For each task, the following sections describe the requirements and limitations specific to the task. For example, when you create your RDS Custom DB for Oracle instance, use either the db.m5 or db.r5 instance classes running Oracle Linux 7 Update 9. For general requirements that apply to RDS Custom, see RDS Custom for Oracle requirements and limitations (p. 999).

**Step 1: Create or reuse a symmetric encryption AWS KMS key**

*Customer managed keys* are AWS KMS keys in your AWS account that you create, own, and manage. A customer managed symmetric encryption KMS key is required for RDS Custom. When you create an RDS Custom for Oracle DB instance, you supply the KMS key identifier. For more information, see Configuring a DB instance for Amazon RDS Custom for Oracle (p. 1035).

You have the following options:

- If you have an existing customer managed KMS key in your AWS account, you can use it with RDS Custom. No further action is necessary.
- If you already created a customer managed symmetric encryption KMS key for a different RDS Custom engine, you can reuse the same KMS key. No further action is necessary.
- If you don't have an existing customer managed symmetric encryption KMS key in your account, create a KMS key by following the instructions in Creating keys in the AWS Key Management Service Developer Guide.
- If you're creating a CEV or RDS Custom DB instance, and your KMS key is in a different AWS account, make sure to use the AWS CLI. You can't use the AWS console with cross-account KMS keys.

**Important**

RDS Custom doesn't support AWS managed KMS keys.

Make sure that your symmetric encryption key grants access to the kms:Decrypt and kms:GenerateDataKey operations to the AWS Identity and Access Management (IAM) role in your IAM instance profile. If you have a new symmetric encryption key in your account, no changes are required. Otherwise, make sure that your symmetric encryption key's policy grants access to these operations.

For more information, see Step 3: Configure IAM and your Amazon VPC (p. 1003).

For more information about configuring IAM for RDS Custom for Oracle, see Step 3: Configure IAM and your Amazon VPC (p. 1003).

**Step 2: Download and install the AWS CLI**

AWS provides you with a command-line interface to use RDS Custom features. You can use either version 1 or version 2 of the AWS CLI.

For information about downloading and installing the AWS CLI, see Installing or updating the latest version of the AWS CLI.

Skip this step if either of the following is true:

- You plan to access RDS Custom only from the AWS Management Console.
- You have already downloaded the AWS CLI for Amazon RDS or a different RDS Custom DB engine.

**Step 3: Configure IAM and your Amazon VPC**

You use an IAM role or IAM user (known as an IAM entity) to create an RDS Custom DB instance using the console or AWS CLI. This IAM entity must have the necessary permissions for instance creation.
Your RDS Custom DB instance is in a virtual private cloud (VPC) based on the Amazon VPC service, just like an Amazon EC2 instance or Amazon RDS instance. You provide and configure your own VPC. Thus, you have full control over your instance networking setup.

You can configure your IAM identity and virtual private cloud (VPC) using either of the following techniques:

- Configure IAM and your VPC using AWS CloudFormation (p. 1004) (recommended)
- Follow the procedures in Create your IAM role and instance profile manually (p. 1007) and Configure your VPC manually (p. 1011)

We strongly recommend that you configure your RDS Custom for Oracle environment using AWS CloudFormation. This technique is the easiest and least error-prone.

Configure IAM and your VPC using AWS CloudFormation

A CloudFormation stack is a collection of AWS resources that you can manage as a single unit. To simplify RDS Custom configuration, you can use the AWS CloudFormation template files to create CloudFormation stacks. For more information, see Creating a stack on the AWS CloudFormation console in AWS CloudFormation User Guide.

AWS CloudFormation configuration steps

- IAM and VPC resources created by CloudFormation (p. 1004)
- Step 1: Download the CloudFormation template files (p. 1004)
- Step 2: Configure IAM using CloudFormation (p. 1005)
- Step 3: Configure your VPC using CloudFormation (p. 1006)

IAM and VPC resources created by CloudFormation

When you use the CloudFormation templates, they create stacks that includes the following resources in your AWS account:

- An Amazon EC2 instance profile named AWSRDSCustomInstanceProfile-\textit{region}
- An IAM role named AWSRDSCustomInstanceRole-\textit{region}
- A DB subnet group named rds-custom-private
- The following VPC endpoints, which are necessary for your DB instance to communicate with dependent AWS services:
  - com.amazonaws.\textit{region}.ec2messages
  - com.amazonaws.\textit{region}.events
  - com.amazonaws.\textit{region}.logs
  - com.amazonaws.\textit{region}.monitoring
  - com.amazonaws.\textit{region}.s3
  - com.amazonaws.\textit{region}.secretsmanager
  - com.amazonaws.\textit{region}.ssm
  - com.amazonaws.\textit{region}.ssmmessages

Unlike RDS Custom for SQL Server, RDS Custom for Oracle doesn’t create an access control list or security groups. You must attach your own security group, subnets, and route tables.

Step 1: Download the CloudFormation template files

A CloudFormation template is a declaration of the AWS resources that make up a stack. The template is stored as a JSON file.
To download the CloudFormation template files
1. Open the context (right-click) menu for the link `custom-oracle-iam.zip` and choose **Save Link As**.
2. Save the file to your computer.
3. Repeat the previous steps for the link `custom-vpc.zip`.
   If you already configured your VPC for RDS Custom, skip this step.

Step 2: Configure IAM using CloudFormation

When you use the CloudFormation template for IAM, it creates the following required resources:

- An instance profile named `AWSRDSCustomInstanceProfile-region`
- A service role named `AWSRDSCustomInstanceRole-region`
- An access policy named `AWSRDSCustomIamRolePolicy` that is attached to the service role

To configure IAM using CloudFormation

2. Start the Create Stack wizard, and choose **Create Stack**.
3. On the **Create stack** page, do the following:
   a. For **Prepare template**, choose **Template is ready**.
   b. For **Template source**, choose **Upload a template file**.
   c. For **Choose file**, navigate to, then choose `custom-oracle-iam.json`.
   d. Choose **Next**.
4. On the **Specify stack details** page, do the following:
   a. For **Stack name**, enter `custom-oracle-iam`.
   b. Choose **Next**.
5. On the **Configure stack options** page, choose **Next**.
6. On the **Review custom-oracle-iam** page, do the following:
   a. Select the **I acknowledge that AWS CloudFormation might create IAM resources with custom names** check box.
   b. Choose **Submit**.

CloudFormation creates the IAM roles that RDS Custom for Oracle requires. In the left panel, when `custom-oracle-iam` shows **CREATE_COMPLETE**, proceed to the next step.

7. In the left panel, choose `custom-oracle-iam`. In the right panel, do the following:
   a. Choose **Stack info**. Your stack has an ID in the format `arn:aws:cloudformation:region:account-no:stack/custom-oracle-iam/identifier`.
   b. Choose **Resources**. You should see the following:
      - An instance profile named `AWSRDSCustomInstanceProfile-region`
      - A service role named `AWSRDSCustomInstanceRole-region`

When you create your RDS Custom DB instance, you need to supply the instance profile ID.
Step 3: Configure your VPC using CloudFormation

If you've already configured your VPC for a different RDS Custom engine, and want to reuse the existing VPC, skip this step. This section assumes that the following:

- You've already used CloudFormation to create your IAM instance profile and role.
- You know your route table ID.

For a DB instance to be private, it must be in a private subnet. For a subnet to be private, it must not be associated with a route table that has a default internet gateway. For more information, see Configure route tables in the Amazon VPC User Guide.

When you use the CloudFormation template for your VPC, it creates the following required resources:

- A private VPC
- A subnet group named rds-custom-private
- VPC endpoints that use the naming format vpce-string

To configure your VPC using CloudFormation

2. Start the Create Stack wizard, and choose Create Stack and then With new resources (standard).
3. On the Create stack page, do the following:
   a. For Prepare template, choose Template is ready.
   b. For Template source, choose Upload a template file.
   c. For Choose file, navigate to, then choose custom-vpc.json.
   d. Choose Next.
4. On the Specify stack details page, do the following:
   a. For Stack name, enter custom-vpc.
   b. For Parameters, choose the private subnets to use for RDS Custom DB instances.
   c. Choose the private VPC ID to use for RDS Custom DB instances.
   d. Enter the route table associated with the private subnets.
   e. Choose Next.
5. On the Configure stack options page, choose Next.

CloudFormation configures your private VPC. In the left panel, when custom-vpc shows CREATE_COMPLETE, proceed to the next step.

7. (Optional) Review the details of your VPC. In the Stacks pane, choose custom-vpc. In the right pane, do the following:
   b. Choose Resources. You should see a subnet group named rds-custom-private and several VPC endpoints that use the naming format vpce-string. Each endpoint corresponds to an AWS service that RDS Custom needs to communicate with.
   c. Choose Parameters. You should see the private subnets, private VPC, and the route table that you specified when you created the stack. When you create a DB instance, you need to supply the VPC ID and subnet group.
Create your IAM role and instance profile manually

Configuration is easiest when you use CloudFormation. However, you can also configure IAM manually. For manual setup, you create the following resources:

- An IAM instance profile named AWSRDSCustomInstanceProfile-region, where region is the AWS Region where you plan to deploy your DB instances.
- An IAM role AWSRDSCustomInstanceRole-region for the instance profile.

The following steps show how to create the instance profile and role and then add the role to your profile.

To create the RDS Custom instance profile and add the necessary role to it

1. Create the IAM role that uses the naming format AWSRDSCustomInstanceRole-region with a trust policy that Amazon EC2 can use to assume this role.
2. Add an access policy to AWSRDSCustomInstanceRole-region.
3. Create an IAM instance profile for RDS Custom that uses the naming format AWSRDSCustomInstanceProfile-region.
4. Add the AWSRDSCustomInstanceRole-region IAM role to the instance profile.

Step 1: Create the role AWSRDSCustomInstanceRoleForRdsCustomInstance

In this step, you create the role using the naming format AWSRDSCustomInstanceRole-region. Using the trust policy, Amazon EC2 can assume the role. The following example assumes that you have set the environment variable $REGION to the AWS Region in which you want to create your DB instance.

```
aws iam create-role \
  --role-name AWSRDSCustomInstanceRole-$REGION \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Action": "sts:AssumeRole",
        "Effect": "Allow",
        "Principal": {
          "Service": "ec2.amazonaws.com"
        }
      }
    ],
    "Service": "ec2.amazonaws.com"
  }'

aws iam create-instance-profile \
  --instance-profile-name AWSRDSCustomInstanceProfile-$REGION
```

Step 2: Add an access policy to AWSRDSCustomInstanceRoleForRdsCustomInstance

When you embed an inline policy in an IAM role, the inline policy is used as part of the role's access (permissions) policy. You create the AWSRDSCustomIamRolePolicy policy that permits Amazon EC2 to send and receive messages and perform various actions.

The following example creates the access policy named AWSRDSCustomIamRolePolicy and adds it to the IAM role AWSRDSCustomInstanceRole-region. This example assumes that you have set the following environment variables:

$REGION

Set this variable to the AWS Region in which you plan to create your DB instance.

$ACCOUNT_ID

Set this variable to your AWS account number.
Set this variable to the Amazon Resource Name (ARN) of the AWS KMS key that you want to use for your RDS Custom DB instances. To specify more than one KMS key, add it to the Resources section of statement ID (Sid) 11.

```bash
aws iam put-role-policy
  --role-name AWSRDSCustomInstanceRole-$REGION
  --policy-name AWSRDSCustomIamRolePolicy
  --policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "1",
      "Effect": "Allow",
      "Action": [
        "ssm:DescribeAssociation",
        "ssm:GetDeployablePatchSnapshotForInstance",
        "ssm:GetDocument",
        "ssm:GetManifest",
        "ssm:GetParameter",
        "ssm:GetParameters",
        "ssm:ListAssociations",
        "ssm:ListInstanceAssociations",
        "ssm:PutInventory",
        "ssm:PutComplianceItems",
        "ssm:PutConfigurationPackageResult",
        "ssm:UpdateAssociationStatus",
        "ssm:UpdateInstanceAssociationStatus",
        "ssm:UpdateInstanceInformation",
        "ssm:GetConnectionStatus",
        "ssm:DescribeInstanceInformation",
        "ssmmessages:CreateControlChannel",
        "ssmmessages:CreateDataChannel",
        "ssmmessages:OpenControlChannel",
        "ssmmessages:OpenDataChannel"
      ],
      "Resource": ["*"]
    },
    {
      "Sid": "2",
      "Effect": "Allow",
      "Action": [
        "ec2messages:AcknowledgeMessage",
        "ec2messages:DeleteMessage",
        "ec2messages:FailMessage",
        "ec2messages:GetEndpoint",
        "ec2messages:GetMessages",
        "ec2messages:SendReply"
      ],
      "Resource": ["*"]
    },
    {
      "Sid": "3",
      "Effect": "Allow",
      "Action": [
        "logs:PutRetentionPolicy",
        "logs:PutLogEvents",
        "logs:DescribeLogStreams",
        "logs:CreateLogStream",
        "logs:DeleteLogStream",
        "logs:GetLogEvents",
        "logs:GetLogGroup_retention_policy",
        "logs:GetLogGroupName",
        "logs:GetLogGroupTags",
        "logs:PutLogGroupTags",
        "logs:PutRetentionPolicy"
      ],
      "Resource": ["*"]
    }
  ]
}'
}
"logs:DescribeLogGroups",
"logs:CreateLogStream",
"logs:CreateLogGroup"
],
"Resource": [
  "arn:aws:logs:'$REGION':*:log-group:rds-custom-instance*"
]
},
{
  "Sid": "4",
  "Effect": "Allow",
  "Action": [
    "s3:putObject",
    "s3:getObject",
    "s3:getObjectVersion"
  ],
  "Resource": [
    "arn:aws:s3:::do-not-delete-rds-custom-*/*"
  ]
},
{
  "Sid": "5",

  "Sid": "7",
  "Effect": "Allow",
  "Action": [
    "secretsmanager:GetSecretValue",
    "secretsmanager:DescribeSecret"
  ],
  "Resource": [
  ]
},
{
  "Sid": "8",
  "Effect": "Allow",
  "Action": [
    "s3:ListBucketVersions"
  ],
  "Resource": [}
"arn:aws:s3:::do-not-delete-rds-custom-**"
],
{
  "Sid": "9",
  "Effect": "Allow",
  "Action": "ec2:CreateSnapshots",
  "Resource": [
    "arn:aws:ec2:*:*:instance/**",
    "arn:aws:ec2:*:*:volume/**"
  ],
  "Condition": {
    "StringEquals": {
      "ec2:ResourceTag/AWSRDSCustom": "custom-oracle"
    }
  }
},
{
  "Sid": "10",
  "Effect": "Allow",
  "Action": "ec2:CreateSnapshots",
  "Resource": [
    "arn:aws:ec2:::snapshot/**"
  ],
  "Condition": {
    "StringEquals": {
      "ec2:ResourceTag/AWSRDSCustom": "custom-oracle"
    }
  }
},
{
  "Sid": "11",
  "Effect": "Allow",
  "Action": [
    "kms:Decrypt",
    "kms:GenerateDataKey"
  ],
  "Resource": [
    "arn:aws:kms:'$REGION':'$ACCOUNT_ID':key/'$KMS_KEY'"
  ],
  "Condition": {
    "StringLike": {
      "ec2:CreateAction": [
        "CreateSnapshots"
      ]
    }
  }
},
{
  "Sid": "12",
  "Effect": "Allow",
  "Action": "ec2:CreateTags",
  "Resource": "**",
  "Condition": {
    "StringLike": {
      "ec2:CreateAction": [
        "CreateSnapshots"
      ]
    }
  }
}
]
}

Step 3: Create your RDS Custom instance profile

An instance profile is a container that includes a single IAM role. RDS Custom uses the instance profile to pass the role to the instance.

If you use the CLI to create a role, you create the role and instance profile as separate actions, with potentially different names. Create your IAM instance profile as follows, naming it using the format AWSRDSCustomInstanceProfile-\$REGION. The following example assumes that you have set the environment variable \$REGION to the AWS Region in which you want to create your DB instance.

```bash
aws iam create-instance-profile \
```
Step 4: Add AWSRDSCustomInstanceRoleForRdsCustomInstance to your RDS Custom instance profile

Add your IAM role to the instance profile that you previously created. The following example assumes that you have set the environment variable $REGION to the AWS Region in which you want to create your DB instance.

```
aws iam add-role-to-instance-profile 
  --instance-profile-name AWSRDSCustomInstanceProfile-$REGION 
  --role-name AWSRDSCustomInstanceRole-$REGION
```

Configure your VPC manually

If you don’t want to use AWS CloudFormation, you can configure your VPC endpoints manually.

Topics

- Create VPC endpoints for dependent AWS services (p. 1011)
- Configure the instance metadata service (p. 1012)

Create VPC endpoints for dependent AWS services

RDS Custom sends communication from your DB instance to other AWS services. To make sure that RDS Custom can communicate, it validates network connectivity to the following AWS services:

- Amazon CloudWatch
- Amazon CloudWatch Logs
- Amazon CloudWatch Events
- Amazon EC2
- Amazon EventBridge
- Amazon S3
- AWS Secrets Manager
- AWS Systems Manager

If RDS Custom can’t communicate with the necessary services, it publishes the following event:

```
Database instance in incompatible-network. SSM Agent connection not available. Amazon RDS can’t connect to the dependent AWS services.
```

To avoid incompatible-network errors, make sure that VPC components involved in communication between your RDS Custom DB instance and AWS services satisfy the following requirements:

- The DB instance can make outbound connections on port 443 to other AWS services.
- The VPC allows incoming responses to requests originating from your RDS Custom DB instance.
- RDS Custom can correctly resolve the domain names of endpoints for each AWS service.

RDS Custom relies on AWS Systems Manager connectivity for its automation. For information about how to configure VPC endpoints, see Creating VPC endpoints for Systems Manager. For the list of endpoints in each Region, see AWS Systems Manager endpoints and quotas in the Amazon Web Services General Reference.
If you already configured a VPC for a different RDS Custom DB engine, you can reuse that VPC and skip this process.

**Configure the instance metadata service**

Make sure that your instance can do the following:

- Access the instance metadata service using Instance Metadata Service Version 2 (IMDSv2).
- Allow outbound communications through port 80 (HTTP) to the IMDS link IP address.
- Request instance metadata from `http://169.254.169.254`, the IMDSv2 link.

For more information, see [Use IMDSv2](https://docs.aws.amazon.com/AmazonEC2/latest/UserGuide/using-imds-v2.html) in the *Amazon EC2 User Guide for Linux Instances*.

RDS Custom for Oracle automation uses IMDSv2 by default, by setting `HttpTokens=enabled` on the underlying Amazon EC2 instance. However, you can use IMDSv1 if you want. For more information, see [Configure the instance metadata options](https://docs.aws.amazon.com/AmazonEC2/latest/UserGuide/using-imds-v1.html) in the *Amazon EC2 User Guide for Linux Instances*.

**Step 4: Grant required permissions to your IAM user or role**

Make sure that the IAM user or role that creates the CEV or RDS Custom DB instance has either of the following policies:

- The `AdministratorAccess` policy
- The `AmazonRDSFullAccess` policy with required permissions for Amazon S3 and AWS KMS (required for both CEV and DB creation), CEV creation, and DB instance creation.

**Topics**

- [IAM permissions required for Amazon S3 and AWS KMS](#)
- [IAM permissions required for creating a CEV](#)
- [IAM permissions required for creating a DB instance from a CEV](#)

**IAM permissions required for Amazon S3 and AWS KMS**

To create CEVs or RDS Custom for Oracle DB instances, the IAM identity needs to access Amazon S3 and AWS KMS. The following sample JSON policy grants the required permissions.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "CreateS3Bucket",
            "Effect": "Allow",
            "Action": [
                "s3:CreateBucket",
                "s3:PutBucketPolicy",
                "s3:PutBucketObjectLockConfiguration",
                "s3:PutBucketVersioning"
            ],
            "Resource": "arn:aws:s3:::do-not-delete-rds-custom-*"
        },
        {
            "Sid": "CreateKmsGrant",
            "Effect": "Allow",
            "Action": [
                "kms:CreateGrant",
                "kms:DescribeKey"
            ],
            "Resource": "*"
        }
    ]
}
```
For more information about the `kms:CreateGrant` permission, see [AWS KMS key management](p. 2606).

**IAM permissions required for creating a CEV**

To create a CEV, the IAM identity needs the following additional permissions:

- `s3:GetObjectAcl`
- `s3:GetObject`
- `s3:GetObjectTagging`
- `s3:ListBucket`
- `mediaimport:CreateDatabaseBinarySnapshot`

The following sample JSON policy grants the additional permissions necessary to access bucket `my-custom-installation-files` and its contents.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AccessToS3MediaBucket",
      "Effect": "Allow",
      "Action": [
        "s3:GetObjectAcl",
        "s3:GetObject",
        "s3:GetObjectTagging",
        "s3:ListBucket"
      ],
      "Resource": [
        "arn:aws:s3:::my-custom-installation-files",
        "arn:aws:s3:::my-custom-installation-files/*"
      ]
    },
    {
      "Sid": "PermissionForByom",
      "Effect": "Allow",
      "Action": [
        "mediaimport:CreateDatabaseBinarySnapshot"
      ],
      "Resource": "*"
    }
  ]
}
```

You can grant similar permissions for Amazon S3 to caller accounts using an S3 bucket policy.

**IAM permissions required for creating a DB instance from a CEV**

To create an RDS Custom for Oracle DB instance from an existing CEV, the IAM entity needs the following additional permissions:

- `iam:SimulatePrincipalPolicy`
- `cloudtrail:CreateTrail`
- `cloudtrail:StartLogging`
The following sample JSON policy grants the permissions necessary to validate an IAM role and log information to an AWS CloudTrail.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ValidateIamRole",
            "Effect": "Allow",
            "Action": "iam:SimulatePrincipalPolicy",
            "Resource": "*"
        },
        {
            "Sid": "CreateCloudTrail",
            "Effect": "Allow",
            "Action": [
                "cloudtrail:CreateTrail",
                "cloudtrail:StartLogging"
            ],
            "Resource": "arn:aws:cloudtrail:*:*:trail/do-not-delete-rds-custom-*"
        }
    ]
}
```
Working with custom engine versions for Amazon RDS Custom for Oracle

A custom engine version (CEV) for Amazon RDS Custom for Oracle is a binary volume snapshot of a database engine and specific Amazon Machine Image (AMI). By default, RDS Custom for Oracle uses the latest available AMI managed by RDS Custom, but you can specify an AMI that was used in a previous CEV. You store your database installation files in Amazon S3. RDS Custom uses the installation files and the AMI to create your CEV for you.

Topics
- Preparing to create a CEV (p. 1015)
- Creating a CEV (p. 1026)
- Modifying CEV status (p. 1030)
- Viewing CEV details (p. 1031)
- Deleting a CEV (p. 1033)

Preparing to create a CEV

To create a CEV, access the installation files and patches that are stored in your Amazon S3 bucket for any of the following releases:

- Oracle Database 19c
- Oracle Database 18c
- Oracle Database 12c Release 2 (12.2)
- Oracle Database 12c Release 1 (12.1)

For example, you can use the April 2021 RU/RUR for Oracle Database 19c, or any valid combination of installation files and patches. For more information on the versions and Regions supported by RDS Custom for Oracle, see RDS Custom with RDS for Oracle.

Topics
- Step 1 (Optional): Download the manifest templates (p. 1015)
- Step 2: Download your database installation files and patches from Oracle Software Delivery Cloud (p. 1016)
- Step 3: Upload your installation files to Amazon S3 (p. 1017)
- Step 4 (Optional): Share your installation media in S3 across AWS accounts (p. 1018)
- Step 5: Prepare the CEV manifest (p. 1020)
- Step 6 (Optional): Validate the CEV manifest (p. 1026)
- Step 7: Add necessary IAM permissions (p. 1026)

Step 1 (Optional): Download the manifest templates

A CEV manifest is a JSON document that includes the list of database installation .zip files for your CEV. To create a CEV, do the following:

1. Identify the Oracle database installation files that you want to include in your CEV.
2. Download the installation files.
3. Create a JSON manifest that lists the installation files.
RDS Custom for Oracle provides JSON manifest templates with our recommended .zip files for each supported Oracle Database release. For example, the following template is for the 19.17.0.0.0 RU.

```json
{
    "mediaImportTemplateVersion": "2020-08-14",
    "databaseInstallationFileNames": [
        "V982063-01.zip"
    ],
    "opatchFileNames": [
        "p6880880_190000_Linux-x86-64.zip"
    ],
    "psuRuPatchFileNames": [
        "p34419443_190000_Linux-x86-64.zip",
        "p3441846_190000_Linux-x86-64.zip"
    ],
    "otherPatchFileNames": [
        "p28852325_190000_Linux-x86-64.zip",
        "p29997937_190000_Linux-x86-64.zip",
        "p31355037_190000_Linux-x86-64.zip",
        "p32327201_190000_Linux-x86-64.zip",
        "p33613829_190000_Linux-x86-64.zip",
        "p34066614_190000_Linux-x86-64.zip",
        "p34533061_190000_Linux-x86-64.zip",
        "p4535150_190000_Generic.zip",
        "p28730253_190000_Linux-x86-64.zip",
        "p29230589_1917000DBRU_Generic.zip",
        "p33125873_1917000DBRU_Linux-x86-64.zip",
        "p34446152_1917000DBRU_Linux-x86-64.zip"
    ]
}
```

Each template has an associated readme that includes instructions for downloading the patches, URLs for the .zip files, and file checksums. You can use these templates as they are or modify them with your own patches. To review the templates, download custom-oracle-manifest.zip to your local disk and then open it with a file archiving application. For more information, see Step 5: Prepare the CEV manifest (p. 1020).

**Step 2: Download your database installation files and patches from Oracle Software Delivery Cloud**

When you have identified the installation files that you want for your CEV, download them to your local system. The Oracle Database installation files and patches are hosted on Oracle Software Delivery Cloud. Each CEV requires a base release, such as Oracle Database 19c or Oracle Database 12c Release 2 (12.2), and an optional list of patches.

**To download the database installation files for Oracle Database**

1. Go to [https://edelivery.oracle.com/](https://edelivery.oracle.com/) and sign in.
2. In the box, enter Oracle Database Enterprise Edition and choose Search.
3. Choose one of the following base releases:
   - DLP: Oracle Database Enterprise Edition 19.3.0.0.0 (Oracle Database Enterprise Edition).
   - Choose DLP: Oracle Database 12c Enterprise Edition 18.0.0.0.0 (Oracle Database Enterprise Edition).
   - Choose DLP: Oracle Database 12c Enterprise Edition 12.2.0.1.0 (Oracle Database Enterprise Edition).
   - Choose DLP: Oracle Database 12c Enterprise Edition 12.1.0.2.0 (Oracle Database Enterprise Edition).
4. Choose Continue.
5. Clear the Download Queue check box.

6. Choose the option that corresponds to your base release:

- **Oracle Database 19.3.0.0.0 - Long Term Release.**
- **Oracle Database 18.0.0.0.0**
- **Oracle Database 12.2.0.1.0.**
- **Oracle Database 12.1.0.2.0.**

7. Choose **Linux x86-64** in Platform/Languages.

8. Choose **Continue**, and then sign the waiver.

9. Choose the .zip file that corresponds to your database release:

<table>
<thead>
<tr>
<th>Database release</th>
<th>Zip files</th>
<th>SHA-256 hash</th>
</tr>
</thead>
<tbody>
<tr>
<td>19c</td>
<td>V982063-01.zip</td>
<td>BA8329C757133DA313ED3B6D7F86C5AC42CD9970A28BF2E6233F325233AA8D</td>
</tr>
<tr>
<td>18c</td>
<td>V978967-01.zip</td>
<td>C96A4FD768787AF9827200833FE10B172691CF84E42816B138C1D24DE63AB9</td>
</tr>
<tr>
<td>12.2</td>
<td>V839960-01.zip</td>

</tr>
<tr>
<td>12.1</td>
<td>V46095-01_1of2.zip</td>
<td>81FDC2AF41687B4E547A3A18F796424D8C1AF36406D2160F65B0AF6A9CD4739</td>
</tr>
<tr>
<td></td>
<td>V46095-01_2of2.zip</td>
<td>03DA14F5E875304B28F0F3BB02AF0EC33227885B99C9865DF70749D1E220AC0</td>
</tr>
</tbody>
</table>

10. Download your desired Oracle patches from updates.oracle.com or support.oracle.com to your local system. You can find the URLs for the patches in the following locations:

- The readme files in the .zip file that you downloaded in Step 1 (Optional): Download the manifest templates (p. 1015)
- The patches listed in each Release Update (RU) in Release notes for Amazon Relational Database Service (Amazon RDS) for Oracle

### Step 3: Upload your installation files to Amazon S3

Upload your Oracle installation and patch files to Amazon S3 using the AWS CLI. The S3 bucket that contains your installation files must be in the same AWS Region as your CEV.

Choose either of the following options:

- **Use aws s3 cp** to upload a single .zip file.
  
  Upload each installation .zip file separately. Don't combine the .zip files into a single .zip file.

- **Use aws s3 sync** to upload a directory.

List your installation files using either the AWS Management Console or the AWS CLI.

Examples in this section use the following placeholders:

- **install-or-patch-file.zip** – Oracle installation media file. For example, p32126828_190000_Linux-x86-64.zip is a patch.
- **my-custom-installation-files** – Your Amazon S3 bucket designated for your uploaded installation files.
- **123456789012/cev1** – An optional prefix in your Amazon S3 bucket.
• **source-bucket** – An Amazon S3 bucket where you can optionally stage files.

The following example uploads `install-or-patch-file.zip` to the `123456789012/cev1` folder in the RDS Custom Amazon S3 bucket. Run a separate `aws s3` command for each .zip that you want to upload.

For Linux, macOS, or Unix:

```
aws s3 cp install-or-patch-file.zip \\
    s3://my-custom-installation-files/123456789012/cev1/
```

For Windows:

```
aws s3 cp install-or-patch-file.zip ^
    s3://my-custom-installation-files/123456789012/cev1/
```

Verify that your S3 bucket is in the AWS Region where you plan to run the `create-custom-db-engine-version` command.

```
aws s3api get-bucket-location --bucket my-custom-installation-files
```

List the files in your RDS Custom Amazon S3 bucket as follows.

```
aws s3 ls \\
    s3://my-custom-installation-files/123456789012/cev1/
```

The following example uploads the files in your local `cev1` folder to the `123456789012/cev1` folder in your Amazon S3 bucket.

