needed, with no disruption to client connections.
- **Cost-effective** – When you use Aurora Serverless v1, you pay only for the database resources that you consume, on a per-second basis.
- **Highly available storage** – Aurora Serverless v1 uses the same fault-tolerant, distributed storage system with six-way replication as Aurora to protect against data loss.

Use cases for Aurora Serverless v1

Aurora Serverless v1 is designed for the following use cases:

- **Infrequently used applications** – You have an application that is only used for a few minutes several times per day or week, such as a low-volume blog site. With Aurora Serverless v1, you pay for only the database resources that you consume on a per-second basis.
- **New applications** – You’re deploying a new application and you’re unsure about the instance size you need. By using Aurora Serverless v1, you can create a database endpoint and have the database autoscale to the capacity requirements of your application.
- **Variable workloads** – You’re running a lightly used application, with peaks of 30 minutes to several hours a few times each day, or several times per year. Examples are applications for human resources, budgeting, and operational reporting applications. With Aurora Serverless v1, you no longer need to provision for peak or average capacity.
- **Unpredictable workloads** – You’re running daily workloads that have sudden and unpredictable increases in activity. An example is a traffic site that sees a surge of activity when it starts raining. With Aurora Serverless v1, your database autoscales capacity to meet the needs of the application’s peak load and scales back down when the surge of activity is over.
- **Development and test databases** – Your developers use databases during work hours but don’t need them on nights or weekends. With Aurora Serverless v1, your database automatically shuts down when it’s not in use.
- **Multi-tenant applications** – With Aurora Serverless v1, you don’t have to individually manage database capacity for each application in your fleet. Aurora Serverless v1 manages individual database capacity for you.

Limitations of Aurora Serverless v1

The following limitations apply to Aurora Serverless v1:
• Aurora Serverless v1 doesn't support the following features:
  • Aurora global databases
  • Aurora Replicas
  • AWS Identity and Access Management (IAM) database authentication
  • Backtracking in Aurora
  • Database activity streams
  • Kerberos authentication
  • Performance Insights
  • RDS Proxy
  • Viewing logs in the AWS Management Console

• Connections to an Aurora Serverless v1 DB cluster are closed automatically if held open for longer than one day.

• All Aurora Serverless v1 DB clusters have the following limitations:
  • You can't export Aurora Serverless v1 snapshots to Amazon S3 buckets.
  • You can't use AWS Database Migration Service and Change Data Capture (CDC) with Aurora Serverless v1 DB clusters. Only provisioned Aurora DB clusters support CDC with AWS DMS as a source.
  • You can't save data to text files in Amazon S3 or load text file data to Aurora Serverless v1 from S3.
  • You can't attach an IAM role to an Aurora Serverless v1 DB cluster. However, you can load data to Aurora Serverless v1 from Amazon S3 by using the aws_s3 extension with the `aws_s3.table_import_from_s3` function and the `credentials` parameter. For more information, see Importing data from Amazon S3 into an Aurora PostgreSQL DB cluster (p. 1514).
  • When using the query editor, a Secrets Manager secret is created for the DB credentials to access the database. If you delete the credentials from the query editor, the associated secret is also deleted from Secrets Manager. You can't recover this secret after it's deleted.

• Aurora MySQL–based DB clusters running Aurora Serverless v1 don't support the following:
  • Invoking AWS Lambda functions from within your Aurora MySQL DB cluster. However, AWS Lambda functions can make calls to your Aurora Serverless v1 DB cluster.
  • Restoring a snapshot from a DB instance that isn't Aurora MySQL or RDS for MySQL.
  • Replicating data using replication based on binary logs (binlogs). This limitation is true regardless of whether your Aurora MySQL-based DB cluster Aurora Serverless v1 is the source or the target of the replication. To replicate data into an Aurora Serverless v1 DB cluster from a MySQL DB instance outside Aurora, such as one running on Amazon EC2, consider using AWS Database Migration Service. For more information, see the AWS Database Migration Service User Guide.
  • Creating users with host-based access (`'username' '@' IP_address'`). This is because Aurora Serverless v1 uses a router fleet between the client and the database host for seamless scaling. The IP address that the Aurora Serverless DB cluster sees is that of the router host and not your client. For more information, see Aurora Serverless v1 architecture (p. 2029).

Instead, use the wildcard (`'username' '@' %'`).

• Aurora PostgreSQL–based DB clusters running Aurora Serverless v1 have the following limitations:
  • Aurora PostgreSQL query plan management (apg_plan_management extension) isn't supported.
  • The logical replication feature available in Amazon RDS PostgreSQL and Aurora PostgreSQL isn't supported.
  • Outbound communications such as those enabled by Amazon RDS for PostgreSQL extensions aren't supported. For example, you can't access external data with the postgres_fdw/dblink extension. For more information about RDS PostgreSQL extensions, see PostgreSQL on Amazon RDS in the RDS User Guide.

• Currently, certain SQL queries and commands aren't recommended. These include session-level advisory locks, temporary relations, asynchronous notifications (LISTEN), and cursors with hold
(DECLARE name ... CURSOR WITH HOLD FOR query). Also, NOTIFY commands prevent scaling and aren't recommended.

For more information, see Autoscaling for Aurora Serverless v1 (p. 2030).

• You can't set the preferred automated backup window for an Aurora Serverless v1 DB cluster.
• You can set the maintenance window for an Aurora Serverless v1 DB cluster. For more information, see Adjusting the preferred DB cluster maintenance window (p. 350).

Configuration requirements for Aurora Serverless v1

When you create an Aurora Serverless v1 DB cluster, pay attention to the following requirements:

• Use these specific port numbers for each DB engine:
  • Aurora MySQL – 3306
  • Aurora PostgreSQL – 5432

• Create your Aurora Serverless v1 DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service. When you create an Aurora Serverless v1 DB cluster in your VPC, you consume two (2) of the fifty (50) Interface and Gateway Load Balancer endpoints allotted to your VPC. These endpoints are created automatically for you. To increase your quota, you can contact AWS Support. For more information, see Amazon VPC quotas.

• You can't give an Aurora Serverless v1 DB cluster a public IP address. You can access an Aurora Serverless v1 DB cluster only from within a VPC.

• Create subnets in different Availability Zones for the DB subnet group that you use for your Aurora Serverless v1 DB cluster. In other words, you can't have more than one subnet in the same Availability Zone.

• Changes to a subnet group used by an Aurora Serverless v1 DB cluster aren't applied to the cluster.

• You can access an Aurora Serverless v1 DB cluster from AWS Lambda. To do so, you must configure your Lambda function to run in the same VPC as your Aurora Serverless v1 DB cluster. For more information about working with AWS Lambda, see Configuring a Lambda function to access resources in an Amazon VPC in the AWS Lambda Developer Guide.

Using TLS/SSL with Aurora Serverless v1

By default, Aurora Serverless v1 uses the Transport Layer Security/Secure Sockets Layer (TLS/SSL) protocol to encrypt communications between clients and your Aurora Serverless v1 DB cluster. It supports TLS/SSL versions 1.0, 1.1, and 1.2. You don't need to configure your Aurora Serverless v1 DB cluster to use TLS/SSL.

However, the following limitations apply:

• TLS/SSL support for Aurora Serverless v1 DB clusters isn't currently available in the China (Beijing) AWS Region.

• When you create database users for an Aurora MySQL–based Aurora Serverless v1 DB cluster, don't use the REQUIRE clause for SSL permissions. Doing so prevents users from connecting to the Aurora DB instance.

• For both MySQL Client and PostgreSQL Client utilities, session variables that you might use in other environments have no effect when using TLS/SSL between client and Aurora Serverless v1.
For the MySQL Client, when connecting with TLS/SSL's VERIFY_IDENTITY mode, currently you need to use the MySQL 8.0-compatible mysql command. For more information, see Connecting to a DB instance running the MySQL database engine.

Depending on the client that you use to connect to Aurora Serverless v1 DB cluster, you might not need to specify TLS/SSL to get an encrypted connection. For example, to use the PostgreSQL Client to connect to an Aurora Serverless v1 DB cluster running Aurora PostgreSQL-Compatible Edition, connect as you normally do.

```
psql -h endpoint -U user
```

After you enter your password, the PostgreSQL Client shows you see the connection details, including the TLS/SSL version and cipher.

```
psql (12.5 (Ubuntu 12.5-0ubuntu0.20.04.1), server 10.12)
Type "help" for help.
```

**Important**

Aurora Serverless v1 uses the Transport Layer Security/Secure Sockets Layer (TLS/SSL) protocol to encrypt connections by default unless SSL/TLS is disabled by the client application. The TLS/SSL connection terminates at the router fleet. Communication between the router fleet and your Aurora Serverless v1 DB cluster occurs within the service's internal network boundary. You can check the status of the client connection to examine whether the connection to Aurora Serverless v1 is TLS/SSL encrypted. The PostgreSQL pg_stat_ssl and pg_stat_activity tables and its ssl_is_used function don't show the TLS/SSL state for the communication between the client application and Aurora Serverless v1. Similarly, the TLS/SSL state can't be derived from the MySQL status statement.

The Aurora cluster parameters `force_ssl` for PostgreSQL and `require_secure_transport` for MySQL formerly weren't supported for Aurora Serverless v1. These parameters are available now for Aurora Serverless v1. For a complete list of parameters supported by Aurora Serverless v1, call the `DescribeEngineDefaultClusterParameters` API operation. For more information on parameter groups and Aurora Serverless v1, see Parameter groups for Aurora Serverless v1 (p. 2034).

To use the MySQL Client to connect to an Aurora Serverless v1 DB cluster running Aurora MySQL-Compatible Edition, you specify TLS/SSL in your request. The following example includes the Amazon root CA 1 trust store downloaded from Amazon Trust Services, which is necessary for this connection to succeed.

```
mysql -h endpoint -P 3306 -u user -p --ssl-ca=amazon-root-CA-1.pem --ssl-mode=REQUIRED
```

When prompted, enter your password. Soon, the MySQL monitor opens. You can confirm that the session is encrypted by using the status command.

```
mysql> status
-----------------------
mysql  Ver 14.14 Distrib 5.5.62, for Linux (x86_64) using readline 5.1
Connection id:          19
Current database:       ***@*******
Current user:           ********
SSL:                    Cipher in use is ECDHE-RSA-AES256-SHA ...
```

To learn more about connecting to Aurora MySQL database with the MySQL Client, see Connecting to a DB instance running the MySQL database engine.
Aurora Serverless v1 supports all TLS/SSL modes available to the MySQL Client (mysql) and PostgreSQL Client (psql), including those listed in the following table.

<table>
<thead>
<tr>
<th>Description of TLS/SSL mode</th>
<th>mysql</th>
<th>psql</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connect without using TLS/SSL.</td>
<td>DISABLED</td>
<td>disable</td>
</tr>
<tr>
<td>Try the connection using TLS/SSL first, but fall back to non-SSL if necessary.</td>
<td>PREFERRED</td>
<td>prefer (default)</td>
</tr>
<tr>
<td>Enforce using TLS/SSL.</td>
<td>REQUIRED</td>
<td>require</td>
</tr>
<tr>
<td>Enforce TLS/SSL and verify the CA.</td>
<td>VERIFY_CA</td>
<td>verify-ca</td>
</tr>
<tr>
<td>Enforce TLS/SSL, verify the CA, and verify the CA hostname.</td>
<td>VERIFY_IDENTITY</td>
<td>verify-full</td>
</tr>
</tbody>
</table>

Aurora Serverless v1 uses wildcard certificates. If you specify the "verify CA" or the "verify CA and CA hostname" option when using TLS/SSL, first download the Amazon root CA 1 trust store from Amazon Trust Services. After doing so, you can identify this PEM-formatted file in your client command. To do so using the PostgreSQL Client:

For Linux, macOS, or Unix:

```
psql 'host=endpoint user=user sslmode=require sslrootcert=amazon-root-CA-1.pem dbname=db-name'
```

To learn more about working with the Aurora PostgreSQL database using the Postgres Client, see Connecting to a DB instance running the PostgreSQL database engine.

For more information about connecting to Aurora DB clusters in general, see Connecting to an Amazon Aurora DB cluster (p. 204).

**Supported cipher suites for connections to Aurora Serverless v1 DB clusters**

By using configurable cipher suites, you can have more control over the security of your database connections. You can specify a list of cipher suites that you want to allow to secure client TLS/SSL connections to your database. With configurable cipher suites, you can control the connection encryption that your database server accepts. Doing this prevents the use of ciphers that aren't secure or that are no longer used.

Aurora Serverless v1 DB clusters that are based on Aurora MySQL support the same cipher suites as Aurora MySQL provisioned DB clusters. For information about these cipher suites, see Configuring cipher suites for connections to Aurora MySQL DB clusters (p. 816).

Aurora Serverless v1 DB clusters that are based on Aurora PostgreSQL don't support cipher suites.

**How Aurora Serverless v1 works**

Following, you can learn how Aurora Serverless v1 works.
Aurora Serverless v1 architecture

The following image shows an overview of the Aurora Serverless v1 architecture.

Instead of provisioning and managing database servers, you specify Aurora capacity units (ACUs). Each ACU is a combination of approximately 2 gigabytes (GB) of memory, corresponding CPU, and networking. Database storage automatically scales from 10 gibibytes (GiB) to 128 tebibytes (TiB), the same as storage in a standard Aurora DB cluster.

You can specify the minimum and maximum ACU. The minimum Aurora capacity unit is the lowest ACU to which the DB cluster can scale down. The maximum Aurora capacity unit is the highest ACU to which the DB cluster can scale up. Based on your settings, Aurora Serverless v1 automatically creates scaling rules for thresholds for CPU utilization, connections, and available memory.

Aurora Serverless v1 manages the warm pool of resources in an AWS Region to minimize scaling time. When Aurora Serverless v1 adds new resources to the Aurora DB cluster, it uses the router fleet to switch
active client connections to the new resources. At any specific time, you are charged only for the ACUs that are being actively used in your Aurora DB cluster.

**Autoscaling for Aurora Serverless v1**

The capacity allocated to your Aurora Serverless v1 DB cluster seamlessly scales up and down based on the load generated by your client application. Here, load is CPU utilization and the number of connections. When capacity is constrained by either of these, Aurora Serverless v1 scales up. Aurora Serverless v1 also scales up when it detects performance issues that can be resolved by doing so.

You can view scaling events for your Aurora Serverless v1 cluster in the AWS Management Console. During autoscaling, Aurora Serverless v1 resets the EngineUptime metric. The value of the reset metric value doesn't mean that seamless scaling had problems or that Aurora Serverless v1 dropped connections. It's simply the starting point for uptime at the new capacity. To learn more about metrics, see [Monitoring metrics in an Amazon Aurora cluster](p. 509).

When your Aurora Serverless v1 DB cluster has no active connections, it can scale down to zero capacity (0 ACUs). To learn more, see [Pause and resume for Aurora Serverless v1](p. 2032).

When it does need to perform a scaling operation, Aurora Serverless v1 first tries to identify a *scaling point*, a moment when no queries are being processed. Aurora Serverless v1 might not be able to find a scaling point for the following reasons:

- Long-running queries
- In-progress transactions
- Temporary tables or table locks

To increase your Aurora Serverless v1 DB cluster's success rate when finding a scaling point, we recommend that you avoid long-running queries and long-running transactions. To learn more about operations that block scaling and how to avoid them, see [Best practices for working with Aurora Serverless v1](p. 2032).

By default, Aurora Serverless v1 tries to find a scaling point for 5 minutes (300 seconds). You can specify a different timeout period when you create or modify the cluster. The timeout period can be between 60 seconds and 10 minutes (600 seconds). If Aurora Serverless v1 can't find a scaling point within the specified period, the autoscaling operation times out.

By default, if autoscaling doesn't find a scaling point before timing out, Aurora Serverless v1 keeps the cluster at the current capacity. You can change this default behavior when you create or modify your Aurora Serverless v1 DB cluster by selecting the *Force the capacity change* option. For more information, see [Timeout action for capacity changes](p. 2030).

**Timeout action for capacity changes**

If autoscaling times out without finding a scaling point, by default Aurora keeps the current capacity. You can choose to have Aurora force the change by selecting the *Force the capacity change* option. This option is available in the *Autoscaling timeout and action* section of the *Create database* page when you create the cluster.

By default, the *Force the capacity change* option isn't selected. Keep this option clear to have your Aurora Serverless v1 DB cluster's capacity remain unchanged if the scaling operation times out without finding a scaling point.

Selecting this option causes your Aurora Serverless v1 DB cluster to enforce the capacity change, even without a scaling point. Before selecting this option, be aware of the consequences of this selection:
• Any in-process transactions are interrupted, and the following error message appears.

Aurora MySQL version 2 – ERROR 1105 (HY000): The last transaction was aborted due to Seamless
Scaling. Please retry.

You can resubmit the transactions as soon as your Aurora Serverless v1 DB cluster is available.
• Connections to temporary tables and locks are dropped.

We recommend that you select the **Force the capacity change** option only if your application can
recover from dropped connections or incomplete transactions.

The choices that you make in the AWS Management Console when you create an Aurora Serverless v1
DB cluster are stored in the `ScalingConfigurationInfo` object, in the `SecondsBeforeTimeout` and
`TimeoutAction` properties. The value of the `TimeoutAction` property is set to one of the following
values when you create your cluster:

• **RollbackCapacityChange** – This value is set when you select the **Roll back the capacity change**
option. This is the default behavior.
• **ForceApplyCapacityChange** – This value is set when you select the **Force the capacity change**
option.

You can get the value of this property on an existing Aurora Serverless v1 DB cluster by using the
`describe-db-clusters` AWS CLI command, as shown following.

For Linux, macOS, or Unix:

```bash
aws rds describe-db-clusters --region region --db-cluster-identifier your-cluster-name
--query '*[].{ScalingConfigurationInfo:ScalingConfigurationInfo}'
```

For Windows:

```bash
aws rds describe-db-clusters --region region --db-cluster-identifier your-cluster-name
--query '*[].{ScalingConfigurationInfo:ScalingConfigurationInfo}'
```

As an example, the following shows the query and response for an Aurora Serverless v1 DB cluster
named `west-coast-sles` in the US West (N. California) Region.

```bash
$ aws rds describe-db-clusters --region us-west-1 --db-cluster-identifier west-coast-sles
--query '*[].{ScalingConfigurationInfo:ScalingConfigurationInfo}'

[  
   {  
      "ScalingConfigurationInfo": {  
         "MinCapacity": 1,  
         "MaxCapacity": 64,  
         "AutoPause": false,  
         "SecondsBeforeTimeout": 300,  
         "SecondsUntilAutoPause": 300,  
         "TimeoutAction": "RollbackCapacityChange"  
      }  
   }  
]
```

As the response shows, this Aurora Serverless v1 DB cluster uses the default setting.
For more information, see Creating an Aurora Serverless v1 DB cluster (p. 2040). After creating your Aurora Serverless v1, you can modify the timeout action and other capacity settings at any time. To learn how, see Modifying an Aurora Serverless v1 DB cluster (p. 2051).

Pause and resume for Aurora Serverless v1

You can choose to pause your Aurora Serverless v1 DB cluster after a given amount of time with no activity. You specify the amount of time with no activity before the DB cluster is paused. When you select this option, the default inactivity time is five minutes, but you can change this value. This is an optional setting.

When the DB cluster is paused, no compute or memory activity occurs, and you are charged only for storage. If database connections are requested when an Aurora Serverless v1 DB cluster is paused, the DB cluster automatically resumes and services the connection requests.

When the DB cluster resumes activity, it has the same capacity as it had when Aurora paused the cluster. The number of ACUs depends on how much Aurora scaled the cluster up or down before pausing it.

**Note**

If a DB cluster is paused for more than seven days, the DB cluster might be backed up with a snapshot. In this case, Aurora restores the DB cluster from the snapshot when there is a request to connect to it.

Determining the maximum number of database connections for Aurora Serverless v1

The following examples are for an Aurora Serverless v1 DB cluster that’s compatible with MySQL 5.7. You can use a MySQL client or the query editor, if you’ve configured access to it. For more information, see Running queries in the query editor (p. 2096).

To find the maximum number of database connections

1. **Find the capacity range for your Aurora Serverless v1 DB cluster using the AWS CLI.**

   ```bash
   aws rds describe-db-clusters
   --db-cluster-identifier my-serverless-57-cluster
   --query 'DBClusters[*].ScalingConfigurationInfo[0]'
   ```

   The result shows that its capacity range is 1–4 ACUs.

   ```
   {
     "MinCapacity": 1,
     "AutoPause": true,
     "MaxCapacity": 4,
     "TimeoutAction": "RollbackCapacityChange",
     "SecondsUntilAutoPause": 3600
   }
   ```

2. **Run the following SQL query to find the maximum number of connections.**

   ```sql
   select @max_connections;
   ```

   The result shown is for the minimum capacity of the cluster, 1 ACU.

   ```
   @max_connections
   ```
3. Scale the cluster to 8–32 ACUs.

   For more information on scaling, see Modifying an Aurora Serverless v1 DB cluster (p. 2051).

4. Confirm the capacity range.

   ```json
   {
      "MinCapacity": 8,
      "AutoPause": true,
      "MaxCapacity": 32,
      "TimeoutAction": "RollbackCapacityChange",
      "SecondsUntilAutoPause": 3600
   }
   ```

5. Find the maximum number of connections.

   ```sql
   select @@max_connections;
   ```

   The result shown is for the minimum capacity of the cluster, 8 ACUs.

   ```
   @@max_connections
   1000
   ```

6. Scale the cluster to the maximum possible, 256–256 ACUs.

7. Confirm the capacity range.

   ```json
   {
      "MinCapacity": 256,
      "AutoPause": true,
      "MaxCapacity": 256,
      "TimeoutAction": "RollbackCapacityChange",
      "SecondsUntilAutoPause": 3600
   }
   ```

8. Find the maximum number of connections.

   ```sql
   select @@max_connections;
   ```

   The result shown is for 256 ACUs.

   ```
   @@max_connections
   6000
   ```

   **Note**

   The max_connections value doesn't scale linearly with the number of ACUs.

9. Scale the cluster back down to 1–4 ACUs.

   ```json
   {
      "MinCapacity": 1,
      "AutoPause": true,
      "MaxCapacity": 4,
      "TimeoutAction": "RollbackCapacityChange",
      "SecondsUntilAutoPause": 3600
   }
   ```

   This time, the max_connections value is for 4 ACUs.
Parameter groups for Aurora Serverless v1

When you create your Aurora Serverless v1 DB cluster, you choose a specific Aurora DB engine and an associated DB cluster parameter group. Unlike provisioned Aurora DB clusters, an Aurora Serverless v1 DB cluster has a single read/write DB instance that's configured with a DB cluster parameter group only—it doesn't have a separate DB parameter group. During autoscaling, Aurora Serverless v1 needs to be able to change parameters for the cluster to work best for the increased or decreased capacity. Thus, with an Aurora Serverless v1 DB cluster, some of the changes that you might make to parameters for a particular DB engine type might not apply.

For example, an Aurora PostgreSQL–based Aurora Serverless v1 DB cluster can't use apg_plan_mgmt.capture_plan_baselines and other parameters that might be used on provisioned Aurora PostgreSQL DB clusters for query plan management.

You can get a list of default values for the default parameter groups for the various Aurora DB engines by using the describe-engine-default-cluster-parameters CLI command and querying the AWS Region. The following are values that you can use for the --db-parameter-group-family option.

<table>
<thead>
<tr>
<th>Aurora MySQL version 2</th>
<th>aurora-mysql5.7</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora PostgreSQL version 11</td>
<td>aurora-postgresql11</td>
</tr>
<tr>
<td>Aurora PostgreSQL version 13</td>
<td>aurora-postgresql13</td>
</tr>
</tbody>
</table>

We recommend that you configure your AWS CLI with your AWS access key ID and AWS secret access key, and that you set your AWS Region before using AWS CLI commands. Providing the Region to your CLI configuration saves you from entering the --region parameter when running commands. To learn more about configuring AWS CLI, see Configuration basics in the AWS Command Line Interface User Guide.

The following example gets a list of parameters from the default DB cluster group for Aurora MySQL version 2.

For Linux, macOS, or Unix:

```
aws rds describe-engine-default-cluster-parameters \
   --db-parameter-group-family aurora-mysql5.7 --query \
   'EngineDefaults.Parameters[*].
   {ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} | ![contains(SupportedEngineModes, 'serverless') == 'true'] | ![].{param:ParameterName}'
```
For Windows:

```bash
aws rds describe-engine-default-cluster-parameters ^
--db-parameter-group-family aurora-mysql5.7 --query ^
"EngineDefaults.Parameters[*].{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} | ![contains(SupportedEngineModes, 'serverless') == 'true'] | [*].{param:ParameterName}" ^
--output text
```

### Modifying parameter values for Aurora Serverless v1

As explained in Working with parameter groups (p. 212), you can't directly change values in a default parameter group, regardless of its type (DB cluster parameter group, DB parameter group). Instead, you create a custom parameter group based on the default DB cluster parameter group for your Aurora DB engine and change settings as needed on that parameter group. For example, you might want to change some of the settings for your Aurora Serverless v1 DB cluster to log queries or to upload DB engine specific logs (p. 2036) to Amazon CloudWatch.

#### To create a custom DB cluster parameter group

1. Sign in to the AWS Management Console and then open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Choose **Parameter groups**.
3. Choose **Create parameter group** to open the Parameter group details pane.
4. Choose the appropriate default DB cluster group for the DB engine you want to use for your Aurora Serverless v1 DB cluster. Be sure that you choose the following options:
   a. For **Parameter group family**, choose the appropriate family for your chosen DB engine. Be sure that your choice has the prefix `aurora-` in its name.
   b. For **Type**, choose **DB Cluster Parameter Group**.
   c. For **Group name** and **Description**, enter meaningful names for you or others who might need to work with your Aurora Serverless v1 DB cluster and its parameters.
   d. Choose **Create**.

Your custom DB cluster parameter group is added to the list of parameter groups available in your AWS Region. You can use your custom DB cluster parameter group when you create new Aurora Serverless v1 DB clusters. You can also modify an existing Aurora Serverless v1 DB cluster to use your custom DB cluster parameter group. After your Aurora Serverless v1 DB cluster starts using your custom DB cluster parameter group, you can change values for dynamic parameters using either the AWS Management Console or the AWS CLI.

You can also use the console to view a side-by-side comparison of the values in your custom DB cluster parameter group compared to the default DB cluster parameter group, as shown in the following screenshot.
When you change parameter values on an active DB cluster, Aurora Serverless v1 starts a seamless scale in order to apply the parameter changes. If your Aurora Serverless v1 DB cluster is in a paused state, it resumes and starts scaling so that it can make the change. The scaling operation for a parameter group change always forces a capacity change (p. 2030), so be aware that modifying parameters might result in dropped connections if a scaling point can't be found during the scaling period.

Logging for Aurora Serverless v1

By default, error logs for Aurora Serverless v1 are enabled and automatically uploaded to Amazon CloudWatch. You can also have your Aurora Serverless v1 DB cluster upload Aurora database-engine specific logs to CloudWatch. To do this, enable configuration parameters in your custom DB cluster parameter group. Your Aurora Serverless v1 DB cluster then uploads all available logs to Amazon CloudWatch. At this point, you can use CloudWatch to analyze log data, create alarms, and view metrics.

For Aurora MySQL, you can turn on the following logs to have them automatically uploaded from your Aurora Serverless v1 DB cluster to Amazon CloudWatch.

<table>
<thead>
<tr>
<th>Aurora MySQL log</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>general_log</td>
<td>Creates the general log. Set to 1 to turn on. Default is off (0).</td>
</tr>
<tr>
<td>log_queries_not_using_indexes</td>
<td>Logs any queries to the slow query log that don't use an index. Default is off (0). Set to 1 to turn on this log.</td>
</tr>
<tr>
<td>long_query_time</td>
<td>Prevents fast-running queries from being logged in the slow query log. Can be set to a float between 0 and 3,1536,000. Default is 0 (not active).</td>
</tr>
<tr>
<td>server_audit_events</td>
<td>The list of events to capture in the logs. Supported values are CONNECT, QUERY,</td>
</tr>
</tbody>
</table>
Aurora MySQL log | Description
--- | ---
QUERY_DCL, QUERY_DDL, QUERY_DML, and TABLE. |  
server_audit_logging | Set to 1 to turn on server audit logging. If you turn this on, you can specify the audit events to send to CloudWatch by listing them in the server_audit_events parameter. 
slow_query_log | Creates a slow query log. Set to 1 to turn on the slow query log. Default is off (0).

For more information, see Using Advanced Auditing with an Amazon Aurora MySQL DB cluster (p. 980).

For Aurora PostgreSQL, you can enable the following logs on your Aurora Serverless v1 DB cluster and have them automatically uploaded to Amazon CloudWatch along with the regular error logs.

<table>
<thead>
<tr>
<th>Aurora PostgreSQL log</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>log_connections</td>
<td>Turned on by default and can't be changed. It logs details for all new client connections.</td>
</tr>
<tr>
<td>log_disconnections</td>
<td>Turned on by default and can't be changed. Logs all client disconnections.</td>
</tr>
<tr>
<td>log_lock_waits</td>
<td>Default is 0 (off). Set to 1 to log lock waits.</td>
</tr>
<tr>
<td>log_min_duration_statement</td>
<td>The minimum duration (in milliseconds) for a statement to run before it's logged.</td>
</tr>
<tr>
<td>log_min_messages</td>
<td>Sets the message levels that are logged. Supported values are debug5, debug4, debug3, debug2, debug1, info, notice, warning, error, log, fatal, panic. To log performance data to the postgres log, set the value to debug1.</td>
</tr>
<tr>
<td>log_temp_files</td>
<td>Logs the use of temporary files that are above the specified kilobytes (kB).</td>
</tr>
<tr>
<td>log_statement</td>
<td>Controls the specific SQL statements that get logged. Supported values are none, ddl, mod, and all. Default is none.</td>
</tr>
</tbody>
</table>

After you turn on logs for Aurora MySQL or Aurora PostgreSQL for your Aurora Serverless v1 DB cluster, you can view the logs in CloudWatch.

**Viewing Aurora Serverless v1 logs with Amazon CloudWatch**

Aurora Serverless v1 automatically uploads ("publishes") to Amazon CloudWatch all logs that are enabled in your custom DB cluster parameter group. You don't need to choose or specify the log types. Uploading logs starts as soon as you enable the log configuration parameter. If you later disable the log parameter, further uploads stop. However, all the logs that have already been published to CloudWatch remain until you delete them.
For more information on using CloudWatch with Aurora MySQL logs, see Monitoring log events in Amazon CloudWatch (p. 1086).

For more information about CloudWatch and Aurora PostgreSQL, see Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs (p. 1548).

To view logs for your Aurora Serverless v1 DB cluster

2. Choose your AWS Region.
3. Choose Log groups.
4. Choose your Aurora Serverless v1 DB cluster log from the list. For error logs, the naming pattern is as follows.

/aws/rds/cluster/cluster-name/error

For example, in the following screenshot you can find listings for logs published for an Aurora PostgreSQL Aurora Serverless v1 DB cluster named western-sles. You can also find several listings for Aurora MySQL Aurora Serverless v1 DB cluster, west-coast-sles. Choose the log that you’re interested in to start exploring its content.

Aurora Serverless v1 and maintenance

Maintenance for Aurora Serverless v1 DB cluster, such as applying the latest features, fixes, and security updates, is performed automatically for you. Aurora Serverless v1 has a maintenance window that you can view in the AWS Management Console in Maintenance & backups for your Aurora Serverless v1 DB cluster. You can find the date and time that maintenance might be performed and if any maintenance is pending for your Aurora Serverless v1 DB cluster, as shown following.
You can set the maintenance window when you create the Aurora Serverless v1 DB cluster, and you can modify the window later. For more information, see Adjusting the preferred DB cluster maintenance window (p. 350).

Maintenance windows are used for scheduled major version upgrades. Minor version upgrades and patches are applied immediately during scaling, which happens according to your setting for TimeoutAction. If TimeoutAction is set to RollbackCapacityChange, Aurora forcibly updates the cluster after 7 days from the first patch attempt, or earlier if needed.

Whenever possible, Aurora Serverless v1 performs maintenance in a nondisruptive manner. When maintenance is required, your Aurora Serverless v1 DB cluster scales its capacity to handle the necessary operations. Before scaling, Aurora Serverless v1 looks for a scaling point. It does so for up to seven days if necessary.

At the end of each day that Aurora Serverless v1 can't find a scaling point, it creates a cluster event. This event notifies you of the pending maintenance and the need to scale to perform maintenance. The notification includes the date when Aurora Serverless v1 can force the DB cluster to scale.

Until that time, your Aurora Serverless v1 DB cluster continues looking for a scaling point and behaves according to its TimeoutAction setting. That is, if it can't find a scaling point before timing out, it abandons the capacity change if it's configured to RollbackCapacityChange. Or it forces the change if it's set to ForceApplyCapacityChange. As with any change that's forced without an appropriate scaling point, this might interrupt your workload.

For more information, see Timeout action for capacity changes (p. 2030).

**Aurora Serverless v1 and failover**

If the DB instance for an Aurora Serverless v1 DB cluster becomes unavailable or the Availability Zone (AZ) it's in fails, Aurora recreates the DB instance in a different AZ. However, the Aurora Serverless v1 cluster isn't a Multi-AZ cluster. That's because it consists of a single DB instance in a single AZ. Thus, this failover mechanism takes longer than for an Aurora cluster with provisioned or Aurora Serverless v2 instances. The Aurora Serverless v1 failover time is undefined because it depends on demand and capacity availability in other AZs within the given AWS Region.

Because Aurora separates computation capacity and storage, the storage volume for the cluster is spread across multiple AZs. Your data remains available even if outages affect the DB instance or the associated AZ.

**Aurora Serverless v1 and snapshots**

The cluster volume for an Aurora Serverless v1 cluster is always encrypted. You can choose the encryption key, but you can't disable encryption. To copy or share a snapshot of an Aurora Serverless v1 cluster, encrypt the snapshot using your own AWS KMS key. For more information, see Copying a DB cluster snapshot (p. 442). To learn more about encryption and Amazon Aurora, see Encrypting an Amazon Aurora DB cluster (p. 2381)
Creating an Aurora Serverless v1 DB cluster

The following procedure creates an Aurora Serverless v1 cluster without any of your schema objects or data. If you want to create an Aurora Serverless v1 cluster that's a duplicate of an existing provisioned or Aurora Serverless v1 cluster, you can perform a snapshot restore or cloning operation instead. For those details, see Restoring from a DB cluster snapshot (p. 439) and Cloning a volume for an Amazon Aurora DB cluster (p. 303). You can't convert an existing provisioned cluster to Aurora Serverless v1. You also can't convert an existing Aurora Serverless v1 cluster back to a provisioned cluster.

When you create an Aurora Serverless v1 DB cluster, you can set the minimum and maximum capacity for the cluster. A capacity unit is equivalent to a specific compute and memory configuration. Aurora Serverless v1 creates scaling rules for thresholds for CPU utilization, connections, and available memory and seamlessly scales to a range of capacity units as needed for your applications. For more information see Aurora Serverless v1 architecture (p. 2029).

You can set the following specific values for your Aurora Serverless v1 DB cluster:

- **Minimum Aurora capacity unit** – Aurora Serverless v1 can reduce capacity down to this capacity unit.
- **Maximum Aurora capacity unit** – Aurora Serverless v1 can increase capacity up to this capacity unit.

You can also choose the following optional scaling configuration options:

- **Force scaling the capacity to the specified values when the timeout is reached** – You can choose this setting if you want Aurora Serverless v1 to force Aurora Serverless v1 to scale even if it can't find a scaling point before it times out. If you want Aurora Serverless v1 to cancel capacity changes if it can't find a scaling point, don't choose this setting. For more information, see Timeout action for capacity changes (p. 2030).
- **Pause compute capacity after consecutive minutes of inactivity** – You can choose this setting if you want Aurora Serverless v1 to scale to zero when there's no activity on your DB cluster for an amount of time you specify. With this setting enabled, your Aurora Serverless v1 DB cluster automatically resumes processing and scales to the necessary capacity to handle the workload when database traffic resumes. To learn more, see Pause and resume for Aurora Serverless v1 (p. 2032).

Before you can create an Aurora Serverless v1 DB cluster, you need an AWS account. You also need to have completed the setup tasks for working with Amazon Aurora. For more information, see Setting up your environment for Amazon Aurora (p. 119). You also need to complete other preliminary steps for creating any Aurora DB cluster. To learn more, see Creating an Amazon Aurora DB cluster (p. 179).

Aurora Serverless v1 is available in certain AWS Regions and for specific Aurora MySQL and Aurora PostgreSQL versions only. For more information, see Aurora Serverless v1 (p. 56).

**Note**

The cluster volume for an Aurora Serverless v1 cluster is always encrypted. When you create your Aurora Serverless v1 DB cluster, you can't turn off encryption, but you can choose to use your own encryption key. With Aurora Serverless v2, you can choose whether to encrypt the cluster volume.

You can create an Aurora Serverless v1 DB cluster with the AWS Management Console, the AWS CLI, or the RDS API.

**Note**

If you receive the following error message when trying to create your cluster, your account needs additional permissions.

Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.

See Using service-linked roles for Amazon Aurora (p. 2475) for more information.
You can’t directly connect to the DB instance on your Aurora Serverless v1 DB cluster. To connect to your Aurora Serverless v1 DB cluster, you use the database endpoint. You can find the endpoint for your Aurora Serverless v1 DB cluster on the Connectivity & security tab for your cluster in the AWS Management Console. For more information, see Connecting to an Amazon Aurora DB cluster (p. 204).

**Console**

Use the following general procedure. For more information on creating an Aurora DB cluster using the AWS Management Console, see Creating an Amazon Aurora DB cluster (p. 179).

**To create a new Aurora Serverless v1 DB cluster**

1. Sign in to the AWS Management Console.
2. Choose an AWS Region that supports Aurora Serverless v1.
3. Choose Amazon RDS from the AWS Services list.
4. Choose Create database.
5. On the Create database page:
   a. Choose Standard create for the database creation method.
   b. Continue creating the Aurora Serverless v1 DB cluster by using the steps from the following examples.

   **Note**
   If you choose a version of the DB engine that doesn't support Aurora Serverless v1, the Serverless option doesn't display for DB instance class.

**Example for Aurora MySQL**

Use the following procedure.

**To create an Aurora Serverless v1 DB cluster for Aurora MySQL**

1. For Engine type, choose Aurora (MySQL Compatible).
2. Choose the Aurora MySQL version, compatible with Aurora Serverless v1, that you want for your DB cluster. The supported versions are shown on the right side of the page.
3. For **DB instance class**, choose **Serverless**.

4. Set the **Capacity range** for the DB cluster.

5. Adjust values as needed in the **Additional scaling configuration** section of the page. To learn more about capacity settings, see [Autoscaling for Aurora Serverless v1](p. 2030).
To enable the Data API for your Aurora Serverless v1 DB cluster, select the Data API check box under Additional configuration in the Connectivity section.

To learn more about the Data API, see Using the Data API for Aurora Serverless v1 (p. 2063).

7. Choose other database settings as needed, then choose Create database.

Example for Aurora PostgreSQL

Use the following procedure.

To create an Aurora Serverless v1 DB cluster for Aurora PostgreSQL

1. For Engine type, choose Aurora (PostgreSQL Compatibile).
2. Choose the Aurora PostgreSQL version, compatible with Aurora Serverless v1, that you want for your DB cluster. The supported versions are shown on the right side of the page.
3. For **DB instance class**, choose **Serverless**.
4. If you chose an Aurora PostgreSQL version 13 minor version, choose **Serverless v1** from the menu.
   
   **Note**
   Aurora PostgreSQL version 13 also supports Aurora Serverless v2.
5. Set the **Capacity range** for the DB cluster.
6. Adjust values as needed in the **Additional scaling configuration** section of the page. To learn more about capacity settings, see [Autoscaling for Aurora Serverless v1](p. 2030).
7. To use the Data API with your Aurora Serverless v1 DB cluster, select the Data API check box under Additional configuration in the Connectivity section.

To learn more about the Data API, see Using the Data API for Aurora Serverless v1 (p. 2063).

8. Choose other database settings as needed, then choose Create database.

**AWS CLI**

To create a new Aurora Serverless v1 DB cluster with the AWS CLI, run the `create-db-cluster` command and specify serverless for the --engine-mode option.

You can optionally specify the --scaling-configuration option to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections.

The following command examples create a new Serverless DB cluster by setting the --engine-mode option to serverless. The examples also specify values for the --scaling-configuration option. These examples also specify the --manage-master-user-password option to generate the master user password and manage it in Secrets Manager. For more information, see Password management with Amazon Aurora and AWS Secrets Manager (p. 2371). Alternatively, you can use the --master-password option to specify and manage the password yourself.
Example for Aurora MySQL

The following command creates a new Aurora MySQL–compatible Serverless DB cluster. Valid capacity values for Aurora MySQL are 1, 2, 4, 8, 16, 32, 64, 128, and 256.

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster --db-cluster-identifier sample-cluster \
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.3 \
  --engine-mode serverless \
  --scaling-configuration MinCapacity=4,MaxCapacity=32,SecondsUntilAutoPause=1000,AutoPause=true \
  --master-username username --manage-master-user-password
```

For Windows:

```bash
aws rds create-db-cluster --db-cluster-identifier sample-cluster \
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.3 \
  --engine-mode serverless \
  --scaling-configuration MinCapacity=4,MaxCapacity=32,SecondsUntilAutoPause=1000,AutoPause=true \
  --master-username username --manage-master-user-password
```

Example for Aurora PostgreSQL

The following command creates a new PostgreSQL 13.9–compatible Serverless DB cluster. Valid capacity values for Aurora PostgreSQL are 2, 4, 8, 16, 32, 64, 192, and 384.

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster --db-cluster-identifier sample-cluster \
  --engine aurora-postgresql --engine-version 13.9 \
  --engine-mode serverless \
  --scaling-configuration MinCapacity=8,MaxCapacity=64,SecondsUntilAutoPause=1000,AutoPause=true \
  --master-username username --manage-master-user-password
```

For Windows:

```bash
aws rds create-db-cluster --db-cluster-identifier sample-cluster \
  --engine aurora-postgresql --engine-version 13.9 \
  --engine-mode serverless \
  --scaling-configuration MinCapacity=8,MaxCapacity=64,SecondsUntilAutoPause=1000,AutoPause=true \
  --master-username username --manage-master-user-password
```

RDS API

To create a new Aurora Serverless v1 DB cluster with the RDS API, run the `CreateDBCluster` operation and specify serverless for the `EngineMode` parameter.

You can optionally specify the `ScalingConfiguration` parameter to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.
Restoring an Aurora Serverless v1 DB cluster

You can configure an Aurora Serverless v1 DB cluster when you restore a provisioned DB cluster snapshot with the AWS Management Console, the AWS CLI, or the RDS API.

When you restore a snapshot to an Aurora Serverless v1 DB cluster, you can set the following specific values:

- **Minimum Aurora capacity unit** – Aurora Serverless v1 can reduce capacity down to this capacity unit.
- **Maximum Aurora capacity unit** – Aurora Serverless v1 can increase capacity up to this capacity unit.
- **Timeout action** – The action to take when a capacity modification times out because it can’t find a scaling point. Aurora Serverless v1 DB cluster can force your DB cluster to the new capacity settings if set the Force scaling the capacity to the specified values... option. Or, it can roll back the capacity change to cancel it if you don’t choose the option. For more information, see Timeout action for capacity changes (p. 2030).
- **Pause after inactivity** – The amount of time with no database traffic to scale to zero processing capacity. When database traffic resumes, Aurora automatically resumes processing capacity and scales to handle the traffic.

For general information about restoring a DB cluster from a snapshot, see Restoring from a DB cluster snapshot (p. 439).

Console

You can restore a DB cluster snapshot to an Aurora DB cluster with the AWS Management Console.

To restore a DB cluster snapshot to an Aurora DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region that hosts your source DB cluster.
3. In the navigation pane, choose Snapshots, and choose the DB cluster snapshot that you want to restore.
4. For Actions, choose Restore Snapshot.
5. On the Restore DB Cluster page, choose Serverless for Capacity type.
6. In the **DB cluster identifier** field, type the name for your restored DB cluster, and complete the other fields.

7. In the **Capacity settings** section, modify the scaling configuration.
Choose **Restore DB Cluster**.

To connect to an Aurora Serverless v1 DB cluster, use the database endpoint. For details, see the instructions in **Connecting to an Amazon Aurora DB cluster (p. 204)**.

**Note**

If you encounter the following error message, your account requires additional permissions: Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later. For more information, see **Using service-linked roles for Amazon Aurora (p. 2475)**.

**AWS CLI**

You can configure an Aurora Serverless DB cluster when you restore a provisioned DB cluster snapshot with the AWS Management Console, the AWS CLI, or the RDS API.

When you restore a snapshot to an Aurora Serverless DB cluster, you can set the following specific values:

- **Minimum Aurora capacity unit** – Aurora Serverless can reduce capacity down to this capacity unit.
- **Maximum Aurora capacity unit** – Aurora Serverless can increase capacity up to this capacity unit.
- **Timeout action** – The action to take when a capacity modification times out because it can't find a scaling point. Aurora Serverless v1 DB cluster can force your DB cluster to the new capacity settings if set the **Force scaling the capacity to the specified values**... option. Or, it can roll back the capacity...
change to cancel it if you don't choose the option. For more information, see Timeout action for capacity changes (p. 2030).

- **Pause after inactivity** – The amount of time with no database traffic to scale to zero processing capacity. When database traffic resumes, Aurora automatically resumes processing capacity and scales to handle the traffic.

**Note**
The version of the DB cluster snapshot must be compatible with Aurora Serverless v1. For the list of supported versions, see Aurora Serverless v1 (p. 56).

To restore a snapshot to an Aurora Serverless v1 cluster with MySQL 5.7 compatibility, include the following additional parameters:

- `--engine aurora-mysql`
- `--engine-version 5.7`

The `--engine` and `--engine-version` parameters let you create a MySQL 5.7-compatible Aurora Serverless v1 cluster from a MySQL 5.6-compatible Aurora or Aurora Serverless v1 snapshot. The following example restores a snapshot from a MySQL 5.6-compatible cluster named `mydbclustersnapshot` to a MySQL 5.7-compatible Aurora Serverless v1 cluster named `mynewdbcluster`.

For Linux, macOS, or Unix:

```bash
aws rds restore-db-cluster-from-snapshot
  --db-cluster-identifier mynewdbcluster
  --snapshot-identifier mydbclustersnapshot
  --engine-mode serverless
  --engine aurora-mysql
  --engine-version 5.7
```

For Windows:

```bash
aws rds restore-db-cluster-from-snapshot
  --db-instance-identifier mynewdbcluster
  --db-snapshot-identifier mydbclustersnapshot
  --engine aurora-mysql
  --engine-version 5.7
```

You can optionally specify the `--scaling-configuration` option to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

In the following example, you restore from a previously created DB cluster snapshot named `mydbclustersnapshot` to a new DB cluster named `mynewdbcluster`. You set the `--scaling-configuration` so that the new Aurora Serverless v1 DB cluster can scale from 8 ACUs to 64 ACUs (Aurora capacity units) as needed to process the workload. After processing completes and after 1000 seconds with no connections to support, the cluster shuts down until connection requests prompt it to restart.

For Linux, macOS, or Unix:

```bash
aws rds restore-db-cluster-from-snapshot
```
RDS API

To configure an Aurora Serverless v1 DB cluster when you restore from a DB cluster using the RDS API, run the `RestoreDBClusterFromSnapshot` operation and specify `serverless` for the `EngineMode` parameter.

You can optionally specify the `ScalingConfiguration` parameter to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

Modifying an Aurora Serverless v1 DB cluster

After you configure an Aurora Serverless v1 DB cluster, you can modify certain properties with the AWS Management Console, the AWS CLI, or the RDS API. Most of the properties you can modify are the same as for other kinds of Aurora clusters.

The most relevant changes for Aurora Serverless v1 are the following:

- Modifying the scaling configuration (p. 2051)
- Upgrading the major version (p. 2053)
- Converting from Aurora Serverless v1 to provisioned (p. 2054)

Modifying the scaling configuration of an Aurora Serverless v1 DB cluster

You can set the minimum and maximum capacity for the DB cluster. Each capacity unit is equivalent to a specific compute and memory configuration. Aurora Serverless automatically creates scaling rules for thresholds for CPU utilization, connections, and available memory. You can also set whether Aurora Serverless pauses the database when there's no activity and then resumes when activity begins again.

You can set the following specific values for the scaling configuration:

- **Minimum Aurora capacity unit** – Aurora Serverless can reduce capacity down to this capacity unit.
- **Maximum Aurora capacity unit** – Aurora Serverless can increase capacity up to this capacity unit.
- **Autoscaling timeout and action** – This section specifies how long Aurora Serverless waits to find a scaling point before timing out. It also specifies the action to take when a capacity modification times out because it can't find a scaling point. Aurora can force the capacity change to set the capacity to
the specified value as soon as possible. Or, it can roll back the capacity change to cancel it. For more information, see "Timeout action for capacity changes (p. 2030)."

- **Pause after inactivity** – Use the optional Scale the capacity to 0 ACUs when cluster is idle setting to scale the database to zero processing capacity while it's inactive. When database traffic resumes, Aurora automatically resumes processing capacity and scales to handle the traffic.

**Console**

You can modify the scaling configuration of an Aurora DB cluster with the AWS Management Console.

**To modify an Aurora Serverless v1 DB cluster**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the Aurora Serverless v1 DB cluster that you want to modify.
4. For **Actions**, choose **Modify cluster**.
5. In the **Capacity settings** section, modify the scaling configuration.
6. Choose **Continue**.
7. On the **Modify DB cluster** page, review your modifications, then choose when to apply them.
8. Choose **Modify cluster**.

**AWS CLI**

To modify the scaling configuration of an Aurora Serverless v1 DB cluster using the AWS CLI, run the `modify-db-cluster` AWS CLI command. Specify the `--scaling-configuration` option to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

In this example, you modify the scaling configuration of an Aurora Serverless v1 DB cluster named `sample-cluster`.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster \
  --db-cluster-identifier sample-cluster \
  --scaling-configuration
  MinCapacity=8,MaxCapacity=64,SecondsUntilAutoPause=500,TimeoutAction='ForceApplyCapacityChange',AutoPause=true
```

For Windows:

```bash
aws rds modify-db-cluster ^
  --db-cluster-identifier sample-cluster ^
  --scaling-configuration
  MinCapacity=8,MaxCapacity=64,SecondsUntilAutoPause=500,TimeoutAction='ForceApplyCapacityChange',AutoPause=true
```

**RDS API**

You can modify the scaling configuration of an Aurora DB cluster with the `ModifyDBCluster` API operation. Specify the `ScalingConfiguration` parameter to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections. Valid capacity values include the following:
• Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
• Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

Upgrading the major version of an Aurora Serverless v1 DB cluster

You can upgrade the major version for an Aurora Serverless v1 DB cluster compatible with PostgreSQL 11 to a corresponding PostgreSQL 13–compatible version.

Console

You can perform an in-place upgrade of an Aurora Serverless v1 DB cluster using the AWS Management Console.

To upgrade an Aurora Serverless v1 DB cluster

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the Aurora Serverless v1 DB cluster that you want to upgrade.
4. For Actions, choose Modify cluster.
5. For Version, choose an Aurora PostgreSQL version 13 version number.

The following example shows an in-place upgrade from Aurora PostgreSQL 11.16 to 13.9.
If you perform a major version upgrade, leave all of the other properties the same. To change any other properties, do another Modify operation after the upgrade finishes.

6. Choose Continue.
7. On the Modify DB cluster page, review your modifications, then choose when to apply them.
8. Choose Modify cluster.

AWS CLI

To perform an in-place upgrade from a PostgreSQL 11–compatible Aurora Serverless v1 DB cluster to a PostgreSQL 13–compatible one, specify the --engine-version parameter with an Aurora PostgreSQL version 13 version number that's compatible with Aurora Serverless v1. Also include the --allow-major-version-upgrade parameter.

In this example, you modify the major version of a PostgreSQL 11–compatible Aurora Serverless v1 DB cluster named sample-cluster. Doing so performs an in-place upgrade to a PostgreSQL 13–compatible Aurora Serverless v1 DB cluster.

```bash
aws rds modify-db-cluster --db-cluster-identifier sample-cluster --engine-version 13.9 --allow-major-version-upgrade
```

For Windows:

```bash
aws rds modify-db-cluster --db-cluster-identifier sample-cluster --engine-version 13.9 --allow-major-version-upgrade
```

RDS API

To perform an in-place upgrade from a PostgreSQL 11–compatible Aurora Serverless v1 DB cluster to a PostgreSQL 13–compatible one, specify the EngineVersion parameter with an Aurora PostgreSQL version 13 version number that's compatible with Aurora Serverless v1. Also include the AllowMajorVersionUpgrade parameter.

Converting an Aurora Serverless v1 DB cluster to provisioned

You can convert an Aurora Serverless v1 DB cluster to a provisioned DB cluster. To perform the conversion, you change the DB instance class to Provisioned. You can use this conversion as part of upgrading your DB cluster from Aurora Serverless v1 to Aurora Serverless v2. For more information, see Upgrading from an Aurora Serverless v1 cluster to Aurora Serverless v2 (p. 1983).

The conversion process creates a reader DB instance in the DB cluster, promotes the reader instance to a writer instance, and then deletes the original Aurora Serverless v1 instance. When you convert the DB cluster, you can't perform any other modifications at the same time, such as changing the DB engine version or DB cluster parameter group. The conversion operation is applied immediately, and can't be undone.

During the conversion, a backup DB cluster snapshot is taken of the DB cluster in case an error occurs. The identifier for the DB cluster snapshot has the form pre-modify-engine-mode-DB_cluster_identifier-timestamp.

Aurora uses the current default DB minor engine version for the provisioned DB cluster.
If you don’t provide a DB instance class for your converted DB cluster, Aurora recommends one based on the maximum capacity of the original Aurora Serverless v1 DB cluster. The recommended capacity to instance class mappings are shown in the following table.

<table>
<thead>
<tr>
<th>Serverless maximum capacity (ACUs)</th>
<th>Provisioned DB instance class</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>db.t3.small</td>
</tr>
<tr>
<td>2</td>
<td>db.t3.medium</td>
</tr>
<tr>
<td>4</td>
<td>db.t3.large</td>
</tr>
<tr>
<td>8</td>
<td>db.r5.large</td>
</tr>
<tr>
<td>16</td>
<td>db.r5.xlarge</td>
</tr>
<tr>
<td>32</td>
<td>db.r5.2xlarge</td>
</tr>
<tr>
<td>64</td>
<td>db.r5.4xlarge</td>
</tr>
<tr>
<td>128</td>
<td>db.r5.8xlarge</td>
</tr>
<tr>
<td>192</td>
<td>db.r5.12xlarge</td>
</tr>
<tr>
<td>256</td>
<td>db.r5.16xlarge</td>
</tr>
<tr>
<td>384</td>
<td>db.r5.24xlarge</td>
</tr>
</tbody>
</table>

**Note**
Depending on the DB instance class you choose, and your database usage, you might see different costs for a provisioned DB cluster compared to Aurora Serverless v1.

If you convert your Aurora Serverless v1 DB cluster to a burstable (db.t*) DB instance class, you might incur additional costs for using the DB cluster. For more information, see [DB instance class types](#) (p. 84).

**AWS CLI**

To convert an Aurora Serverless v1 DB cluster to a provisioned cluster, run the `modify-db-cluster` AWS CLI command.

The following parameters are required:

- `--db-cluster-identifier` – The Aurora Serverless v1 DB cluster that you’re converting to provisioned.
- `--engine-mode` – Use the value `provisioned`.
- `--allow-engine-mode-change`
- `--db-cluster-instance-class` – Choose the DB instance class for the provisioned DB cluster based on the capacity of the Aurora Serverless v1 DB cluster.

In this example, you convert an Aurora Serverless v1 DB cluster named `sample-cluster` and use the `db.r5.xlarge` DB instance class.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster \
  --db-cluster-identifier sample-cluster \
  --engine-mode provisioned \
  --allow-engine-mode-change \
```
Scaling Aurora Serverless v1 DB cluster capacity manually

Typically, Aurora Serverless v1 DB clusters scale seamlessly based on the workload. However, capacity might not always scale fast enough to meet sudden extremes, such as an exponential increase in transactions. In such cases you can initiate the scaling operation manually by setting a new capacity value. After you set the capacity explicitly, Aurora Serverless v1 automatically scales the DB cluster. It does so based on the cooldown period for scaling down.

You can explicitly set the capacity of an Aurora Serverless v1 DB cluster to a specific value with the AWS Management Console, the AWS CLI, or the RDS API.

Console

You can set the capacity of an Aurora DB cluster with the AWS Management Console.

To modify an Aurora Serverless v1 DB cluster

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the Aurora Serverless v1 DB cluster that you want to modify.
4. For Actions, choose Set capacity.
5. In the Scale database capacity window, choose the following:
   a. For the Scale DB cluster to drop-down selector, choose the new capacity that you want for your DB cluster.
   b. For the If a seamless scaling point cannot be found check box, choose the behavior that you want for your Aurora Serverless v1 DB cluster's TimeoutAction setting, as follows:
      • Clear this option if you want your capacity to remain unchanged if Aurora Serverless v1 can't find a scaling point before timing out.
• Select this option if you want to force your Aurora Serverless v1 DB cluster change its capacity even if it can't find a scaling point before timing out. This option can result Aurora Serverless v1 dropping connections that prevent it from finding a scaling point.

c. For **seconds**, enter the amount of time you want to allow your Aurora Serverless v1 DB cluster to look for a scaling point before timing out. You can specify anywhere from 10 seconds to 600 seconds (10 minutes). The default is five minutes (300 seconds). This following example forces the Aurora Serverless v1 DB cluster to scale down to 2 ACUs even if it can't find a scaling point within five minutes.

6. Choose **Apply**.

To learn more about scaling points, **TimeoutAction**, and cooldown periods, see [Autoscaling for Aurora Serverless v1](p. 2030).

**AWS CLI**

To set the capacity of an Aurora Serverless v1 DB cluster using the AWS CLI, run the `modify-current-db-cluster-capacity` AWS CLI command, and specify the `--capacity` option. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

In this example, you set the capacity of an Aurora Serverless v1 DB cluster named `sample-cluster` to **64**.

```
aws rds modify-current-db-cluster-capacity --db-cluster-identifier sample-cluster --capacity 64
```
RDS API

You can set the capacity of an Aurora DB cluster with the `ModifyCurrentDBClusterCapacity` API operation. Specify the `Capacity` parameter. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

Viewing Aurora Serverless v1 DB clusters

After you create one or more Aurora Serverless v1 DB clusters, you can view which DB clusters are type `Serverless` and which are type `Instance`. You can also view the current number of Aurora capacity units (ACUs) each Aurora Serverless v1 DB cluster is using. Each ACU is a combination of processing (CPU) and memory (RAM) capacity.

To view your Aurora Serverless v1 DB clusters

1. Sign in to the AWS Management Console and open the Amazon RDS console at `https://console.aws.amazon.com/rds/`.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you created the Aurora Serverless v1 DB clusters.
3. In the navigation pane, choose Databases.

   For each DB cluster, the DB cluster type is shown under Role. The Aurora Serverless v1 DB clusters show `Serverless` for the type. You can view an Aurora Serverless v1 DB cluster's current capacity under Size.

4. Choose the name of an Aurora Serverless v1 DB cluster to display its details.

   On the Connectivity & security tab, note the database endpoint. Use this endpoint to connect to your Aurora Serverless v1 DB cluster.
Choose the **Configuration** tab to view the capacity settings.

A *scaling event* is generated when the DB cluster scales up, scales down, pauses, or resumes. Choose the **Logs & events** tab to see recent events. The following image shows examples of these events.

### Monitoring capacity and scaling events for your Aurora Serverless v1 DB cluster

You can view your Aurora Serverless v1 DB cluster in CloudWatch to monitor the capacity allocated to the DB cluster with the `ServerlessDatabaseCapacity` metric. You can also monitor all of the standard Aurora CloudWatch metrics, such as `CPUUtilization`, `DatabaseConnections`, `Queries`, and so on.

You can have Aurora publish some or all database logs to CloudWatch. You select the logs to publish by enabling the configuration parameters such as `general_log` and `slow_query_log` in the DB cluster parameter group (p. 2034) associated with the Aurora Serverless v1 cluster. Unlike provisioned clusters, Aurora Serverless v1 clusters don't require you to specify in the DB cluster settings which log types to upload to CloudWatch. Aurora Serverless v1 clusters automatically upload all the available logs. When you disable a log configuration parameter, publishing of the log to CloudWatch stops. You can also delete the logs in CloudWatch if they are no longer needed.

To get started with Amazon CloudWatch for your Aurora Serverless v1 DB cluster, see Viewing Aurora Serverless v1 logs with Amazon CloudWatch (p. 2037). To learn more about how to monitor Aurora DB clusters through CloudWatch, see Monitoring log events in Amazon CloudWatch (p. 1086).

To connect to an Aurora Serverless v1 DB cluster, use the database endpoint. For more information, see Connecting to an Amazon Aurora DB cluster (p. 204).

**Note**

You can't connect directly to specific DB instances in your Aurora Serverless v1 DB clusters.

### Deleting an Aurora Serverless v1 DB cluster

When you create an Aurora Serverless v1 DB cluster using the AWS Management Console, the **Enable default protection** option is enabled by default unless you deselect it. That means that you can't
immediately delete an Aurora Serverless v1 DB cluster that has Deletion protection enabled. To delete Aurora Serverless v1 DB clusters that have deletion protection by using the AWS Management Console, you first modify the cluster to remove this protection. For information about using the AWS CLI for this task, see AWS CLI (p. 2061).

To disable deletion protection using the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose DB clusters.
3. Choose your Aurora Serverless v1 DB cluster from the list.
4. Choose Modify to open your DB cluster's configuration. The Modify DB cluster page opens the Settings, Capacity settings, and other configuration details for your Aurora Serverless v1 DB cluster. Deletion protection is in the Additional configuration section.
5. Clear the Enable deletion protection check box in the Additional configuration properties card.
6. Choose Continue. The Summary of modifications appears.
7. Choose Modify cluster to accept the summary of modifications. You can also choose Back to modify your changes or Cancel to discard your changes.

After deletion protection is no longer active, you can delete your Aurora Serverless v1 DB cluster by using the AWS Management Console.

Console

To delete an Aurora Serverless v1 DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the Resources section, choose DB Clusters.
3. Choose the Aurora Serverless v1 DB cluster that you want to delete.
4. For Actions, choose Delete. You're prompted to confirm that you want to delete your Aurora Serverless v1 DB cluster.
5. We recommend that you keep the preselected options:
   - Yes for Create final snapshot?
   - Your Aurora Serverless v1 DB cluster name plus -final-snapshot for Final snapshot name. However, you can change the name for your final snapshot in this field.

   ![Image of the delete confirmation prompt]

If you choose No for Create final snapshot? you can't restore your DB cluster using snapshots or point-in-time recovery.
6. Choose Delete DB cluster.
Aurora Serverless v1 deletes your DB cluster. If you chose to have a final snapshot, you see your Aurora Serverless v1 DB cluster’s status change to “Backing-up” before it’s deleted and no longer appears in the list.

**AWS CLI**

Before you begin, configure your AWS CLI with your AWS Access Key ID, AWS Secret Access Key, and the AWS Region where your Aurora Serverless v1 DB cluster is. For more information, see [Configuration basics](https://docs.aws.amazon.com/cli/latest/userguide/) in the AWS Command Line Interface User Guide.

You can't delete an Aurora Serverless v1 DB cluster until after you first disable deletion protection for clusters configured with this option. If you try to delete a cluster that has this protection option enabled, you see the following error message.

```
An error occurred (InvalidParameterCombination) when calling the DeleteDBCluster operation: Cannot delete protected Cluster, please disable deletion protection and try again.
```

You can change your Aurora Serverless v1 DB cluster's deletion-protection setting by using the `modify-db-cluster` AWS CLI command as shown in the following:

```
aws rds modify-db-cluster --db-cluster-identifier your-cluster-name --no-deletion-protection
```

This command returns the revised properties for the specified DB cluster. You can now delete your Aurora Serverless v1 DB cluster.

We recommend that you always create a final snapshot whenever you delete an Aurora Serverless v1 DB cluster. The following example of using the AWS CLI `delete-db-cluster` shows you how. You provide the name of your DB cluster and a name for the snapshot.

For Linux, macOS, or Unix:

```
aws rds delete-db-cluster --db-cluster-identifier your-cluster-name --no-skip-final-snapshot --final-db-snapshot-identifier name-your-snapshot
```

For Windows:

```
aws rds delete-db-cluster --db-cluster-identifier your-cluster-name --no-skip-final-snapshot --final-db-snapshot-identifier name-your-snapshot
```

### Aurora Serverless v1 and Aurora database engine versions

Aurora Serverless v1 is available in certain AWS Regions and for specific Aurora MySQL and Aurora PostgreSQL versions only. For the current list of AWS Regions that support Aurora Serverless v1 and the specific Aurora MySQL and Aurora PostgreSQL versions available in each Region, see [Aurora Serverless v1](p. 56).

Aurora Serverless v1 uses its associated Aurora database engine to identify specific supported releases for each database engine supported, as follows:
• Aurora MySQL Serverless
• Aurora PostgreSQL Serverless

When minor releases of the database engines become available for Aurora Serverless v1, they are applied automatically in the various AWS Regions where Aurora Serverless v1 is available. In other words, you don’t need to upgrade your Aurora Serverless v1 DB cluster to get a new minor release for your cluster’s DB engine when it’s available for Aurora Serverless v1.

Aurora MySQL Serverless

If you want to use Aurora MySQL-Compatible Edition for your Aurora Serverless v1 DB cluster, you can choose an Aurora MySQL version 2 that’s compatible with MySQL 5.7. To learn about enhancements and bug fixes for Aurora MySQL version 2, see Database engine updates for Amazon Aurora MySQL version 2 in the Release Notes for Aurora MySQL.

Aurora PostgreSQL Serverless

If you want to use Aurora PostgreSQL for your Aurora Serverless v1 DB cluster, you can choose among Aurora PostgreSQL 11-compatible and 13-compatible versions. Minor releases for Aurora PostgreSQL-Compatible Edition include only changes that are backward-compatible. Your Aurora Serverless v1 DB cluster is transparently upgraded when an Aurora PostgreSQL minor release becomes available for Aurora Serverless v1 in your AWS Region.

For example, the minor version Aurora PostgreSQL 11.16 release was transparently applied to all Aurora Serverless v1 DB clusters running the previous Aurora PostgreSQL version. For more information about the Aurora PostgreSQL version 11.16 update, see PostgreSQL 11.16 in the Release Notes for Aurora PostgreSQL.
Using the Data API for Aurora Serverless v1

By using the Data API for Aurora Serverless v1, you can work with a web-services interface to your Aurora Serverless v1 DB cluster. The Data API doesn't require a persistent connection to the DB cluster. Instead, it provides a secure HTTP endpoint and integration with AWS SDKs. You can use the endpoint to run SQL statements without managing connections.

All calls to the Data API are synchronous. By default, a call times out if it's not finished processing within 45 seconds. However, you can continue running a SQL statement if the call times out by using the `continueAfterTimeout` parameter. For an example, see Running a SQL transaction (p. 2082).

Users don't need to pass credentials with calls to the Data API, because the Data API uses database credentials stored in AWS Secrets Manager. To store credentials in Secrets Manager, users must be granted the appropriate permissions to use Secrets Manager, and also the Data API. For more information about authorizing users, see Authorizing access to the Data API (p. 2064).

You can also use Data API to integrate Aurora Serverless v1 with other AWS applications such as AWS Lambda, AWS AppSync, and AWS Cloud9. The API provides a more secure way to use AWS Lambda. It enables you to access your DB cluster without your needing to configure a Lambda function to access resources in a virtual private cloud (VPC). For more information, see AWS Lambda, AWS AppSync, and AWS Cloud9.

You can enable the Data API when you create the Aurora Serverless v1 cluster. You can also modify the configuration later. For more information, see Enabling the Data API (p. 2066).

After you enable the Data API, you can also use the query editor for Aurora Serverless v1. For more information, see Using the query editor for Aurora Serverless v1 (p. 2095).

**Note**
Currently, the Data API and query editor aren't supported for Aurora Serverless v2.

**Topics**
- Region and version availability (p. 2063)
- Authorizing access to the Data API (p. 2064)
- Enabling the Data API (p. 2066)
- Creating an Amazon VPC endpoint for the Data API (AWS PrivateLink) (p. 2068)
- Calling the Data API (p. 2070)
- Using the Java client library for Data API (p. 2084)
- Processing query results in JSON format (p. 2086)
- Troubleshooting Data API issues (p. 2091)
- Logging Data API calls with AWS CloudTrail (p. 2092)

Region and version availability

The Data API is available only for Aurora Serverless v1 DB clusters using specific Aurora MySQL and Aurora PostgreSQL versions, and in specific AWS Regions. For more information, see Data API for Aurora Serverless v1 (p. 59).
If you require cryptographic modules validated by FIPS 140-2 when accessing the Data API through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.

Authorizing access to the Data API

Users can invoke Data API operations only if they are authorized to do so. You can give a user permission to use the Data API by attaching an AWS Identity and Access Management (IAM) policy that defines their privileges. You can also attach the policy to a role if you're using IAM roles. An AWS managed policy, AmazonRDSDataFullAccess, includes permissions for the RDS Data API.

The AmazonRDSDataFullAccess policy also includes permissions for the user to get the value of a secret from AWS Secrets Manager. Users need to use Secrets Manager to store secrets that they can use in their calls to the Data API. Using secrets means that users don't need to include database credentials for the resources that they target in their calls to the Data API. The Data API transparently calls Secrets Manager, which allows (or denies) the user's request for the secret. For information about setting up secrets to use with the Data API, see Storing database credentials in AWS Secrets Manager (p. 2066).

The AmazonRDSDataFullAccess policy provides complete access (through the Data API) to resources. You can narrow the scope by defining your own policies that specify the Amazon Resource Name (ARN) of a resource.

For example, the following policy shows an example of the minimum required permissions for a user to access the Data API for the DB cluster identified by its ARN. The policy includes the needed permissions to access Secrets Manager and get authorization to the DB instance for the user.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "SecretsManagerDbCredentialsAccess",
         "Effect": "Allow",
         "Action": ["secretsmanager:GetSecretValue"],
         "Resource": "arn:aws:secretsmanager:*:*:secret:rds-db-credentials/*"
      },
      {
         "Sid": "RDSDataServiceAccess",
         "Effect": "Allow",
      }
   ]
}
```

We recommend that you use a specific ARN for the "Resources" element in your policy statements (as shown in the example) rather than a wildcard (*).

Working with tag-based authorization

The Data API and Secrets Manager both support tag-based authorization. Tags are key-value pairs that label a resource, such as an RDS cluster, with an additional string value, for example:
You can apply tags to your resources for cost allocation, operations support, access control, and many other reasons. If you don't already have tags on your resources and you want to apply them, you can learn more at Tagging Amazon RDS resources. You can use the tags in your policy statements to limit access to the RDS clusters that are labeled with these tags. As an example, an Aurora DB cluster might have tags that identify its environment as either production or development.

The following example shows how you can use tags in your policy statements. This statement requires that both the cluster and the secret passed in the Data API request have an environment:production tag.

Here's how the policy gets applied: When a user makes a call using the Data API, the request is sent to the service. The Data API first verifies that the cluster ARN passed in the request is tagged with environment:production. It then calls Secrets Manager to retrieve the value of the user's secret in the request. Secrets Manager also verifies that the user's secret is tagged with environment:production. If so, Data API then uses the retrieved value for the user's DB password. Finally, if that's also correct, the Data API request is invoked successfully for the user.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "SecretsManagerDbCredentialsAccess",
         "Effect": "Allow",
         "Action": ["secretsmanager:GetSecretValue"],
         "Resource": "arn:aws:secretsmanager:*:*:secret:rds-db-credentials/*",
         "Condition": {
            "StringEquals": {
               "aws:ResourceTag/environment": ["production"]
            }
         }
      },
      {
         "Sid": "RDSDataServiceAccess",
         "Effect": "Allow",
         "Action": ["rds-data:*"],
         "Condition": {
            "StringEquals": {
               "aws:ResourceTag/environment": ["production"]
            }
         }
      }
   ]
}
```

The example shows separate actions for rds-data and secretsmanager for the Data API and Secrets Manager. However, you can combine actions and define tag conditions in many different ways to support your specific use cases. For more information, see Using identity-based policies (IAM policies) for Secrets Manager.
In the "Condition" element of the policy, you can choose tag keys from among the following:

- `aws:TagKeys`
- `aws:ResourceTag/${TagKey}`

To learn more about resource tags and how to use `aws:TagKeys`, see [Controlling access to AWS resources using resource tags](https://docs.aws.amazon.com/iam/latest/userguide/resource-tags.html).

**Note**
Both the Data API and AWS Secrets Manager authorize users. If you don't have permissions for all actions defined in a policy, you get an `AccessDeniedException` error.

### Storing database credentials in AWS Secrets Manager

When you call the Data API, you can pass credentials for the Aurora Serverless v1 DB cluster by using a secret in Secrets Manager. To pass credentials in this way, you specify the name of the secret or the Amazon Resource Name (ARN) of the secret.

#### To store DB cluster credentials in a secret

1. Use Secrets Manager to create a secret that contains credentials for the Aurora DB cluster.
   
   For instructions, see [Create a database secret](https://docs.aws.amazon.com/secretsmanager/latest/userguide/create-secret.html) in the [AWS Secrets Manager User Guide](https://docs.aws.amazon.com/secretsmanager/latest/userguide/).  
2. Use the Secrets Manager console to view the details for the secret you created, or run the `aws secretsmanager describe-secret` AWS CLI command.
   
   Note the name and ARN of the secret. You can use them in calls to the Data API.

For more information about using Secrets Manager, see the [AWS Secrets Manager User Guide](https://docs.aws.amazon.com/secretsmanager/latest/userguide/).

To understand how Amazon Aurora manages identity and access management, see [How Amazon Aurora works with IAM](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-serverless-iam.html).

For more information about creating an IAM policy, see [Creating IAM Policies](https://docs.aws.amazon.com/iam/latest/userguide/policies-create.html) in the [IAM User Guide](https://docs.aws.amazon.com/iam/latest/userguide/policies-create.html). For information about adding an IAM policy to a user, see [Adding and Removing IAM Identity Permissions](https://docs.aws.amazon.com/iam/latest/userguide/policies-permissions.html) in the [IAM User Guide](https://docs.aws.amazon.com/iam/latest/userguide/policies-permissions.html).

### Enabling the Data API

To use the Data API, enable it for your Aurora Serverless v1 DB cluster. You can enable the Data API when you create or modify the DB cluster.

**Note**
Currently, you can't use the Data API with Aurora Serverless v2 DB instances.

#### Console

You can enable the Data API by using the RDS console when you create or modify an Aurora Serverless v1 DB cluster. When you create an Aurora Serverless v1 DB cluster, you do so by enabling the Data API in the RDS console's **Connectivity** section. When you modify an Aurora Serverless v1 DB cluster, you do so by enabling the Data API in the RDS console's **Network & Security** section.

The following screenshot shows the enabled **Data API** when modifying an Aurora Serverless v1 DB cluster.
For instructions, see Creating an Aurora Serverless v1 DB cluster (p. 2040) and Modifying an Aurora Serverless v1 DB cluster (p. 2051).

**AWS CLI**

When you create or modify an Aurora Serverless v1 DB cluster using AWS CLI commands, the Data API is enabled when you specify `--enable-http-endpoint`.

You can specify the `--enable-http-endpoint` using the following AWS CLI commands:

- `create-db-cluster`
- `modify-db-cluster`

The following example modifies `sample-cluster` to enable the Data API.

For Linux, macOS, or Unix:

```sh
aws rds modify-db-cluster --db-cluster-identifier sample-cluster --enable-http-endpoint
```

For Windows:

```sh
aws rds modify-db-cluster --db-cluster-identifier sample-cluster --enable-http-endpoint
```

**RDS API**

When you create or modify an Aurora Serverless v1 DB cluster using Amazon RDS API operations, you enable the Data API by setting the `EnableHttpEndpoint` value to `true`.

You can set the `EnableHttpEndpoint` value using the following API operations:

- `CreateDBCluster`
- `ModifyDBCluster`
Creating an Amazon VPC endpoint for the Data API (AWS PrivateLink)

Amazon VPC enables you to launch AWS resources, such as Aurora DB clusters and applications, into a virtual private cloud (VPC). AWS PrivateLink provides private connectivity between VPCs and AWS services with high security on the Amazon network. Using AWS PrivateLink, you can create Amazon VPC endpoints, which enable you to connect to services across different accounts and VPCs based on Amazon VPC. For more information about AWS PrivateLink, see VPC Endpoint Services (AWS PrivateLink) in the Amazon Virtual Private Cloud User Guide.

You can call the Data API with Amazon VPC endpoints. Using an Amazon VPC endpoint keeps traffic between applications in your Amazon VPC and the Data API in the AWS network, without using public IP addresses. Amazon VPC endpoints can help you meet compliance and regulatory requirements related to limiting public internet connectivity. For example, if you use an Amazon VPC endpoint, you can keep traffic between an application running on an Amazon EC2 instance and the Data API in the VPCs that contain them.

After you create the Amazon VPC endpoint, you can start using it without making any code or configuration changes in your application.

To create an Amazon VPC endpoint for the Data API

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose Endpoints, and then choose Create Endpoint.
3. On the Create Endpoint page, for Service category, choose AWS services. For Service Name, choose rds-data.
4. For VPC, choose the VPC to create the endpoint in.

Choose the VPC that contains the application that makes Data API calls.
5. For **Subnets**, choose the subnet for each Availability Zone (AZ) used by the AWS service that is running your application.

To create an Amazon VPC endpoint, specify the private IP address range in which the endpoint will be accessible. To do this, choose the subnet for each Availability Zone. Doing so restricts the VPC endpoint to the private IP address range specific to each Availability Zone and also creates an Amazon VPC endpoint in each Availability Zone.

6. For **Enable DNS name**, select **Enable for this endpoint**.

Private DNS resolves the standard Data API DNS hostname (https://rds-data.region.amazonaws.com) to the private IP addresses associated with the DNS hostname specific to your Amazon VPC endpoint. As a result, you can access the Data API VPC endpoint using the AWS CLI or AWS SDKs without making any code or configuration changes to update the Data API endpoint URL.

7. For **Security group**, choose a security group to associate with the Amazon VPC endpoint.

Choose the security group that allows access to the AWS service that is running your application. For example, if an Amazon EC2 instance is running your application, choose the security group that allows access to the Amazon EC2 instance. The security group enables you to control the traffic to the Amazon VPC endpoint from resources in your VPC.

8. For **Policy**, choose **Full Access** to allow anyone inside the Amazon VPC to access the Data API through this endpoint. Or choose **Custom** to specify a policy that limits access.

If you choose **Custom**, enter the policy in the policy creation tool.

9. Choose **Create endpoint**.

After the endpoint is created, choose the link in the AWS Management Console to view the endpoint details.
The endpoint **Details** tab shows the DNS hostnames that were generated while creating the Amazon VPC endpoint.

You can use the standard endpoint (`rds-data.region.amazonaws.com`) or one of the VPC-specific endpoints to call the Data API within the Amazon VPC. The standard Data API endpoint automatically routes to the Amazon VPC endpoint. This routing occurs because the Private DNS hostname was enabled when the Amazon VPC endpoint was created.

When you use an Amazon VPC endpoint in a Data API call, all traffic between your application and the Data API remains in the Amazon VPCs that contain them. You can use an Amazon VPC endpoint for any type of Data API call. For information about calling the Data API, see [Calling the Data API](#) (p. 2070).

## Calling the Data API

With the Data API enabled on your Aurora Serverless v1 DB cluster, you can run SQL statements on the Aurora DB cluster by using the Data API or the AWS CLI. The Data API supports the programming languages supported by the AWS SDKs. For more information, see [Tools to build on AWS](#).

**Note**

Currently, the Data API doesn't support arrays of Universal Unique Identifiers (UUIDs).

The Data API provides the following operations to perform SQL statements.

<table>
<thead>
<tr>
<th>Data API operation</th>
<th>AWS CLI command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ExecuteStatement</td>
<td><code>aws rds-data execute-statement</code></td>
<td>Runs a SQL statement on a database.</td>
</tr>
<tr>
<td>BatchExecuteStatement</td>
<td><code>aws rds-data batch-execute-statement</code></td>
<td>Runs a batch SQL statement over an array of data for bulk update and insert operations. You can run a data manipulation language (DML) statement with an array of parameter sets. A batch SQL statement can provide a significant performance improvement over individual insert and update statements.</td>
</tr>
</tbody>
</table>

You can use either operation to run individual SQL statements or to run transactions. For transactions, the Data API provides the following operations.
The operations for performing SQL statements and supporting transactions have the following common Data API parameters and AWS CLI options. Some operations support other parameters or options.

<table>
<thead>
<tr>
<th>Data API operation</th>
<th>AWS CLI command option</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>resourceArn</td>
<td>--resource-arn</td>
<td>Yes</td>
<td>The Amazon Resource Name (ARN) of the Aurora Serverless v1 DB cluster.</td>
</tr>
<tr>
<td>secretArn</td>
<td>--secret-arn</td>
<td>Yes</td>
<td>The name or ARN of the secret that enables access to the DB cluster.</td>
</tr>
</tbody>
</table>

You can use parameters in Data API calls to ExecuteStatement and BatchExecuteStatement, and when you run the AWS CLI commands execute-statement and batch-execute-statement. To use a parameter, you specify a name-value pair in the SqlParameter data type. You specify the value with the Field data type. The following table maps Java Database Connectivity (JDBC) data types to the data types that you specify in Data API calls.

<table>
<thead>
<tr>
<th>JDBC data type</th>
<th>Data API data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER, TINYINT, SMALLINT, BIGINT</td>
<td>LONG (or STRING)</td>
</tr>
<tr>
<td>FLOAT, REAL, DOUBLE</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>STRING</td>
</tr>
<tr>
<td>BOOLEAN, BIT</td>
<td>BOOLEAN</td>
</tr>
<tr>
<td>BLOB, BINARY, LONGVARBINARY, VARBINARY</td>
<td>BLOB</td>
</tr>
<tr>
<td>CLOB</td>
<td>STRING</td>
</tr>
<tr>
<td>Other types (including types related to date and time)</td>
<td>STRING</td>
</tr>
</tbody>
</table>

**Note**
You can specify the LONG or STRING data type in your Data API call for LONG values returned by the database. We recommend that you do so to avoid losing precision for extremely large numbers, which can happen when you work with JavaScript.
Certain types, such as DECIMAL and TIME, require a hint so that the Data API passes String values to the database as the correct type. To use a hint, include values for typeHint in the SqlParameter data type. The possible values for typeHint are the following:

- **DATE** – The corresponding String parameter value is sent as an object of DATE type to the database. The accepted format is YYYY-MM-DD.
- **DECIMAL** – The corresponding String parameter value is sent as an object of DECIMAL type to the database.
- **JSON** – The corresponding String parameter value is sent as an object of JSON type to the database.
- **TIME** – The corresponding String parameter value is sent as an object of TIME type to the database. The accepted format is HH:MM:SS [.FFF].
- **TIMESTAMP** – The corresponding String parameter value is sent as an object of TIMESTAMP type to the database. The accepted format is YYYY-MM-DD HH:MM:SS [.FFF].
- **UUID** – The corresponding String parameter value is sent as an object of UUID type to the database.

**Note**
For Amazon Aurora PostgreSQL, the Data API always returns the Aurora PostgreSQL data type TIMESTAMPTZ in UTC time zone.

## Calling the Data API with the AWS CLI

You can call the Data API using the AWS CLI.

The following examples use the AWS CLI for the Data API. For more information, see AWS CLI reference for the Data API.

In each example, replace the Amazon Resource Name (ARN) for the DB cluster with the ARN for your Aurora Serverless v1 DB cluster. Also, replace the secret ARN with the ARN of the secret in Secrets Manager that allows access to the DB cluster.

**Note**
The AWS CLI can format responses in JSON.

### Topics
- [Starting a SQL transaction](p. 2072)
- [Running a SQL statement](p. 2073)
- [Running a batch SQL statement over an array of data](p. 2076)
- [Committing a SQL transaction](p. 2077)
- [Rolling back a SQL transaction](p. 2078)

### Starting a SQL transaction

You can start a SQL transaction using the `aws rds-data begin-transaction` CLI command. The call returns a transaction identifier.

**Important**
A transaction times out if there are no calls that use its transaction ID in three minutes. If a transaction times out before it's committed, it's rolled back automatically. Data definition language (DDL) statements inside a transaction cause an implicit commit. We recommend that you run each DDL statement in a separate `execute-statement` command with the `--continue-after-timeout` option.
In addition to the common options, specify the `--database` option, which provides the name of the database.

For example, the following CLI command starts a SQL transaction.

For Linux, macOS, or Unix:

```bash
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret"
```

For Windows:

```bash
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret"
```

The following is an example of the response.

```json
{
  "transactionId": "ABC1234567890xyz"
}
```

### Running a SQL statement

You can run a SQL statement using the `aws rds-data execute-statement` CLI command.

You can run the SQL statement in a transaction by specifying the transaction identifier with the `--transaction-id` option. You can start a transaction using the `aws rds-data begin-transaction` CLI command. You can end and commit a transaction using the `aws rds-data commit-transaction` CLI command.

**Important**
If you don't specify the `--transaction-id` option, changes that result from the call are committed automatically.

In addition to the common options, specify the following options:

- `--sql (required)` – A SQL statement to run on the DB cluster.
- `--transaction-id (optional)` – The identifier of a transaction that was started using the `begin-transaction` CLI command. Specify the transaction ID of the transaction that you want to include the SQL statement in.
- `--parameters (optional)` – The parameters for the SQL statement.
- `--include-result-metadata | --no-include-result-metadata (optional)` – A value that indicates whether to include metadata in the results. The default is `--no-include-result-metadata`.
- `--database (optional)` – The name of the database.

The `--database` option might not work when you run a SQL statement after running `--sql "use database_name;"` in the previous request. We recommend that you use the `--database` option instead of running `--sql "use database_name;"` statements.

- `--continue-after-timeout | --no-continue-after-timeout (optional)` – A value that indicates whether to continue running the statement after the call times out. The default is `--no-continue-after-timeout`. 
For data definition language (DDL) statements, we recommend continuing to run the statement after the call times out to avoid errors and the possibility of corrupted data structures.

- `--format-records-as "JSON" | "NONE"` – An optional value that specifies whether to format the result set as a JSON string. The default is "NONE". For usage information about processing JSON result sets, see Processing query results in JSON format (p. 2086).

The DB cluster returns a response for the call.

**Note**
- The response size limit is 1 MiB. If the call returns more than 1 MiB of response data, the call is terminated.
- The maximum number of requests per second is 1,000.

For example, the following CLI command runs a single SQL statement and omits the metadata in the results (the default).

For Linux, macOS, or Unix:

```bash
```

For Windows:

```bash
```

The following is an example of the response.

```json
{
    "numberOfRecordsUpdated": 0,
    "records": [
        {
            "longValue": 1
        },
        {
            "stringValue": "ValueOne"
        },
        {
            "longValue": 2
        },
        {
            "stringValue": "ValueTwo"
        },
        {
            "longValue": 3
        }
    ]
}
```
The following CLI command runs a single SQL statement in a transaction by specifying the --transaction-id option.

For Linux, macOS, or Unix:

```bash
```

For Windows:

```bash
```

The following is an example of the response.

```json
{
  "numberOfRecordsUpdated": 1
}
```

The following CLI command runs a single SQL statement with parameters.

For Linux, macOS, or Unix:

```bash
```

For Windows:

```bash
```

The following is an example of the response.

```json
{
  "numberOfRecordsUpdated": 1
}
```
The following CLI command runs a data definition language (DDL) SQL statement. The DDL statement renames column `job` to column `role`.

Important
For DDL statements, we recommend continuing to run the statement after the call times out. When a DDL statement terminates before it is finished running, it can result in errors and possibly corrupted data structures. To continue running a statement after a call times out, specify the `--continue-after-timeout` option.

For Linux, macOS, or Unix:

```
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret"  
--sql "alter table mytable change column job role varchar(100)" --continue-after-timeout
```

For Windows:

```
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" ^  
--sql "alter table mytable change column job role varchar(100)" --continue-after-timeout
```

The following is an example of the response.

```
{
  "generatedFields": [],
  "numberOfRecordsUpdated": 0
}
```

Note
The `generatedFields` data isn't supported by Aurora PostgreSQL. To get the values of generated fields, use the `RETURNING` clause. For more information, see Returning data from modified rows in the PostgreSQL documentation.

Running a batch SQL statement over an array of data

You can run a batch SQL statement over an array of data by using the `aws rds-data batch-execute-statement` CLI command. You can use this command to perform a bulk import or update operation.

You can run the SQL statement in a transaction by specifying the transaction identifier with the `--transaction-id` option. You can start a transaction by using the `aws rds-data begin-transaction` CLI command. You can end and commit a transaction by using the `aws rds-data commit-transaction` CLI command.

Important
If you don't specify the `--transaction-id` option, changes that result from the call are committed automatically.

In addition to the common options, specify the following options:

- `--sql` (required) – A SQL statement to run on the DB cluster.

  Tip
  For MySQL-compatible statements, don't include a semicolon at the end of the `--sql` parameter. A trailing semicolon might cause a syntax error.
• --transaction-id (optional) – The identifier of a transaction that was started using the begin-transaction CLI command. Specify the transaction ID of the transaction that you want to include the SQL statement in.
• --parameter-set (optional) – The parameter sets for the batch operation.
• --database (optional) – The name of the database.

The DB cluster returns a response to the call.

Note

There isn't a fixed upper limit on the number of parameter sets. However, the maximum size of the HTTP request submitted through the Data API is 4 MiB. If the request exceeds this limit, the Data API returns an error and doesn't process the request. This 4 MiB limit includes the size of the HTTP headers and the JSON notation in the request. Thus, the number of parameter sets that you can include depends on a combination of factors, such as the size of the SQL statement and the size of each parameter set.

The response size limit is 1 MiB. If the call returns more than 1 MiB of response data, the call is terminated.
The maximum number of requests per second is 1,000.

For example, the following CLI command runs a batch SQL statement over an array of data with a parameter set.

For Linux, macOS, or Unix:

```
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" \
--sql "insert into mytable values (:id, :val)" \
--parameter-sets "[{{"name":"id","value": {"longValue": 1}},{{"name":"val","value": {"stringValue": "ValueOne"}}}], 
[{{"name":"id","value": {"longValue": 2}},{{"name":"val","value": {"stringValue": "ValueTwo"}}}], 
[{{"name":"id","value": {"longValue": 3}},{{"name":"val","value": {"stringValue": "ValueThree"}}}]"
```

For Windows:

```
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" ^
--sql "insert into mytable values (:id, :val)" ^
--parameter-sets "[{{"name":"id","value": {"longValue": 1}},{{"name":"val","value": {"stringValue": "ValueOne"}}}], ^
[{{"name":"id","value": {"longValue": 2}},{{"name":"val","value": {"stringValue": "ValueTwo"}}}], ^
[{{"name":"id","value": {"longValue": 3}},{{"name":"val","value": {"stringValue": "ValueThree"}}}]"
```

Note

Don't include line breaks in the --parameter-sets option.

Committing a SQL transaction

Using the aws rds-data commit-transaction CLI command, you can end a SQL transaction that you started with aws rds-data begin-transaction and commit the changes.

In addition to the common options, specify the following option:
• --transaction-id (required) – The identifier of a transaction that was started using the `begin-transaction` CLI command. Specify the transaction ID of the transaction that you want to end and commit.

For example, the following CLI command ends a SQL transaction and commits the changes.

For Linux, macOS, or Unix:

```
  --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" \
  --transaction-id "ABC1234567890xyz"
```

For Windows:

```
  --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" 
  --transaction-id "ABC1234567890xyz"
```

The following is an example of the response.

```
{
  "transactionStatus": "Transaction Committed"
}
```

**Rolling back a SQL transaction**

Using the `aws rds-data rollback-transaction` CLI command, you can roll back a SQL transaction that you started with `aws rds-data begin-transaction`. Rolling back a transaction cancels its changes.

**Important**

If the transaction ID has expired, the transaction was rolled back automatically. In this case, an `aws rds-data rollback-transaction` command that specifies the expired transaction ID returns an error.

In addition to the common options, specify the following option:

• --transaction-id (required) – The identifier of a transaction that was started using the `begin-transaction` CLI command. Specify the transaction ID of the transaction that you want to roll back.

For example, the following AWS CLI command rolls back a SQL transaction.

For Linux, macOS, or Unix:

```
  --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" \
  --transaction-id "ABC1234567890xyz"
```

For Windows:

```
  --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" 
  --transaction-id "ABC1234567890xyz"
```
Calling the Data API from a Python application

You can call the Data API from a Python application.

The following examples use the AWS SDK for Python (Boto). For more information about Boto, see the AWS SDK for Python (Boto 3) documentation.

In each example, replace the DB cluster’s Amazon Resource Name (ARN) with the ARN for your Aurora Serverless v1 DB cluster. Also, replace the secret ARN with the ARN of the secret in Secrets Manager that allows access to the DB cluster.

Topics

- Running a SQL query (p. 2079)
- Running a DML SQL statement (p. 2080)
- Running a SQL transaction (p. 2081)

Running a SQL query

You can run a SELECT statement and fetch the results with a Python application.

The following example runs a SQL query.

```python
import boto3
rdsData = boto3.client('rds-data')
cluster_arn = 'arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster'
secret_arn = 'arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret'
response1 = rdsData.execute_statement(
    resourceArn = cluster_arn,
    secretArn = secret_arn,
    database = 'mydb',
    sql = 'select * from employees limit 3')

print (response1['records'])
```

```json
[  
  {  
    'stringValue': 'ROSALEZ'
  },  
  {  
    'stringValue': 'ALEJANDRO'
  },  
  {  
    'stringValue': 'PAMELA'
  }]
```
Running a DML SQL statement

You can run a data manipulation language (DML) statement to insert, update, or delete data in your database. You can also use parameters in DML statements.

**Important**

If a call isn't part of a transaction because it doesn't include the `transactionID` parameter, changes that result from the call are committed automatically.

The following example runs an insert SQL statement and uses parameters.

```python
import boto3

cluster_arn = 'arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster'
secret_arn = 'arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret'

rdsData = boto3.client('rds-data')

param1 = {'name':'firstname', 'value':{'stringValue': 'JACKSON'}}
param2 = {'name':'lastname', 'value':{'stringValue': 'MATEO'}}
paramSet = [param1, param2]

response2 = rdsData.execute_statement(resourceArn=cluster_arn,
  secretArn=secret_arn,
  database='mydb',
  sql='insert into employees(first_name, last_name)
VALUES(:firstname, :lastname)',
  parameters = paramSet)
```
Running a SQL transaction

You can start a SQL transaction, run one or more SQL statements, and then commit the changes with a Python application.

**Important**
A transaction times out if there are no calls that use its transaction ID in three minutes. If a transaction times out before it's committed, it's rolled back automatically. If you don't specify a transaction ID, changes that result from the call are committed automatically.

The following example runs a SQL transaction that inserts a row in a table.

```
import boto3
rdsData = boto3.client('rds-data')
cluster_arn = 'arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster'
secret_arn = 'arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret'
tr = rdsData.begin_transaction(
    resourceArn = cluster_arn,
    secretArn = secret_arn,
    database = 'mydb')
response3 = rdsData.execute_statement(
    resourceArn = cluster_arn,
    secretArn = secret_arn,
    database = 'mydb',
    sql = 'insert into employees(first_name, last_name) values('XIULAN', 'WANG')',
    transactionId = tr['transactionId'])

cr = rdsData.commit_transaction(
    resourceArn = cluster_arn,
    secretArn = secret_arn,
    transactionId = tr['transactionId'])

cr['transactionStatus']
'Transaction Committed'

response3['numberOfRecordsUpdated']
1
```

**Note**
If you run a data definition language (DDL) statement, we recommend continuing to run the statement after the call times out. When a DDL statement terminates before it is finished running, it can result in errors and possibly corrupted data structures. To continue running a statement after a call times out, set the `continueAfterTimeout` parameter to `true`.

Calling the Data API from a Java application

You can call the Data API from a Java application.

The following examples use the AWS SDK for Java. For more information, see the [AWS SDK for Java Developer Guide](https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/).

In each example, replace the DB cluster's Amazon Resource Name (ARN) with the ARN for your Aurora Serverless v1 DB cluster. Also, replace the secret ARN with the ARN of the secret in Secrets Manager that allows access to the DB cluster.
Running a SQL query

You can run a SELECT statement and fetch the results with a Java application.

The following example runs a SQL query.

```java
package com.amazonaws.rdsdata.examples;
import com.amazonaws.services.rdsdata.AWSRDSData;
import com.amazonaws.services.rdsdata.AWSRDSDataClient;
import com.amazonaws.services.rdsdata.model.ExecuteStatementRequest;
import com.amazonaws.services.rdsdata.model.ExecuteStatementResult;
import com.amazonaws.services.rdsdata.model.Field;
import java.util.List;
public class FetchResultsExample {
    public static final String RESOURCE_ARN = "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster";
    public static void main(String[] args) {
        AWSRDSData rdsData = AWSRDSDataClient.builder().build();
        ExecuteStatementRequest request = new ExecuteStatementRequest()
            .withResourceArn(RESOURCE_ARN)
            .withSecretArn(SECRET_ARN)
            .withDatabase("mydb")
            .withSql("select * from mytable");
        ExecuteStatementResult result = rdsData.executeStatement(request);
        for (List<Field> fields: result.getRecords()) {
            String stringValue = fields.get(0).getStringValue();
            long numberValue = fields.get(1).getLongValue();
            System.out.println(String.format("Fetched row: string = %s, number = %d",
                  stringValue, numberValue));
        }
    }
}
```

Running a SQL transaction

You can start a SQL transaction, run one or more SQL statements, and then commit the changes with a Java application.

**Important**

A transaction times out if there are no calls that use its transaction ID in three minutes. If a transaction times out before it's committed, it's rolled back automatically.

If you don't specify a transaction ID, changes that result from the call are committed automatically.

The following example runs a SQL transaction.
package com.amazonaws.rdsdata.examples;

import com.amazonaws.services.rdsdata.AWSRDSData;
import com.amazonaws.services.rdsdata.AWSRDSDataClient;
import com.amazonaws.services.rdsdata.model.BeginTransactionRequest;
import com.amazonaws.services.rdsdata.model.BeginTransactionResult;
import com.amazonaws.services.rdsdata.model.CommitTransactionRequest;
import com.amazonaws.services.rdsdata.model.ExecuteStatementRequest;

public class TransactionExample {
    public static final String RESOURCE_ARN = "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster";

    public static void main(String[] args) {
        AWSRDSData rdsData = AWSRDSDataClient.builder().build();

        BeginTransactionRequest beginTransactionRequest = new BeginTransactionRequest()
            .withResourceArn(RESOURCE_ARN)
            .withSecretArn(SECRET_ARN)
            .withDatabase("mydb");
        BeginTransactionResult beginTransactionResult = rdsData.beginTransaction(beginTransactionRequest);
        String transactionId = beginTransactionResult.getTransactionId();

        ExecuteStatementRequest executeStatementRequest = new ExecuteStatementRequest()
            .withTransactionId(transactionId)
            .withResourceArn(RESOURCE_ARN)
            .withSecretArn(SECRET_ARN)
            .withSql("INSERT INTO test_table VALUES ('hello world!')");
        rdsData.executeStatement(executeStatementRequest);

        CommitTransactionRequest commitTransactionRequest = new CommitTransactionRequest()
            .withTransactionId(transactionId)
            .withResourceArn(RESOURCE_ARN)
            .withSecretArn(SECRET_ARN);
        rdsData.commitTransaction(commitTransactionRequest);
    }
}

Note
If you run a data definition language (DDL) statement, we recommend continuing to run the statement after the call times out. When a DDL statement terminates before it is finished running, it can result in errors and possibly corrupted data structures. To continue running a statement after a call times out, set the continueAfterTimeout parameter to true.

Running a batch SQL operation

You can run bulk insert and update operations over an array of data with a Java application. You can run a DML statement with array of parameter sets.

Important
If you don't specify a transaction ID, changes that result from the call are committed automatically.

The following example runs a batch insert operation.

package com.amazonaws.rdsdata.examples;
import com.amazonaws.services.rdsdata.AWSRDSData;
import com.amazonaws.services.rdsdata.AWSRDSDataClient;
import com.amazonaws.services.rdsdata.model.BatchExecuteStatementRequest;
import com.amazonaws.services.rdsdata.model.Field;
import com.amazonaws.services.rdsdata.model.SqlParameter;

import java.util.Arrays;

public class BatchExecuteExample {
    public static final String RESOURCE_ARN = "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster";

    public static void main(String[] args) {
        AWSRDSData rdsData = AWSRDSDataClient.builder().build();

        BatchExecuteStatementRequest request = new BatchExecuteStatementRequest()
                .withDatabase("test")
                .withResourceArn(RESOURCE_ARN)
                .withSecretArn(SECRET_ARN)
                .withSql("INSERT INTO test_table2 VALUES (:string, :number)")
                .withParameterSets(Arrays.asList(
                        Arrays.asList(
                                new SqlParameter().withName("string").withValue(new Field().withStringValue("Hello"))
                                ,
                                new SqlParameter().withName("number").withValue(new Field().withLongValue(1L))
                        ),
                        Arrays.asList(
                                new SqlParameter().withName("string").withValue(new Field().withStringValue("World"))
                                ,
                                new SqlParameter().withName("number").withValue(new Field().withLongValue(2L))
                        )
                ));

        rdsData.batchExecuteStatement(request);
    }
}

Using the Java client library for Data API

You can download and use a Java client library for the Data API. This Java client library provides an alternative way to use the Data API. Using this library, you can map your client-side classes to requests and responses of the Data API. This mapping support can ease integration with some specific Java types, such as Date, Time, and BigDecimal.

Downloading the Java client library for Data API

The Data API Java client library is open source in GitHub at the following location:

You can build the library manually from the source files, but the best practice is to consume the library using Apache Maven dependency management. Add the following dependency to your Maven POM file.

For version 2.x, which is compatible with AWS SDK 2.x, use the following:

<dependency>
    <groupId>software.amazon.rdsdata</groupId>
    <artifactId>rds-data-api-client-library-java</artifactId>
</dependency>
<version>2.0.0</version>

For version 1.x, which is compatible with AWS SDK 1.x, use the following:

<dependency>
  <groupId>software.amazon.rdsdata</groupId>
  <artifactId>rds-data-api-client-library-java</artifactId>
  <version>1.0.8</version>
</dependency>

Java client library examples

Following, you can find some common examples of using the Data API Java client library. These examples assume that you have a table accounts with two columns: accountId and name. You also have the following data transfer object (DTO).

```java
public class Account {
    int accountId;
    String name;
    // getters and setters omitted
}
```

The client library enables you to pass DTOs as input parameters. The following example shows how customer DTOs are mapped to input parameter sets.

```java
var account1 = new Account(1, "John");
var account2 = new Account(2, "Mary");
client.forSql("INSERT INTO accounts(accountId, name) VALUES(:accountId, :name)"
 .withParamSets(account1, account2)
 .execute();
```

In some cases, it's easier to work with simple values as input parameters. You can do so with the following syntax.

```java
client.forSql("INSERT INTO accounts(accountId, name) VALUES(:accountId, :name)"
 .withParameter("accountId", 3)
 .withParameter("name", "Zhang")
 .execute();
```

The following is another example that works with simple values as input parameters.

```java
client.forSql("INSERT INTO accounts(accountId, name) VALUES(?, ?)", 4, "Carlos")
 .execute();
```

The client library provides automatic mapping to DTOs when a result is returned. The following examples show how the result is mapped to your DTOs.

```java
List<Account> result = client.forSql("SELECT * FROM accounts")
 .execute()
 .mapToList(Account.class);

Account result = client.forSql("SELECT * FROM accounts WHERE account_id = 1")
 .execute();
```
In many cases, the database result set contains only a single value. In order to simplify retrieving such results, the client library offers the following API:

```java
int numberOfAccounts = client.forSql("SELECT COUNT(*) FROM accounts")
    .execute()
    .singleValue(Integer.class);
```

**Note**
The `mapToList` function converts a SQL result set into a user-defined object list. We don't support using the `.withFormatRecordsAs(RecordsFormatType.JSON)` statement in an `ExecuteStatement` call for the Java client library, because it serves the same purpose. For more information, see Processing query results in JSON format (p. 2086).

## Processing query results in JSON format

When you call the `ExecuteStatement` operation, you can choose to have the query results returned as a string in JSON format. That way, you can use your programming language's JSON parsing capabilities to interpret and reformat the result set. Doing so can help to avoid writing extra code to loop through the result set and interpret each column value.

To request the result set in JSON format, you pass the optional `formatRecordsAs` parameter with a value of `JSON`. The JSON-formatted result set is returned in the `formattedRecords` field of the `ExecuteStatementResponse` structure.

The `BatchExecuteStatement` action doesn't return a result set. Thus, the JSON option doesn't apply to that action.

To customize the keys in the JSON hash structure, define column aliases in the result set. You can do so by using the `AS` clause in the column list of your SQL query.

You might use the JSON capability to make the result set easier to read and map its contents to language-specific frameworks. Because the volume of the ASCII-encoded result set is larger than the default representation, you might choose the default representation for queries that return large numbers of rows or large column values that consume more memory than is available to your application.

### Topics
- Retrieving query results in JSON format (p. 2086)
- Data Type Mapping (p. 2087)
- Troubleshooting (p. 2087)
- Examples (p. 2088)

## Retrieving query results in JSON format

To receive the result set as a JSON string, include `.withFormatRecordsAs(RecordsFormatType.JSON)` in the `ExecuteStatement` call. The return value comes back as a JSON string in the `formattedRecords` field. In this case, the `columnMetadata` is null. The column labels are the keys of the object that represents each row. These column names are repeated for each row in the result set. The column values are quoted strings, numeric values, or special values representing true, false, or null. Column metadata such as length constraints and the precise type for numbers and strings isn't preserved in the JSON response.
If you omit the `.withFormatRecordsAs()` call or specify a parameter of NONE, the result set is returned in binary format using the `Records` and `columnMetadata` fields.

### Data Type Mapping

The SQL values in the result set are mapped to a smaller set of JSON types. The values are represented in JSON as strings, numbers, and some special constants such as `true`, `false`, and `null`. You can convert these values into variables in your application, using strong or weak typing as appropriate for your programming language.

<table>
<thead>
<tr>
<th>JDBC data type</th>
<th>JSON data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER, TINYINT, SMALLINT, BIGINT</td>
<td>Number by default. String if the <code>LongReturnType</code> option is set to STRING.</td>
</tr>
<tr>
<td>FLOAT, REAL, DOUBLE</td>
<td>Number</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>String by default. Number if the <code>DecimalReturnType</code> option is set to <code>DOUBLE_OR_LONG</code>.</td>
</tr>
<tr>
<td>STRING</td>
<td>String</td>
</tr>
<tr>
<td>BOOLEAN, BIT</td>
<td>Boolean</td>
</tr>
<tr>
<td>BLOB, BINARY, VARBINARY, LONGVARBINARY</td>
<td>String in base64 encoding.</td>

<tr>
<td>ARRAY</td>
<td>Array</td>
</tr>
<tr>
<td>NULL</td>
<td>null</td>
</tr>
<tr>
<td>Other types (including types related to date and time)</td>
<td>String</td>
</tr>
</tbody>
</table>

### Troubleshooting

The JSON response is limited to 10 megabytes. If the response is larger than this limit, your program receives a `BadRequestException` error. In this case, you can resolve the error using one of the following techniques:

- **Reduce the number of rows in the result set.** To do so, add a LIMIT clause. You might split a large result set into multiple smaller ones by submitting several queries with LIMIT and OFFSET clauses. If the result set includes rows that are filtered out by application logic, you can remove those rows from the result set by adding more conditions in the `WHERE` clause.
- **Reduce the number of columns in the result set.** To do so, remove items from the select list of the query.
- **Shorten the column labels by using column aliases in the query.** Each column name is repeated in the JSON string for each row in the result set. Thus, a query result with long column names and many rows could exceed the size limit. In particular, use column aliases for complicated expressions to avoid having the entire expression repeated in the JSON string.
- **Although with SQL you can use column aliases to produce a result set having more than one column with the same name, duplicate key names aren't allowed in JSON.** The RDS Data API returns an error if...
you request the result set in JSON format and more than one column has the same name. Thus, make sure that all the column labels have unique names.

Examples

The following Java examples show how to call ExecuteStatement with the response as a JSON-formatted string, then interpret the result set. Substitute the appropriate values for the `databaseName`, `secretStoreArn`, and `clusterArn` parameters.

The following Java example demonstrates a query that returns a decimal numeric value in the result set. The `assertThat` calls test that the fields of the response have the expected properties based on the rules for JSON result sets.

This example works with the following schema and sample data:

```java
create table test_simplified_json (a float);
insert into test_simplified_json values(10.0);
```

```java
public void JSON_result_set_demo() {
    var sql = "select * from test_simplified_json";
    var request = new ExecuteStatementRequest()
        .withDatabase(databaseName)
        .withSecretArn(secretStoreArn)
        .withResourceArn(clusterArn)
        .withSql(sql)
        .withFormatRecordsAs(RecordsFormatType.JSON);
    var result = rdsdataClient.executeStatement(request);
}
```

The value of the `formattedRecords` field from the preceding program is:

```java
[{
"a":10.0
}]
```

The `Records` and `ColumnMetadata` fields in the response are both null, due to the presence of the JSON result set.

The following Java example demonstrates a query that returns an integer numeric value in the result set. The example calls `getFormattedRecords` to return only the JSON-formatted string and ignore the other response fields that are blank or null. The example deserializes the result into a structure representing a list of records. Each record has fields whose names correspond to the column aliases from the result set. This technique simplifies the code that parses the result set. Your application doesn't have to loop through the rows and columns of the result set and convert each value to the appropriate type.

This example works with the following schema and sample data:

```java
create table test_simplified_json (a int);
insert into test_simplified_json values(17);
```

```java
public void JSON_deserialization_demo() {
    var sql = "select * from test_simplified_json";
    var request = new ExecuteStatementRequest()
        .withDatabase(databaseName)
        .withSecretArn(secretStoreArn)
        .withResourceArn(clusterArn)
        .withSql(sql)
        .withFormatRecordsAs(RecordsFormatType.JSON);
    var result = rdsdataClient.executeStatement(request);
    var formattedRecords = result.getFormattedRecords();
    var records = formatJsonArray(formattedRecords);
    var record = records.get(0);
    var a = record.get("a").asDouble();
    var result = rdsdataClient.executeStatement(request);
}
```
Amazon Aurora User Guide for Aurora
Examples
.getFormattedRecords();
/* Turn the result set into a Java object, a list of records.
Each record has a field 'a' corresponding to the column
labelled 'a' in the result set. */
private static class Record { public int a; }
var recordsList = new ObjectMapper().readValue(
response, new TypeReference<List<Record>>() {
});
}

The value of the formattedRecords ﬁeld from the preceding program is:
[{"a":17}]

To retrieve the a column of result row 0, the application would refer to recordsList.get(0).a.
In contrast, the following Java example shows the kind of code that's required to construct a data
structure holding the result set when you don't use the JSON format. In this case, each row of the
result set contains ﬁelds with information about a single user. Building a data structure to represent
the result set requires looping through the rows. For each row, the code retrieves the value of each
ﬁeld, performs an appropriate type conversion, and assigns the result to the corresponding ﬁeld in the
object representing the row. Then the code adds the object representing each user to the data structure
representing the entire result set. If the query was changed to reorder, add, or remove ﬁelds in the result
set, the application code would have to change also.
/* Verbose result-parsing code that doesn't use the JSON result set format */
for (var row: response.getRecords()) {
var user = User.builder()
.userId(row.get(0).getLongValue())
.firstName(row.get(1).getStringValue())
.lastName(row.get(2).getStringValue())
.dob(Instant.parse(row.get(3).getStringValue()))
.build();
result.add(user);
}

The following sample values show the values of the formattedRecords ﬁeld for result sets with
diﬀerent numbers of columns, column aliases, and column data types.
If the result set includes multiple rows, each row is represented as an object that is an array element.
Each column in the result set becomes a key in the object. The keys are repeated for each row in the
result set. Thus, for result sets consisting of many rows and columns, you might need to deﬁne short
column aliases to avoid exceeding the length limit for the entire response.
This example works with the following schema and sample data:
create table sample_names (id int, name varchar(128));
insert into sample_names values (0, "Jane"), (1, "Mohan"), (2, "Maria"), (3, "Bruce"), (4,
"Jasmine");

[{"id":0,"name":"Jane"},{"id":1,"name":"Mohan"},
{"id":2,"name":"Maria"},{"id":3,"name":"Bruce"},{"id":4,"name":"Jasmine"}]

If a column in the result set is deﬁned as an expression, the text of the expression becomes the JSON key.
Thus, it's typically convenient to deﬁne a descriptive column alias for each expression in the select list of
the query. For example, the following query includes expressions such as function calls and arithmetic
operations in its select list.