For Linux, macOS, or Unix:

```
aws s3 sync cev1 \\
    s3://my-custom-installation-files/123456789012/cev1/
```

For Windows:

```
aws s3 sync cev1 ^
    s3://my-custom-installation-files/123456789012/cev1/
```

The following example uploads all files in `source-bucket` to the `123456789012/cev1` folder in your Amazon S3 bucket.

For Linux, macOS, or Unix:

```
aws s3 sync s3://source-bucket/ \\
    s3://my-custom-installation-files/123456789012/cev1/
```

For Windows:

```
aws s3 sync s3://source-bucket/ ^
    s3://my-custom-installation-files/123456789012/cev1/
```

**Step 4 (Optional): Share your installation media in S3 across AWS accounts**

For the purposes of this section, the Amazon S3 bucket that contains your uploaded Oracle installation files is your `media bucket`. Your organization might use multiple AWS accounts in an AWS Region. If so,
you might want to use one AWS account to populate your media bucket and a different AWS account to create CEVs. If you don't intend to share your media bucket, skip to the next section.

This section assumes the following:

- You can access the account that created your media bucket and a different account in which you intend to create CEVs.
- You intend to create CEVs in only one AWS Region. If you intend to use multiple Regions, create a media bucket in each Region.
- You're using the CLI. If you're using the Amazon S3 console, adapt the following steps.

To configure your media bucket for sharing across AWS accounts

1. **Log in** to the AWS account that contains the S3 bucket into which you uploaded your installation media.
2. **Start with either a blank JSON policy template or an existing policy that you can adapt.**

   The following command retrieves an existing policy and saves it as *my-policy.json*. In this example, the S3 bucket containing your installation files is named *oracle-media-bucket*.

   ```bash
   aws s3api get-bucket-policy
   --bucket oracle-media-bucket
   --query Policy
   --output text > my-policy.json
   ```

3. **Edit the media bucket permissions as follows:**
   - In the `Resource` element of your template, specify the S3 bucket into which you uploaded your Oracle Database installation files.
   - In the `Principal` element, specify the ARNs for all AWS accounts that you intend to use to create CEVs. You can add the root, a user, or a role to the S3 bucket allow list. For more information, see [IAM identifiers](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles_iamând_identifiers.html) in the *AWS Identity and Access Management User Guide*.

   ```json
   {  
     "Version": "2008-10-17",
     "Statement": [
       {
         "Sid": "GrantAccountsAccess",
         "Effect": "Allow",
         "Principal": {
           "AWS": [
             "arn:aws:iam::account-1:root",
             "arn:aws:iam::account-2:user/user-name-with-path",
             "arn:aws:iam::account-3:role/role-name-with-path",
             ...
           ],
           "Action": [
             "s3:GetObject",
             "s3:GetObjectAcl",
             "s3:GetObjectTagging",
             "s3:ListBucket",
             "s3:GetBucketLocation"
           ],
           "Resource": [
             "arn:aws:s3:::oracle-media-bucket",
             "arn:aws:s3:::oracle-media-bucket/*"
           ]
       }
     ]
   }
   ```
4. Attach the policy to your media bucket.

In the following example, `oracle-media-bucket` is the name of the S3 bucket that contains your installation files, and `my-policy.json` is the name of your JSON file.

```bash
aws s3api put-bucket-policy \
--bucket oracle-media-bucket \
--policy file://my-policy.json
```

5. Log in to an AWS account in which you intend to create CEVs.

6. Verify that this account can access the media bucket in the AWS account that created it.

```bash
aws s3 ls --query "Buckets[].Name"
```

For more information, see `aws s3 ls` in the `AWS CLI Command Reference`.

7. Create a CEV by following the steps in Creating a CEV (p. 1026).

**Step 5: Prepare the CEV manifest**

A CEV manifest is a JSON document that includes the following:

- (Required) The list of installation .zip files that you uploaded to Amazon S3. RDS Custom applies the patches in the order in which they're listed in the manifest.
- (Optional) Installation parameters that set nondefault values for the Oracle base, Oracle home, and the ID and name of the UNIX/Linux user and group. Be aware that you can't modify the installation parameters for an existing CEV or an existing DB instance. You also can't upgrade from one CEV to another CEV when the installation parameters have different settings.

For sample CEV manifests, see the JSON templates that you downloaded in Step 1 (Optional): Download the manifest templates (p. 1015). You can also review the samples in CEV manifest examples (p. 1023).

**Topics**

- JSON fields in the CEV manifest (p. 1020)
- Creating the CEV manifest (p. 1023)
- CEV manifest examples (p. 1023)

**JSON fields in the CEV manifest**

<table>
<thead>
<tr>
<th>JSON field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MediaImportTemplateVersion</td>
<td>Version of the CEV manifest. The date is in the format YYYY-MM-DD.</td>
</tr>
<tr>
<td>databaseInstallationFileName</td>
<td>Ordered list of installation files for the database.</td>
</tr>
<tr>
<td>opatchFileNames</td>
<td>Ordered list of OPatch installers used for the Oracle DB engine. Only one value is valid. Values for opatchFileNames must start with p6880880_.</td>
</tr>
<tr>
<td>psuRuPatchFileNames</td>
<td>The PSU and RU patches for this database.</td>
</tr>
<tr>
<td>JSON field</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Important</strong></td>
<td>If you include <code>psuRuPatchFileNames</code>, <code>opatchFileNames</code> is required. Values for <code>opatchFileNames</code> must start with <code>p6880880_</code>.</td>
</tr>
<tr>
<td><strong>OtherPatchFileNames</strong></td>
<td>The patches that aren't in the list of PSU and RU patches. RDS Custom applies these patches after applying the PSU and RU patches.</td>
</tr>
<tr>
<td></td>
<td><strong>Important</strong> If you include <code>OtherPatchFileNames</code>, <code>opatchFileNames</code> is required. Values for <code>opatchFileNames</code> must start with <code>p6880880_</code>.</td>
</tr>
<tr>
<td>JSON field</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>installationParameters</td>
<td>Nondefault settings for the Oracle base, Oracle home, and the ID and name of the UNIX/Linux user and group. You can set the following parameters:</td>
</tr>
<tr>
<td>oracleBase</td>
<td>The directory under which your Oracle binaries are installed. It is the mount point of the binary volume that stores your files. The Oracle base directory can include multiple Oracle homes. For example, if <code>/home/oracle/oracle.19.0.0.0.ru-2020-04.rur-2020-04.r1.EE.1</code> is one of your Oracle home directories, then <code>/home/oracle</code> is the Oracle base directory. A user-specified Oracle base directory is not a symbolic link. If you don't specify the Oracle base, the default directory is <code>/rdsdbbin</code>.</td>
</tr>
<tr>
<td>oracleHome</td>
<td>The directory in which your Oracle database binaries are installed. For example, if you specify <code>/home/oracle/</code> as your Oracle base, then you might specify <code>/home/oracle/oracle.19.0.0.0.ru-2020-04.rur-2020-04.r1.EE.1/</code> as your Oracle home. A user-specified Oracle home directory is not a symbolic link. The Oracle home value is referenced by the <code>$ORACLE_HOME</code> environment variable. If you don't specify the Oracle home, the default naming format is <code>/rdsdbbin/oracle.maj...version.custom.r1.engine-edition.1</code>.</td>
</tr>
<tr>
<td>unixName</td>
<td>The name of the UNIX user that owns the Oracle software. RDS Custom assumes this user when running local database commands. If you specify both <code>unixUid</code> and <code>unixName</code>, RDS Custom creates the user if it doesn't exist, and then assigns the UID to the user if it's not the same as the initial UID. The default user name is <code>rdsdb</code>.</td>
</tr>
<tr>
<td>unixUid</td>
<td>The ID (UID) of the UNIX user that owns the Oracle software. If you specify both <code>unixUid</code> and <code>unixName</code>, RDS Custom creates the user if it doesn't exist, and then assigns the UID to the user if it's not the same as the initial UID. The default UID is 61001. This is the UID of the user <code>rdsdb</code>.</td>
</tr>
<tr>
<td>unixGroupName</td>
<td>The name of the UNIX group. The UNIX user that owns the Oracle software belongs to this group. The default group name is <code>rdsdb</code>.</td>
</tr>
<tr>
<td>unixGroupID</td>
<td>The ID of the UNIX group to which the UNIX user belongs. The default group ID is 1000. This is the ID of the group <code>rdsdb</code>.</td>
</tr>
</tbody>
</table>
Each Oracle Database release has a different list of supported installation files. When you create your
CEV manifest, make sure to specify only files that are supported by RDS Custom for Oracle. Otherwise,
CEV creation fails with an error. All patches listed in Release notes for Amazon Relational Database
Service (Amazon RDS) for Oracle are supported.

Creating the CEV manifest

To create a CEV manifest

1. List all installation files that you plan to apply, in the order that you want to apply them.
2. Correlate the installation files with the JSON fields described in JSON fields in the CEV
manifest (p. 1020).
3. Do either of the following:
   • Create the CEV manifest as a JSON text file.
   • Edit the CEV manifest template when you create the CEV in the console. For more information, see
     Creating a CEV (p. 1026).

CEV manifest examples

The following examples show CEV manifest files for different Oracle Database releases. If you include a
JSON field in your manifest, make sure that it isn't empty. For example, the following CEV manifest isn't
valid because otherPatchFileNames is empty.

```
{
  "mediaImportTemplateVersion": "2020-08-14",
  "databaseInstallationFileNames": [
    "V982063-01.zip"
  ],
  "opatchFileNames": [
    "p6880880_190000_Linux-x86-64.zip"
  ],
  "psuRuPatchFileNames": [
    "p32126828_190000_Linux-x86-64.zip"
  ],
  "otherPatchFileNames": []
}
```

Topics

- Sample CEV manifest for Oracle Database 12c Release 1 (12.1) (p. 1023)
- Sample CEV manifest for Oracle Database 12c Release 2 (12.2) (p. 1024)
- Sample CEV manifest for Oracle Database 18c (p. 1025)
- Sample CEV manifest for Oracle Database 19c (p. 1026)

Example Sample CEV manifest for Oracle Database 12c Release 1 (12.1)

In the following example for the July 2021 PSU for Oracle Database 12c Release 1 (12.1), RDS Custom
applies the patches in the order specified. Thus, RDS Custom applies p32768233, then p32876425, then
p18759211, and so on. The example sets new values for the UNIX user and group, and the Oracle home
and Oracle base.

```
{
  "mediaImportTemplateVersion": "2020-08-14",
  "databaseInstallationFileNames": [
    "V982063-01.zip"
  ],
  "opatchFileNames": [
    "p6880880_190000_Linux-x86-64.zip"
  ],
  "psuRuPatchFileNames": [
    "p32126828_190000_Linux-x86-64.zip"
  ],
  "otherPatchFileNames": []
}
```
Example Sample CEV manifest for Oracle Database 12c Release 2 (12.2)

In following example for the October 2021 PSU for Oracle Database 12c Release 2 (12.2), RDS Custom applies p33261817, then p33192662, then p29213893, and so on. The example sets new values for the UNIX user and group, and the Oracle home and Oracle base.

```json
{
    "mediaImportTemplateVersion": "2020-08-14",
    "databaseInstallationFileNames": [
        "V839960-01.zip"
    ],

        "p264835919_121020_Linux-x86-64.zip",
        "p23262847_12102201020_Linux-x86-64.zip",
        "p21171382_12102201020_Generic.zip",
        "p21091901_12102210720_Linux-x86-64.zip",
        "p33013352_12102210720_Linux-x86-64.zip",
        "p25015302_12102210720_Linux-x86-64.zip",
        "p23711335_12102191015_Generic.zip",
        "p19504946_121020_Linux-x86-64.zip"
    ],
    "installationParameters": {
        "unixGroupName": "dba",
        "unixGroupId": 12345,
        "unixUname": "oracle",
        "unixUid": 12345,
        "oracleHome": "/home/oracle/oracle.12.1.0.2",
        "oracleBase": "/home/oracle"
    }
}
```
Example Sample CEV manifest for Oracle Database 18c

In following example for the October 2021 PSU for Oracle Database 18c, RDS Custom applies p32126855, then p28730253, then p27539475, and so on. The example sets new values for the UNIX user and group, and the Oracle home and Oracle base.

```json
{
  "mediaImportTemplateVersion": "2020-08-14",
  "databaseInstallationFileNames": [
    "V978967-01.zip"
  ],
  "opatchFileNames": [
    "p6880880_180000_Linux-x86-64.zip"
  ],
  "psuRuPatchFileNames": [
    "p32126855_180000_Linux-x86-64.zip"
  ],
  "otherPatchFileNames": [
    "p28730253_180000_Linux-x86-64.zip",

Example Sample CEV manifest for Oracle Database 19c

In the following example for Oracle Database 19c, RDS Custom applies p32126828, then p29213893, then p29782284, and so on. The example sets new values for the UNIX user and group, and the Oracle home and Oracle base.

```

    ],
    "installationParameters": {
        "unixGroupName": "dba",
        "unixGroupId": 12345,
        "unixUname": "oracle",
        "unixUid": 12345,
        "oracleHome": "/home/oracle/oracle.19.0.0.0.ru-2020-04.rur-2020-04.r1.EE.1",
        "oracleBase": "/home/oracle"
    }
}
```

**Step 6 (Optional): Validate the CEV manifest**

Optionally, verify that manifest is a valid JSON file by running the `json.tool` Python script. For example, if you change into the directory containing a CEV manifest named `manifest.json`, run the following command.

```
python -m json.tool < manifest.json
```

**Step 7: Add necessary IAM permissions**

Make sure that the IAM principal that creates the CEV has the necessary policies described in Step 4: **Grant required permissions to your IAM user or role (p. 1012)**.

**Creating a CEV**

You can create a CEV using the AWS Management Console or the AWS CLI. Specify either the multitenant or non-multitenant architecture. For more information, see Multitenant architecture considerations (p. 1035).
Make sure that the Amazon S3 bucket containing your installation files is in the same AWS Region as your CEV. Otherwise, the process to create a CEV fails.

Typically, creating a CEV takes about two hours. After the CEV is created, you can use it to create an RDS Custom DB instance. For more information, see Creating an RDS Custom for Oracle DB instance (p. 1035).

Console

To create a CEV

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Custom engine versions.

   The Custom engine versions page shows all CEVs that currently exist. If you haven't created any CEVs, the page is empty.
3. Choose Create custom engine version.
4. In Engine options, do the following:
   a. For Engine type, choose Oracle.
   b. For Architecture settings, optionally choose Multitenant architecture to create a Multitenant CEV, which uses the engine custom-oracle-ee-cdb. You can create an RDS Custom for Oracle CDB with a Multitenant CEV only. If you don't choose this option, your CEV is a non-CDB, which uses the engine custom-oracle-ee.

      Note
      The architecture that you choose is a permanent characteristic of your CEV. You can't modify your CEV to use a different architecture later.
   c. For Engine version, choose the major engine version.
5. In Version details, do the following:
   a. Enter a valid name in Custom engine version name.

      The name format is major-engine-version.customized_string. You can use 1–50 alphanumeric characters, underscores, dashes, and periods. For example, you might enter the name 19.cdb_cev1.
   b. (Optional) Enter a description for your CEV.
6. In Installation media, do the following:
   a. (Optional) For AMI ID, enter an AMI that you previously used to create a CEV. To obtain valid AMI IDs, use either of the following techniques:
      
      • In the console, choose Custom engine versions in the left navigation pane, and choose the name of a CEV. The AMI ID used by the CEV appears in the Configuration tab.
      
      • In the AWS CLI, use the describe-db-engine-versions command. Search the output for ImageID.

      If you don't enter an AMI ID, RDS Custom uses the most recent available AMI.
   b. For S3 location of manifest files, enter the location of the Amazon S3 bucket that you specified in Step 3: Upload your installation files to Amazon S3 (p. 1017). For example, enter s3://my-custom-installation-files/806242271698/cev1/.
   c. For CEV manifest, enter the JSON manifest that you created in Creating the CEV manifest (p. 1023).
7. In the KMS key section, select Enter a key ARN to list the available AWS KMS keys. Then select your KMS key from the list.
An AWS KMS key is required for RDS Custom. For more information, see Step 1: Create or reuse a symmetric encryption AWS KMS key (p. 1003).

8. (Optional) Choose Add new tag to create a key-value pair for your CEV.

9. Choose Create custom engine version.

If the CEV manifest has an invalid form, the console displays Error validating the CEV manifest. Fix the problems, and try again.

The Custom engine versions page appears. Your CEV is shown with the status Creating. The process to create the CEV takes approximately two hours.

AWS CLI

To create a CEV by using the AWS CLI, run the create-custom-db-engine-version command.

The following options are required:

- --engine engine-type, where engine-type is either custom-oracle-ee-cdb for a CDB or custom-oracle-ee for a non-CDB. You can create CDBs only from a CEV created with custom-oracle-ee-cdb. You can create non-CDBs only from a CEV created with custom-oracle-ee.
- --engine-version major-engine-version.customized_string
- --kms-key-id
- --manifest manifest_string or --manifest file:file_name

Newline characters aren't permitted in manifest_string. Make sure to escape double quotes (") in the JSON code by prefixing them with a backslash (\).

The following example shows the manifest_string for 19c from Step 5: Prepare the CEV manifest (p. 1020). The example sets new values for the Oracle base, Oracle home, and the ID and name of the UNIX/Linux user and group. If you copy this string, remove all newline characters before pasting it into your command.

```
{"mediaImportTemplateVersion": ":2020-08-14",
"databaseInstallationFileNames": ["V982063-01.zip"],
"opatchFileNames": ["p6880880_190000_Linux-x86-64.zip"],
"psuRuPatchFileNames": ["p32126828_190000_Linux-x86-64.zip"],
"otherPatchFileNames": ["p29213893_1910000DBRU_Generic.zip"],
"p29782284_1910000DBRU_Generic.zip","p28730253_190000_Linux-x86-64.zip",
"p29374604_1910000DBRU_Generic.zip","p28852325_190000_Linux-x86-64.zip",
"p29997937_190000_Linux-x86-64.zip","p31335037_190000_Linux-x86-64.zip","p31335142_190000_Generic.zip"]
"installationParameters":{
  "unixGroupName": "dba",
  "unixUname": "oracle",
  "oracleHome": "/home/oracle/oracle.19.0.0.0.ru-2020-04.rur-2020-04.r1.EE.1",
  "oracleBase": "/home/oracle/oracle.19.0.0.0.ru-2020-04.rur-2020-04.r1.EE.1"
}
```

- --database-installation-files-s3-bucket-name s3-bucket-name, where s3-bucket-name is the bucket name that you specified in Step 3: Upload your installation files to Amazon S3 (p. 1017). The AWS Region in which you run create-custom-db-engine-version must be the same Region as your Amazon S3 bucket.

You can also specify the following options:

- --description my-cev-description
- --database-installation-files-s3-prefix prefix, where prefix is the folder name that you specified in Step 3: Upload your installation files to Amazon S3 (p. 1017).
• `--image-id ami-id`, where `ami-id` is an AMI ID that want to reuse. To find valid IDs, run the `describe-db-engine-versions` command, and then search the output for `ImageID`. By default, RDS Custom for Oracle uses the most recent available AMI.

The following example creates a Multitenant CEV named `19.cdb_cev1`. The example reuses an existing AMI rather than use the latest available AMI. Make sure that the name of your CEV starts with the major engine version number.

Example

For Linux, macOS, or Unix:

```bash
aws rds create-custom-db-engine-version \
  --engine custom-oracle-ee-cdb \
  --engine-version 19.cdb_cev1 \
  --database-installation-files-s3-bucket-name us-east-1-123456789012-custom-installation-files \
  --database-installation-files-s3-prefix 123456789012/cev1 \
  --kms-key-id my-kms-key \
  --description "test cev" \
  --manifest manifest_string \
  --image-id ami-012a345678901bcde
```

For Windows:

```bash
aws rds create-custom-db-engine-version ^ \
  --engine custom-oracle-ee-cdb ^ \
  --engine-version 19.cdb_cev1 ^ \
  --database-installation-files-s3-bucket-name us-east-1-123456789012-custom-installation-files ^ \
  --database-installation-files-s3-prefix 123456789012/cev1 ^ \
  --kms-key-id my-kms-key ^ \
  --description "test cev" ^ \
  --manifest manifest_string ^ \
  --image-id ami-012a345678901bcde
```

Example

Get details about your CEV by using the `describe-db-engine-versions` command.

```bash
aws rds describe-db-engine-versions \
  --engine custom-oracle-ee-cdb \
  --include-all
```

The following partial sample output shows the engine, parameter groups, manifest, and other information.

```json
{
  "DBEngineVersions": [
    {
      "Engine": "custom-oracle-ee-cdb",
      "EngineVersion": "19.cdb_cev1",
      "DBParameterGroupFamily": "custom-oracle-ee-cdb-19",
      "DBEngineDescription": "Containerized Database for Oracle Custom EE",
      "DBEngineVersionDescription": "test cev",
      "Image": {
        "ImageId": "ami-012a345678901bcde",
        "Status": "active"
      }
    }
  ]
}
```
Failure to create a CEV

If the process to create a CEV fails, RDS Custom issues RDS-EVENT-0198 with the message Creation failed for custom engine version major-engine-version.cev_name, and includes details about the failure. For example, the event prints missing files.

You can't modify a failed CEV. You can only delete it, then try again to create a CEV after fixing the causes of the failure. For information about troubleshooting the reasons for CEV creation failure, see Troubleshooting custom engine version creation for RDS Custom for Oracle (p. 1079).

Modifying CEV status

You can modify a CEV using the AWS Management Console or the AWS CLI. You can modify the CEV description or its availability status. Your CEV has one of the following status values:

- available – You can use this CEV to create a new RDS Custom DB instance or upgrade a DB instance. This is the default status for a newly created CEV.
- inactive – You can't create or upgrade an RDS Custom instance with this CEV. You can't restore a DB snapshot to create a new RDS Custom DB instance with this CEV.

You can change the CEV from any supported status to any other supported status. You might change status to prevent the accidental use of a CEV or make a discontinued CEV eligible for use again. For example, you might change the status of your CEV from available to inactive, and from inactive back to available.

Console

To modify a CEV

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Custom engine versions.
3. Choose a CEV whose description or status you want to modify.
4. For Actions, choose Modify.
5. Make any of the following changes:
   - For **CEV status settings**, choose a new availability status.
For Version description, enter a new description.

6. Choose Modify CEV.

If the CEV is in use, the console displays You can't modify the CEV status. Fix the problems, and try again.

The Custom engine versions page appears.

AWS CLI

To modify a CEV by using the AWS CLI, run the modify-custom-db-engine-version command. You can find CEVs to modify by running the describe-db-engine-versions command.

The following options are required:

• --engine custom-oracle-ee
• --engine-version cev, where cev is the name of the custom engine version that you want to modify
• --status status, where status is the availability status that you want to assign to the CEV

The following example changes a CEV named 19.my_cev1 from its current status to inactive.

Example

For Linux, macOS, or Unix:

```
aws rds modify-custom-db-engine-version \\
--engine custom-oracle-ee \\
--engine-version 19.my_cev1 \\
--status inactive
```

For Windows:

```
aws rds modify-custom-db-engine-version ^
--engine custom-oracle-ee ^
--engine-version 19.my_cev1 ^
--status inactive
```

Viewing CEV details

You can view details about your CEV manifest and the command used to create your CEV by using the AWS Management Console or the AWS CLI.

Console

To view CEV details

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Custom engine versions.

   The Custom engine versions page shows all CEVs that currently exist. If you haven't created any CEVs, the page is empty.
3. Choose the name of the CEV that you want to view.
4. **Choose Configuration** to view the installation parameters specified in your manifest.

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Databases</th>
<th>Snapshots</th>
<th>Manifest</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Configuration</strong></td>
<td></td>
<td></td>
<td></td>
</tr>

<td></td>
</tr>
</tbody>
</table>

AWS CLI

To view details about a CEV by using the AWS CLI, run the `describe-db-engine-versions` command.

The following options are required:

- `--engine custom-oracle-ee`
- `--engine-version major-engine-version.customized_string`

The following example creates a CEV named `19.my_cev1`. Make sure that the name of your CEV starts with the major engine version number.

**Example**

For Linux, macOS, or Unix:
aws rds describe-db-engine-versions \
  --engine custom-oracle-ee \
  --engine-version 19.my_cev1

For Windows:

aws rds describe-db-engine-versions ^ \
  --engine custom-oracle-ee ^ \
  --engine-version 19.my_cev1

The following partial sample output shows the engine, parameter groups, manifest, and other information.

```

```

Deleting a CEV

You can delete a CEV using the AWS Management Console or the AWS CLI. Typically, deletion takes a few minutes.

To delete a CEV, it can't be in use by any of the following:

- An RDS Custom DB instance
- A snapshot of an RDS Custom DB instance
- An automated backup of your RDS Custom DB instance
To delete a CEV

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Custom engine versions.
3. Choose a CEV whose description or status you want to delete.
4. For Actions, choose Delete.
   
   The Delete cev_name? dialog box appears.
5. Enter delete me, and then choose Delete.

   In the Custom engine versions page, the banner shows that your CEV is being deleted.

AWS CLI

To delete a CEV by using the AWS CLI, run the delete-custom-db-engine-version command.

The following options are required:

- --engine custom-oracle-ee
- --engine-version cev, where cev is the name of the custom engine version to be deleted

The following example deletes a CEV named 19.my_cev1.

Example

For Linux, macOS, or Unix:

```
aws rds delete-custom-db-engine-version \
   --engine custom-oracle-ee \
   --engine-version 19.my_cev1
```  

For Windows:

```
aws rds delete-custom-db-engine-version ^
   --engine custom-oracle-ee ^
   --engine-version 19.my_cev1
```
Configuring a DB instance for Amazon RDS Custom for Oracle

You can create an RDS Custom DB instance, and then connect to it using Secure Shell (SSH) or AWS Systems Manager.

Topics

- Multitenant architecture considerations (p. 1035)
- Creating an RDS Custom for Oracle DB instance (p. 1035)
- RDS Custom service-linked role (p. 1040)
- Connecting to your RDS Custom DB instance using Session Manager (p. 1040)
- Connecting to your RDS Custom DB instance using SSH (p. 1041)
- Logging in to your RDS Custom for Oracle database as SYS (p. 1045)
- Installing additional software components on your RDS Custom for Oracle DB instance (p. 1046)

Multitenant architecture considerations

If you create an Amazon RDS Custom for Oracle DB instance with the multitenant architecture (custom-oracle-ee-cdb engine type), your database is a container database (CDB). If you don't specify the multitenant architecture, your database is a traditional non-CDB that uses the custom-oracle-ee engine type. A non-CDB can't contain pluggable databases (PDBs). For more information, see Database architecture for Amazon RDS Custom for Oracle (p. 997).

When you create an RDS Custom for Oracle CDB instance, consider the following:

- You can create a multitenant database only from an Oracle Database 19c CEV.
- You can create a CDB instance only if the CEV uses the custom-oracle-ee-cdb engine type.
- By default, your CDB is named RDSCDB, which is also the name of the Oracle System ID (Oracle SID). You can choose a different name.
- You CDB contains only one initial PDB. The PDB name defaults to ORCL. You can choose a different name for your initial PDB, but the Oracle SID and the PDB name can't be the same.
- RDS Custom for Oracle doesn't supply APIs for PDBs. To create additional PDBs, use the Oracle SQL command `CREATE PLUGGABLE DATABASE`. RDS Custom for Oracle doesn't restrict the number of PDBs that you can create. In general, you are responsible for creating and managing PDBs, as in an on-premises deployment.
- If you create a PDB using Oracle SQL, we recommend that you take a manual snapshot afterward in case you need to perform point-in-time recovery (PITR).
- You can't rename existing PDBs using Amazon RDS APIs. You also can't rename the CDB using the `modify-db-instance` command.
- The open mode for the CDB root is `READ WRITE` on the primary and `MOUNTED` on a mounted standby database. RDS Custom for Oracle attempts to open all PDBs when opening the CDB. If RDS Custom for Oracle can't open all PDBs, it issues the event `tenant database shutdown`.

Creating an RDS Custom for Oracle DB instance

Create an Amazon RDS Custom for Oracle DB instance using either the AWS Management Console or the AWS CLI. The procedure is similar to the procedure for creating an Amazon RDS DB instance. For more information, see Creating an Amazon RDS DB instance (p. 300).
If you included installation parameters in your CEV manifest, then your DB instance uses the Oracle base, Oracle home, and the ID and name of the UNIX/Linux user and group that you specified. The oratab file, which is created by Oracle Database during installation, points to the real installation location rather than to a symbolic link. When RDS Custom for Oracle runs commands, it runs as the configured OS user rather than the default user rdsdb. For more information, see Step 5: Prepare the CEV manifest (p. 1020).

Before you attempt to create or connect to an RDS Custom DB instance, complete the tasks in Setting up your environment for Amazon RDS Custom for Oracle (p. 1002).

Console

To create an RDS Custom for Oracle DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose Create database.
4. In Choose a database creation method, select Standard create.
5. In the Engine options section, do the following:
   a. For Engine type, choose Oracle.
   b. For Database management type, choose Amazon RDS Custom.
   c. For Architecture settings, do one of the following:
      • Select Multitenant architecture to create a container database (CDB). At creation, your CDB contains one PDB seed and one initial PDB.
        Note
        The Multitenant architecture setting is supported only for Oracle Database 19c.
      • Clear Multitenant architecture to create a non-CDB. A non-CDB can't contain PDBs.
   e. For Custom engine version, choose an existing RDS Custom custom engine version (CEV). A CEV has the following format: major-engine-version.customized_string. An example identifier is 19.cdb_cev1.
      If you chose Multitenant architecture in the previous step, you can only specify CEV that uses the custom-oracle-ee-cdb engine type. The console filters out CEVs that were created with the custom-oracle-ee engine type.
6. In Templates, choose Production.
7. In the Settings section, do the following:
   a. For DB instance identifier, enter a unique name for your DB instance.
   b. For Master username, enter a username. You can retrieve this value from the console later.
      When you connect to a non-CDB, the master user is the user for the non-CDB. When you connect to a CDB, the master user is the user for the PDB. To connect to the CDB root, log in to the host, start a SQL client, and create an administrative user with SQL commands.
   c. Clear Auto generate a password.
8. Choose a DB instance class.
   For supported classes, see DB instance class support for RDS Custom for Oracle (p. 999).
9. In the Storage section, do the following:
   a. For Storage type, choose an SSD type: io1, gp2, or gp3. You have the following additional options:
• For io1 or gp3, choose a rate for **Provisioned IOPS**. The default is 1000 for io1 and 12000 for gp3.
  
  • For gp3, choose a rate for **Storage throughput**. The default is 500 MiBps.

b. For **Allocated storage**, choose a storage size. The default is 40 GiB.

10. For **Connectivity**, specify your **Virtual private cloud (VPC)**, **DB subnet group**, and **VPC security group (firewall)**.

11. For **RDS Custom security**, do the following:

  a. For **IAM instance profile**, choose the instance profile for your RDS Custom for Oracle DB instance.

     The IAM instance profile must begin with AWSRDSCustom, for example `AWSRDSCustomInstanceProfileForRdsCustomInstance`.

  b. For **Encryption**, choose **Enter a key ARN** to list the available AWS KMS keys. Then choose your key from the list.

     An AWS KMS key is required for RDS Custom. For more information, see [Step 1: Create or reuse a symmetric encryption AWS KMS key](p. 1003).

12. For **Database options**, do the following:

  a. (Optional) For **System ID (SID)**, enter a value for the Oracle SID, which is also the name of your CDB. The SID is the name of the Oracle database instance that manages your database files. In this context, the term "Oracle database instance" refers exclusively to the system global area (SGA) and Oracle background processes. If you don't specify a SID, the value defaults to `RDSCDB`.

  b. (Optional) For **Initial database name**, enter a name. The default value is `ORCL`. In the multitenant architecture, the initial database name is the PDB name.

     **Note**
     The SID and PDB name must be different.

  c. For **Backup retention period** choose a value. You can't choose 0 days.

  d. For the remaining sections, specify your preferred RDS Custom DB instance settings. For information about each setting, see [Settings for DB instances](p. 308). The following settings don't appear in the console and aren't supported:

     • Processor features
     • Storage autoscaling
     • Availability & durability
     • **Password and Kerberos authentication** option in **Database authentication** (only **Password authentication** is supported)
     • **Database options** group in **Additional configuration**
     • **Performance Insights**
     • **Log exports**
     • **Enable auto minor version upgrade**
     • **Deletion protection**

13. Choose **Create database**.

    **Important**
    When you create an RDS Custom for Oracle DB instance, you might receive the following error: The service-linked role is in the process of being created. Try again later. If you do, wait a few minutes and then try again to create the DB instance.

    The **View credential details** button appears on the **Databases** page.
To view the master user name and password for the RDS Custom DB instance, choose **View credential details**.

To connect to the DB instance as the master user, use the user name and password that appear.

**Important**
You can't view the master user password again in the console. If you don't record it, you might have to change it. To change the master user password after the RDS Custom DB instance is available, log in to the database and run an `ALTER USER` command. You can't reset the password using the **Modify** option in the console.

14. Choose **Databases** to view the list of RDS Custom DB instances.
15. Choose the RDS Custom DB instance that you just created.

On the RDS console, the details for the new RDS Custom DB instance appear:

- The DB instance has a status of **creating** until the RDS Custom DB instance is created and ready for use. When the state changes to **available**, you can connect to the DB instance. Depending on the instance class and storage allocated, it can take several minutes for the new DB instance to be available.
- **Role** has the value **Instance (RDS Custom)**.
- **RDS Custom automation mode** has the value **Full automation**. This setting means that the DB instance provides automatic monitoring and instance recovery.

**AWS CLI**

You create an RDS Custom DB instance by using the **create-db-instance** AWS CLI command.

The following options are required:

- `--db-instance-identifier`
- `--db-instance-class` (for a list of supported instance classes, see [DB instance class support for RDS Custom for Oracle](p. 999))
- `--engine engine-type` (where `engine-type` is `custom-oracle-ee-cdb` for a CDB and `custom-oracle-ee` for a non-CDB)
- `--engine-version cev` (where `cev` is the name of the custom engine version that you specified in [Creating a CEV](p. 1026))
- `--kms-key-id my-kms-key`
- `--backup-retention-period days` (where `days` is a value greater than 0)
- `--no-auto-minor-version-upgrade`
- `--custom-iam-instance-profile AWSRDSCustomInstanceRole-us-east-1` (where `region` is the AWS Region where you are creating your DB instance)

The following example creates an RDS Custom DB instance named `my-cdb-instance`. The database is a CDB with the nondefault name `MYCDB`. The nondefault PDB name is `MYPDB`. The backup retention period is three days.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance
  --engine custom-oracle-ee-cdb
  --db-instance-identifier my-cdb-instance
  --engine-version 19.cdb_cev1
```

1038
Configuring an RDS Custom for Oracle DB instance

```
--db-name MYPDB 
--db-system-id MYCDB 
--allocated-storage 250 
--db-instance-class db.m5.xlarge 
--db-subnet-group mydbsubnetgroup 
--master-username myawsuser 
--master-user-password mypassword 
--backup-retention-period 3 
--port 8200 
--license-model bring-your-own-license 
--kms-key-id my-kms-key 
--no-auto-minor-version-upgrade 
--custom-iam-instance-profile AWSRDSCustomInstanceRole-us-east-1
```

For Windows:

```
aws rds create-db-instance 
  --engine custom-oracle-ee-cdb 
  --db-instance-identifier my-cdb-instance 
  --engine-version 19.cdb_cev1 
  --db-name MYPDB 
  --db-system-id MYCDB 
  --allocated-storage 250 
  --db-instance-class db.m5.xlarge 
  --db-subnet-group mydbsubnetgroup 
  --master-username myawsuser 
  --master-user-password mypassword 
  --backup-retention-period 3 
  --port 8200 
  --license-model bring-your-own-license 
  --kms-key-id my-kms-key 
  --no-auto-minor-version-upgrade 
  --custom-iam-instance-profile AWSRDSCustomInstanceRole-us-east-1
```

**Note**

Specify a password other than the prompt shown here as a security best practice.

Get details about your instance by using the `describe-db-instances` command.

**Example**

```
aws rds describe-db-instances --db-instance-identifier my-cdb-instance
```

The following partial output shows the engine, parameter groups, and other information.

```
{
  "DBInstanceIdentifier": "my-cdb-instance",
  "DBInstanceClass": "db.m5.xlarge",
  "Engine": "custom-oracle-ee-cdb",
  "DBInstanceStatus": "available",
  "MasterUsername": "admin",
  "DBName": "MYPDB",
  "DBSystemID": "MYCDB",
  "Endpoint": {
    "Address": "my-cdb-instance.abcdefghijkl.us-east-1.rds.amazonaws.com",
    "Port": 1521,
    "HostedZoneId": "A1B2CDEFGH34IJ"
  },
  "AllocatedStorage": 100,
  "InstanceCreateTime": "2023-04-12T18:52:16.353000+00:00",
  "PreferredBackupWindow": "08:46-09:16",
```
"BackupRetentionPeriod": 7,
"DBSecurityGroups": [],
"VpcSecurityGroups": [
  {
    "VpcSecurityGroupId": "sg-0a1bcd2e",
    "Status": "active"
  }
],
"DBParameterGroups": [
  {
    "DBParameterGroupName": "default.custom-oracle-ee-cdb-19",
    "ParameterApplyStatus": "in-sync"
  }
],
...

RDS Custom service-linked role

A service-linked role gives Amazon RDS Custom access to resources in your AWS account. It makes using RDS Custom easier because you don't have to manually add the necessary permissions. RDS Custom defines the permissions of its service-linked roles, and unless defined otherwise, only RDS Custom can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy can't be attached to any other IAM entity.

When you create an RDS Custom DB instance, both the Amazon RDS and RDS Custom service-linked roles are created (if they don't already exist) and used. For more information, see Using service-linked roles for Amazon RDS (p. 2701).

The first time that you create an RDS Custom for Oracle DB instance, you might receive the following error: The service-linked role is in the process of being created. Try again later. If you do, wait a few minutes and then try again to create the DB instance.

Connecting to your RDS Custom DB instance using Session Manager

After you create your RDS Custom DB instance, you can connect to it using AWS Systems Manager Session Manager. This is the preferred technique when your DB instance isn't publicly accessible.

Session Manager allows you to access Amazon EC2 instances through a browser-based shell or through the AWS CLI. For more information, see AWS Systems Manager Session Manager.

Console

To connect to your DB instance using Session Manager

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the RDS Custom DB instance to which you want to connect.
3. Choose Configuration.
4. Note the Resource ID for your DB instance. For example, the resource ID might be db-ABCDEFGHIJKLMNOPQRS0123456.
5. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
6. In the navigation pane, choose Instances.
7. Look for the name of your EC2 instance, and then click the instance ID associated with it. For example, the instance ID might be i-abcdefghijklm01234.
8. Choose **Connect**.
9. Choose **Session Manager**.
10. Choose **Connect**.

A window opens for your session.

**AWS CLI**

You can connect to your RDS Custom DB instance using the AWS CLI. This technique requires the Session Manager plugin for the AWS CLI. To learn how to install the plugin, see [Install the Session Manager plugin for the AWS CLI](#).

To find the DB resource ID of your RDS Custom DB instance, use `aws rds describe-db-instances`.

```
aws rds describe-db-instances \
  --query 'DBInstances[*].[DBInstanceIdentifier,DbiResourceId]' \
  --output text
```

The following sample output shows the resource ID for your RDS Custom instance. The prefix is `db-`.

```
db-ABCDEFGHIJKLMNOPQRSTUVWXYZ0123456
```

To find the EC2 instance ID of your DB instance, use `aws ec2 describe-instances`. The following example uses `db-ABCDEFGHIJKLMNOPQRSTUVWXYZ0123456` for the resource ID.

```
aws ec2 describe-instances \
  --filters "Name=tag:Name,Values=db-ABCDEFGHIJKLMNOPQRSTUVWXYZ0123456" \
  --output text \n  --query 'Reservations[*].Instances[*].InstanceId'
```

The following sample output shows the EC2 instance ID.

```
i-abcdefghijklmnopqrstuvwxyz01234
```

Use the `aws ssm start-session` command, supplying the EC2 instance ID in the `--target` parameter.

```
aws ssm start-session --target "i-abcdefghijklmnopqrstuvwxyz01234"
```

A successful connection looks like the following.

```
Starting session with SessionId: yourid-abcdefghijklmnopqrstuvwxyz 
[ssm-user@ip-123-45-67-89 bin]$
```

### Connecting to your RDS Custom DB instance using SSH

The Secure Shell Protocol (SSH) is a network protocol that supports encrypted communication over an unsecured network. After you create your RDS Custom DB instance, you can connect to it using an ssh client. For more information, see [Connecting to your Linux instance using SSH](#).

Your SSH connection technique depends on whether your DB instance is private, meaning that it doesn't accept connections from the public internet. In this case, you must use SSH tunneling to connect the ssh
utility to your instance. This technique transports data with a dedicated data stream (tunnel) inside an existing SSH session. You can configure SSH tunneling using AWS Systems Manager.

**Note**
Various strategies are supported for accessing private instances. To learn how to connect an ssh client to private instances using bastion hosts, see [Linux Bastion Hosts on AWS](https://docs.aws.amazon.com/ssh/latest/userguide/). To learn how to configure port forwarding, see [Port Forwarding Using AWS Systems Manager Session Manager](https://docs.aws.amazon.com/ssh/latest/userguide/).

If your DB instance is in a public subnet and has the publicly available setting, then no SSH tunneling is required. You can connect with SSH just as would to a public Amazon EC2 instance.

To connect an ssh client to your DB instance, complete the following steps:

1. **Step 1: Configure your DB instance to allow SSH connections**
2. **Step 2: Retrieve your SSH secret key and EC2 instance ID**
3. **Step 3: Connect to your EC2 instance using the ssh utility**

### Step 1: Configure your DB instance to allow SSH connections
To make sure that your DB instance can accept SSH connections, do the following:

- Make sure that your DB instance security group permits inbound connections on port 22 for TCP.
  
  To learn how to configure the security group for your DB instance, see [Controlling access with security groups](https://docs.aws.amazon.com/ssh/latest/userguide/).
- If you don't plan to use SSH tunneling, make sure your DB instance resides in a public subnet and is publicly accessible.

In the console, the relevant field is **Publicly accessible** on the **Connectivity & security** tab of the database details page. To check your settings in the CLI, run the following command:

```bash
aws rds describe-db-instances
   --query 'DBInstances[*].{DBInstanceIdentifier:DBInstanceIdentifier,PubliclyAccessible:PubliclyAccessible}'
   --output table
```

To change the accessibility settings for your DB instance, see [Modifying an Amazon RDS DB instance](https://docs.aws.amazon.com/ssh/latest/userguide/).

### Step 2: Retrieve your SSH secret key and EC2 instance ID
To connect to the DB instance using SSH, you need the SSH key pair associated with the instance. RDS Custom creates the SSH key pair on your behalf, naming it with the prefix `do-not-delete-rds-custom-ssh-privatekey-db-`. AWS Secrets Manager stores your SSH private key as a secret.

Retrieve your SSH secret key using either AWS Management Console or the AWS CLI. If your instance has a public DNS, and you don't intend to use SSH tunneling, then also retrieve the DNS name. You specify the DNS name for public connections.

#### Console

**To retrieve the secret SSH key**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom DB instance to which you want to connect.
3. Choose **Configuration**.

4. Note the **Resource ID** value. For example, the DB instance resource ID might be `db-ABCD0F0GH1JKL0MN0PQR0S0123456`.

5. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

6. In the navigation pane, choose **Instances**.

7. Find the name of your EC2 instance, and choose the instance ID associated with it. For example, the EC2 instance ID might be `i-abcdefgijklm01234`.

8. In **Details**, find **Key pair name**. The pair name includes the DB instance resource ID. For example, the pair name might be `do-not-delete-rds-custom-ssh-privatekey-db-ABCD0F0GH1JKL0MN0PQR0S0123456-0d726c`.

9. If your EC2 instance is public, note the **Public IPv4 DNS**. For the example, the public Domain Name System (DNS) address might be `ec2-12-345-678-901.us-east-2.compute.amazonaws.com`.

11. Choose the secret that has the same name as your key pair.

12. Choose **Retrieve secret value**.

13. Copy the SSH private key into a text file, and then save the file with the `.pem` extension. For example, save the file as `/tmp/do-not-delete-rds-custom-ssh-privatekey-db-ABCD0F0GH1JKL0MN0PQR0S0123456-0d726c.pem`.

**AWS CLI**

To retrieve the SSH private key and save it in a `.pem` file, you can use the AWS CLI.

1. Find the DB resource ID of your RDS Custom DB instance using `aws rds describe-db-instances`.

   ```bash
   aws rds describe-db-instances --query 'DBInstances[*].[DBInstanceIdentifier,DbiResourceId]' --output text
   ``

   The following sample output shows the resource ID for your RDS Custom instance. The prefix is `db-`.

   ```bash
   db-ABCD0F0GH1JKL0MN0PQR0S0123456
   ```

2. Find the EC2 instance ID of your DB instance using `aws ec2 describe-instances`. The following example uses `db-ABCD0F0GH1JKL0MN0PQR0S0123456` for the resource ID.

   ```bash
   aws ec2 describe-instances --filters "Name=tag:Name,Values=db-ABCD0F0GH1JKL0MN0PQR0S0123456" --output text
   --query 'Reservations[*].Instances[*].InstanceId'
   ``

   The following sample output shows the EC2 instance ID.

   ```bash
   i-abcdefgijklm01234
   ```

3. To find the key name, specify the EC2 instance ID. The following example describes EC2 instance `i-0bdc4219e66944afa`.

   ```bash
   aws ec2 describe-instances --instance-ids i-0bdc4219e66944afa --output text
   --query 'Reservations[*].Instances[*].KeyName'
   ```
The following sample output shows the key name, which uses the prefix do-not-delete-rds-custom-ssh-privatekey-.

```bash
do-not-delete-rds-custom-ssh-privatekey-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c
```

4. Save the private key in a .pem file named after the key using `aws secretsmanager`. The following example saves the file in your /tmp directory.

```bash
aws secretsmanager get-secret-value \
  --secret-id do-not-delete-rds-custom-ssh-privatekey-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c \
  --query SecretString \
  --output text >/tmp/do-not-delete-rds-custom-ssh-privatekey-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c.pem
```

**Step 3: Connect to your EC2 instance using the ssh utility**

Your connection technique depends on whether you are connecting to a private DB instance or connecting to a public instance. A private connection requires you to configure SSH tunneling through AWS Systems Manager.

**To connect to an EC2 instance using the ssh utility**

1. For private connections, modify your SSH configuration file to proxy commands to AWS Systems Manager Session Manager. For public connections, skip to Step 2.

   Add the following lines to `~/.ssh/config`. These lines proxy SSH commands for hosts whose names begin with `i-` or `mi-`.

   ```
   Host i-.* mi-.*
   ProxyCommand sh -c "aws ssm start-session --target %h --document-name AWS-StartSSHSession --parameters 'portNumber=%p'"
   ```

2. Change to the directory that contains your .pem file. Using `chmod`, set the permissions to 400.

   ```
cd /tmp
chmod 400 do-not-delete-rds-custom-ssh-privatekey-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c.pem
```

3. Run the ssh utility, specifying the .pem file and either the public DNS name (for public connections) or the EC2 instance ID (for private connections). Log in as user `ec2-user`.

   The following example connects to a public instance using the DNS name `ec2-12-345-678-901.us-east-2.compute.amazonaws.com`.

   ```bash
   ssh -i "do-not-delete-rds-custom-ssh-privatekey-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c.pem" ec2-user@ec2-12-345-678-901.us-east-2.compute.amazonaws.com
   ```

   The following example connects to a private instance using the EC2 instance ID `i-0bdc4219e66944afa`.

   ```bash
   ssh -i "do-not-delete-rds-custom-ssh-privatekey-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c.pem"
   ```
Logging in to your RDS Custom for Oracle database as SYS

After you create your RDS Custom DB instance, you can log in to your Oracle database as user SYS, which gives you SYSDBA privileges. You have the following login options:

- Get the SYS password from Secrets Manager, and specify this password in your SQL client.
- Use OS authentication to log in to your database. In this case, you don’t need a password.

Finding the SYS password for your RDS Custom for Oracle database

You can log in to your Oracle database as SYS or SYSTEM or by specifying the master user name in an API call. The password for SYS and SYSTEM is stored in Secrets Manager. The secret uses the naming format do-not-delete-rds-custom-resource_id-uuid. You can find the password using the AWS Management Console.

**Console**

**To find the SYS password for your database in Secrets Manager**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the RDS console, complete the following steps:
   a. In the navigation pane, choose Databases.
   b. Choose the name of your RDS Custom for Oracle DB instance.
   c. Choose Configuration.
   d. Copy the value underneath Resource ID. For example, you resource ID might be db-ABC12CDE3FGH4I5JKLMNO6PQR7.
4. In the Secrets Manager console, complete the following steps:
   a. In the left navigation pane, choose Secrets.
   b. Filter the secrets by the resource ID that you copied in step 5.
   c. Choose the secret named do-not-delete-rds-custom-resource_id-uuid, where resource_id is the resource ID that you copied in step 5. For example, if your resource ID is db-ABC12CDE3FGH4I5JKLMNO6PQR7, your secret will be named do-not-delete-rds-custom-db-ABC12CDE3FGH4I5JKLMNO6PQR7.
   d. In Secret value, choose Retrieve secret value.
   e. In Key/value, copy the value for password.
5. Install SQL*Plus on your DB instance and log in to your database as SYS. For more information, see Step 3: Connect your SQL client to an Oracle DB instance (p. 231).

Logging in to your RDS Custom for Oracle database using OS authentication

The OS user rdsdb owns the Oracle database binaries. You can switch to the rdsdb user and log in to your RDS Custom for Oracle database without a password.

1. Connect to your DB instance with AWS Systems Manager. For more information, see Connecting to your RDS Custom DB instance using Session Manager (p. 1040).

3. For the latest database version that appears on the web page, copy the .rpm links (not the .zip links) for the Instant Client Basic Package and SQL*Plus Package. For example, the following links are for Oracle Database version 21.9:
   - https://download.oracle.com/otn_software/linux/instantclient/219000/oracle-instantclient-basic-21.9.0.0.0-1.el8.x86_64.rpm
   - https://download.oracle.com/otn_software/linux/instantclient/219000/oracle-instantclient-sqlplus-21.9.0.0.0-1.el8.x86_64.rpm

4. In your SSH session, run the wget command to download the .rpm files from the links that you obtained in the previous step. The following example downloads the .rpm files for Oracle Database version 21.9:
   ```
   wget https://download.oracle.com/otn_software/linux/instantclient/219000/oracle-instantclient-basic-21.9.0.0.0-1.el8.x86_64.rpm
   wget https://download.oracle.com/otn_software/linux/instantclient/219000/oracle-instantclient-sqlplus-21.9.0.0.0-1.el8.x86_64.rpm
   ```

5. Install the packages by running the yum command as follows:
   ```
   sudo yum install oracle-instantclient-*.rpm
   ```

6. Switch to the rdsdb user.
   ```
   sudo su - rdsdb
   ```

7. Log in to your database using OS authentication.
   ```
   $ sqlplus / as sysdba
   SQL*Plus: Release 21.0.0.0.0 - Production on Wed Apr 12 20:11:08 2023
   Version 21.9.0.0.0
   Copyright (c) 1982, 2020, Oracle. All rights reserved.
   
   Connected to:

   ```

## Installing additional software components on your RDS Custom for Oracle DB instance

In a newly created DB instance, your database environment includes Oracle binaries, a database, and a database listener. You might want to install additional software on the host operating system of the DB instance. For example, you might want to install Oracle Application Express (APEX), the Oracle Enterprise Manager (OEM) agent, or the Guardium S-TAP agent. For guidelines and high-level instructions, see the detailed AWS blog post Install additional software components on Amazon RDS Custom for Oracle.
Managing an Amazon RDS Custom for Oracle DB instance

Amazon RDS Custom supports a subset of the usual management tasks for Amazon RDS DB instances. Following, you can find instructions for the supported RDS Custom for Oracle management tasks using the AWS Management Console and the AWS CLI.

Topics

- Working with container databases (CDBs) in RDS Custom for Oracle
- Working with high availability features for RDS Custom for Oracle
- Customizing your RDS Custom environment
- Modifying your RDS Custom for Oracle DB instance
- Changing the time zone of an RDS Custom for Oracle DB instance
- Changing the character set of an RDS Custom for Oracle DB instance
- Setting the NLS_LANG value in RDS Custom for Oracle
- Support for Transparent Data Encryption
- Tagging RDS Custom for Oracle resources
- Deleting an RDS Custom for Oracle DB instance

Working with container databases (CDBs) in RDS Custom for Oracle

You can either create your RDS Custom for Oracle DB instance with the Oracle Multitenant architecture (custom-oracle-ee-cdb engine type) or with the traditional non-CDB architecture (custom-oracle-ee engine type). When you create a container database (CDB), it contains one pluggable database (PDB) and one PDB seed. You can create additional PDBs manually using Oracle SQL.

PDB and CDB names

When you create an RDS Custom for Oracle CDB instance, you specify a name for the initial PDB. By default, your initial PDB is named ORCL. You can choose a different name.

By default, your CDB is named RDSCDB. You can choose a different name. The CDB name is also the name of your Oracle system identifier (SID), which uniquely identifies the memory and processes that manage your CDB. For more information about the Oracle SID, see Oracle System Identifier (SID) in Oracle Database Concepts.

You can't rename existing PDBs using Amazon RDS APIs. You also can't rename the CDB using the modify-db-instance command.

PDB management

In the RDS Custom for Oracle shared responsibility model, you are responsible for managing PDBs and creating any additional PDBs. RDS Custom doesn't restrict the number of PDBs. You can manually create, modify, and delete PDBs by connecting to the CDB root and running a SQL statement. Create PDBs on an Amazon EBS data volume to prevent the DB instance from going outside the support perimeter.

To modify your CDBs or PDBs, complete the following steps:

1. Pause automation to prevent interference with RDS Custom actions.
2. Modify your CDB or PDBs.
3. Back up any modified PDBs.
4. Resume RDS Custom automation.

**Automatic recovery of the CDB root**

RDS Custom keeps the CDB root open in the same way as it keeps a non-CDB open. If the state of the CDB root changes, the monitoring and recovery automation attempts to recover the CDB root to the desired state. You receive RDS event notifications when the root CDB is shut down (RDS-EVENT-0004) or restarted (RDS-EVENT-0006), similar to the non-CDB architecture. RDS Custom attempts to open all PDBs in READ WRITE mode at DB instance startup. If some PDBs can't be opened, RDS Custom publishes the following event: tenant database shutdown.

**Working with high availability features for RDS Custom for Oracle**

To support replication between RDS Custom for Oracle instances, you can configure high availability (HA) with Oracle Data Guard. The primary DB instance automatically synchronizes data to the standby instances.

You can configure your high availability environment in the following ways:

- Configure standby instances in different Availability Zones (AZs) to be resilient to AZ failures.
- Place your standby databases in mounted or read-only mode.
- Fail over or switch over from the primary database to a standby database with no data loss.
- Migrate data by configuring high availability for your on-premises instance, and then failing over or switching over to the RDS Custom standby database.

To learn how to configure high availability, see the whitepaper Build high availability for Amazon RDS Custom for Oracle using read replicas. You can perform the following tasks:

- Use a virtual private network (VPN) tunnel to encrypt data in transit for your high availability instances. Encryption in transit isn't configured automatically by RDS Custom.
- Configure Oracle Fast-Failover Observer (FSFO) to monitor your high availability instances.
- Allow the observer to perform automatic failover when necessary conditions are met.

**Customizing your RDS Custom environment**

RDS Custom for Oracle includes built-in features that allow you to customize your DB instance environment without pausing automation. For example, you can use RDS APIs to customize your environment as follows:

- Create and restore DB snapshots to create a clone environment.
- Create read replicas.
- Modify storage settings.
- Change the CEV to apply release updates

For some customizations, such as changing the time zone or character set, you can't use the RDS APIs. In these cases, you need to change the environment manually by accessing your Amazon EC2 instance as the root user or logging in to your Oracle database as SYSDBA.

To customize your instance manually, you must pause and resume RDS Custom automation. This pause ensures that your customizations don't interfere with RDS Custom automation. In this way, you avoid breaking the support perimeter, which places the instance in the unsupported-configuration state.
until you fix the underlying issues. Pausing and resuming are the only supported automation tasks when you modify an RDS Custom for Oracle DB instance.

**General steps for customizing your RDS Custom environment**

To customize your RDS Custom DB instance, complete the following steps:

1. Pause RDS Custom automation for a specified period using the console or CLI.
2. Identify your underlying Amazon EC2 instance.
3. Connect to your underlying Amazon EC2 instance using SSH keys or AWS Systems Manager.
4. Verify your current configuration settings at the database or operating system layer.

   You can validate your changes by comparing the initial configuration to the changed configuration. Depending on the type of customization, use OS tools or database queries.

5. Customize your RDS Custom for Oracle DB instance as needed.
6. Reboot your instance or database, if required.

   **Note**
   In an on-premises Oracle CDB, you can preserve a specified open mode for PDBs using a built-in command or after a startup trigger. This mechanism brings PDBs to a specified state when the CDB restarts. When opening your CDB, RDS Custom automation discards any user-specified preserved states and attempts to open all PDBs. If RDS Custom can't open all PDBs, the following event is issued: The following PDBs failed to open: list-of-PDBs.

7. Verify your new configuration settings by comparing them with the previous settings.
8. Resume RDS Custom automation in either of the following ways:
   - Resume automation manually.
   - Wait for the pause period to end. In this case, RDS Custom resumes monitoring and instance recovery automatically.

9. Verify the RDS Custom automation framework

   If you followed the preceding steps correctly, RDS Custom starts an automated backup. The status of the instance in the console shows **Available**.

For best practices and step-by-step instructions, see the AWS blog posts Make configuration changes to an Amazon RDS Custom for Oracle instance: Part 1 and Recreate an Amazon RDS Custom for Oracle database: Part 2.

**Pausing and resuming your RDS Custom DB instance**

You can pause and resume automation for your DB instance using the console or CLI.

**Console**

**To pause or resume RDS Custom automation**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom DB instance that you want to modify.
3. Choose **Modify**. The **Modify DB instance** page appears.
4. For **RDS Custom automation mode**, choose one of the following options:
   - **Paused** pauses the monitoring and instance recovery for the RDS Custom DB instance. Enter the pause duration that you want (in minutes) for **Automation mode duration**. The minimum value is 60 minutes (default). The maximum value is 1,440 minutes.
• **Full automation** resumes automation.

5. Choose **Continue** to check the summary of modifications.

   A message indicates that RDS Custom will apply the changes immediately.

6. If your changes are correct, choose **Modify DB instance**. Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

   On the RDS console, the details for the modification appear. If you paused automation, the **Status** of your RDS Custom DB instance indicates **Automation paused**.

7. (Optional) In the navigation pane, choose **Databases**, and then your RDS Custom DB instance.

   In the **Summary** pane, **RDS Custom automation mode** indicates the automation status. If automation is paused, the value is **Paused. Automation resumes in num minutes**.

**AWS CLI**

To pause or resume RDS Custom automation, use the `modify-db-instance` AWS CLI command. Identify the DB instance using the required parameter `--db-instance-identifier`. Control the automation mode with the following parameters:

- `--automation-mode` specifies the pause state of the DB instance. Valid values are `all-paused`, which pauses automation, and `full`, which resumes it.
- `--resume-full-automation-mode-minutes` specifies the duration of the pause. The default value is 60 minutes.

**Note**

Regardless of whether you specify `--no-apply-immediately` or `--apply-immediately`, RDS Custom applies modifications asynchronously as soon as possible.

In the command response, `ResumeFullAutomationModeTime` indicates the resume time as a UTC timestamp. When the automation mode is `all-paused`, you can use `modify-db-instance` to resume automation mode or extend the pause period. No other `modify-db-instance` options are supported.

The following example pauses automation for `my-custom-instance` for 90 minutes.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
   --db-instance-identifier my-custom-instance \
   --automation-mode all-paused \
   --resume-full-automation-mode-minutes 90
```

For Windows:

```bash
aws rds modify-db-instance ^
   --db-instance-identifier my-custom-instance ^
   --automation-mode all-paused ^
   --resume-full-automation-mode-minutes 90
```

The following example extends the pause duration for an extra 30 minutes. The 30 minutes is added to the original time shown in `ResumeFullAutomationModeTime`.

**Example**

For Linux, macOS, or Unix:
aws rds modify-db-instance \\n  --db-instance-identifier *my-custom-instance* \\n  --automation-mode all-paused \\n  --resume-full-automation-mode-minutes 30

For Windows:

aws rds modify-db-instance ^ \\n  --db-instance-identifier *my-custom-instance* ^ \\n  --automation-mode all-paused ^ \\n  --resume-full-automation-mode-minutes 30

The following example resumes full automation for *my-custom-instance*.

**Example**

For Linux, macOS, or Unix:

aws rds modify-db-instance \\n  --db-instance-identifier *my-custom-instance* \\n  --automation-mode full \\n
For Windows:

aws rds modify-db-instance ^ \\n  --db-instance-identifier *my-custom-instance* ^ \\n  --automation-mode full

In the following partial sample output, the pending `AutomationMode` value is full.

```
{

}
Modifying your RDS Custom for Oracle DB instance

Modifying an RDS Custom for Oracle DB instance is similar to modifying an Amazon RDS instance, but you can only do the following:

- Change the DB instance class.
- Increase the allocated storage for your DB instance.
- Change the storage type to io1, gp2, or gp3.
- Change the Provisioned IOPS, if you’re using the io1 or gp3 storage types.

Topics

- [Requirements and limitations when modifying your DB instance storage](#)
- [Requirements and limitations when modifying your DB instance class](#)
- [How RDS Custom creates your DB instance when you modify the instance class](#)
- [Modifying the instance class or storage for your RDS Custom for Oracle DB instance](#)

Requirements and limitations when modifying your DB instance storage

Consider the following requirements and limitations when you modify the storage for an RDS Custom for Oracle DB instance:

- The minimum allocated storage for RDS Custom for Oracle is 40 GiB, and the maximum is 64 TiB.
- As with Amazon RDS, you can’t decrease the allocated storage. This is a limitation of Amazon EBS volumes.
• Storage autoscaling isn't supported for RDS Custom DB instances.

• Any storage volumes that you attach manually to your RDS Custom DB instance are outside the support perimeter.

For more information, see RDS Custom support perimeter (p. 985).

• Magnetic (standard) Amazon EBS storage isn't supported for RDS Custom. You can choose only the io1, gp2, or gp3 SSD storage types.

For more information about Amazon EBS storage, see Amazon RDS DB instance storage (p. 101).
For general information about storage modification, see Working with storage for Amazon RDS DB instances (p. 478).

Requirements and limitations when modifying your DB instance class

Consider the following requirements and limitations when you modify the instance class for an RDS Custom for Oracle DB instance:

• Your DB instance must be in the available state.

• Your DB instance must have a minimum of 100 MiB of free space on the root volume, data volume, and binary volume.

• You can assign only a single elastic IP (EIP) to your RDS Custom for Oracle DB instance when using the default elastic network interface (ENI). If you attach multiple ENIs to your DB instance, the modify operation fails.

• All RDS Custom for Oracle tags must be present.

• If you use RDS Custom for Oracle replication, note the following requirements and limitations:
  • For primary DB instances and read replicas, you can change the instance class for only one DB instance at a time.
  • If your RDS Custom for Oracle DB instance has an on-premises primary or replica database, make sure to manually update private IP addresses on the on-premises DB instance after the modification completes. This action is necessary to preserve Oracle DataGuard functionality. RDS Custom for Oracle publishes an event when the modification succeeds.
  • You can't modify your RDS Custom for Oracle DB instance class when the primary or read replica DB instances have FSFO (Fast-Start Failover) configured.

How RDS Custom creates your DB instance when you modify the instance class

When you modify your instance class, RDS Custom creates your DB instance as follows:

• Creates the Amazon EC2 instance.

• Creates the root volume from the latest DB snapshot. RDS Custom for Oracle doesn't retain information added to the root volume after the latest DB snapshot.

• Creates Amazon CloudWatch alarms.

• Creates an Amazon EC2 SSH key pair if you have deleted the original key pair. Otherwise, RDS Custom for Oracle retains the original key pair.

• Creates new resources using the tags that are attached to your DB instance when you initiate the modification. RDS Custom doesn't transfer tags to the new resources when they are attached directly to underlying resources.

• Transfers the binary and data volumes with the most recent modifications to the new DB instance.

• Transfers the elastic IP address (EIP). If the DB instance is publicly accessible, then RDS Custom temporarily attaches a public IP address to the new DB instance before transferring the EIP. If the DB instance isn't publicly accessible, RDS Custom doesn't create public IP addresses.
Modifying the instance class or storage for your RDS Custom for Oracle DB instance

You can modify the DB instance class or storage using the console, AWS CLI, or RDS API.

Console

To modify an RDS Custom for Oracle DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB instance that you want to modify.
4. Choose Modify.
5. Make the following changes as needed:
   a. Change the value for DB instance class. For supported classes, see DB instance class support for RDS Custom for Oracle (p. 999).
   b. Enter a new value for Allocated storage. It must be greater than the current value, and from 40 GiB–64 TiB.
   c. Change the value for Storage type to General Purpose SSD (gp2), General Purpose SSD (gp3), or Provisioned IOPS (io1).
   d. If you use Provisioned IOPS (io1) or General Purpose SSD (gp3), you can change the Provisioned IOPS value.
6. Choose Continue.
7. Choose Apply immediately or Apply during the next scheduled maintenance window.
8. Choose Modify DB instance.

AWS CLI

To modify the storage for an RDS Custom for Oracle DB instance, use the modify-db-instance AWS CLI command. Set the following parameters as needed:

   • --db-instance-class – A new instance class. For supported classes, see DB instance class support for RDS Custom for Oracle (p. 999).
   • --allocated-storage – Amount of storage to be allocated for the DB instance, in gibibytes. It must be greater than the current value, and from 40–65,536 GiB.
   • --storage-type – The storage type: gp2, gp3, or io1.
   • --iops – Provisioned IOPS for the DB instance, if using the io1 or gp3 storage types.
   • --apply-immediately – Use --apply-immediately to apply the storage changes immediately.
     Or use --no-apply-immediately (the default) to apply the changes during the next maintenance window.

The following example changes the DB instance class of my-custom-instance to db.m5.16xlarge. The command also changes the storage size to 1 TiB, storage type to io1, and Provisioned IOPS to 3000.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier my-custom-instance \
  --db-instance-class db.m5.16xlarge \
```
Changing the time zone of an RDS Custom for Oracle DB instance

You change the time zone of an RDS Custom for Oracle DB instance manually. This approach contrasts with RDS for Oracle, where you use the `TIME_ZONE` option in a custom DB option group.

You can change time zones for RDS Custom for Oracle DB instances multiple times. However, we recommend not changing them more than once every 48 hours. We also recommend changing them only when the latest restorable time is within the last 30 minutes.

If you don't follow these recommendations, cleaning up redo logs might remove more logs than intended. Redo log timestamps might also be converted incorrectly to UTC, which can prevent the redo log files from being downloaded and replayed correctly. This in turn can prevent point-in-time recovery (PITR) from performing correctly.

Changing the time zone of an RDS Custom for Oracle DB instance has the following limitations:

- PITR is supported for recovery times before RDS Custom automation is paused, and after automation is resumed.
  
  For more information about PITR, see [Restoring an RDS Custom for Oracle instance to a point in time](p. 1067).
- Changing the time zone of an existing read replica causes downtime. We recommend changing the time zone of the DB instance before creating read replicas.
  
  You can create a read replica from a DB instance with a modified time zone. For more information about read replicas, see [Working with Oracle replicas for RDS Custom for Oracle](p. 1060).

Use the following procedures to change the time zone of an RDS Custom for Oracle DB instance.

Make sure to follow these procedures. If they aren't followed, it can result in these issues:

- Disruption of redo log download and replay
- Incorrect redo log timestamps
- Cleanup of redo logs on the host that doesn't use the redo log retention period

### To change the time zone for a primary DB instance

1. Pause RDS Custom automation. For more information, see [Pausing and resuming your RDS Custom DB instance](p. 1049).
2. (Optional) Change the time zone of the DB instance, for example by using the following command.

```bash
aws rds modify-db-instance
  --db-instance-identifier my-custom-instance
  --db-instance-class db.m5.16xlarge
  --storage-type io1
  --iops 3000
  --allocated-storage 1024
  --apply-immediately
```
ALTER DATABASE SET TIME_ZONE = 'US/Pacific';

3. Shut down the DB instance.
4. Log in to the host and change the system time zone.
5. Start the DB instance.
6. Resume RDS Custom automation.

**To change the time zone for a primary DB instance and its read replicas**

1. Pause RDS Custom automation on the primary DB instance.
2. Pause RDS Custom automation on the read replicas.
3. (Optional) Change the time zone of the primary and read replicas, for example by using the following command.

   ```sql
   ALTER DATABASE SET TIME_ZONE = 'US/Pacific';
   ```

4. Shut down the primary DB instance.
5. Shut down the read replicas.
6. Log in to the host and change the system time zone for the read replicas.
7. Change the system time zone for the primary DB instance.
8. Mount the read replicas.
9. Start the primary DB instance.
10. Resume RDS Custom automation on the primary DB instance and then on the read replicas.

**Changing the character set of an RDS Custom for Oracle DB instance**

RDS Custom for Oracle defaults to the character set US7ASCII. You might want to specify different character sets to meet language or multibyte character requirements. When you use RDS Custom for Oracle, you can pause automation and then change the character set of your database manually.

Changing the character set of an RDS Custom for Oracle DB instance has the following requirements:

- You can only change the character on a newly provisioned RDS Custom instance that has an empty or starter database with no application data. For all other scenarios, change the character set using DMU (Database Migration Assistant for Unicode).
- You can only change to a character set supported by RDS for Oracle. For more information, see [Supported DB character sets](p. 1817).

**To change the character set of an RDS Custom for Oracle DB instance**

1. Pause RDS Custom automation. For more information, see [Pausing and resuming your RDS Custom DB instance](p. 1049).
2. Log in to your database as a user with SYSDBA privileges.
3. Restart the database in restricted mode, change the character set, and then restart the database in normal mode.

   Run the following script in your SQL client:

   ```sql
   SHUTDOWN IMMEDIATE;
   ```
STARTUP RESTRICT;
ALTER DATABASE CHARACTER SET INTERNAL_CONVERT AL32UTF8;
SHUTDOWN IMMEDIATE;
STARTUP;
SELECT VALUE FROM NLS_DATABASE_PARAMETERS WHERE PARAMETER = 'NLS_CHARACTERSET';

Verify that the output shows the correct character set:

<table>
<thead>
<tr>
<th>VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>AL32UTF8</td>
</tr>
</tbody>
</table>

4. Resume RDS Custom automation. For more information, see Pausing and resuming your RDS
Custom DB instance (p. 1049).

### Setting the NLS_LANG value in RDS Custom for Oracle

A *locale* is a set of information addressing linguistic and cultural requirements that corresponds to a given language and country. To specify locale behavior for Oracle software, set the NLS_LANG environment variable on your client host. This variable sets the language, territory, and character set used by the client application in a database session.

For RDS Custom for Oracle, you can set only the language in the NLS_LANG variable: the territory and character use defaults. The language is used for Oracle database messages, collation, day names, and month names. Each supported language has a unique name, for example, American, French, or German. If language is not specified, the value defaults to American.

After you create your RDS Custom for Oracle database, you can set NLS_LANG on your client host to a language other than English. To see a list of languages supported by Oracle Database, log in to your RDS Custom for Oracle database and run the following query:

```
SELECT VALUE FROM V$NLS_VALID_VALUES WHERE PARAMETER='LANGUAGE' ORDER BY VALUE;
```

You can set NLS_LANG on the host command line. The following example sets the language to German for your client application using the Z shell on Linux.

```
export NLS_LANG=German
```

Your application reads the NLS_LANG value when it starts and then communicates it to the database when it connects.

For more information, see Choosing a Locale with the NLS_LANG Environment Variable in the Oracle Database Globalization Support Guide.

### Support for Transparent Data Encryption

RDS Custom supports Transparent Data Encryption (TDE) for RDS Custom for Oracle DB instances.

However, you can't enable TDE using an option in a custom option group as you can in RDS for Oracle. You turn on TDE manually. For information about using Oracle Transparent Data Encryption, see Securing stored data using Transparent Data Encryption in the Oracle documentation.

### Tagging RDS Custom for Oracle resources

You can tag RDS Custom resources as with Amazon RDS resources, but with some important differences:
Don't create or modify the AWSRDSCustom tag that's required for RDS Custom automation. If you do, you might break the automation.

Tags added to RDS Custom DB instances during creation are propagated to all other related RDS Custom resources.

Tags aren't propagated when you add them to RDS Custom resources after DB instance creation.

For general information about resource tagging, see Tagging Amazon RDS resources (p. 461).

Deleting an RDS Custom for Oracle DB instance

To delete an RDS Custom DB instance, do the following:

- Provide the name of the DB instance.
- Clear the option to take a final DB snapshot of the DB instance.
- Choose or clear the option to retain automated backups.

You can delete an RDS Custom DB instance using the console or the CLI. The time required to delete the DB instance can vary depending on the backup retention period (that is, how many backups to delete) and how much data is deleted.

Console

To delete an RDS Custom DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the RDS Custom DB instance that you want to delete. RDS Custom DB instances show the role Instance (RDS Custom).
3. For Actions, choose Delete.
4. To retain automated backups, choose Retain automated backups.
5. Enter delete me in the box.
6. Choose Delete.

AWS CLI

You delete an RDS Custom DB instance by using the delete-db-instance AWS CLI command. Identify the DB instance using the required parameter --db-instance-identifier. The remaining parameters are the same as for an Amazon RDS DB instance, with the following exceptions:

- --skip-final-snapshot is required.
- --no-skip-final-snapshot isn't supported.
- --final-db-snapshot-identifier isn't supported.

The following example deletes the RDS Custom DB instance named my-custom-instance, and retains automated backups.

Example

For Linux, macOS, or Unix:

```
aws rds delete-db-instance \  
  --db-instance-identifier my-custom-instance 
```
--skip-final-snapshot \
--no-delete-automated-backups

For Windows:

```bash
aws rds delete-db-instance ^
   --db-instance-identifier my-custom-instance ^
   --skip-final-snapshot ^
   --no-delete-automated-backups
```
Working with Oracle replicas for RDS Custom for Oracle

You can create Oracle replicas for RDS Custom for Oracle DB instances. Both container databases (CDBs) and non-CDBs are supported. Creating an RDS Custom for Oracle replica is similar to creating an RDS for Oracle replica, but with important differences. For general information about creating and managing Oracle replicas, see Working with DB instance read replicas (p. 438) and Working with read replicas for Amazon RDS for Oracle (p. 1989).

Topics

- Overview of RDS Custom for Oracle replication (p. 1060)
- Guidelines and limitations for RDS Custom for Oracle replication (p. 1061)
- Promoting an RDS Custom for Oracle replica to a standalone DB instance (p. 1063)

Overview of RDS Custom for Oracle replication

The architecture of RDS Custom for Oracle replication is analogous to RDS for Oracle replication. A primary DB instance replicates asynchronously to one or more Oracle replicas.

As with RDS for Oracle, you can create up to five managed Oracle replicas of your RDS Custom for Oracle primary DB instance. You can also create your own manually configured (external) Oracle replicas. External replicas don't count toward your DB instance limit. They also lie outside the RDS Custom support perimeter. For more information about the support perimeter, see RDS Custom support perimeter (p. 985).
Replica naming convention

Oracle replica names are based on the database unique name. The format is `DB ÖlIQUE_NAME_X`, with letters appended sequentially. For example, if your database unique name is ORCL, the first two replicas are named ORCL_A and ORCL_B. The first six letters, A–F, are reserved for RDS Custom. RDS Custom copies database parameters from your primary DB instance to the replicas. For more information, see `DB ÖlIQUE_NAME` in the Oracle documentation.

Replica backup retention

By default, RDS Custom Oracle replicas use the same backup retention period as your primary DB instance. You can modify the backup retention period to 1–35 days. RDS Custom supports backing up, restoring, and point-in-time recovery (PITR). For more information about backing up and restoring RDS Custom DB instances, see Backing up and restoring an Amazon RDS Custom for Oracle DB instance (p. 1065).

Note

While creating a Oracle replica, RDS Custom temporarily pauses the cleanup of redo log files. In this way, RDS Custom ensures that it can apply these logs to the new Oracle replica after it becomes available.

Replica promotion

You can promote managed Oracle replicas in RDS Custom for Oracle using the console, promote-read-replica AWS CLI command, or PromoteReadReplica API. If you delete your primary DB instance, and all replicas are healthy, RDS Custom for Oracle promotes your managed replicas to standalone instances automatically. If a replica has paused automation or is outside the support perimeter, you must fix the replica before RDS Custom can promote it automatically. You can only promote external Oracle replicas manually.

Guidelines and limitations for RDS Custom for Oracle replication

When you create RDS Custom for Oracle replicas, not all RDS Oracle replica options are supported.

Topics

- General guidelines for RDS Custom for Oracle replication (p. 1061)
- General limitations for RDS Custom for Oracle replication (p. 1062)
- Networking requirements and limitations for RDS Custom for Oracle replication (p. 1062)
- External replica limitations for RDS Custom for Oracle (p. 1062)
- Replica promotion limitations for RDS Custom for Oracle (p. 1063)
- Replica promotion guidelines for RDS Custom for Oracle (p. 1063)

General guidelines for RDS Custom for Oracle replication

When working with RDS Custom for Oracle, follow these guidelines:

- Don't modify the RDS_DATAGUARD user. This user is reserved for RDS Custom for Oracle automation. Modifying this user can result in undesired outcomes, such as an inability to create Oracle replicas for your RDS Custom for Oracle DB instance.
- Don't change the replication user password. It is required to administer the Oracle Data Guard configuration on the RDS Custom host. If you change the password, RDS Custom for Oracle might put your Oracle replica outside the support perimeter. For more information, see RDS Custom support perimeter (p. 985).

The password is stored in AWS Secrets Manager, tagged with the DB resource ID. Each Oracle replica has its own secret in Secrets Manager. The format for the secret is the following.
• Don't change the DB_UNIQUE_NAME for the primary DB instance. Changing the name causes any restore operation to become stuck.
• Don't specify the clause STANDBYS=NONE in a CREATE PLUGGABLE DATABASE command in an RDS Custom CDB. This way, if a failover occurs, your standby CDB contains all PDBs.

General limitations for RDS Custom for Oracle replication

RDS Custom for Oracle replicas have the following limitations:

• You can't create RDS Custom for Oracle replicas in read-only mode. However, you can manually change the mode of mounted replicas to read-only, and from read-only to mounted. For more information, see the documentation for the create-db-instance-read-replica AWS CLI command.
• You can't create cross-Region RDS Custom for Oracle replicas.
• You can't change the value of the Oracle Data Guard CommunicationTimeout parameter. This parameter is set to 15 seconds for RDS Custom for Oracle DB instances.

Networking requirements and limitations for RDS Custom for Oracle replication

Make sure that your network configuration supports RDS Custom for Oracle replicas. Consider the following:

• Make sure to enable port 1140 for both inbound and outbound communication within your virtual private cloud (VPC) for the primary DB instance and all of its replicas. This is required for Oracle Data Guard communication between read replicas.
• RDS Custom for Oracle validates the network while creating a Oracle replica. If the primary DB instance and the new replica can't connect over the network, RDS Custom for Oracle doesn't create the replica and places it in the INCOMPATIBLE_NETWORK state.
• For external Oracle replicas, such as those you create on Amazon EC2 or on-premises, use another port and listener for Oracle Data Guard replication. Trying to use port 1140 could cause conflicts with RDS Custom automation.
• The /rdsdbdata/config/tnsnames.ora file contains network service names mapped to listener protocol addresses. Note the following requirements and recommendations:
  • Entries in tnsnames.ora prefixed with rds_custom_ are reserved for RDS Custom when handling Oracle replica operations.
    When creating manual entries in tnsnames.ora, don't use this prefix.
  • In some cases, you might want to switch over or fail over manually, or use failover technologies such as Fast-Start Failover (FSFO). If so, make sure to manually synchronize tnsnames.ora entries from the primary DB instance to all of the standby instances. This recommendation applies to both Oracle replicas managed by RDS Custom and to external Oracle replicas.
    RDS Custom automation updates tnsnames.ora entries on only the primary DB instance. Make sure also to synchronize when you add or remove a Oracle replica.
    If you don't synchronize the tnsnames.ora files and switch over or fail over manually, Oracle Data Guard on the primary DB instance might not be able to communicate with the Oracle replicas.

External replica limitations for RDS Custom for Oracle

RDS Custom for Oracle external replicas, which include on-premises replicas, have the following limitations:
• RDS Custom for Oracle doesn't detect instance role changes upon manual failover, such as FSFO, for external Oracle replicas.

RDS Custom for Oracle does detect changes for managed replicas. The role change is noted in the event log. You can also see the new state by using the `describe-db-instances` AWS CLI command.

• RDS Custom for Oracle doesn't detect high replication lag for external Oracle replicas.

RDS Custom for Oracle does detect lag for managed replicas. High replication lag produces the `Replication has stopped` event. You can also see the replication status by using the `describe-db-instances` AWS CLI command, but there might be a delay for it to be updated.

• RDS Custom for Oracle doesn't promote external Oracle replicas automatically if you delete your primary DB instance.

  The automatic promotion feature is available only for managed Oracle replicas. For information about promoting Oracle replicas manually, see the white paper [Enabling high availability with Data Guard on Amazon RDS Custom for Oracle](https://docs.aws.amazon.com/rds-custom/oracle/latest/userguide/Enabling-high-availability-with-Data-Guard.html).

### Replica promotion limitations for RDS Custom for Oracle

Promoting RDS Custom for Oracle managed Oracle replicas is the same as promoting RDS managed replicas, with some differences. Note the following limitations for RDS Custom for Oracle replicas:

• You can't promote a replica while RDS Custom for Oracle is backing it up.

• You can't change the backup retention period to 0 when you promote your Oracle replica.

• You can't promote your replica when it isn't in a healthy state.

  If you issue `delete-db-instance` on the primary DB instance, RDS Custom for Oracle validates that each managed Oracle replica is healthy and available for promotion. A replica might be ineligible for promotion because automation is paused or it is outside the support perimeter. In such cases, RDS Custom for Oracle publishes an event explaining the issue so that you can repair your Oracle replica manually.

### Replica promotion guidelines for RDS Custom for Oracle

When promoting a replica, note the following guidelines:

• Don't initiate a failover while RDS Custom for Oracle is promoting your replica. Otherwise, the promotion workflow could become stuck.

• Don't switch over your primary DB instance while RDS Custom for Oracle is promoting your Oracle replica. Otherwise, the promotion workflow could become stuck.

• Don't shut down your primary DB instance while RDS Custom for Oracle is promoting your Oracle replica. Otherwise, the promotion workflow could become stuck.

• Don't try to restart replication with your newly promoted DB instance as a target. After RDS Custom for Oracle promotes your Oracle replica, it becomes a standalone DB instance and no longer has the replica role.

For more information, see [Troubleshooting replica promotion for RDS Custom for Oracle](https://docs.aws.amazon.com/rds-custom/oracle/latest/userguide/Troubleshooting-replica-promotion-for-RDS-Custom-for-Oracle.html) (p. 1086).

### Promoting an RDS Custom for Oracle replica to a standalone DB instance

Just as with RDS for Oracle, you can promote an RDS Custom for Oracle replica to a standalone DB instance. When you promote a Oracle replica, RDS Custom for Oracle reboots the DB instance before it...
becomes available. For more information about promoting Oracle replicas, see Promoting a read replica to be a standalone DB instance (p. 447).

The following steps show the general process for promoting a Oracle replica to a DB instance:

1. Stop any transactions from being written to the primary DB instance.
2. Wait for RDS Custom for Oracle to apply all updates to your Oracle replica.
3. Promote your Oracle replica by choosing the Promote option on the Amazon RDS console, the AWS CLI command `promote-read-replica`, or the PromoteReadReplica Amazon RDS API operation.

Promoting a Oracle replica takes a few minutes to complete. During the process, RDS Custom for Oracle stops replication and reboots your replica. When the reboot completes, the Oracle replica is available as a standalone DB instance.

**Console**

To promote an RDS Custom for Oracle replica to a standalone DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the Amazon RDS console, choose Databases.
   
The Databases pane appears. Each Oracle replica shows Replica in the Role column.
3. Choose the RDS Custom for Oracle replica that you want to promote.
4. For Actions, choose Promote.
5. On the Promote Oracle replica page, enter the backup retention period and the backup window for the newly promoted DB instance. You can't set this value to 0.
6. When the settings are as you want them, choose Promote Oracle replica.

**AWS CLI**

To promote your RDS Custom for Oracle replica to a standalone DB instance, use the AWS CLI `promote-read-replica` command.

**Example**

For Linux, macOS, or Unix:

```
aws rds promote-read-replica \\n--db-instance-identifier my-custom-read-replica \\n--backup-retention-period 2 \\n--preferred-backup-window 23:00-24:00
```

For Windows:

```
aws rds promote-read-replica ^
--db-instance-identifier my-custom-read-replica ^
--backup-retention-period 2 ^
--preferred-backup-window 23:00-24:00
```

**RDS API**

To promote your RDS Custom for Oracle replica to be a standalone DB instance, call the Amazon RDS API `PromoteReadReplica` operation with the required parameter `DBInstanceIdentifier`. 
Back up and restore an Amazon RDS Custom for Oracle DB instance

Like Amazon RDS, RDS Custom creates and saves automated backups of your RDS Custom for Oracle DB instance during the backup window of your DB instance. You can also back up your DB instance manually.

The procedure is identical to taking a snapshot of an Amazon RDS DB instance. The first snapshot of an RDS Custom DB instance contains the data for the full DB instance. Subsequent snapshots are incremental.

Restore DB snapshots using either the AWS Management Console or the AWS CLI.

Topics
- Creating an RDS Custom for Oracle snapshot (p. 1065)
- Restoring from an RDS Custom for Oracle DB snapshot (p. 1066)
- Restoring an RDS Custom for Oracle instance to a point in time (p. 1067)
- Deleting an RDS Custom for Oracle snapshot (p. 1070)
- Deleting RDS Custom for Oracle automated backups (p. 1070)

Creating an RDS Custom for Oracle snapshot

RDS Custom for Oracle creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases. When your DB instance contains a container database (CDB), the snapshot of the instance includes the root CDB and all PDBs.

When you create an RDS Custom for Oracle snapshot, specify which RDS Custom DB instance to back up. Give your snapshot a name so you can restore from it later.

When you create a snapshot, RDS Custom for Oracle creates an Amazon EBS snapshot for every volume attached to the DB instance. RDS Custom for Oracle uses the EBS snapshot of the root volume to register a new Amazon Machine Image (AMI). To make snapshots easy to associate with a specific DB instance, they're tagged with DBSnapshotIdentifier, DbiResourceId, and VolumeType.

Creating a DB snapshot results in a brief I/O suspension. This suspension can last from a few seconds to a few minutes, depending on the size and class of your DB instance. The snapshot creation time varies with the size of your database. Because the snapshot includes the entire storage volume, the size of files, such as temporary files, also affects snapshot creation time. To learn more about creating snapshots, see Creating a DB snapshot (p. 613).

Create an RDS Custom for Oracle snapshot using the console or the AWS CLI.

Console

To create an RDS Custom snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. In the list of RDS Custom DB instances, choose the instance for which you want to take a snapshot.
4. For Actions, choose Take snapshot.
   
   The Take DB snapshot window appears.
5. For Snapshot name, enter the name of the snapshot.
Choose **Take snapshot**.

**AWS CLI**

You create a snapshot of an RDS Custom DB instance by using the `create-db-snapshot` AWS CLI command.

Specify the following options:

- `--db-instance-identifier` – Identifies which RDS Custom DB instance you are going to back up
- `--db-snapshot-identifier` – Names your RDS Custom snapshot so you can restore from it later

In this example, you create a DB snapshot called `my-custom-snapshot` for an RDS Custom DB instance called `my-custom-instance`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-snapshot \
  --db-instance-identifier my-custom-instance \
  --db-snapshot-identifier my-custom-snapshot
```

For Windows:

```bash
aws rds create-db-snapshot ^
  --db-instance-identifier my-custom-instance ^
  --db-snapshot-identifier my-custom-snapshot
```

**Restoring from an RDS Custom for Oracle DB snapshot**

When you restore an RDS Custom for Oracle DB instance, you provide the name of the DB snapshot and a name for the new instance. You can't restore from a snapshot to an existing RDS Custom DB instance. A new RDS Custom for Oracle DB instance is created when you restore.

The restore process differs in the following ways from restore in Amazon RDS:

- Before restoring a snapshot, RDS Custom for Oracle backs up existing configuration files. These files are available on the restored instance in the directory `/rdsdbdata/config/backup`. RDS Custom for Oracle restores the DB snapshot with default parameters and overwrites the previous database configuration files with existing ones. Thus, the restored instance doesn't preserve custom parameters and changes to database configuration files.
- The restored database has the same name as in the snapshot. You can't specify a different name. (For RDS Custom for Oracle, the default is `ORCL`.)

**Console**

**To restore an RDS Custom DB instance from a DB snapshot**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Snapshots**.
3. Choose the DB snapshot that you want to restore from.
4. For **Actions**, choose **Restore snapshot**.
5. On the Restore DB instance page, for DB instance identifier, enter the name for your restored RDS Custom DB instance.
6. Choose Restore DB instance.

AWS CLI

You restore an RDS Custom DB snapshot by using the restore-db-instance-from-db-snapshot AWS CLI command.