2089


select count(*), max(id), 4+7 from sample_names;

Those expressions are passed through to the JSON result set as keys.

[["count(*)":5,"max(id)":4,"4+7":11]]

Adding AS columns with descriptive labels makes the keys simpler to interpret in the JSON result set.

select count(*) as rows, max(id) as largest_id, 4+7 as addition_result from sample_names;

With the revised SQL query, the column labels defined by the AS clauses are used as the key names.

[["rows":5,"largest_id":4,"addition_result":11]]

The value for each key-value pair in the JSON string can be a quoted string. The string might contain unicode characters. If the string contains escape sequences or the " or \ characters, those characters are preceded by backslash escape characters. The following examples of JSON strings demonstrate these possibilities. For example, the string_with_escape_sequences result contains the special characters backspace, newline, carriage return, tab, form feed, and \.

[["quoted_string":"hello"]
[["unicode_string":"###"]
[["string_with_escape_sequences":"\b \n \r \t \f \"\"]

The value for each key-value pair in the JSON string can also represent a number. The number might be an integer, a floating-point value, a negative value, or a value represented as exponential notation. The following examples of JSON strings demonstrate these possibilities.

[["integer_value":17]]
[["float_value":10.0]]
[["negative_value":-9223372036854775808,"positive_value":9223372036854775807]]
[["very_small_floating_point_value":4.9E-324,"very_large_floating_point_value":1.7976931348623157E308]]

Boolean and null values are represented with the unquoted special keywords true, false, and null. The following examples of JSON strings demonstrate these possibilities.

[["boolean_value_1":true,"boolean_value_2":false]]
[["unknown_value":null]]

If you select a value of a BLOB type, the result is represented in the JSON string as a base64-encoded value. To convert the value back to its original representation, you can use the appropriate decoding function in your application’s language. For example, in Java you call the function Base64.getDecoder().decode(). The following sample output shows the result of selecting a BLOB value of hello world and returning the result set as a JSON string.

[["blob_column":"aGVsbG8gd29ybGQ="]]

The following Python example shows how to access the values from the result of a call to the Python execute_statement function. The result set is a string value in the field response['formattedRecords']. The code turns the JSON string into a data structure by calling the json.loads function. Then each row of the result set is a list element within the data structure, and within each row you can refer to each field of the result set by name.
import json
result = json.loads(response['formattedRecords'])
print(result[0]['id'])

The following Javascript example shows how to access the values from the result of a call
to the Javascript executeStatement function. The result set is a string value in the field
response.formattedRecords. The code turns the JSON string into a data structure by calling the
JSON.parse function. Then each row of the result set is an array element within the data structure, and
within each row you can refer to each field of the result set by name.

<script>
    const result = JSON.parse(response.formattedRecords);
    document.getElementById("display").innerHTML = result[0].id;
</script>

Troubleshooting Data API issues

Use the following sections, titled with common error messages, to help troubleshoot problems that you
have with the Data API.

Topics
- Transaction <transaction_ID> is not found (p. 2091)
- Packet for query is too large (p. 2091)
- Database response exceeded size limit (p. 2092)
- HttpEndpoint is not enabled for cluster <cluster_ID> (p. 2092)

Transaction <transaction_ID> is not found

In this case, the transaction ID specified in a Data API call wasn't found. The cause for this issue is
appended to the error message, and is one of the following:

- Transaction may be expired.
  Make sure that each transactional call runs within three minutes of the previous one.

- It's also possible that the specified transaction ID wasn't created by a BeginTransaction call. Make sure
  that your call has a valid transaction ID.

- One previous call resulted in a termination of your transaction.
  The transaction was already ended by your CommitTransaction or RollbackTransaction call.

- Transaction has been aborted due to an error from a previous call.
  Check whether your previous calls have thrown any exceptions.

For information about running transactions, see Calling the Data API (p. 2070).

Packet for query is too large

In this case, the result set returned for a row was too large. The Data API size limit is 64 KB per row in the
result set returned by the database.
To solve this issue, make sure that each row in a result set is 64 KB or less.

**Database response exceeded size limit**

In this case, the size of the result set returned by the database was too large. The Data API limit is 1 MiB in the result set returned by the database.

To solve this issue, make sure that calls to the Data API return 1 MiB of data or less. If you need to return more than 1 MiB, you can use multiple `ExecuteStatement` calls with the LIMIT clause in your query.

For more information about the LIMIT clause, see [SELECT syntax](https://dev.mysql.com/doc/refman/8.0/en/select.html) in the MySQL documentation.

**HttpEndpoint is not enabled for cluster <cluster_ID>**

Check the following potential causes for this issue:

- The Data API isn't enabled for the Aurora Serverless v1 DB cluster. To use the Data API with an Aurora Serverless v1 DB cluster, the Data API must be enabled for the DB cluster. For information about enabling the Data API, see [Enabling the Data API](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-data-api.enabling.html) (p. 2066).
- The DB cluster was renamed after the Data API was enabled for it. In that case, turn off the Data API for that cluster and then enable it again.
- The ARN you specified doesn't precisely match the ARN of the cluster. Check that the ARN returned from another source or constructed by program logic matches the ARN of the cluster exactly. For example, make sure that the ARN you use has the correct letter case for all alphabetic characters.

If the Data API has not been enabled for the DB cluster, enable it. Make sure that it's an Aurora Serverless v1 cluster. Currently, you can't use the Data API with Aurora Serverless v2.

If the DB cluster was renamed after the Data API was enabled for the DB cluster, disable the Data API and then enable it again.

For information about enabling the Data API, see [Enabling the Data API](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-data-api.enabling.html) (p. 2066).

**Logging Data API calls with AWS CloudTrail**

Data API is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Data API. CloudTrail captures all API calls for Data API as events, including calls from the Amazon RDS console and from code calls to the Data API operations. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Data API. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in Event history. Using the data collected by CloudTrail, you can determine a lot of information. This information includes the request that was made to Data API, the IP address the request was made from, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the [AWS CloudTrail User Guide](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/cloudtrail.html).

**Working with Data API information in CloudTrail**

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Data API, that activity is recorded in a CloudTrail event along with other AWS service events in Event history. You can view, search, and download recent events in your AWS account. For more information, see [Viewing events with CloudTrail event history](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/cloudtrail.html) in the [AWS CloudTrail User Guide](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/cloudtrail.html).
For an ongoing record of events in your AWS account, including events for Data API, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all AWS Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following topics in the AWS CloudTrail User Guide:

- Overview for creating a trail
- CloudTrail supported services and integrations
- Configuring Amazon SNS notifications for CloudTrail
- Receiving CloudTrail log files from multiple Regions and Receiving CloudTrail log files from multiple accounts

All Data API operations are logged by CloudTrail and documented in the Amazon RDS data service API reference. For example, calls to the BatchExecuteStatement, BeginTransaction, CommitTransaction, and ExecuteStatement operations generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentity element.

### Understanding Data API log file entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the ExecuteStatement operation.

```json
{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "IAMUser",
    "principalId": "AKIAIOSFODNN7EXAMPLE",
    "arn": "arn:aws:iam::123456789012:user/johndoe",
    "accountId": "123456789012",
    "accessKeyId": "AKIAI44QH8DHBEXAMPLE",
    "userName": "johndoe"
  },
  "eventTime": "2019-12-18T00:49:34Z",
  "eventSource": "rdsdata.amazonaws.com",
  "eventName": "ExecuteStatement",
  "awsRegion": "us-east-1",
  "sourceIPAddress": "192.0.2.0",
  "userAgent": "aws-cli/1.16.102 Python/3.7.2 Windows/10 botocore/1.12.92",
  "requestParameters": {
    "continueAfterTimeout": false,
    "database": "**********
```
Including Data API events from an AWS CloudTrail trail

Most Data API users rely on the events in an AWS CloudTrail trail to provide a record of Data API operations. The trail can be a valuable source of data for auditing critical events, such as a SQL statement that deleted rows in a table. In some cases, the metadata in a CloudTrail log entry can help you to avoid or resolve errors.

However, because the Data API can generate a large number of events, you can exclude Data API events from a CloudTrail trail. This per-trail setting excludes all Data API events. You can't exclude particular Data API events.

To exclude Data API events from a trail, do the following:

- In the CloudTrail console, choose the Exclude Amazon RDS Data API events setting when you create a trail or update a trail.
- In the CloudTrail API, use the PutEventSelectors operation. Add the ExcludeManagementEventSources attribute to your event selectors with a value of rdsdata.amazonaws.com. For more information, see Creating, updating, and managing trails with the AWS Command Line Interface in the AWS CloudTrail User Guide.

Warning

Excluding Data API events from a CloudTrail log can obscure Data API actions. Be cautious when giving principals the cloudtrail:PutEventSelectors permission that is required to perform this operation.

You can turn off this exclusion at any time by changing the console setting or the event selectors for a trail. The trail will then start recording Data API events. However, it can't recover Data API events that occurred while the exclusion was effective.

When you exclude Data API events by using the console or API, the resulting CloudTrail PutEventSelectors API operation is also logged in your CloudTrail logs. If Data API events don't appear in your CloudTrail logs, look for a PutEventSelectors event with the ExcludeManagementEventSources attribute set to rdsdata.amazonaws.com.

For more information, see Logging management events for trails in the AWS CloudTrail User Guide.
Using the query editor for Aurora Serverless v1

With the query editor for Aurora Serverless v1, you can run SQL queries in the RDS console. You can run any valid SQL statement on the Aurora Serverless v1 DB cluster, including data manipulation and data definition statements.

The query editor requires an Aurora Serverless v1 DB cluster with the Data API enabled. For information about creating an Aurora Serverless v1 DB cluster with the Data API enabled, see Using the Data API for Aurora Serverless v1 (p. 2063).

Note
The Data API and query editor aren't supported for Aurora Serverless v2.

Availability of the query editor

The query editor is available only for Aurora Serverless v1 DB clusters using specific Aurora MySQL and Aurora PostgreSQL versions that support the Data API. The query editor is available only in AWS Regions where the Data API is supported. For more information, see Data API for Aurora Serverless v1 (p. 59).

Authorizing access to the query editor

A user must be authorized to run queries in the query editor. You can authorize a user to run queries in the query editor by adding the AmazonRDSDataFullAccess policy, a predefined AWS Identity and Access Management (IAM) policy, to that user.

Note
Make sure to use the same user name and password when you create the user as you did for the database user, such as the master user name and password. For more information, see Creating an IAM user in your AWS account in the AWS Identity and Access Management User Guide.

You can also create an IAM policy that grants access to the query editor. After you create the policy, add it to each user that requires access to the query editor.

The following policy provides the minimum required permissions for a user to access the query editor.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "QueryEditor0",
      "Effect": "Allow",
      "Action": ["rds-db:RunQuery"]
    }
  ]
}
```
Running queries in the query editor

You can run SQL statements on an Aurora Serverless v1 DB cluster in the query editor.

**To run a query in the query editor**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you created the Aurora Serverless v1 DB clusters that you want to query.
3. In the navigation pane, choose Databases.
4. Choose the Aurora Serverless v1 DB cluster that you want to run SQL queries on.
5. For Actions, choose Query. If you haven’t connected to the database before, the Connect to database page opens.
6. Enter the following information:
   a. For **Database instance or cluster**, choose the Aurora Serverless v1 DB cluster that you want to run SQL queries on.
   b. For **Database username**, choose the user name of the database user to connect with, or choose **Add new database credentials**. If you choose **Add new database credentials**, enter the user name for the new database credentials in **Enter database username**.
   c. For **Enter database password**, enter the password for the database user that you chose.
   d. In the last box, enter the name of the database or schema that you want to use for the Aurora DB cluster.
   e. Choose **Connect to database**.

   **Note**

   If your connection is successful, your connection and authentication information are stored in AWS Secrets Manager. You don't need to enter the connection information again.

7. In the query editor, enter the SQL query that you want to run on the database.
Each SQL statement can commit automatically, or you can run SQL statements in a script as part of a transaction. To control this behavior, choose the gear icon above the query window.

The **Query Editor Settings** window appears.
If you choose **Auto-commit**, every SQL statement commits automatically. If you choose **Transaction**, you can run a group of statements in a script. Statements are automatically committed at the end of the script unless explicitly committed or rolled back before then. Also, you can choose to stop a running script if an error occurs by enabling **Stop on error**.

**Note**

In a group of statements, data definition language (DDL) statements can cause previous data manipulation language (DML) statements to commit. You can also include **COMMIT** and **ROLLBACK** statements in a group of statements in a script.

After you make your choices in the **Query Editor Settings** window, choose **Save**.

8. Choose **Run** or press Ctrl+Enter, and the query editor displays the results of your query.

After running the query, save it to **Saved queries** by choosing **Save**.

Export the query results to spreadsheet format by choosing **Export to csv**.

You can find, edit, and rerun previous queries. To do so, choose the **Recent** tab or the **Saved queries** tab, choose the query text, and then choose **Run**.

To change the database, choose **Change database**.

## Database Query Metadata Service (DBQMS) API reference

The Database Query Metadata Service (dbqms) is an internal-only service. It provides your recent and saved queries for the query editor on the AWS Management Console for multiple AWS services, including Amazon RDS.

The following DBQMS actions are supported:

**Topics**

- [CreateFavoriteQuery](#)
- [CreateQueryHistory](#)
- [CreateTab](#)
CreateFavoriteQuery

Save a new favorite query. Each user can create up to 1000 saved queries. This limit is subject to change in the future.

CreateQueryHistory

Save a new query history entry.

CreateTab

Save a new query tab. Each user can create up to 10 query tabs.

DeleteFavoriteQueries

Delete one or more saved queries.

DeleteQueryHistory

Delete query history entries.

DeleteTab

Delete query tab entries.

DescribeFavoriteQueries

List saved queries created by a user in a given account.

DescribeQueryHistory

List query history entries.

DescribeTabs

List query tabs created by a user in a given account.
GetQueryString
Retrieve full query text from a query ID.

UpdateFavoriteQuery
Update the query string, description, name, or expiration date.

UpdateQueryHistory
Update the status of query history.

UpdateTab
Update the query tab name and query string.
Code examples for Aurora using AWS SDKs

The following code examples show how to use Aurora with an AWS software development kit (SDK).

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Cross-service examples are sample applications that work across multiple AWS services.

For a complete list of AWS SDK developer guides and code examples, see Using this service with an AWS SDK (p. 176). This topic also includes information about getting started and details about previous SDK versions.

Get started

Hello Aurora

The following code examples show how to get started using Aurora.

.NET

AWS SDK for .NET

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```csharp
using Amazon.RDS;
using Amazon.RDS.Model;
using Microsoft.Extensions.DependencyInjection;
using Microsoft.Extensions.Hosting;
namespace AuroraActions;
public static class HelloAurora
{
    static async Task Main(string[] args)
    {
        // Use the AWS .NET Core Setup package to set up dependency injection for
        // Amazon Relational Database Service (Amazon RDS).
        // Use your AWS profile name, or leave it blank to use the default profile.
        using var host = Host.CreateDefaultBuilder(args)
            .ConfigureServices((_, services) =>
```
services.AddAWSService<IAmazonRDS>(()).Build();

// Now the client is available for injection. Fetching it directly here for
// example purposes only.
var rdsClient = host.Services.GetRequiredService<IAmazonRDS>();

// You can use await and any of the async methods to get a response.
var response = await rdsClient.DescribeDBClustersAsync(new
DescribeDBClustersRequest { IncludeShared = true });
Console.WriteLine($"Hello Amazon RDS Aurora! Let's list some clusters in
this account: ").
foreach (var cluster in response.DBClusters)
{
    Console.WriteLine($"Cluster: database: {cluster.DatabaseName}
identifier: {cluster.DBClusterIdentifier}.");
}
}

• For API details, see DescribeDBClusters in AWS SDK for .NET API Reference.

C++

SDK for C++

Note
There’s more on GitHub. Find the complete example and learn how to set up and run in
the AWS Code Examples Repository.

Code for the CMakeLists.txt CMake file.

```markdown
# Set the minimum required version of CMake for this project.
cmake_minimum_required(VERSION 3.13)

# Set the AWS service components used by this project.
set(SERVICE_COMPONENTS rds)

# Set this project's name.
project("hello_aurora")

# Set the C++ standard to use to build this target.
# At least C++ 11 is required for the AWS SDK for C++.
set(CMAKE_CXX_STANDARD 11)

# Use the MSVC variable to determine if this is a Windows build.
set(WINDOWS_BUILD ${MSVC})
if (WINDOWS_BUILD)
    # Set the location where CMake can find the installed libraries
    # for the AWS SDK.
    string(REPLACE ";" "/aws-cpp-sdk-all;" SYSTEM_MODULE_PATH
"${CMAKE_SYSTEM_PREFIX_PATH}/aws-cpp-sdk-all")
    list(APPEND CMAKE_PREFIX_PATH ${SYSTEM_MODULE_PATH})
endif()

# Find the AWS SDK for C++ package.
find_package(AWSSDK REQUIRED COMPONENTS ${SERVICE_COMPONENTS})

if (WINDOWS_BUILD)
    # Copy relevant AWS SDK for C++ libraries into the current binary directory
    # for running and debugging.
```
```cpp
#include <aws/core/Aws.h>
#include <aws/rds/RDSClient.h>
#include <aws/rds/model/DescribeDBClustersRequest.h>
#include <iostream>

/*
 * A "Hello Aurora" starter application which initializes an Amazon Relational
 * Database Service (Amazon RDS) client
 * and describes the Amazon Aurora (Aurora) clusters.
 *
 * main function
 *
 * Usage: 'hello_aurora'
 */

int main(int argc, char **argv) {
    Aws::SDKOptions options;

    // Optionally change the log level for debugging.
    // options.loggingOptions.logLevel = Utils::Logging::LogLevel::Debug;
    Aws::InitAPI(options); // Should only be called once.
    int result = 0;
    {
        Aws::Client::ClientConfiguration clientConfig;
        // Optional: Set to the AWS Region (overrides config file).
        // clientConfig.region = "us-east-1";
        Aws::RDS::RDSClient rdsClient(clientConfig);
        Aws::String marker; // Used for pagination.
        std::vector<Aws::String> clusterIds;
        do {
            Aws::RDS::Model::DescribeDBClustersRequest request;
            Aws::RDS::Model::DescribeDBClustersOutcome outcome = rdsClient.DescribeDBClusters(request);

            if (outcome.IsSuccess()) {
                for (auto &cluster: outcome.GetResult().GetDBClusters()) {
                    clusterIds.push_back(cluster.GetDBClusterIdentifier());
                }
                marker = outcome.GetResult().GetMarker();
            } else {
                result = 1;
                std::cerr << "Error with Aurora::GDescribeDBClusters. " << outcome.GetError().GetMessage() << std::endl;
                break;
            }
        } while (marker != "");
        for (auto &cluster: outcome.GetResult().GetDBClusters()) {
            std::cout << "Cluster ID " << cluster.GetDBClusterIdentifier() << std::endl;
        }
    }
    Aws::ShutdownAPI();
    return result;
}
```

Code for the hello_aurora.cpp source file.
while (!marker.empty());

std::cout << clusterIds.size() << " Aurora clusters found." << std::endl;
for (auto &clusterId: clusterIds) {
    std::cout << " clusterId " << clusterId << std::endl;
}

Aws::ShutdownAPI(options); // Should only be called once.
return 0;

• For API details, see DescribeDBClusters in AWS SDK for C++ API Reference.

Go

SDK for Go V2

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

package main

import (
    "context"
    "fmt"
    "github.com/aws/aws-sdk-go-v2/aws"
    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/service/rds"
)

// main uses the AWS SDK for Go V2 to create an Amazon Aurora client and list up to 20 DB clusters in your account.
// This example uses the default settings specified in your shared credentials and config files.
func main() {
    sdkConfig, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        fmt.Println("Couldn't load default configuration. Have you set up your AWS account?")
        fmt.Println(err)
        return
    }
    auroraClient := rds.NewFromConfig(sdkConfig)
    const maxClusters = 20
    fmt.Printf("Let's list up to %v DB clusters.\n", maxClusters)
    output, err := auroraClient.DescribeDBClusters(context.TODO(), &rds.DescribeDBClustersInput{MaxRecords: aws.Int32(maxClusters)})
    if err != nil {
        fmt.Println("Couldn't list DB clusters: %v\n", err)
        return
    }
    if len(output.DBClusters) == 0 {
        fmt.Println("No DB clusters found.")
    } else {
        for _, cluster := range output.DBClusters {

2105
fmt.Printf("DB cluster %v has database %v.\n", *cluster.DBClusterIdentifier, *cluster.DatabaseName)
}
)
)

- For API details, see DescribeDBClusters in AWS SDK for Go API Reference.

**Rust**

**SDK for Rust**

**Note**
This documentation is for an SDK in preview release. The SDK is subject to change and should not be used in production.

**Note**
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
use aws_sdk_rds::Client;

#[derive(Debug)]
struct Error(String);
impl std::fmt::Display for Error {
    fn fmt(&self, f: &mut std::fmt::Formatter<">'_>) -> std::fmt::Result {
        write!(f, "{}", self.0)
    }
}
impl std::error::Error for Error {

#[tokio::main]
async fn main() -> Result<(), Error> {
    tracing_subscriber::fmt::init();
    let sdk_config = aws_config::from_env().load().await;
    let client = Client::new(&sdk_config);

    let describe_db_clusters_output = client
        .describe_db_clusters()
        .send()
        .await
        .map_err(|e| Error(e.to_string()))?

    println!("Found {} clusters: ",
        describe_db_clusters_output.db_clusters().len());
    for cluster in describe_db_clusters_output.db_clusters() {
        let name = cluster.database_name().unwrap_or("Unknown");
        let engine = cluster.engine().unwrap_or("Unknown");
        let id = cluster.db_cluster_identifier().unwrap_or("Unknown");
        let class = cluster.db_cluster_instance_class().unwrap_or("Unknown");
        println!("\tDatabase: {name}",);
        println!("\tEngine: {engine}",);
        println!("\tID: {id}",);
        println!("\tInstance: {class}",);
    }
    Ok(())
}
```
For API details, see DescribeDBClusters in AWS SDK for Rust API reference.

  - Create a lending library REST API (p. 2348)
  - Create an Aurora Serverless work item tracker (p. 2348)

**Actions for Aurora using AWS SDKs**

The following code examples demonstrate how to perform individual Aurora actions with AWS SDKs. These excerpts call the Aurora API and are code excerpts from larger programs that must be run in context. Each example includes a link to GitHub, where you can find instructions for setting up and running the code.

The following examples include only the most commonly used actions. For a complete list, see the Amazon Aurora API Reference.

**Examples**

- Create an Aurora DB cluster using an AWS SDK (p. 2108)
- Create an Aurora DB cluster parameter group using an AWS SDK (p. 2120)
- Create an Aurora DB cluster snapshot using an AWS SDK (p. 2126)
- Create a DB instance in an Aurora DB cluster using an AWS SDK (p. 2138)
- Delete an Aurora DB cluster using an AWS SDK (p. 2150)
- Delete an Aurora DB cluster parameter group using an AWS SDK (p. 2159)
- Delete an Aurora DB instance using an AWS SDK (p. 2169)
- Describe Aurora DB cluster parameter groups using an AWS SDK (p. 2179)
- Describe Aurora DB cluster snapshots using an AWS SDK (p. 2183)
- Describe Aurora DB clusters using an AWS SDK (p. 2187)
Create a DB cluster

- Describe Aurora DB instances using an AWS SDK (p. 2199)
- Describe Aurora database engine versions using an AWS SDK (p. 2209)
- Describe options for Aurora DB instances using an AWS SDK (p. 2216)
- Describe parameters from an Aurora DB cluster parameter group using an AWS SDK (p. 2223)
- Update parameters in an Aurora DB cluster parameter group using an AWS SDK (p. 2230)

Create an Aurora DB cluster using an AWS SDK

The following code examples show how to create an Aurora DB cluster.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Get started with DB clusters (p. 2237)

.NET

AWS SDK for .NET

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```csharp
/// <summary>
/// Create a new cluster and database.
/// </summary>
/// <param name="dbName">The name of the new database.</param>
/// <param name="clusterIdentifier">The identifier of the cluster.</param>
/// <param name="parameterGroupName">The name of the parameter group.</param>
/// <param name="dbEngine">The engine to use for the new cluster.</param>
/// <param name="dbEngineVersion">The version of the engine to use.</param>
/// <param name="adminName">The admin username.</param>
/// <param name="adminPassword">The primary admin password.</param>
/// <returns>The cluster object.</returns>
public async Task<DBCluster> CreateDBClusterWithAdminAsync(
    string dbName,

Create a DB cluster parameter group

For API details, see [CreateDBCluster](#) in *AWS SDK for Rust API reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using this service with an AWS SDK](p. 176). This topic also includes information about getting started and details about previous SDK versions.

Create an Aurora DB cluster parameter group using an AWS SDK

The following code examples show how to create an Aurora DB cluster parameter group.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Get started with DB clusters (p. 2237)

### .NET

**AWS SDK for .NET**

**Note**

There’s more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```csharp
/// <summary>
/// Create a custom cluster parameter group.
/// </summary>
/// <param name="parameterGroupFamily">The family of the parameter group.</param>
/// <param name="groupName">The name for the new parameter group.</param>
/// <param name="description">A description for the new parameter group.</param>
/// <returns>The new parameter group object.</returns>
public async Task<DBClusterParameterGroup> CreateCustomClusterParameterGroupAsync(
    string parameterGroupFamily,
    string groupName,
    string description)
{
    var request = new CreateDBClusterParameterGroupRequest
    {
        DBClusterParameterGroupName = groupName,
        DBParameterGroupFamily = parameterGroupFamily,
        DBClusterParameterGroupName = groupName,
```

2120
Create a DB cluster parameter group

```csharp
Description = description,
}
var response = await _amazonRDS.CreateDBClusterParameterGroupAsync(request);
return response.DBClusterParameterGroup;
}
```

- For API details, see CreateDBClusterParameterGroup in AWS SDK for .NET API Reference.

**C++**

**SDK for C++**

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```cpp
Aws::Client::ClientConfiguration clientConfig;
// Optional: Set to the AWS Region (overrides config file).
// clientConfig.region = "us-east-1";
Aws::RDS::RDSClient client(clientConfig);
Aws::RDS::Model::CreateDBClusterParameterGroupRequest request;
request.SetDBClusterParameterGroupName(CLUSTER_PARAMETER_GROUP_NAME);
request.SetDBParameterGroupFamily(dbParameterGroupFamily);
request.SetDescription("Example cluster parameter group.");

Aws::RDS::Model::CreateDBClusterParameterGroupOutcome outcome =
    client.CreateDBClusterParameterGroup(request);

if (outcome.IsSuccess()) {
    std::cout << "The DB cluster parameter group was successfully created." << std::endl;
} else {
    std::cerr << "Error with Aurora::CreateDBClusterParameterGroup. "
        << outcome.GetError().GetMessage()
        << std::endl;
    return false;
}
```

- For API details, see CreateDBClusterParameterGroup in AWS SDK for C++ API Reference.

**Go**

**SDK for Go V2**

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```go
type DbClusters struct {
    AuroraClient *rds.Client
```
Create a DB cluster parameter group

// CreateParameterGroup creates a DB cluster parameter group that is based on the specified
// parameter group family.
func (clusters *DbClusters) CreateParameterGroup(
    parameterGroupName string, parameterGroupFamily string, description string) (*types.DBClusterParameterGroup, error) {

    output, err := clusters.AuroraClient.CreateDBClusterParameterGroup(context.TODO(),
        &rds.CreateDBClusterParameterGroupInput{
            DBClusterParameterGroupName: aws.String(parameterGroupName),
            DBParameterGroupFamily:     aws.String(parameterGroupFamily),
            Description:                aws.String(description),
        })

    if err != nil {
        log.Printf(" Couldn't create parameter group %v: %v\n", parameterGroupName, err)
        return nil, err
    } else {
        return output.DBClusterParameterGroup, err
    }
}

## Create an Aurora DB cluster snapshot using an AWS SDK

The following code examples show how to create an Aurora DB cluster snapshot.
Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Get started with DB clusters (p. 2237)

.NET

AWS SDK for .NET

**Note**
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```csharp
/// <summary>
/// Create a snapshot of a cluster.
/// </summary>
/// <param name="dbClusterIdentifier">DB cluster identifier.</param>
/// <param name="snapshotIdentifier">Identifier for the snapshot.</param>
/// <returns>DB snapshot object.</returns>
public async Task<DBClusterSnapshot>
CreateClusterSnapshotByIdentifierAsync(string dbClusterIdentifier, string snapshotIdentifier)
{
    var response = await _amazonRDS.CreateDBClusterSnapshotAsync(
        new CreateDBClusterSnapshotRequest()
        {
            DBClusterIdentifier = dbClusterIdentifier,
            DBClusterSnapshotIdentifier = snapshotIdentifier,
        });
    return response.DBClusterSnapshot;
}
```

For API details, see CreateDBClusterSnapshot in AWS SDK for .NET API Reference.

C++

SDK for C++

**Note**
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```cpp
Aws::Client::ClientConfiguration clientConfig;
// Optional: Set to the AWS Region (overrides config file).
// clientConfig.region = "us-east-1";
Aws::RDS::RDSClient client(clientConfig);

Aws::RDS::Model::CreateDBClusterSnapshotRequest request;
request.SetDBClusterIdentifier(DB_CLUSTER_IDENTIFIER);
request.SetDBClusterSnapshotIdentifier(snapshotID);

Aws::RDS::Model::CreateDBClusterSnapshotOutcome outcome =
    client.CreateDBClusterSnapshot(request);

if (outcome.IsSuccess()) {
    std::cout << "Snapshot creation has started." << std::endl;
}
```
Create a DB cluster snapshot

```cpp
} else {
    std::cerr << "Error with Aurora::CreateDBClusterSnapshot. "
    << outcome.GetError().GetMessage()
    << std::endl;
    cleanUpResources(CLUSTER_PARAMETER_GROUP_NAME,
                     DB_CLUSTER_IDENTIFIER, DB_INSTANCE_IDENTIFIER,
                     client);
    return false;
}
```

**Create a DB instance in an Aurora DB cluster using an AWS SDK**

The following code examples show how to create a DB instance in an Aurora DB cluster.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Get started with DB clusters (p. 2237)

**AWS SDK for .NET**

**Note**

There’s more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```csharp
/// <summary>
/// Create an Amazon Relational Database Service (Amazon RDS) DB instance
/// with a particular set of properties. Use the action
/// DescribeDBInstancesAsync
/// to determine when the DB instance is ready to use.
/// </summary>
/// <param name="dbInstanceIdentifier">DB instance identifier.</param>
/// <param name="dbClusterIdentifier">DB cluster identifier.</param>
/// <param name="dbEngine">The engine for the DB instance.</param>
/// <param name="dbEngineVersion">Version for the DB instance.</param>
/// <param name="instanceClass">Class for the DB instance.</param>
/// <returns>DB instance object.</returns>
public async Task<DBInstance> CreateDBInstanceInClusterAsync(
    string dbClusterIdentifier,
    string dbInstanceIdentifier,
    string dbEngine,
    string dbEngineVersion,
    string instanceClass)
{
    // When creating the instance within a cluster, do not specify the name or
    // size.
    var response = await _amazonRDS.CreateDBInstanceAsync(
        new CreateDBInstanceRequest()
        {
            DBClusterIdentifier = dbClusterIdentifier,
            DBInstanceIdentifier = dbInstanceIdentifier,
            Engine = dbEngine,
            EngineVersion = dbEngineVersion,
            DBInstanceClass = instanceClass
        });
    return response.DBInstance;
}
```

**Go**

**SDK for Go V2**

*Note*

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws-samples/aws-code-examples).

```go
type DbClusters struct {
    AuroraClient *rds.Client
}

// CreateInstanceInCluster creates a database instance in an existing DB cluster. 
// The first database that is
// created defaults to a read-write DB instance.
func (clusters *DbClusters) CreateInstanceInCluster(clusterName string, 
    instanceName string, 
    ...
dbEngine string, dbInstanceClass string) (*types.DBInstance, error) {
    output, err := clusters.AuroraClient.CreateDBInstance(context.TODO(),
        &rds.CreateDBInstanceInput{
            DBInstanceIdentifier: aws.String(instanceName),
            DBClusterIdentifier:  aws.String(clusterName),
            Engine:               aws.String(dbEngine),
            DBInstanceClass:      aws.String(dbInstanceClass),
        })
    if err != nil {
        log.Printf("Couldn't create instance %v: %v\n", instanceName, err)
        return nil, err
    } else {
        return output.DBInstance, nil
    }
}

For API details, see CreateDBInstance in AWS SDK for Go API Reference.

Java SDK for Java 2.x

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

public static String createDBInstanceCluster(RdsClient rdsClient,
        String dbInstanceIdentifier,
        String dbInstanceClusterIdentifier,
        String instanceClass){
    try {
        CreateDbInstanceRequest instanceRequest =
            CreateDbInstanceRequest.builder()
                .dbInstanceIdentifier(dbInstanceIdentifier)
                .dbClusterIdentifier(dbInstanceClusterIdentifier)
                .engine("aurora-mysql")
                .dbInstanceClass(instanceClass)
                .build();

        CreateDbInstanceResponse response =
            rdsClient.createDBInstance(instanceRequest);
        System.out.print("The status is " +
            response.dbInstance().dbInstanceStatus());
        return response.dbInstance().dbInstanceArn();
    } catch (RdsException e) {
        System.err.println(e.getMessage());
        System.exit(1);
        return "";
    }
}

Delete an Aurora DB cluster using an AWS SDK

The following code examples show how to delete an Aurora DB cluster.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Get started with DB clusters (p. 2237)

.NET

**AWS SDK for .NET**

*Note*
There’s more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```csharp
/// <summary>
/// Delete a particular DB cluster.
/// </summary>
/// <param name="dbClusterIdentifier">DB cluster identifier.</param>
/// <returns>DB cluster object.</returns>
public async Task<DBCluster> DeleteDBClusterByIdentifierAsync(string dbClusterIdentifier)
{
    var response = await _amazonRDS.DeleteDBClusterAsync(
        new DeleteDBClusterRequest()
        {
            DBClusterIdentifier = dbClusterIdentifier,
            SkipFinalSnapshot = true
        });

    return response.DBCluster;
}
```

- For API details, see [DeleteDBCluster](https://docs.aws.amazon.com/sdk-for-net/v3/api/aws-rds/index.html#aws-rds-types-model-deletedbcusterrequest) in AWS SDK for .NET API Reference.

C++

**SDK for C++**

*Note*
There’s more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```c++
Aws::Client::ClientConfiguration clientConfig;
// Optional: Set to the AWS Region (overrides config file).
// clientConfig.region = "us-east-1";

Aws::RDS::RDSClient client(clientConfig);

Aws::RDS::Model::DeleteDBClusterRequest request;
```
request.SetDBClusterIdentifier(dbClusterIdentifier);
request.SetSkipFinalSnapshot(true);

Aws::RDS::Model::DeleteDBClusterOutcome outcome =
    client.DeleteDBCluster(request);

if (outcome.IsSuccess()) {
    std::cout << "DB cluster deletion has started."
    << std::endl;
    clusterDeleting = true;
    std::cout << "Waiting for DB cluster to delete before deleting the
    parameter group."
    << std::endl;
    std::cout << "This may take a while." << std::endl;
} else {
    std::cerr << "Error with Aurora::DeleteDBCluster. "
    << outcome.GetError().GetMessage()
    << std::endl;
    result = false;
}

• For API details, see DeleteDBCluster in AWS SDK for C++ API Reference.

Go

SDK for Go V2

Note
There's more on GitHub. Find the complete example and learn how to set up and run in
the AWS Code Examples Repository.

type DbClusters struct {
    AuroraClient *rds.Client
}

// DeleteDbCluster deletes a DB cluster without keeping a final snapshot.
func (clusters *DbClusters) DeleteDbCluster(clusterName string) error {
    _, err := clusters.AuroraClient.DeleteDBCluster(context.TODO(),

```
Delete an Aurora DB cluster parameter group using an AWS SDK

The following code examples show how to delete an Aurora DB cluster parameter group.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Get started with DB clusters (p. 2237)

.NET

AWS SDK for .NET

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```csharp
/// <summary>
/// Delete a particular parameter group by name.
/// </summary>
/// <param name="groupName">The name of the parameter group.</param>
/// <returns>True if successful.</returns>
public async Task<bool> DeleteClusterParameterGroupByNameAsync(string groupName)
{
    var request = new DeleteDBClusterParameterGroupRequest
    {
        DBClusterParameterGroupName = groupName,
    };

    var response = await _amazonRDS.DeleteDBClusterParameterGroupAsync(request);
}
```

- For API details, see DeleteDBClusterParameterGroup in AWS SDK for .NET API Reference.
C++

SDK for C++

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```cpp
Aws::Client::ClientConfiguration clientConfig;
// Optional: Set to the AWS Region (overrides config file).
// clientConfig.region = "us-east-1";
Aws::RDS::RDSClient client(clientConfig);
Aws::RDS::Model::DeleteDBClusterParameterGroupRequest request;
request.SetDBClusterParameterGroupName(parameterGroupName);
Aws::RDS::Model::DeleteDBClusterParameterGroupOutcome outcome =
    client.DeleteDBClusterParameterGroup(request);
if (outcome.IsSuccess()) {
    std::cout << "The DB parameter group was successfully deleted."
    << std::endl;
} else {
    std::cerr << "Error with Aurora::DeleteDBClusterParameterGroup. "
        << outcome.GetError().GetMessage() << std::endl;
    result = false;
}
```

    .build(),
);

tokio::time::pause();
```
Delete an Aurora DB instance using an AWS SDK

The following code examples show how to delete an Aurora DB instance.

**Action examples** are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Get started with DB clusters (p. 2237)](#)

**.NET**

**AWS SDK for .NET**

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://aws.amazon.com/code-examples/).

```csharp
/// <summary>
/// Delete a particular DB instance.
/// </summary>
/// <param name="dbInstanceIdentifier">DB instance identifier.</param>
/// <returns>DB instance object.</returns>
public async Task<DBInstance> DeleteDBInstanceByIdentifierAsync(string dbInstanceIdentifier)
{
    var response = await _amazonRDS.DeleteDBInstanceAsync(
        new DeleteDBInstanceRequest()
        { DBInstanceIdentifier = dbInstanceIdentifier, SkipFinalSnapshot = true, });
    
    return response;
}
```
Delete a DB instance

```
DeleteAutomatedBackups = true
});

return response.DBInstance;
```

Describe Aurora DB cluster parameter groups using an AWS SDK

The following code examples show how to describe Aurora DB cluster parameter groups.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Get started with DB clusters (p. 2237)

.NET

AWS SDK for .NET

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```csharp
/// <summary>
/// Get the description of a DB cluster parameter group by name.
/// </summary>
/// <param name="name">The name of the DB parameter group to describe.</param>
/// <returns>The parameter group description.</returns>
public async Task<DBClusterParameterGroup?>
DescribeCustomDBClusterParameterGroupAsync(string name)
{
    var response = await _amazonRDS.DescribeDBClusterParameterGroupsAsync(
        new DescribeDBClusterParameterGroupsRequest()
        {
            DBClusterParameterGroupName = name
        });
    return response.DBClusterParameterGroups.FirstOrDefault();
}
```

- For API details, see DescribeDBClusterParameterGroups in AWS SDK for .NET API Reference.

C++

SDK for C++

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```c++
Aws::Client::ClientConfiguration clientConfig;
// Optional: Set to the AWS Region (overrides config file).
// clientConfig.region = "us-east-1";
Aws::RDS::RDSClient client(clientConfig);

Aws::RDS::Model::DescribeDBClusterParameterGroupsRequest request;
request.SetDBClusterParameterGroupName(CLUSTER_PARAMETER_GROUP_NAME);

Aws::RDS::Model::DescribeDBClusterParameterGroupsOutcome outcome =
    client.DescribeDBClusterParameterGroups(request);
```
if (outcome.IsSuccess()) {
    std::cout << "DB cluster parameter group named '" <<
    CLUSTER_PARAMETER_GROUP_NAME << "' already exists." <<
    std::endl;
    dbParameterGroupFamily =
    outcome.GetResult().GetDBClusterParameterGroups()[0].GetDBParameterGroupFamily();
} else {
    std::cerr << "Error with Aurora::DescribeDBClusterParameterGroups. "
    << outcome.GetError().GetMessage() << std::endl;
    return false;
}

**Kotlin**

**SDK for Kotlin**

**Note**

This is prerelease documentation for a feature in preview release. It is subject to change.

**Note**

There’s more on GitHub. Find the complete example and learn how to set up and run it in the [AWS Code Examples Repository](https://github.com/aws-samples/aws-sdk-for-kotlin).

suspend fun describeDbClusterParameters(dbClusterGroupName: String?, flag: Int) {
    val dbParameterGroupsRequest: DescribeDbClusterParametersRequest
    dbParameterGroupsRequest = if (flag == 0) {
        DescribeDbClusterParametersRequest {
            dbClusterParameterGroupName = dbClusterGroupName
        }
    } else {
        DescribeDbClusterParametersRequest {
    }
Describe DB clusters

```kotlin
RdsClient { region = "us-west-2" }.use { rdsClient ->
val response =
rdsClient.describeDbClusterParameters(dbParameterGroupsRequest)
response.parameters?.forEach { para ->
  // Only print out information about either auto_increment_offset or
  // auto_increment_increment.
  val paraName = para.parameterName
  if (paraName != null) {
    if (paraName.compareTo("auto_increment_offset") == 0 ||
        paraName.compareTo("auto_increment_increment") == 0) {
      println("*** The parameter name is $paraName")
      println("*** The parameter value is $para.parameterValue")
      println("*** The parameter data type is $para.dataType")
      println("*** The parameter description is $para.description")
      println("*** The parameter allowed values is
      ${para.allowedValues}")
    }
  }
}
```

Python

SDK for Python (Boto3)

**Note**
There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```python
class AuroraWrapper:
    """Encapsulates Aurora DB cluster actions."""
    def __init__(self, rds_client):
        """""""param rds_client: A Boto3 Amazon Relational Database Service (Amazon RDS) client."
        """
        self.rds_client = rds_client

    @classmethod
def from_client(cls):
        """""""Instantiates this class from a Boto3 client."
        """
        rds_client = boto3.client("rds")
        return cls(rds_client)

def get_db_cluster(self, cluster_name):
    """""""Gets data about an Aurora DB cluster.
    """
    :param cluster_name: The name of the DB cluster to retrieve.
    :return: The retrieved DB cluster.
```

2191
Describe DB clusters

```python
try:
    response = self.rds_client.describe_db_clusters(
        DBClusterIdentifier=cluster_name
    )
    cluster = response["DBClusters"][-1]
except ClientError as err:
    if err.response["Error"]['Code'] == "DBClusterNotFoundFault":
        logger.info("Cluster %s does not exist.", cluster_name)
    else:
        logger.error("Couldn't verify the existence of DB cluster %s. Here's why:
        %s: %s",
        cluster_name,
        err.response["Error"]['Code'],
        err.response["Error"]['Message'],
    )
    raise
else:
    return cluster
```

### Describe Aurora DB instances using an AWS SDK

The following code examples show how to describe Aurora DB instances.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

• Get started with DB clusters (p. 2237)

.NET

AWS SDK for .NET

Note
There’s more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
/// <summary>
/// Returns a list of DB instances.
/// </summary>
/// <param name="dbInstanceIdentifier">Optional name of a specific DB instance.</param>
/// <returns>List of DB instances.</returns>
public async Task<List<DBInstance>> DescribeDBInstancesPagedAsync(string? dbInstanceIdentifier = null)
{
    var results = new List<DBInstance>();
    var instancesPaginator = _amazonRDS.Paginators.DescribeDBInstances(new DescribeDBInstancesRequest
    {
        DBInstanceIdentifier = dbInstanceIdentifier
    });
    // Get the entire list using the paginator.
    await foreach (var instances in instancesPaginator.DBInstances)
    {
        results.Add(instances);
    }
    return results;
}

• For API details, see DescribeDBInstances in AWS SDK for .NET API Reference.

C++

SDK for C++

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

**Note**
There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws-samples/aws-sdk-java-v2/tree/master/code-examples/kotlin/dms).

```kotlin
suspend fun waitDBAuroraInstanceReady(dbInstanceIdentifierVal: String?) {
  var instanceReady = false
  var instanceReadyStr: String
  println("Waiting for instance to become available.")
```
```kotlin
val instanceRequest = DescribeDbInstancesRequest {
    dbInstanceIdentifier = dbInstanceIdentifierVal
}

var endpoint = ""
RdsClient { region = "us-west-2" }.use { rdsClient ->
    while (!instanceReady) {
        val response = rdsClient.describeDbInstances(instanceRequest)
        response.dbInstances?.forEach { instance ->
            instanceReadyStr = instance.dbInstanceStatus.toString()
            if (instanceReadyStr.contains("available")) {
                endpoint = instance.endpoint?.address.toString()
                instanceReady = true
            } else {
                print(".")
                delay(sleepTime * 1000)
            }
        }
    }
}
println("Database instance is available! The connection endpoint is $endpoint")

• For API details, see `DescribeDBInstances` in [AWS SDK for Kotlin API reference](https://docs.aws.amazon.com/sdk-for-kotlin/v1/api/latest/ja/com.amazonaws.services.rds/).
Describe DB instances

```python
    db_inst = response["DBInstances"][0]
    except ClientError as err:
        if err.response["Error"]["Code"] == "DBInstanceNotFound":
            logger.info("Instance %s does not exist.", instance_id)
        else:
            logger.error("Couldn't get DB instance %s. Here's why: %s: %s",
                         instance_id,
                         err.response["Error"]["Code"],
                         err.response["Error"]["Message"],
                     )
        raise
    else:
        return db_inst
```

Describe Aurora database engine versions using an AWS SDK

The following code examples show how to describe Aurora database engine versions.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

• Get started with DB clusters (p. 2237)
.NET

AWS SDK for .NET

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```csharp
/// <summary>
/// Get a list of DB engine versions for a particular DB engine.
/// </summary>
/// <param name="engine">The name of the engine.</param>
/// <param name="parameterGroupFamily">Optional parameter group family name.</param>
/// <returns>A list of DBEngineVersions.</returns>
public async Task<List<DBEngineVersion>>
DescribeDBEngineVersionsForEngineAsync(string engine,
string? parameterGroupFamily = null)
{
    var response = await _amazonRDS.DescribeDBEngineVersionsAsync(
new DescribeDBEngineVersionsRequest()
{ Engine = engine,
    DBParameterGroupFamily = parameterGroupFamily
});
    return response.DBEngineVersions;
}
```

* For API details, see DescribeDBEngineVersions in AWS SDK for .NET API Reference.

C++

SDK for C++

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```cpp
Aws::Client::ClientConfiguration clientConfig;
// Optional: Set to the AWS Region (overrides config file).
// clientConfig.region = "us-east-1";
Aws::RDS::RDSClient client(clientConfig);

bool AwsDoc::Aurora::getDBEngineVersions(const Aws::String &engineName,
const Aws::String &parameterGroupFamily,
Aws::Vector<Aws::RDS::Model::DBEngineVersion> &engineVersionsResult,
```
const Aws::RDS::RDSClient &client) {
    Aws::RDS::Model::DescribeDBEngineVersionsRequest request;
    request.SetEngine(engineName);
    if (!parameterGroupFamily.empty()) {
        request.SetDBParameterGroupFamily(parameterGroupFamily);
    }
    Aws::RDS::Model::DescribeDBEngineVersionsOutcome outcome =
        client.DescribeDBEngineVersions(request);
    if (outcome.IsSuccess()) {
        engineVersionsResult = outcome.GetResult().GetDBEngineVersions();
    } else {
        std::cerr << "Error with Aurora::DescribeDBEngineVersionsRequest. "
                  << outcome.GetError().GetMessage() 
                  << std::endl;
    }
    return outcome.IsSuccess();
}

## Update parameters in an Aurora DB cluster parameter group using an AWS SDK

The following code examples show how to update parameters in an Aurora DB cluster parameter group.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:
• Get started with DB clusters (p. 2237)

.NET

AWS SDK for .NET

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```csharp
/// <summary>
/// Modify the specified integer parameters with new values from user input.
/// </summary>
/// <param name="groupName">The group name for the parameters.</param>
/// <param name="parameters">The list of integer parameters to modify.</param>
/// <param name="newValue">Optional int value to set for parameters.</param>
/// <returns>The name of the group that was modified.</returns>
public async Task<string> ModifyIntegerParametersInGroupAsync(string groupName, List<Parameter> parameters, int newValue = 0)
{
    foreach (var p in parameters)
    {
        if (p.IsModifiable && p.DataType == "integer")
        {
            while (newValue == 0)
            {
                Console.WriteLine($"Enter a new value for {p.ParameterName} from the allowed values {p.AllowedValues} ");
                var choice = Console.ReadLine();
                int.TryParse(choice, out newValue);
            }
            p.ParameterValue = newValue.ToString();
        }
    }
    var request = new ModifyDBClusterParameterGroupRequest
    {
        Parameters = parameters,
        DBClusterParameterGroupName = groupName,
    };
    var result = await _amazonRDS.ModifyDBClusterParameterGroupAsync(request);
    return result.DBClusterParameterGroupName;
}
```

For API details, see ModifyDBClusterParameterGroup in AWS SDK for Rust API reference.

For a complete list of AWS SDK developer guides and code examples, see Using this service with an AWS SDK (p. 176). This topic also includes information about getting started and details about previous SDK versions.

Scenarios for Aurora using AWS SDKs

The following code examples show you how to implement common scenarios in Aurora with AWS SDKs. These scenarios show you how to accomplish specific tasks by calling multiple functions within Aurora. Each scenario includes a link to GitHub, where you can find instructions on how to set up and run the code.

Examples

- Get started with Aurora DB clusters using an AWS SDK (p. 2237)

Get started with Aurora DB clusters using an AWS SDK

The following code examples show how to:

- Create a custom Aurora DB cluster parameter group and set parameter values.
- Create a DB cluster that uses the parameter group.
- Create a DB instance that contains a database.
- Take a snapshot of the DB cluster, then clean up resources.

.NET

AWS SDK for .NET

Note
There’s more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario at a command prompt.

```csharp
using Amazon.RDS;
using Amazon.RDS.Model;
using AuroraActions;
using Microsoft.Extensions.DependencyInjection;
using Microsoft.Extensions.Hosting;
using Microsoft.Extensions.Logging;
using Microsoft.Extensions.Logging.Console;
using Microsoft.Extensions.Logging.Debug;

namespace AuroraScenario;

/// <summary>
/// Scenario for Amazon Aurora examples.
/// </summary>
```
public class AuroraScenario
{
  /*
  Before running this .NET code example, set up your development environment, including your credentials.

  This .NET example performs the following tasks:
  1. Return a list of the available DB engine families for Aurora MySql using the DescribeDBEngineVersionsAsync method.
  2. Select an engine family and create a custom DB cluster parameter group using the CreateDBClusterParameterGroupAsync method.
  3. Get the parameter group using the DescribeDBClusterParameterGroupsAsync method.
  4. Get some parameters in the group using the DescribeDBClusterParametersAsync method.
  5. Parse and display some parameters in the group.
  6. Modify the auto_increment_offset and auto_increment_increment parameters using the ModifyDBClusterParameterGroupAsync method.
  7. Get and display the updated parameters using the DescribeDBClusterParametersAsync method with a source of "user".
  8. Get a list of allowed engine versions using the DescribeDBEngineVersionsAsync method.
  9. Create an Aurora DB cluster that contains a MySql database and uses the parameter group using the CreateDBClusterAsync method.
  10. Wait for the DB cluster to be ready using the DescribeDBClustersAsync method.
  11. Display and select from a list of instance classes available for the selected engine and version using the paginated DescribeOrderableDBInstanceOptions method.
  12. Create a database instance in the cluster using the CreateDBInstanceAsync method.
  13. Wait for the DB instance to be ready using the DescribeDBInstances method.
  14. Display the connection endpoint string for the new DB cluster.
  15. Create a snapshot of the DB cluster using the CreateDBClusterSnapshotAsync method.
  16. Wait for DB snapshot to be ready using the DescribeDBClusterSnapshotsAsync method.
  17. Delete the DB instance using the DeleteDBInstanceAsync method.
  18. Delete the DB cluster using the DeleteDBClusterAsync method.
  19. Wait for DB cluster to be deleted using the DescribeDBClustersAsync methods.
  20. Delete the cluster parameter group using the DeleteDBClusterParameterGroupAsync method.

Go

SDK for Go V2

Note
There’s more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario at a command prompt.

```go
// GetStartedClusters is an interactive example that shows you how to use the AWS SDK for Go
// with Amazon Aurora to do the following:
// 1. Create a custom DB cluster parameter group and set parameter values.
// 2. Create an Aurora DB cluster that is configured to use the parameter group.
// 3. Create a DB instance in the DB cluster that contains a database.
// 4. Take a snapshot of the DB cluster.
// 5. Delete the DB instance, DB cluster, and parameter group.
type GetStartedClusters struct {
    sdkConfig  aws.Config
    dbClusters actions.DbClusters
    questioner demotools.IQuestioner
    helper     IScenarioHelper
    isTestRun  bool
}

// NewGetStartedClusters constructs a GetStartedClusters instance from a configuration.
// It uses the specified config to get an Amazon Relational Database Service (Amazon RDS)
// client and create wrappers for the actions used in the scenario.

Java

**SDK for Java 2.x**

*Note*
There’s more on GitHub. Find the complete example and learn how to set up and run in the *AWS Code Examples Repository*.

```java
/**
 * Before running this Java (v2) code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 * This example requires an AWS Secrets Manager secret that contains the database credentials. If you do not create a secret, this example will not work. For details, see:
 * https://docs.aws.amazon.com/secretsmanager/latest/userguide/integrating_how-services-use-secrets_RS.html
 * This Java example performs the following tasks:
 * 2. Selects an engine family and creates a custom DB cluster parameter group by invoking the `describeDBClusterParameters` method.
 * 3. Gets the parameter groups by invoking the `describeDBClusterParameterGroups` method.
 * 4. Gets parameters in the group by invoking the `describeDBClusterParameters` method.
 * 5. Modifies the `auto_increment_offset` parameter by invoking the `modifyDbClusterParameterGroupRequest` method.
 * 6. Gets and displays the updated parameters.
 */
```
* 7. Gets a list of allowed engine versions by invoking the describeDbEngineVersions method.
* 8. Creates an Aurora DB cluster database cluster that contains a MySQL database.
* 9. Waits for DB instance to be ready.
* 10. Gets a list of instance classes available for the selected engine.
* 11. Creates a database instance in the cluster.
* 12. Waits for DB instance to be ready.
* 13. Creates a snapshot.
* 14. Waits for DB snapshot to be ready.
* 15. Deletes the DB cluster.
* 16. Deletes the DB cluster group.
*/

Kotlin

SDK for Kotlin

**Note**
This is prerelease documentation for a feature in preview release. It is subject to change.

**Note**
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```kotlin
/**
Before running this Kotlin code example, set up your development environment, including your credentials.
For more information, see the following documentation topic:
https://docs.aws.amazon.com/sdk-for-kotlin/latest/developer-guide/setup.html

This example requires an AWS Secrets Manager secret that contains the database credentials. If you do not create a secret, this example will not work. For more details, see:
https://docs.aws.amazon.com/secretsmanager/latest/userguide/integrating_how-services-use-secrets_RS.html

This Kotlin example performs the following tasks:
1. Returns a list of the available DB engines.
2. Creates a custom DB parameter group.
3. Gets the parameter groups.
4. Gets the parameters in the group.
5. Modifies the auto_increment_increment parameter.
6. Displays the updated parameter value.
7. Gets a list of allowed engine versions.
8. Creates an Aurora DB cluster database.
9. Waits for DB instance to be ready.
10. Gets a list of instance classes available for the selected engine.
11. Creates a database instance in the cluster.
12. Waits for the database instance in the cluster to be ready.
13. Creates a snapshot.
14. Waits for DB snapshot to be ready.
15. Deletes the DB instance.
16. Deletes the DB cluster.
```
17. Deletes the DB cluster group.

Cross-service examples for Aurora using AWS SDKs

The following sample applications use AWS SDKs to combine Aurora with other AWS services. Each example includes a link to GitHub, where you can find instructions on how to set up and run the application.

Examples

- Create a lending library REST API (p. 2348)
- Create an Aurora Serverless work item tracker (p. 2348)

Create a lending library REST API

The following code example shows how to create a lending library where patrons can borrow and return books by using a REST API backed by an Amazon Aurora database.

Python

SDK for Python (Boto3)

Shows how to use the AWS SDK for Python (Boto3) with the Amazon Relational Database Service (Amazon RDS) API and AWS Chalice to create a REST API backed by an Amazon Aurora database. The web service is fully serverless and represents a simple lending library where patrons can borrow and return books. Learn how to:

- Create and manage a serverless Aurora database cluster.
- Use AWS Secrets Manager to manage database credentials.
- Implement a data storage layer that uses Amazon RDS to move data into and out of the database.
- Use AWS Chalice to deploy a serverless REST API to Amazon API Gateway and AWS Lambda.
- Use the Requests package to send requests to the web service.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- API Gateway
- Aurora
- Lambda
- Secrets Manager

Create an Aurora Serverless work item tracker

The following code examples show how to create a web application that tracks work items in an Amazon Aurora Serverless database and uses Amazon Simple Email Service (Amazon SES) to send reports.
.NET

AWS SDK for .NET

Shows how to use the AWS SDK for .NET to create a web application that tracks work items in an Amazon Aurora database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with a RESTful .NET backend.

- Integrate a React web application with AWS services.
- List, add, update, and delete items in an Aurora table.
- Send an email report of filtered work items using Amazon SES.
- Deploy and manage example resources with the included AWS CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

C++

SDK for C++

Shows how to create a web application that tracks and reports on work items stored in an Amazon Aurora Serverless database.

For complete source code and instructions on how to set up a C++ REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

Java

SDK for Java 2.x

Shows how to create a web application that tracks and reports on work items stored in an Amazon RDS database.

For complete source code and instructions on how to set up a Spring REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on GitHub.

For complete source code and instructions on how to set up and run an example that uses the JDBC API, see the full example on GitHub.

Services used in this example

- Aurora
Create an Aurora Serverless work item tracker

- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

JavaScript

**SDK for JavaScript (v3)**

Shows how to use the AWS SDK for JavaScript (v3) to create a web application that tracks work items in an Amazon Aurora database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with an Express Node.js backend.

- Integrate a React.js web application with AWS services.
- List, add, and update items in an Aurora table.
- Send an email report of filtered work items by using Amazon SES.
- Deploy and manage example resources with the included AWS CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

**Services used in this example**

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

Kotlin

**SDK for Kotlin**

*Note*

This is prerelease documentation for a feature in preview release. It is subject to change.

Shows how to create a web application that tracks and reports on work items stored in an Amazon RDS database.

For complete source code and instructions on how to set up a Spring REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on GitHub.

**Services used in this example**

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

PHP

**SDK for PHP**

Shows how to use the AWS SDK for PHP to create a web application that tracks work items in an Amazon RDS database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with a RESTful PHP backend.
• Integrate a React.js web application with AWS services.
• List, add, update, and delete items in an Amazon RDS table.
• Send an email report of filtered work items using Amazon SES.
• Deploy and manage example resources with the included AWS CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

**Services used in this example**

• Aurora
• Amazon RDS
• Amazon RDS Data Service
• Amazon SES

**Python**

**SDK for Python (Boto3)**

Shows how to use the AWS SDK for Python (Boto3) to create a REST service that tracks work items in an Amazon Aurora Serverless database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses the Flask web framework to handle HTTP routing and integrates with a React webpage to present a fully functional web application.

• Build a Flask REST service that integrates with AWS services.
• Read, write, and update work items that are stored in an Aurora Serverless database.
• Create an AWS Secrets Manager secret that contains database credentials and use it to authenticate calls to the database.
• Use Amazon SES to send email reports of work items.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

**Services used in this example**

• Aurora
• Amazon RDS
• Amazon RDS Data Service
• Amazon SES

For a complete list of AWS SDK developer guides and code examples, see Using this service with an AWS SDK (p. 176). This topic also includes information about getting started and details about previous SDK versions.
Best practices with Amazon Aurora

Following, you can find information on general best practices and options for using or migrating data to an Amazon Aurora DB cluster.

Some of the best practices for Amazon Aurora are specific to a particular database engine. For more information about Aurora best practices specific to a database engine, see the following.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Best practices</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Aurora MySQL</td>
<td>See [Best practices with Amazon Aurora MySQL (p. 1102)]</td>
</tr>
<tr>
<td>Amazon Aurora PostgreSQL</td>
<td>See [Best practices with Amazon Aurora PostgreSQL (p. 1466)]</td>
</tr>
</tbody>
</table>

**Note**
For common recommendations for Aurora, see [Viewing Amazon Aurora recommendations (p. 527)].

**Topics**
- Basic operational guidelines for Amazon Aurora (p. 2352)
- DB instance RAM recommendations (p. 2352)
- Monitoring Amazon Aurora (p. 2353)
- Working with DB parameter groups and DB cluster parameter groups (p. 2353)
- Amazon Aurora best practices video (p. 2354)

Basic operational guidelines for Amazon Aurora

The following are basic operational guidelines that everyone should follow when working with Amazon Aurora. The Amazon RDS Service Level Agreement requires that you follow these guidelines:

- Monitor your memory, CPU, and storage usage. You can set up Amazon CloudWatch to notify you when usage patterns change or when you approach the capacity of your deployment. This way, you can maintain system performance and availability.
- If your client application is caching the Domain Name Service (DNS) data of your DB instances, set a time-to-live (TTL) value of less than 30 seconds. The underlying IP address of a DB instance can change after a failover. Thus, caching the DNS data for an extended time can lead to connection failures if your application tries to connect to an IP address that no longer is in service. Aurora DB clusters with multiple read replicas can experience connection failures also when connections use the reader endpoint and one of the read replica instances is in maintenance or is deleted.
- Test failover for your DB cluster to understand how long the process takes for your use case. Testing failover can help you ensure that the application that accesses your DB cluster can automatically connect to the new DB cluster after failover.

DB instance RAM recommendations

To optimize performance, allocate enough RAM so that your working set resides almost completely in memory. To determine whether your working set is almost all in memory, examine the following metrics in Amazon CloudWatch:
Monitoring Amazon Aurora

Amazon Aurora provides various metrics and insights that you can monitor to determine the health and performance of your Aurora DB cluster. You can use various tools, such as the AWS Management Console, AWS CLI, and CloudWatch API, to view Aurora metrics. You can view the combined Performance Insights and CloudWatch metrics in the Performance Insights dashboard and monitor your DB instance. To use this monitoring view, Performance Insights must be turned on for your DB instance. For information about this monitoring view, see Viewing combined metrics in the Amazon RDS console (p. 538).

You can create a performance analysis report for a specific time period and view the insights identified and the recommendations to resolve the issues. For more information see, Creating a performance analysis report (p. 586).

Working with DB parameter groups and DB cluster parameter groups

We recommend that you try out DB parameter group and DB cluster parameter group changes on a test DB cluster before applying parameter group changes to your production DB cluster. Improperly setting DB engine parameters can have unintended adverse effects, including degraded performance and system instability.

Always use caution when modifying DB engine parameters, and back up your DB cluster before modifying a DB parameter group. For information about backing up your DB cluster, see Backing up and restoring an Amazon Aurora DB cluster (p. 426).
Amazon Aurora best practices video

The AWS Online Tech Talks channel on YouTube includes a video presentation on best practices for creating and configuring an Amazon Aurora DB cluster to be more secure and highly available. See Amazon Aurora best practices for high availability.
Performing a proof of concept with Amazon Aurora

Following, you can find an explanation of how to set up and run a proof of concept for Aurora. A *proof of concept* is an investigation that you do to see if Aurora is a good fit with your application. The proof of concept can help you understand Aurora features in the context of your own database applications and how Aurora compares with your current database environment. It can also show what level of effort you need to move data, port SQL code, tune performance, and adapt your current management procedures.

In this topic, you can find an overview and a step-by-step outline of the high-level procedures and decisions involved in running a proof of concept, listed following. For detailed instructions, you can follow links to the full documentation for specific subjects.

Overview of an Aurora proof of concept

When you conduct a proof of concept for Amazon Aurora, you learn what it takes to port your existing data and SQL applications to Aurora. You exercise the important aspects of Aurora at scale, using a volume of data and activity that's representative of your production environment. The objective is to feel confident that the strengths of Aurora match up well with the challenges that cause you to outgrow your previous database infrastructure. At the end of a proof of concept, you have a solid plan to do larger-scale performance benchmarking and application testing. At this point, you understand the biggest work items on your way to a production deployment.

The following advice about best practices can help you avoid common mistakes that cause problems during benchmarking. However, this topic doesn't cover the step-by-step process of performing benchmarks and doing performance tuning. Those procedures vary depending on your workload and the Aurora features that you use. For detailed information, consult performance-related documentation such as *Managing performance and scaling for Aurora DB clusters* (p. 297), *Amazon Aurora MySQL performance enhancements* (p. 779), *Managing Amazon Aurora PostgreSQL* (p. 1397), and *Monitoring DB load with Performance Insights on Amazon Aurora* (p. 559).

The information in this topic applies mainly to applications where your organization writes the code and designs the schema and that support the MySQL and PostgreSQL open-source database engines. If you're testing a commercial application or code generated by an application framework, you might not have the flexibility to apply all of the guidelines. In such cases, check with your AWS representative to see if there are Aurora best practices or case studies for your type of application.

1. Identify your objectives

When you evaluate Aurora as part of a proof of concept, you choose what measurements to make and how to evaluate the success of the exercise.

You must ensure that all of the functionality of your application is compatible with Aurora. Because Aurora major versions are wire-compatible with corresponding major versions of MySQL and PostgreSQL, most applications developed for those engines are also compatible with Aurora. However, you must still validate compatibility on a per-application basis.
2. Understand your workload characteristics

For example, some of the configuration choices that you make when you set up an Aurora cluster influence whether you can or should use particular database features. You might start with the most general-purpose kind of Aurora cluster, known as provisioned. You might then decide if a specialized configuration such as serverless or parallel query offers benefits for your workload.

Use the following questions to help identify and quantify your objectives:

- Does Aurora support all functional use cases of your workload?
- What dataset size or load level do you want? Can you scale to that level?
- What are your specific query throughput or latency requirements? Can you reach them?
- What is the minimum acceptable amount of planned or unplanned downtime for your workload? Can you achieve it?
- What are the necessary metrics for operational efficiency? Can you accurately monitor them?
- Does Aurora support your specific business goals, such as cost reduction, increase in deployment, or provisioning speed? Do you have a way to quantify these goals?
- Can you meet all security and compliance requirements for your workload?

Take some time to build knowledge about Aurora database engines and platform capabilities, and review the service documentation. Take note of all the features that can help you achieve your desired outcomes. One of these might be workload consolidation, described in the AWS Database Blog post How to plan and optimize Amazon Aurora with MySQL compatibility for consolidated workloads.

Another might be demand-based scaling, described in Using Amazon Aurora Auto Scaling with Aurora Replicas (p. 328) in the Amazon Aurora User Guide. Others might be performance gains or simplified database operations.

2. Understand your workload characteristics

Evaluate Aurora in the context of your intended use case. Aurora is a good choice for online transaction processing (OLTP) workloads. You can also run reports on the cluster that holds the real-time OLTP data without provisioning a separate data warehouse cluster. You can recognize if your use case falls into these categories by checking for the following characteristics:

- High concurrency, with dozens, hundreds, or thousands of simultaneous clients.
- Large volume of low-latency queries (milliseconds to seconds).
- Short, real-time transactions.
- Highly selective query patterns, with index-based lookups.
- For HTAP, analytical queries that can take advantage of Aurora parallel query.

One of the key factors affecting your database choices is the velocity of the data. High velocity involves data being inserted and updated very frequently. Such a system might have thousands of connections and hundreds of thousands of simultaneous queries reading from and writing to a database. Queries in high-velocity systems usually affect a relatively small number of rows, and typically access multiple columns in the same row.

Aurora is designed to handle high-velocity data. Depending on the workload, an Aurora cluster with a single r4.16xlarge DB instance can process more than 600,000 SELECT statements per second. Again depending on workload, such a cluster can process 200,000 INSERT, UPDATE, and DELETE statements per second. Aurora is a row store database and is ideally suited for high-volume, high-throughput, and highly parallelized OLTP workloads.

Aurora can also run reporting queries on the same cluster that handles the OLTP workload. Aurora supports up to 15 replicas (p. 104), each of which is on average within 10–20 milliseconds of the
primary instance. Analysts can query OLTP data in real time without copying the data to a separate data warehouse cluster. With Aurora clusters using the parallel query feature, you can offload much of the processing, filtering, and aggregation work to the massively distributed Aurora storage subsystem.

Use this planning phase to familiarize yourself with the capabilities of Aurora, other AWS services, the AWS Management Console, and the AWS CLI. Also, check how these work with the other tooling that you plan to use in the proof of concept.

3. Practice with the AWS Management Console or AWS CLI

As a next step, practice with the AWS Management Console or the AWS CLI, to become familiar with these tools and with Aurora.

Practice with the AWS Management Console

The following initial activities with Aurora database clusters are mainly so you can familiarize yourself with the AWS Management Console environment and practice setting up and modifying Aurora clusters. If you use the MySQL-compatible and PostgreSQL-compatible database engines with Amazon RDS, you can build on that knowledge when you use Aurora.

By taking advantage of the Aurora shared storage model and features such as replication and snapshots, you can treat entire database clusters as another kind of object that you freely manipulate. You can set up, tear down, and change the capacity of Aurora clusters frequently during the proof of concept. You aren't locked into early choices about capacity, database settings, and physical data layout.

To get started, set up an empty Aurora cluster. Choose the provisioned capacity type and regional location for your initial experiments.

Connect to that cluster using a client program such as a SQL command-line application. Initially, you connect using the cluster endpoint. You connect to that endpoint to perform any write operations, such as data definition language (DDL) statements and extract, transform, load (ETL) processes. Later in the proof of concept, you connect query-intensive sessions using the reader endpoint, which distributes the query workload among multiple DB instances in the cluster.

Scale the cluster out by adding more Aurora Replicas. For those procedures, see Replication with Amazon Aurora (p. 104). Scale the DB instances up or down by changing the AWS instance class. Understand how Aurora simplifies these kinds of operations, so that if your initial estimates for system capacity are inaccurate, you can adjust later without starting over.

Create a snapshot and restore it to a different cluster.

Examine cluster metrics to see activity over time, and how the metrics apply to the DB instances in the cluster.

It’s useful to become familiar with how to do these things through the AWS Management Console in the beginning. After you understand what you can do with Aurora, you can progress to automating those operations using the AWS CLI. In the following sections, you can find more details about the procedures and best practices for these activities during the proof-of-concept period.

Practice with the AWS CLI

We recommend automating deployment and management procedures, even in a proof-of-concept setting. To do so, become familiar with the AWS CLI if you’re not already. If you use the MySQL-
compatible and PostgreSQL-compatible database engines with Amazon RDS, you can build on that knowledge when you use Aurora.

Aurora typically involves groups of DB instances arranged in clusters. Thus, many operations involve determining which DB instances are associated with a cluster and then performing administrative operations in a loop for all the instances.

For example, you might automate steps such as creating Aurora clusters, then scaling them up with larger instance classes or scaling them out with additional DB instances. Doing so helps you to repeat any stages in your proof of concept and explore what-if scenarios with different kinds or configurations of Aurora clusters.

Learn the capabilities and limitations of infrastructure deployment tools such as AWS CloudFormation. You might find activities that you do in a proof-of-concept context aren't suitable for production use. For example, the AWS CloudFormation behavior for modification is to create a new instance and delete the current one, including its data. For more details on this behavior, see Update behaviors of stack resources in the AWS CloudFormation User Guide.

4. Create your Aurora cluster

With Aurora, you can explore what-if scenarios by adding DB instances to the cluster and scaling up the DB instances to more powerful instance classes. You can also create clusters with different configuration settings to run the same workload side by side. With Aurora, you have a lot of flexibility to set up, tear down, and reconfigure DB clusters. Given this, it's helpful to practice these techniques in the early stages of the proof-of-concept process. For the general procedures to create Aurora clusters, see Creating an Amazon Aurora DB cluster (p. 179).

Where practical, start with a cluster using the following settings. Skip this step only if you have certain specific use cases in mind. For example, you might skip this step if your use case requires a specialized kind of Aurora cluster. Or you might skip it if you need a particular combination of database engine and version.

- Amazon Aurora.
- MySQL 5.7 compatibility. This combination of database engine and version has wide compatibility with other Aurora features and substantial customer usage for production applications.
- Turn off Easy create. For the proof of concept, we recommend that you be aware of all the settings you choose so that you can create identical or slightly different clusters later.
- Regional. The Global setting is for specific high availability scenarios. You can try it out later after your initial functional and performance experiments.
- One writer, multiple readers. This is the most widely used, general purpose kind of cluster. This setting persists for the life of the cluster. Thus, if you later do experiments with other kinds of clusters such as serverless or parallel query, you create other clusters and compare and contrast the results on each.
- Choose the Dev/Test template. This choice isn't significant for your proof-of-concept activities.
- For DB instance class, choose Memory optimized classes and one of the xlarge instance classes. You can adjust the instance class up or down later.
- Under Multi-AZ Deployment, choose Create an Aurora Replica or Reader node in a different AZ. Many of the most useful aspects of Aurora involve clusters of multiple DB instances. It makes sense to always start with at least two DB instances in any new cluster. Using a different Availability Zone for the second DB instance helps to test different high availability scenarios.
- When you pick names for the DB instances, use a generic naming convention. Don't refer to any cluster DB instance as the "master" or "writer," because different DB instances assume those roles as needed. We recommend using something like clustername-az-serialnumber, for example myprodappdb-a-01. These pieces uniquely identify the DB instance and its placement.
5. Set up your schema

On the Aurora cluster, set up databases, tables, indexes, foreign keys, and other schema objects for your application. If you're moving from another MySQL-compatible or PostgreSQL-compatible database system, expect this stage to be simple and straightforward. You use the same SQL syntax and command line or other client applications that you're familiar with for your database engine.

To issue SQL statements on your cluster, find its cluster endpoint and supply that value as the connection parameter to your client application. You can find the cluster endpoint on the Connectivity tab of the detail page of your cluster. The cluster endpoint is the one labeled Writer. The other endpoint, labeled Reader, represents a read-only connection that you can supply to end users who run reports or other read-only queries. For help with any issues around connecting to your cluster, see Connecting to an Amazon Aurora DB cluster (p. 204).

If you're porting your schema and data from a different database system, expect to make some schema changes at this point. These schema changes are to match the SQL syntax and capabilities available in Aurora. You might leave out certain columns, constraints, triggers, or other schema objects at this point. Doing so can be useful particularly if these objects require rework for Aurora compatibility and aren't significant for your objectives with the proof of concept.

If you're migrating from a database system with a different underlying engine than Aurora's, consider using the AWS Schema Conversion Tool (AWS SCT) to simplify the process. For details, see the AWS Schema Conversion Tool User Guide. For general details about migration and porting activities, see the Migrating Your Databases to Amazon Aurora AWS whitepaper.

During this stage, you can evaluate whether there are inefficiencies in your schema setup, for example in your indexing strategy or other table structures such as partitioned tables. Such inefficiencies can be amplified when you deploy your application on a cluster with multiple DB instances and a heavy workload. Consider whether you can fine-tune such performance aspects now, or during later activities such as a full benchmark test.

6. Import your data

During the proof of concept, you bring across the data, or a representative sample, from your former database system. If practical, set up at least some data in each of your tables. Doing so helps to test compatibility of all data types and schema features. After you have exercised the basic Aurora features, scale up the amount of data. By the time you finish the proof of concept, you should test your ETL tools, queries, and overall workload with a dataset that's big enough to draw accurate conclusions.

You can use several techniques to import either physical or logical backup data to Aurora. For details, see Migrating data to an Amazon Aurora MySQL DB cluster (p. 836) or Migrating data to Amazon Aurora with PostgreSQL compatibility (p. 1265) depending on the database engine you're using in the proof of concept.
Experiment with the ETL tools and technologies that you're considering. See which one best meets your needs. Consider both throughput and flexibility. For example, some ETL tools perform a one-time transfer, and others involve ongoing replication from the old system to Aurora.

If you're migrating from a MySQL-compatible system to Aurora MySQL, you can use the native data transfer tools. The same applies if you're migrating from a PostgreSQL-compatible system to Aurora PostgreSQL. If you're migrating from a database system that uses a different underlying engine than Aurora does, you can experiment with the AWS Database Migration Service (AWS DMS). For details about AWS DMS, see the [AWS Database Migration Service User Guide](#).

For details about migration and porting activities, see the AWS whitepaper [Aurora migration handbook](#).

### 7. Port your SQL code

Trying out SQL and associated applications requires different levels of effort depending on different cases. In particular, the level of effort depends on whether you move from a MySQL-compatible or PostgreSQL-compatible system or another kind.

- If you're moving from RDS for MySQL or RDS for PostgreSQL, the SQL changes are small enough that you can try the original SQL code with Aurora and manually incorporate needed changes.
- Similarly, if you move from an on-premises database compatible with MySQL or PostgreSQL, you can try the original SQL code and manually incorporate changes.
- If you're coming from a different commercial database, the required SQL changes are more extensive. In this case, consider using the AWS SCT.

During this stage, you can evaluate whether there are inefficiencies in your schema setup, for example in your indexing strategy or other table structures such as partitioned tables. Consider whether you can fine-tune such performance aspects now, or during later activities such as a full benchmark test.

You can verify the database connection logic in your application. To take advantage of Aurora distributed processing, you might need to use separate connections for read and write operations, and use relatively short sessions for query operations. For information about connections, see [9. Connect to Aurora](#).

Consider if you had to make compromises and tradeoffs to work around issues in your production database. Build time into the proof-of-concept schedule to make improvements to your schema design and queries. To judge if you can achieve easy wins in performance, operating cost, and scalability, try the original and modified applications side by side on different Aurora clusters.

For details about migration and porting activities, see the AWS whitepaper [Aurora migration handbook](#).

### 8. Specify configuration settings

You can also review your database configuration parameters as part of the Aurora proof-of-concept exercise. You might already have MySQL or PostgreSQL configuration settings tuned for performance and scalability in your current environment. The Aurora storage subsystem is adapted and tuned for a distributed cloud-based environment with a high-speed storage subsystem. As a result, many former database engine settings don't apply. We recommend conducting your initial experiments with the default Aurora configuration settings. Reapply settings from your current environment only if you encounter performance and scalability bottlenecks. If you're interested, you can look more deeply into this subject in [Introducing the Aurora storage engine](#) on the AWS Database Blog.

Aurora makes it easy to reuse the optimal configuration settings for a particular application or use case. Instead of editing a separate configuration file for each DB instance, you manage sets of parameters that
you assign to entire clusters or specific DB instances. For example, the time zone setting applies to all DB instances in the cluster, and you can adjust the page cache size setting for each DB instance.

You start with one of the default parameter sets, and apply changes to only the parameters that you need to fine-tune. For details about working with parameter groups, see Amazon Aurora DB cluster and DB instance parameters (p. 215). For the configuration settings that are or aren't applicable to Aurora clusters, see Aurora MySQL configuration parameters (p. 1115) or Amazon Aurora PostgreSQL parameters (p. 1728) depending on your database engine.

### 9. Connect to Aurora

As you find when doing your initial schema and data setup and running sample queries, you can connect to different endpoints in an Aurora cluster. The endpoint to use depends on whether the operation is a read such as SELECT statement, or a write such as a CREATE or INSERT statement. As you increase the workload on an Aurora cluster and experiment with Aurora features, it's important for your application to assign each operation to the appropriate endpoint.

By using the cluster endpoint for write operations, you always connect to a DB instance in the cluster that has read/write capability. By default, only one DB instance in an Aurora cluster has read/write capability. This DB instance is called the primary instance. If the original primary instance becomes unavailable, Aurora activates a failover mechanism and a different DB instance takes over as the primary.

Similarly, by directing SELECT statements to the reader endpoint, you spread the work of processing queries among the DB instances in the cluster. Each reader connection is assigned to a different DB instance using round-robin DNS resolution. Doing most of the query work on the read-only DB Aurora Replicas reduces the load on the primary instance, freeing it to handle DDL and DML statements.

Using these endpoints reduces the dependency on hard-coded hostnames, and helps your application to recover more quickly from DB instance failures.

**Note**

Aurora also has custom endpoints that you create. Those endpoints usually aren't needed during a proof of concept.

The Aurora Replicas are subject to a replica lag, even though that lag is usually 10 to 20 milliseconds. You can monitor the replication lag and decide whether it is within the range of your data consistency requirements. In some cases, your read queries might require strong read consistency (read-after-write consistency). In these cases, you can continue using the cluster endpoint for them and not the reader endpoint.

To take full advantage of Aurora capabilities for distributed parallel execution, you might need to change the connection logic. Your objective is to avoid sending all read requests to the primary instance. The read-only Aurora Replicas are standing by, with all the same data, ready to handle SELECT statements. Code your application logic to use the appropriate endpoint for each kind of operation. Follow these general guidelines:

- Avoid using a single hard-coded connection string for all database sessions.
- If practical, enclose write operations such as DDL and DML statements in functions in your client application code. That way, you can make different kinds of operations use specific connections.
- Make separate functions for query operations. Aurora assigns each new connection to the reader endpoint to a different Aurora Replica to balance the load for read-intensive applications.
- For operations involving sets of queries, close and reopen the connection to the reader endpoint when each set of related queries is finished. Use connection pooling if that feature is available in your software stack. Directing queries to different connections helps Aurora to distribute the read workload among the DB instances in the cluster.
10. Run your workload

After the schema, data, and configuration settings are in place, you can begin exercising the cluster by running your workload. Use a workload in the proof of concept that mirrors the main aspects of your production workload. We recommend always making decisions about performance using real-world tests and workloads rather than synthetic benchmarks such as sysbench or TPC-C. Wherever practical, gather measurements based on your own schema, query patterns, and usage volume.

As much as practical, replicate the actual conditions under which the application will run. For example, you typically run your application code on Amazon EC2 instances in the same AWS Region and the same virtual private cloud (VPC) as the Aurora cluster. If your production application runs on multiple EC2 instances spanning multiple Availability Zones, set up your proof-of-concept environment in the same way. For more information on AWS Regions, see Regions and Availability Zones in the Amazon RDS User Guide. To learn more about the Amazon VPC service, see What is Amazon VPC? in the Amazon VPC User Guide.

After you've verified that the basic features of your application work and you can access the data through Aurora, you can exercise aspects of the Aurora cluster. Some features you might want to try are concurrent connections with load balancing, concurrent transactions, and automatic replication.

By this point, the data transfer mechanisms should be familiar, and so you can run tests with a larger proportion of sample data.

This stage is when you can see the effects of changing configuration settings such as memory limits and connection limits. Revisit the procedures that you explored in 8. Specify configuration settings (p. 2360).

You can also experiment with mechanisms such as creating and restoring snapshots. For example, you can create clusters with different AWS instance classes, numbers of AWS Replicas, and so on. Then on each cluster, you can restore the same snapshot containing your schema and all your data. For the details of that cycle, see Creating a DB cluster snapshot (p. 437) and Restoring from a DB cluster snapshot (p. 439).

11. Measure performance

Best practices in this area are designed to ensure that all the right tools and processes are set up to quickly isolate abnormal behaviors during workload operations. They're also set up to see that you can reliably identify any applicable causes.

You can always see the current state of your cluster, or examine trends over time, by examining the Monitoring tab. This tab is available from the console detail page for each Aurora cluster or DB instance. It displays metrics from the Amazon CloudWatch monitoring service in the form of charts. You can filter the metrics by name, by DB instance, and by time period.

To have more choices on the Monitoring tab, enable Enhanced Monitoring and Performance Insights in the cluster settings. You can also enable those choices later if you didn't choose them when setting up the cluster.

To measure performance, you rely mostly on the charts showing activity for the whole Aurora cluster. You can verify whether the Aurora Replicas have similar load and response times. You can also see how the work is split up between the read/write primary instance and the read-only Aurora Replicas. If there is some imbalance between the DB instances or an issue affecting only one DB instance, you can examine the Monitoring tab for that specific instance.
After the environment and the actual workload are set up to emulate your production application, you can measure how well Aurora performs. The most important questions to answer are as follows:

- How many queries per second is Aurora processing? You can examine the Throughput metrics to see the figures for various kinds of operations.
- How long does it take, on average for Aurora to process a given query? You can examine the Latency metrics to see the figures for various kinds of operations.

To do so, look at the Monitoring tab for a given Aurora cluster in the Amazon RDS console as illustrated following.

If you can, establish baseline values for these metrics in your current environment. If that's not practical, construct a baseline on the Aurora cluster by executing a workload equivalent to your production application. For example, run your Aurora workload with a similar number of simultaneous users and queries. Then observe how the values change as you experiment with different instance classes, cluster size, configuration settings, and so on.

If the throughput numbers are lower than you expect, investigate further the factors affecting database performance for your workload. Similarly, if the latency numbers are higher than you expect, further investigate. To do so, monitor the secondary metrics for the DB server (CPU, memory, and so on). You can see whether the DB instances are close to their limits. You can also see how much extra capacity your DB instances have to handle more concurrent queries, queries against larger tables, and so on.

**Tip**

To detect metric values that fall outside the expected ranges, set up CloudWatch alarms.

When evaluating the ideal Aurora cluster size and capacity, you can find the configuration that achieves peak application performance without over-provisioning resources. One important factor is finding
the appropriate size for the DB instances in the Aurora cluster. Start by selecting an instance size that has similar CPU and memory capacity to your current production environment. Collect throughput and latency numbers for the workload at that instance size. Then, scale the instance up to the next larger size. See if the throughput and latency numbers improve. Also scale the instance size down, and see if the latency and throughput numbers remain the same. Your goal is to get the highest throughput, with the lowest latency, on the smallest instance possible.

Tip
Size your Aurora clusters and associated DB instances with enough existing capacity to handle sudden, unpredictable traffic spikes. For mission-critical databases, leave at least 20 percent spare CPU and memory capacity.

Run performance tests long enough to measure database performance in a warm, steady state. You might need to run the workload for many minutes or even a few hours before reaching this steady state. It's normal at the beginning of a run to have some variance. This variance happens because each Aurora Replica warms up its caches based on the SELECT queries that it handles.

Aurora performs best with transactional workloads involving multiple concurrent users and queries. To ensure that you're driving enough load for optimal performance, run benchmarks that use multithreading, or run multiple instances of the performance tests concurrently. Measure performance with hundreds or even thousands of concurrent client threads. Simulate the number of concurrent threads that you expect in your production environment. You might also perform additional stress tests with more threads to measure Aurora scalability.

12. Exercise Aurora high availability

Many of the main Aurora features involve high availability. These features include automatic replication, automatic failover, automatic backups with point-in-time restore, and ability to add DB instances to the cluster. The safety and reliability from features like these are important for mission-critical applications.

To evaluate these features requires a certain mindset. In earlier activities, such as performance measurement, you observe how the system performs when everything works correctly. Testing high availability requires you to think through worst-case behavior. You must consider various kinds of failures, even if such conditions are rare. You might intentionally introduce problems to make sure that the system recovers correctly and quickly.

Tip
For a proof of concept, set up all the DB instances in an Aurora cluster with the same AWS instance class. Doing so makes it possible to try out Aurora availability features without major changes to performance and scalability as you take DB instances offline to simulate failures.

We recommend using at least two instances in each Aurora cluster. The DB instances in an Aurora cluster can span up to three Availability Zones (AZs). Locate each of the first two or three DB instances in a different AZ. When you begin using larger clusters, spread your DB instances across all of the AZs in your AWS Region. Doing so increases fault tolerance capability. Even if a problem affects an entire AZ, Aurora can fail over to a DB instance in a different AZ. If you run a cluster with more than three instances, distribute the DB instances as evenly as you can over all three AZs.

Tip
The storage for an Aurora cluster is independent from the DB instances. The storage for each Aurora cluster always spans three AZs. When you test high availability features, always use DB instances with identical capacity in your test cluster. Doing so avoids unpredictable changes in performance, latency, and so on whenever one DB instance takes over for another.

To learn how to simulate failure conditions to test high availability features, see Testing Amazon Aurora MySQL using fault injection queries (p. 894).
As part of your proof-of-concept exercise, one objective is to find the ideal number of DB instances and the optimal instance class for those DB instances. Doing so requires balancing the requirements of high availability and performance.

For Aurora, the more DB instances that you have in a cluster, the greater the benefits for high availability. Having more DB instances also improves scalability of read-intensive applications. Aurora can distribute multiple connections for SELECT queries among the read-only Aurora Replicas.

On the other hand, limiting the number of DB instances reduces the replication traffic from the primary node. The replication traffic consumes network bandwidth, which is another aspect of overall performance and scalability. Thus, for write-intensive OLTP applications, prefer to have a smaller number of large DB instances rather than many small DB instances.

In a typical Aurora cluster, one DB instance (the primary instance) handles all the DDL and DML statements. The other DB instances (the Aurora Replicas) handle only SELECT statements. Although the DB instances don't do exactly the same amount of work, we recommend using the same instance class for all the DB instances in the cluster. That way, if a failure happens and Aurora promotes one of the read-only DB instances to be the new primary instance, the primary instance has the same capacity as before.

If you need to use DB instances of different capacities in the same cluster, set up failover tiers for the DB instances. These tiers determine the order in which Aurora Replicas are promoted by the failover mechanism. Put DB instances that are a lot larger or smaller than the others into a lower failover tier. Doing so ensures that they are chosen last for promotion.

Exercise the data recovery features of Aurora, such as automatic point-in-time restore, manual snapshots and restore, and cluster backtracking. If appropriate, copy snapshots to other AWS Regions and restore into other AWS Regions to mimic DR scenarios.

Investigate your organization's requirements for restore time objective (RTO), restore point objective (RPO), and geographic redundancy. Most organizations group these items under the broad category of disaster recovery. Evaluate the Aurora high availability features described in this section in the context of your disaster recovery process to ensure that your RTO and RPO requirements are met.

13. What to do next

At the end of a successful proof-of-concept process, you confirm that Aurora is a suitable solution for you based on the anticipated workload. Throughout the preceding process, you've checked how Aurora works in a realistic operational environment and measured it against your success criteria.

After you get your database environment up and running with Aurora, you can move on to more detailed evaluation steps, leading to your final migration and production deployment. Depending on your situation, these other steps might or might not be included in the proof-of-concept process. For details about migration and porting activities, see the AWS whitepaper Aurora migration handbook.

In another next step, consider the security configurations relevant for your workload and designed to meet your security requirements in a production environment. Plan what controls to put in place to protect access to the Aurora cluster master user credentials. Define the roles and responsibilities of database users to control access to data stored in the Aurora cluster. Take into account database access requirements for applications, scripts, and third-party tools or services. Explore AWS services and features such as AWS Secrets Manager and AWS Identity and Access Management (IAM) authentication.

At this point, you should understand the procedures and best practices for running benchmark tests with Aurora. You might find you need to do additional performance tuning. For details, see Managing performance and scaling for Aurora DB clusters (p. 297), Amazon Aurora MySQL performance enhancements (p. 779), Managing Amazon Aurora PostgreSQL (p. 1397), and Monitoring DB load with Performance Insights on Amazon Aurora (p. 559). If you do additional tuning, make sure that you're
familiar with the metrics that you gathered during the proof of concept. For a next step, you might create new clusters with different choices for configuration settings, database engine, and database version. Or you might create specialized kinds of Aurora clusters to match the needs of specific use cases.

For example, you can explore Aurora parallel query clusters for hybrid transaction/analytical processing (HTAP) applications. If wide geographic distribution is crucial for disaster recovery or to minimize latency, you can explore Aurora global databases. If your workload is intermittent or you're using Aurora in a development/test scenario, you can explore Aurora Serverless clusters.

Your production clusters might also need to handle high volumes of incoming connections. To learn those techniques, see the AWS whitepaper Aurora MySQL database administrator’s handbook – Connection management.

If, after the proof of concept, you decide that your use case is not suited for Aurora, consider these other AWS services:

- For purely analytic use cases, workloads benefit from a columnar storage format and other features more suitable to OLAP workloads. AWS services that address such use cases include the following:
  - Amazon Redshift
  - Amazon EMR
  - Amazon Athena
- Many workloads benefit from a combination of Aurora with one or more of these services. You can move data between these services by using these:
  - AWS Glue
  - AWS DMS
  - Importing from Amazon S3, as described in the Amazon Aurora User Guide
  - Exporting to Amazon S3, as described in the Amazon Aurora User Guide
  - Many other popular ETL tools
Security in Amazon Aurora

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS compliance programs. To learn about the compliance programs that apply to Amazon Aurora (Aurora), see AWS services in scope by compliance program.

- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your organization’s requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Amazon Aurora. The following topics show you how to configure Amazon Aurora to meet your security and compliance objectives. You also learn how to use other AWS services that help you monitor and secure your Amazon Aurora resources.

You can manage access to your Amazon Aurora resources and your databases on a DB cluster. The method you use to manage access depends on what type of task the user needs to perform with Amazon Aurora:

- Run your DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service for the greatest possible network access control. For more information about creating a DB cluster in a VPC, see Amazon VPC VPCs and Amazon Aurora (p. 2478).

- Use AWS Identity and Access Management (IAM) policies to assign permissions that determine who is allowed to manage Amazon Aurora resources. For example, you can use IAM to determine who is allowed to create, describe, modify, and delete DB clusters, tag resources, or modify security groups.

  To review IAM policy examples, see Identity-based policy examples for Amazon Aurora (p. 2409).

- Use security groups to control what IP addresses or Amazon EC2 instances can connect to your databases on a DB cluster. When you first create a DB cluster, its firewall prevents any database access except through rules specified by an associated security group.

  Use Secure Socket Layer (SSL) or Transport Layer Security (TLS) connections with DB clusters running the Aurora MySQL or Aurora PostgreSQL. For more information on using SSL/TLS with a DB cluster, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 2385).

- Use Amazon Aurora encryption to secure your DB clusters and snapshots at rest. Amazon Aurora encryption uses the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your DB cluster. For more information, see Encrypting Amazon Aurora resources (p. 2381).

- Use the security features of your DB engine to control who can log in to the databases on a DB cluster. These features work just as if the database was on your local network.

  For information about security with Aurora MySQL, see Security with Amazon Aurora MySQL (p. 813). For information about security with Aurora PostgreSQL, see Security with Amazon Aurora PostgreSQL (p. 1233).
Database authentication with Amazon Aurora

Amazon Aurora supports several ways to authenticate database users.

Password authentication is available by default for all DB clusters. For Aurora MySQL and Aurora PostgreSQL, you can also add either or both IAM database authentication and Kerberos authentication for the same DB cluster.

Password, Kerberos, and IAM database authentication use different methods of authenticating to the database. Therefore, a specific user can log in to a database using only one authentication method.

For PostgreSQL, use only one of the following role settings for a user of a specific database:

- To use IAM database authentication, assign the rds_iam role to the user.
• To use Kerberos authentication, assign the `rds_ad` role to the user.
• To use password authentication, don't assign either the `rds_iam` or `rds_ad` roles to the user.

Don't assign both the `rds_iam` and `rds_ad` roles to a user of a PostgreSQL database either directly or indirectly by nested grant access. If the `rds_iam` role is added to the master user, IAM authentication takes precedence over password authentication so the master user has to log in as an IAM user.

**Important**
We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

**Topics**
- Password authentication (p. 2369)
- IAM database authentication (p. 2369)
- Kerberos authentication (p. 2369)

**Password authentication**

With *password authentication*, your database performs all administration of user accounts. You create users with SQL statements such as `CREATE USER`, with the appropriate clause required by the DB engine for specifying passwords. For example, in MySQL the statement is `CREATE USER name IDENTIFIED BY password`, while in PostgreSQL, the statement is `CREATE USER name WITH PASSWORD password`.

With password authentication, your database controls and authenticates user accounts. If a DB engine has strong password management features, they can enhance security. Database authentication might be easier to administer using password authentication when you have small user communities. Because clear text passwords are generated in this case, integrating with AWS Secrets Manager can enhance security.

For information about using Secrets Manager with Amazon Aurora, see [Creating a basic secret](#) and [Rotating secrets for supported Amazon RDS databases](#) in the *AWS Secrets Manager User Guide*. For information about programmatically retrieving your secrets in your custom applications, see [Retrieving the secret value](#) in the *AWS Secrets Manager User Guide*.

**IAM database authentication**

You can authenticate to your DB cluster using AWS Identity and Access Management (IAM) database authentication. IAM database authentication works with Aurora MySQL and Aurora PostgreSQL. With this authentication method, you don't need to use a password when you connect to a DB cluster. Instead, you use an authentication token.

For more information about IAM database authentication, including information about availability for specific DB engines, see [IAM database authentication (p. 2432)](#).

**Kerberos authentication**

Amazon Aurora supports external authentication of database users using Kerberos and Microsoft Active Directory. Kerberos is a network authentication protocol that uses tickets and symmetric-key cryptography to eliminate the need to transmit passwords over the network. Kerberos has been built into Active Directory and is designed to authenticate users to network resources, such as databases.

Amazon Aurora support for Kerberos and Active Directory provides the benefits of single sign-on and centralized authentication of database users. You can keep your user credentials in Active Directory.
Active Directory provides a centralized place for storing and managing credentials for multiple DB clusters.

You can make it possible for your database users to authenticate against DB clusters in two ways. They can use credentials stored either in AWS Directory Service for Microsoft Active Directory or in your on-premises Active Directory.

Aurora supports Kerberos authentication for Aurora MySQL and Aurora PostgreSQL DB clusters. For more information about Kerberos authentication for Aurora MySQL, see Using Kerberos authentication for Aurora MySQL (p. 823).

With Kerberos authentication, Aurora PostgreSQL DB clusters support one- and two-way forest trust relationships. For more information, see Using Kerberos authentication with Aurora PostgreSQL (p. 1252).
Password management with Amazon Aurora and AWS Secrets Manager

Amazon Aurora integrates with Secrets Manager to manage master user passwords for your DB clusters.

Topics
- Region and version availability (p. 2371)
- Limitations for Secrets Manager integration with Amazon Aurora (p. 2371)
- Overview of managing master user passwords with AWS Secrets Manager (p. 2371)
- Benefits of managing master user passwords with Secrets Manager (p. 2372)
- Permissions required for Secrets Manager integration (p. 2372)
- Enforcing Aurora management of the master user password in AWS Secrets Manager (p. 2373)
- Managing the master user password for a DB cluster with Secrets Manager (p. 2373)
- Rotating the master user password secret for a DB cluster (p. 2376)
- Viewing the details about a secret for a DB cluster (p. 2378)

Region and version availability

Feature availability and support varies across specific versions of each database engine and across AWS Regions. For more information about version and Region availability with Secrets Manager integration with Amazon Aurora, see Secrets Manager integration (p. 53).

Limitations for Secrets Manager integration with Amazon Aurora

Managing master user passwords with Secrets Manager isn’t supported for the following features:

- Amazon RDS Blue/Green Deployments
- DB clusters that are part of an Aurora global database
- Aurora Serverless v1 DB clusters
- Aurora MySQL cross-Region read replicas
- Managing master user password with Secrets Manager for a read replica

Overview of managing master user passwords with AWS Secrets Manager

With AWS Secrets Manager, you can replace hard-coded credentials in your code, including database passwords, with an API call to Secrets Manager to retrieve the secret programmatically. For more information about Secrets Manager, see the AWS Secrets Manager User Guide. For pricing information, see AWS Secrets Manager pricing.

You can specify that Aurora manages the master user password in Secrets Manager for an Amazon Aurora DB cluster when you perform one of the following operations:

- Create the DB cluster
• Modify the DB cluster
• Restore the DB cluster from Amazon S3 (Aurora MySQL only)

When you specify that Aurora manages the master user password in Secrets Manager, Aurora generates the password and stores it in Secrets Manager. You can interact directly with the secret to retrieve the credentials for the master user. You can also specify a customer managed key to encrypt the secret, or use the KMS key that is provided by Secrets Manager.

Aurora manages the settings for the secret and rotates the secret every seven days by default. You can modify some of the settings, such as the rotation schedule. If you delete a DB cluster that manages a secret in Secrets Manager, the secret and its associated metadata are also deleted.

To connect to a DB cluster with the credentials in a secret, you can retrieve the secret from Secrets Manager. For more information, see Retrieve secrets from AWS Secrets Manager and Connect to a SQL database with credentials in an AWS Secrets Manager secret in the AWS Secrets Manager User Guide.

Benefits of managing master user passwords with Secrets Manager

Managing Aurora master user passwords with Secrets Manager provides the following benefits:

• Aurora automatically generates database credentials.
• Aurora automatically stores and manages database credentials in AWS Secrets Manager.
• Aurora rotates database credentials regularly, without requiring application changes.
• Secrets Manager secures database credentials from human access and plain text view.
• Secrets Manager allows retrieval of database credentials in secrets for database connections.
• Secrets Manager allows fine-grained control of access to database credentials in secrets using IAM.
• You can optionally separate database encryption from credentials encryption with different KMS keys.
• You can eliminate manual management and rotation of database credentials.
• You can monitor database credentials easily with AWS CloudTrail and Amazon CloudWatch.

For more information about the benefits of Secrets Manager, see the AWS Secrets Manager User Guide.

Permissions required for Secrets Manager integration

Users must have the required permissions to perform operations related to Secrets Manager integration. You can create IAM policies that grant permissions to perform specific API operations on the specified resources they need. You can then attach those policies to the IAM permission sets or roles that require those permissions. For more information, see Identity and access management for Amazon Aurora (p. 2400).

For create, modify, or restore operations, the user who specifies that Aurora manages the master user password in Secrets Manager must have permissions to perform the following operations:

• kms:DescribeKey
• secretsmanager:CreateSecret
• secretsmanager:TagResource

For create, modify, or restore operations, the user who specifies the customer managed key to encrypt the secret in Secrets Manager must have permissions to perform the following operations:
Amazon Aurora User Guide for Aurora
Enforcing Aurora management

• kms:Decrypt
• kms:GenerateDataKey
• kms:CreateGrant

For modify operations, the user who rotates the master user password in Secrets Manager must have permissions to perform the following operation:

• secretsmanager:RotateSecret

Enforcing Aurora management of the master user password in AWS Secrets Manager

You can use IAM condition keys to enforce Aurora management of the master user password in AWS Secrets Manager. The following policy doesn't allow users to create or restore DB instances or DB clusters unless the master user password is managed by Aurora in Secrets Manager.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": ["rds:CreateDBInstance", "rds:CreateDBCluster",
                        "rds:RestoreDBInstanceFromS3", "rds:RestoreDBClusterFromS3"],
            "Resource": "*",
            "Condition": {
                "Bool": {
                    "rds:ManageMasterUserPassword": false
                }
            }
        }
    ]
}
```

Note
This policy enforces password management in AWS Secrets Manager at creation. However, you can still disable Secrets Manager integration and manually set a master password by modifying the cluster.
To prevent this, include rds:ModifyDBInstance, rds:ModifyDBCluster in the action block of the policy. Be aware, this prevents the user from applying any further modifications to existing clusters that don't have Secrets Manager integration enabled.

For more information about using condition keys in IAM policies, see Policy condition keys for Aurora (p. 2407) and Example policies: Using condition keys (p. 2416).

Managing the master user password for a DB cluster with Secrets Manager

You can configure Aurora management of the master user password in Secrets Manager when you perform the following actions:

• Creating an Amazon Aurora DB cluster (p. 179)
• Modifying an Amazon Aurora DB cluster (p. 269)
• Migrating data from an external MySQL database to an Amazon Aurora MySQL DB cluster (p. 839)
You can use the RDS console, the AWS CLI, or the RDS API to perform these actions.

**Console**

Follow the instructions for creating or modifying a DB cluster with the RDS console:

- Creating a DB cluster (p. 183)
- Modifying a DB instance in a DB cluster (p. 270)

In the RDS console, you can modify any DB instance to specify the master user password management settings for the entire DB cluster.

- Restoring an Amazon Aurora MySQL DB cluster from an Amazon S3 bucket (p. 845)

When you use the RDS console to perform one of these operations, you can specify that the master user password is managed by Aurora in Secrets Manager. To do so when you are creating or restoring a DB cluster, select Manage master credentials in AWS Secrets Manager in Credential settings. When you are modifying a DB cluster, select Manage master credentials in AWS Secrets Manager in Settings.

The following image is an example of the Manage master credentials in AWS Secrets Manager setting when you are creating or restoring a DB cluster.

![Manage master credentials in AWS Secrets Manager](image)

When you select this option, Aurora generates the master user password and manages it throughout its lifecycle in Secrets Manager.
You can choose to encrypt the secret with a KMS key that Secrets Manager provides or with a customer managed key that you create. After Aurora is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements.

For more information about the available settings when you are creating a DB cluster, see Settings for Aurora DB clusters (p. 190). For more information about the available settings when you are modifying a DB cluster, see Settings for Amazon Aurora (p. 272).

**AWS CLI**

To specify that Aurora manages the master user password in Secrets Manager, specify the `--manage-master-user-password` option in one of the following commands:

- `create-db-cluster`
- `modify-db-cluster`
- `restore-db-cluster-from-s3`

When you specify the `--manage-master-user-password` option in these commands, Aurora generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `--master-user-secret-kms-key-id` option to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN. After Aurora is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements.

For more information about the available settings when you are creating a DB cluster, see Settings for Aurora DB clusters (p. 190). For more information about the available settings when you are modifying a DB cluster, see Settings for Amazon Aurora (p. 272).

This example creates a DB cluster and specifies that Aurora manages the password in Secrets Manager. The secret is encrypted using the KMS key that is provided by Secrets Manager.
Example

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster
  --db-cluster-identifier sample-cluster
  --engine aurora-mysql
  --engine-version 8.0
  --master-username admin
  --manage-master-user-password
```

For Windows:

```bash
aws rds create-db-cluster
  --db-cluster-identifier sample-cluster
  --engine aurora-mysql
  --engine-version 8.0
  --master-username admin
  --manage-master-user-password
```

RDS API

To specify that Aurora manages the master user password in Secrets Manager, set the
`ManageMasterUserPassword` parameter to `true` in one of the following operations:

- `CreateDBCluster`
- `ModifyDBCluster`
- `RestoreDBClusterFromS3`

When you set the `ManageMasterUserPassword` parameter to `true` in one of these operations, Aurora
generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is
provided by Secrets Manager. Use the `MasterUserSecretKmsKeyId` parameter to specify a customer
managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS
key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN. After Aurora is
managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt
the secret.

Rotating the master user password secret for a DB
cluster

When Aurora rotates a master user password secret, Secrets Manager generates a new secret version
for the existing secret. The new version of the secret contains the new master user password. Aurora
changes the master user password for the DB cluster to match the password for the new secret version.

You can rotate a secret immediately instead of waiting for a scheduled rotation. To rotate a master
user password secret in Secrets Manager, modify the DB cluster. For information about modifying a DB
cluster, see Modifying an Amazon Aurora DB cluster (p. 269).

You can rotate a master user password secret immediately with the RDS console, the AWS CLI, or the RDS
API.

Console

To rotate a master user password secret using the RDS console, modify the DB cluster and select Rotate
secret immediately in Settings.
Follow the instructions for modifying a DB cluster with the RDS console in Modifying the DB cluster by using the console, CLI, and API (p. 269). You must choose Apply immediately on the confirmation page.

**AWS CLI**

To rotate a master user password secret using the AWS CLI, use the modify-db-cluster command and specify the --rotate-master-user-password option. You must specify the --apply-immediately option when you rotate the master password.

This example rotates a master user password secret.

**Example**

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
  --db-cluster-identifier mydbcluster \
  --rotate-master-user-password \
  --apply-immediately
```

For Windows:

```
aws rds modify-db-cluster ^
  --db-cluster-identifier mydbcluster ^
  --rotate-master-user-password ^
  --apply-immediately
```
RDS API

You can rotate a master user password secret using the ModifyDBCluster operation and setting the RotateMasterUserPassword parameter to true. You must set the ApplyImmediately parameter to true when you rotate the master password.

Viewing the details about a secret for a DB cluster

You can retrieve your secrets using the console (https://console.aws.amazon.com/secretsmanager/) or the AWS CLI (get-secret-value Secrets Manager command).

You can find the Amazon Resource Name (ARN) of a secret managed by Aurora in Secrets Manager with the RDS console, the AWS CLI, or the RDS API.

Console

To view the details about a secret managed by Aurora in Secrets Manager

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the name of the DB cluster to show its details.
4. Choose the Configuration tab.

In Master Credentials ARN, you can view the secret ARN.

AWS CLI

You can use the RDS AWS CLI describe-db-clusters command to find the following information about a secret managed by Aurora in Secrets Manager:

- SecretArn – The ARN of the secret
- SecretStatus – The status of the secret

The possible status values include the following:
Viewing the details about a secret for a DB cluster

- creating – The secret is being created.
- active – The secret is available for normal use and rotation.
- rotating – The secret is being rotated.
- impaired – The secret can be used to access database credentials, but it can't be rotated. A secret might have this status if, for example, permissions are changed so that RDS can no longer access the secret or the KMS key for the secret.

When a secret has this status, you can correct the condition that caused the status. If you correct the condition that caused status, the status remains impaired until the next rotation. Alternatively, you can modify the DB cluster to turn off automatic management of database credentials, and then modify the DB cluster again to turn on automatic management of database credentials. To modify the DB cluster, use the --manage-master-user-password option in the modify-db-cluster command.

- KmsKeyId – The ARN of the KMS key that is used to encrypt the secret

Specify the --db-cluster-identifier option to show output for a specific DB cluster. This example shows the output for a secret that is used by a DB cluster.

**Example**

```bash
grep -i -e "\"SecretArn\"" -e "\"SecretStatus\"" -e "\"KmsKeyId\"" --db-cluster-identifier mydbcluster
```

The following sample shows the output for a secret:

```bash
"MasterUserSecret": {
  "SecretArn": "arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx",
  "SecretStatus": "active",
  "KmsKeyId": "arn:aws:kms:eu-west-1:123456789012:key/0987dcba-09fe-87dc-65ba-ab0987654321"
}
```

When you have the secret ARN, you can view details about the secret using the get-secret-value Secrets Manager CLI command.

This example shows the details for the secret in the previous sample output.