If the snapshot you are restoring from is for a private DB instance, make sure to specify both the correct db-subnet-group-name and no-publicly-accessible. Otherwise, the DB instance defaults to publicly accessible. The following options are required:

- db-snapshot-identifier – Identifies the snapshot from which to restore
- db-instance-identifier – Specifies the name of the RDS Custom DB instance to create from the DB snapshot
- custom-iam-instance-profile – Specifies the instance profile associated with the underlying Amazon EC2 instance of an RDS Custom DB instance.

The following code restores the snapshot named my-custom-snapshot for my-custom-instance.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-db-snapshot
   --db-snapshot-identifier my-custom-snapshot
   --db-instance-identifier my-custom-instance
   --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance
   --no-publicly-accessible
```

For Windows:

```
aws rds restore-db-instance-from-db-snapshot
   --db-snapshot-identifier my-custom-snapshot
   --db-instance-identifier my-custom-instance
   --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance
   --no-publicly-accessible
```

Restoring an RDS Custom for Oracle instance to a point in time

You can restore a DB instance to a specific point in time (PITR), creating a new DB instance. To support PITR, your DB instances must have backup retention set to a nonzero value.

The latest restorable time for an RDS Custom for Oracle DB instance depends on several factors, but is typically within 5 minutes of the current time. To see the latest restorable time for a DB instance, use the AWS CLI describe-db-instances command and look at the value returned in the LatestRestorableTime field for the DB instance. To see the latest restorable time for each DB instance in the Amazon RDS console, choose Automated backups.

You can restore to any point in time within your backup retention period. To see the earliest restorable time for each DB instance, choose Automated backups in the Amazon RDS console.

For general information about PITR, see Restoring a DB instance to a specified time (p. 660).

Topics
• PITR considerations for RDS Custom for Oracle (p. 1068)

PITR considerations for RDS Custom for Oracle

In RDS Custom for Oracle, PITR differs in the following important ways from PITR in Amazon RDS:

• The restored database has the same name as in the source DB instance. You can’t specify a different name. The default is ORCL.
• AWSRDSCustomIamRolePolicy requires new permissions. For more information, see Step 2: Add an access policy to AWSRDSCustomInstanceRoleForRdsCustomInstance (p. 1007).
• All RDS Custom for Oracle DB instances must have backup retention set to a nonzero value.
• If you change the operating system or DB instance time zone, PITR might not work. For information about changing time zones, see Changing the time zone of an RDS Custom for Oracle DB instance (p. 1055).
• If you set automation to ALL_PAUSED, RDS Custom pauses the upload of archived redo logs, including logs created before the latest restorable time (LRT). We recommend that you pause automation for a brief period.

To illustrate, assume that your LRT is 10 minutes ago. You pause automation. During the pause, RDS Custom doesn't upload archived redo logs. If your DB instance crashes, you can only recover to a time before the LRT that existed when you paused. When you resume automation, RDS Custom resumes uploading logs. The LRT advances. Normal PITR rules apply.
• In RDS Custom, you can manually specify an arbitrary number of hours to retain archived redo logs before RDS Custom deletes them after upload. Specify the number of hours as follows:
  1. Create a text file named /opt/aws/rdscustomagent/config/reo_logs_custom_configuration.json.
  2. Add a JSON object in the following format: \{"archivedLogRetentionHours" : "num_of_hours"\}. The number must be an integer in the range 1–840.
• Assume that you plug a non-CDB into a container database (CDB) as a PDB and then attempt PITR. The operation succeeds only if you previously backed up the PDB. After you create or modify a PDB, we recommend that you always back it up.
• We recommend that you don't customize database initialization parameters. For example, modifying the following parameters affects PITR:
  • CONTROL_FILE_RECORD_KEEP_TIME affects the rules for uploading and deleting logs.
  • LOG_ARCHIVE_DEST_\n doesn't support multiple destinations.
  • ARCHIVE_LAG_TARGET affects the latest restorable time.
• If you customize database initialization parameters, we strongly recommend that you only customize the following:
  • COMPATIBLE
  • MAX_STRING_SIZE
  • DB_FILES
  • UNDO_TABLESPACE
  • ENABLE_PLUGGABLE_DATABASE
  • CONTROL_FILES
  • AUDIT_TRAIL
  • AUDIT_TRAIL_DEST
For all other initialization parameters, RDS Custom restores the default values. If you modify a parameter that isn't in the preceding list, it might have an adverse effect on PITR and lead to unpredictable results. For example, CONTROL_FILE_RECORD_KEEP_TIME affects the rules for uploading and deleting logs.
You can restore an RDS Custom DB instance to a point in time using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To restore an RDS Custom DB instance to a specified time**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Automated backups.
3. Choose the RDS Custom DB instance that you want to restore.
4. For Actions, choose Restore to point in time. The Restore to point in time window appears.
5. Choose Latest restorable time to restore to the latest possible time, or choose Custom to choose a time.
   - If you chose Custom, enter the date and time to which you want to restore the instance.
6. For DB instance identifier, enter the name of the target restored RDS Custom DB instance. The name must be unique.
7. Choose other options as needed, such as DB instance class.
8. Choose Restore to point in time.

**AWS CLI**

You restore a DB instance to a specified time by using the `restore-db-instance-to-point-in-time` AWS CLI command to create a new RDS Custom DB instance.

Use one of the following options to specify the backup to restore from:

- `--source-db-instance-identifier mysourcedbname`
- `--source-dbi-resource-id dbinstanceresourceID`
- `--source-db-instance-automated-backups-arn backupARN`

The custom-iam-instance-profile option is required.

The following example restores my-custom-db-instance to a new DB instance named my-restored-custom-db-instance, as of the specified time.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds restore-db-instance-to-point-in-time \
    --source-db-instance-identifier my-custom-db-instance \
    --target-db-instance-identifier my-restored-custom-db-instance \
    --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance \
    --restore-time 2022-10-14T23:45:00Z
```

For Windows:
Deleting an RDS Custom for Oracle snapshot

You can delete DB snapshots managed by RDS Custom for Oracle when you no longer need them. The deletion procedure is the same for both Amazon RDS and RDS Custom DB instances.

The Amazon EBS snapshots for the binary and root volumes remain in your account for a longer time because they might be linked to some instances running in your account or to other RDS Custom for Oracle snapshots. These EBS snapshots are automatically deleted after they’re no longer related to any existing RDS Custom for Oracle resources (DB instances or backups).

**Console**

**To delete a snapshot of an RDS Custom DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Snapshots.
3. Choose the DB snapshot that you want to delete.
4. For Actions, choose Delete snapshot.
5. Choose Delete on the confirmation page.

**AWS CLI**

To delete an RDS Custom snapshot, use the AWS CLI command `delete-db-snapshot`.

The following option is required:

- `--db-snapshot-identifier` – The snapshot to be deleted

The following example deletes the `my-custom-snapshot` DB snapshot.

**Example**

For Linux, macOS, or Unix:

```
aws rds delete-db-snapshot \n   --db-snapshot-identifier my-custom-snapshot
```

For Windows:

```
aws rds delete-db-snapshot ^
   --db-snapshot-identifier my-custom-snapshot
```

Deleting RDS Custom for Oracle automated backups

You can delete retained automated backups for RDS Custom for Oracle when they are no longer needed. The procedure is the same as the procedure for deleting Amazon RDS backups.
To delete a retained automated backup

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Automated backups.
3. Choose Retained.
4. Choose the retained automated backup that you want to delete.
5. For Actions, choose Delete.
6. On the confirmation page, enter delete me and choose Delete.

AWS CLI

You can delete a retained automated backup by using the AWS CLI command delete-db-instance-automated-backup.

The following option is used to delete a retained automated backup:

- --dbi-resource-id – The resource identifier for the source RDS Custom DB instance.

You can find the resource identifier for the source DB instance of a retained automated backup by using the AWS CLI command describe-db-instance-automated-backups.

The following example deletes the retained automated backup with source DB instance resource identifier custom-db-123ABCEXAMPLE.

Example

For Linux, macOS, or Unix:

```
aws rds delete-db-instance-automated-backup  \
  --dbi-resource-id custom-db-123ABCEXAMPLE
```

For Windows:

```
aws rds delete-db-instance-automated-backup ^
  --dbi-resource-id custom-db-123ABCEXAMPLE
```
Migrating an on-premises database to RDS Custom for Oracle

Before you migrate an on-premises Oracle database to RDS Custom for Oracle, you need to consider the following factors:

- The amount of downtime the application can afford
- The size of the source database
- Network connectivity
- A requirement for a fallback plan
- The source and target Oracle database version and DB instance OS types
- Available replication tools, such as AWS Database Migration Service, Oracle GoldenGate, or third-party replication tools

Based on these factors, you can choose physical migration, logical migration, or a combination. If you choose physical migration, you can use the following techniques:

**RMAN duplication**

Active database duplication doesn't require a backup of your source database. It duplicates the live source database to the destination host by copying database files over the network to the auxiliary instance. The RMAN DUPLICATE command copies the required files as image copies or backup sets. To learn this technique, see the AWS blog post [Physical migration of Oracle databases to Amazon RDS Custom using RMAN duplication](https://aws.amazon.com/blogs/database/physical-migration-of-oracle-databases-to-amazon-rds-custom-using-rman-duplication/).

**Oracle Data Guard**

In this technique, you back up a primary on-premises database and copy the backups to an Amazon S3 bucket. You then copy the backups to your RDS Custom for Oracle standby DB instance. After performing the necessary configuration, you manually switch over your primary database to your RDS Custom for Oracle standby database. To learn this technique, see the AWS blog post [Physical migration of Oracle databases to Amazon RDS Custom using Data Guard](https://aws.amazon.com/blogs/database/physical-migration-of-oracle-databases-to-amazon-rds-custom-using-data-guard/).

For general information about logically importing data into RDS for Oracle, see [Importing data into Oracle on Amazon RDS](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/USER_ImportData.html) (p. 1963).
Upgrading a DB instance for Amazon RDS Custom for Oracle

You can upgrade an Amazon RDS Custom DB instance by modifying it to use a new custom engine version (CEV). For general information about upgrades, see Upgrading a DB instance engine version (p. 429).

Topics

• Requirements for RDS Custom for Oracle upgrades (p. 1073)
• Considerations for RDS Custom for Oracle upgrades (p. 1073)
• Viewing valid upgrade targets for RDS Custom for Oracle DB instances (p. 1074)
• Upgrading an RDS Custom DB instance (p. 1075)
• Viewing pending upgrades for RDS Custom DB instances (p. 1075)
• Troubleshooting an upgrade failure for an RDS Custom for Oracle DB instance (p. 1076)

Requirements for RDS Custom for Oracle upgrades

When upgrading your RDS Custom for Oracle DB instance to a target CEV, make sure you meet the following requirements:

• The target CEV to which you are upgrading must exist.
• The target CEV must use the installation parameter settings that are in the manifest of the current CEV. For example, you can't upgrade a database that uses the default Oracle home to a CEV that uses a nondefault Oracle home.
• The target CEV must use a new minor database version, not a new major version. For example, you can't upgrade from an Oracle Database 12c CEV to an Oracle Database 19c CEV. But you can upgrade from version 21.0.0.0.ru-2023-04.rur-2023-04.r1 to version 21.0.0.0.ru-2023-07.rur-2023-07.r1.

Considerations for RDS Custom for Oracle upgrades

When planning an upgrade, consider the following:

• We strongly recommend that you upgrade your RDS Custom for Oracle DB instance using CEVs. RDS Custom for Oracle automation synchronizes the patch metadata with the database binary on your DB instance.

In special circumstances, RDS Custom supports applying a "one-off" patch directly to the underlying Amazon EC2 instance directly using OPATCH. A valid use case might be a patch that you want to apply immediately, but the RDS Custom team is upgrading the CEV feature, causing a delay. To apply a patch manually, perform the following steps:
1. Pause RDS Custom automation.
2. Apply your patch to the database binaries on the Amazon EC2 instance.
3. Resume RDS Custom automation.

A disadvantage of the preceding technique is that you must apply the patch manually to every instance that you want to upgrade. In contrast, when you create a new CEV, you can create or upgrade multiple DB instances using the same CEV.

• When you upgrade your primary DB instance, RDS Custom for Oracle upgrades your read replicas automatically. You don't have to upgrade read replicas manually.
• When you upgrade your RDS Custom for Oracle DB instance to a new CEV, RDS Custom performs out-of-place patching that replaces the entire database volume with a new volume that uses your target
database version. Thus, we strongly recommend that you don't use the bin volume for installations or for storing permanent data or files.

- When you upgrade a container database (CDB), RDS Custom for Oracle checks that all PDBs are open or could be opened. If these conditions aren't met, RDS Custom stops the check and returns the database to its original state without attempting the upgrade. If the conditions are met, RDS Custom patches the CDB root first, and then patches all other PDBs (including PDB$SEED) in parallel.

After the patching process completes, RDS Custom attempts to open all PDBs. If any PDBs fail to open, you receive the following event: The following PDBs failed to open: list-of-PDBs. If RDS Custom fails to patch the CDB root or any PDBs, the instance is put into the PATCH_DB_FAILED state.

- You might want to perform a major version upgrade and a conversion of non-CDB to CDB at the same time. In this case, we recommend that you proceed as follows:
  1. Create a new RDS Custom DB instance that uses the Oracle Multitenant architecture.
  2. Plug in a non-CDB into your CDB root, creating it as a PDB. Make sure that the non-CDB is the same major version as your CDB.
  3. Convert your PDB by running the noncdb_to_pdb.sql Oracle script.
  4. Validate your CDB instance.
  5. Upgrade your CDB instance.

**Viewing valid upgrade targets for RDS Custom for Oracle DB instances**

You can see existing CEVs on the **Custom engine versions** page in the AWS Management Console.

You can also use the `describe-db-engine-versions` AWS CLI command to find valid upgrades for your DB instances, as shown in the following example. This example assumes that a DB instance was created using the version 19.my_cev1, and that the upgrade versions 19.my_cev2 and 19.my_cev exist.

```bash
aws rds describe-db-engine-versions --engine custom-oracle-ee --engine-version 19.my_cev1
```

The output resembles the following.

```json
{
  "DBEngineVersions": [
    {
      "Engine": "custom-oracle-ee",
      "EngineVersion": "19.my_cev1",
      ...
      "ValidUpgradeTarget": [
        {
          "Engine": "custom-oracle-ee",
          "EngineVersion": "19.my_cev2",
          "Description": "19.my_cev2 description",
          "AutoUpgrade": false,
          "IsMajorVersionUpgrade": false
        },
        {
          "Engine": "custom-oracle-ee",
          "EngineVersion": "19.my_cev3",
          "Description": "19.my_cev3 description",
          "AutoUpgrade": false,
          "IsMajorVersionUpgrade": false
        }
      ]
    }
  ...
```

1074
Upgrading an RDS Custom DB instance

To upgrade your RDS Custom DB instance, you modify it to use a new CEV.

Read replicas managed by RDS Custom are automatically upgraded after the primary DB instance is upgraded.

Console

To upgrade an RDS Custom DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the RDS Custom DB instance that you want to modify.
4. For DB engine version, choose the CEV to upgrade to, such as 19.my_cev3.
5. Choose Continue to check the summary of modifications.
6. If your changes are correct, choose Modify DB instance. Or choose Back to edit your changes or Cancel to cancel your changes.

AWS CLI

To upgrade an RDS Custom DB instance, use the modify-db-instance AWS CLI command with the following parameters:

- --db-instance-identifier – The DB instance to be upgraded
- --engine-version – The new CEV
- --no-apply-immediately | --apply-immediately – Whether to perform the upgrade immediately or wait until the scheduled maintenance window

The following example upgrades my-custom-instance to version 19.my_cev3.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier my-custom-instance \
  --engine-version 19.my_cev3 \
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier my-custom-instance ^
  --engine-version 19.my_cev3 ^
  --apply-immediately
```

Viewing pending upgrades for RDS Custom DB instances

You can see pending upgrades for your Amazon RDS Custom DB instances by using the describe-db-instances or describe-pending-maintenance-actions AWS CLI command.
However, this approach doesn't work if you used the `--apply-immediately` option or if the upgrade is in progress.

The following `describe-db-instances` command shows pending upgrades for `my-custom-instance`.

```bash
aws rds describe-db-instances --db-instance-identifier my-custom-instance
```

The output resembles the following.

```json
{
   "DBInstances": [
       {
           "DBInstanceIdentifier": "my-custom-instance",
           "EngineVersion": "19.my_cev1",
           ...,
           "PendingModifiedValues": {
               "EngineVersion": "19.my_cev3"
           }
       }
   ]
}
```

The following shows use of the `describe-pending-maintenance-actions` command.

```bash
aws rds describe-pending-maintenance-actions
```

The output resembles the following.

```json
{
   "PendingMaintenanceActions": [
       {
           "PendingMaintenanceActionDetails": [
               {
                   "Action": "db-upgrade",
                   "Description": "Upgrade to 19.my_cev3"
               }
           ]
       }
   ]
}
```

**Troubleshooting an upgrade failure for an RDS Custom for Oracle DB instance**

If an RDS Custom DB instance upgrade fails, an RDS event is generated and the DB instance status becomes `upgrade-failed`.

You can see this status by using the `describe-db-instances` AWS CLI command, as shown in the following example.

```bash
aws rds describe-db-instances --db-instance-identifier my-custom-instance
```

The output resembles the following.
After an upgrade failure, all database actions are blocked except for modifying the DB instance to perform the following tasks:

- Retrying the same upgrade
- Pausing and resuming RDS Custom automation
- Point-in-time recovery (PITR)
- Deleting the DB instance

**Note**
If automation has been paused for the RDS Custom DB instance, you can't retry the upgrade until you resume automation.
The same actions apply to an upgrade failure for an RDS-managed read replica as for the primary.

For more information, see [Troubleshooting upgrades for RDS Custom for Oracle](#).
Troubleshooting DB issues for Amazon RDS Custom for Oracle

The shared responsibility model of RDS Custom provides OS shell–level access and database administrator access. RDS Custom runs resources in your account, unlike Amazon RDS, which runs resources in a system account. With greater access comes greater responsibility. In the following sections, you can learn how to troubleshoot issues with Amazon RDS Custom DB instances.

**Note**
This section explains how to troubleshoot RDS Custom for Oracle. For troubleshooting RDS Custom for SQL Server, see Troubleshooting DB issues for Amazon RDS Custom for SQL Server (p. 1185).

**Topics**
- Viewing RDS Custom events (p. 1078)
- Viewing RDS Custom events (p. 1078)
- Troubleshooting custom engine version creation for RDS Custom for Oracle (p. 1079)
- Fixing unsupported configurations in RDS Custom for Oracle (p. 1080)
- Troubleshooting upgrades for RDS Custom for Oracle (p. 1085)
- Troubleshooting replica promotion for RDS Custom for Oracle (p. 1086)

**Viewing RDS Custom events**

The procedure for viewing events is the same for RDS Custom and Amazon RDS DB instances. For more information, see Viewing Amazon RDS events (p. 852).

To view RDS Custom event notification using the AWS CLI, use the describe-events command. RDS Custom introduces several new events. The event categories are the same as for Amazon RDS. For the list of events, see Amazon RDS event categories and event messages (p. 874).

The following example retrieves details for the events that have occurred for the specified RDS Custom DB instance.

```bash
aws rds describe-events "
--source-identifier my-custom-instance 
--source-type db-instance"
```

**Viewing RDS Custom events**

The procedure for subscribing to events is the same for RDS Custom and Amazon RDS DB instances. For more information, see Subscribing to Amazon RDS event notification (p. 860).

To subscribe to RDS Custom event notification using the CLI, use the create-event-subscription command. Include the following required parameters:

- `--subscription-name`
- `--sns-topic-arn`

The following example creates a subscription for backup and recovery events for an RDS Custom DB instance in the current AWS account. Notifications are sent to an Amazon Simple Notification Service (Amazon SNS) topic, specified by `--sns-topic-arn`.

```bash
aws rds create-event-subscription "
```

1078
Troubleshooting custom engine version creation for RDS Custom for Oracle

When CEV creation fails, RDS Custom issues RDS-EVENT-0198 with the message Creation failed for custom engine version major-engine-version.cev_name, and includes details about the failure. For example, the event prints missing files.

CEV creation might fail because of the following issues:

- The Amazon S3 bucket containing your installation files isn't in the same AWS Region as your CEV.
- When you request CEV creation in an AWS Region for the first time, RDS Custom creates an S3 bucket for storing RDS Custom resources (such as CEV artifacts, AWS CloudTrail logs, and transaction logs).

CEV creation fails if RDS Custom can't create the S3 bucket. Either the caller doesn't have S3 permissions as described in Step 4: Grant required permissions to your IAM user or role (p. 1012), or the number of S3 buckets has reached the limit.

- The caller doesn't have permissions to get files from your S3 bucket that contains the installation media files. These permissions are described in Step 7: Add necessary IAM permissions (p. 1026).
- Your IAM policy has an aws:SourceIp condition. Make sure to follow the recommendations in AWS Denies access to AWS based on the source IP in the AWS Identity and Access Management User Guide. Also make sure that the caller has the S3 permissions described in Step 4: Grant required permissions to your IAM user or role (p. 1012).
- Installation media files listed in the CEV manifest aren't in your S3 bucket.
- The SHA-256 checksums of the installation files are unknown to RDS Custom.

Confirm that the SHA-256 checksums of the provided files match the SHA-256 checksum on the Oracle website. If the checksums match, contact AWS Support and provide the failed CEV name, file name, and checksum.

- The OPatch version is incompatible with your patch files. You might get the following message: OPatch is lower than minimum required version. Check that the version meets the requirements for all patches, and try again. To apply an Oracle patch, you must use a compatible version of the OPatch utility. You can find the required version of the Opatch utility in the readme file for the patch. Download the most recent OPatch utility from My Oracle Support, and try creating your CEV again.
- The patches specified in the CEV manifest are in the wrong order.

You can view RDS events either on the RDS console (in the navigation pane, choose Events) or by using the describe-events AWS CLI command. The default duration is 60 minutes. If no events are returned, specify a longer duration, as shown in the following example.

```
aws rds describe-events --duration 360
```

Currently, the MediaImport service that imports files from Amazon S3 to create CEVs isn’t integrated with AWS CloudTrail. Therefore, if you turn on data logging for Amazon RDS in CloudTrail, calls to the MediaImport service such as the CreateCustomDbEngineVersion event aren’t logged.

However, you might see calls from the API gateway that accesses your Amazon S3 bucket. These calls come from the MediaImport service for the CreateCustomDbEngineVersion event.
Fixing unsupported configurations in RDS Custom for Oracle

In the shared responsibility model, it’s your responsibility to fix configuration issues that put your RDS Custom for Oracle DB instance into the unsupported-configuration state. If the issue is with the AWS infrastructure, you can use the console or the AWS CLI to fix it. If the issue is with the operating system or the database configuration, you can log in to the host to fix it.

**Note**
This section explains how to fix unsupported configurations in RDS Custom for Oracle. For information about RDS Custom for SQL Server, see Fixing unsupported configurations in RDS Custom for SQL Server (p. 1188).

In the following table, you can find descriptions of the notifications and events that the support perimeter sends and how to fix them. These notifications and the support perimeter are subject to change. For background on the support perimeter, see RDS Custom support perimeter (p. 985). For event descriptions, see Amazon RDS event categories and event messages (p. 874).

<table>
<thead>
<tr>
<th>Configuration</th>
<th>RDS event message</th>
<th>Description</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database health</td>
<td>You need to manually recover the database on EC2 instance [i-xxxxxxxxxxxxxxxxxxx].</td>
<td>The support perimeter monitors the DB instance state. It also monitors how many restarts occurred during the previous hour and day. You’re notified when the instance is in a state where it still exists, but you can’t interact with it.</td>
<td>Log in to your host and examine the database state. ps -eo pid,state,command</td>
</tr>
<tr>
<td>Oracle Data Guard role</td>
<td>The database role [LOGICAL STANDBY] isn't supported. Validate the Oracle Data Guard configuration for the database on Amazon EC2 instance [i-xxxxxxxxxxxxxxxxxxx].</td>
<td>The support perimeter monitors the current database role every 15 seconds and sends a CloudWatch notification if the database role has changed. The Oracle Data Guard DATABASE_ROLE parameter must be either PRIMARY or PHYSICAL STANDBY.</td>
<td>Restore your Oracle Data Guard database role to a supported value. RDS Custom only supports PRIMARY and PHYSICAL STANDBY roles. You can use the following statement to check the role: SELECT DATABASE_ROLE FROM V$DATABASE; If your RDS Custom for Oracle DB instance is standalone, you can use either of the following statements to change it back to the PRIMARY role: ALTER DATABASE COMMIT TO SWITCHOVER PRIMARY;</td>

<td>-----------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Database archive lag target</td>
<td>The monitored Archive Lag Target database parameter on Amazon EC2 instance [i-xxxxxxxxxxxxxxxxxxxx] has changed from [300] to [0]. The RDS Custom instance is using an unsupported configuration because of the following [1] issue(s): (1) The archive lag target database parameter on Amazon EC2 instance [i-xxxxxxxxxxxxxxxxxxxx] is out of desired range {&quot;lowerbound&quot;:60,&quot;upperbound&quot;:7200}. The support perimeter monitors the ARCHIVE_LAG_TARGET database parameter to verify that the DB instance's latest restorable time is within reasonable bounds.</td>
<td>Log in to your host, connect to your RDS Custom for Oracle DB instance, and change the ARCHIVE_LAG_TARGET parameter to a value from 60–7200. For example, use the following SQL command. ALTER SYSTEM SET ARCHIVE_LAG_TARGET=300 SCOPE=BOTH;</td>
<td>Your DB instance becomes available within 30 minutes.</td>
</tr>
<tr>
<td>Database log mode</td>
<td>The monitored log mode of the database on Amazon EC2 instance [i-xxxxxxxxxxxxxxxxxxxx] has changed from [ARCHIVELOG] to [NOARCHIVELOG]. The DB instance log mode must be set to ARCHIVELOG.</td>
<td>Log in to your host and shut down your RDS Custom for Oracle DB instance. Use the following SQL statement to initiate a consistent shutdown. SHUTDOWN IMMEDIATE;</td>
<td>The RDS Custom agent restarts your DB instance and sets the log mode to ARCHIVELOG. Your DB instance becomes available within 30 minutes.</td>
</tr>
</tbody>
</table>

1081
<table>
<thead>
<tr>
<th>Configuration</th>
<th>RDS event message</th>
<th>Description</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operating system</td>
<td>The monitored state of the RDS Custom agent on EC2 instance [i-xxxxxxxxxxxxxxxxxx] has changed from RUNNING to STOPPED.</td>
<td>The RDS Custom agent must always be running. The agent publishes the IamAlive metric to Amazon CloudWatch every 30 seconds. An alarm is triggered if the metric hasn't been published for 30 seconds. The support perimeter also monitors the RDS Custom agent process state on the host every 30 minutes. On RDS Custom for Oracle, the DB instance goes outside the support perimeter if the RDS Custom agent stops.</td>
<td>Log in to your host and make sure that the RDS Custom agent is running. You can use the following command to find the status of the agent. <code>service rdscustomagent status</code> You can use the following command to start the agent. <code>service rdscustomagent start</code> When the RDS Custom agent is running again, the IamAlive metric is published to CloudWatch, and the alarm switches to the OK state. This switch notifies the support perimeter that the agent is running.</td>
</tr>
<tr>
<td>RDS Custom agent status</td>
<td>The AWS Systems Manager agent on EC2 instance [i-xxxxxxxxxxxxxxxxxx] is currently unreachable. Make sure you have correctly configured the network, agent, and IAM permissions.</td>
<td>The SSM agent must always be running. The RDS Custom agent is responsible for making sure that the Systems Manager agent is running. If the SSM agent was down and restarted, the RDS Custom agent publishes a metric to CloudWatch. The RDS Custom agent has an alarm on the metric set to trigger when there has been a restart in each of the previous three minutes. The support perimeter also monitors the SSM agent process state on the host every 30 minutes.</td>
<td>For more information, see Troubleshooting SSM Agent.</td>
</tr>
<tr>

<td>----------------------</td>
<td>-----------------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>sudo configurations</td>
<td>The sudo configurations on EC2 instance [i-xxxxxxxxxxxxxxxxxxxxx] have changed.</td>
<td>The support perimeter monitors that certain OS users are allowed to run certain commands on the box. It monitors sudo configurations against the supported state. When the sudo configurations aren't supported, the RDS Custom tries to overwrite them back to the previous supported state. If that is successful, the following notification is sent: RDS Custom successfully overwrote your configuration.</td>
<td>If the overwrite is unsuccessful, you can log in to your host and investigate why recent changes to the sudo configurations aren't supported. You can use the following command. visudo -c -f /etc/sudoers.d/individual_sudo_files After the support perimeter determines that the sudo configurations are supported, your RDS Custom for Oracle DB instance becomes available within 30 minutes.</td>
</tr>
</tbody>
</table>

**AWS resources**

<p>| Amazon EC2 instance state | The state of the EC2 instance [i-xxxxxxxxxxxxxxxxxxxxx] has changed from [RUNNING] to [STOPPING]. The Amazon EC2 instance [i-xxxxxxxxxxxxxxxxxxxxx] has been terminated and can't be found. Delete the database instance to clean up resources. The Amazon EC2 instance [i-xxxxxxxxxxxxxxxxxxxxx] has been stopped. Start the instance, and restore the host configuration. For more information, see the troubleshooting documentation. | The support perimeter monitors EC2 instance state-change notifications. The EC2 instance must always be running. | If your EC2 instance is stopped, start it and remount the binary and data volumes. If your EC2 instance is terminated, delete your RDS Custom for Oracle DB instance. |</p>
<table>
<thead>
<tr>
<th>Configuration</th>
<th>RDS event message</th>
<th>Description</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon EC2 instance attributes</td>
<td>The attributes of Amazon EC2 instance [i-xxxxxxxxxxxxxxxxxxxx] have changed.</td>
<td>The support perimeter monitors the instance type of the EC2 instance where the RDS Custom DB instance is running. The EC2 instance type must stay the same as when you set it up during RDS Custom DB instance creation.</td>
<td>Change the EC2 instance type back to the original type using the EC2 console or CLI. To change the instance type because of scaling requirements, begin point-in-time recovery and specify the new instance type and class. This action results in a new RDS Custom DB instance with a new host and Domain Name System (DNS) name.</td>
</tr>
<tr>
<td>Amazon Elastic Block Store (Amazon EBS) volumes</td>
<td>The following Amazon EBS volumes are attached to Amazon EC2 instance [i-xxxxxxxxxxxxxxxxxxxx]: [vol-01234abcd56789ef0, vol-0def6789abcd01234]].</td>
<td>RDS Custom creates two types of EBS volume, besides the root volume created from the Amazon Machine Image (AMI), and associates them with the EC2 instance. The binary volume is where the database software binaries are located. The data volumes are where database files are located. The storage configurations that you set when creating the DB instance are used to configure the data volumes. The support perimeter monitors the following: - The initial EBS volumes created with the DB instance are still associated. - The initial EBS volumes still have the same configurations as initially set: storage type, size, Provisioned IOPS, and storage throughput. - No additional EBS volumes are attached to the DB instance.</td>
<td>If you detached any initial EBS volumes, contact AWS Support. If you modified the storage type, Provisioned IOPS, or storage throughput of an EBS volume, revert the modification to the original value. If you modified the storage size of an EBS volume, contact AWS Support. (RDS Custom for Oracle only) If you attached any additional EBS volumes, do either of the following: - Detach the additional EBS volumes from the RDS Custom DB instance. - Contact AWS Support.</td>
</tr>
</tbody>
</table>
Troubleshooting upgrades for RDS Custom for Oracle

Your upgrade of an RDS Custom for Oracle instance might fail. Following, you can find techniques that you can use during upgrades of RDS Custom DB for Oracle DB instances:

- Examine the upgrade output log files in the /tmp directory on your DB instance. The names of the logs depend on your DB engine version. For example, you might see logs that contain the strings catupgrd or catup.
- Examine the alert.log file located in the /rdsdbdata/log/trace directory.
- Run the following grep command in the root directory to track the upgrade OS process. This command shows where the log files are being written and determine the state of the upgrade process.