**Example**

For Linux, macOS, or Unix:

```bash
aws secretsmanager get-secret-value \
  --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

For Windows:

```bash
aws secretsmanager get-secret-value ^
  --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

**RDS API**

You can view the ARN, status, and KMS key for a secret managed by Aurora in Secrets Manager using the DescribeDBClusters RDS operation and setting the DBClusterIdentifier parameter to a DB cluster identifier. Details about the secret are included in the output.
When you have the secret ARN, you can view details about the secret using the `GetSecretValue` Secrets Manager operation.

## Data protection in Amazon RDS

The AWS shared responsibility model applies to data protection in Amazon Relational Database Service. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. This content includes the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see the AWS Shared Responsibility Model and GDPR blog post on the AWS Security Blog.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual users with AWS IAM Identity Center or AWS Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with AWS CloudTrail.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.

We strongly recommend that you never put confidential or sensitive information, such as your customers’ email addresses, into tags or free-form text fields such as a Name field. This includes when you work with Amazon RDS or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

- Internetwork traffic privacy (p. 2399)

## Protecting data using encryption

You can enable encryption for database resources. You can also encrypt connections to DB clusters.

### Topics
- Encrypting Amazon Aurora resources (p. 2381)
- AWS KMS key management (p. 2384)
- Using SSL/TLS to encrypt a connection to a DB cluster (p. 2385)
- Rotating your SSL/TLS certificate (p. 2391)
Data encryption

Encrypting Amazon Aurora resources

Amazon Aurora can encrypt your Amazon Aurora DB clusters. Data that is encrypted at rest includes the underlying storage for DB clusters, its automated backups, read replicas, and snapshots.

Amazon Aurora encrypted DB clusters use the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your Amazon Aurora DB clusters. After your data is encrypted, Amazon Aurora handles authentication of access and decryption of your data transparently with a minimal impact on performance. You don’t need to modify your database client applications to use encryption.

**Note**
For encrypted and unencrypted DB clusters, data that is in transit between the source and the read replicas is encrypted, even when replicating across AWS Regions.

**Topics**
- Overview of encrypting Amazon Aurora resources (p. 2381)
- Encrypting an Amazon Aurora DB cluster (p. 2381)
- Determining whether encryption is turned on for a DB cluster (p. 2382)
- Availability of Amazon Aurora encryption (p. 2383)
- Limitations of Amazon Aurora encrypted DB clusters (p. 2383)

Overview of encrypting Amazon Aurora resources

Amazon Aurora encrypted DB clusters provide an additional layer of data protection by securing your data from unauthorized access to the underlying storage. You can use Amazon Aurora encryption to increase data protection of your applications deployed in the cloud, and to fulfill compliance requirements for encryption at rest.

For an Amazon Aurora encrypted DB cluster, all DB instances, logs, backups, and snapshots are encrypted. You can also encrypt a read replica of an Amazon Aurora encrypted cluster. Amazon Aurora uses an AWS KMS key to encrypt these resources. For more information about KMS keys, see AWS KMS keys in the AWS Key Management Service Developer Guide and AWS KMS key management (p. 2384). Each DB instance in the DB cluster is encrypted using the same KMS key as the DB cluster. If you copy an encrypted snapshot, you can use a different KMS key to encrypt the target snapshot than the one that was used to encrypt the source snapshot.

You can use an AWS managed key, or you can create customer managed keys. To manage the customer managed keys used for encrypting and decrypting your Amazon Aurora resources, you use the AWS Key Management Service (AWS KMS). AWS KMS combines secure, highly available hardware and software to provide a key management system scaled for the cloud. Using AWS KMS, you can create customer managed keys and define the policies that control how these customer managed keys can be used. AWS KMS supports CloudTrail, so you can audit KMS key usage to verify that customer managed keys are being used appropriately. You can use your customer managed keys with Amazon Aurora and supported AWS services such as Amazon S3, Amazon EBS, and Amazon Redshift. For a list of services that are integrated with AWS KMS, see AWS Service Integration.

Encrypting an Amazon Aurora DB cluster

To encrypt a new DB cluster, choose **Enable encryption** on the console. For information on creating a DB cluster, see Creating an Amazon Aurora DB cluster (p. 179).

If you use the create-db-cluster AWS CLI command to create an encrypted DB cluster, set the --storage-encrypted parameter. If you use the CreateDBCluster API operation, set the StorageEncrypted parameter to true.
When you create an encrypted DB cluster, you can choose a customer managed key or the AWS managed key for Amazon Aurora to encrypt your DB cluster. If you don't specify the key identifier for a customer managed key, Amazon Aurora uses the AWS managed key for your new DB cluster. Amazon Aurora creates an AWS managed key for Amazon Aurora for your AWS account. Your AWS account has a different AWS managed key for Amazon Aurora for each AWS Region.

For more information about KMS keys, see AWS KMS keys in the AWS Key Management Service Developer Guide.

Once you have created an encrypted DB cluster, you can't change the KMS key used by that DB cluster. Therefore, be sure to determine your KMS key requirements before you create your encrypted DB cluster.

If you use the AWS CLI create-db-cluster command to create an encrypted DB cluster with a customer managed key, set the --kms-key-id parameter to any key identifier for the KMS key. If you use the Amazon RDS API CreateDBInstance operation, set the KmsKeyId parameter to any key identifier for the KMS key. To use a customer managed key in a different AWS account, specify the key ARN or alias ARN.

Important
Amazon Aurora can lose access to the KMS key for a DB cluster. For example, Aurora loses access when the KMS key isn't enabled, or when Aurora access to a KMS key is revoked. In these cases, the encrypted DB cluster goes into inaccessible-encryption-credentials-recoverable state. The DB cluster remains in this state for seven days. When you start the DB cluster during that time, it checks if the KMS key is active and recovers the DB cluster if it is. Restart the DB cluster using the AWS CLI command start-db-cluster or AWS Management Console.

If the DB cluster isn't recovered, then it goes into the terminal inaccessible-encryption-credentials state. In this case, you can only restore the DB cluster from a backup. We strongly recommend that you always turn on backups for encrypted DB instances to guard against the loss of encrypted data in your databases.

Determining whether encryption is turned on for a DB cluster

You can use the AWS Management Console, AWS CLI, or RDS API to determine whether encryption at rest is turned on for a DB cluster.

Console

To determine whether encryption at rest is turned on for a DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the name of the DB cluster that you want to check to view its details.
4. Choose the Configuration tab and check the Encryption value.

   It shows either Enabled or Not enabled.
AWS CLI

To determine whether encryption at rest is turned on for a DB cluster by using the AWS CLI, call the `describe-db-clusters` command with the following option:

- `--db-cluster-identifier` – The name of the DB cluster.

The following example uses a query to return either TRUE or FALSE regarding encryption at rest for the `mydb` DB cluster.

**Example**

```
aws rds describe-db-clusters --db-cluster-identifier mydb --query "[*].{StorageEncrypted:StorageEncrypted}" --output text
```

RDS API

To determine whether encryption at rest is turned on for a DB cluster by using the Amazon RDS API, call the `DescribeDBClusters` operation with the following parameter:

- `DBClusterIdentifier` – The name of the DB cluster.

Availability of Amazon Aurora encryption

Amazon Aurora encryption is currently available for all database engines and storage types.

**Note**

Amazon Aurora encryption is not available for the `db.t2.micro` DB instance class.

Limitations of Amazon Aurora encrypted DB clusters

The following limitations exist for Amazon Aurora encrypted DB clusters:
• You can't turn off encryption on an encrypted DB cluster.
• You can't create an encrypted snapshot of an unencrypted DB cluster.
• A snapshot of an encrypted DB cluster must be encrypted using the same KMS key as the DB cluster.
• You can't convert an unencrypted DB cluster to an encrypted one. However, you can restore an unencrypted snapshot to an encrypted Aurora DB cluster. To do this, specify a KMS key when you restore from the unencrypted snapshot.
• You can't create an encrypted Aurora Replica from an unencrypted Aurora DB cluster. You can't create an unencrypted Aurora Replica from an encrypted Aurora DB cluster.
• To copy an encrypted snapshot from one AWS Region to another, you must specify the KMS key in the destination AWS Region. This is because KMS keys are specific to the AWS Region that they are created in.

The source snapshot remains encrypted throughout the copy process. Amazon Aurora uses envelope encryption to protect data during the copy process. For more information about envelope encryption, see Envelope encryption in the AWS Key Management Service Developer Guide.
• You can't unencrypt an encrypted DB cluster. However, you can export data from an encrypted DB cluster and import the data into an unencrypted DB cluster.

AWS KMS key management

Amazon Aurora automatically integrates with AWS Key Management Service (AWS KMS) for key management. Amazon Aurora uses envelope encryption. For more information about envelope encryption, see Envelope encryption in the AWS Key Management Service Developer Guide.

You can use two types of AWS KMS keys to encrypt your DB clusters.

• If you want full control over a KMS key, you must create a customer managed key. For more information about customer managed keys, see Customer managed keys in the AWS Key Management Service Developer Guide.

You can't share a snapshot that has been encrypted using the AWS managed key of the AWS account that shared the snapshot.
• AWS managed keys are KMS keys in your account that are created, managed, and used on your behalf by an AWS service that is integrated with AWS KMS. By default, the RDS AWS managed key (aws/rdss) is used for encryption. You can't manage, rotate, or delete the RDS AWS managed key. For more information about AWS managed keys, see AWS managed keys in the AWS Key Management Service Developer Guide.

To manage KMS keys used for Amazon Aurora encrypted DB clusters, use the AWS Key Management Service (AWS KMS) in the AWS KMS console, the AWS CLI, or the AWS KMS API. To view audit logs of every action taken with an AWS managed or customer managed key, use AWS CloudTrail. For more information about key rotation, see Rotating AWS KMS keys.

Important
If you turn off or revoke permissions to a KMS key used by an RDS database, RDS puts your database into a terminal state when access to the KMS key is required. This change could be immediate, or deferred, depending on the use case that required access to the KMS key. In this state, the DB cluster is no longer available, and the current state of the database can't be recovered. To restore the DB cluster, you must re-enable access to the KMS key for RDS, and then restore the DB cluster from the latest available backup.

Authorizing use of a customer managed key

When Aurora uses a customer managed key in cryptographic operations, it acts on behalf of the user who is creating or changing the Aurora resource.
To create an Aurora resource using a customer managed key, a user must have permissions to call the following operations on the customer managed key:

- `kms:CreateGrant`
- `kms:DescribeKey`

You can specify these required permissions in a key policy, or in an IAM policy if the key policy allows it.

You can make the IAM policy stricter in various ways. For example, if you want to allow the customer managed key to be used only for requests that originate in Aurora, you can use the `kms:ViaService condition key` with the `rds.<region>.amazonaws.com` value. Also, you can use the keys or values in the Amazon RDS encryption context (p. 2385) as a condition for using the customer managed key for encryption.

For more information, see Allowing users in other accounts to use a KMS key in the AWS Key Management Service Developer Guide and Key policies in AWS KMS.

### Amazon RDS encryption context

When Aurora uses your KMS key, or when Amazon EBS uses the KMS key on behalf of Aurora, the service specifies an encryption context. The encryption context is additional authenticated data (AAD) that AWS KMS uses to ensure data integrity. When an encryption context is specified for an encryption operation, the service must specify the same encryption context for the decryption operation. Otherwise, decryption fails. The encryption context is also written to your AWS CloudTrail logs to help you understand why a given KMS key was used. Your CloudTrail logs might contain many entries describing the use of a KMS key, but the encryption context in each log entry can help you determine the reason for that particular use.

At minimum, Aurora always uses the DB instance ID for the encryption context, as in the following JSON-formatted example:

```
{ "aws:rds:db-id": "db-CQYSMDPBRZ7BPMH7Y3RTD6SQY" }
```

This encryption context can help you identify the DB instance for which your KMS key was used.

When your KMS key is used for a specific DB instance and a specific Amazon EBS volume, both the DB instance ID and the Amazon EBS volume ID are used for the encryption context, as in the following JSON-formatted example:

```
{
  "aws:rds:db-id": "db-BRG7VYS3SVIFQW7234EJQOM5RQ",
  "aws:ebs:id": "vol-ad8c6542"
}
```

### Using SSL/TLS to encrypt a connection to a DB cluster

You can use Secure Socket Layer (SSL) or Transport Layer Security (TLS) from your application to encrypt a connection to a DB cluster running Aurora MySQL or Aurora PostgreSQL.

SSL/TLS connections provide a layer of security by encrypting data that moves between your client and DB cluster. Optionally, your SSL/TLS connection can perform server identity verification by validating the server certificate installed on your DB cluster. To require server identity verification, follow this general process:

1. Choose the certificate authority (CA) that signs the DB server certificate, for your database. For more information about certificate authorities, see Certificate authorities (p. 2386).
2. Download a certificate bundle to use when you are connecting to the database. To download a certificate bundle, see **Certificate bundles for all AWS Regions (p. 2389)** and **Certificate bundles for specific AWS Regions (p. 2389)**.

   **Note**
   
   All certificates are only available for download using SSL/TLS connections.

3. Connect to the database using your DB engine's process for implementing SSL/TLS connections. Each DB engine has its own process for implementing SSL/TLS. To learn how to implement SSL/TLS for your database, follow the link that corresponds to your DB engine:

   - [Security with Amazon Aurora MySQL (p. 813)](p. 813)
   - [Security with Amazon Aurora PostgreSQL (p. 1233)](p. 1233)

## Certificate authorities

The **certificate authority (CA)** is the certificate that identifies the root CA at the top of the certificate chain. The CA signs the **DB server certificate**, which is installed on each DB instance. The DB server certificate identifies the DB instance as a trusted server.

![Certificate authority diagram]

Amazon RDS provides the following CAs to sign the DB server certificate for a DB instance.

<table>
<thead>
<tr>
<th>Certificate authority (CA)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rds-ca-2019</td>
<td>Uses a certificate authority with RSA 2048 private key algorithm and SHA256 signing algorithm. This CA expires in 2024 and doesn't support automatic server certificate rotation. If you are using this CA and want to keep the same standard, we recommend that you switch to the rds-ca-rsa2048-g1 CA.</td>
</tr>
<tr>
<td>rds-ca-rsa2048-g1</td>
<td>Uses a certificate authority with RSA 2048 private key algorithm and SHA256 signing algorithm in most AWS Regions.</td>
</tr>
</tbody>
</table>
Certificate authority (CA) | Description
--- | ---
 | In the AWS GovCloud (US) Regions, this CA uses a certificate authority with RSA 2048 private key algorithm and SHA384 signing algorithm.
 | This CA remains valid for longer than the rds-ca-2019 CA. This CA supports automatic server certificate rotation.
 | Uses a certificate authority with RSA 4096 private key algorithm and SHA384 signing algorithm. This CA supports automatic server certificate rotation.
 | Uses a certificate authority with ECC 384 private key algorithm and SHA384 signing algorithm. This CA supports automatic server certificate rotation.

Note
If you are using the AWS CLI, you can see the validities of the certificate authorities listed above by using `describe-certificates`.

These CA certificates are included in the regional and global certificate bundle. When you use the rds-ca-rsa2048-g1, rds-ca-rsa4096-g1, or rds-ca-ecc384-g1 CA with a database, RDS manages the DB server certificate on the database. RDS rotates the DB server certificate automatically before it expires.

Setting the CA for your database

You can set the CA for a database when you perform the following tasks:

- Create an Aurora DB cluster – You can set the CA for a DB instance in an Aurora cluster when you create the first DB instance in the DB cluster using the AWS CLI or RDS API. Currently, you can't set the CA for the DB instances in a DB cluster when you create the DB cluster using the RDS console. For instructions, see [Creating an Amazon Aurora DB cluster](p. 179).
- Modify a DB instance – You can set the CA for a DB instance in a DB cluster by modifying it. For instructions, see [Modifying a DB instance in a DB cluster](p. 270).

Note
If you are using the AWS CLI, you can override the default CA for your AWS account by using the `modify-certificates` command.

The available CAs depend on the DB engine and DB engine version. When you use the AWS Management Console, you can choose the CA using the Certificate authority setting, as shown in the following image.

The console only shows the CAs that are available for the DB engine and DB engine version. If you are using the AWS CLI, you can set the CA for a DB instance using the `create-db-instance` or `modify-db-instance` command.

If you are using the AWS CLI, you can see the available CAs for your account by using the `describe-certificates` command. This command also shows the expiration date for each CA in `ValidTill` in the...
output. You can find the CAs that are available for a specific DB engine and DB engine version using the `describe-db-engine-versions` command.

The following example shows the CAs available for the default RDS for PostgreSQL DB engine version.

```
aws rds describe-db-engine-versions --default-only --engine postgres
```

Your output is similar to the following. The available CAs are listed in `SupportedCACertificateIdentifiers`. The output also shows whether the DB engine version supports rotating the certificate without restart in `SupportsCertificateRotationWithoutRestart`.

```
{
   "DBEngineVersions": [
      {
         "Engine": "postgres",
         "MajorEngineVersion": "13",
         "EngineVersion": "13.4",
         "DBParameterGroupFamily": "postgres13",
         "DBEngineDescription": "PostgreSQL",
         "DBEngineVersionDescription": "PostgreSQL 13.4-R1",
         "ValidUpgradeTarget": [],
         "SupportsLogExportsToCloudwatchLogs": false,
         "SupportsReadReplica": true,
         "SupportedFeatureNames": [
            "Lambda"
         ],
         "Status": "available",
         "SupportsParallelQuery": false,
         "SupportsGlobalDatabases": false,
         "SupportsBabelfish": false,
         "SupportsCertificateRotationWithoutRestart": true,
         "SupportedCACertificateIdentifiers": [
            "rds-ca-2019",
            "rds-ca-rsa2048-g1",
            "rds-ca-ecc384-g1",
            "rds-ca-rsa4096-g1"
         ]
      }
   ]
}
```

**DB server certificate validities**

The validity of DB server certificate depends on the DB engine and DB engine version. If the DB engine version supports rotating the certificate without restart, the validity of the DB server certificate is 1 year. Otherwise the validity is 3 years.

For more information about DB server certificate rotation, see [Automatic server certificate rotation](p. 2397).

**Viewing the CA for your database**

You can view the details about the CA for a DB instance by viewing the Connectivity & security tab in the console, as in the following image.
If you are using the AWS CLI, you can view the details about the CA for a DB instance by using the `describe-db-instances` command.

To check the contents of your CA certificate bundle, use the following command:

```
keytool -printcert -v -file global-bundle.pem
```

### Certificate bundles for all AWS Regions

To get a certificate bundle that contains both the intermediate and root certificates for all AWS Regions, download it from https://truststore.pki.rds.amazonaws.com/global/global-bundle.pem.

If your application is on Microsoft Windows and requires a PKCS7 file, you can download the PKCS7 certificate bundle. This bundle contains both the intermediate and root certificates at https://truststore.pki.rds.amazonaws.com/global/global-bundle.p7b.

**Note**

Amazon RDS Proxy and Aurora Serverless use certificates from the AWS Certificate Manager (ACM). If you are using RDS Proxy, you don't need to download Amazon RDS certificates or update applications that use RDS Proxy connections. For more information about using TLS/SSL with RDS Proxy, see Using TLS/SSL with RDS Proxy (p. 1884).

If you are using Aurora Serverless, downloading Amazon RDS certificates isn't required. For more information about using TLS/SSL with Aurora Serverless, see Using TLS/SSL with Aurora Serverless v1 (p. 2026).

### Certificate bundles for specific AWS Regions

To get a certificate bundle that contains both the intermediate and root certificates for an AWS Region, download it from the link for the AWS Region in the following table.

<table>
<thead>
<tr>
<th>AWS Region</th>
<th>Certificate bundle (PEM)</th>
<th>Certificate bundle (PKCS7)</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (N. Virginia)</td>
<td><code>us-east-1-bundle.pem</code></td>
<td><code>us-east-1-bundle.p7b</code></td>
</tr>
<tr>
<td>US East (Ohio)</td>
<td><code>us-east-2-bundle.pem</code></td>
<td><code>us-east-2-bundle.p7b</code></td>
</tr>
<tr>
<td>US West (N. California)</td>
<td><code>us-west-1-bundle.pem</code></td>
<td><code>us-west-1-bundle.p7b</code></td>
</tr>
</tbody>
</table>
## AWS Region

<table>
<thead>
<tr>
<th>AWS Region</th>
<th>Certificate bundle (PEM)</th>
<th>Certificate bundle (PKCS7)</th>
</tr>
</thead>
<tbody>
<tr>
<td>US West (Oregon)</td>
<td>us-west-2-bundle.pem</td>
<td>us-west-2-bundle.p7b</td>
</tr>
<tr>
<td>Africa (Cape Town)</td>
<td>af-south-1-bundle.pem</td>
<td>af-south-1-bundle.p7b</td>
</tr>
<tr>
<td>Asia Pacific (Hong Kong)</td>
<td>ap-east-1-bundle.pem</td>
<td>ap-east-1-bundle.p7b</td>
</tr>
<tr>
<td>Asia Pacific (Hyderabad)</td>
<td>ap-south-2-bundle.pem</td>
<td>ap-south-2-bundle.p7b</td>
</tr>
<tr>
<td>Asia Pacific (Jakarta)</td>
<td>ap-southeast-3-bundle.pem</td>
<td>ap-southeast-3-bundle.p7b</td>

### AWS GovCloud (US) certificates

If your application is on Microsoft Windows and requires a PKCS7 file, you can download the PKCS7 certificate bundle. This bundle contains both the intermediate and root certificates at [https://truststore.pki.us-gov-west-1.rds.amazonaws.com/global/global-bundle.p7b](https://truststore.pki.us-gov-west-1.rds.amazonaws.com/global/global-bundle.p7b).
To get a certificate bundle that contains both the intermediate and root certificates for an AWS GovCloud (US) Region, download from the link for the AWS GovCloud (US) Region in the following table.

<table>
<thead>
<tr>
<th>AWS GovCloud (US) Region</th>
<th>Certificate bundle (PEM)</th>
<th>Certificate bundle (PKCS7)</th>
</tr>
</thead>
</table>

Rotating your SSL/TLS certificate

Amazon RDS Certificate Authority certificates rds-ca-2019 are set to expire in August, 2024. If you use or plan to use Secure Sockets Layer (SSL) or Transport Layer Security (TLS) with certificate verification to connect to your RDS DB instances, you should consider using one of the new CA certificates rds-ca-rsa2048-g1, rds-ca-rsa4096-g1 or rds-ca-ecc384-g1. If you currently do not use SSL/TLS with certificate verification, you might still have an expired CA certificate and must update them to a new CA certificate if you plan to use SSL/TLS with certificate verification to connect to your RDS databases.

Follow these instructions to complete your updates. Before you update your DB instances to use the new CA certificate, make sure that you update your clients or applications connecting to your RDS databases.

Amazon RDS provides new CA certificates as an AWS security best practice. For information about the new certificates and the supported AWS Regions, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 2385).

**Note**

Amazon RDS Proxy and Aurora Serverless use certificates from the AWS Certificate Manager (ACM). If you are using RDS Proxy, when you rotate your SSL/TLS certificate, you don't need to update applications that use RDS Proxy connections. For more information about using TLS/SSL with RDS Proxy, see Using TLS/SSL with RDS Proxy (p. 1884).

If you are using Aurora Serverless, rotating your SSL/TLS certificate isn't required. For more information about using TLS/SSL with Aurora Serverless, see Using TLS/SSL with Aurora Serverless v1 (p. 2026).

**Note**

If you are using a Go version 1.15 application with a DB instance that was created or updated to the rds-ca-2019 certificate prior to July 28, 2020, you must update the certificate again. Update the certificate to rds-ca-rsa2048-g1, rds-ca-rsa4096-g1, or rds-ca-ecc384-g1 depending on your engine. Run the `modify-db-instance` command shown in the AWS CLI section using the describe-db-engine-versions command. If you created your DB instance or updated its certificate after July 28, 2020, no action is required. For more information, see Go GitHub issue #39568.

Topics

- Updating your CA certificate by modifying your DB instance (p. 2391)
- Updating your CA certificate by applying DB cluster maintenance (p. 2394)
- Automatic server certificate rotation (p. 2397)
- Sample script for importing certificates into your trust store (p. 2397)

Updating your CA certificate by modifying your DB instance

The following example updates your CA certificate from rds-ca-2019 to rds-ca-rsa2048-g1. You can choose a different certificate. For more information, see Certificate authorities (p. 2386).
To update your CA certificate by modifying your DB instance

1. Download the new SSL/TLS certificate as described in Using SSL/TLS to encrypt a connection to a DB cluster (p. 2385).

2. Update your applications to use the new SSL/TLS certificate.

   The methods for updating applications for new SSL/TLS certificates depend on your specific applications. Work with your application developers to update the SSL/TLS certificates for your applications.

   For information about checking for SSL/TLS connections and updating applications for each DB engine, see the following topics:

   • Updating applications to connect to Aurora MySQL DB clusters using new TLS certificates (p. 819)
   • Updating applications to connect to Aurora PostgreSQL DB clusters using new SSL/TLS certificates (p. 1249)

   For a sample script that updates a trust store for a Linux operating system, see Sample script for importing certificates into your trust store (p. 2397).

   **Note**
   The certificate bundle contains certificates for both the old and new CA, so you can upgrade your application safely and maintain connectivity during the transition period. If you are using the AWS Database Migration Service to migrate a database to a DB cluster, we recommend using the certificate bundle to ensure connectivity during the migration.

3. Modify the DB instance to change the CA from rds-ca-2019 to rds-ca-rsa2048-g1. To check if your database requires a restart to update the CA certificates, use the describe-db-engine-versions command and check the SupportsCertificateRotationWithoutRestart flag.

   **Note**
   Reboot your Babelfish cluster after modifying to update the CA certificate.

   **Important**
   If you are experiencing connectivity issues after certificate expiry, use the apply immediately option by specifying Apply immediately in the console or by specifying the --apply-immediately option using the AWS CLI. By default, this operation is scheduled to run during your next maintenance window.

   To set an override for your cluster CA that's different from the default RDS CA, use the modify-certificates CLI command.

You can use the AWS Management Console or the AWS CLI to change the CA certificate from rds-ca-2019 to rds-ca-rsa2048-g1 for a DB instance.

**Console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose Databases, and then choose the DB instance that you want to modify.

3. Choose Modify.
The **Modify DB Instance** page appears.

4. In the *Connectivity* section, choose `rds-ca-rsa2048-g1`.

5. Choose **Continue** and check the summary of modifications.

6. To apply the changes immediately, choose **Apply immediately**.

7. On the confirmation page, review your changes. If they are correct, choose **Modify DB Instance** to save your changes.

   **Important**

   When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

   Or choose **Back** to edit your changes or **Cancel** to cancel your changes.
AWS CLI

To use the AWS CLI to change the CA from rds-ca-2019 to rds-ca-rsa2048-g1 for a DB instance, call the modify-db-instance command. Specify the DB instance identifier and the --ca-certificate-identifier option.

Important
When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

Example

The following code modifies mydbinstance by setting the CA certificate to rds-ca-rsa2048-g1.

Important
Use --apply-immediately to apply the update immediately. By default, this operation is scheduled to run during your next maintenance window.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance --db-instance-identifier mydbinstance --ca-certificate-identifier rds-ca-rsa2048-g1
```

For Windows:

```bash
aws rds modify-db-instance ^ --db-instance-identifier mydbinstance ^ --ca-certificate-identifier rds-ca-rsa2048-g1
```

Note
If your cluster requires reboot, you can use the modify-db-cluster CLI command and specify the --no-certificate-rotation-restart option.

Updating your CA certificate by applying DB cluster maintenance

Complete the following steps to update your CA certificate by applying DB cluster instance maintenance.

To update your CA certificate by applying DB cluster maintenance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.

   In the navigation pane, there is a Certificate update option that shows the total number of affected DB cluster.
Choose **Certificate update** in the navigation pane.

The **Databases requiring certificate update** page appears.
Note
This page only shows the DB instances for the current AWS Region. If you have DB cluster in more than one AWS Region, check this page in each AWS Region to see all DB instances with old SSL/TLS certificates.

3. Choose the DB cluster you want to update.

You can schedule the certificate rotation for your next maintenance window by choosing Schedule. Apply the rotation immediately by choosing Apply now.

Important
If you experience connectivity issues after certificate expiry, use the Apply now option.

4. a. If you choose Schedule, you are prompted to confirm the CA certificate rotation. This prompt also states the scheduled window for your update.

b. If you choose Apply now, you are prompted to confirm the CA certificate rotation.
Important
Before scheduling the CA certificate rotation on your database, update any client applications that use SSL/TLS and the server certificate to connect. These updates are specific to your DB engine. After you have updated these client applications, you can confirm the CA certificate rotation.

To continue, choose the check box, and then choose Confirm.

5. Repeat steps 3 and 4 for each DB cluster that you want to update.

Automatic server certificate rotation

If your CA supports automatic server certificate rotation, RDS automatically handles the rotation of the DB server certificate. RDS uses the same root CA for this automatic rotation, so you don't need to download a new CA bundle. See Certificate authorities (p. 2386).

The rotation and validity of your DB server certificate depend on your DB engine:

- If your DB engine supports rotation without restart, RDS automatically rotates the DB server certificate without requiring any action from you. RDS attempts to rotate your DB server certificate in your preferred maintenance window at the DB server certificate half life. The new DB server certificate is valid for 12 months.
- If your DB engine doesn't support rotation without restart, RDS notifies you about a maintenance event at least 6 months before the DB server certificate expires. The new DB server certificate is valid for 36 months.

Use the describe-db-engine-versions command and inspect the SupportsCertificateRotationWithoutRestart flag to identify whether the DB engine version supports rotating the certificate without restart. For more information, see Setting the CA for your database (p. 2387).

Sample script for importing certificates into your trust store

The following are sample shell scripts that import the certificate bundle into a trust store.
Each sample shell script uses keytool, which is part of the Java Development Kit (JDK). For information about installing the JDK, see [JDK Installation Guide](#).

**Topics**

- [Sample script for importing certificates on Linux (p. 2398)](#)
- [Sample script for importing certificates on macOS (p. 2398)](#)

### Sample script for importing certificates on Linux

The following is a sample shell script that imports the certificate bundle into a trust store on a Linux operating system.

```bash
mydir=tmp/certs
if [ ! -e "${mydir}" ]
then
    mkdir -p "${mydir}"
fi

truststore=${mydir}/rds-truststore.jks
storepassword=changeit

awk 'split_after == 1 {n++;split_after=0} /-----END CERTIFICATE-----/ {split_after=1}{print > "rds-ca-" n ".pem"} < $(mydir)/global-bundle.pem

for CERT in rds-ca-*; do
    alias=$(openssl x509 -noout -text -in $CERT | perl -ne 'next unless /Subject:/; s/.*(CN=|CN = )//; print')
    echo "Importing $alias"
    keytool -import -file ${CERT} -alias "${alias}" -storepass ${storepassword} -keystore ${truststore} -noprompt
    rm $CERT
done

done

echo "Trust store content is: 

keytool -list -v -keystore "$truststore" -storepass ${storepassword} | grep Alias | cut -d " " -f3- while read alias
     do
         expiry=`keytool -list -v -keystore "$truststore" -storepass ${storepassword} -alias "$alias" | grep Valid | perl -ne 'if(/until: (.*?)\n/) { print "$1\n"; }'`'
         echo " Certificate $alias expires in "$expiry"
     done

### Sample script for importing certificates on macOS

The following is a sample shell script that imports the certificate bundle into a trust store on macOS.

```bash
mydir=tmp/certs
if [ ! -e "$mydir" ]
then
    mkdir -p "$mydir"
fi

truststore=${mydir}/rds-truststore.jks
```
Internetwork traffic privacy

Connections are protected both between Amazon Aurora and on-premises applications and between Amazon Aurora and other AWS resources within the same AWS Region.

Traffic between service and on-premises clients and applications

You have two connectivity options between your private network and AWS:

- An AWS Site-to-Site VPN connection. For more information, see What is AWS Site-to-Site VPN?
- An AWS Direct Connect connection. For more information, see What is AWS Direct Connect?

You get access to Amazon Aurora through the network by using AWS-published API operations. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.
Identity and access management for Amazon Aurora

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be authenticated (signed in) and authorized (have permissions) to use Amazon RDS resources. IAM is an AWS service that you can use with no additional charge.

Topics
- Audience (p. 2400)
- Authenticating with identities (p. 2400)
- Managing access using policies (p. 2403)
- How Amazon Aurora works with IAM (p. 2404)
- Identity-based policy examples for Amazon Aurora (p. 2409)
- AWS managed policies for Amazon RDS (p. 2422)
- Amazon RDS updates to AWS managed policies (p. 2426)
- Preventing cross-service confused deputy problems (p. 2430)
- IAM database authentication (p. 2432)
- Troubleshooting Amazon Aurora identity and access (p. 2460)

Audience

How you use AWS Identity and Access Management (IAM) differs, depending on the work you do in Amazon Aurora.

Service user – If you use the Aurora service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more Aurora features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in Aurora, see Troubleshooting Amazon Aurora identity and access (p. 2460).

Service administrator – If you're in charge of Aurora resources at your company, you probably have full access to Aurora. It's your job to determine which Aurora features and resources your employees should access. You must then submit requests to your administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with Aurora, see How Amazon Aurora works with IAM (p. 2404).

Administrator – If you're an administrator, you might want to learn details about how you can write policies to manage access to Aurora. To view example Aurora identity-based policies that you can use in IAM, see Identity-based policy examples for Amazon Aurora (p. 2409).

Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. You must be authenticated (signed in to AWS) as the AWS account root user, as an IAM user, or by assuming an IAM role.

You can sign in to AWS as a federated identity by using credentials provided through an identity source. AWS IAM Identity Center (IAM Identity Center) users, your company's single sign-on authentication,
and your Google or Facebook credentials are examples of federated identities. When you sign in as a federated identity, your administrator previously set up identity federation using IAM roles. When you access AWS by using federation, you are indirectly assuming a role.

Depending on the type of user you are, you can sign in to the AWS Management Console or the AWS access portal. For more information about signing in to AWS, see How to sign in to your AWS account in the AWS Sign-In User Guide.

If you access AWS programmatically, AWS provides a software development kit (SDK) and a command line interface (CLI) to cryptographically sign your requests by using your credentials. If you don't use AWS tools, you must sign requests yourself. For more information about using the recommended method to sign requests yourself, see Signing AWS API requests in the IAM User Guide.

Regardless of the authentication method that you use, you might be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see Multi-factor authentication in the AWS IAM Identity Center User Guide and Using multi-factor authentication (MFA) in AWS in the IAM User Guide.

**AWS account root user**

When you create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account root user and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you don't use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see Tasks that require root user credentials in the IAM User Guide.

**Federated identity**

As a best practice, require human users, including users that require administrator access, to use federation with an identity provider to access AWS services by using temporary credentials.

A federated identity is a user from your enterprise user directory, a web identity provider, the AWS Directory Service, the Identity Center directory, or any user that accesses AWS services by using credentials provided through an identity source. When federated identities access AWS accounts, they assume roles, and the roles provide temporary credentials.

For centralized access management, we recommend that you use AWS IAM Identity Center. You can create users and groups in IAM Identity Center, or you can connect and synchronize to a set of users and groups in your own identity source for use across all your AWS accounts and applications. For information about IAM Identity Center, see What is IAM Identity Center? in the AWS IAM Identity Center User Guide.

**IAM users and groups**

An IAM user is an identity within your AWS account that has specific permissions for a single person or application. Where possible, we recommend relying on temporary credentials instead of creating IAM users who have long-term credentials such as passwords and access keys. However, if you have specific use cases that require long-term credentials with IAM users, we recommend that you rotate access keys. For more information, see Rotate access keys regularly for use cases that require long-term credentials in the IAM User Guide.

An IAM group is an identity that specifies a collection of IAM users. You can't sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named IAMAdmins and give that group permissions to administer IAM resources.
Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see When to create an IAM user (instead of a role) in the IAM User Guide.

You can authenticate to your DB cluster using IAM database authentication.

IAM database authentication works with Aurora. For more information about authenticating to your DB cluster using IAM, see IAM database authentication (p. 2432).

IAM roles

An IAM role is an identity within your AWS account that has specific permissions. It is similar to a user, but is not associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by switching roles. You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see Using IAM roles in the IAM User Guide.

IAM roles with temporary credentials are useful in the following situations:

- **Temporary user permissions** – A user can assume an IAM role to temporarily take on different permissions for a specific task.

- **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see Creating a role for a third-party Identity Provider in the IAM User Guide. If you use IAM Identity Center, you configure a permission set. To control what your identities can access after they authenticate, IAM Identity Center correlates the permission set to a role in IAM. For information about permissions sets, see Permission sets in the AWS IAM Identity Center User Guide.

- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.

- **Cross-service access** – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.

- **Principal permissions** – When you use an IAM user or role to perform actions in AWS, you are considered a principal. Policies grant permissions to a principal. When you use some services, you might perform an action that then triggers another action in a different service. In this case, you must have permissions to perform both actions. To see whether an action requires additional dependent actions in a policy, see Actions, Resources, and Condition Keys for Amazon RDS in the Service Authorization Reference.

- **Service role** – A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role within IAM. For more information, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

- **Service-linked role** – A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

- **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached.
to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see Using an IAM role to grant permissions to applications running on Amazon EC2 instances in the IAM User Guide.

To learn whether to use IAM roles, see When to create an IAM role (instead of a user) in the IAM User Guide.

Managing access using policies

You control access in AWS by creating policies and attaching them to IAM identities or AWS resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. AWS evaluates these policies when an entity (root user, user, or IAM role) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see Overview of JSON policies in the IAM User Guide.

An administrator can use policies to specify who has access to AWS resources, and what actions they can perform on those resources. Every IAM entity (permission set or role) starts with no permissions. In other words, by default, users can do nothing, not even change their own password. To give a user permission to do something, an administrator must attach a permissions policy to a user. Or the administrator can add the user to a group that has the intended permissions. When an administrator gives permissions to a group, all users in that group are granted those permissions.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the iam:GetRole action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

Identity-based policies

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as a permission set or role. These policies control what actions that identity can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Creating IAM policies in the IAM User Guide.

Identity-based policies can be further categorized as inline policies or managed policies. Inline policies are embedded directly into a single permission set or role. Managed policies are standalone policies that you can attach to multiple permission sets and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see Choosing between managed policies and inline policies in the IAM User Guide.

For information about AWS managed policies that are specific to Amazon Aurora, see AWS managed policies for Amazon RDS (p. 2422).

Other policy types

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- Permissions boundaries – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (permission set or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the permission set or role in the Principal field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see Permissions boundaries for IAM entities in the IAM User Guide.
• **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for grouping and centrally managing multiple AWS accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each AWS account root user. For more information about Organizations and SCPs, see [How SCPs work](awsorganizationsguide) in the [AWS Organizations User Guide](awsorganizationsguide).

• **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's permissions are the intersection of the permission sets or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see [Session policies](iamguide) in the [IAM User Guide](iamguide).

**Multiple policy types**

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see [Policy evaluation logic](iamguide) in the [IAM User Guide](iamguide).

**How Amazon Aurora works with IAM**

Before you use IAM to manage access to Amazon Aurora, you should understand what IAM features are available to use with Aurora.

**IAM features you can use with Amazon Aurora**

Aurora identity-based policies

| Supports identity-based policies | Yes |

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Creating IAM policies in the IAM User Guide.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. You can't specify the principal in an identity-based policy because it applies to the user or role to which it is attached. To learn about all of the elements that you can use in a JSON policy, see IAM JSON policy elements reference in the IAM User Guide.

Identity-based policy examples for Aurora

To view examples of Aurora identity-based policies, see Identity-based policy examples for Amazon Aurora (p. 2409).

Resource-based policies within Aurora

| Supports resource-based policies | No |

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM role trust policies and Amazon S3 bucket policies. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. Adding a cross-account principal to a resource-based policy is only half of establishing the trust relationship. When the principal and the resource are in different AWS accounts, an IAM administrator in the trusted account must also grant the principal entity (user or role) permission to access the resource. They grant permission by attaching an identity-based policy to the entity. However, if a resource-based policy grants access to a principal in the same account, no additional identity-based policy is required. For more information, see How IAM roles differ from resource-based policies in the IAM User Guide.
Policy actions for Aurora

<table>
<thead>
<tr>
<th>Supports policy actions</th>
<th>Yes</th>
</tr>
</thead>
</table>

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Action element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated AWS API operation. There are some exceptions, such as permission-only actions that don't have a matching API operation. There are also some operations that require multiple actions in a policy. These additional actions are called dependent actions.

Include actions in a policy to grant permissions to perform the associated operation.

Policy actions in Aurora use the following prefix before the action: rds:. For example, to grant someone permission to describe DB instances with the Amazon RDS DescribeDBInstances API operation, you include the rds:DescribeDBInstances action in their policy. Policy statements must include either an Action or NotAction element. Aurora defines its own set of actions that describe tasks that you can perform with this service.

To specify multiple actions in a single statement, separate them with commas as follows.

```
"Action": [
    "rds:action1",
    "rds:action2"
]
```

You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word Describe, include the following action.

```
"Action": "rds:Describe*
```

To see a list of Aurora actions, see Actions Defined by Amazon RDS in the Service Authorization Reference.

Policy resources for Aurora

<table>
<thead>
<tr>
<th>Supports policy resources</th>
<th>Yes</th>
</tr>
</thead>
</table>

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Resource JSON policy element specifies the object or objects to which the action applies. Statements must include either a Resource or a NotResource element. As a best practice, specify a resource using its Amazon Resource Name (ARN). You can do this for actions that support a specific resource type, known as resource-level permissions.

For actions that don't support resource-level permissions, such as listing operations, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*
```
The DB instance resource has the following Amazon Resource Name (ARN).

```
arn:{$Partition}:rds:{$Region}:{$Account}:{$ResourceType}:{$Resource}
```

For more information about the format of ARNs, see Amazon Resource Names (ARNs) and AWS service namespaces.

For example, to specify the dbtest DB instance in your statement, use the following ARN.

```
```

To specify all DB instances that belong to a specific account, use the wildcard (*).

```
"Resource": "arn:aws:rds:us-east-1:123456789012:db:*"
```

Some RDS API operations, such as those for creating resources, can't be performed on a specific resource. In those cases, use the wildcard (*).

```
"Resource": "*"
```

Many Amazon RDS API operations involve multiple resources. For example, CreateDBInstance creates a DB instance. You can specify that an user must use a specific security group and parameter group when creating a DB instance. To specify multiple resources in a single statement, separate the ARNs with commas.

```
"Resource": [
    "resource1",
    "resource2"
]
```

To see a list of Aurora resource types and their ARNs, see Resources Defined by Amazon RDS in the Service Authorization Reference. To learn with which actions you can specify the ARN of each resource, see Actions Defined by Amazon RDS.

**Policy condition keys for Aurora**

<table>
<thead>
<tr>
<th>Supports service-specific policy condition keys</th>
<th>Yes</th>
</tr>
</thead>
</table>

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Condition element (or Condition block) lets you specify conditions in which a statement is in effect. The Condition element is optional. You can create conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request.

If you specify multiple Condition elements in a statement, or multiple keys in a single Condition element, AWS evaluates them using a logical AND operation. If you specify multiple values for a single condition key, AWS evaluates the condition using a logical OR operation. All of the conditions must be met before the statement's permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see IAM policy elements: variables and tags in the IAM User Guide.
AWS supports global condition keys and service-specific condition keys. To see all AWS global condition keys, see [AWS global condition context keys](https://docs.aws.amazon.com/IAM/latest/UserGuide/IAM_condition-keys.html) in the *IAM User Guide*.

Aurora defines its own set of condition keys and also supports using some global condition keys. To see all AWS global condition keys, see [AWS global condition context keys](https://docs.aws.amazon.com/IAM/latest/UserGuide/IAM_condition-keys.html) in the *IAM User Guide*.

All RDS API operations support the `aws:RequestedRegion` condition key.

To see a list of Aurora condition keys, see [Condition Keys for Amazon RDS](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-supported-iam-condition-keys.html) in the *Service Authorization Reference*. To learn with which actions and resources you can use a condition key, see [Actions Defined by Amazon RDS](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-supported-iam-condition-keys.html).

### Access control lists (ACLs) in Aurora

<table>
<thead>
<tr>
<th>Supports access control lists (ACLs)</th>
<th>No</th>
</tr>
</thead>
</table>

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

### Attribute-based access control (ABAC) in policies with Aurora tags

<table>
<thead>
<tr>
<th>Supports attribute-based access control (ABAC) in policies with Aurora tags</th>
<th>Yes</th>
</tr>
</thead>
</table>

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes. In AWS, these attributes are called *tags*. You can attach tags to IAM entities (users or roles) and to many AWS resources. Tagging entities and resources is the first step of ABAC. Then you design ABAC policies to allow operations when the principal's tag matches the tag on the resource that they are trying to access.

ABAC is helpful in environments that are growing rapidly and helps with situations where policy management becomes cumbersome.

To control access based on tags, you provide tag information in the `condition` element of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is *Yes* for the service. If a service supports all three condition keys for only some resource types, then the value is *Partial*.

For more information about tagging Aurora resources, see [Specifying conditions: Using custom tags](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-supported-iam-condition-keys.html) in the *Aurora User Guide*. To view an example identity-based policy for limiting access to a resource based on the tags on that resource, see [Grant permission for actions on a resource with a specific tag with two different values](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-supported-iam-condition-keys.html).

### Using temporary credentials with Aurora

<table>
<thead>
<tr>
<th>Supports temporary credentials</th>
<th>Yes</th>
</tr>
</thead>
</table>
Some AWS services don't work when you sign in using temporary credentials. For additional information, including which AWS services work with temporary credentials, see AWS services that work with IAM in the IAM User Guide.

You are using temporary credentials if you sign in to the AWS Management Console using any method except a user name and password. For example, when you access AWS using your company's single sign-on (SSO) link, that process automatically creates temporary credentials. You also automatically create temporary credentials when you sign in to the console as a user and then switch roles. For more information about switching roles, see Switching to a role (console) in the IAM User Guide.

You can manually create temporary credentials using the AWS CLI or AWS API. You can then use those temporary credentials to access AWS. AWS recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see Temporary security credentials in IAM.

Cross-service principal permissions for Aurora

<table>
<thead>
<tr>
<th>Supports principal permissions</th>
<th>Yes</th>
</tr>
</thead>
</table>

When you use an IAM user or role to perform actions in AWS, you are considered a principal. Policies grant permissions to a principal. When you use some services, you might perform an action that then triggers another action in a different service. In this case, you must have permissions to perform both actions. To see whether an action requires additional dependent actions in a policy, see Actions, Resources, and Condition Keys for Amazon RDS in the Service Authorization Reference.

Service roles for Aurora

<table>
<thead>
<tr>
<th>Supports service roles</th>
<th>Yes</th>
</tr>
</thead>
</table>

A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

Warning
Changing the permissions for a service role might break Aurora functionality. Edit service roles only when Aurora provides guidance to do so.

Service-linked roles for Aurora

<table>
<thead>
<tr>
<th>Supports service-linked roles</th>
<th>Yes</th>
</tr>
</thead>
</table>

A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

For details about using Aurora service-linked roles, see Using service-linked roles for Amazon Aurora (p. 2475).

Identity-based policy examples for Amazon Aurora

By default, permission sets and roles don't have permission to create or modify Aurora resources. They also can't perform tasks using the AWS Management Console, AWS CLI, or AWS API. An administrator
must create IAM policies that grant permission sets and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the permission sets or roles that require those permissions.

To learn how to create an IAM identity-based policy using these example JSON policy documents, see Creating policies on the JSON tab in the IAM User Guide.

- Allow a user to perform any describe action on any RDS resource (p. 2413)
- Allow a user to create a DB instance that uses the specified DB parameter group and subnet group (p. 2413)
- Grant permission for actions on a resource with a specific tag with two different values (p. 2414)
- Prevent a user from deleting a DB instance (p. 2415)
- Deny all access to a resource (p. 2415)
- Example policies: Using condition keys (p. 2416)
- Specifying conditions: Using custom tags (p. 2417)

Policy best practices

Identity-based policies determine whether someone can create, access, or delete Amazon RDS resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- Get started with AWS managed policies and move toward least-privilege permissions – To get started granting permissions to your users and workloads, use the AWS managed policies that grant permissions for many common use cases. They are available in your AWS account. We recommend that you reduce permissions further by defining AWS customer managed policies that are specific to your use cases. For more information, see AWS managed policies or AWS managed policies for job functions in the IAM User Guide.

- Apply least-privilege permissions – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as least-privilege permissions. For more information about using IAM to apply permissions, see Policies and permissions in IAM in the IAM User Guide.

- Use conditions in IAM policies to further restrict access – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific AWS service, such as AWS CloudFormation. For more information, see IAM JSON policy elements: Condition in the IAM User Guide.

- Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see IAM Access Analyzer policy validation in the IAM User Guide.

- Require multi-factor authentication (MFA) – If you have a scenario that requires IAM users or a root user in your AWS account, turn on MFA for additional security. To require MFA when API operations are
called, add MFA conditions to your policies. For more information, see Configuring MFA-protected API access in the IAM User Guide.

For more information about best practices in IAM, see Security best practices in IAM in the IAM User Guide.

Using the Aurora console

To access the Amazon Aurora console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the Amazon Aurora resources in your AWS account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won't function as intended for entities (users or roles) with that policy.

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that you're trying to perform.

To ensure that those entities can still use the Aurora console, also attach the following AWS managed policy to the entities.

AmazonRDSReadOnlyAccess

For more information, see Adding permissions to a user in the IAM User Guide.

Allow users to view their own permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ViewOwnUserInfo",
            "Effect": "Allow",
            "Action": [
                "iam:GetUserPolicy",
                "iam:ListGroupsForUser",
                "iam:ListAttachedUserPolicies",
                "iam:ListUserPolicies",
                "iam:GetUser"
            ],
            "Resource": [
                "arn:aws:iam::*:user/${aws:username}"
            ]
        },
        {
            "Sid": "NavigateInConsole",
            "Effect": "Allow",
            "Action": [
                "iam:GetGroupPolicy",
                "iam:GetPolicyVersion",
                "iam:GetPolicy",
                "iam:ListAttachedGroupPolicies",
                "iam:ListGroupPolicies",
                "iam:ListPolicyVersions",
                "iam:ListPolicies",
                "iam:ListUsers"
            ],
            "Resource": "*
        }
    ]
}
```
Identity-based policy examples

Allow a user to create DB instances in an AWS account

The following is an example policy that allows the user with the ID 123456789012 to create DB instances for your AWS account. The policy requires that the name of the new DB instance begin with `test`. The new DB instance must also use the MySQL database engine and the `db.t2.micro` DB instance class. In addition, the new DB instance must use an option group and a DB parameter group that starts with `default`, and it must use the default subnet group.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowCreateDBInstanceOnly",
      "Effect": "Allow",
      "Action": ["rds:CreateDBInstance"],
      "Resource": ["arn:aws:rds:*:123456789012:db:test*",
                    "arn:aws:rds:*:123456789012:og:default*",
                    "arn:aws:rds:*:123456789012:pg:default*",
                    "arn:aws:rds:*:123456789012:subgrp:default"],
      "Condition": {
        "StringEquals": {
          "rds:DatabaseEngine": "mysql",
          "rds:DatabaseClass": "db.t2.micro"
        }
      }
    }
  ]
}
```

The policy includes a single statement that specifies the following permissions for the user:

- The policy allows the user to create a DB instance using the `CreateDBInstance` API operation (this also applies to the `create-db-instance` AWS CLI command and the AWS Management Console).
- The Resource element specifies that the user can perform actions on or with resources. You specify resources using an Amazon Resources Name (ARN). This ARN includes the name of the service that the resource belongs to (rds), the AWS Region (* indicates any region in this example), the AWS account number (123456789012 is the account number in this example), and the type of resource. For more information about creating ARNs, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 390).

The Resource element in the example specifies the following policy constraints on resources for the user:

- The DB instance identifier for the new DB instance must begin with `test` (for example, `testCustomerData1`, `test-region2-data`).
- The option group for the new DB instance must begin with `default`.
- The DB parameter group for the new DB instance must begin with `default`.
- The subnet group for the new DB instance must be the default subnet group.
- The Condition element specifies that the DB engine must be MySQL and the DB instance class must be `db.t2.micro`. The Condition element specifies the conditions when a policy should take effect. You can add additional permissions or restrictions by using the Condition element. For more information about specifying conditions, see Policy condition keys for Aurora (p. 2407). This example
specifies the rds:DatabaseEngine and rds:DatabaseClass conditions. For information about
the valid condition values for rds:DatabaseEngine, see the list under the Engine parameter in
CreateDBInstance. For information about the valid condition values for rds:DatabaseClass, see
Supported DB engines for DB instance classes (p. 86).

The policy doesn't specify the Principal element because in an identity-based policy you don't specify
the principal who gets the permission. When you attach policy to a user, the user is the implicit principal.
When you attach a permission policy to an IAM role, the principal identified in the role's trust policy gets
the permissions.

To see a list of Aurora actions, see Actions Defined by Amazon RDS in the Service Authorization Reference.

Permissions required to use the console

For a user to work with the console, that user must have a minimum set of permissions. These
permissions allow the user to describe the Amazon Aurora resources for their AWS account and to
provide other related information, including Amazon EC2 security and network information.

If you create an IAM policy that is more restrictive than the minimum required permissions, the console
doesn't function as intended for users with that IAM policy. To ensure that those users can still use the
console, also attach the AmazonRDSReadOnlyAccess managed policy to the user, as described in
Managing access using policies (p. 2403).

You don't need to allow minimum console permissions for users that are making calls only to the AWS
CLI or the Amazon RDS API.

The following policy grants full access to all Amazon Aurora resources for the root AWS account:

AmazonRDSFullAccess

Allow a user to perform any describe action on any RDS resource

The following permissions policy grants permissions to a user to run all of the actions that begin with
Describe. These actions show information about an RDS resource, such as a DB instance. The wildcard
character (*) in the Resource element indicates that the actions are allowed for all Amazon Aurora
resources owned by the account.

```
{
   "Version": "2012-10-17",
   "Statement": [ 
      {
         "Sid": "AllowRDSDescribe",
         "Effect": "Allow",
         "Action": "rds:Describe*",
         "Resource": "*"
      }
   ]
}
```

Allow a user to create a DB instance that uses the specified DB parameter group and subnet group

The following permissions policy grants permissions to allow a user to only create a DB instance that
must use the mydbpg DB parameter group and the mydbsubnetgroup DB subnet group.
Identity-based policy examples

Grant permission for actions on a resource with a specific tag with two different values

You can use conditions in your identity-based policy to control access to Aurora resources based on tags. The following policy allows permission to perform the CreateDBSnapshot API operation on DB instances with either the stage tag set to development or test.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowAnySnapshotName",
            "Effect": "Allow",
            "Action": [
                "rds:CreateDBSnapshot"
            ],
            "Resource": "arn:aws:rds::*:123456789012:snapshot::*"
        },
        {
            "Sid": "AllowDevTestToCreateSnapshot",
            "Effect": "Allow",
            "Action": [
                "rds:CreateDBSnapshot"
            ],
            "Resource": "arn:aws:rds::*:123456789012:db::*",
            "Condition": {
                "StringEquals": {
                    "rds:db-tag/stage": [
                        "development",
                        "test"
                    ]
                }
            }
        }
    ]
}
```

The following policy allows permission to perform the ModifyDBInstance API operation on DB instances with either the stage tag set to development or test.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowChangingParameterOptionSecurityGroups",
            "Effect": "Allow",
            "Action": 
```
Identity-based policy examples

Prevent a user from deleting a DB instance

The following permissions policy grants permissions to prevent a user from deleting a specific DB instance. For example, you might want to deny the ability to delete your production DB instances to any user that is not an administrator.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyDelete1",
      "Effect": "Deny",
      "Action": "rds:DeleteDBInstance",
    }
  ]
}
```

Deny all access to a resource

You can explicitly deny access to a resource. Deny policies take precedence over allow policies. The following policy explicitly denies a user the ability to manage a resource:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "rds:*",
    }
  ]
}
```
Example policies: Using condition keys

Following are examples of how you can use condition keys in Amazon Aurora IAM permissions policies.

Example 1: Grant permission to create a DB instance that uses a specific DB engine and isn't MultiAZ

The following policy uses an RDS condition key and allows a user to create only DB instances that use the MySQL database engine and don't use MultiAZ. The Condition element indicates the requirement that the database engine is MySQL.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowMySQLCreate",
      "Effect": "Allow",
      "Action": "rds:CreateDBInstance",
      "Resource": "+",
      "Condition": {
        "StringEquals": {
          "rds:DatabaseEngine": "mysql"
        },
        "Bool": {
          "rds:MultiAz": false
        }
      }
    }
  ]
}
```

Example 2: Explicitly deny permission to create DB instances for certain DB instance classes and create DB instances that use Provisioned IOPS

The following policy explicitly denies permission to create DB instances that use the DB instance classes r3.8xlarge and m4.10xlarge, which are the largest and most expensive DB instance classes. This policy also prevents users from creating DB instances that use Provisioned IOPS, which incurs an additional cost.