```
ps -aux | grep upg
```

The following shows sample output.

```
root  18884  0.0  0.0 235428  8172 ?        S<   17:03   0:00 /usr/bin/sudo -u rdsdb /rdsdbbin/scripts/oracle-control ORCL op_apply_upgrade_sh RDS-UPGRADE/2.upgrade.sh
rdsdb 18886  0.0  0.0 153968 12164 ?        S<   17:03   0:00 /usr/bin/perl -T -w /rdsdbbin/scripts/oracle-control ORCL op_apply_upgrade_sh RDS-UPGRADE/2.upgrade.sh
rdsdb 18887  0.0  0.0 113196  3032 ?        S<   17:03   0:00 /bin/sh /rdsdbbin/oracle/rdbms/admin/RDS-UPGRADE/2.upgrade.sh
rdsdb 18900  0.0  0.0 113196  1812 ?        S<   17:03   0:00 /bin/sh /rdsdbbin/oracle/rdbms/admin/RDS-UPGRADE/2.upgrade.sh
rdsdb 18901  0.1  0.0 167652 20620 ?        S<   17:03   0:07 /rdsdbbin/oracle/perl/bin/perl catctl.pl -n 4 -d /rdsdbbin/oracle/rdbms/admin -l /tmp catupgrd.sql
root  29944  0.0  0.0 112724  2316 pts/0 S+   18:43   0:00 grep --color=auto upg
```

- Run the following SQL query to verify the current state of the components to find the database version and the options installed on the DB instance.

```
SET LINESIZE 180
COLUMN COMP_ID FORMAT A15
COLUMN COMP_NAME FORMAT A40 TRUNC
COLUMN STATUS FORMAT A15 TRUNC
SELECT COMP_ID, COMP_NAME, VERSION, STATUS FROM DBA_REGISTRY ORDER BY 1;
```

The output resembles the following.
Troubleshooting RDS Custom for Oracle

You can promote managed Oracle replicas in RDS Custom for Oracle using the console, promote-read-replica AWS CLI command, or PromoteReadReplica API. If you delete your primary DB instance, and all replicas are healthy, RDS Custom for Oracle promotes your managed replicas to standalone instances automatically. If a replica has paused automation or is outside the support perimeter, you must fix the replica before RDS Custom can promote it automatically. For more information, see Replica promotion limitations for RDS Custom for Oracle (p. 1063).

The replica promotion workflow might become stuck in the following situation:

- The primary DB instance is in the state STORAGE_FULL.
- The primary DB can't archive all of its online redo logs.
- A gap exists between the archived redo log files on your Oracle replica and the primary database.

To respond to the stuck workflow, complete the following steps:

1. Synchronize the redo log gap on your Oracle replica DB instance.
2. Force the promotion of your read replica to the latest applied redo log. Run the following commands in SQL*Plus:

   ```sql
   ALTER DATABASE ACTIVATE STANDBY DATABASE;
   SHUTDOWN IMMEDIATE
   STARTUP
   ```

3. Contact AWS Support and request it to move your DB instance to available status.
Working with RDS Custom for SQL Server

Following, you can find instructions for creating, managing, and maintaining your RDS Custom for SQL Server DB instances.

Topics
- RDS Custom for SQL Server workflow (p. 1087)
- Requirements and limitations for Amazon RDS Custom for SQL Server (p. 1089)
- Setting up your environment for Amazon RDS Custom for SQL Server (p. 1115)
- Bring Your Own Media with RDS Custom for SQL Server (p. 1129)
- Working with custom engine versions for RDS Custom for SQL Server (p. 1131)
- Creating and connecting to a DB instance for Amazon RDS Custom for SQL Server (p. 1146)
- Managing an Amazon RDS Custom for SQL Server DB instance (p. 1154)
- Managing a Multi-AZ deployment for RDS Custom for SQL Server (p. 1163)
- Backing up and restoring an Amazon RDS Custom for SQL Server DB instance (p. 1173)
- Migrating an on-premises database to Amazon RDS Custom for SQL Server (p. 1181)
- Upgrading a DB instance for Amazon RDS Custom for SQL Server (p. 1184)
- Troubleshooting DB issues for Amazon RDS Custom for SQL Server (p. 1185)

RDS Custom for SQL Server workflow

The following diagram shows the typical workflow for RDS Custom for SQL Server.

The steps are as follows:

1. Create an RDS Custom for SQL Server DB instance from an engine version offered by RDS Custom.

For more information, see Creating an RDS Custom for SQL Server DB instance (p. 1146).
2. Connect your application to the RDS Custom DB instance endpoint.
   For more information, see Connecting to your RDS Custom DB instance using AWS Systems Manager (p. 1149) and Connecting to your RDS Custom DB instance using RDP (p. 1151).
3. (Optional) Access the host to customize your software.
4. Monitor notifications and messages generated by RDS Custom automation.

Creating a DB instance for RDS Custom

You create your RDS Custom DB instance using the `create-db-instance` command. The procedure is similar to creating an Amazon RDS instance. However, some of the parameters are different. For more information, see Creating and connecting to a DB instance for Amazon RDS Custom for SQL Server (p. 1146).

Database connection

Like an Amazon RDS DB instance, your RDS Custom for SQL Server DB instance resides in a VPC. Your application connects to the RDS Custom instance using a client such as SQL Server Management Suite (SSMS), just as in RDS for SQL Server.

RDS Custom customization

You can access the RDS Custom host to install or customize software. To avoid conflicts between your changes and the RDS Custom automation, you can pause the automation for a specified period. During this period, RDS Custom doesn't perform monitoring or instance recovery. At the end of the period, RDS Custom resumes full automation. For more information, see Pausing and resuming RDS Custom automation (p. 1154).
Requirements and limitations for Amazon RDS Custom for SQL Server

Following, you can find a summary of the Amazon RDS Custom for SQL Server requirements and limitations for quick reference. Requirements and limitations also appear in the relevant sections.

Topics

- Region and version availability (p. 1089)
- General requirements for RDS Custom for SQL Server (p. 1089)
- DB instance class support for RDS Custom for SQL Server (p. 1089)
- Limitations for RDS Custom for SQL Server (p. 1090)
- Collation and character support for RDS Custom for SQL Server DB instances (p. 1090)
- Local time zone for RDS Custom for SQL Server DB instances (p. 1107)

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of Amazon RDS with Amazon RDS Custom for SQL Server, see RDS Custom for SQL Server (p. 153).

General requirements for RDS Custom for SQL Server

Make sure to follow these requirements for Amazon RDS Custom for SQL Server:

- Use the instance classes shown in DB instance class support for RDS Custom for SQL Server (p. 1089). The only storage types supported are solid state drives (SSD) of types gp2, gp3, and io1. The maximum storage limit is 16 TiB.
- Make sure that you have a symmetric encryption AWS KMS key to create an RDS Custom DB instance. For more information, see Make sure that you have a symmetric encryption AWS KMS key (p. 1120).
- Make sure that you create an AWS Identity and Access Management (IAM) role and instance profile. For more information, see Creating your IAM role and instance profile manually (p. 1121).
- Make sure to supply a networking configuration that RDS Custom can use to access other AWS services. For specific requirements, see Configure networking, instance profile, and encryption (p. 1117).
- The combined number of RDS Custom and Amazon RDS DB instances can't exceed your quota limit. For example, if your quota is 40 DB instances, you can have 20 RDS Custom for SQL Server DB instances and 20 Amazon RDS DB instances.

DB instance class support for RDS Custom for SQL Server

RDS Custom for SQL Server supports the DB instance classes shown in the following table.

<table>
<thead>
<tr>
<th>SQL Server edition</th>
<th>RDS Custom support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enterprise Edition</td>
<td>db.r5.xlarge–db.r5.24xlarge</td>
</tr>
<tr>
<td></td>
<td>db.m5.xlarge–db.m5.24xlarge</td>
</tr>
<tr>
<td>Standard Edition</td>
<td>db.r5.large–db.r5.24xlarge</td>
</tr>
<tr>
<td></td>
<td>db.m5.large–db.m5.24xlarge</td>
</tr>
</tbody>
</table>
SQL Server edition | RDS Custom support
---|---
Web Edition | db.r5.large–db.r5.4xlarge
| db.m5.large–db.m5.4xlarge

**Limitations for RDS Custom for SQL Server**

The following limitations apply to RDS Custom for SQL Server:

- You can't create read replicas in Amazon RDS for RDS Custom for SQL Server DB instances. However, you can configure high availability automatically with a Multi-AZ deployment. For more information, see [Managing a Multi-AZ deployment for RDS Custom for SQL Server](p. 1163).

- Transparent Data Encryption (TDE) for database encryption isn't supported for RDS Custom for SQL Server. However, you can use KMS for storage-level encryption. For more information on using KMS with RDS Custom for SQL Server, see [Make sure that you have a symmetric encryption AWS KMS key](p. 1120).

- For an RDS Custom for SQL Server DB instance that wasn't created with a custom engine version (CEV), changes to the Microsoft Windows operating system or C: drive aren't guaranteed to persist. For example, you will lose these changes when you scale compute or initiate a snapshot restore operation. If the RDS Custom for SQL Server DB instance was created with a CEV, then those changes are persisted.

- Not all options are supported. For example, when you create an RDS Custom for SQL Server DB instance, you can't do the following:
  - Change the number of CPU cores and threads per core on the DB instance class.
  - Turn on storage autoscaling.
  - Configure Kerberos authentication using the AWS Management Console. However, you can configure Windows Authentication manually and use Kerberos.
  - Specify your own DB parameter group, option group, or character set.
  - Turn on Performance Insights.
  - Turn on automatic minor version upgrade.
  - The maximum DB instance storage is 16 TiB.

**Collation and character support for RDS Custom for SQL Server DB instances**

RDS Custom for SQL Server supports a wide range of server collations, both in traditional and UTF-8 encoding, for the SQL_Latin, Japanese, German, and Arabic locales. The default server collation is `SQL_Latin1_General_CP1_CI_AS`, however, you can select another supported collation to use. You can select a collation using the same procedure that RDS for SQL Server uses. For more information, see [Collations and character sets for Microsoft SQL Server](p. 1623).

The following requirements and limitations apply when working with server collations on RDS Custom for SQL Server:

- You can set the server collation when you create an RDS Custom for SQL Server DB instance. You can't modify the server-level collation after the DB instance is created.

- You can't modify the server level collation when restoring from a DB snapshot or during a point in time recovery (PITR).
When you create a DB instance from an RDS Custom for SQL Server CEV, the DB instance doesn't inherit the server collation from the CEV. Instead, the default server collation of SQL_Latin1_General_CP1_CI_AS is used. If you've configured a non-default server collation on a RDS Custom for SQL Server CEV and want to use that same server collation on a new DB instance, be sure to select that same collation when you create the DB instance from the CEV.

**Note**
If the collation you select while creating the DB instance is different from the collation of the CEV, the Microsoft SQL Server system databases on the new RDS Custom for SQL Server DB instance will be rebuilt to use the updated collation. The rebuild process is only performed on the new RDS Custom for SQL Server DB instance and has no impact on the CEV itself. Any previous modifications that you made to the system databases on the CEV will not be retained on the new RDS Custom for SQL Server DB instance once the system databases are rebuilt. Examples of some modifications include user-defined objects in the master database, scheduled jobs in the msdb database, or changes to default database settings in the model database on your CEV. You can manually recreate your modifications once the new RDS Custom for SQL Server DB instance is created.

When you create a DB instance from an RDS Custom for SQL Server custom engine version (CEV) and select a different collation from that of the CEV, ensure that your golden image (AMI) used for CEV creation meets the following requirements so the Microsoft SQL Server system databases on the new DB instance can be rebuilt:

- For SQL Server 2019, ensure the setup.exe file is located in the following path: `C:\Program Files\Microsoft SQL Server\150\Setup Bootstrap\SQL2019\setup.exe`
- Copies of the data and log templates for the master, model, and msdb databases must exist in their default locations. For more information, see [Rebuild system databases](#) in the Microsoft public documentation.
- Ensure your SQL Server Database Engine uses `NT Service\MSSQLSERVER` or `NT AUTHORITY\NETWORK SERVICE` as the service account. Any other account will not have the required permissions on the `C:\` drive when configuring a non-default server collation for the DB instance.

If the server collation selected for a new DB instance is the same as that configured on your CEV, the Microsoft SQL Server system databases on the new RDS Custom for SQL Server DB instance do not undergo the rebuild process. Any previous modifications that you made to the system databases on the CEV will automatically persist to the new RDS Custom for SQL Server DB instance.

You can set your collation to one of the values listed in the following table.

Local time zone for RDS Custom for SQL Server DB instances

The time zone of an RDS Custom for SQL Server DB instance is set by default. The current default is Coordinated Universal Time (UTC). You can set the time zone of your DB instance to a local time zone instead, to match the time zone of your applications.

You set the time zone when you first create your DB instance. You can create your DB instance by using the AWS Management Console, the Amazon RDS API CreateDBInstance action, or the AWS CLI create-db-instance command.

If your DB instance is part of a Multi-AZ deployment, then when you fail over, your time zone remains the local time zone that you set.

When you request a point-in-time restore, you specify the time to restore to. The time is shown in your local time zone. For more information, see Restoring a DB instance to a specified time (p. 660).

The following are limitations to setting the local time zone on your DB instance:

- You can configure the time zone for a DB instance during instance creation, but you can't modify the time zone of an existing RDS Custom for SQL Server DB instance.
- If the time zone is modified for an existing RDS Custom for SQL Server DB instance, RDS Custom changes the DB instance status to unsupported-configuration, and sends event notifications.
- You can't restore a snapshot from a DB instance in one time zone to a DB instance in a different time zone.
- We strongly recommend that you don't restore a backup file from one time zone to a different time zone. If you restore a backup file from one time zone to a different time zone, you must audit your queries and applications for the effects of the time zone change. For more information, see Importing and exporting SQL Server databases using native backup and restore (p. 1435).

Supported time zones

You can set your local time zone to one of the values listed in the following table.

<table>
<thead>
<tr>
<th>Time zone</th>
<th>Standard time offset</th>
<th>Description</th>
<th>Notes</th>
</tr>

Setting up your environment for Amazon RDS Custom for SQL Server

Before you create and manage a DB instance for Amazon RDS Custom for SQL Server DB instance, make sure to perform the following tasks.

Contents

• Prerequisites for setting up RDS Custom for SQL Server (p. 1115)
• Download and install the AWS CLI (p. 1116)
• Grant required permissions to your IAM principal (p. 1116)
• Configure networking, instance profile, and encryption (p. 1117)
  • Configuring with AWS CloudFormation (p. 1117)
    • Resources created by CloudFormation (p. 1118)
    • Downloading the template file (p. 1118)
    • Configuring resources using CloudFormation (p. 1118)
  • Configuring manually (p. 1120)
    • Make sure that you have a symmetric encryption AWS KMS key (p. 1120)
    • Creating your IAM role and instance profile manually (p. 1121)
      • Create the AWSSRDCustomSQLServerInstanceRole IAM role (p. 1121)
      • Add an access policy to AWSSRDCustomSQLServerInstanceRole (p. 1121)
      • Create your RDS Custom for SQL Server instance profile (p. 1125)
      • Add AWSSRDCustomSQLServerInstanceRole to your RDS Custom for SQL Server instance profile (p. 1125)
  • Configuring your VPC manually (p. 1125)
    • Configure your VPC security group (p. 1126)
    • Configure endpoints for dependent AWS services (p. 1126)
    • Configure the instance metadata service (p. 1128)

Prerequisites for setting up RDS Custom for SQL Server

Before creating an RDS Custom for SQL Server DB instance, make sure that your environment meets the requirements described in this topic. As part of this setup process, make sure to configure the following prerequisites:

• Configure the specified AWS Identity and Access Management (IAM) users and roles.
  
  These are either used to create an RDS Custom DB instance or passed as a parameter in a creation request.

• Confirm there aren’t any service control policies (SCPs) restricting account level permissions.
  
  If the account that you’re using is part of an AWS Organization, it might have service control policies (SCPs) restricting account level permissions. Make sure that the SCPs don’t restrict the permissions on users and roles that you create using the following procedures.

For more information about SCPs, see Service control policies (SCPs) in the AWS Organizations User Guide. Use the describe-organization AWS CLI command to check whether your account is part of an AWS Organization.

For more information about AWS Organizations, see What is AWS Organizations in the AWS Organizations User Guide.
Note
For a step-by-step tutorial on how to set up prerequisites and launch Amazon RDS Custom for SQL Server, see the blog post Get started with Amazon RDS Custom for SQL Server using a CloudFormation template (Network setup).

For each task, you can find descriptions following for the requirements and limitations specific to that task. For example, when you create your RDS Custom for SQL Server DB instance, use one of the SQL Server instances listed in DB instance class support for RDS Custom for SQL Server (p. 1089).

For general requirements that apply to RDS Custom for SQL Server, see General requirements for RDS Custom for SQL Server (p. 1089).

Download and install the AWS CLI
AWS provides you with a command-line interface to use RDS Custom features. You can use either version 1 or version 2 of the AWS CLI.

For information about downloading and installing the AWS CLI, see Installing or updating the latest version of the AWS CLI.

Skip this step if either of the following is true:
- You plan to access RDS Custom only from the AWS Management Console.
- You have already downloaded the AWS CLI for Amazon RDS or a different RDS Custom DB engine.

Grant required permissions to your IAM principal
You use an IAM role or IAM user (referred to as the IAM principal) for creating an RDS Custom for SQL Server DB instance using the console or CLI. This IAM principal must have either of the following policies for successful DB instance creation:

- The AdministratorAccess policy
- The AmazonRDSFullAccess policy with the following additional permissions:

  ```json
  {  
    "Version": "2012-10-17",  
    "Statement": [  
      {  
        "Sid": "ValidateIamRole",  
        "Effect": "Allow",  
        "Action": ["iam:SimulatePrincipalPolicy",  
                    "cloudtrail:CreateTrail",  
                    "cloudtrail:StartLogging",  
                    "s3:CreateBucket",  
                    "s3:PutBucketPolicy",  
                    "s3:PutBucketObjectLockConfiguration",  
                    "s3:PutBucketVersioning",  
                    "kms:CreateGrant",  
                    "kms:DescribeKey"]  
      }  
  ]
  }
  ``

For more information about the kms:CreateGrant permission, see AWS KMS key management (p. 2606).

The following sample JSON policy grants the required permissions.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ValidateIamRole",
            "Effect": "Allow",
            "Action": ["iam:SimulatePrincipalPolicy",
                        "cloudtrail:CreateTrail",
                        "cloudtrail:StartLogging",
                        "s3:CreateBucket",
                        "s3:PutBucketPolicy",
                        "s3:PutBucketObjectLockConfiguration",
                        "s3:PutBucketVersioning",
                        "kms:CreateGrant",
                        "kms:DescribeKeyId"]
        }
    ]
}
```
Also, the IAM principal requires the `iam:PassRole` permission on the IAM role. That must be attached to the instance profile passed in the `custom-iam-instance-profile` parameter in the request to create the RDS Custom DB instance. The instance profile and its attached role are created later in Configure networking, instance profile, and encryption (p. 1117).

Make sure that the previously listed permissions aren't restricted by service control policies (SCPs), permission boundaries, or session policies associated with the IAM principal.

### Configure networking, instance profile, and encryption

You can configure your IAM instance profile role, virtual private cloud (VPC), and AWS KMS symmetric encryption key by using either of the following processes:

- **Configuring with AWS CloudFormation (p. 1117)** (recommended)
- **Configuring manually (p. 1120)**

If your account is part of an AWS Organization, make sure that the permissions required by the instance profile role aren't restricted by service control policies (SCPs).

The following networking configurations are designed to work best with DB instances that aren't publicly accessible. That is, you can't connect directly to the DB instance from outside the VPC.

### Configuring with AWS CloudFormation

To simplify setup, you can use an AWS CloudFormation template file to create a CloudFormation stack. To learn how to create stacks, see Creating a stack on the AWS CloudFormation console in the AWS CloudFormation User Guide.
For a tutorial on how to launch Amazon RDS Custom for SQL Server using an AWS CloudFormation template, see Get started with Amazon RDS Custom for SQL Server using an AWS CloudFormation template in the AWS Database Blog.

Topics
- Resources created by CloudFormation (p. 1118)
- Downloading the template file (p. 1118)
- Configuring resources using CloudFormation (p. 1118)

Resources created by CloudFormation

Successfully creating the CloudFormation stack creates the following resources in your AWS account:

- Symmetric encryption KMS key for encryption of data managed by RDS Custom.
- Instance profile and associated IAM role for attaching to RDS Custom instances.
- VPC with the CIDR range specified as the CloudFormation parameter. The default value is 10.0.0.0/16.
- Two private subnets with the CIDR range specified in the parameters, and two different Availability Zones in the AWS Region. The default values for the subnet CIDRs are 10.0.128.0/20 and 10.0.144.0/20.
- DHCP option set for the VPC with domain name resolution to an Amazon Domain Name System (DNS) server.
- Route table to associate with two private subnets and no access to the internet.
- Network access control list (ACL) to associate with two private subnets and access restricted to HTTPS.
- VPC security group to be associated with the RDS Custom instance. Access is restricted for outbound HTTPS to AWS service endpoints that are required by RDS Custom.
- VPC security group to be associated with VPC endpoints that are created for AWS service endpoints that are required by RDS Custom.
- DB subnet group in which RDS Custom instances are created.
- VPC endpoints for each of the AWS service endpoints that are required by RDS Custom.

Use the following procedures to create the CloudFormation stack for RDS Custom for SQL Server.

Downloading the template file

To download the template file
1. Open the context (right-click) menu for the link custom-sqlserver-onboard.zip and choose Save Link As.
2. Save and extract the file to your computer.

Configuring resources using CloudFormation

To configure resources using CloudFormation
2. To start the Create Stack wizard, choose Create Stack.
   The Create stack page appears.
3. For Prerequisite - Prepare template, choose Template is ready.
4. For Specify template, do the following:
5. Choose Next.

The Specify stack details page appears.

6. For **Stack name**, enter `rds-custom-sqlserver`.

7. For **Parameters**, do the following:
   a. To keep the default options, choose Next.
   b. To change options, choose the appropriate CIDR block range for the VPC and two of its subnets, and then choose Next.

   Read the description of each parameter carefully before changing parameters.

8. On the **Configure stack options page**, choose Next.

9. On the **Review rds-custom-sqlserver** page, do the following:
   a. For **Capabilities**, select the I acknowledge that AWS CloudFormation might create IAM resources with custom names check box.
   b. Choose Create stack.

10. **(Optional):** You can update the SQS permissions in the instance profile role.

    If you want to deploy only a Single-AZ DB instance, you can edit the CloudFormation template file to remove SQS permissions. SQS permissions are only required for a Multi-AZ deployment and allow RDS Custom for SQL Server to call Amazon SQS to perform specific actions. Because they are not required for a Single-AZ deployment, you may opt to remove these permissions to follow the principle of least privilege.

    If you want to configure a Multi-AZ deployment, you don't need to remove the SQS permissions.

    **Note**
    If you remove the SQS permissions and later choose to modify to a Multi-AZ deployment, the Multi-AZ creation will fail. You would need to re-add the SQS permissions before modifying to a Multi-AZ deployment.

    To make this optional change to the CloudFormation template, open the CloudFormation console at [https://console.aws.amazon.com/cloudformation](https://console.aws.amazon.com/cloudformation), and edit the template file by removing the following lines:

    ```json
    {
      "Sid": "SendMessageToSQSQueue",
      "Effect": "Allow",
      "Action": [
        "SQS:SendMessage",
        "SQS:ReceiveMessage",
        "SQS:DeleteMessage",
        "SQS:GetQueueUrl"
      ],
      "Resource": [
        "Fn::Sub": "arn:${AWS::Partition}:sqs:${AWS::Region}:${AWS::AccountId}:do-not-delete-rds-custom-*"
      ],
      "Condition": {
        "StringLike": {
          "aws:ResourceTag/AWSRDSCustom": "custom-sqlserver"
        }
      }
    }
    ```
CloudFormation creates the resources that RDS Custom for SQL Server requires. If the stack creation fails, read through the **Events** tab to see which resource creation failed and its status reason.

The **Outputs** tab for this CloudFormation stack in the console should have information about all resources to be passed as parameters for creating an RDS Custom for SQL Server DB instance. Make sure to use the VPC security group and DB subnet group created by CloudFormation for RDS Custom DB instances. By default, RDS tries to attach the default VPC security group, which might not have the access that you need.

**Note**
When you delete a CloudFormation stack, all of the resources created by the stack are deleted except the KMS key. The KMS key goes into a pending-deletion state and is deleted after 30 days. To keep the KMS key, perform a [CancelKeyDeletion](#) operation during the 30-day grace period.

If you used CloudFormation to create resources, you can skip Configuring manually (p. 1120).

**Configuring manually**

If you choose to configure resources manually, perform the following tasks.

**Note**
To simplify setup, you can use the AWS CloudFormation template file to create a CloudFormation stack rather than a manual configuration. For more information, see Configuring with AWS CloudFormation (p. 1117).

**Topics**
- Make sure that you have a symmetric encryption AWS KMS key (p. 1120)
- Creating your IAM role and instance profile manually (p. 1121)
- Configuring your VPC manually (p. 1125)

**Make sure that you have a symmetric encryption AWS KMS key**

A symmetric encryption AWS KMS key is required for RDS Custom. When you create an RDS Custom for SQL Server DB instance, make sure to supply the KMS key identifier. For more information, see [Creating and connecting to a DB instance for Amazon RDS Custom for SQL Server](#).

You have the following options:

- If you have an existing customer managed KMS key in your AWS account, you can use it with RDS Custom. No further action is necessary.
- If you already created a customer managed symmetric encryption KMS key for a different RDS Custom engine, you can reuse the same KMS key. No further action is necessary.
- If you don't have an existing customer managed symmetric encryption KMS key in your account, create a KMS key by following the instructions in [Creating keys](#) in the [AWS Key Management Service Developer Guide](#).
- If you're creating a CEV or RDS Custom DB instance, and your KMS key is in a different AWS account, make sure to use the AWS CLI. You can't use the AWS console with cross-account KMS keys.

**Important**
RDS Custom doesn't support AWS managed KMS keys.
Make sure that your symmetric encryption key grants access to the kms:Decrypt and kms:GenerateDataKey operations to the AWS Identity and Access Management (IAM) role in your IAM instance profile. If you have a new symmetric encryption key in your account, no changes are required. Otherwise, make sure that your symmetric encryption key's policy grants access to these operations.

For more information, see Step 3: Configure IAM and your Amazon VPC (p. 1003).

Creating your IAM role and instance profile manually

To use RDS Custom for SQL Server, create an IAM instance profile and IAM role as described following.

To create the IAM instance profile and IAM roles for RDS Custom for SQL Server

1. Create the IAM role named AWSRDSCustomSQLServerInstanceRole with a trust policy that lets Amazon EC2 assume this role.
2. Add an access policy to AWSRDSCustomSQLServerInstanceRole.
3. Create an IAM instance profile for RDS Custom for SQL Server that is named AWSRDSCustomSQLServerInstanceProfile.
4. Add AWSRDSCustomSQLServerInstanceRole to the instance profile.

Create the AWSRDSCustomSQLServerInstanceRole IAM role

The following example creates the AWSRDSCustomSQLServerInstanceRole role. The trust policy lets Amazon EC2 assume the role.

```bash
aws iam create-role
    --role-name AWSRDSCustomSQLServerInstanceRole
    --assume-role-policy-document '{
        "Version": "2012-10-17",
        "Statement": [
            {
                "Action": "sts:AssumeRole",
                "Effect": "Allow",
                "Principal": {
                    "Service": "ec2.amazonaws.com"
                }
            }
        ]
    }'
```

Add an access policy to AWSRDSCustomSQLServerInstanceRole

When you embed an inline policy in a role, the inline policy is used as part of the role's access (permissions) policy. You create the AWSRDSCustomSQLServerIamRolePolicy policy, which lets Amazon EC2 get and receive messages and perform various actions.

Make sure that the permissions in the access policy aren't restricted by SCPs or permission boundaries associated with the instance role profile.

The following example creates the access policy named AWSRDSCustomSQLServerIamRolePolicy, and adds it to the AWSRDSCustomSQLServerInstanceRole role. This example assumes that the '$REGION', $ACCOUNT_ID, and '$CUSTOMER_KMS_KEY_ID' variables have been set. '$CUSTOMER_KMS_KEY_ID' is the ID, not the Amazon Resource Name (ARN), of the KMS key that you defined in Make sure that you have a symmetric encryption AWS KMS key (p. 1120).