Explicitly denying permission supersedes any other permissions granted. This ensures that identities do not accidentally get permission that you never want to grant.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyLargeCreate",
      "Effect": "Deny",
      "Action": "rds:CreateDBInstance",
      "Resource": "+",
      "Condition": {
        "StringEquals": {
          "rds:DatabaseClass": [
            "db.r3.8xlarge",
            "db.m4.10xlarge"
          ]
        }
      }
    }
  ]
}
```
Example 3: Limit the set of tag keys and values that can be used to tag a resource

The following policy uses an RDS condition key and allows the addition of a tag with the key stage to be added to a resource with the values test, qa, and production.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds:AddTagsToResource",
        "rds:RemoveTagsFromResource"
      ],
      "Resource": "*",
      "Condition": {
        "streq": {
          "rds:req-tag/stage": [
            "test",
            "qa",
            "production"
          ]
        }
      }
    }
  ]
}
```

Specifying conditions: Using custom tags

Amazon Aurora supports specifying conditions in an IAM policy using custom tags.

For example, suppose that you add a tag named environment to your DB instances with values such as beta, staging, production, and so on. If you do, you can create a policy that restricts certain users to DB instances based on the environment tag value.

**Note**

Custom tag identifiers are case-sensitive.

The following table lists the RDS tag identifiers that you can use in a Condition element.

<table>
<thead>
<tr>
<th>RDS tag identifier</th>
<th>Applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>db-tag</td>
<td>DB instances, including read replicas</td>
</tr>
</tbody>
</table>
Identity-based policy examples

<table>
<thead>
<tr>
<th>RDS tag identifier</th>
<th>Applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>snapshot-tag</td>
<td>DB snapshots</td>
</tr>
<tr>
<td>ri-tag</td>
<td>Reserved DB instances</td>
</tr>
<tr>
<td>og-tag</td>
<td>DB option groups</td>
</tr>
<tr>
<td>pg-tag</td>
<td>DB parameter groups</td>
</tr>
<tr>
<td>subgrp-tag</td>
<td>DB subnet groups</td>
</tr>
<tr>
<td>es-tag</td>
<td>Event subscriptions</td>
</tr>
<tr>
<td>cluster-tag</td>
<td>DB clusters</td>
</tr>
<tr>
<td>cluster-pg-tag</td>
<td>DB cluster parameter groups</td>
</tr>
<tr>
<td>cluster-snapshot-tag</td>
<td>DB cluster snapshots</td>
</tr>
</tbody>
</table>

The syntax for a custom tag condition is as follows:

"Condition":{"StringEquals":{"rds:rds-tag-identifier/tag-name": 
["value"]} }

For example, the following Condition element applies to DB instances with a tag named environment and a tag value of production.

"Condition":{"StringEquals":{"rds:db-tag/environment": ["production"]} }

For information about creating tags, see Tagging Amazon RDS resources (p. 382).

**Important**

If you manage access to your RDS resources using tagging, we recommend that you secure access to the tags for your RDS resources. You can manage access to tags by creating policies for the AddTagsToResource and RemoveTagsFromResource actions. For example, the following policy denies users the ability to add or remove tags for all resources. You can then create policies to allow specific users to add or remove tags.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"DenyTagUpdates",
         "Effect":"Deny",
         "Action":[
            "rds:AddTagsToResource",
            "rds:RemoveTagsFromResource"
         ],
         "Resource":"
      }
   ]
}
```

To see a list of Aurora actions, see Actions Defined by Amazon RDS in the Service Authorization Reference.

**Example policies: Using custom tags**

Following are examples of how you can use custom tags in Amazon Aurora IAM permissions policies. For more information about adding tags to an Amazon Aurora resource, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 390).
Note
All examples use the us-west-2 region and contain fictitious account IDs.

Example 1: Grant permission for actions on a resource with a specific tag with two different values

The following policy allows permission to perform the CreateDBSnapshot API operation on DB instances with either the stage tag set to development or test.

```json
{
  "Version":"2012-10-17",
  "Statement":[
    {
      "Sid":"AllowAnySnapshotName",
      "Effect":"Allow",
      "Action":
      ["rds:CreateDBSnapshot" ],
      "Resource":"arn:aws:rds::*:123456789012:db:**"
    },
    {
      "Sid":"AllowDevTestToCreateSnapshot",
      "Effect":"Allow",
      "Action":
      ["rds:CreateDBSnapshot" ],
      "Resource":"arn:aws:rds::*:123456789012:db:***",
      "Condition":{
        "StringEquals":{
          "rds:db-tag/stage":
          ["development",
           "test"
          ]
        }
      }
    }
  ]
}
```

The following policy allows permission to perform the ModifyDBInstance API operation on DB instances with either the stage tag set to development or test.

```json
{
  "Version":"2012-10-17",
  "Statement":[
    {
      "Sid":"AllowChangingParameterOptionSecurityGroups",
      "Effect":"Allow",
      "Action":
      ["rds:ModifyDBInstance" ],
      "Resource":
      ["arn:aws:rds::*:123456789012:pg:***",
       "arn:aws:rds::*:123456789012:secgrp:***",
       "arn:aws:rds::*:123456789012:og:***"
      ]
    },
    {
      "Sid":"AllowDevTestToModifyInstance",
      "Effect":"Allow",
      "Action":
      ["rds:ModifyDBInstance" ]
    }
  ]
}
```
Example 2: Explicitly deny permission to create a DB instance that uses specified DB parameter groups

The following policy explicitly denies permission to create a DB instance that uses DB parameter groups with specific tag values. You might apply this policy if you require that a specific customer-created DB parameter group always be used when creating DB instances. Policies that use Deny are most often used to restrict access that was granted by a broader policy.

 Explicitly denying permission supersedes any other permissions granted. This ensures that identities to not accidentally get permission that you never want to grant.

```
{  
  "Version":"2012-10-17", 
  "Statement": [  
    {  
      "Sid":"DenyProductionCreate", 
      "Effect":"Deny",  
      "Action":"rds:CreateDBInstance", 
      "Resource":"arn:aws:rds:*:123456789012:pg:*", 
      "Condition": {  
        "StringEquals": {  
          "rds:pg-tag/usage":"prod"  
        }  
      }  
    }  
  ]}
```

Example 3: Grant permission for actions on a DB instance with an instance name that is prefixed with a user name

The following policy allows permission to call any API (except to AddTagsToResource or RemoveTagsFromResource) on a DB instance that has a DB instance name that is prefixed with the user's name and that has a tag called stage equal to devo or that has no tag called stage.

The Resource line in the policy identifies a resource by its Amazon Resource Name (ARN). For more information about using ARNs with Amazon Aurora resources, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 390).

```
{  
  "Version":"2012-10-17", 
  "Statement": [  
    {  
      "Sid":"AllowFullDevAccessNoTags", 
      "Effect":"Allow",  
      "NotAction": [  
        "rds:db-tag/stage": [  
          "development",  
          "test"  
        ]  
      ]  
    ]  
  ]}
```
"rds:AddTagsToResource",
"rds:RemoveTagsFromResource"
],
"Resource":"arn:aws:rds::123456789012:db:${aws:username}*",
"Condition":{
  "StringEqualsIfExists":{
    "rds:db-tag/stage":"devo"
  }
}
}
AWS managed policies for Amazon RDS

To add permissions to permission sets and roles, it's easier to use AWS managed policies than to write policies yourself. It takes time and expertise to create IAM customer managed policies that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see AWS managed policies in the IAM User Guide.

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (permission sets and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services don't remove permissions from an AWS managed policy, so policy updates don't break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the ReadOnlyAccess AWS managed policy provides read-only access to all AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see AWS managed policies for job functions in the IAM User Guide.

Topics
- AWS managed policy: AmazonRDSReadOnlyAccess (p. 2422)
- AWS managed policy: AmazonRDSFullAccess (p. 2422)
- AWS managed policy: AmazonRDSDataFullAccess (p. 2423)
- AWS managed policy: AmazonRDSEnhancedMonitoringRole (p. 2423)
- AWS managed policy: AmazonRDSPerformanceInsightsReadOnly (p. 2424)
- AWS managed policy: AmazonRDSPerformanceInsightsFullAccess (p. 2424)
- AWS managed policy: AmazonRDSDirectoryServiceAccess (p. 2424)
- AWS managed policy: AmazonRDSServiceRolePolicy (p. 2425)

AWS managed policy: AmazonRDSReadOnlyAccess

This policy allows read-only access to Amazon RDS through the AWS Management Console.

Permissions details

This policy includes the following permissions:

- rds – Allows principals to describe Amazon RDS resources and list the tags for Amazon RDS resources.
- cloudwatch – Allows principals to get Amazon CloudWatch metric statistics.
- ec2 – Allows principals to describe Availability Zones and networking resources.
- logs – Allows principals to describe CloudWatch Logs log streams of log groups, and get CloudWatch Logs log events.
- devops-guru – Allows principals to describe resources that have Amazon DevOps Guru coverage, which is specified either by CloudFormation stack names or resource tags.

For more information about this policy, including the JSON policy document, see AmazonRDSReadOnlyAccess in the AWS Managed Policy Reference Guide.

AWS managed policy: AmazonRDSFullAccess

This policy provides full access to Amazon RDS through the AWS Management Console.
Permissions details

This policy includes the following permissions:

- rds – Allows principals full access to Amazon RDS.
- application-autoscaling – Allows principals describe and manage Application Auto Scaling scaling targets and policies.
- cloudwatch – Allows principals get CloudWatch metric statics and manage CloudWatch alarms.
- ec2 – Allows principals to describe Availability Zones and networking resources.
- logs – Allows principals to describe CloudWatch Logs log streams of log groups, and get CloudWatch Logs log events.
- outposts – Allows principals to get AWS Outposts instance types.
- pi – Allows principals to get Performance Insights metrics.
- sns – Allows principals to Amazon Simple Notification Service (Amazon SNS) subscriptions and topics, and to publish Amazon SNS messages.
- devops-guru – Allows principals to describe resources that have Amazon DevOps Guru coverage, which is specified either by CloudFormation stack names or resource tags.

For more information about this policy, including the JSON policy document, see AmazonRDSFullAccess in the AWS Managed Policy Reference Guide.

AWS managed policy: AmazonRDSDataFullAccess

This policy allows full access to use the Data API and the query editor on Aurora Serverless clusters in a specific AWS account. This policy allows the AWS account to get the value of a secret from AWS Secrets Manager.

You can attach the AmazonRDSDataFullAccess policy to your IAM identities.

Permissions details

This policy includes the following permissions:

- dbqms – Allows principals to access, create, delete, describe, and update queries. The Database Query Metadata Service (dbqms) is an internal-only service. It provides your recent and saved queries for the query editor on the AWS Management Console for multiple AWS services, including Amazon RDS.
- rds-data – Allows principals to run SQL statements on Aurora Serverless databases.
- secretsmanager – Allows principals to get the value of a secret from AWS Secrets Manager.

For more information about this policy, including the JSON policy document, see AmazonRDSDataFullAccess in the AWS Managed Policy Reference Guide.

AWS managed policy: AmazonRDSEnhancedMonitoringRole

This policy provides access to Amazon CloudWatch Logs for Amazon RDS Enhanced Monitoring.

Permissions details

This policy includes the following permissions:

- logs – Allows principals to create CloudWatch Logs log groups and retention policies, and to create and describe CloudWatch Logs log streams of log groups. It also allows principals to put and get CloudWatch Logs log events.
For more information about this policy, including the JSON policy document, see 
AmazonRDSEnhancedMonitoringRole in the AWS Managed Policy Reference Guide.

AWS managed policy:
AmazonRDSPerformanceInsightsReadOnly

This policy provides read-only access to Amazon RDS Performance Insights for Amazon RDS DB instances and Amazon Aurora DB clusters.

This policy now includes S.id (statement ID) as an identifier for the policy statement.

Permissions details

This policy includes the following permissions:

• rds – Allows principals to describe Amazon RDS DB instances and Amazon Aurora DB clusters.
• pi – Allows principals make calls to the Amazon RDS Performance Insights API and access Performance Insights metrics.

For more information about this policy, including the JSON policy document, see 
AmazonRDSPerformanceInsightsReadOnly in the AWS Managed Policy Reference Guide.

AWS managed policy:
AmazonRDSPerformanceInsightsFullAccess

This policy provides full access to Amazon RDS Performance Insights for Amazon RDS DB instances and Amazon Aurora DB clusters.

This policy now includes S.id (statement ID) as an identifier for the policy statement.

Permissions details

This policy includes the following permissions:

• rds – Allows principals to describe Amazon RDS DB instances and Amazon Aurora DB clusters.
• pi – Allows principals make calls to the Amazon RDS Performance Insights API, and create, view, and delete performance analysis reports.
• cloudwatch – Allows principals to list all the Amazon CloudWatch metrics, and get metric data and statistics.

For more information about this policy, including the JSON policy document, see 

AWS managed policy: AmazonRDSDirectoryServiceAccess

This policy allows Amazon RDS to make calls to the AWS Directory Service.

Permissions details

This policy includes the following permission:

• ds – Allows principals to describe AWS Directory Service directories and control authorization to AWS Directory Service directories.
For more information about this policy, including the JSON policy document, see AmazonRDSDirectoryServiceAccess in the AWS Managed Policy Reference Guide.

AWS managed policy: AmazonRDSServiceRolePolicy

You can't attach the AmazonRDSServiceRolePolicy policy to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to perform actions on your behalf. For more information, see Service-linked role permissions for Amazon Aurora (p. 2475).
# Amazon RDS updates to AWS managed policies

View details about updates to AWS managed policies for Amazon RDS since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the Amazon RDS Document history page.

Preventing cross-service confused deputy problems

The confused deputy problem is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem.

Cross-service impersonation can occur when one service (the calling service) calls another service (the called service). The calling service can be manipulated to use its permissions to act on another customer's resources in a way that it shouldn't have permission to access. To prevent this, AWS provides tools that can help you protect your data for all services with service principals that have been given access to resources in your account. For more information, see The confused deputy problem in the IAM User Guide.

To limit the permissions that Amazon RDS gives another service for a specific resource, we recommend using the aws:SourceArn and aws:SourceAccount global condition context keys in resource policies.

In some cases, the aws:SourceArn value doesn't contain the account ID, for example when you use the Amazon Resource Name (ARN) for an Amazon S3 bucket. In these cases, make sure to use both global condition context keys to limit permissions. In some cases, you use both global condition context keys and the aws:SourceArn value contains the account ID. In these cases, make sure that the aws:SourceAccount value and the account in the aws:SourceArn use the same account ID when they're used in the same policy statement. If you want only one resource to be associated with the cross-service access, use aws:SourceArn. If you want to allow any resource in the specified AWS account to be associated with the cross-service use, use aws:SourceAccount.

Make sure that the value of aws:SourceArn is an ARN for an Amazon RDS resource type. For more information, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 390).

The most effective way to protect against the confused deputy problem is to use the aws:SourceArn global condition context key with the full ARN of the resource. In some cases, you might not know the full ARN of the resource or you might be specifying multiple resources. In these cases, use the aws:SourceArn global context condition key with wildcards (*) for the unknown portions of the ARN. An example is arn:aws:rds:*:123456789012:.*.

The following example shows how you can use the aws:SourceArn and aws:SourceAccount global condition context keys in Amazon RDS to prevent the confused deputy problem.

```json
{
  "Version": "2012-10-17",
  "Statement": {
    "Sid": "ConfusedDeputyPreventionExamplePolicy",
    "Effect": "Allow",
    "Principal": {
      "Service": "rds.amazonaws.com"
    },
    "Action": "sts:AssumeRole",
    "Condition": {
      "ArnLike": {
        "aws:SourceArn": "arn:aws:rds:us-east-1:123456789012:db:mydbinstance"
      },
      "StringEquals": {
        "aws:SourceAccount": "123456789012"
      }
    }
  }
}
```

For more examples of policies that use the aws:SourceArn and aws:SourceAccount global condition context keys, see the following sections:
• [Granting permissions to publish notifications to an Amazon SNS topic](p. 695)
• [Setting up access to an Amazon S3 bucket](p. 1516) (PostgreSQL import)
• [Setting up access to an Amazon S3 bucket](p. 1530) (PostgreSQL export)
IAM database authentication

You can authenticate to your DB cluster using AWS Identity and Access Management (IAM) database authentication. IAM database authentication works with Aurora MySQL, and Aurora PostgreSQL. With this authentication method, you don’t need to use a password when you connect to a DB cluster. Instead, you use an authentication token.

An authentication token is a unique string of characters that Amazon Aurora generates on request. Authentication tokens are generated using AWS Signature Version 4. Each token has a lifetime of 15 minutes. You don’t need to store user credentials in the database, because authentication is managed externally using IAM. You can also still use standard database authentication. The token is only used for authentication and doesn’t affect the session after it is established.

IAM database authentication provides the following benefits:

- Network traffic to and from the database is encrypted using Secure Socket Layer (SSL) or Transport Layer Security (TLS). For more information about using SSL/TLS with Amazon Aurora, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 2385).
- You can use IAM to centrally manage access to your database resources, instead of managing access individually on each DB cluster.
- For applications running on Amazon EC2, you can use profile credentials specific to your EC2 instance to access your database instead of a password, for greater security.

In general, consider using IAM database authentication when your applications create fewer than 200 connections per second, and you don’t want to manage usernames and passwords directly in your application code.

The AWS JDBC Driver for MySQL supports IAM database authentication. For more information, see AWS IAM Database Authentication in the AWS JDBC Driver for MySQL GitHub repository.

Topics

- Region and version availability (p. 2432)
- CLI and SDK support (p. 2433)
- Limitations for IAM database authentication (p. 2433)
- Recommendations for IAM database authentication (p. 2433)
- Unsupported AWS global condition context keys (p. 2434)
- Enabling and disabling IAM database authentication (p. 2434)
- Creating and using an IAM policy for IAM database access (p. 2436)
- Creating a database account using IAM authentication (p. 2439)
- Connecting to your DB cluster using IAM authentication (p. 2440)

Region and version availability

Feature availability and support varies across specific versions of each Aurora database engine, and across AWS Regions. For more information on version and Region availability with Aurora and IAM database authentication, see IAM database authentication in Aurora (p. 36).

For Aurora MySQL, all supported DB instance classes support IAM database authentication, except for db.t2.small and db.t3.small. For information about the supported DB instance classes, see Supported DB engines for DB instance classes (p. 86).
CLI and SDK support

IAM database authentication is available for the AWS CLI and for the following language-specific AWS SDKs:

- AWS SDK for .NET
- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for JavaScript
- AWS SDK for PHP
- AWS SDK for Python (Boto3)
- AWS SDK for Ruby

Limitations for IAM database authentication

When using IAM database authentication, the following limitations apply:

- The maximum number of connections per second for your DB cluster might be limited depending on its DB instance class and your workload.
- Currently, IAM database authentication doesn't support all global condition context keys.

For more information about global condition context keys, see AWS global condition context keys in the IAM User Guide.

- For PostgreSQL, if the IAM role (rds_iam) is added to a user (including the RDS master user), IAM authentication takes precedence over password authentication, so the user must log in as an IAM user.
- For Aurora PostgreSQL, you cannot use IAM authentication to establish a replication connection.
- You cannot use a custom Route 53 DNS record instead of the DB cluster endpoint to generate the authentication token.

Recommendations for IAM database authentication

We recommend the following when using IAM database authentication:

- Use IAM database authentication when your application requires fewer than 200 new IAM database authentication connections per second.

The database engines that work with Amazon Aurora don't impose any limits on authentication attempts per second. However, when you use IAM database authentication, your application must generate an authentication token. Your application then uses that token to connect to the DB cluster. If you exceed the limit of maximum new connections per second, then the extra overhead of IAM database authentication can cause connection throttling.

Consider using connection pooling in your applications to mitigate constant connection creation. This can reduce the overhead from IAM DB authentication and allow your applications to reuse existing connections. Alternatively, consider using RDS Proxy for these use cases. RDS Proxy has additional costs. See RDS Proxy pricing.

- The size of an IAM database authentication token depends on many things including the number of IAM tags, IAM service policies, ARN lengths, as well as other IAM and database properties. The minimum size of this token is generally about 1 KB but can be larger. Since this token is used as the password in the connection string to the database using IAM authentication, you should ensure that
your database driver (e.g., ODBC) and/or any tools do not limit or otherwise truncate this token due
to its size. A truncated token will cause the authentication validation done by the database and IAM to
fail.

- If you are using temporary credentials when creating an IAM database authentication token, the
temporary credentials must still be valid when using the IAM database authentication token to make a
connection request.

### Unsupported AWS global condition context keys

IAM database authentication does not support the following subset of AWS global condition context
tokens:

- `aws:Referer`
- `aws:SourceIp`
- `aws:SourceVpc`
- `aws:SourceVpce`
- `aws:UserAgent`
- `aws:VpcSourceIp`

For more information, see [AWS global condition context keys](https://docs.aws.amazon.com/IAM/latest/UserGuide/reference_policies_condition-context.html) in the IAM User Guide.

### Enabling and disabling IAM database authentication

By default, IAM database authentication is disabled on DB clusters. You can enable or disable IAM
database authentication using the AWS Management Console, AWS CLI, or the API.

You can enable IAM database authentication when you perform one of the following actions:

- To create a new DB cluster with IAM database authentication enabled, see [Creating an Amazon Aurora
  DB cluster](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-create-cluster.html).
- To modify a DB cluster to enable IAM database authentication, see [Modifying an Amazon Aurora DB
  cluster](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-update-cluster.html).
- To restore a DB cluster from a snapshot with IAM database authentication enabled, see [Restoring from
  a DB cluster snapshot](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-snapshot-recovery.html).
- To restore a DB cluster to a point in time with IAM database authentication enabled, see [Restoring a
  DB cluster to a specified time](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-point-in-time-recovery.html).

### Console

Each creation or modification workflow has a Database authentication section, where you can
enable or disable IAM database authentication. In that section, choose Password and IAM database
authentication to enable IAM database authentication.

**To enable or disable IAM database authentication for an existing DB cluster**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Databases.
3. Choose the DB cluster that you want to modify.

**Note**

You can only enable IAM authentication if all DB instances in the DB cluster are compatible
with IAM. Check the compatibility requirements in [Region and version availability](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-create-cluster.html).
4. Choose Modify.
5. In the Database authentication section, choose Password and IAM database authentication to enable IAM database authentication. Choose Password authentication or Password and Kerberos authentication to disable IAM authentication.
6. Choose Continue.
7. To apply the changes immediately, choose Immediately in the Scheduling of modifications section.
8. Choose Modify cluster.

AWS CLI

To create a new DB cluster with IAM authentication by using the AWS CLI, use the create-db-cluster command. Specify the --enable-iam-database-authentication option.

To update an existing DB cluster to have or not have IAM authentication, use the AWS CLI command modify-db-cluster. Specify either the --enable-iam-database-authentication or --no-enable-iam-database-authentication option, as appropriate.

Note
You can only enable IAM authentication if all DB instances in the DB cluster are compatible with IAM. Check the compatibility requirements in Region and version availability (p. 2432).

By default, Aurora performs the modification during the next maintenance window. If you want to override this and enable IAM DB authentication as soon as possible, use the --apply-immediately parameter.

If you are restoring a DB cluster, use one of the following AWS CLI commands:

- restore-db-cluster-to-point-in-time
- restore-db-cluster-from-db-snapshot

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the --enable-iam-database-authentication or --no-enable-iam-database-authentication option, as appropriate.

RDS API

To create a new DB instance with IAM authentication by using the API, use the API operation CreateDBCluster. Set the EnableIAMDatabaseAuthentication parameter to true.

To update an existing DB cluster to have IAM authentication, use the API operation ModifyDBCluster. Set the EnableIAMDatabaseAuthentication parameter to true to enable IAM authentication, or false to disable it.

Note
You can only enable IAM authentication if all DB instances in the DB cluster are compatible with IAM. Check the compatibility requirements in Region and version availability (p. 2432).

If you are restoring a DB cluster, use one of the following API operations:

- RestoreDBClusterFromSnapshot
- RestoreDBClusterToPointInTime

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the EnableIAMDatabaseAuthentication parameter to true to enable IAM authentication, or false to disable it.
Creating and using an IAM policy for IAM database access

To allow a user or role to connect to your DB cluster, you must create an IAM policy. After that, you attach the policy to a permissions set or role.

**Note**

To learn more about IAM policies, see [Identity and access management for Amazon Aurora](p. 2400).

The following example policy allows a user to connect to a DB cluster using IAM database authentication.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds-db:connect"
      ],
      "Resource": [
      ]
    }
  ]
}
```

**Important**

A user with administrator permissions can access DB clusters without explicit permissions in an IAM policy. If you want to restrict administrator access to DB clusters, you can create an IAM role with the appropriate, lesser privileged permissions and assign it to the administrator.

**Note**

Don't confuse the `rds-db:` prefix with other RDS API operation prefixes that begin with `rds:`. You use the `rds-db:` prefix and the `rds-db:connect` action only for IAM database authentication. They aren't valid in any other context.

The example policy includes a single statement with the following elements:

- **Effect** – Specify `Allow` to grant access to the DB cluster. If you don't explicitly allow access, then access is denied by default.
- **Action** – Specify `rds-db:connect` to allow connections to the DB cluster.
- **Resource** – Specify an Amazon Resource Name (ARN) that describes one database account in one DB cluster. The ARN format is as follows.

```
arn:aws:rds-db:region:account-id:dbuser:DbClusterResourceId/db-user-name
```

In this format, replace the following:

- **region** is the AWS Region for the DB cluster. In the example policy, the AWS Region is `us-east-2`.
- **account-id** is the AWS account number for the DB cluster. In the example policy, the account number is 1234567890. The user must be in the same account as the account for the DB cluster.

To perform cross-account access, create an IAM role with the policy shown above in the account for the DB cluster and allow your other account to assume the role.

- **DbClusterResourceId** is the identifier for the DB cluster. This identifier is unique to an AWS Region and never changes. In the example policy, the identifier is `cluster-ABCDEFGHIJKL01234`.
To find a DB cluster resource ID in the AWS Management Console for Amazon Aurora, choose the DB cluster to see its details. Then choose the **Configuration** tab. The **Resource ID** is shown in the **Configuration** section.

Alternatively, you can use the AWS CLI command to list the identifiers and resource IDs for all of your DB cluster in the current AWS Region, as shown following.

```
aws rds describe-db-clusters --query "DBClusters[*].
[DBClusterIdentifier,DbClusterResourceId]"
```

**Note**

If you are connecting to a database through RDS Proxy, specify the proxy resource ID, such as `prx-ABCDEFGHJKL01234`. For information about using IAM database authentication with RDS Proxy, see [Connecting to a proxy using IAM authentication (p. 1898)](Connecting to a proxy using IAM authentication).  

- **db-user-name** is the name of the database account to associate with IAM authentication. In the example policy, the database account is `db_user`.

You can construct other ARNs to support various access patterns. The following policy allows access to two different database accounts in a DB cluster.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds-db:connect"
      ],
      "Resource": [
jane_doe",
mary_roe"
      ]
    }
  ]
}
```

The following policy uses the "*" character to match all DB clusters and database accounts for a particular AWS account and AWS Region.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds-db:connect"
      ],
      "Resource": [
      ]
    }
  ]
}
```
The following policy matches all of the DB clusters for a particular AWS account and AWS Region. However, the policy only grants access to DB clusters that have a jane_doe database account.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": ["rds-db:connect"],
      ]
   ]
}
```

The user or role has access to only those databases that the database user does. For example, suppose that your DB cluster has a database named dev, and another database named test. If the database user jane_doe has access only to dev, any users or roles that access that DB cluster with the jane_doe user also have access only to dev. This access restriction is also true for other database objects, such as tables, views, and so on.

An administrator must create IAM policies that grant entities permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the permission sets or roles that require those permissions. For examples of policies, see Identity-based policy examples for Amazon Aurora (p. 2409).

**Attaching an IAM policy to a permission set or role**

After you create an IAM policy to allow database authentication, you need to attach the policy to a permission set or role. For a tutorial on this topic, see Create and attach your first customer managed policy in the IAM User Guide.

As you work through the tutorial, you can use one of the policy examples shown in this section as a starting point and tailor it to your needs. At the end of the tutorial, you have a permission set with an attached policy that can make use of the rds-db:connect action.

**Note**

You can map multiple permission sets or roles to the same database user account. For example, suppose that your IAM policy specified the following resource ARN.

```text
arn:aws:rds-db:us-east-2:123456789012:dbuser:cluster-12ABC34DEFG5HI6JKLMN0P78QR/jane_doe
```

If you attach the policy to Jane, Bob, and Diego, then each of those users can connect to the specified DB cluster using the jane_doe database account.
Creating a database account using IAM authentication

With IAM database authentication, you don't need to assign database passwords to the user accounts you create. If you remove a user that is mapped to a database account, you should also remove the database account with the DROP USER statement.

**Note**
The user name used for IAM authentication must match the case of the user name in the database.

**Topics**
- Using IAM authentication with Aurora MySQL (p. 2439)
- Using IAM authentication with Aurora PostgreSQL (p. 2439)

Using IAM authentication with Aurora MySQL

With Aurora MySQL, authentication is handled by AWSAuthenticationPlugin—an AWS-provided plugin that works seamlessly with IAM to authenticate your users. Connect to the DB cluster as the master user or a different user who can create users and grant privileges. After connecting, issue the CREATE USER statement, as shown in the following example.

```
CREATE USER jane_doe IDENTIFIED WITH AWSAuthenticationPlugin AS 'RDS';
```

The IDENTIFIED WITH clause allows Aurora MySQL to use the AWSAuthenticationPlugin to authenticate the database account (jane_doe). The AS 'RDS' clause refers to the authentication method. Make sure the specified database user name is the same as a resource in the IAM policy for IAM database access. For more information, see Creating and using an IAM policy for IAM database access (p. 2436).

**Note**
If you see the following message, it means that the AWS-provided plugin is not available for the current DB cluster.
```
ERROR 1524 (HY000): Plugin 'AWSAuthenticationPlugin' is not loaded
```
To troubleshoot this error, verify that you are using a supported configuration and that you have enabled IAM database authentication on your DB cluster. For more information, see Region and version availability (p. 2432) and Enabling and disabling IAM database authentication (p. 2434).

After you create an account using AWSAuthenticationPlugin, you manage it in the same way as other database accounts. For example, you can modify account privileges with GRANT and REVOKE statements, or modify various account attributes with the ALTER USER statement.

Database network traffic is encrypted using SSL/TLS when using IAM. To allow SSL connections, modify the user account with the following command.

```
ALTER USER 'jane_doe'@'%' REQUIRE SSL;
```

Using IAM authentication with Aurora PostgreSQL

To use IAM authentication with Aurora PostgreSQL, connect to the DB cluster as the master user or a different user who can create users and grant privileges. After connecting, create database users and then grant them the rds_iam role as shown in the following example.

```
CREATE USER db_userx;
```
Make sure the specified database user name is the same as a resource in the IAM policy for IAM database access. For more information, see Creating and using an IAM policy for IAM database access (p. 2436).

Note that a PostgreSQL database user can use either IAM or Kerberos authentication but not both, so this user can’t also have the rds_ad role. This also applies to nested memberships. For more information, see Step 7: Create PostgreSQL users for your Kerberos principals (p. 1261).

Connecting to your DB cluster using IAM authentication

With IAM database authentication, you use an authentication token when you connect to your DB cluster. An authentication token is a string of characters that you use instead of a password. After you generate an authentication token, it’s valid for 15 minutes before it expires. If you try to connect using an expired token, the connection request is denied.

Every authentication token must be accompanied by a valid signature, using AWS signature version 4. (For more information, see Signature Version 4 signing process in the AWS General Reference.) The AWS CLI and an AWS SDK, such as the AWS SDK for Java or AWS SDK for Python (Boto3), can automatically sign each token you create.

You can use an authentication token when you connect to Amazon Aurora from another AWS service, such as AWS Lambda. By using a token, you can avoid placing a password in your code. Alternatively, you can use an AWS SDK to programmatically create and programmatically sign an authentication token.

After you have a signed IAM authentication token, you can connect to an Aurora DB cluster. Following, you can find out how to do this using either a command line tool or an AWS SDK, such as the AWS SDK for Java or AWS SDK for Python (Boto3).

For more information, see the following blog posts:

- Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL
- Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL

Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- Enabling and disabling IAM database authentication (p. 2434)
- Creating and using an IAM policy for IAM database access (p. 2436)
- Creating a database account using IAM authentication (p. 2439)

Topics

- Connecting to your DB cluster using IAM authentication from the command line: AWS CLI and mysql client (p. 2441)
- Connecting to your DB cluster using IAM authentication from the command line: AWS CLI and psql client (p. 2443)
- Connecting to your DB cluster using IAM authentication and the AWS SDK for .NET (p. 2444)
- Connecting to your DB cluster using IAM authentication and the AWS SDK for Go (p. 2447)
- Connecting to your DB cluster using IAM authentication and the AWS SDK for Java (p. 2451)
- Connecting to your DB cluster using IAM authentication and the AWS SDK for Python (Boto3) (p. 2458)
Connecting to your DB cluster using IAM authentication from the command line: AWS CLI and mysql client

You can connect from the command line to an Aurora DB cluster with the AWS CLI and mysql command line tool as described following.

Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- Enabling and disabling IAM database authentication (p. 2434)
- Creating and using an IAM policy for IAM database access (p. 2436)
- Creating a database account using IAM authentication (p. 2439)

Note
For information about connecting to your database using SQL Workbench/J with IAM authentication, see the blog post Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL.

Topics

- Generating an IAM authentication token (p. 2441)
- Connecting to a DB cluster (p. 2441)

Generating an IAM authentication token

The following example shows how to get a signed authentication token using the AWS CLI.

```
aws rds generate-db-auth-token \
   --hostname rdsmysql.123456789012.us-west-2.rds.amazonaws.com \
   --port 3306 \
   --region us-west-2 \
   --username jane_doe
```

In the example, the parameters are as follows:

- --hostname – The host name of the DB cluster that you want to access
- --port – The port number used for connecting to your DB cluster
- --region – The AWS Region where the DB cluster is running
- --username – The database account that you want to access

The first several characters of the token look like the following.

```
rdsmysql.123456789012.us-west-2.rds.amazonaws.com:3306/?Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```

Note
You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

Connecting to a DB cluster

The general format for connecting is shown following.
mysql --host=hostName --port=portNumber --ssl-ca=full_path_to_ssl_certificate --enable-cleartext-plugin --user=userName --password=authToken

The parameters are as follows:

- **--host** – The host name of the DB cluster that you want to access
- **--port** – The port number used for connecting to your DB cluster
- **--ssl-ca** – The full path to the SSL certificate file that contains the public key

For more information, see Using TLS with Aurora MySQL DB clusters (p. 814).

To download an SSL certificate, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 2385).

- **--enable-cleartext-plugin** – A value that specifies that AWSAuthenticationPlugin must be used for this connection
  
  If you are using a MariaDB client, the --enable-cleartext-plugin option isn't required.

- **--user** – The database account that you want to access
- **--password** – A signed IAM authentication token

The authentication token consists of several hundred characters. It can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows one way to perform this workaround. In the example, /sample_dir/ is the full path to the SSL certificate file that contains the public key.

```
RDSHOST="mysqlcluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
TOKEN="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 3306 --region us-west-2 --username jane_doe )"

mysql --host=$RDSHOST --port=3306 --ssl-ca=/sample_dir/global-bundle.pem --enable-cleartext-plugin --user=jane_doe --password=$TOKEN
```

When you connect using AWSAuthenticationPlugin, the connection is secured using SSL. To verify this, type the following at the mysql> command prompt.

```
show status like 'Ssl%';
```

The following lines in the output show more details.

```
+---------------+-------------+
| Variable_name | Value       |
+---------------+-------------+
| ...           | ...         |
| Ssl_cipher    | AES256-SHA  |
| ...           | ...         |
| Ssl_version   | TLSv1.1     |
| ...           | ...         |
+-----------------------------+
```

If you want to connect to a DB cluster through a proxy, see Connecting to a proxy using IAM authentication (p. 1898).
Connecting to your DB cluster using IAM authentication from the command line: AWS CLI and psql client

You can connect from the command line to an Aurora PostgreSQL DB cluster with the AWS CLI and psql command line tool as described following.

Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- Enabling and disabling IAM database authentication (p. 2434)
- Creating and using an IAM policy for IAM database access (p. 2436)
- Creating a database account using IAM authentication (p. 2439)

Note

For information about connecting to your database using pgAdmin with IAM authentication, see the blog post Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL.

Topics

- Generating an IAM authentication token (p. 2443)
- Connecting to an Aurora PostgreSQL cluster (p. 2443)

Generating an IAM authentication token

The authentication token consists of several hundred characters so it can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows how to use the AWS CLI to get a signed authentication token using the `generate-db-auth-token` command, and store it in a `PGPASSWORD` environment variable.

```bash
export RDSHOST="mypostgres-cluster.cluster-123456789012.us-west-2.rds.amazonaws.com"
export PGPASSWORD="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --region us-west-2 --username jane_doe )"
```

In the example, the parameters to the `generate-db-auth-token` command are as follows:

- `--hostname` – The host name of the DB cluster (cluster endpoint) that you want to access
- `--port` – The port number used for connecting to your DB cluster
- `--region` – The AWS Region where the DB cluster is running
- `--username` – The database account that you want to access

The first several characters of the generated token look like the following.

```
mypostgres-cluster.cluster-123456789012.us-west-2.rds.amazonaws.com:5432/?Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```

Note

You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

Connecting to an Aurora PostgreSQL cluster

The general format for using psql to connect is shown following.
psql "host=hostName port=portNumber sslmode=verify-full sslrootcert=full_path_to_ssl_certificate dbname=DBName user=userName password=authToken"

The parameters are as follows:

- host – The host name of the DB cluster (cluster endpoint) that you want to access
- port – The port number used for connecting to your DB cluster
- sslmode – The SSL mode to use

When you use sslmode=verify-full, the SSL connection verifies the DB cluster endpoint against the endpoint in the SSL certificate.

- sslrootcert – The full path to the SSL certificate file that contains the public key

For more information, see [Securing Aurora PostgreSQL data with SSL/TLS](p. 1243).

To download an SSL certificate, see [Using SSL/TLS to encrypt a connection to a DB cluster](p. 2385).

- dbname – The database that you want to access
- user – The database account that you want to access
- password – A signed IAM authentication token

**Note**

You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

The following example shows using psql to connect. In the example, psql uses the environment variable RDSHOST for the host and the environment variable PGPASSWORD for the generated token. Also, `/sample_dir/` is the full path to the SSL certificate file that contains the public key.

```bash
export RDSHOST="mypostgres-cluster.cluster-123456789012.us-west-2.rds.amazonaws.com"
export PGPASSWORD="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --region us-west-2 --username jane_doe )"

psql "host=$RDSHOST port=5432 sslmode=verify-full sslrootcert=/sample_dir/global-bundle.pem dbname=DBName user=jane_doe password=$PGPASSWORD"
```

If you want to connect to a DB cluster through a proxy, see [Connecting to a proxy using IAM authentication](p. 1898).

**Connecting to your DB cluster using IAM authentication and the AWS SDK for .NET**

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the AWS SDK for .NET as described following.

**Prerequisites**

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- [Enabling and disabling IAM database authentication](p. 2434)
- [Creating and using an IAM policy for IAM database access](p. 2436)
- [Creating a database account using IAM authentication](p. 2439)

**Examples**
The following code examples show how to generate an authentication token, and then use it to connect to a DB cluster.

To run this code example, you need the AWS SDK for .NET, found on the AWS site. The AWSSDK . CORE and the AWSSDK .RDS packages are required. To connect to a DB cluster, use the .NET database connector for the DB engine, such as MySqlConnector for MariaDB or MySQL, or Npgsql for PostgreSQL.

This code connects to an Aurora MySQL DB cluster. Modify the values of the following variables as needed:

- server – The endpoint of the DB cluster that you want to access
- user – The database account that you want to access
- database – The database that you want to access
- port – The port number used for connecting to your DB cluster
- SslMode – The SSL mode to use
- SslCa – The full path to the SSL certificate for Amazon Aurora

When you use SslMode=Required, the SSL connection verifies the DB cluster endpoint against the endpoint in the SSL certificate.

To download a certificate, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 2385).

**Note**
You cannot use a custom Route S3 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

```csharp
using System;
using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;
using Amazon;

namespace ubuntu
{
    class Program
    {
        static void Main(string[] args)
        {
            var pwd = Amazon.RDS.Util.RDSShiftTokenGenerator.GenerateAuthToken(RegionEndpoint.USEast1, "mysqlcluster.cluster-123456789012.us-east-1.rds.amazonaws.com", 3306, "jane_doe");
            // for debug only Console.Write("{0}\n", pwd); // this verifies the token is generated

            MySqlConnection conn = new
            MySqlConnection($"server=mysqlcluster.cluster-123456789012.us-east-1.rds.amazonaws.com;user=jane_doe;database=mydB;port=3306;password={pwd};SslMode=Required;SslCa=full_path_to_ssl_certificate");

            conn.Open();

            // Define a query
            MySqlCommand sampleCommand = new MySqlCommand("SHOW DATABASES;", conn);

            // Execute a query
            MySqlDataReader mysqlDataRdr = sampleCommand.ExecuteReader();

            // Read all rows and output the first column in each row while (mysqlDataRdr.Read())
                Console.WriteLine(mysqlDataRdr[0]);
            mysqlDataRdr.Close();
        }
    }
}
```
This code connects to an Aurora PostgreSQL DB cluster.

Modify the values of the following variables as needed:

- **Server** – The endpoint of the DB cluster that you want to access
- **User ID** – The database account that you want to access
- **Database** – The database that you want to access
- **Port** – The port number used for connecting to your DB cluster
- **SSL Mode** – The SSL mode to use

When you use **SSL Mode=Required**, the SSL connection verifies the DB cluster endpoint against the endpoint in the SSL certificate.

- **Root Certificate** – The full path to the SSL certificate for Amazon Aurora

To download a certificate, see [Using SSL/TLS to encrypt a connection to a DB cluster](p. 2385).

**Note**

You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.
If you want to connect to a DB cluster through a proxy, see Connecting to a proxy using IAM authentication (p. 1898).

Connecting to your DB cluster using IAM authentication and the AWS SDK for Go

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the AWS SDK for Go as described following.

Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- Enabling and disabling IAM database authentication (p. 2434)
- Creating and using an IAM policy for IAM database access (p. 2436)
- Creating a database account using IAM authentication (p. 2439)

Examples

To run these code examples, you need the AWS SDK for Go, found on the AWS site.

Modify the values of the following variables as needed:

- dbName – The database that you want to access
- dbUser – The database account that you want to access
- dbHost – The endpoint of the DB cluster that you want to access

Note

You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

- dbPort – The port number used for connecting to your DB cluster
- region – The AWS Region where the DB cluster is running

In addition, make sure the imported libraries in the sample code exist on your system.

Important

The examples in this section use the following code to provide credentials that access a database from a local environment:

creds := credentials.NewEnvCredentials()
If you are accessing a database from an AWS service, such as Amazon EC2 or Amazon ECS, you can replace the code with the following code:

sess := session.Must(session.NewSession())
creds := sess.Config.Credentials
If you make this change, make sure you add the following import:

"github.com/aws/aws-sdk-go/aws/session"

Connecting using IAM authentication and the AWS SDK for Go V2

You can connect to a DB cluster using IAM authentication and the AWS SDK for Go V2.
The following code examples show how to generate an authentication token, and then use it to connect to a DB cluster.

This code connects to an Aurora MySQL DB cluster.

```go
package main

import (
    "context"
    "database/sql"
    "fmt"
    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/feature/rds/auth"
    _ "github.com/go-sql-driver/mysql"
)

func main() {
    var dbName string = "DatabaseName"
    var dbUser string = "DatabaseUser"
    var dbHost string = "mysqlcluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
    var dbPort int = 3306
    var dbEndpoint string = fmt.Sprintf("%s:%d", dbHost, dbPort)
    var region string = "us-east-1"

    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        panic("configuration error: " + err.Error())
    }

    authenticationToken, err := auth.BuildAuthToken(
        context.TODO(), dbEndpoint, region, dbUser, cfg.Credentials)
    if err != nil {
        panic("failed to create authentication token: " + err.Error())
    }

    dsn := fmt.Sprintf("%s:%s@tcp(%s)/%s?tls=true&allowCleartextPasswords=true",
        dbUser, authenticationToken, dbEndpoint, dbName,
    )

    db, err := sql.Open("mysql", dsn)
    if err != nil {
        panic(err)
    }

    err = db.Ping()
    if err != nil {
        panic(err)
    }
}
```

This code connects to an Aurora PostgreSQL DB cluster.

```go
package main

import (
    "context"
    "database/sql"
    "fmt"
    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/feature/rds/auth"
    _ "github.com/lib/pq"
)

func main() {
    var dbName string = "DatabaseName"
    var dbUser string = "DatabaseUser"
    var dbHost string = "mysqlcluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
    var dbPort int = 5432
    var dbEndpoint string = fmt.Sprintf("%s:%d", dbHost, dbPort)
    var region string = "us-east-1"

    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        panic("configuration error: " + err.Error())
    }

    authenticationToken, err := auth.BuildAuthToken(
        context.TODO(), dbEndpoint, region, dbUser, cfg.Credentials)
    if err != nil {
        panic("failed to create authentication token: " + err.Error())
    }

    dsn := fmt.Sprintf("%s:%s@tcp(%s)/%s?tls=true&allowCleartextPasswords=true",
        dbUser, authenticationToken, dbEndpoint, dbName,
    )

    // Connect to the database
    db, err := sql.Open("mysql", dsn)
    if err != nil {
        panic(err)
    }

    err = db.Ping()
    if err != nil {
        panic(err)
    }
}
```
func main() {
    var dbName string = "DatabaseName"
    var dbUser string = "DatabaseUser"
    var dbHost string = "postgresmycluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
    var dbPort int = 5432
    var dbEndpoint string = fmt.Sprintf("%s:%d", dbHost, dbPort)
    var region string = "us-east-1"

    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        panic("configuration error: " + err.Error())
    }

    authenticationToken, err := auth.BuildAuthToken(
        context.TODO(), dbEndpoint, region, dbUser, cfg.Credentials)
    if err != nil {
        panic("failed to create authentication token: " + err.Error())
    }

    dsn := fmt.Sprintf("host=%s port=%d user=%s password=%s dbname=%s",
        dbHost, dbPort, dbUser, authenticationToken, dbName,
    )

    db, err := sql.Open("postgres", dsn)
    if err != nil {
        panic(err)
    }

    err = db.Ping()
    if err != nil {
        panic(err)
    }
}

If you want to connect to a DB cluster through a proxy, see [Connecting to a proxy using IAM authentication](p. 1898).

Connecting using IAM authentication and the AWS SDK for Go V1.

You can connect to a DB cluster using IAM authentication and the AWS SDK for Go V1.

The following code examples show how to generate an authentication token, and then use it to connect to a DB cluster.

This code connects to an Aurora MySQL DB cluster.

```go
package main

import (  
    "database/sql"  
    "fmt"  
    "log"  
    "github.com/aws/aws-sdk-go/aws/credentials"  
    "github.com/aws/aws-sdk-go/service/rds/rdsutils"  
    // "github.com/go-sql-driver/mysql"
)

func main() {
    dbName := "app"
    
    var dbUser string = "DatabaseUser"
    var dbHost string = "postgresmycluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
    var dbPort int = 5432
    var dbEndpoint string = fmt.Sprintf("%s:%d", dbHost, dbPort)
    var region string = "us-east-1"

    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        panic("configuration error: " + err.Error())
    }

    authenticationToken, err := auth.BuildAuthToken(
        context.TODO(), dbEndpoint, region, dbUser, cfg.Credentials)
    if err != nil {
        panic("failed to create authentication token: " + err.Error())
    }

    dsn := fmt.Sprintf("host=%s port=%d user=%s password=%s dbname=%s",
        dbHost, dbPort, dbUser, authenticationToken, dbName,
    )

    db, err := sql.Open("postgres", dsn)
    if err != nil {
        panic(err)
    }

    err = db.Ping()
    if err != nil {
        panic(err)
    }
}
```
package main

import (  
    "database/sql"
    "fmt"
    
    "github.com/aws/aws-sdk-go/aws/credentials"
    "github.com/aws/aws-sdk-go/service/rds/rdsutils"
    "github.com/lib/pq"
)

func main() {  
    dbName := "app"  
    dbUser := "jane_doe"  
    dbHost := "postgresmycluster.cluster-123456789012.us-east-1.rds.amazonaws.com"  
    dbPort := 5432  
    dbEndpoint := fmt.Sprintf("%s:%d", dbHost, dbPort)  
    region := "us-east-1"  
    creds := credentials.NewEnvCredentials()  
    authToken, err := rdsutils.BuildAuthToken(dbEndpoint, region, dbUser, creds)  
    if err != nil {  
        panic(err)  
    }  
    dsn := fmt.Sprintf("host=%s port=%d user=%s password=%s dbname=%s",  
                      dbHost, dbPort, dbUser, authToken, dbName,  
                      )  
    db, err := sql.Open("postgres", dsn)  
    if err != nil {  
        panic(err)  
    }  
    err = db.Ping()  
    if err != nil {  
        panic(err)  
    }  
}
If you want to connect to a DB cluster through a proxy, see Connecting to a proxy using IAM authentication (p. 1898).

**Connecting to your DB cluster using IAM authentication and the AWS SDK for Java**

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the AWS SDK for Java as described following.

**Prerequisites**

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- Enabling and disabling IAM database authentication (p. 2434)
- Creating and using an IAM policy for IAM database access (p. 2436)
- Creating a database account using IAM authentication (p. 2439)
- Set up the AWS SDK for Java

**Topics**

- Generating an IAM authentication token (p. 2451)
- Manually constructing an IAM authentication token (p. 2452)
- Connecting to a DB cluster (p. 2455)

**Generating an IAM authentication token**

If you are writing programs using the AWS SDK for Java, you can get a signed authentication token using the `RdsIamAuthTokenGenerator` class. Using this class requires that you provide AWS credentials. To do this, you create an instance of the `DefaultAWSCredentialsProviderChain` class. `DefaultAWSCredentialsProviderChain` uses the first AWS access key and secret key that it finds in the default credential provider chain. For more information about AWS access keys, see Managing access keys for users.

**Note**

You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

After you create an instance of `RdsIamAuthTokenGenerator`, you can call the `getAuthToken` method to obtain a signed token. Provide the AWS Region, host name, port number, and user name. The following code example illustrates how to do this.

```java
package com.amazonaws.codesamples;

import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.services.rds.auth.GetIamAuthTokenRequest;
import com.amazonaws.services.rds.auth.RdsIamAuthTokenGenerator;

public class GenerateRDSAuthToken {
    public static void main(String[] args) {
        String region = "us-west-2";
        String hostname = "rdsmysql.123456789012.us-west-2.rds.amazonaws.com";
        String port = "3306";
    }
}
```
Manually constructing an IAM authentication token

In Java, the easiest way to generate an authentication token is to use RdsIamAuthTokenGenerator. This class creates an authentication token for you, and then signs it using AWS signature version 4. For more information, see Signature version 4 signing process in the AWS General Reference.

However, you can also construct and sign an authentication token manually, as shown in the following code example.
public static void main(String[] args) throws Exception {
    String region = "us-west-2";
    String instanceName = "rdsmysql.123456789012.us-west-2.rds.amazonaws.com";
    String port = "3306";
    String username = "jane_doe";
    Date now = new Date();
    String date = new SimpleDateFormat("yyyyMMdd").format(now);
    String dateTimeStamp = new SimpleDateFormat("yyyyMMdd'T'HHmmss'Z'"').format(now);
    DefaultAWSCredentialsProviderChain creds = new DefaultAWSCredentialsProviderChain();
    String awsAccessKey = creds.getCredentials().getAWSAccessKeyId();
    String awsSecretKey = creds.getCredentials().getAWSSecretKey();
    String expiryMinutes = "900";
    System.out.println("Step 1: Create a canonical request:");
    String canonicalString = createCanonicalString(username, awsAccessKey, date,
    dateTimeStamp, region, expiryMinutes, instanceName, port);
    System.out.println(canonicalString);
    System.out.println();
    System.out.println("Step 2: Create a string to sign:");
    String stringToSign = createStringToSign(dateTimeStamp, canonicalString,
    awsAccessKey, date, region);
    System.out.println(stringToSign);
    System.out.println();
    System.out.println("Step 3: Calculate the signature:");
    String signature = BinaryUtils.toHex(calculateSignature(stringToSign,
    newSigningKey(awsSecretKey, date, region, serviceName)));
    System.out.println(signature);
    System.out.println();
    System.out.println("Step 4: Add the signing info to the request");
    System.out.println(appendSignature(signature));
    System.out.println();
}

//Step 1: Create a canonical request date should be in format YYYYMMDD and dateTime
// should be in format YYYYMMDDTHHMMSSZ
public static String createCanonicalString(String user, String accessKey, String date,
    String dateTime, String region, String expiryPeriod, String hostName, String port) throws
    Exception {
    canonicalQueryParameters.put("Action", action);
    canonicalQueryParameters.put("DBUser", user);
    canonicalQueryParameters.put("X-Amz-Algorithm", "AWS4-HMAC-SHA256");
    canonicalQueryParameters.put("X-Amz-Credential", accessKey + "%2F" + date + "%2F" +
    region + "%2F" + serviceName + "%2Faws4_request");
    canonicalQueryParameters.put("X-Amz-Expires", expiryPeriod);
    canonicalQueryParameters.put("X-Amz-SignedHeaders", signedHeader);
    String canonicalQueryString = "";
    while(!canonicalQueryParameters.isEmpty()) {
        String currentQueryParameter = canonicalQueryParameters.firstKey();
        String currentQueryParameterValue = canonicalQueryParameters.remove(currentQueryParameter);
        canonicalQueryString = canonicalQueryString + currentQueryParameter + "=" +
        currentQueryParameterValue;
        if (!currentQueryParameterValue.equals("X-Amz-SignedHeaders")) {
            canonicalqueryString += ";";
        }
    }
    String canonicalHeaders = "host:" + hostName + "":" + port + 
    \n";
requestWithoutSignature = hostName + ":" + port + "/?" + canonicalQueryString;

String hashedPayload = BinaryUtils.toHex(hash(payload));
return httpMethod + '\n' + canonicalURIParameter + '\n' + canonicalQueryString + '
' + canonicalHeaders + '\n' + signedHeader + '\n' + hashedPayload;

//Step 2: Create a string to sign using sig v4
public static String createStringToSign(String dateTime, String canonicalRequest,
String accessKey, String date, String region) throws Exception {
    String credentialScope = date + "/" + region + "/" + serviceName + "/aws4_request";
    return algorithm + '\n' + dateTime + '\n' + credentialScope + '\n' + BinaryUtils.toHex(hash(canonicalRequest));
}

//Step 3: Calculate signature
/**
 * Step 3 of the &AWS; Signature version 4 calculation. It involves deriving
 * the signing key and computing the signature. Refer to
 * http://docs.aws.amazon.com/general/latest/gr/sigv4-calculate-signature.html
 */
public static byte[] calculateSignature(String stringToSign,
    byte[] signingKey) {
    return sign(stringToSign.getBytes(Charset.forName("UTF-8")), signingKey,
        SigningAlgorithm.HmacSHA256);
}

public static byte[] sign(byte[] data, byte[] key,
    SigningAlgorithm algorithm) throws SdkClientException {
    try {
        byte[] data = stringData.getBytes(UTF8); 
        return sign(data, key, algorithm);
    } catch (Exception e) {
        throw new SdkClientException("Unable to calculate a request signature: " + e.getMessage(), e);
    }
}

public static byte[] newSigningKey(String secretKey,
    String dateStamp, String regionName, String serviceName) {
    byte[] kSecret = ("AWS4" + secretKey).getBytes(Charset.forName("UTF-8"));
    byte[] kDate = sign(dateStamp, kSecret, SigningAlgorithm.HmacSHA256);
    byte[] kRegion = sign(regionName, kDate, SigningAlgorithm.HmacSHA256);
    byte[] kService = sign(serviceName, kRegion,
        SigningAlgorithm.HmacSHA256);
    return sign(AWS4_TERMINATOR, kService, SigningAlgorithm.HmacSHA256);
}

public static byte[] sign(String stringData, byte[] key,
    SigningAlgorithm algorithm) throws SdkClientException {
    try {
        byte[] data = stringData.getBytes(UTF8);
        return sign(data, key, algorithm);
    } catch (Exception e) {
        throw new SdkClientException("Unable to calculate a request signature: " + e.getMessage(), e);
    }
}
Connecting to a DB cluster

The following code example shows how to generate an authentication token, and then use it to connect to a cluster running Aurora MySQL.

To run this code example, you need the AWS SDK for Java, found on the AWS site. In addition, you need the following:

- MySQL Connector/J. This code example was tested with mysql-connector-java-5.1.33-bin.jar.
- An intermediate certificate for Amazon Aurora that is specific to an AWS Region. (For more information, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 2385).) At runtime, the class loader looks for the certificate in the same directory as this Java code example, so that the class loader can find it.
- Modify the values of the following variables as needed:
  - RDS_INSTANCE_HOSTNAME – The host name of the DB cluster that you want to access.
  - RDS_INSTANCE_PORT – The port number used for connecting to your PostgreSQL DB cluster.
  - REGION_NAME – The AWS Region where the DB cluster is running.
  - DB_USER – The database account that you want to access.
  - SSL_CERTIFICATE – An SSL certificate for Amazon Aurora that is specific to an AWS Region.

  To download a certificate for your AWS Region, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 2385). Place the SSL certificate in the same directory as this Java program file, so that the class loader can find the certificate at runtime.

This code example obtains AWS credentials from the default credential provider chain.

**Note**

Specify a password for DEFAULT_KEY_STORE_PASSWORD other than the prompt shown here as a security best practice.

```java

If you want to connect to a DB cluster through a proxy, see Connecting to a proxy using IAM authentication (p. 1898).

Connecting to your DB cluster using IAM authentication and the AWS SDK for Python (Boto3)

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the AWS SDK for Python (Boto3) as described following.

Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- Enabling and disabling IAM database authentication (p. 2434)
- Creating and using an IAM policy for IAM database access (p. 2436)
- Creating a database account using IAM authentication (p. 2439)

In addition, make sure the imported libraries in the sample code exist on your system.
Examples

The code examples use profiles for shared credentials. For information about the specifying credentials, see [Credentials](#) in the AWS SDK for Python (Boto3) documentation.

The following code examples show how to generate an authentication token, and then use it to connect to a DB cluster.

To run this code example, you need the [AWS SDK for Python (Boto3)](https://aws.amazon.com/sdk-for-python), found on the AWS site.

Modify the values of the following variables as needed:

- **ENDPOINT** – The endpoint of the DB cluster that you want to access
- **PORT** – The port number used for connecting to your DB cluster
- **USER** – The database account that you want to access
- **REGION** – The AWS Region where the DB cluster is running
- **DBNAME** – The database that you want to access
- **SSLCERTIFICATE** – The full path to the SSL certificate for Amazon Aurora

For `ssl_ca`, specify an SSL certificate. To download an SSL certificate, see [Using SSL/TLS to encrypt a connection to a DB cluster](#).

**Note**

You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

This code connects to an Aurora MySQL DB cluster.

Before running this code, install the PyMySQL driver by following the instructions in the [Python Package Index](https://pypi.org/project/PyMySQL/).

```python
import pymysql
import sys
import boto3
import os

ENDPOINT="mysqlcluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
PORT="3306"
USER="jane_doe"
REGION="us-east-1"
DBNAME="mydb"

os.environ['LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN'] = '1'

# gets the credentials from .aws/credentials
session = boto3.Session(profile_name='default')
client = session.client('rds')

token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USER, Region=REGION)

try:
    conn = pymysql.connect(host=ENDPOINT, user=USER, passwd=token, port=PORT, database=DBNAME, ssl_ca='SSLCERTIFICATE')
    cur = conn.cursor()
    cur.execute("""SELECT now()"""")
    query_results = cur.fetchall()
    print(query_results)
except Exception as e:
    print("Database connection failed due to {}".format(e))
```
This code connects to an Aurora PostgreSQL DB cluster.

Before running this code, install psycopg2 by following the instructions in Psycopg documentation.

```python
import psycopg2
import sys
import boto3
import os

ENDPOINT="postgresmycluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
PORT="5432"
USER="jane_doe"
REGION="us-east-1"
DBNAME="mydb"

# gets the credentials from .aws/credentials
session = boto3.Session(profile_name='RDSCreds')
client = session.client('rds')
token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USER, Region=REGION)

try:
    conn = psycopg2.connect(host=ENDPOINT, port=PORT, database=DBNAME, user=USER, password=token, sslrootcert="SSLCERTIFICATE")
    cur = conn.cursor()
    cur.execute("SELECT now()")
    query_results = cur.fetchall()
    print(query_results)
except Exception as e:
    print("Database connection failed due to {}".format(e))
```

If you want to connect to a DB cluster through a proxy, see Connecting to a proxy using IAM authentication (p. 1898).

Troubleshooting Amazon Aurora identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with Aurora and IAM.

Topics

- I'm not authorized to perform an action in Aurora (p. 2460)
- I'm not authorized to perform iam:PassRole (p. 2461)
- I want to allow people outside of my AWS account to access my Aurora resources (p. 2461)

I'm not authorized to perform an action in Aurora

If the AWS Management Console tells you that you're not authorized to perform an action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your sign-in credentials.

The following example error occurs when the mateojackson user tries to use the console to view details about a widget but does not have rds:GetWidget permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform:
rds:GetWidget on resource: my-example-widget
```
In this case, Mateo asks his administrator to update his policies to allow him to access the my-example-widget resource using the ids:GetWidget action.

I'm not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the iam:PassRole action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your sign-in credentials. Ask that person to update your policies to allow you to pass a role to Aurora.

Some AWS services allow you to pass an existing role to that service, instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when a user named marymajor tries to use the console to perform an action in Aurora. However, the action requires the service to have permissions granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform: iam:PassRole
```

In this case, Mary asks her administrator to update her policies to allow her to perform the iam:PassRole action.

I want to allow people outside of my AWS account to access my Aurora resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Aurora supports these features, see How Amazon Aurora works with IAM (p. 2404).
- To learn how to provide access to your resources across AWS accounts that you own, see Providing access to an IAM user in another AWS account that you own in the IAM User Guide.
- To learn how to provide access to your resources to third-party AWS accounts, see Providing access to AWS accounts owned by third parties in the IAM User Guide.
- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the IAM User Guide.
- To learn the difference between using roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.

Logging and monitoring in Amazon Aurora

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon Aurora and your AWS solutions. You should collect monitoring data from all of the parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. AWS provides several tools for monitoring your Amazon Aurora resources and responding to potential incidents:

Amazon CloudWatch Alarms

Using Amazon CloudWatch alarms, you watch a single metric over a time period that you specify. If the metric exceeds a given threshold, a notification is sent to an Amazon SNS topic or AWS Auto Scaling policy. CloudWatch alarms do not invoke actions because they are in a particular state. Rather the state must have changed and been maintained for a specified number of periods.
AWS CloudTrail Logs

CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon Aurora. CloudTrail captures all API calls for Amazon Aurora as events, including calls from the console and from code calls to Amazon RDS API operations. Using the information collected by CloudTrail, you can determine the request that was made to Amazon Aurora, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see Monitoring Amazon Aurora API calls in AWS CloudTrail (p. 742).

Enhanced Monitoring

Amazon Aurora provides metrics in real time for the operating system (OS) that your DB cluster runs on. You can view the metrics for your DB cluster using the console, or consume the Enhanced Monitoring JSON output from Amazon CloudWatch Logs in a monitoring system of your choice. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 631).

Amazon RDS Performance Insights

Performance Insights expands on existing Amazon Aurora monitoring features to illustrate your database's performance and help you analyze any issues that affect it. With the Performance Insights dashboard, you can visualize the database load and filter the load by waits, SQL statements, hosts, or users. For more information, see Monitoring DB load with Performance Insights on Amazon Aurora (p. 559).

Database Logs

You can view, download, and watch database logs using the AWS Management Console, AWS CLI, or RDS API. For more information, see Monitoring Amazon Aurora log files (p. 722).

Amazon Aurora Recommendations

Amazon Aurora provides automated recommendations for database resources. These recommendations provide best practice guidance by analyzing DB cluster configuration, usage, and performance data. For more information, see Viewing Amazon Aurora recommendations (p. 527).

Amazon Aurora Event Notification

Amazon Aurora uses the Amazon Simple Notification Service (Amazon SNS) to provide notification when an Amazon Aurora event occurs. These notifications can be in any notification form supported by Amazon SNS for an AWS Region, such as an email, a text message, or a call to an HTTP endpoint. For more information, see Working with Amazon RDS event notification (p. 690).

AWS Trusted Advisor

Trusted Advisor draws upon best practices learned from serving hundreds of thousands of AWS customers. Trusted Advisor inspects your AWS environment and then makes recommendations when opportunities exist to save money, improve system availability and performance, or help close security gaps. All AWS customers have access to five Trusted Advisor checks. Customers with a Business or Enterprise support plan can view all Trusted Advisor checks.

Trusted Advisor has the following Amazon Aurora-related checks:
- Amazon Aurora Idle DB Instances
- Amazon Aurora Security Group Access Risk
- Amazon Aurora Backups
- Amazon Aurora Multi-AZ
- Aurora DB Instance Accessibility

For more information on these checks, see Trusted Advisor best practices (checks).

Database activity streams

Database activity streams can protect your databases from internal threats by controlling DBA access to the database activity streams. Thus, the collection, transmission, storage, and subsequent
processing of the database activity stream is beyond the access of the DBAs that manage the database. Database activity streams can provide safeguards for your database and meet compliance and regulatory requirements. For more information, see Monitoring Amazon Aurora with Database Activity Streams (p. 746).

For more information about monitoring Aurora see Monitoring metrics in an Amazon Aurora cluster (p. 509).
Compliance validation for Amazon Aurora

Third-party auditors assess the security and compliance of Amazon Aurora as part of multiple AWS compliance programs. These include SOC, PCI, FedRAMP, HIPAA, and others.

For a list of AWS services in scope of specific compliance programs, see AWS services in scope by compliance program. For general information, see AWS compliance programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading reports in AWS Artifact.

Your compliance responsibility when using Amazon Aurora is determined by the sensitivity of your data, your organization's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- **Security and compliance quick start guides** – These deployment guides discuss architectural considerations and provide steps for deploying security- and compliance-focused baseline environments on AWS.
- **Architecting for HIPAA Security and Compliance on Amazon Web Services** – This whitepaper describes how companies can use AWS to create HIPAA-compliant applications.
- **AWS compliance resources** – This collection of workbooks and guides that might apply to your industry and location.
- **AWS Config** – This AWS service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- **AWS Security Hub** – This AWS service provides a comprehensive view of your security state within AWS. Security Hub uses security controls to evaluate your AWS resources and to check your compliance against security industry standards and best practices. For a list of supported services and controls, see Security Hub controls reference.
Resilience in Amazon Aurora

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see AWS global infrastructure.

In addition to the AWS global infrastructure, Aurora offers features to help support your data resiliency and backup needs.

Backup and restore

Aurora backs up your cluster volume automatically and retains restore data for the length of the backup retention period. Aurora backups are continuous and incremental so you can quickly restore to any point within the backup retention period. No performance impact or interruption of database service occurs as backup data is being written. You can specify a backup retention period, from 1 to 35 days, when you create or modify a DB cluster.

If you want to retain a backup beyond the backup retention period, you can also take a snapshot of the data in your cluster volume. Aurora retains incremental restore data for the entire backup retention period. Thus, you need to create a snapshot only for data that you want to retain beyond the backup retention period. You can create a new DB cluster from the snapshot.

You can recover your data by creating a new Aurora DB cluster from the backup data that Aurora retains, or from a DB cluster snapshot that you have saved. You can quickly create a new copy of a DB cluster from backup data to any point in time during your backup retention period. The continuous and incremental nature of Aurora backups during the backup retention period means you don't need to take frequent snapshots of your data to improve restore times.

For more information, see Backing up and restoring an Amazon Aurora DB cluster (p. 426).

Replication

Aurora Replicas are independent endpoints in an Aurora DB cluster, best used for scaling read operations and increasing availability. Up to 15 Aurora Replicas can be distributed across the Availability Zones that a DB cluster spans within an AWS Region. The DB cluster volume is made up of multiple copies of the data for the DB cluster. However, the data in the cluster volume is represented as a single, logical volume to the primary DB instance and to Aurora Replicas in the DB cluster. If the primary DB instance fails, an Aurora Replica is promoted to be the primary DB instance.

Aurora also supports replication options that are specific to Aurora MySQL and Aurora PostgreSQL.

For more information, see Replication with Amazon Aurora (p. 104).

Failover

Aurora stores copies of the data in a DB cluster across multiple Availability Zones in a single AWS Region. This storage occurs regardless of whether the DB instances in the DB cluster span multiple Availability Zones. When you create Aurora Replicas across Availability Zones, Aurora automatically provisions and maintains them synchronously. The primary DB instance is synchronously replicated across Availability Zones to Aurora Replicas to provide data redundancy, eliminate I/O freezes, and minimize latency spikes during system backups. Running a DB cluster with high availability can enhance availability during
planned system maintenance, and help protect your databases against failure and Availability Zone disruption.

For more information, see High availability for Amazon Aurora (p. 102).
Infrastructure security in Amazon Aurora

As a managed service, Amazon Relational Database Service is protected by AWS global network security. For information about AWS security services and how AWS protects infrastructure, see AWS Cloud Security. To design your AWS environment using the best practices for infrastructure security, see Infrastructure Protection in Security Pillar AWS Well-Architected Framework.

You use AWS published API calls to access Amazon RDS through the network. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

In addition, Aurora offers features to help support infrastructure security.

Security groups

Security groups control the access that traffic has in and out of a DB cluster. By default, network access is turned off to a DB cluster. You can specify rules in a security group that allow access from an IP address range, port, or security group. After ingress rules are configured, the same rules apply to all DB clusters that are associated with that security group.

For more information, see Controlling access with security groups (p. 2471).

Public accessibility

When you launch a DB instance inside a virtual private cloud (VPC) based on the Amazon VPC service, you can turn on or off public accessibility for that DB instance. To designate whether the DB instance that you create has a DNS name that resolves to a public IP address, you use the Public accessibility parameter. By using this parameter, you can designate whether there is public access to the DB instance. You can modify a DB instance to turn on or off public accessibility by modifying the Public accessibility parameter.

For more information, see Hiding a DB cluster in a VPC from the internet (p. 2484).

Note

If your DB instance is in a VPC but isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy (p. 2399).
Amazon RDS API and interface VPC endpoints (AWS PrivateLink)

You can establish a private connection between your VPC and Amazon RDS API endpoints by creating an *interface VPC endpoint*. Interface endpoints are powered by [AWS PrivateLink](https://aws.amazon.com/privatelink/).

AWS PrivateLink enables you to privately access Amazon RDS API operations without an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. DB instances in your VPC don't need public IP addresses to communicate with Amazon RDS API endpoints to launch, modify, or terminate DB instances and DB clusters. Your DB instances also don't need public IP addresses to use any of the available RDS API operations. Traffic between your VPC and Amazon RDS doesn't leave the Amazon network.

Each interface endpoint is represented by one or more elastic network interfaces in your subnets. For more information on elastic network interfaces, see [Elastic network interfaces](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/what-is-elastic-network-interface.html) in the *Amazon EC2 User Guide*.

For more information about VPC endpoints, see [Interface VPC endpoints (AWS PrivateLink)](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/what-is-elastic-network-interface.html) in the *Amazon VPC User Guide*. For more information about RDS API operations, see [Amazon RDS API Reference](https://docs.aws.amazon.com/AmazonRDS/latest/APIReference/). You don't need an interface VPC endpoint to connect to a DB cluster. For more information, see [Scenarios for accessing a DB cluster in a VPC](https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUG/using-vpc-endpoints.html).

**Considerations for VPC endpoints**

Before you set up an interface VPC endpoint for Amazon RDS API endpoints, ensure that you review [Interface endpoint properties and limitations](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/what-is-elastic-network-interface.html) in the *Amazon VPC User Guide*.

All RDS API operations relevant to managing Amazon Aurora resources are available from your VPC using AWS PrivateLink.

VPC endpoint policies are supported for RDS API endpoints. By default, full access to RDS API operations is allowed through the endpoint. For more information, see [Controlling access to services with VPC endpoints](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/what-is-elastic-network-interface.html) in the *Amazon VPC User Guide*.

**Availability**

Amazon RDS API currently supports VPC endpoints in the following AWS Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
Creating an interface VPC endpoint for Amazon RDS API

You can create a VPC endpoint for the Amazon RDS API using either the Amazon VPC console or the AWS Command Line Interface (AWS CLI). For more information, see Creating an interface endpoint in the Amazon VPC User Guide.

Create a VPC endpoint for Amazon RDS API using the service name com.amazonaws.region.rds.

Excluding AWS Regions in China, if you enable private DNS for the endpoint, you can make API requests to Amazon RDS with the VPC endpoint using its default DNS name for the AWS Region, for example rds.us-east-1.amazonaws.com. For the China (Beijing) and China (Ningxia) AWS Regions, you can make API requests with the VPC endpoint using rds-api.cn-north-1.amazonaws.com.cn and rds-api.cn-northwest-1.amazonaws.com.cn, respectively.

For more information, see Accessing a service through an interface endpoint in the Amazon VPC User Guide.

Creating a VPC endpoint policy for Amazon RDS API

You can attach an endpoint policy to your VPC endpoint that controls access to Amazon RDS API. The policy specifies the following information:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

For more information, see Controlling access to services with VPC endpoints in the Amazon VPC User Guide.

Example: VPC endpoint policy for Amazon RDS API actions
The following is an example of an endpoint policy for Amazon RDS API. When attached to an endpoint, this policy grants access to the listed Amazon RDS API actions for all principals on all resources.

```
{
  "Statement": [
    {
      "Principal": "*",
      "Effect": "Allow",
      "Action": [
        "rds:createDBInstance",
        "rds:modifyDBInstance",
        "rds:CreateDBSnapshot"
      ],
      "Resource": "*"
    }
  ]
}
```

**Example: VPC endpoint policy that denies all access from a specified AWS account**

The following VPC endpoint policy denies AWS account 123456789012 all access to resources using the endpoint. The policy allows all actions from other accounts.

```
{
  "Statement": [
    {
      "Action": "*",
      "Effect": "Allow",
      "Resource": "*",
      "Principal": "*"
    },
    {
      "Action": "*",
      "Effect": "Deny",
      "Resource": "*",
      "Principal": {
        "AWS": [
          "123456789012"
        ]
      }
    }
  ]
}
```

### Security best practices for Amazon Aurora

Use AWS Identity and Access Management (IAM) accounts to control access to Amazon RDS API operations, especially operations that create, modify, or delete Amazon Aurora resources. Such resources include DB clusters, security groups, and parameter groups. Also use IAM to control actions that perform common administrative actions such as backing up and restoring DB clusters.

- Create an individual user for each person who manages Amazon Aurora resources, including yourself. Don't use AWS root credentials to manage Amazon Aurora resources.
- Grant each user the minimum set of permissions required to perform his or her duties.
- Use IAM groups to effectively manage permissions for multiple users.
- Rotate your IAM credentials regularly.
- Configure AWS Secrets Manager to automatically rotate the secrets for Amazon Aurora. For more information, see [Rotating your AWS Secrets Manager secrets](#) in the AWS Secrets Manager User Guide.
Controlling access with security groups

VPC security groups control the access that traffic has in and out of a DB cluster. By default, network access is turned off for a DB cluster. You can specify rules in a security group that allow access from an IP address range, port, or security group. After ingress rules are configured, the same rules apply to all DB clusters that are associated with that security group. You can specify up to 20 rules in a security group.

Overview of VPC security groups

Each VPC security group rule makes it possible for a specific source to access a DB cluster in a VPC that is associated with that VPC security group. The source can be a range of addresses (for example, 203.0.113.0/24), or another VPC security group. By specifying a VPC security group as the source, you allow incoming traffic from all instances (typically application servers) that use the source VPC security group. VPC security groups can have rules that govern both inbound and outbound traffic. However, the outbound traffic rules typically don't apply to DB clusters. Outbound traffic rules apply only if the DB cluster acts as a client. You must use the Amazon EC2 API or the Security Group option on the VPC console to create VPC security groups.

When you create rules for your VPC security group that allow access to the clusters in your VPC, you must specify a port for each range of addresses that the rule allows access for. For example, if you want to turn on Secure Shell (SSH) access for instances in the VPC, create a rule allowing access to TCP port 22 for the specified range of addresses.

You can configure multiple VPC security groups that allow access to different ports for different instances in your VPC. For example, you can create a VPC security group that allows access to TCP port 80 for web servers in your VPC. You can then create another VPC security group that allows access to TCP port 3306 for Aurora MySQL DB instances in your VPC.

Note

In an Aurora DB cluster, the VPC security group associated with the DB cluster is also associated with all of the DB instances in the DB cluster. If you change the VPC security group for the DB cluster or for a DB instance, the change is applied automatically to all of the DB instances in the DB cluster.

For more information on VPC security groups, see Security groups in the Amazon Virtual Private Cloud User Guide.
Security group scenario

A common use of a DB cluster in a VPC is to share data with an application server running in an Amazon EC2 instance in the same VPC, which is accessed by a client application outside the VPC. For this scenario, you use the RDS and VPC pages on the AWS Management Console or the RDS and EC2 API operations to create the necessary instances and security groups:

1. Create a VPC security group (for example, sg-0123ec2example) and define inbound rules that use the IP addresses of the client application as the source. This security group allows your client application to connect to EC2 instances in a VPC that uses this security group.

2. Create an EC2 instance for the application and add the EC2 instance to the VPC security group (sg-0123ec2example) that you created in the previous step.

3. Create a second VPC security group (for example, sg-6789rdsexample) and create a new rule by specifying the VPC security group that you created in step 1 (sg-0123ec2example) as the source.

4. Create a new DB cluster and add the DB cluster to the VPC security group (sg-6789rdsexample) that you created in the previous step. When you create the DB cluster, use the same port number as the one specified for the VPC security group (sg-6789rdsexample) rule that you created in step 3.

The following diagram shows this scenario.
Creating a VPC security group

You can create a VPC security group for a DB instance by using the VPC console. For information about creating a security group, see Provide access to the DB cluster in the VPC by creating a security group (p. 122) and Security groups in the Amazon Virtual Private Cloud User Guide.

Associating a security group with a DB cluster

You can associate a security group with a DB cluster by using Modify cluster on the RDS console, the ModifyDBCluster Amazon RDS API, or the modify-db-cluster AWS CLI command.
Master user account privileges

When you create a new DB cluster, the default master user that you use gets certain privileges for that DB cluster. You can't change the master user name after the DB cluster is created.

**Important**
We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

**Note**
If you accidentally delete the permissions for the master user, you can restore them by modifying the DB cluster and setting a new master user password. For more information about modifying a DB cluster, see Modifying an Amazon Aurora DB cluster (p. 269).

The following table shows the privileges and database roles the master user gets for each of the database engines.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>System privilege</th>
<th>Database role</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL</td>
<td>Version 2: ALTER, ALTER ROUTINE, CREATE, CREATE ROUTINE, CREATE TEMPORARY TABLES, CREATE USER, CREATE VIEW, DELETE, DROP, EVENT, EXECUTE, GRANT OPTION, INDEX, INSERT, LOAD FROM S3, LOCK TABLES, PROCESS, REFERENCES, RELOAD, REPLICA</td>
<td>rds_superuser_role</td>
</tr>
<tr>
<td></td>
<td>Version 3: ALTER, APPLICATION_PASSWORD_ADMIN, ALTER ROUTINE, CONNECTION_ADMIN, CREATE, CREATE ROLE, CREATE ROUTINE, CREATE TEMPORARY TABLES, CREATE USER, CREATE VIEW, DELETE, DROP, DROP ROLE, EVENT, EXECUTE, INDEX, INSERT, LOCK TABLES, PROCESS, REFERENCES, RELOAD, REPLICA</td>
<td>For more information about rds_superuser_role, see Role-based privilege model (p. 797).</td>

<tr>
<td></td>
<td></td>
<td>For more information about RDS_SUPERUSER, see Understanding PostgreSQL roles and permissions (p. 1233).</td>
</tr>
</tbody>
</table>
Using service-linked roles for Amazon Aurora

Amazon Aurora uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Amazon Aurora. Service-linked roles are predefined by Amazon Aurora and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes using Amazon Aurora easier because you don't have to manually add the necessary permissions. Amazon Aurora defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon Aurora can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete the roles only after first deleting their related resources. This protects your Amazon Aurora resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS services that work with IAM and look for the services that have Yes in the Service-Linked Role column. Choose a Yes with a link to view the service-linked role documentation for that service.

Service-linked role permissions for Amazon Aurora

Amazon Aurora uses the service-linked role named AWSServiceRoleForRDS to allow Amazon RDS to call AWS services on behalf of your DB clusters.

The AWSServiceRoleForRDS service-linked role trusts the following services to assume the role:

- rds.amazonaws.com

This service-linked role has a permissions policy attached to it called AmazonRDSServiceRolePolicy that grants it permissions to operate in your account. The role permissions policy allows Amazon Aurora to complete the following actions on the specified resources:

For more information about this policy, including the JSON policy document, see AmazonRDSServiceRolePolicy in the AWS Managed Policy Reference Guide.

Note
You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message:

Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.

Make sure you have the following permissions enabled:

```json
{
    "Action": "iam:CreateServiceLinkedRole",
    "Effect": "Allow",
    "Resource": "arn:aws:iam::*:role/aws-service-role/rds.amazonaws.com/AWSServiceRoleForRDS",
    "Condition": {
        "StringLike": {
            "iam:AWSServiceName": "rds.amazonaws.com"
        }
    }
}
```

For more information, see Service-linked role permissions in the IAM User Guide.
Creating a service-linked role for Amazon Aurora

You don't need to manually create a service-linked role. When you create a DB cluster, Amazon Aurora creates the service-linked role for you.

**Important**
If you were using the Amazon Aurora service before December 1, 2017, when it began supporting service-linked roles, then Amazon Aurora created the AWSServiceRoleForRDS role in your account. To learn more, see A new role appeared in my AWS account.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a DB cluster, Amazon Aurora creates the service-linked role for you again.

Editing a service-linked role for Amazon Aurora

Amazon Aurora does not allow you to edit the AWSServiceRoleForRDS service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the IAM User Guide.

Deleting a service-linked role for Amazon Aurora

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must delete all of your DB clusters before you can delete the service-linked role.

Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first confirm that the role has no active sessions and remove any resources used by the role.

**To check whether the service-linked role has an active session in the IAM console**

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane of the IAM console, choose Roles. Then choose the name (not the check box) of the AWSServiceRoleForRDS role.
3. On the Summary page for the chosen role, choose the Access Advisor tab.
4. On the Access Advisor tab, review recent activity for the service-linked role.

**Note**
If you are unsure whether Amazon Aurora is using the AWSServiceRoleForRDS role, you can try to delete the role. If the service is using the role, then the deletion fails and you can view the AWS Regions where the role is being used. If the role is being used, then you must wait for the session to end before you can delete the role. You cannot revoke the session for a service-linked role.

If you want to remove the AWSServiceRoleForRDS role, you must first delete all of your DB clusters.

**Deleting all of your clusters**

Use one of the following procedures to delete a single cluster. Repeat the procedure for each of your clusters.
To delete a cluster (console)
1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the Databases list, choose the cluster that you want to delete.
3. For Cluster Actions, choose Delete.
4. Choose Delete.

To delete a cluster (CLI)
See delete-db-cluster in the AWS CLI Command Reference.

To delete a cluster (API)
See DeleteDBCluster in the Amazon RDS API Reference.

You can use the IAM console, the IAM CLI, or the IAM API to delete the AWSServiceRoleForRDS service-linked role. For more information, see Deleting a service-linked role in the IAM User Guide.
Amazon VPC VPCs and Amazon Aurora

Amazon Virtual Private Cloud (Amazon VPC) makes it possible for you to launch AWS resources, such as Aurora DB clusters, into a virtual private cloud (VPC).

When you use a VPC, you have control over your virtual networking environment. You can choose your own IP address range, create subnets, and configure routing and access control lists. There is no additional cost to run your DB cluster in a VPC.

Accounts have a default VPC. All new DB clusters are created in the default VPC unless you specify otherwise.

**Topics**

- Working with a DB cluster in a VPC (p. 2478)
- Scenarios for accessing a DB cluster in a VPC (p. 2489)
- Tutorial: Create a VPC for use with a DB cluster (IPv4 only) (p. 2494)
- Tutorial: Create a VPC for use with a DB cluster (dual-stack mode) (p. 2499)

Following, you can find a discussion about VPC functionality relevant to Amazon Aurora DB clusters. For more information about Amazon VPC, see Amazon VPC Getting Started Guide and Amazon VPC User Guide.

**Working with a DB cluster in a VPC**

Your DB cluster is in a virtual private cloud (VPC). A VPC is a virtual network that is logically isolated from other virtual networks in the AWS Cloud. Amazon VPC makes it possible for you to launch AWS resources, such as an Amazon Aurora DB cluster or Amazon EC2 instance, into a VPC. The VPC can either be a default VPC that comes with your account or one that you create. All VPCs are associated with your AWS account.

Your default VPC has three subnets that you can use to isolate resources inside the VPC. The default VPC also has an internet gateway that can be used to provide access to resources inside the VPC from outside the VPC.

For a list of scenarios involving Amazon Aurora DB clusters in a VPC, see Scenarios for accessing a DB cluster in a VPC (p. 2489).

**Topics**

- Working with a DB cluster in a VPC (p. 2479)
- Working with DB subnet groups (p. 2479)
- Shared subnets (p. 2480)
- Amazon Aurora IP addressing (p. 2480)
- Hiding a DB cluster in a VPC from the internet (p. 2484)
- Creating a DB cluster in a VPC (p. 2486)

In the following tutorials, you can learn to create a VPC that you can use for a common Amazon Aurora scenario:

- Tutorial: Create a VPC for use with a DB cluster (IPv4 only) (p. 2494)
- Tutorial: Create a VPC for use with a DB cluster (dual-stack mode) (p. 2499)
Working with a DB cluster in a VPC

Here are some tips on working with a DB cluster in a VPC:

- Your VPC must have at least two subnets. These subnets must be in two different Availability Zones in the AWS Region where you want to deploy your DB cluster. A subnet is a segment of a VPC’s IP address range that you can specify and that you can use to group DB clusters based on your security and operational needs.
- If you want your DB cluster in the VPC to be publicly accessible, make sure to turn on the VPC attributes DNS hostnames and DNS resolution.
- Your VPC must have a DB subnet group that you create. You create a DB subnet group by specifying the subnets you created. Amazon Aurora chooses a subnet and an IP address within that subnet to associate with the primary DB instance in your DB cluster. The primary DB instance uses the Availability Zone that contains the subnet.
- Your VPC must have a VPC security group that allows access to the DB cluster.

For more information, see Scenarios for accessing a DB cluster in a VPC (p. 2489).

- The CIDR blocks in each of your subnets must be large enough to accommodate spare IP addresses for Amazon Aurora to use during maintenance activities, including failover and compute scaling. For example, a range such as 10.0.0.0/24 and 10.0.1.0/24 is typically large enough.
- A VPC can have an instance tenancy attribute of either default or dedicated. All default VPCs have the instance tenancy attribute set to default, and a default VPC can support any DB instance class.

If you choose to have your DB cluster in a dedicated VPC where the instance tenancy attribute is set to dedicated, the DB instance class of your DB cluster must be one of the approved Amazon EC2 dedicated instance types. For example, the r5.large EC2 dedicated instance corresponds to the db.r5.large DB instance class. For information about instance tenancy in a VPC, see Dedicated instances in the Amazon Elastic Compute Cloud User Guide.

For more information about the instance types that can be in a dedicated instance, see Amazon EC2 dedicated instances on the EC2 pricing page.

**Note**
When you set the instance tenancy attribute to dedicated for a DB cluster, it doesn’t guarantee that the DB cluster will run on a dedicated host.

Working with DB subnet groups

Subnets are segments of a VPC’s IP address range that you designate to group your resources based on security and operational needs. A DB subnet group is a collection of subnets (typically private) that you create in a VPC and that you then designate for your DB clusters. By using a DB subnet group, you can specify a particular VPC when creating DB clusters using the AWS CLI or RDS API. If you use the console, you can choose the VPC and subnet groups you want to use.

Each DB subnet group should have subnets in at least two Availability Zones in a given AWS Region. When creating a DB cluster in a VPC, you choose a DB subnet group for it. From the DB subnet group, Amazon Aurora chooses a subnet and an IP address within that subnet to associate with the primary DB instance in your DB cluster. The DB uses the Availability Zone that contains the subnet.

The subnets in a DB subnet group are either public or private. The subnets are public or private, depending on the configuration that you set for their network access control lists (network ACLs) and routing tables. For a DB cluster to be publicly accessible, all of the subnets in its DB subnet group must be public. If a subnet that's associated with a publicly accessible DB cluster changes from public to private, it can affect DB cluster availability.

To create a DB subnet group that supports dual-stack mode, make sure that each subnet that you add to the DB subnet group has an Internet Protocol version 6 (IPv6) CIDR block associated with it. For more
When Amazon Aurora creates a DB cluster in a VPC, it assigns a network interface to your DB cluster by using an IP address from your DB subnet group. However, we strongly recommend that you use the Domain Name System (DNS) name to connect to your DB cluster. We recommend this because the underlying IP address changes during failover.

**Note**
For each DB cluster that you run in a VPC, make sure to reserve at least one address in each subnet in the DB subnet group for use by Amazon Aurora for recovery actions.

### Shared subnets

You can create a DB cluster in a shared VPC.

Some considerations to keep in mind while using shared VPCs:

- You can move a DB cluster from a shared VPC subnet to a non-shared VPC subnet and vice-versa.
- Participants in a shared VPC must create a security group in the VPC to allow them to create a DB cluster.
- Owners and participants in a shared VPC can access the database by using SQL queries. However, only the creator of a resource can make any API calls on the resource.

### Amazon Aurora IP addressing

IP addresses enable resources in your VPC to communicate with each other, and with resources over the internet. Amazon Aurora supports both IPv4 and IPv6 addressing protocols. By default, Amazon Aurora and Amazon VPC use the IPv4 addressing protocol. You can't turn off this behavior. When you create a VPC, make sure to specify an IPv4 CIDR block (a range of private IPv4 addresses). You can optionally assign an IPv6 CIDR block to your VPC and subnets, and assign IPv6 addresses from that block to DB clusters in your subnet.

Support for the IPv6 protocol expands the number of supported IP addresses. By using the IPv6 protocol, you ensure that you have sufficient available addresses for the future growth of the internet. New and existing RDS resources can use IPv4 and IPv6 addresses within your VPC. Configuring, securing, and translating network traffic between the two protocols used in different parts of an application can cause operational overhead. You can standardize on the IPv6 protocol for Amazon RDS resources to simplify your network configuration.

**Topics**
- IPv4 addresses (p. 2480)
- IPv6 addresses (p. 2481)
- Dual-stack mode (p. 2481)

### IPv4 addresses

When you create a VPC, you must specify a range of IPv4 addresses for the VPC in the form of a CIDR block, such as 10.0.0.0/16. A DB subnet group defines the range of IP addresses in this CIDR block that a DB cluster can use. These IP addresses can be private or public.

A private IPv4 address is an IP address that's not reachable over the internet. You can use private IPv4 addresses for communication between your DB cluster and other resources, such as Amazon EC2 instances, in the same VPC. Each DB cluster has a private IP address for communication in the VPC.
A public IP address is an IPv4 address that’s reachable from the internet. You can use public addresses for communication between your DB cluster and resources on the internet, such as a SQL client. You control whether your DB cluster receives a public IP address.

For a tutorial that shows you how to create a VPC with only private IPv4 addresses that you can use for a common Amazon Aurora scenario, see Tutorial: Create a VPC for use with a DB cluster (IPv4 only) (p. 2494).

**IPv6 addresses**

You can optionally associate an IPv6 CIDR block with your VPC and subnets, and assign IPv6 addresses from that block to the resources in your VPC. Each IPv6 address is globally unique.

The IPv6 CIDR block for your VPC is automatically assigned from Amazon's pool of IPv6 addresses. You can't choose the range yourself.

When connecting to an IPv6 address, make sure that the following conditions are met:

- The client is configured so that client to database traffic over IPv6 is allowed.
- RDS security groups used by the DB instance are configured correctly so that client to database traffic over IPv6 is allowed.
- The client operating system stack allows traffic on the IPv6 address, and operating system drivers and libraries are configured to choose the correct default DB instance endpoint (either IPv4 or IPv6).

For more information about IPv6, see IP Addressing in the Amazon VPC User Guide.

**Dual-stack mode**

When a DB cluster can communicate over both the IPv4 and IPv6 addressing protocols, it's running in dual-stack mode. So, resources can communicate with the DB cluster over IPv4, IPv6, or both. RDS disables Internet Gateway access for IPv6 endpoints of private dual-stack mode DB instances. RDS does this to ensure that your IPv6 endpoints are private and can only be accessed from within your VPC.

**Topics**

- Dual-stack mode and DB subnet groups (p. 2481)
- Working with dual-stack mode DB instances (p. 2482)
- Modifying IPv4-only DB clusters to use dual-stack mode (p. 2482)
- Availability of dual-stack network DB clusters (p. 2484)
- Limitations for dual-stack network DB clusters (p. 2484)

For a tutorial that shows you how to create a VPC with both IPv4 and IPv6 addresses that you can use for a common Amazon Aurora scenario, see Tutorial: Create a VPC for use with a DB cluster (dual-stack mode) (p. 2499).

**Dual-stack mode and DB subnet groups**

To use dual-stack mode, make sure that each subnet in the DB subnet group that you associate with the DB cluster has an IPv6 CIDR block associated with it. You can create a new DB subnet group or modify an existing DB subnet group to meet this requirement. After a DB cluster is in dual-stack mode, clients can connect to it normally. Make sure that client security firewalls and RDS DB instance security groups are accurately configured to allow traffic over IPv6. To connect, clients use the DB cluster primary instance's endpoint. Client applications can specify which protocol is preferred when connecting to a database. In dual-stack mode, the DB cluster detects the client's preferred network protocol, either IPv4 or IPv6, and uses that protocol for the connection.
If a DB subnet group stops supporting dual-stack mode because of subnet deletion or CIDR disassociation, there's a risk of an incompatible network state for DB instances that are associated with the DB subnet group. Also, you can't use the DB subnet group when you create a new dual-stack mode DB cluster.

To determine whether a DB subnet group supports dual-stack mode by using the AWS Management Console, view the Network type on the details page of the DB subnet group. To determine whether a DB subnet group supports dual-stack mode by using the AWS CLI, run the `describe-db-subnet-groups` command and view SupportedNetworkTypes in the output.

Read replicas are treated as independent DB instances and can have a network type that's different from the primary DB instance. If you change the network type of a read replica's primary DB instance, the read replica isn't affected. When you are restoring a DB instance, you can restore it to any network type that's supported.

**Working with dual-stack mode DB instances**

When you create or modify a DB cluster, you can specify dual-stack mode to allow your resources to communicate with your DB cluster over IPv4, IPv6, or both.

When you use the AWS Management Console to create or modify a DB instance, you can specify dual-stack mode in the Network type section. The following image shows the Network type section in the console.

<table>
<thead>
<tr>
<th>Network type</th>
<th>Info</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPv4</td>
<td>Your resources can communicate only over the IPv4 addressing protocol.</td>
</tr>
<tr>
<td>Dual-stack mode</td>
<td>Your resources can communicate over IPv4, IPv6, or both.</td>
</tr>
</tbody>
</table>

When you use the AWS CLI to create or modify a DB cluster, set the `--network-type` option to `DUAL` to use dual-stack mode. When you use the RDS API to create or modify a DB cluster, set the `NetworkType` parameter to `DUAL` to use dual-stack mode. When you are modifying the network type of a DB instance, downtime is possible. If dual-stack mode isn't supported by the specified DB engine version or DB subnet group, the NetworkTypeNotSupported error is returned.

For more information about creating a DB cluster, see Creating an Amazon Aurora DB cluster (p. 179). For more information about modifying a DB cluster, see Modifying an Amazon Aurora DB cluster (p. 269).

To determine whether a DB cluster is in dual-stack mode by using the console, view the Network type on the Connectivity & security tab for the DB cluster.

**Modifying IPv4-only DB clusters to use dual-stack mode**

You can modify an IPv4-only DB cluster to use dual-stack mode. To do so, change the network type of the DB cluster. The modification might result in downtime.

It is recommended that you change the network type of your Amazon Aurora DB clusters during a maintenance window. Currently, setting the network type of new instances to dual-stack mode isn't supported. You can set network type manually by using the `modify-db-cluster` command.

Before modifying a DB cluster to use dual-stack mode, make sure that its DB subnet group supports dual-stack mode. If the DB subnet group associated with the DB cluster doesn't support dual-stack mode, specify a different DB subnet group that supports it when you modify the DB cluster. Modifying the DB subnet group of a DB cluster can cause downtime.

If you modify the DB subnet group of a DB cluster before you change the DB cluster to use dual-stack mode, make sure that the DB subnet group is valid for the DB cluster before and after the change.
We recommend that you run the `modify-db-cluster` API with only the `--network-type` parameter with value DUAL to change the network of an Amazon Aurora cluster to dual-stack mode. Adding other parameters along with the `--network-type` parameter in the same API call could result in downtime.

If you can’t connect to the DB cluster after the change, make sure that the client and database security firewalls and route tables are accurately configured to allow traffic to the database on the selected network (either IPv4 or IPv6). You might also need to modify operating system parameter, libraries, or drivers to connect using an IPv6 address.

To modify an IPv4-only DB cluster to use dual-stack mode

1. Modify a DB subnet group to support dual-stack mode, or create a DB subnet group that supports dual-stack mode:
   a. Associate an IPv6 CIDR block with your VPC.
      For instructions, see Add an IPv6 CIDR block to your VPC in the Amazon VPC User Guide.
   b. Attach the IPv6 CIDR block to all of the subnets in your the DB subnet group.
      For instructions, see Add an IPv6 CIDR block to your subnet in the Amazon VPC User Guide.
   c. Confirm that the DB subnet group supports dual-stack mode.
      If you are using the AWS Management Console, select the DB subnet group, and make sure that the Supported network types value is Dual, IPv4.
      If you are using the AWS CLI, run the `describe-db-subnet-groups` command, and make sure that the SupportedNetworkType value for the DB instance is Dual, IPv4.

2. Modify the security group associated with the DB cluster to allow IPv6 connections to the database, or create a new security group that allows IPv6 connections.

   For instructions, see Security group rules in the Amazon VPC User Guide.

3. Modify the DB cluster to support dual-stack mode. To do so, set the Network type to Dual-stack mode.

   If you are using the console, make sure that the following settings are correct:
   - **Network type** – Dual-stack mode
     
     | Network type | Info |
     |--------------|------|
     | IPv4         | Your resources can communicate only over the IPv4 addressing protocol. |
     | Dual-stack mode | Your resources can communicate over IPv4, IPv6, or both. |
   - **DB subnet group** – The DB subnet group that you configured in a previous step
   - **Security group** – The security that you configured in a previous step

   If you are using the AWS CLI, make sure that the following settings are correct:
   - `--network-type` – dual
   - `--db-subnet-group-name` – The DB subnet group that you configured in a previous step
   - `--vpc-security-group-ids` – The VPC security group that you configured in a previous step

   For example:
4. Confirm that the DB cluster supports dual-stack mode.

   If you are using the console, choose the Configuration tab for the DB cluster. On that tab, make sure that the Network type value is Dual-stack mode.

   If you are using the AWS CLI, run the `describe-db-clusters` command, and make sure that the NetworkType value for the DB cluster is dual.

   Run the `dig` command on the writer DB instance endpoint to identify the IPv6 address associated with it.

   ```
   dig db-instance-endpoint AAAA
   ```

   Use the writer DB instance endpoint, not the IPv6 address, to connect to the DB cluster.

**Availability of dual-stack network DB clusters**

The following DB engine versions support dual-stack network DB clusters, except in the Asia Pacific (Hyderabad), Asia Pacific (Melbourne), Europe (Spain), Europe (Zurich), Israel (Tel Aviv), and Middle East (UAE) Regions:

- **Aurora MySQL versions:**
  - 3.02 and higher 3 versions
  - 2.09.1 and higher 2 versions

   For more information about Aurora MySQL versions, see the [Release Notes for Aurora MySQL](https://aws.amazon.com/rds/marketplace/aurora/mysql/release-notes/).

- **Aurora PostgreSQL versions:**
  - 14.3 and higher 14 versions
  - 13.7 and higher 13 versions

   For more information about Aurora PostgreSQL versions, see the [Release Notes for Aurora PostgreSQL](https://aws.amazon.com/rds/marketplace/aurora/postgresql/release-notes/).

**Limitations for dual-stack network DB clusters**

The following limitations apply to dual-stack network DB clusters:

- DB clusters can't use the IPv6 protocol exclusively. They can use IPv4 exclusively, or they can use the IPv4 and IPv6 protocol (dual-stack mode).
- Amazon RDS doesn't support native IPv6 subnets.
- DB clusters that use dual-stack mode must be private. They can't be publicly accessible.
- Dual-stack mode doesn't support the db.r3 DB instance classes.
- You can't use RDS Proxy with dual-stack mode DB clusters.

**Hiding a DB cluster in a VPC from the internet**

One common Amazon Aurora scenario is to have a VPC in which you have an EC2 instance with a public-facing web application and a DB cluster with a database that isn't publicly accessible. For example, you can create a VPC that has a public subnet and a private subnet. Amazon EC2 instances that function as web servers can be deployed in the public subnet. The DB clusters are deployed in the private subnet.
In such a deployment, only the web servers have access to the DB clusters. For an illustration of this scenario, see A DB cluster in a VPC accessed by an EC2 instance in the same VPC (p. 2489).

When you launch a DB cluster inside a VPC, the DB cluster has a private IP address for traffic inside the VPC. This private IP address isn't publicly accessible. You can use the Public access option to designate whether the DB cluster also has a public IP address in addition to the private IP address. If the DB cluster is designated as publicly accessible, its DNS endpoint resolves to the private IP address from within the VPC. It resolves to the public IP address from outside of the VPC. Access to the DB cluster is ultimately controlled by the security group it uses. That public access is not permitted if the security group assigned to the DB cluster doesn't include inbound rules that permit it. In addition, for a DB cluster to be publicly accessible, the subnets in its DB subnet group must have an internet gateway. For more information, see Can't connect to Amazon RDS DB instance (p. 2511)

You can modify a DB cluster to turn on or off public accessibility by modifying the Public access option. The following illustration shows the Public access option in the Additional connectivity configuration section. To set the option, open the Additional connectivity configuration section in the Connectivity section.
Creating a DB cluster in a VPC

The following procedures help you create a DB cluster in a VPC. To use the default VPC, you can begin with step 2, and use the VPC and DB subnet group have already been created for you. If you want to create an additional VPC, you can create a new VPC.

**Note**

If you want your DB cluster in the VPC to be publicly accessible, you must update the DNS information for the VPC by enabling the VPC attributes DNS hostnames and DNS resolution. For information about updating the DNS information for a VPC instance, see [Updating DNS support for your VPC](#).
Follow these steps to create a DB instance in a VPC:

- **Step 1: Create a VPC (p. 2487)**
- **Step 2: Create a DB subnet group (p. 2487)**
- **Step 3: Create a VPC security group (p. 2489)**
- **Step 4: Create a DB instance in the VPC (p. 2489)**

**Step 1: Create a VPC**

Create a VPC with subnets in at least two Availability Zones. You use these subnets when you create a DB subnet group. If you have a default VPC, a subnet is automatically created for you in each Availability Zone in the AWS Region.

For more information, see Create a VPC with private and public subnets (p. 2495), or see Create a VPC in the Amazon VPC User Guide.

**Step 2: Create a DB subnet group**

A DB subnet group is a collection of subnets (typically private) that you create for a VPC and that you then designate for your DB clusters. A DB subnet group allows you to specify a particular VPC when you create DB clusters using the AWS CLI or RDS API. If you use the console, you can just choose the VPC and subnets you want to use. Each DB subnet group must have at least one subnet in at least two Availability Zones in the AWS Region. As a best practice, each DB subnet group should have at least one subnet for every Availability Zone in the AWS Region.

For a DB cluster to be publicly accessible, the subnets in the DB subnet group must have an internet gateway. For more information about internet gateways for subnets, see Connect to the internet using an internet gateway in the Amazon VPC User Guide.

When you create a DB cluster in a VPC, you can choose a DB subnet group. Amazon Aurora chooses a subnet and an IP address within that subnet to associate with your DB cluster. If no DB subnet groups exist, Amazon Aurora creates a default subnet group when you create a DB cluster. Amazon Aurora creates and associates an Elastic Network Interface to your DB cluster with that IP address. The DB cluster uses the Availability Zone that contains the subnet.

In this step, you create a DB subnet group and add the subnets that you created for your VPC.

**To create a DB subnet group**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Subnet groups.
3. Choose Create DB Subnet Group.
4. For Name, type the name of your DB subnet group.
5. For Description, type a description for your DB subnet group.
6. For VPC, choose the default VPC or the VPC that you created.
7. In the Add subnets section, choose the Availability Zones that include the subnets from Availability Zones, and then choose the subnets from Subnets.
Create DB Subnet Group

To create a new subnet group, give it a name and a description, and choose an existing VPC. You will then be able to add subnets related to that VPC.

**Subnet group details**

**Name**
You won't be able to modify the name after your subnet group has been created.

mydbsubnetgroup

Must contain from 1 to 255 characters. Alphanumeric characters, spaces, hyphens, underscores, and periods are allowed.

**Description**

My DB Subnet Group

**VPC**
Choose a VPC identifier that corresponds to the subnets you want to use for your DB subnet group. You won't be able to choose a different VPC identifier after your subnet group has been created.

tutorial-vpc (vpc-06bfe38b853eaf014)

**Add subnets**

**Availability Zones**
Choose the Availability Zones that include the subnets you want to add.

**Subnets**
Choose the subnets that you want to add. The list includes the subnets in the selected Availability Zones.

**Subnets selected (2)**

<table>
<thead>
<tr>
<th>Availability zone</th>
<th>Subnet ID</th>
<th>CIDR block</th>
</tr>
</thead>
<tbody>
<tr>
<td>us-east-1a</td>
<td>subnet-079bd4b8953ae1dd</td>
<td>10.0.0.0/24</td>
</tr>
<tr>
<td>us-east-1c</td>
<td>subnet-057e85b72c46f929a</td>
<td>10.0.1.0/24</td>
</tr>
</tbody>
</table>
8. Choose Create.

Choose Create.

Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see details, including all of the subnets associated with the group, in the details pane at the bottom of the window.

Step 3: Create a VPC security group

Before you create your DB cluster, you can create a VPC security group to associate with your DB cluster. If you don't create a VPC security group, you can use the default security group when you create a DB cluster. For instructions on how to create a security group for your DB cluster, see Create a VPC security group for a private DB cluster (p. 2496), or see Control traffic to resources using security groups in the Amazon VPC User Guide.

Step 4: Create a DB instance in the VPC

In this step, you create a DB cluster and use the VPC name, the DB subnet group, and the VPC security group you created in the previous steps.

Note

If you want your DB cluster in the VPC to be publicly accessible, you must enable the VPC attributes DNS hostnames and DNS resolution. For more information, see DNS attributes for your VPC in the Amazon VPC User Guide.

For details on how to create a DB cluster, see Creating an Amazon Aurora DB cluster (p. 179).

When prompted in the Connectivity section, enter the VPC name, the DB subnet group, and the VPC security group.

Note

Updating VPCs isn't currently supported for Aurora DB clusters.

Scenarios for accessing a DB cluster in a VPC

Amazon Aurora supports the following scenarios for accessing a DB cluster in a VPC:

- An EC2 instance in the same VPC (p. 2489)
- An EC2 instance in a different VPC (p. 2491)
- A client application through the internet (p. 2492)
- A private network (p. 2493)

A DB cluster in a VPC accessed by an EC2 instance in the same VPC

A common use of a DB cluster in a VPC is to share data with an application server that is running in an EC2 instance in the same VPC.

The following diagram shows this scenario.
The simplest way to manage access between EC2 instances and DB clusters in the same VPC is to do the following:

- Create a VPC security group for your DB clusters to be in. This security group can be used to restrict access to the DB clusters. For example, you can create a custom rule for this security group. This might allow TCP access using the port that you assigned to the DB cluster when you created it and an IP address you use to access the DB cluster for development or other purposes.

- Create a VPC security group for your EC2 instances (web servers and clients) to be in. This security group can, if needed, allow access to the EC2 instance from the internet by using the VPC's routing table. For example, you can set rules on this security group to allow TCP access to the EC2 instance over port 22.

- Create custom rules in the security group for your DB clusters that allow connections from the security group you created for your EC2 instances. These rules might allow any member of the security group to access the DB clusters.

There is an additional public and private subnet in a separate Availability Zone. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easy to switch to a Multi-AZ DB instance deployment in the future.

For a tutorial that shows you how to create a VPC with both public and private subnets for this scenario, see Tutorial: Create a VPC for use with a DB cluster (IPv4 only) (p. 2494).
Tip
You can set up network connectivity between an Amazon EC2 instance and a DB cluster automatically when you create the DB cluster. For more information, see Configure automatic network connectivity with an EC2 instance (p. 180).

To create a rule in a VPC security group that allows connections from another security group, do the following:

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc.
2. In the navigation pane, choose Security groups.
3. Choose or create a security group for which you want to allow access to members of another security group. In the preceding scenario, this is the security group that you use for your DB clusters. Choose the Inbound rules tab, and then choose Edit inbound rules.
5. For Type, choose the entry that corresponds to the port you used when you created your DB cluster, such as MYSQL/Aurora.
6. In the Source box, start typing the ID of the security group, which lists the matching security groups. Choose the security group with members that you want to have access to the resources protected by this security group. In the scenario preceding, this is the security group that you use for your EC2 instance.
7. If required, repeat the steps for the TCP protocol by creating a rule with All TCP as the Type and your security group in the Source box. If you intend to use the UDP protocol, create a rule with All UDP as the Type and your security group in Source.
8. Choose Save rules.

The following screen shows an inbound rule with a security group for its source.

For more information about connecting to the DB cluster from your EC2 instance, see Connecting to an Amazon Aurora DB cluster (p. 204).

A DB cluster in a VPC accessed by an EC2 instance in a different VPC

When your DB clusters is in a different VPC from the EC2 instance you are using to access it, you can use VPC peering to access the DB cluster.

The following diagram shows this scenario.
A VPC peering connection is a networking connection between two VPCs that enables you to route traffic between them using private IP addresses. Resources in either VPC can communicate with each other as if they are within the same network. You can create a VPC peering connection between your own VPCs, with a VPC in another AWS account, or with a VPC in a different AWS Region. To learn more about VPC peering, see VPC peering in the Amazon Virtual Private Cloud User Guide.