```bash
aws iam put-role-policy
    --role-name AWSRDSCustomSQLServerInstanceRole
    --policy-name AWSRDSCustomSQLServerIamRolePolicy
    --policy-document '{
        "Version": "2012-10-17",
        "Statement": [
            {
                "Action": "sts:AssumeRole",
                "Effect": "Allow",
                "Principal": {
                    "Service": "ec2.amazonaws.com"
                }
            }]
    }'
```
"Version": "2012-10-17",
"Statement": [
  {
    "Sid": "ssmAgent1",
    "Effect": "Allow",
    "Action": [
      "ssm:GetDeployablePatchSnapshotForInstance",
      "ssm:ListAssociations",
      "ssm:PutInventory",
      "ssm:PutConfigurePackageResult",
      "ssm:UpdateInstanceInformation",
      "ssm:GetManifest"
    ],
    "Resource": "*"
  },
  {
    "Sid": "ssmAgent2",
    "Effect": "Allow",
    "Action": [
      "ssm:ListInstanceAssociations",
      "ssm:PutComplianceItems",
      "ssm:UpdateAssociationStatus",
      "ssm:DescribeAssociation",
      "ssm:DescribeInstanceAssociationStatus"
    ],
    "Resource": "arn:aws:ec2:'$REGION':'$ACCOUNT_ID':instance/**",
    "Condition": {

Create your RDS Custom for SQL Server instance profile

Create your instance profile as follows, naming it AWSRDSCustomSQLServerInstanceProfile.

```
aws iam create-instance-profile \
  --instance-profile-name AWSRDSCustomSQLServerInstanceProfile
```

Add AWSRDSCustomSQLServerInstanceRole to your RDS Custom for SQL Server instance profile

Add the AWSRDSCustomInstanceRoleForRdsCustomInstance role to the AWSRDSCustomSQLServerInstanceProfile profile.

```
aws iam add-role-to-instance-profile \
  --instance-profile-name AWSRDSCustomSQLServerInstanceProfile \
  --role-name AWSRDSCustomSQLServerInstanceRole
```

Configuring your VPC manually

Your RDS Custom DB instance is in a virtual private cloud (VPC) based on the Amazon VPC service, just like an Amazon EC2 instance or Amazon RDS instance. You provide and configure your own VPC. Thus, you have full control over your instance networking setup.

RDS Custom sends communication from your DB instance to other AWS services. To make sure that RDS Custom can communicate, it validates network connectivity to the following AWS services:

- Amazon CloudWatch
- Amazon CloudWatch Logs
- Amazon CloudWatch Events
- Amazon EC2
- Amazon EventBridge
- Amazon S3
- AWS Secrets Manager
- AWS Systems Manager

If RDS Custom can't communicate with the necessary services, it publishes the following event:

```
Database instance in incompatible-network. SSM Agent connection not available. Amazon RDS can't connect to the dependent AWS services.
```
To avoid incompatible-network errors, make sure that VPC components involved in communication between your RDS Custom DB instance and AWS services satisfy the following requirements:

- The DB instance can make outbound connections on port 443 to other AWS services.
- The VPC allows incoming responses to requests originating from your RDS Custom DB instance.
- RDS Custom can correctly resolve the domain names of endpoints for each AWS service.

RDS Custom relies on AWS Systems Manager connectivity for its automation. For information about how to configure VPC endpoints, see Creating VPC endpoints for Systems Manager. For the list of endpoints in each Region, see AWS Systems Manager endpoints and quotas in the Amazon Web Services General Reference.

If you already configured a VPC for a different RDS Custom DB engine, you can reuse that VPC and skip this process.

Topics

- Configure your VPC security group (p. 1126)
- Configure endpoints for dependent AWS services (p. 1126)
- Configure the instance metadata service (p. 1128)

Configure your VPC security group

A security group acts as a virtual firewall for a VPC instance, controlling both inbound and outbound traffic. An RDS Custom DB instance has a default security group that protects the instance. Make sure that your security group permits traffic between RDS Custom and other AWS services.

To configure your security group for RDS Custom

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc.
2. Allow RDS Custom to use the default security group, or create your own security group.
   For detailed instructions, see Provide access to your DB instance in your VPC by creating a security group (p. 177).
3. Make sure that your security group permits outbound connections on port 443. RDS Custom needs this port to communicate with dependent AWS services.
4. If you have a private VPC and use VPC endpoints, make sure that the security group associated with the DB instance allows outbound connections on port 443 to VPC endpoints. Also make sure that the security group associated with the VPC endpoint allows inbound connections on port 443 from the DB instance.
   If incoming connections aren't allowed, the RDS Custom instance can't connect to the AWS Systems Manager and Amazon EC2 endpoints. For more information, see Create a Virtual Private Cloud endpoint in the AWS Systems Manager User Guide.

For more information about security groups, see Security groups for your VPC in the Amazon VPC Developer Guide.

Configure endpoints for dependent AWS services

Make sure that your VPC allows outbound traffic to the following AWS services with which the DB instance communicates:

- Amazon CloudWatch
We recommend that you add endpoints for every service to your VPC using the following instructions. However, you can use any solution that lets your VPC communicate with AWS service endpoints. For example, you can use Network Address Translation (NAT) or AWS Direct Connect.

To configure endpoints for AWS services with which RDS Custom works

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. On the navigation bar, use the Region selector to choose the AWS Region.
3. In the navigation pane, choose Endpoints. In the main pane, choose Create Endpoint.
4. For Service category, choose AWS services.
5. For Service Name, choose the endpoint shown in the table.
6. For VPC, choose your VPC.
7. For Subnets, choose a subnet from each Availability Zone to include.

The VPC endpoint can span multiple Availability Zones. AWS creates an elastic network interface for the VPC endpoint in each subnet that you choose. Each network interface has a Domain Name System (DNS) host name and a private IP address.
8. For Security group, choose or create a security group.

You can use security groups to control access to your endpoint, much as you use a firewall. For more information about security groups, see Security groups for your VPC in the Amazon VPC User Guide.
9. Optionally, you can attach a policy to the VPC endpoint. Endpoint policies can control access to the AWS service to which you are connecting. The default policy allows all requests to pass through the endpoint. If you're using a custom policy, make sure that requests from the DB instance are allowed in the policy.
10. Choose Create endpoint.

The following table explains how to find the list of endpoints that your VPC needs for outbound communications.

<table>
<thead>
<tr>
<th>Service</th>
<th>Endpoint format</th>
<th>Notes and links</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS Systems Manager</td>
<td>Use the following endpoint formats:</td>
<td>For the list of endpoints in each Region, see AWS Systems Manager endpoints and</td>

### Configure the Instance Metadata Service

Make sure that your instance can do the following:

- Access the instance metadata service using Instance Metadata Service Version 2 (IMDSv2).
- Allow outbound communications through port 80 (HTTP) to the IMDS link IP address.
- Request instance metadata from http://169.254.169.254, the IMDSv2 link.

For more information, see [Use IMDSv2](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/instance-metadata-service.html) in the Amazon EC2 User Guide for Linux Instances.
Bring Your Own Media with RDS Custom for SQL Server

RDS Custom for SQL Server supports two licensing models: License Included (LI) and Bring Your Own Media (BYOM).

**With BYOM, you can do the following:**

1. Provide and install your own Microsoft SQL Server binaries with supported cumulative updates (CU) on an AWS EC2 Windows AMI.
2. Save the AMI as a golden image, which is a template that you can use to create a custom engine version (CEV).
3. Create a CEV from your golden image.
4. Create new RDS Custom for SQL Server DB instances by using your CEV.

Amazon RDS then manages your DB instances for you.

**Note**
If you also have a License Included (LI) RDS Custom for SQL Server DB instance, you can't use the SQL Server software from this DB instance with BYOM. You must bring your own SQL Server binaries to BYOM.

**Requirements for BYOM for RDS Custom for SQL Server**

The same general requirements for custom engine versions with RDS Custom for SQL Server also apply to BYOM. For more information, see [Requirements for RDS Custom for SQL Server CEVs](p. 1135).

When using BYOM, make sure that you meet the following additional requirements:

- Use only SQL Server 2019 Enterprise and Standard edition. These are the only supported editions.
- Grant the SQL Server sysadmin (SA) server role privilege to `NT AUTHORITY\SYSTEM`.
- Keep the Windows Server OS configured with UTC time.

Amazon EC2 Windows instances are set to the UTC time zone by default. For more information about viewing and changing the time for a Windows instance, see [Set the time for a Windows instance](p. 468).

- Open TCP port 1433 and UDP port 1434 to allow SSM connections.

**Limitations of BYOM for RDS Custom for SQL Server**

The same general limitations for RDS Custom for SQL Server also apply to BYOM. For more information, see [Requirements and limitations for Amazon RDS Custom for SQL Server](p. 1089).

With BYOM, the following additional limitations apply:

- Only the default SQL Server instance (MSSQLSERVER) is supported. Named SQL Server instances aren’t supported. RDS Custom for SQL Server detects and monitors only the default SQL Server instance.
- Only a single installation of SQL Server is supported on each AMI. Multiple installations of different SQL Server versions aren’t supported.
- SQL Server Web edition isn’t supported with BYOM.
- Evaluation versions of SQL Server editions aren’t supported with BYOM. When you install SQL Server, don’t select the checkbox for using an evaluation version.
Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information, see Region availability for RDS Custom for SQL Server CEVs (p. 1134) and Version support for RDS Custom for SQL Server CEVs (p. 1135).

Creating an RDS Custom for SQL Server DB instance with BYOM

To prepare and create an RDS Custom for SQL Server DB instance with BYOM, see Preparing a CEV using Bring Your Own Media (BYOM) (p. 1133).
Working with custom engine versions for RDS Custom for SQL Server

A custom engine version (CEV) for RDS Custom for SQL Server is an Amazon Machine Image (AMI) that includes Microsoft SQL Server.

The basic steps of the CEV workflow are as follows:

1. Choose an AWS EC2 Windows AMI to use as a base image for a CEV. You have the option to use pre-installed Microsoft SQL Server, or bring your own media to install SQL Server yourself.
2. Install other software on the operating system (OS) and customize the configuration of the OS and SQL Server to meet your enterprise needs.
3. Save the AMI as a golden image
4. Create a custom engine version (CEV) from your golden image.
5. Create new RDS Custom for SQL Server DB instances by using your CEV.

Amazon RDS then manages these DB instances for you.

A CEV allows you to maintain your preferred baseline configuration of the OS and database. Using a CEV ensures that the host configuration, such as any third-party agent installation or other OS customizations, are persisted on RDS Custom for SQL Server DB instances. With a CEV, you can quickly deploy fleets of RDS Custom for SQL Server DB instances with the same configuration.

Topics
- Preparing to create a CEV for RDS Custom for SQL Server (p. 1131)
- Creating a CEV for RDS Custom for SQL Server (p. 1136)
- Modifying a CEV for RDS Custom for SQL Server (p. 1140)
- Viewing CEV details for Amazon RDS Custom for SQL Server (p. 1142)
- Deleting a CEV for RDS Custom for SQL Server (p. 1144)

Preparing to create a CEV for RDS Custom for SQL Server

You can create a CEV using an Amazon Machine Image (AMI) that contains pre-installed, License Included (LI) Microsoft SQL Server, or with an AMI on which you install your own SQL Server installation media (BYOM).

Contents
- Preparing a CEV using pre-installed SQL Server (LI) (p. 1131)
- Preparing a CEV using Bring Your Own Media (BYOM) (p. 1133)
- Region availability for RDS Custom for SQL Server CEVs (p. 1134)
- Version support for RDS Custom for SQL Server CEVs (p. 1135)
- Requirements for RDS Custom for SQL Server CEVs (p. 1135)
- Limitations for RDS Custom for SQL Server CEVs (p. 1135)

Preparing a CEV using pre-installed SQL Server (LI)

The following steps to create a CEV using pre-installed Microsoft SQL Server (LI) use an AMI with SQL Server CU20 Release number 2023.05.10 as an example. When you create a CEV, choose an AMI with
the most recent release number. This ensures that you are using a supported version of Windows Server and SQL Server with the latest Cumulative Update (CU).

To create a CEV using pre-installed Microsoft SQL Server (LI)

1. Choose the latest available AWS EC2 Windows Amazon Machine Image (AMI) with License Included (LI) Microsoft Windows Server and SQL Server.
   a. Search for CU20 within the Windows AMI version history.
   b. Note the Release number. For SQL Server 2019 CU20, the release number is 2023.05.10.
   c. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
   d. In the left navigation panel of the Amazon EC2 console choose Images, then AMIs.
   e. Choose Public images.
   f. Enter 2023.05.10 into the search box. A list of AMIs appears.
   g. Enter Windows_Server-2019-English-Full-SQL_2019 into the search box to filter the results. The following results should appear.
   h. Choose the AMI with the SQL Server edition that you want to use.
2. Create or launch an EC2 instance from your chosen AMI.
3. Log in to the EC2 instance and install additional software or customize the OS and database configuration to meet your requirements.
4. Run Sysprep on the EC2 instance. For more information prepping an AMI using Sysprep, see Create a standardized Amazon Machine Image (AMI) using Sysprep.
5. Save the AMI that contains your installed SQL Server version, other software, and customizations. This will be your golden image.

6. Create a new CEV by providing the AMI ID of the image that you created. For detailed steps on creating a CEV, see Creating a CEV for RDS Custom for SQL Server (p. 1136).

7. Create a new RDS Custom for SQL Server DB instance using the CEV. For detailed steps, see Create an RDS Custom for SQL Server DB instance from a CEV (p. 1138).

Preparing a CEV using Bring Your Own Media (BYOM)

The following steps use an AMI with Windows Server 2019 Release number 2023.05.10 as an example. When creating a CEV, choose an AMI with the most recent release number. This ensures that you are using the latest supported version of Windows Server.

To create a CEV using BYOM

1. Choose the latest available AWS EC2 Windows Amazon Machine Image (AMI) with Microsoft Windows Server.
   a. View the monthly AMI updates table within the Windows AMI version history.
   b. Note the latest available Release number. For example, the release number for Windows Server 2019 might be 2023.05.10. Although the Changes column may show SQL Server CUs installed, the release number also includes an AMI for Windows Server 2019, without SQL Server pre-installed. You can use this AMI for BYOM.
   c. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
   d. In the left navigation panel of the Amazon EC2 console, choose Images, then AMIs.
   e. Choose Public images.
   f. Enter Windows_Server-2019-English-Full-Base-2023.05.10 into the search box. The following results should appear:
g. Choose the AMI with the supported Windows Server version that you want to use.

2. Create or launch an EC2 instance from your chosen AMI.

3. Log in to the EC2 instance and copy your SQL Server installation media to it.

4. Install SQL Server. Make sure that you do the following:

   a. Review Requirements for BYOM for RDS Custom for SQL Server (p. 1129).
   b. Set the instance root directory to the default C:\Program Files\Microsoft SQL Server. Don't change this directory.
   c. Set the SQL Server Database Engine Account Name to either NT Service\MSSQLSERVER or NT AUTHORITY\NETWORK SERVICE.
   d. Set the SQL Server Startup mode to Manual.
   e. Choose SQL Server Authentication mode as Mixed.
   f. Leave the current settings for the default Data directories and TempDB locations.

5. Grant the SQL Server sysadmin (SA) server role privilege to NT AUTHORITY\SYSTEM:

   USE [master]
   GO
   EXEC master..sp_addsrvrolemember @loginame = N'NT AUTHORITY\SYSTEM', @rolename = N'sysadmin'
   GO

6. Install additional software or customize the OS and database configuration to meet your requirements.

7. Run Sysprep on the EC2 instance. For more information, see Create a standardized Amazon Machine Image (AMI) using Sysprep.

8. Save the AMI that contains your installed SQL Server version, other software, and customizations. This will be your golden image.

9. Create a new CEV by providing the AMI ID of the image that you created. For detailed steps, see Creating a CEV for RDS Custom for SQL Server (p. 1136).

10. Create a new RDS Custom for SQL Server DB instance using the CEV. For detailed steps, see Create an RDS Custom for SQL Server DB instance from a CEV (p. 1138).

Region availability for RDS Custom for SQL Server CEVs

Custom engine version (CEV) support for RDS Custom for SQL Server is available in the following AWS Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (Oregon)
- Asia Pacific (Mumbai)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
• Asia Pacific (Sydney)
• Asia Pacific (Tokyo)
• Canada (Central)
• Europe (Frankfurt)
• Europe (Ireland)
• Europe (London)
• Europe (Stockholm)
• South America (São Paulo)

Version support for RDS Custom for SQL Server CEVs

CEV creation for RDS Custom for SQL Server is supported for the following AWS EC2 Windows AMIs:

• For CEVs using pre-installed media, AWS EC2 Windows AMIs with License Included (LI) Microsoft
  Windows Server 2019 and SQL Server 2019
• For CEVs using bring your own media (BYOM), AWS EC2 Windows AMIs with Microsoft Windows Server
  2019

CEV creation for RDS Custom for SQL Server is supported for the following operating system (OS) and
database editions:

• For CEVs using pre-installed media, SQL Server 2019 with CU17, CU18, or CU20, for Enterprise,
  Standard, and Web editions
• For CEVs using bring your own media (BYOM), SQL Server 2019 with CU17, CU18, or CU20, for
  Enterprise and Standard editions
• For CEVs using pre-installed media or bring your own media (BYOM), Windows Server 2019 is the only
  supported OS

Requirements for RDS Custom for SQL Server CEVs

The following requirements apply to creating a CEV for RDS Custom for SQL Server:

• The AMI used to create a CEV must be based on an OS and database configuration supported by RDS
  Custom for SQL Server. For more information on supported configurations, see Requirements and
  limitations for Amazon RDS Custom for SQL Server (p. 1089).
• The CEV must have a unique name. You can't create a CEV with the same name as an existing CEV.
• You must name the CEV using a naming pattern of SQL Server major version + minor version +
customized string. The major version + minor version must match the SQL Server version provided with
  the AMI. For example, you can name an AMI with SQL Server 2019 CU17 as 15.00.4249.2.my_cevtest.
• You must prepare an AMI using Sysprep. For more information about prepping an AMI using Sysprep,
  see Create a standardized Amazon Machine Image (AMI) using Sysprep.
• You are responsible for maintaining the life cycle of the AMI. An RDS Custom for SQL Server DB
  instance created from a CEV doesn’t store a copy of the AMI. It maintains a pointer to the AMI that you
  used to create the CEV. The AMI must exist for an RDS Custom for SQL Server DB instance to remain
  operable.

Limitations for RDS Custom for SQL Server CEVs

The following limitations apply to custom engine versions with RDS Custom for SQL Server:

• You can’t delete a CEV if there are resources, such as DB instances or DB snapshots, associated with it.
To create an RDS Custom for SQL Server DB instance, a CEV must have a status of pending-validation, available, failed, or validating. You can't create an RDS Custom for SQL Server DB instance using a CEV if the CEV status is incompatible-image-configuration.

To modify a RDS Custom for SQL Server DB instance to use a new CEV, the CEV must have a status of available.

You can't create an AMI or CEV from an existing RDS Custom for SQL Server DB instance.

You can't modify an existing CEV to use a different AMI. However, you can modify an RDS Custom for SQL Server DB instance to use a different CEV. For more information, see Modifying an RDS Custom for SQL Server DB instance (p. 1157).

Cross-Region copy of CEVs isn't supported.

Cross-account copy of CEVs isn't supported.

SQL Server Transparent Data Encryption (TDE) isn't supported.

You can't restore or recover a CEV after you delete it. However, you can create a new CEV from the same AMI.

A RDS Custom for SQL Server DB instance stores your SQL Server database files in the D:\drive. The AMI associated with a CEV should store the Microsoft SQL Server system database files in the C:\ drive.

An RDS Custom for SQL Server DB instance retains your configuration changes made to SQL Server. Any configuration changes to the OS on a running RDS Custom for SQL Server DB instance created from a CEV aren't retained. If you need to make a permanent configuration change to the OS and have it retained as your new baseline configuration, create a new CEV and modify the DB instance to use the new CEV.

**Important**
Modifying an RDS Custom for SQL Server DB instance to use a new CEV is an offline operation. You can perform the modification immediately or schedule it to occur during a weekly maintenance window.

When you modify a CEV, Amazon RDS doesn't push those modifications to any associated RDS Custom for SQL Server DB instances. You must modify each RDS Custom for SQL Server DB instance to use the new or updated CEV. For more information, see Modifying an RDS Custom for SQL Server DB instance (p. 1157).

**Important**
If an AMI used by a CEV is deleted, any modifications that may require host replacement, for example, scale compute, will fail. The RDS Custom for SQL Server DB instance will then be placed outside of the RDS support perimeter. We recommend that you avoid deleting any AMI that's associated to a CEV.

---

**Creating a CEV for RDS Custom for SQL Server**

You can create a custom engine version (CEV) using the AWS Management Console or the AWS CLI. You can then use the CEV to create an RDS Custom for SQL Server DB instance.

Make sure that the Amazon Machine Image (AMI) is in the same AWS account and Region as your CEV. Otherwise, the process to create a CEV fails.

For more information, see Creating and connecting to a DB instance for Amazon RDS Custom for SQL Server (p. 1146).

**Important**
The steps to create a CEV are the same for AMIs created with pre-installed SQL Server and those created using bring your own media (BYOM).
To create a CEV

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Custom engine versions. The Custom engine versions page shows all CEVs that currently exist. If you haven't created any CEVs, the table is empty.
3. Choose Create custom engine version.
4. For Engine type, choose Microsoft SQL Server.
6. For Major version, choose the major engine version that's installed on your AMI.
7. In Version details, enter a valid name in Custom engine version name. The name format is major-engine-version.minor-engine-version.customized_string. You can use 1–50 alphanumeric characters, underscores, dashes, and periods. For example, you might enter the name 15.00.4249.2.my_cevtest.
   Optionally, enter a description for your CEV.
8. For Installation Media, browse to or enter the AMI ID that you'd like to create the CEV from.
9. In the Tags section, add any tags to identify the CEV.
10. Choose Create custom engine version.

The Custom engine versions page appears. Your CEV is shown with the status pending-validation.

AWS CLI

To create a CEV by using the AWS CLI, run the create-custom-db-engine-version command.

The following options are required:

- --engine
- --engine-version
- --image-id

You can also specify the following options:

- --kms-key-id
- --description
- --region
- --tags

The following example creates a CEV named 15.00.4249.2.my_cevtest. Make sure that the name of your CEV begins with the major engine version number.

Example

For Linux, macOS, or Unix:

```bash
aws rds create-custom-db-engine-version \   
  --engine custom-sqlserver-ee \   
  --engine-version 15.00.4249.2.my_cevtest 
```
The following partial output shows the engine, parameter groups, and other information.

```
"DBEngineVersions": [
  {
    "Engine": "custom-sqlserver-ee",
    "MajorEngineVersion": "15.00",
    "EngineVersion": "15.00.4249.2.my_cevtest",
    "DBEngineDescription": "Microsoft SQL Server Enterprise Edition for RDS Custom for SQL Server",
    "DBEngineVersionDescription": "Custom SQL Server EE 15.00.4249.2 cev test",
    "KMSKeyId": "arn:aws:kms:us-east-1:<your-account-id>:key/<my-kms-key-id>",
    "Image": [
      {"ImageId": "ami-0r93cx31t5sr596482",
       "Status": "pending-validation"
      },
      {"CreateTime": "2022-11-20T19:30:01.831000+00:00",
       "SupportsLogExportsToCloudwatchLogs": false,
       "SupportsReadReplica": false,
       "Status": "pending-validation",
       "SupportsParallelQuery": false,
       "SupportsGlobalDatabases": false,
       "TagList": []
      }
    ],
    "CreateTime": "2022-11-20T19:30:01.831000+00:00",
    "SupportsLogExportsToCloudwatchLogs": false,
    "SupportsReadReplica": false,
    "Status": "pending-validation",
    "SupportsParallelQuery": false,
    "SupportsGlobalDatabases": false,
    "TagList": []
  }
]
```

If the process to create a CEV fails, RDS Custom for SQL Server issues RDS-EVENT-0198 with the message “Creation failed for custom engine version major-engine-version.cev_name.” The message includes details about the failure, for example, the event prints missing files. To find troubleshooting ideas for CEV creation issues, see Troubleshooting CEV errors for RDS Custom for SQL Server (p. 1186).

Create an RDS Custom for SQL Server DB instance from a CEV

After you successfully create a CEV, the CEV status shows pending-validation. You can now create a new RDS Custom for SQL Server DB instance using the CEV. To create a new RDS Custom for SQL Server DB instance from a CEV, see Creating an RDS Custom for SQL Server DB instance (p. 1146).

Lifecycle of a CEV

The CEV lifecycle includes the following statuses.

<table>
<thead>
<tr>
<th>CEV status</th>
<th>Description</th>
<th>Troubleshooting suggestions</th>
</tr>
</thead>
<tbody>
<tr>
<td>pending-validation</td>
<td>A CEV was created and is pending the validation of the associated AMI. A CEV will remain in pending-validation until an RDS Custom for SQL Server DB instance is created.</td>
<td>If there are no existing tasks, create a new RDS Custom for SQL Server DB instance from the CEV. When creating the RDS Custom for SQL Server DB instance, the system attempts to validate the associated AMI for a CEV.</td>
</tr>
<tr>
<td>CEV status</td>
<td>Description</td>
<td>Troubleshooting suggestions</td>
</tr>
<tr>
<td>------------</td>
<td>-------------</td>
<td>----------------------------</td>
</tr>
<tr>
<td>validating</td>
<td>A creation task for the RDS Custom for SQL Server DB instance based on a new CEV is in progress. When creating the RDS Custom for SQL Server DB instance, the system attempts to validate the associated AMI of a CEV.</td>
<td>Wait for the creation task of the existing RDS Custom for SQL Server DB instance to complete. You can use the RDS EVENTS console to review detailed event messages for troubleshooting.</td>
</tr>
<tr>
<td>available</td>
<td>The CEV was successfully validated. A CEV will enter the available status once an RDS Custom for SQL Server DB instance has been successfully created from it.</td>
<td>The CEV doesn't require any additional validation. It can be used to create additional RDS Custom for SQL Server DB instances or modify existing ones.</td>
</tr>
<tr>
<td>inactive</td>
<td>The CEV has been modified to an inactive state.</td>
<td>You can't create or upgrade an RDS Custom DB instance with this CEV. Also, you can't restore a DB snapshot to create a new RDS Custom DB instance with this CEV. For information about how to change the state to ACTIVE, see [Modifying a CEV for RDS Custom for SQL Server](p. 1140).</td>
</tr>
<tr>
<td>failed</td>
<td>The create DB instance step failed for this CEV before it could validate the AMI. Alternatively, the underlying AMI used by the CEV isn't in an available state.</td>
<td>Troubleshoot the root cause for why the system couldn't create the DB instance. View the detailed error message and try to create a new DB instance again. Ensure that the underlying AMI used by the CEV is in an available state.</td>
</tr>
<tr>
<td>CEV status</td>
<td>Description</td>
<td>Troubleshooting suggestions</td>
</tr>
<tr>
<td>----------------------------</td>
<td>---------------------------------------------------</td>
<td>-----------------------------------------------------------------------</td>
</tr>
<tr>
<td>incompatible-image-configuration</td>
<td>There was an error validating the AMI.</td>
<td>View the technical details of the error. You can't attempt to validate the AMI with this CEV again. Review the following recommendations:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Ensure your CEV is named using the required naming pattern of SQL Server major version + minor version + customized string.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Ensure the SQL Server version in the CEV name matches the version provided with the AMI.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Ensure the OS build version meets the minimum required build version.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Ensure the OS major version meets the minimum required major version.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Create a new CEV using the correct information.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If needed, create a new EC2 instance using a supported AMI and run the Sysprep process on it.</td>
</tr>
</tbody>
</table>

Modifying a CEV for RDS Custom for SQL Server

You can modify a CEV using the AWS Management Console or the AWS CLI. You can modify the CEV description or its availability status. Your CEV has one of the following status values:

- **available** – You can use this CEV to create a new RDS Custom DB instance or upgrade a DB instance. This is the default status for a newly created CEV.
- **inactive** – You can't create or upgrade an RDS Custom DB instance with this CEV. You can't restore a DB snapshot to create a new RDS Custom DB instance with this CEV.

You can change the CEV status from available to inactive or from inactive to available. You might change the status to INACTIVE to prevent the accidental use of a CEV or to make a discontinued CEV eligible for use again.

**Console**

**To modify a CEV**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Custom engine versions.
3. Choose a CEV whose description or status you want to modify.
4. For Actions, choose Modify.
5. Make any of the following changes:
   - For **CEV status settings**, choose a new availability status.
   - For **Version description**, enter a new description.
6. Choose Modify CEV.
If the CEV is in use, the console displays **You can't modify the CEV status.** Fix the problems, then try again.

The **Custom engine versions** page appears.

**AWS CLI**

To modify a CEV by using the AWS CLI, run the `modify-custom-db-engine-version` command. You can find CEVs to modify by running the `describe-db-engine-versions` command.

The following options are required:

- `--engine`
- `--engine-version <cev>`, where `<cev>` is the name of the custom engine version that you want to modify
- `--status <status>`, where `<status>` is the availability status that you want to assign to the CEV

The following example changes a CEV named `15.00.4249.2.my_cevtest` from its current status to `inactive`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-custom-db-engine-version \
  --engine custom-sqlserver-ee \
  --engine-version 15.00.4249.2.my_cevtest \
  --status inactive
```

For Windows:

```bash
aws rds modify-custom-db-engine-version ^
  --engine custom-sqlserver-ee ^
  --engine-version 15.00.4249.2.my_cevtest ^
  --status inactive
```

**Modifying an RDS Custom for SQL Server DB instance to use a new CEV**

You can modify an existing RDS Custom for SQL Server DB instance to use a different CEV. The changes that you can make include:

- Changing the CEV
- Changing the DB instance class
- Changing the backup retention period and backup window
- Changing the maintenance window

**Console**

**To modify an RDS Custom for SQL Server DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/)
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify.
4. Choose **Modify**.
5. Make the following changes as needed:
   a. For **DB engine version**, choose a different CEV.
   b. Change the value for **DB instance class**. For supported classes, see [DB instance class support for RDS Custom for SQL Server](p. 1089).
   c. Change the value for **Backup retention period**.
   d. For **Backup window**, set values for the **Start time** and **Duration**.
   e. For **DB instance maintenance window**, set values for the **Start day**, **Start time**, and **Duration**.
6. Choose **Continue**.
7. Choose **Apply immediately** or **Apply during the next scheduled maintenance window**.
8. Choose **Modify DB instance**.