A DB cluster in a VPC accessed by a client application through the internet

To access a DB clusters in a VPC from a client application through the internet, you configure a VPC with a single public subnet, and an internet gateway to enable communication over the internet.

The following diagram shows this scenario.

We recommend the following configuration:

- A VPC of size /16 (for example CIDR: 10.0.0.0/16). This size provides 65,536 private IP addresses.
- A subnet of size /24 (for example CIDR: 10.0.0.0/24). This size provides 256 private IP addresses.
- An Amazon Aurora DB cluster that is associated with the VPC and the subnet. Amazon RDS assigns an IP address within the subnet to your DB cluster.
- An internet gateway which connects the VPC to the internet and to other AWS products.
A security group associated with the DB cluster. The security group's inbound rules allow your client application to access to your DB cluster.

For information about creating a DB clusters in a VPC, see Creating a DB cluster in a VPC (p. 2486).

A DB cluster in a VPC accessed by a private network

If your DB cluster isn't publicly accessible, you have the following options for accessing it from a private network:

- An AWS Site-to-Site VPN connection. For more information, see What is AWS Site-to-Site VPN?
- An AWS Direct Connect connection. For more information, see What is AWS Direct Connect?
- An AWS Client VPN connection. For more information, see What is AWS Client VPN?

The following diagram shows a scenario with an AWS Site-to-Site VPN connection.

For more information, see Internetwork traffic privacy (p. 2399).
Tutorial: Create a VPC for use with a DB cluster (IPv4 only)

A common scenario includes a DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service. This VPC shares data with a web server that is running in the same VPC. In this tutorial, you create the VPC for this scenario.

The following diagram shows this scenario. For information about other scenarios, see Scenarios for accessing a DB cluster in a VPC (p. 2489).

Your DB cluster needs to be available only to your web server, and not to the public internet. Thus, you create a VPC with both public and private subnets. The web server is hosted in the public subnet, so that it can reach the public internet. The DB cluster is hosted in a private subnet. The web server can connect to the DB cluster because it is hosted within the same VPC. But the DB cluster isn't available to the public internet, providing greater security.

This tutorial configures an additional public and private subnet in a separate Availability Zone. These subnets aren't used by the tutorial. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easier to configure more than one Aurora DB instance.

This tutorial describes configuring a VPC for Amazon Aurora DB clusters. For a tutorial that shows you how to create a web server for this VPC scenario, see Tutorial: Create a web server and an Amazon Aurora DB cluster (p. 151). For more information about Amazon VPC, see Amazon VPC Getting Started Guide and Amazon VPC User Guide.
Tip
You can set up network connectivity between an Amazon EC2 instance and a DB cluster automatically when you create the DB cluster. The network configuration is similar to the one described in this tutorial. For more information, see Configure automatic network connectivity with an EC2 instance (p. 180).

Create a VPC with private and public subnets

Use the following procedure to create a VPC with both public and private subnets.

To create a VPC and subnets

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the top-right corner of the AWS Management Console, choose the Region to create your VPC in. This example uses the US West (Oregon) Region.
3. In the upper-left corner, choose VPC dashboard. To begin creating a VPC, choose Create VPC.
4. For Resources to create under VPC settings, choose VPC and more.
5. For the VPC settings, set these values:
   - Name tag auto-generation – tutorial
   - IPv4 CIDR block – 10.0.0.0/16
   - IPv6 CIDR block – No IPv6 CIDR block
   - Tenancy – Default
   - Number of Availability Zones (AZs) – 2
   - Customize AZs – Keep the default values.
   - Number of public subnet – 2
   - Number of private subnets – 2
   - Customize subnets CIDR blocks – Keep the default values.
   - NAT gateways ($) – None
   - VPC endpoints – None
   - DNS options – Keep the default values.
6. Choose Create VPC.

Create a VPC security group for a public web server

Next, you create a security group for public access. To connect to public EC2 instances in your VPC, you add inbound rules to your VPC security group. These allow traffic to connect from the internet.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose VPC Dashboard, choose Security Groups, and then choose Create security group.
3. On the Create security group page, set these values:
   - Security group name: tutorial-securitygroup
   - Description: Tutorial Security Group
   - VPC: Choose the VPC that you created earlier, for example: vpc-identifier (tutorial-vpc)
4. Add inbound rules to the security group.
   a. Determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH). To determine your public IP address, in a different browser window or tab,
you can use the service at https://checkip.amazonaws.com. An example of an IP address is 203.0.113.25/32.

In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, find the range of IP addresses used by client computers.

**Warning**
If you use 0.0.0.0/0 for SSH access, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances using SSH.

b. In the **Inbound rules** section, choose **Add rule**.

c. Set the following values for your new inbound rule to allow SSH access to your Amazon EC2 instance. If you do this, you can connect to your Amazon EC2 instance to install the web server and other utilities. You also connect to your EC2 instance to upload content for your web server.

- **Type**: SSH
- **Source**: The IP address or range from Step a, for example: 203.0.113.25/32.

d. Choose **Add rule**.

e. Set the following values for your new inbound rule to allow HTTP access to your web server:

- **Type**: HTTP
- **Source**: 0.0.0.0/0

5. Choose **Create security group** to create the security group.

Note the security group ID because you need it later in this tutorial.

### Create a VPC security group for a private DB cluster

To keep your DB cluster private, create a second security group for private access. To connect to private DB clusters in your VPC, you add inbound rules to your VPC security group that allow traffic from your web server only.

**To create a VPC security group**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:

   - **Security group name**: tutorial-db-securitygroup
   - **Description**: Tutorial DB Instance Security Group
   - **VPC**: Choose the VPC that you created earlier, for example: `vpc-identifier` (tutorial-vpc)

4. Add inbound rules to the security group.

   a. In the **Inbound rules** section, choose **Add rule**.
   
   b. Set the following values for your new inbound rule to allow MySQL traffic on port 3306 from your Amazon EC2 instance. If you do this, you can connect from your web server to your DB cluster. By doing so, you can store and retrieve data from your web application to your database.

   - **Type**: MySQL/Aurora
   - **Source**: The identifier of the `tutorial-securitygroup` security group that you created previously in this tutorial, for example: `sg-9edd5cfd`.
5. Choose **Create security group** to create the security group.

**Create a DB subnet group**

A **DB subnet group** is a collection of subnets that you create in a VPC and that you then designate for your DB clusters. A DB subnet group makes it possible for you to specify a particular VPC when creating DB clusters.

**To create a DB subnet group**

1. Identify the private subnets for your database in the VPC.
   a. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
   b. Choose **VPC Dashboard**, and then choose **Subnets**.
   c. Note the subnet IDs of the subnets named `tutorial-subnet-private1-us-west-2a` and `tutorial-subnet-private2-us-west-2b`.

   You need the subnet IDs when you create your DB subnet group.
2. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).

   Make sure that you connect to the Amazon RDS console, not to the Amazon VPC console.
3. In the navigation pane, choose **Subnet groups**.
4. Choose **Create DB subnet group**.
5. On the **Create DB subnet group** page, set these values in **Subnet group details**:
   - **Name**: `tutorial-db-subnet-group`
   - **Description**: **Tutorial DB Subnet Group**
   - **VPC**: `tutorial-vpc (vpc-identifier)`
6. In the **Add subnets** section, choose the **Availability Zones** and **Subnets**.

   For this tutorial, choose **us-west-2a** and **us-west-2b** for the **Availability Zones**. For **Subnets**, choose the private subnets you identified in the previous step.
7. Choose **Create**.

   Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see details in the details pane at the bottom of the window. These details include all of the subnets associated with the group.

**Note**

If you created this VPC to complete **Tutorial: Create a web server and an Amazon Aurora DB cluster (p. 151)**, create the DB cluster by following the instructions in **Create an Amazon Aurora DB cluster (p. 157)**.

**Deleting the VPC**

After you create the VPC and other resources for this tutorial, you can delete them if they are no longer needed.

**Note**

If you added resources in the VPC that you created for this tutorial, you might need to delete these before you can delete the VPC. For example, these resources might include Amazon EC2 instances or Amazon RDS DB clusters. For more information, see **Delete your VPC** in the Amazon **VPC User Guide**.
To delete a VPC and related resources

1. Delete the DB subnet group.
   a. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   b. In the navigation pane, choose Subnet groups.
   c. Select the DB subnet group you want to delete, such as tutorial-db-subnet-group.
   d. Choose Delete, and then choose Delete in the confirmation window.

2. Note the VPC ID.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose VPC Dashboard, and then choose VPCs.
   c. In the list, identify the VPC that you created, such as tutorial-vpc.
   d. Note the VPC ID of the VPC that you created. You need the VPC ID in later steps.

3. Delete the security groups.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose VPC Dashboard, and then choose Security Groups.
   c. Select the security group for the Amazon RDS DB instance, such as tutorial-db-securitygroup.
   d. For Actions, choose Delete security groups, and then choose Delete on the confirmation page.
   e. On the Security Groups page, select the security group for the Amazon EC2 instance, such as tutorial-securitygroup.
   f. For Actions, choose Delete security groups, and then choose Delete on the confirmation page.

4. Delete the VPC.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose VPC Dashboard, and then choose VPCs.
   c. Select the VPC you want to delete, such as tutorial-vpc.
   d. For Actions, choose Delete VPC.

      The confirmation page shows other resources that are associated with the VPC that will also be deleted, including the subnets associated with it.
   e. On the confirmation page, enter delete, and then choose Delete.
Tutorial: Create a VPC for use with a DB cluster (dual-stack mode)

A common scenario includes a DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service. This VPC shares data with a public Amazon EC2 instance that is running in the same VPC.

In this tutorial, you create the VPC for this scenario that works with a database running in dual-stack mode. Dual-stack mode to enable connection over the IPv6 addressing protocol. For more information about IP addressing, see Amazon Aurora IP addressing (p. 2480).

Dual-stack network clusters are supported in most regions. For more information see Availability of dual-stack network DB clusters (p. 2484). To see the limitations of dual-stack mode, see Limitations for dual-stack network DB clusters (p. 2484).

The following diagram shows this scenario.

For information about other scenarios, see Scenarios for accessing a DB cluster in a VPC (p. 2489).

Your DB cluster needs to be available only to your Amazon EC2 instance, and not to the public internet. Thus, you create a VPC with both public and private subnets. The Amazon EC2 instance is hosted in the public subnet, so that it can reach the public internet. The DB cluster is hosted in a private subnet. The Amazon EC2 instance can connect to the DB cluster because it's hosted within the same VPC. However, the DB cluster is not available to the public internet, providing greater security.
This tutorial configures an additional public and private subnet in a separate Availability Zone. These subnets aren't used by the tutorial. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easy to configure more than one Aurora DB instance.

To create a DB cluster that uses dual-stack mode, specify Dual-stack mode for the Network type setting. You can also modify a DB cluster with the same setting. For more information about creating a DB cluster, see Creating an Amazon Aurora DB cluster (p. 179). For more information about modifying a DB cluster, see Modifying an Amazon Aurora DB cluster (p. 269).

This tutorial describes configuring a VPC for Amazon Aurora DB clusters. For more information about Amazon VPC, see Amazon VPC User Guide.

Create a VPC with private and public subnets

Use the following procedure to create a VPC with both public and private subnets.

To create a VPC and subnets

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the upper-right corner of the AWS Management Console, choose the Region to create your VPC in. This example uses the US East (Ohio) Region.
3. In the upper-left corner, choose VPC dashboard. To begin creating a VPC, choose Create VPC.
4. For Resources to create under VPC settings, choose VPC and more.
5. For the remaining VPC settings, set these values:
   - Name tag auto-generation – tutorial-dual-stack
   - IPv4 CIDR block – 10.0.0.0/16
   - IPv6 CIDR block – Amazon-provided IPv6 CIDR block
   - Tenancy – Default
   - Number of Availability Zones (AZs) – 2
   - Customize AZs – Keep the default values.
   - Number of public subnet – 2
   - Number of private subnets – 2
   - Customize subnets CIDR blocks – Keep the default values.
   - NAT gateways ($) – None
   - Egress only internet gateway – No
   - VPC endpoints – None
   - DNS options – Keep the default values.

   Note
   Amazon RDS requires at least two subnets in two different Availability Zones to support Multi-AZ DB instance deployments. This tutorial creates a Single-AZ deployment, but the requirement makes it easy to convert to a Multi-AZ DB instance deployment in the future.

6. Choose Create VPC.

Create a VPC security group for a public Amazon EC2 instance

Next, you create a security group for public access. To connect to public EC2 instances in your VPC, add inbound rules to your VPC security group that allow traffic to connect from the internet.
To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose VPC Dashboard, choose Security Groups, and then choose Create security group.
3. On the Create security group page, set these values:
   - Security group name: tutorial-dual-stack-securitygroup
   - Description: Tutorial Dual-Stack Security Group
   - VPC: Choose the VPC that you created earlier, for example: vpc-identifier (tutorial-dual-stack-vpc)
4. Add inbound rules to the security group.
   a. Determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH).
      An example of an Internet Protocol version 4 (IPv4) address is 203.0.113.25/32. An example of an Internet Protocol version 6 (IPv6) address range is 2001:db8:1234:1a00::/64.
      In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, find the range of IP addresses used by client computers.
      Warning
      If you use 0.0.0.0/0 for IPv4 or ::0 for IPv6, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances.
   b. In the Inbound rules section, choose Add rule.
   c. Set the following values for your new inbound rule to allow Secure Shell (SSH) access to your Amazon EC2 instance. If you do this, you can connect to your EC2 instance to install SQL clients and other applications. Specify an IP address so you can access your EC2 instance:
      - Type: SSH
      - Source: The IP address or range from step a. An example of an IPv4 IP address is 203.0.113.25/32. An example of an IPv6 IP address is 2001:db8::/32.
5. Choose Create security group to create the security group.
   Note the security group ID because you need it later in this tutorial.

Create a VPC security group for a private DB cluster

To keep your DB cluster private, create a second security group for private access. To connect to private DB clusters in your VPC, add inbound rules to your VPC security group. These allow traffic from your Amazon EC2 instance only.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose VPC Dashboard, choose Security Groups, and then choose Create security group.
3. On the Create security group page, set these values:
   - Security group name: tutorial-dual-stack-db-securitygroup
   - Description: Tutorial Dual-Stack DB Instance Security Group
   - VPC: Choose the VPC that you created earlier, for example: vpc-identifier (tutorial-dual-stack-vpc)
4. Add inbound rules to the security group:
   a. In the Inbound rules section, choose Add rule.
   b. Set the following values for your new inbound rule to allow MySQL traffic on port 3306 from your Amazon EC2 instance. If you do, you can connect from your EC2 instance to your DB cluster. Doing this means that you can send data from your EC2 instance to your database.
      - **Type:** MySQL/Aurora
      - **Source:** The identifier of the tutorial-dual-stack-securitygroup security group that you created previously in this tutorial, for example sg-9edd5cfb.

5. To create the security group, choose Create security group.

### Create a DB subnet group

A **DB subnet group** is a collection of subnets that you create in a VPC and that you then designate for your DB clusters. By using a DB subnet group, you can specify a particular VPC when creating DB clusters. To create a DB subnet group that is DUAL compatible, all subnets must be DUAL compatible. To be DUAL compatible, a subnet must have an IPv6 CIDR associated with it.

#### To create a DB subnet group

1. Identify the private subnets for your database in the VPC.
   a. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
   b. Choose VPC Dashboard, and then choose Subnets.
   c. Note the subnet IDs of the subnets named tutorial-dual-stack-subnet-private1-us-west-2a and tutorial-dual-stack-subnet-private2-us-west-2b.

     You will need the subnet IDs when you create your DB subnet group.

2. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).

   Make sure that you connect to the Amazon RDS console, not to the Amazon VPC console.

3. In the navigation pane, choose Subnet groups.

4. Choose Create DB subnet group.

5. On the Create DB subnet group page, set these values in Subnet group details:
   - **Name:** tutorial-dual-stack-db-subnet-group
   - **Description:** Tutorial Dual-Stack DB Subnet Group
   - **VPC:** tutorial-dual-stack-vpc (vpc-identifier)

6. In the Add subnets section, choose values for the Availability Zones and Subnets options.

    For this tutorial, choose us-east-2a and us-east-2b for the Availability Zones. For Subnets, choose the private subnets you identified in the previous step.

7. Choose Create.

Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see its details. These include the supported addressing protocols and all of the subnets associated with the group and the network type supported by the DB subnet group.

### Create an Amazon EC2 instance in dual-stack mode

To create an Amazon EC2 instance, follow the instructions in Launch an instance using the new launch instance wizard in the Amazon EC2 User Guide for Linux Instances.
On the **Configure Instance Details** page, set these values and keep the other values as their defaults:

- **Network** – Choose an existing VPC with both public and private subnets, such as **tutorial-dual-stack-vpc** (vpc-identifier) created in **Create a VPC with private and public subnets** (p. 2500).
- **Subnet** – Choose an existing public subnet, such as **subnet-identifier | tutorial-dual-stack-subnet-public1-us-east-2a | us-east-2a** created in **Create a VPC security group for a public Amazon EC2 instance** (p. 2500).
- **Auto-assign Public IP** – Choose **Enable**.
- **Auto-assign IPv6 IP** – Choose **Enable**.
- **Firewall (security groups)** – Choose **Select an existing security group**.
- **Common security groups** – Choose an existing security group, such as the **tutorial-securitygroup** created in **Create a VPC security group for a public Amazon EC2 instance** (p. 2500). Make sure that the security group that you choose includes inbound rules for Secure Shell (SSH) and HTTP access.

### Create a DB cluster in dual-stack mode

In this step, you create a DB cluster that runs in dual-stack mode.

**To create a DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the upper-right corner of the console, choose the AWS Region where you want to create the DB cluster. This example uses the US East (Ohio) Region.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.
5. On the **Create database** page, make sure that the **Standard create** option is chosen, and then choose the Aurora MySQL DB engine type.
6. In the **Connectivity** section, set these values:

   - **Network type** – Choose **Dual-stack mode**.

     ![Network type](image)

     - **IPv4**
       - **Your resources can communicate only over the IPv4 addressing protocol.**
     - **Dual-stack mode**
       - **Your resources can communicate over IPv4, IPv6, or both.**

   - **Virtual private cloud (VPC)** – Choose an existing VPC with both public and private subnets, such as **tutorial-dual-stack-vpc** (vpc-identifier) created in **Create a VPC with private and public subnets** (p. 2500).
     The VPC must have subnets in different Availability Zones.
   - **DB subnet group** – Choose a DB subnet group for the VPC, such as **tutorial-dual-stack-db-subnet-group** created in **Create a DB subnet group** (p. 2502).
   - **Public access** – Choose **No**.
   - **VPC security group (firewall)** – Select **Choose existing**.
   - **Existing VPC security groups** – Choose an existing VPC security group that is configured for private access, such as **tutorial-dual-stack-db-securitygroup** created in **Create a VPC security group for a private DB cluster** (p. 2501).
Remove other security groups, such as the default security group, by choosing the X associated with each.

- **Availability Zone** – Choose us-west-2a.

  To avoid cross-AZ traffic, make sure the DB instance and the EC2 instance are in the same Availability Zone.

7. For the remaining sections, specify your DB cluster settings. For information about each setting, see Settings for Aurora DB clusters (p. 190).

## Connect to your Amazon EC2 instance and DB cluster

After you create your Amazon EC2 instance and DB cluster in dual-stack mode, you can connect to each one using the IPv6 protocol. To connect to an Amazon EC2 instance using the IPv6 protocol, follow the instructions in Connect to your Linux instance in the Amazon EC2 User Guide for Linux Instances.

To connect to your Aurora MySQL DB cluster from the Amazon EC2 instance, follow the instructions in Connect to an Aurora MySQL DB cluster (p. 134).

## Deleting the VPC

After you create the VPC and other resources for this tutorial, you can delete them if they are no longer needed.

If you added resources in the VPC that you created for this tutorial, you might need to delete these before you can delete the VPC. Examples of resources are Amazon EC2 instances or DB clusters. For more information, see Delete your VPC in the Amazon VPC User Guide.

### To delete a VPC and related resources

1. Delete the DB subnet group:
   a. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   b. In the navigation pane, choose **Subnet groups**.
   c. Select the DB subnet group to delete, such as tutorial-db-subnet-group.
   d. Choose **Delete**, and then choose **Delete** in the confirmation window.

2. Note the VPC ID:
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose **VPC Dashboard**, and then choose **VPCs**.
   c. In the list, identify the VPC you created, such as tutorial-dual-stack-vpc.
   d. Note the **VPC ID** value of the VPC that you created. You need this VPC ID in subsequent steps.

3. Delete the security groups:
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose **VPC Dashboard**, and then choose **Security Groups**.
   c. Select the security group for the Amazon RDS DB instance, such as tutorial-dual-stack-db-securitygroup.
   d. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.
   e. On the **Security Groups** page, select the security group for the Amazon EC2 instance, such as tutorial-dual-stack-securitygroup.
   f. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.

4. Delete the NAT gateway:
Amazon Aurora User Guide for Aurora
Tutorial: Create a VPC for use with a DB cluster (dual-stack mode)

a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
b. Choose VPC Dashboard, and then choose NAT Gateways.
c. Select the NAT gateway of the VPC that you created. Use the VPC ID to identify the correct NAT gateway.
d. For Actions, choose Delete NAT gateway.
e. On the confirmation page, enter delete, and then choose Delete.

5. Delete the VPC:
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose VPC Dashboard, and then choose VPCs.
   c. Select the VPC that you want to delete, such as tutorial-dual-stack-vpc.
   d. For Actions, choose Delete VPC.
      
The confirmation page shows other resources that are associated with the VPC that will also be deleted, including the subnets associated with it.
   e. On the confirmation page, enter delete, and then choose Delete.

6. Release the Elastic IP addresses:
   a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
   b. Choose EC2 Dashboard, and then choose Elastic IPs.
   c. Select the Elastic IP address that you want to release.
   d. For Actions, choose Release Elastic IP addresses.
   e. On the confirmation page, choose Release.
Quotas and constraints for Amazon Aurora

Following, you can find a description of the resource quotas and naming constraints for Amazon Aurora.

Topics
- Quotas in Amazon Aurora (p. 2506)
- Naming constraints in Amazon Aurora (p. 2509)
- Amazon Aurora size limits (p. 2510)

Quotas in Amazon Aurora

Each AWS account has quotas, for each AWS Region, on the number of Amazon Aurora resources that can be created. After a quota for a resource has been reached, additional calls to create that resource fail with an exception.

The following table lists the resources and their quotas per AWS Region.

<table>
<thead>

</tr>
</tbody>
</table>

**Note**

By default, you can have up to a total of 40 DB instances. RDS DB instances, Aurora DB instances, Amazon Neptune instances, and Amazon DocumentDB instances apply to this quota. If your application requires more DB instances, you can request additional DB instances by opening the [Service Quotas console](https://console.aws.amazon.com/servicequotas). In the navigation pane, choose **AWS services**, Choose [Amazon Relational Database Service (Amazon RDS)](https://aws.amazon.com/rds/), choose a quota, and follow the directions to request a quota increase. For more information, see [Requesting a quota increase](https://docs.aws.amazon.com/service-quotas/latest/userguide/service-quota-request-example.html) in the [Service Quotas User Guide](https://docs.aws.amazon.com/service-quotas/latest/userguide/).
Backups managed by AWS Backup are considered manual DB clustersnapshots, but don’t count toward the manual cluster snapshot quota. For information about AWS Backup, see the AWS Backup Developer Guide.

If you use any RDS API operations and exceed the default quota for the number of calls per second, the Amazon RDS API issues an error like the following one.

ClientError: An error occurred (ThrottlingException) when calling the API_name operation: Rate exceeded.

Here, reduce the number of calls per second. The quota is meant to cover most use cases. If higher limits are needed, request a quota increase by contacting AWS Support. Open the AWS Support Center page, sign in if necessary, and choose Create case. Choose Service limit increase. Complete and submit the form.

Note
This quota can’t be changed in the Amazon RDS Service Quotas console.

## Naming constraints in Amazon Aurora

The following table describes naming constraints in Amazon Aurora.

<table>
<thead>
<tr>
<th>Resource or item</th>
<th>Constraints</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB cluster identifier</td>
<td>Identifiers have these naming constraints:</td>
</tr>
<tr>
<td></td>
<td>• Must contain 1–63 alphanumeric characters or hyphens.</td>
</tr>
<tr>
<td></td>
<td>• First character must be a letter.</td>
</tr>
<tr>
<td></td>
<td>• Can’t end with a hyphen or contain two consecutive hyphens.</td>
</tr>
<tr>
<td></td>
<td>• Must be unique for all DB instances per AWS account, per AWS Region.</td>
</tr>
<tr>
<td>Initial database name</td>
<td>Database name constraints differ between Aurora MySQL and PostgreSQL. For more information, see the available settings when creating each DB cluster.</td>
</tr>
<tr>
<td>Master user name</td>
<td>Master user name constraints differ for each database engine. For more information, see the available settings when creating each DB cluster.</td>
</tr>
<tr>
<td>Master password</td>
<td>The password for the database master user can include any printable ASCII character except /, ‚‚, @, or a space. For Oracle, &amp; is an additional character limitation. The password has the following number of printable ASCII characters depending on the DB engine:</td>
</tr>
<tr>
<td></td>
<td>• Aurora MySQL: 8–41</td>
</tr>
<tr>
<td></td>
<td>• Aurora PostgreSQL: 8–99</td>
</tr>
<tr>
<td>DB parameter group name</td>
<td>These names have these constraints:</td>
</tr>
<tr>
<td></td>
<td>• Must contain 1–255 alphanumeric characters.</td>
</tr>
<tr>
<td></td>
<td>• First character must be a letter.</td>
</tr>
</tbody>
</table>
|                          | • Hyphens are allowed, but the name cannot end with a hyphen or contain two consecutive hyphens.
Amazon Aurora size limits

Storage size limits
An Aurora cluster volume can grow to a maximum size of 128 tebibytes (TiB) for the following engine versions:
- All available Aurora MySQL version 3 versions; Aurora MySQL version 2, versions 2.09 and higher
- All available Aurora PostgreSQL versions
For lower engine versions, the maximum size of an Aurora cluster volume is 64 TiB. For more information, see How Aurora storage automatically resizes (p. 98).
To monitor the remaining storage space, you can use the AuroraVolumeBytesLeftTotal metric. For more information, see Cluster-level metrics for Amazon Aurora (p. 638).

SQL table size limits
For an Aurora MySQL DB cluster, the maximum table size is 64 tebibytes (TiB). For an Aurora PostgreSQL DB cluster, the maximum table size is 32 tebibytes (TiB). We recommend that you follow table design best practices, such as partitioning of large tables.

Table space ID limits
The maximum table space ID for Aurora MySQL is 2147483647. If you frequently create and drop tables, make sure to be aware of your table space IDs and plan to use logical dumps. For more information, see Logical migration from MySQL to Amazon Aurora MySQL by using mysqldump (p. 857).
Troubleshooting for Amazon Aurora

Use the following sections to help troubleshoot problems you have with DB instances in Amazon RDS and Amazon Aurora.

Topics
- Can't connect to Amazon RDS DB instance (p. 2511)
- Amazon RDS security issues (p. 2513)
- Resetting the DB instance owner password (p. 2513)
- Amazon RDS DB instance outage or reboot (p. 2514)
- Amazon RDS DB parameter changes not taking effect (p. 2514)
- Freeable memory issues in Amazon Aurora (p. 2514)
- Amazon Aurora MySQL out-of-memory issues (p. 2515)
- Amazon Aurora MySQL replication issues (p. 2516)

For information about debugging problems using the Amazon RDS API, see Troubleshooting applications on Aurora (p. 2520).

Can't connect to Amazon RDS DB instance

When you can't connect to a DB instance, the following are common causes:

- **Inbound rules** – The access rules enforced by your local firewall and the IP addresses authorized to access your DB instance might not match. The problem is most likely the inbound rules in your security group.

  By default, DB instances don't allow access. Access is granted through a security group associated with the VPC that allows traffic into and out of the DB instance. If necessary, add inbound and outbound rules for your particular situation to the security group. You can specify an IP address, a range of IP addresses, or another VPC security group.

  **Note**
  When adding a new inbound rule, you can choose My IP for Source to allow access to the DB instance from the IP address detected in your browser.

  For more information about setting up security groups, see Provide access to the DB cluster in the VPC by creating a security group (p. 122).

  **Note**
  Client connections from IP addresses within the range 169.254.0.0/16 aren't permitted. This is the Automatic Private IP Addressing Range (APIPA), which is used for local-link addressing.

- **Public accessibility** – To connect to your DB instance from outside of the VPC, such as by using a client application, the instance must have a public IP address assigned to it.

  To make the instance publicly accessible, modify it and choose Yes under Public accessibility. For more information, see Hiding a DB cluster in a VPC from the internet (p. 2484).

- **Port** – The port that you specified when you created the DB instance can't be used to send or receive communications due to your local firewall restrictions. To determine if your network allows the
specified port to be used for inbound and outbound communication, check with your network administrator.

- **Availability** – For a newly created DB instance, the DB instance has a status of creating until the DB instance is ready to use. When the state changes to available, you can connect to the DB instance. Depending on the size of your DB instance, it can take up to 20 minutes before an instance is available.

- **Internet gateway** – For a DB instance to be publicly accessible, the subnets in its DB subnet group must have an internet gateway.

**To configure an internet gateway for a subnet**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the name of the DB instance.
3. In the Connectivity & security tab, write down the values of the VPC ID under VPC and the subnet ID under Subnets.
4. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
5. In the navigation pane, choose Internet Gateways. Verify that there is an internet gateway attached to your VPC. Otherwise, choose Create Internet Gateway to create an internet gateway. Select the internet gateway, and then choose Attach to VPC and follow the directions to attach it to your VPC.
6. In the navigation pane, choose Subnets, and then select your subnet.
7. On the Route Table tab, verify that there is a route with 0.0.0.0/0 as the destination and the internet gateway for your VPC as the target.

If you're connecting to your instance using its IPv6 address, verify that there is a route for all IPv6 traffic (: /0) that points to the internet gateway. Otherwise, do the following:

a. Choose the ID of the route table (rtb-xxxxxxxx) to navigate to the route table.

b. On the Routes tab, choose Edit routes. Choose Add route, use 0.0.0.0/0 as the destination and the internet gateway as the target.

For IPv6, choose Add route, use ::/0 as the destination and the internet gateway as the target.

c. Choose Save routes.

Also, if you are trying to connect to IPv6 endpoint, make sure that client IPv6 address range is authorized to connect to the DB instance.

For more information, see [Working with a DB cluster in a VPC (p. 2478)](#).

**Testing a connection to a DB instance**

You can test your connection to a DB instance using common Linux or Microsoft Windows tools.

From a Linux or Unix terminal, you can test the connection by entering the following. Replace `DB-instance-endpoint` with the endpoint and `port` with the port of your DB instance.

```
nc -zv DB-instance-endpoint port
```

For example, the following shows a sample command and the return value.

```
nc -zv postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 8299
```
Troubleshooting connection authentication

In some cases, you can connect to your DB instance but you get authentication errors. In these cases, you might want to reset the master user password for the DB instance. You can do this by modifying the RDS instance.

Amazon RDS security issues

To avoid security issues, never use your master AWS user name and password for a user account. Best practice is to use your master AWS account to create users and assign those to DB user accounts. You can also use your master account to create other user accounts, if necessary.

For information about creating users, see Creating an IAM user in your AWS account. For information about creating users in AWS IAM Identity Center, see Manage identities in IAM Identity Center.

Error message "failed to retrieve account attributes, certain console functions may be impaired."

You can get this error for several reasons. It might be because your account is missing permissions, or your account hasn't been properly set up. If your account is new, you might not have waited for the account to be ready. If this is an existing account, you might lack permissions in your access policies to perform certain actions such as creating a DB instance. To fix the issue, your administrator needs to provide the necessary roles to your account. For more information, see the IAM documentation.

Resetting the DB instance owner password

If you get locked out of your DB cluster, you can log in as the master user. Then you can reset the credentials for other administrative users or roles. If you can't log in as the master user, the AWS account owner can reset the master user password. For details of which administrative accounts or roles you might need to reset, see Master user account privileges (p. 2474).

You can change the DB instance password by using the Amazon RDS console, the AWS CLI command modify-db-instance, or by using the ModifyDBInstance API operation. For more information about modifying a DB instance in a DB cluster, see Modifying a DB Instance in a DB cluster (p. 270).
Amazon RDS DB instance outage or reboot

A DB instance outage can occur when a DB instance is rebooted. It can also occur when the DB instance is put into a state that prevents access to it, and when the database is restarted. A reboot can occur when you manually reboot your DB instance. A reboot can also occur when you change a DB instance setting that requires a reboot before it can take effect.

A DB instance reboot occurs when you change a setting that requires a reboot, or when you manually cause a reboot. A reboot can occur immediately if you change a setting and request that the change take effect immediately. Or it can occur during the DB instance’s maintenance window.

A DB instance reboot occurs immediately when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0. You then set **Apply Immediately** to `true`.
- You change the DB instance class, and **Apply Immediately** is set to `true`.

A DB instance reboot occurs during the maintenance window when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0, and **Apply Immediately** is set to `false`.
- You change the DB instance class, and **Apply Immediately** is set to `false`.

When you change a static parameter in a DB parameter group, the change doesn't take effect until the DB instance associated with the parameter group is rebooted. The change requires a manual reboot. The DB instance isn't automatically rebooted during the maintenance window.

Amazon RDS DB parameter changes not taking effect

In some cases, you might change a parameter in a DB parameter group but don't see the changes take effect. If so, you likely need to reboot the DB instance associated with the DB parameter group. When you change a dynamic parameter, the change takes effect immediately. When you change a static parameter, the change doesn't take effect until you reboot the DB instance associated with the parameter group.

You can reboot a DB instance using the RDS console. Or you can explicitly call the `RebootDBInstance` API operation. You can reboot without failover if the DB instance is in a Multi-AZ deployment. The requirement to reboot the associated DB instance after a static parameter change helps mitigate the risk of a parameter misconfiguration affecting an API call. An example of this is calling `ModifyDBInstance` to change the DB instance class. For more information, see [Modifying parameters in a DB parameter group](p. 229).

Freeable memory issues in Amazon Aurora

*Freeable memory* is the total random access memory (RAM) on a DB instance that can be made available to the database engine. It's the sum of the free operating-system (OS) memory and the available buffer and page cache memory. The database engine uses most of the memory on the host, but OS processes also use some RAM. Memory currently allocated to the database engine or used by OS processes isn't included in freeable memory. When the database engine is running out of memory, the DB instance can
use the temporary space that is normally used for buffering and caching. As previously mentioned, this
temporary space is included in freeable memory.

You use the FreeableMemory metric in Amazon CloudWatch to monitor the freeable memory. For more
information, see Overview of monitoring metrics in Amazon Aurora (p. 510).

If your DB instance consistently runs low on freeable memory or uses swap space, consider scaling up to
a larger DB instance class. For more information, see Aurora DB instance classes (p. 84).

You can also change the memory settings. For example, on Aurora MySQL, you might adjust the size of
the innodb_buffer_pool_size parameter. This parameter is set by default to 75 percent of physical
memory. For more MySQL troubleshooting tips, see How can I troubleshoot low freeable memory in an
Amazon RDS for MySQL database?

For Aurora Serverless v2, FreeableMemory represents the amount of unused memory that's available
when the Aurora Serverless v2 DB instance is scaled to its maximum capacity. You might have the
instance scaled down to relatively low capacity, but it still reports a high value for FreeableMemory,
because the instance can scale up. That memory isn't available right now, but you can get it if you need
it.

For every Aurora capacity unit (ACU) that the current capacity is below the maximum capacity,
FreeableMemory increases by approximately 2 GiB. Thus, this metric doesn't approach zero until the DB
instance is scaled up as high as it can.

If this metric approaches a value of 0, the DB instance has scaled up as much as it can. It's nearing
the limit of its available memory. Consider increasing the maximum ACU setting for the cluster. If this
metric approaches a value of 0 on a reader DB instance, consider adding additional reader DB instances
to the cluster. That way, the read-only part of the workload can be spread across more DB instances,
reducing the memory usage on each reader DB instance. For more information, see Important Amazon
CloudWatch metrics for Aurora Serverless v2 (p. 2018).

For Aurora Serverless v1, you can change the capacity range to use more ACUs. For more information,
see Modifying an Aurora Serverless v1 DB cluster (p. 2051).

Amazon Aurora MySQL out-of-memory issues

The Aurora MySQL aurora_oom_response instance-level parameter can enable the DB instance
to monitor the system memory and estimate the memory consumed by various statements and
connections. If the system runs low on memory, it can perform a list of actions to release that memory.
It does so in an attempt to avoid out-of-memory (OOM) and database restart. The instance-level
parameter takes a string of comma-separated actions that a DB instance should take when its memory is
low. Valid actions include print, tune, decline, kill_query, or any combination of these. An empty
string means that no action should be taken and effectively turns off the feature.

Note
This parameter is supported for Aurora MySQL versions 2 and 3.

The following are usage examples for the aurora_oom_response parameter:

• print – Only prints the queries taking high amount of memory.
• tune – Tunes the internal table caches to release some memory back to the system.

Aurora MySQL decreases the memory used for caches such as table_open_cache,
table_def_cache, and query_cache in low-memory conditions. Eventually, Aurora MySQL sets
their memory usage back to normal when the system is no longer low on memory.

• decline – Declines new queries once the instance is low on memory.
• kill_query – Ends the queries in descending order of memory consumption until the instance
memory surfaces above the low threshold. Data definition language (DDL) statements aren't ended.
• print, tune – Performs actions described for both print and tune.
• tune, decline, kill_query – Performs the actions described for tune, decline, and kill_query.

For the db.t2.small DB instance class, the aurora_oom_response parameter is set to print, tune by default. For all other DB instance classes, the parameter value is empty by default (disabled).

Amazon Aurora MySQL replication issues

Some MySQL replication issues also apply to Aurora MySQL. You can diagnose and correct these.

Topics
• Diagnosing and resolving lag between read replicas (p. 2516)
• Diagnosing and resolving a MySQL read replication failure (p. 2517)
• Replication stopped error (p. 2518)

Diagnosing and resolving lag between read replicas

After you create a MySQL read replica and the replica is available, Amazon RDS first replicates the changes made to the source DB instance from the time the read replica create operation started. During this phase, the replication lag time for the read replica is greater than 0. You can monitor this lag time in Amazon CloudWatch by viewing the Amazon RDS AuroraBinlogReplicaLag metric.

The AuroraBinlogReplicaLag metric reports the value of the Seconds_Behind_Master field of the MySQL SHOW REPLICA STATUS command. For more information, see SHOW REPLICA STATUS Statement in the MySQL documentation.

When the AuroraBinlogReplicaLag metric reaches 0, the replica has caught up to the source DB instance. If the AuroraBinlogReplicaLag metric returns -1, replication might not be active. To troubleshoot a replication error, see Diagnosing and resolving a MySQL read replication failure (p. 2517). A AuroraBinlogReplicaLag value of -1 can also mean that the Seconds_Behind_Master value can't be determined or is NULL.

Note
Previous versions of Aurora MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using Aurora MySQL version 1 or 2, then use SHOW SLAVE STATUS. Use SHOW REPLICA STATUS for Aurora MySQL version 3 and higher.

The AuroraBinlogReplicaLag metric returns -1 during a network outage or when a patch is applied during the maintenance window. In this case, wait for network connectivity to be restored or for the maintenance window to end before you check the AuroraBinlogReplicaLag metric again.

The MySQL read replication technology is asynchronous. Thus, you can expect occasional increases for the BinLogDiskUsage metric on the source DB instance and for the AuroraBinlogReplicaLag metric on the read replica. For example, consider a situation where a high volume of write operations to the source DB instance occur in parallel. At the same time, write operations to the read replica are serialized using a single I/O thread. Such a situation can lead to a lag between the source instance and read replica.

For more information about read replicas and MySQL, see Replication implementation details in the MySQL documentation.

You can reduce the lag between updates to a source DB instance and the subsequent updates to the read replica by doing the following:
• Set the DB instance class of the read replica to have a storage size comparable to that of the source DB instance.

• Make sure that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the max_allowed_packet parameter in the next section.

• Disable the query cache. For tables that are modified often, using the query cache can increase replica lag because the cache is locked and refreshed often. If this is the case, you might see less replica lag if you disable the query cache. You can disable the query cache by setting the query_cache_type parameter to 0 in the DB parameter group for the DB instance. For more information on the query cache, see Query cache configuration.

• Warm the buffer pool on the read replica for InnoDB for MySQL. For example, suppose that you have a small set of tables that are being updated often and you’re using the InnoDB or XtraDB table schema. In this case, dump those tables on the read replica. Doing this causes the database engine to scan through the rows of those tables from the disk and then cache them in the buffer pool. This approach can reduce replica lag. The following shows an example.

For Linux, macOS, or Unix:

```bash
PROMPT> mysqldump \
   -h <endpoint> \
   --port=<port> \
   -u=<username> \
   -p <password> \
   database_name table1 table2 > /dev/null
```

For Windows:

```bash
PROMPT> mysqldump ^
   -h <endpoint> ^
   --port=<port> ^
   -u=<username> ^
   -p <password> ^
   database_name table1 table2 > /dev/null
```

Diagnosing and resolving a MySQL read replication failure

Amazon RDS monitors the replication status of your read replicas. RDS updates the Replication State field of the read replica instance to Error if replication stops for any reason. You can review the details of the associated error thrown by the MySQL engines by viewing the Replication Error field. Events that indicate the status of the read replica are also generated, including RDS-EVENT-0045 (p. 717), RDS-EVENT-0046 (p. 717), and RDS-EVENT-0047 (p. 716). For more information about events and subscribing to events, see Working with Amazon RDS event notification (p. 690). If a MySQL error message is returned, check the error in the MySQL error message documentation.

Common situations that can cause replication errors include the following:

• The value for the max_allowed_packet parameter for a read replica is less than the max_allowed_packet parameter for the source DB instance.

The max_allowed_packet parameter is a custom parameter that you can set in a DB parameter group. The max_allowed_packet parameter is used to specify the maximum size of data manipulation language (DML) that can be run on the database. In some cases, the max_allowed_packet value for the source DB instance might be larger than the
Replication stopped error

When you call the `mysql.rds_skip_repl_error` command, you might receive an error message stating that replication is down or disabled.

This error message appears because replication is stopped and can't be restarted.

If you need to skip a large number of errors, the replication lag can increase beyond the default retention period for binary log files. In this case, you might encounter a fatal error due to binary log files being purged before they have been replayed on the replica. This purge causes replication to stop, and you can no longer call the `mysql.rds_skip_repl_error` command to skip replication errors.

You can mitigate this issue by increasing the number of hours that binary log files are retained on your replication source. After you have increased the binlog retention time, you can restart replication and call the `mysql.rds_skip_repl_error` command as needed.

To set the binlog retention time, use the `mysql_rds_set_configuration` procedure. Specify a configuration parameter of 'binlog retention hours' along with the number of hours to retain binlog files on the DB.
cluster, up to 2160 (90 days). The default for Aurora MySQL is 24 (1 day). The following example sets the retention period for binlog files to 48 hours.

CALL mysql.rds_set_configuration('binlog retention hours', 48);
Amazon RDS API reference

In addition to the AWS Management Console and the AWS Command Line Interface (AWS CLI), Amazon RDS also provides an API. You can use the API to automate tasks for managing your DB instances and other objects in Amazon RDS.

- For an alphabetical list of API operations, see Actions.
- For an alphabetical list of data types, see Data types.
- For a list of common query parameters, see Common parameters.
- For descriptions of the error codes, see Common errors.

For more information about the AWS CLI, see AWS Command Line Interface reference for Amazon RDS.

Topics
- Using the Query API (p. 2520)
- Troubleshooting applications on Aurora (p. 2520)

Using the Query API

The following sections briefly discuss the parameters and request authentication used with the Query API.

For general information about how the Query API works, see Query requests in the Amazon EC2 API Reference.

Query parameters

HTTP Query-based requests are HTTP requests that use the HTTP verb GET or POST and a Query parameter named Action.

Each Query request must include some common parameters to handle authentication and selection of an action.

Some operations take lists of parameters. These lists are specified using the \texttt{param.\texttt{n}} notation. Values of \texttt{n} are integers starting from 1.

For information about Amazon RDS Regions and endpoints, go to Amazon Relational Database Service (RDS) in the Regions and Endpoints section of the Amazon Web Services General Reference.

Query request authentication

You can only send Query requests over HTTPS, and you must include a signature in every Query request. You must use either AWS signature version 4 or signature version 2. For more information, see Signature Version 4 signing process and Signature version 2 signing process.

Troubleshooting applications on Aurora

Amazon RDS provides specific and descriptive errors to help you troubleshoot problems while interacting with the Amazon RDS API.
Topics

- Retrieving errors (p. 2521)
- Troubleshooting tips (p. 2521)

For information about troubleshooting for Amazon RDS DB instances, see Troubleshooting for Amazon Aurora (p. 2511).

Retrieving errors

Typically, you want your application to check whether a request generated an error before you spend any time processing results. The easiest way to find out if an error occurred is to look for an Error node in the response from the Amazon RDS API.

XPath syntax provides a simple way to search for the presence of an Error node. It also provides a relatively easy way to retrieve the error code and message. The following code snippet uses Perl and the XML::XPath module to determine if an error occurred during a request. If an error occurred, the code prints the first error code and message in the response.

```
use XML::XPath;
my $xp = XML::XPath->new(xml =>$response);
if ( $xp->find('//Error') )
{print "There was an error processing your request:\n", " Error code: ",
  $xp->findvalue('//Error[1]/Code'), "\n", " ",
  $xp->findvalue('//Error[1]/Message'), "\n\n"; }
```

Troubleshooting tips

We recommend the following processes to diagnose and resolve problems with the Amazon RDS API:

- Verify that Amazon RDS is operating normally in the AWS Region that you’re targeting by checking http://status.aws.amazon.com.
- Check the structure of your request. Each Amazon RDS operation has a reference page in the Amazon RDS API Reference. Double-check that you are using parameters correctly. For ideas about what might be wrong, look at the sample requests or user scenarios to see if those examples do similar operations.
- Check AWS re:Post.

Amazon RDS has a development community where you can search for solutions to problems others have experienced along the way. To view the topics, go to AWS re:Post.
The following table describes important changes to the *Amazon Aurora User Guide*. For notification about updates to this documentation, you can subscribe to an RSS feed. For information about Amazon Relational Database Service (Amazon RDS), see the *Amazon Relational Database Service User Guide*.

### Current API version: 2014-10-31

Before August 31, 2018, Amazon Aurora was documented in the *Amazon Relational Database Service User Guide*. For earlier Aurora document history, see Document history in the *Amazon Relational Database Service User Guide*.

You can filter new Amazon Aurora features on the What's New with Database? page. For Products, choose Amazon Aurora. Then search using keywords such as global database or Serverless.

<td>September 7, 2023</td>
</tr>
<tr>
<td>Amazon RDS Extended Support</td>
<td>Amazon Aurora announces the upcoming ability to continue running Aurora MySQL and Aurora PostgreSQL major engine versions in your DB instances past the Aurora end of standard support date. For more information, see Using Amazon RDS Extended Support.</td>
<td>September 1, 2023</td>
</tr>
<tr>
<td>Amazon Aurora MySQL extends support for Percona XtraBackup</td>
<td>You can now perform physical migrations of MySQL 8.0 databases to Aurora MySQL version 3 DB clusters. For more information, see Physical migration from MySQL by using Percona XtraBackup and Amazon S3.</td>
<td>August 24, 2023</td>
</tr>
<tr>
<td>Aurora global database supports global database failover</td>
<td>Aurora global database now supports managed global failover, allowing you to more easily recover from a true Regional disaster or complete service-level outage. To learn more about this feature, see Performing managed failovers for Aurora global databases. The feature previously called &quot;managed planned failover&quot; is now called &quot;switchover.&quot; For information about switchovers, see Performing switchovers for Amazon Aurora global databases.</td>
<td>August 21, 2023</td>
</tr>
<tr>
<td>Update to AWS managed policy permissions</td>
<td>The AmazonRDSFullAccess managed policy has new permissions that allows you to generate, view, and delete the performance analysis report for a time period. For more information, see Amazon RDS updates to AWS managed policies.</td>
<td>August 17, 2023</td>
</tr>
</tbody>
</table>
### Update to AWS managed policy permissions (p. 2522)

The addition of new permissions to AmazonRDSPerformanceInsightsReadOnly managed policy and addition of new managed policy AmazonRDSPerformanceInsightsFullAccess allows you generate a DB load analysis report for a time period. For more information, see [Amazon RDS updates to AWS managed policies](#).

**August 16, 2023**

### Amazon RDS supports DB load time period analysis with Performance Insights (p. 2522)

Performance Insights allows you to create performance analysis reports for a specific period of time. The report provides the insights identified and recommendations to resolve the performance issues. For more information, see [Analyzing DB load for a period of time](#).

**August 16, 2023**

### Amazon Aurora supports retaining automated backups for DB clusters (p. 2522)

You can now retain automated backups for deleted Aurora clusters and restore them to a specified point in time. For more information, see [Retaining automated backups](#).

**August 4, 2023**

### Amazon Aurora is available in the Israel (Tel Aviv) Region (p. 2522)

Amazon Aurora is now available in the Israel (Tel Aviv) Region. For more information, see [Regions and Availability Zones](#).

**August 1, 2023**

### Amazon Aurora MySQL supports local (in-cluster) write forwarding (p. 2522)

You can now forward write operations from a reader DB instance to a writer DB instance within an Aurora MySQL DB cluster. For more information, see [Using write forwarding in an Amazon Aurora MySQL DB cluster](#).

**July 31, 2023**

### Amazon Aurora supports Aurora Serverless v2 in an additional AWS Region (p. 2522)

You can now create Aurora Serverless v2 DB clusters in the Asia Pacific (Melbourne) AWS Region. For information about Aurora Serverless v2, see [Using Aurora Serverless v2](#).

**June 28, 2023**

<td>Amazon RDS Performance Insights introduces new dimensions (p. 2522)</td>
<td>You can group database load according to the dimension groups for database, application (PostgreSQL), and session type (PostgreSQL). Amazon RDS also supports the dimensions db.name, db.application.name (PostgreSQL), and db.session_type.name (PostgreSQL). For more information, see Top load table.</td>
<td>November 24, 2020</td>
</tr>
<tr>
<td>Aurora Serverless supports Aurora PostgreSQL version 10.12 (p. 2522)</td>
<td>Aurora PostgreSQL for Aurora Serverless has been upgraded to Aurora PostgreSQL version 10.12 throughout the AWS Regions where Aurora PostgreSQL for Aurora Serverless is supported. For more information, see Aurora Serverless.</td>
<td>November 4, 2020</td>
</tr>
<tr>
<td>The Data API now supports tag-based authorization (p. 2522)</td>
<td>The Data API supports tag-based authorization. If you've labeled your RDS cluster resources with tags, you can use these tags in your policy statements to control access through the Data API. For more information, see Authorizing access to the Data API.</td>
<td>October 27, 2020</td>
</tr>
<tr>
<td>Amazon Aurora extends support for exporting snapshots to Amazon S3 (p. 2522)</td>
<td>You can now export DB snapshot data to Amazon S3 in all commercial AWS Regions. For more information, see Exporting DB snapshot data to Amazon S3.</td>
<td>October 22, 2020</td>
</tr>
<tr>
<td>Aurora global database supports cloning (p. 2522)</td>
<td>You can now create clones of the primary and secondary DB clusters of your Aurora global databases. You can do so by using the AWS Management Console and choosing the Create clone menu option. You can also use the AWS CLI and run the restore-db-cluster-to-point-in-time command with the --restore-type copy-on-write option. Using the AWS Management Console or the AWS CLI, you can also clone DB clusters from your Aurora global databases across AWS accounts. For more information about cloning, see Cloning an Aurora DB cluster volume.</td>
<td>October 19, 2020</td>
</tr>
<tr>
<td>Feature</td>
<td>Description</td>
<td>Date</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------------</td>
</tr>
<tr>
<td>Amazon Aurora supports dynamic resizing for the cluster volume (p. 2522)</td>
<td>Starting with Aurora MySQL 1.23 and 2.09, and Aurora PostgreSQL 3.3.0 and Aurora PostgreSQL 2.6.0, Aurora reduces the size of the cluster volume after you remove data through operations such as DROP TABLE. To take advantage of this enhancement, upgrade to one of the appropriate versions depending on the database engine that your cluster uses. For information about this feature and how to check used and available storage space for an Aurora cluster, see Managing Performance and Scaling for Aurora DB Clusters.</td>
<td>October 13, 2020</td>
</tr>
<tr>
<td>Amazon Aurora supports volume sizes up to 128 TiB (p. 2522)</td>
<td>New and existing Aurora cluster volumes can now grow to a maximum size of 128 tebibytes (TiB). For more information, see How Aurora storage grows.</td>
<td>September 22, 2020</td>
</tr>
<tr>
<td>Aurora PostgreSQL supports the db.r5 and db.t3 DB instance classes in the China (Ningxia) Region (p. 2522)</td>
<td>You can now create Aurora PostgreSQL DB clusters in the China (Ningxia) Region that use the db.r5 and db.t3 DB instance classes. For more information, see DB instance classes.</td>
<td>September 3, 2020</td>
</tr>
</tbody>
</table>
Starting with Aurora MySQL 2.09 and 1.23, you can take advantage of enhancements to the parallel query feature. Creating a parallel query cluster no longer requires a special engine mode. You can now turn parallel query on and off using the `aurora_parallel_query` configuration option for any provisioned cluster that’s running a compatible Aurora MySQL version. You can upgrade an existing cluster to a compatible Aurora MySQL version and use parallel query, instead of creating a new cluster and importing data into it. You can use Performance Insights for parallel query clusters. You can stop and start parallel query clusters. You can create Aurora parallel query clusters that are compatible with MySQL 5.7. Parallel query works for tables that use the DYNAMIC row format. Parallel query clusters can use AWS Identity and Access Management (IAM) authentication. Reader DB instances in parallel query clusters can take advantage of the READ COMMITTED isolation level. You can also now create parallel query clusters in additional AWS Regions. For more information about the parallel query feature and these enhancements, see Working with parallel query for Aurora MySQL.

You can now change the value of the Aurora MySQL parameter `binlog_rows_query_log_events`. Formerly, this parameter wasn't modifiable.

2560
Query plan management in Aurora PostgreSQL (p. 2522)

Aurora PostgreSQL now provides query plan management that you can use to manage PostgreSQL query execution plans. For more information, see Managing query execution plans for Aurora PostgreSQL.

November 20, 2018

Query editor for Aurora Serverless v1 (beta) (p. 2522)

You can run SQL statements in the Amazon RDS console on Aurora Serverless v1 clusters. For more information, see Using the query editor for Aurora Serverless v1.

November 20, 2018

Data API for Aurora Serverless v1 (beta) (p. 2522)

You can access Aurora Serverless v1 clusters with web services-based applications using the Data API. For more information, see Using the Data API for Aurora Serverless.

November 20, 2018

TLS support for Aurora Serverless v1 (p. 2522)

Aurora Serverless v1 clusters support TLS/SSL encryption. For more information, see TLS/SSL for Aurora Serverless.

November 19, 2018

Custom endpoints (p. 2522)

You can now create endpoints that are associated with an arbitrary set of DB instances. This feature helps with load balancing and high availability for Aurora clusters where some DB instances have different capacity or configuration than others. You can use custom endpoints instead of connecting to a specific DB instance through its instance endpoint. For more information, see Amazon Aurora connection management.

November 12, 2018

IAM authentication support in Aurora PostgreSQL (p. 2522)

Aurora PostgreSQL now supports IAM authentication. For more information see IAM database authentication.

November 8, 2018

Custom parameter groups for restore and point in time recovery (p. 2522)

You can now specify a custom parameter group when you restore a snapshot or perform a point in time recovery operation. For more information, see Restoring from a DB cluster snapshot and Restoring a DB cluster to a specified time.