   **Note**
   When modifying a DB instance from one CEV to another CEV, for example, when upgrading a minor version, the SQL Server system databases, including their data and configurations, are persisted from the current RDS Custom for SQL Server DB instance.

### AWS CLI

To modify a DB instance to use a different CEV by using the AWS CLI, run the `modify-db-instance` command.

The following options are required:

- `--db-instance-identifier`
- `--engine-version cev`, where `cev` is the name of the custom engine version that you want the DB instance to change to.

The following example modifies a DB instance named `my-cev-db-instance` to use a CEV named `15.00.4249.2.my_cevtest_new` and applies the change immediately.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \    
    --db-instance-identifier my-cev-db-instance \    
    --engine-version 15.00.4249.2.my_cevtest_new \    
    --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
    --db-instance-identifier my-cev-db-instance ^
    --engine-version 15.00.4249.2.my_cevtest_new ^
    --apply-immediately
```

### Viewing CEV details for Amazon RDS Custom for SQL Server

You can view details about your CEV by using the AWS Management Console or the AWS CLI.
Console

To view CEV details

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Custom engine versions.
   
   The Custom engine versions page shows all CEVs that currently exist. If you haven't created any CEVs, the page is empty.
3. Choose the name of the CEV that you want to view.
4. Choose Configuration to view the details.

AWS CLI

To view details about a CEV by using the AWS CLI, run the describe-db-engine-versions command.

You can also specify the following options:

• --include-all, to view all CEVs with any lifecycle state. Without the --include-all option, only the CEVs in an available lifecycle state will be returned.

```bash
aws rds describe-db-engine-versions --engine custom-sqlserver-ee --engine-version 15.00.4249.2.my_cevtest --include-all
{
  "DBEngineVersions": [
    {
      "Engine": "custom-sqlserver-ee",
      "MajorEngineVersion": "15.00",
```
You can use filters to view CEVs with a certain lifecycle status. For example, to view CEVs that have a lifecycle status of either pending-validation, available, or failed:

```
aws rds describe-db-engine-versions engine custom-sqlserver-ee region us-west-2 include-all query 'DBEngineVersions[?Status == pending-validation || Status == available || Status == failed]'  
```

**Deleting a CEV for RDS Custom for SQL Server**

You can delete a CEV using the AWS Management Console or the AWS CLI. Typically, this task takes a few minutes.

Before deleting a CEV, make sure it isn't being used by any of the following:

- An RDS Custom DB instance
- A snapshot of an RDS Custom DB instance
- An automated backup of your RDS Custom DB instance

**Console**

To delete a CEV

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Custom engine versions.
3. Choose a CEV whose description or status you want to delete.
4. For Actions, choose Delete.
   
   The **Delete cev_name**? dialog box appears.
5. Enter delete me, and then choose Delete.
In the **Custom engine versions** page, the banner shows that your CEV is being deleted.

**AWS CLI**

To delete a CEV by using the AWS CLI, run the `delete-custom-db-engine-version` command.

The following options are required:

- `--engine custom-sqlserver-ee`
- `--engine-version cev`, where `cev` is the name of the custom engine version to be deleted

The following example deletes a CEV named `15.00.4249.2.my_cevtest`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds delete-custom-db-engine-version \
  --engine custom-sqlserver-ee \
  --engine-version 15.00.4249.2.my_cevtest
```

For Windows:

```bash
aws rds delete-custom-db-engine-version ^
  --engine custom-sqlserver-ee ^
  --engine-version 15.00.4249.2.my_cevtest
```
Creating and connecting to a DB instance for Amazon RDS Custom for SQL Server

You can create an RDS Custom DB instance, and then connect to it using AWS Systems Manager or Remote Desktop Protocol (RDP).

Important
Before you can create or connect to an RDS Custom for SQL Server DB instance, make sure to complete the tasks in Setting up your environment for Amazon RDS Custom for SQL Server (p. 1115).

You can tag RDS Custom DB instances when you create them, but don't create or modify the AWSRDSCustom tag that's required for RDS Custom automation. For more information, see Tagging RDS Custom for SQL Server resources (p. 1160).

The first time that you create an RDS Custom for SQL Server DB instance, you might receive the following error: The service-linked role is in the process of being created. Try again later. If you do, wait a few minutes and then try again to create the DB instance.

Topics
- Creating an RDS Custom for SQL Server DB instance (p. 1146)
- RDS Custom service-linked role (p. 1149)
- Connecting to your RDS Custom DB instance using AWS Systems Manager (p. 1149)
- Connecting to your RDS Custom DB instance using RDP (p. 1151)

Creating an RDS Custom for SQL Server DB instance

Create an Amazon RDS Custom for SQL Server DB instance using either the AWS Management Console or the AWS CLI. The procedure is similar to the procedure for creating an Amazon RDS DB instance.

For more information, see Creating an Amazon RDS DB instance (p. 300).

Console

To create an RDS Custom for SQL Server DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose Create database.
4. Choose Standard create for the database creation method.
5. For Engine options, choose Microsoft SQL Server for the engine type.
6. For Database management type, choose Amazon RDS Custom.
7. In the Edition section, choose the DB engine edition that you want to use. For RDS Custom for SQL Server, the choices are Enterprise, Standard, and Web.
8. (Optional) If you intend to create the DB instance from a CEV, check the Use custom engine version (CEV) check box. Select your CEV in the drop-down list.
9. For Database version, keep the SQL Server 2019 default value.
10. For Templates, choose Production.
11. In the Settings section, enter a unique name for the DB instance identifier.
12. To enter your master password, do the following:
   a. In the Settings section, open Credential Settings.
   b. Clear the Auto generate a password check box.
c. Change the **Master username** value and enter the same password in **Master password** and **Confirm password**.

By default, the new RDS Custom DB instance uses an automatically generated password for the master user.

13. In the **DB instance size** section, choose a value for **DB instance class**.

For supported classes, see [DB instance class support for RDS Custom for SQL Server (p. 1089)](https://docs.aws.amazon.com/rds-custom-questions/latest/interfaces/rds-custom-for-sql-server.html).  

14. Choose **Storage** settings.

15. For **RDS Custom security**, do the following:

   a. For **IAM instance profile**, choose the instance profile for your RDS Custom for SQL Server DB instance.

      The IAM instance profile must begin with AWSRDSCustom, for example `AWSRDSCustomInstanceProfileForRdsCustomInstance`.

   b. For **Encryption**, choose **Enter a key ARN** to list the available AWS KMS keys. Then choose your key from the list.

      An AWS KMS key is required for RDS Custom. For more information, see [Make sure that you have a symmetric encryption AWS KMS key](https://docs.aws.amazon.com/rds-custom-questions/latest/interfaces/rds-custom-for-sql-server.html).

16. For the remaining sections, specify your preferred RDS Custom DB instance settings. For information about each setting, see [Settings for DB instances (p. 308)](https://docs.aws.amazon.com/rds-custom-questions/latest/interfaces/rds-custom-for-sql-server.html). The following settings don't appear in the console and aren't supported:

   - Processor features
   - Storage autoscaling
   - Availability & durability
   - **Password and Kerberos authentication** option in **Database authentication** (only **Password authentication** is supported)
   - **Database options** group in **Additional configuration**
   - **Performance Insights**
   - **Log exports**
   - **Enable auto minor version upgrade**
   - **Deletion protection**

**Backup retention period** is supported, but you can't choose **0 days**.

17. Choose **Create database**.

   The **View credential details** button appears on the **Databases** page.

   To view the master user name and password for the RDS Custom DB instance, choose **View credential details**.

   To connect to the DB instance as the master user, use the user name and password that appear.

   **Important**

   You can't view the master user password again. If you don't record it, you might have to change it. To change the master user password after the RDS Custom DB instance is available, modify the DB instance. For more information about modifying a DB instance, see [Managing an Amazon RDS Custom for SQL Server DB instance (p. 1154)](https://docs.aws.amazon.com/rds-custom-questions/latest/interfaces/rds-custom-for-sql-server.html).

18. Choose **Databases** to view the list of RDS Custom DB instances.

19. Choose the RDS Custom DB instance that you just created.
On the RDS console, the details for the new RDS Custom DB instance appear:

- The DB instance has a status of **creating** until the RDS Custom DB instance is created and ready for use. When the state changes to **available**, you can connect to the DB instance. Depending on the instance class and storage allocated, it can take several minutes for the new DB instance to be available.
- **Role** has the value **Instance (RDS Custom)**.
- **RDS Custom automation mode** has the value **Full automation**. This setting means that the DB instance provides automatic monitoring and instance recovery.

**AWS CLI**

You create an RDS Custom DB instance by using the `create-db-instance` AWS CLI command.

The following options are required:

- `--db-instance-identifier`
- `--db-instance-class` (for a list of supported instance classes, see [DB instance class support for RDS Custom for SQL Server](p. 1089))
- `--engine` (custom-sqlserver-ee, custom-sqlserver-se, or custom-sqlserver-web)
- `--kms-key-id`
- `--custom-iam-instance-profile`

The following example creates an RDS Custom for SQL Server DB instance named `my-custom-instance`. The backup retention period is 3 days.

**Note**

To create a DB instance from a custom engine version (CEV), supply an existing CEV name to the `--engine-version` parameter. For example, `--engine-version 15.00.4249.2.my_cevtest`

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance \
--engine custom-sqlserver-ee \
--engine-version 15.00.4073.23.v1 \
--db-instance-identifier my-custom-instance \
--db-instance-class db.m5.xlarge \
--allocated-storage 20 \ 
--db-subnet-group mydbsubnetgroup \ 
--master-username myuser \ 
--master-user-password mypassword \ 
--backup-retention-period 3 \ 
--no-multi-az \ 
--port 8200 \ 
--kms-key-id mykmskey \ 
--custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance
```

For Windows:

```bash
aws rds create-db-instance ^
--engine custom-sqlserver-ee ^
--engine-version 15.00.4073.23.v1 ^
--db-instance-identifier my-custom-instance ^
--db-instance-class db.m5.xlarge ^
```
Note
Specify a password other than the prompt shown here as a security best practice.

Get details about your instance by using the describe-db-instances command.

```bash
aws rds describe-db-instances --db-instance-identifier my-custom-instance
```

The following partial output shows the engine, parameter groups, and other information.

```json
{
   "DBInstances": [
      {
         "PendingModifiedValues": {},
         "Engine": "custom-sqlserver-ee",
         "MultiAZ": false,
         "DBSecurityGroups": [],
         "DBParameterGroups": [
            {
               "DBParameterGroupName": "default.custom-sqlserver-ee-15",
               "ParameterApplyStatus": "in-sync"
            }
         ],
         "AutomationMode": "full",
         "DBInstanceIdentifier": "my-custom-instance",
         "TagList": []
      }
   ]
}
```

**RDS Custom service-linked role**

A service-linked role gives Amazon RDS Custom access to resources in your AWS account. It makes using RDS Custom easier because you don't have to manually add the necessary permissions. RDS Custom defines the permissions of its service-linked roles, and unless defined otherwise, only RDS Custom can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy can't be attached to any other IAM entity.

When you create an RDS Custom DB instance, both the Amazon RDS and RDS Custom service-linked roles are created (if they don't already exist) and used. For more information, see Using service-linked roles for Amazon RDS (p. 2701).

The first time that you create an RDS Custom for SQL Server DB instance, you might receive the following error: The service-linked role is in the process of being created. Try again later. If you do, wait a few minutes and then try again to create the DB instance.

**Connecting to your RDS Custom DB instance using AWS Systems Manager**

After you create your RDS Custom DB instance, you can connect to it using AWS Systems Manager Session Manager. Session Manager is a Systems Manager capability that you can use to manage Amazon
EC2 instances through a browser-based shell or through the AWS CLI. For more information, see AWS Systems Manager Session Manager.

**Console**

**To connect to your DB instance using Session Manager**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom DB instance to which you want to connect.
3. Choose **Configuration**.
4. Note the **Resource ID** value for your DB instance. For example, the resource ID might be `db-ABCDEFGHIJKLMNOPQRS0123456`.
6. In the navigation pane, choose **Instances**.
7. Look for the name of your EC2 instance, and then choose the instance ID associated with it. For example, the instance ID might be `i-abcdefghijklm01234`.
8. Choose **Connect**.
9. Choose **Session Manager**.
10. Choose **Connect**.

   A window opens for your session.

**AWS CLI**

You can connect to your RDS Custom DB instance using the AWS CLI. This technique requires the Session Manager plugin for the AWS CLI. To learn how to install the plugin, see Install the Session Manager plugin for the AWS CLI.

To find the DB resource ID of your RDS Custom DB instance, use `describe-db-instances`.

```bash
aws rds describe-db-instances \
   --query 'DBInstances[*].[DBInstanceIdentifier,DbiResourceId]' \
   --output text
```

The following sample output shows the resource ID for your RDS Custom instance. The prefix is `db-`.

```
db-ABCDEFGHIJKLMNOPQRS0123456
```

To find the EC2 instance ID of your DB instance, use `aws ec2 describe-instances`. The following example uses `db-ABCDEFGHIJKLMNOPQRS0123456` for the resource ID.

```bash
aws ec2 describe-instances \
   --filters "Name=tag:Name,Values=db-ABCDEFGHIJKLMNOPQRS0123456" \
   --output text \n   --query 'Reservations[*].Instances[*].InstanceId'
```

The following sample output shows the EC2 instance ID.

```
i-abcdefghijklm01234
```

Use the `aws ssm start-session` command, supplying the EC2 instance ID in the `--target` parameter.
aws ssm start-session --target "i-abcdefgijklm01234"

A successful connection looks like the following.

Starting session with SessionId: yourid-abcdefgijklm1234
[ssm-user@ip-123-45-67-89 bin]$ 

Connecting to your RDS Custom DB instance using RDP

After you create your RDS Custom DB instance, you can connect to this instance using an RDP client. The procedure is the same as for connecting to an Amazon EC2 instance. For more information, see Connect to your Windows instance.

To connect to the DB instance, you need the key pair associated with the instance. RDS Custom creates the key pair for you. The pair name uses the prefix do-not-delete-rds-custom-DBInstanceIdentifier. AWS Secrets Manager stores your private key as a secret.

Complete the task in the following steps:

1. **Configure your DB instance to allow RDP connections** (p. 1151).
2. **Retrieve your secret key** (p. 1152).
3. **Connect to your EC2 instance using the RDP utility** (p. 1153).

Configure your DB instance to allow RDP connections

To allow RDP connections, configure your VPC security group and set a firewall rule on the host.

**Configure your VPC security group**

Make sure that the VPC security group associated with your DB instance permits inbound connections on port 3389 for Transmission Control Protocol (TCP). To learn how to configure your VPC security group, see Configure your VPC security group (p. 1126).

**Set the firewall rule on the host**

To permit inbound connections on port 3389 for TCP, set a firewall rule on the host. The following examples show how to do this.

We recommend that you use the specific -Profile value: Public, Private, or Domain. Using Any refers to all three values. You can also specify a combination of values separated by a comma. For more information about setting firewall rules, see Set-NetFirewallRule in the Microsoft documentation.

**To use Systems Manager Session Manager to set a firewall rule**

1. Connect to Session Manager as shown in Connecting to your RDS Custom DB instance using AWS Systems Manager (p. 1149).
2. Run the following command.

```
Set-NetFirewallRule -DisplayName "Remote Desktop - User Mode (TCP-In)" -Direction Inbound -LocalAddress Any -Profile Any
```

**To use Systems Manager CLI commands to set a firewall rule**

1. Use the following command to open RDP on the host.
OPEN_RDP_COMMAND_ID=$(aws ssm send-command --region $AWS_REGION \ --instance-ids $RDS_CUSTOM_INSTANCE_EC2_ID \ --document-name "AWS-RunPowerShellScript" \ --parameters '{"commands": ["Set-NetFirewallRule -DisplayName \"Remote Desktop - User Mode (TCP-In)\" -Direction Inbound -LocalAddress Any -Profile Any"]}' \ --comment "Open RDP port" | jq -r ".Command.CommandId")

2. Use the command ID returned in the output to get the status of the previous command. To use the following query to return the command ID, make sure that you have the jq plug-in installed.

aws ssm list-commands \ --region $AWS_REGION \ --command-id $OPEN_RDP_COMMAND_ID

Retrieve your secret key

Retrieve your secret key using either AWS Management Console or the AWS CLI.

Console

To retrieve the secret key

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the RDS Custom DB instance to which you want to connect.
3. Choose the Configuration tab.
4. Note the DB instance ID for your DB instance, for example, my-custom-instance.
5. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
6. In the navigation pane, choose Instances.
7. Look for the name of your EC2 instance, and then choose the instance ID associated with it.

In this example, the instance ID is i-abcdefghijklm01234.
8. In Details, find Key pair name. The pair name includes the DB identifier. In this example, the pair name is do-not-delete-rds-custom-my-custom-instance-0d726c.
9. In the instance summary, find Public IPv4 DNS. For the example, the public DNS might be ec2-12-345-678-901.us-east-2.compute.amazonaws.com.
11. Choose the secret that has the same name as your key pair.
12. Choose Retrieve secret value.

AWS CLI

To retrieve the private key

1. Get the list of your RDS Custom DB instances by calling the aws rds describe-db-instances command.

aws rds describe-db-instances \ --query 'DBInstances[*.][DBInstanceIdentifier,DbiResourceId]' \ --output text
2. Choose the DB instance identifier from the sample output, for example do-not-delete-rds-custom-my-custom-instance.

3. Find the EC2 instance ID of your DB instance by calling the `aws ec2 describe-instances` command. The following example uses the EC2 instance name to describe the DB instance.

   ```bash
   aws ec2 describe-instances \
   --filters "Name=tag:Name,Values=do-not-delete-rds-custom-my-custom-instance" \
   --output text \
   --query 'Reservations[*].Instances[*].InstanceId'
   
   The following sample output shows the EC2 instance ID.
   
   `i-abcdefghijklm01234`
   
   4. Find the key name by specifying the EC2 instance ID, as shown in the following example.

   ```bash
   aws ec2 describe-instances \
   --instance-ids i-abcdefghijklm01234 \
   --output text \
   --query 'Reservations[*].Instances[*].KeyName'
   
   The following sample output shows the key name, which uses the prefix do-not-delete-rds-custom-DBInstanceIdentifier.
   
   `do-not-delete-rds-custom-my-custom-instance-0d726c`
   
**Connect to your EC2 instance using the RDP utility**

Follow the procedure in [Connect to your Windows instance using RDP](https://docs.aws.amazon.com/en_us) in the *Amazon EC2 User Guide for Windows Instances*. This procedure assumes that you created a .pem file that contains your private key.
Managing an Amazon RDS Custom for SQL Server DB instance

Amazon RDS Custom for SQL Server supports a subset of the usual management tasks for Amazon RDS DB instances. Following, you can find instructions for the supported RDS Custom for SQL Server management tasks using the AWS Management Console and the AWS CLI.

Topics
- Pausing and resuming RDS Custom automation (p. 1154)
- Modifying an RDS Custom for SQL Server DB instance (p. 1157)
- Modifying the storage for an RDS Custom for SQL Server DB instance (p. 1158)
- Tagging RDS Custom for SQL Server resources (p. 1160)
- Deleting an RDS Custom for SQL Server DB instance (p. 1160)
- Starting and stopping an RDS Custom for SQL Server DB instance (p. 1162)

Pausing and resuming RDS Custom automation

RDS Custom automatically provides monitoring and instance recovery for an RDS Custom for SQL Server DB instance. If you need to customize the instance, do the following:

1. Pause RDS Custom automation for a specified period. The pause ensures that your customizations don't interfere with RDS Custom automation.
2. Customize the RDS Custom for SQL Server DB instance as needed.
3. Do either of the following:
   - Resume automation manually.
   - Wait for the pause period to end. In this case, RDS Custom resumes monitoring and instance recovery automatically.

Important
Pausing and resuming automation are the only supported automation tasks when modifying an RDS Custom for SQL Server DB instance.

Console

To pause or resume RDS Custom automation

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the RDS Custom DB instance that you want to modify.
4. For RDS Custom automation mode, choose one of the following options:
   - Paused pauses the monitoring and instance recovery for the RDS Custom DB instance. Enter the pause duration that you want (in minutes) for Automation mode duration. The minimum value is 60 minutes (default). The maximum value is 1,440 minutes.
   - Full automation resumes automation.
5. Choose Continue to check the summary of modifications.

A message indicates that RDS Custom will apply the changes immediately.
6. If your changes are correct, choose **Modify DB instance**. Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

   On the RDS console, the details for the modification appear. If you paused automation, the **Status** of your RDS Custom DB instance indicates **Automation paused**.

7. (Optional) In the navigation pane, choose **Databases**, and then your RDS Custom DB instance.

   In the **Summary** pane, **RDS Custom automation mode** indicates the automation status. If automation is paused, the value is **Paused. Automation resumes in num minutes**.

**AWS CLI**

To pause or resume RDS Custom automation, use the `modify-db-instance` AWS CLI command. Identify the DB instance using the required parameter `--db-instance-identifier`. Control the automation mode with the following parameters:

- `--automation-mode` specifies the pause state of the DB instance. Valid values are `all-paused`, which pauses automation, and `full`, which resumes it.
- `--resume-full-automation-mode-minutes` specifies the duration of the pause. The default value is 60 minutes.

**Note**

Regardless of whether you specify `--no-apply-immediately` or `--apply-immediately`, RDS Custom applies modifications asynchronously as soon as possible.

In the command response, `ResumeFullAutomationModeTime` indicates the resume time as a UTC timestamp. When the automation mode is `all-paused`, you can use `modify-db-instance` to resume automation mode or extend the pause period. No other `modify-db-instance` options are supported.

The following example pauses automation for `my-custom-instance` for 90 minutes.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
   --db-instance-identifier my-custom-instance \
   --automation-mode all-paused \
   --resume-full-automation-mode-minutes 90
```

For Windows:

```bash
aws rds modify-db-instance ^
   --db-instance-identifier my-custom-instance ^
   --automation-mode all-paused ^
   --resume-full-automation-mode-minutes 90
```

The following example extends the pause duration for an extra 30 minutes. The 30 minutes is added to the original time shown in `ResumeFullAutomationModeTime`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
   --db-instance-identifier my-custom-instance \
```

```bash
aws rds modify-db-instance ^
   --db-instance-identifier my-custom-instance ^
   --automation-mode all-paused ^
   --resume-full-automation-mode-minutes 90
```
--automation-mode all-paused \
--resume-full-automation-mode-minutes 30

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier my-custom-instance ^
  --automation-mode all-paused ^
  --resume-full-automation-mode-minutes 30
```

The following example resumes full automation for `my-custom-instance`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier my-custom-instance \
  --automation-mode full
```

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier my-custom-instance ^
  --automation-mode full
```

In the following partial sample output, the pending `AutomationMode` value is full.

```json
{
  "DBInstance": {
    "PubliclyAccessible": true,
    "MasterUsername": "admin",
    "MonitoringInterval": 0,
    "LicenseModel": "bring-your-own-license",
    "VpcSecurityGroups": [
      {
        "Status": "active",
        "VpcSecurityGroupId": "0123456789abcdefg"
      }
    ],
    "InstanceCreateTime": "2020-11-07T19:50:06.193Z",

      }
    ]
  }
}
```
Modifying an RDS Custom for SQL Server DB instance

Modifying an RDS Custom for SQL Server DB instance is similar to doing this for Amazon RDS, but the changes that you can make are limited to the following:

- Changing the DB instance class
- Changing the backup retention period and backup window
- Changing the maintenance window
- Upgrading the DB engine version when a new version becomes available
- Changing the allocated storage, provisioned IOPS, and storage type
- Changing the database port
- Changing the DB instance identifier
- Changing the master credentials
- Allowing and removing Multi-AZ deployments
- Allowing public access
- Changing the security groups
- Changing subnet groups

The following limitations apply to modifying an RDS Custom for SQL Server DB instance:

- Custom DB option and parameter groups aren't supported.
- Any storage volumes that you attach manually to your RDS Custom DB instance are outside the support perimeter.

For more information, see RDS Custom support perimeter (p. 985).
Console

To modify an RDS Custom for SQL Server DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB instance that you want to modify.
4. Choose Modify.
5. Make the following changes as needed:
   a. For DB engine version, choose the new version.
   b. Change the value for DB instance class. For supported classes, see DB instance class support for RDS Custom for SQL Server (p. 1089)
   c. Change the value for Backup retention period.
   d. For Backup window, set values for the Start time and Duration.
   e. For DB instance maintenance window, set values for the Start day, Start time, and Duration.
6. Choose Continue.
7. Choose Apply immediately or Apply during the next scheduled maintenance window.
8. Choose Modify DB instance.

AWS CLI

To modify an RDS Custom for SQL Server DB instance, use the modify-db-instance AWS CLI command. Set the following parameters as needed:

- --db-instance-class – For supported classes, see DB instance class support for RDS Custom for SQL Server (p. 1089)
- --engine-version – The version number of the database engine to which you're upgrading.
- --backup-retention-period – How long to retain automated backups, from 0–35 days.
- --preferred-backup-window – The daily time range during which automated backups are created.
- --preferred-maintenance-window – The weekly time range (in UTC) during which system maintenance can occur.
- --apply-immediately – Use --apply-immediately to apply the storage changes immediately.
  Or use --no-apply-immediately (the default) to apply the changes during the next maintenance window.

Modifying the storage for an RDS Custom for SQL Server DB instance

Modifying storage for an RDS Custom for SQL Server DB instance is similar to modifying storage for an Amazon RDS DB instance, but you can only do the following:

- Increase the allocated storage size.
- Change the storage type. You can use available storage types such as General Purpose or Provisioned IOPS. Provisioned IOPS is supported for gp3 and io1 storage types.
- Change the provisioned IOPS, if you're using the volume types that supports provisioned IOPS, such as io1 or gp3.
The following limitations apply to modifying the storage for an RDS Custom for SQL Server DB instance:

- The minimum allocated storage size for RDS Custom for SQL Server is 20 GiB, and the maximum supported storage size is 16 TiB.
- As with Amazon RDS, you can't decrease the allocated storage. This is a limitation of Amazon Elastic Block Store (Amazon EBS) volumes. For more information, see Working with storage for Amazon RDS DB instances (p. 478).
- Storage autoscaling isn't supported for RDS Custom for SQL Server DB instances.
- Any storage volumes that you manually attach to your RDS Custom DB instance are not considered for storage scaling. Only the RDS-provided default data volumes, i.e., the D drive, are considered for storage scaling.

For more information, see RDS Custom support perimeter (p. 985).

- Scaling storage usually doesn't cause any outage or performance degradation of the DB instance. After you modify the storage size for a DB instance, the status of the DB instance is storage-optimization.
- Storage optimization can take several hours. You can't make further storage modifications for either six (6) hours or until storage optimization has completed on the instance, whichever is longer. For more information, see Working with storage for Amazon RDS DB instances (p. 478).

For more information about storage, see Amazon RDS DB instance storage (p. 101).

For general information about storage modification, see Working with storage for Amazon RDS DB instances (p. 478).

### Console

**To modify the storage for an RDS Custom for SQL Server DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB instance that you want to modify.
4. Choose Modify.
5. Make the following changes as needed:
   a. Enter a new value for Allocated storage. It must be greater than the current value, and from 20 GiB–16 TiB.
   b. Change the value for Storage type. You can use available storage types like General Purpose or Provisioned IOPS. Provisioned IOPS is supported for gp3 and io1 storage types.
   c. If you are specifying volume types that support provisioned IOPS, you can define the Provisioned IOPS value.
6. Choose Continue.
7. Choose Apply immediately or Apply during the next scheduled maintenance window.
8. Choose Modify DB instance.

### AWS CLI

To modify the storage for an RDS Custom for SQL Server DB instance, use the modify-db-instance AWS CLI command. Set the following parameters as needed:

- --allocated-storage – Amount of storage to be allocated for the DB instance, in gibibytes. It must be greater than the current value, and from 20–16,384 GiB.
- --storage-type – The storage type, for example, gp3, gp2, or io1.
• **--iops** – Provisioned IOPS for the DB instance. You can specify this only for storage types that support provisioned IOPS, like io1.

• **--apply-immediately** – Use **--apply-immediately** to apply the storage changes immediately.

Or use **--no-apply-immediately** (the default) to apply the changes during the next maintenance window.

The following example changes the storage size of my-custom-instance to 200 GiB, storage type to io1, and Provisioned IOPS to 3000.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
--db-instance-identifier my-custom-instance \
--storage-type io1 \
--iops 3000 \
--allocated-storage 200 \
--apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
   --db-instance-identifier my-custom-instance ^
   --storage-type io1 ^
   --iops 3000 ^
   --allocated-storage 200 ^
   --apply-immediately
```

**Tagging RDS Custom for SQL Server resources**

You can tag RDS Custom resources as with Amazon RDS resources, but with some important differences:

• Don't create or modify the **AWSRDSCustom** tag that's required for RDS Custom automation. If you do, you might break the automation.

• Tags added to RDS Custom DB instances during creation are propagated to all other related RDS Custom resources.

• Tags aren't propagated when you add them to RDS Custom resources after DB instance creation.

For general information about resource tagging, see [Tagging Amazon RDS resources](#). For Windows:

**Deleting an RDS Custom for SQL Server DB instance**

To delete an RDS Custom for SQL Server DB instance, do the following:

• Provide the name of the DB instance.

• Choose or clear the option to take a final DB snapshot of the DB instance.

• Choose or clear the option to retain automated backups.

You can delete an RDS Custom for SQL Server DB instance using the console or the CLI. The time required to delete the DB instance can vary depending on the backup retention period (that is, how many backups to delete), how much data is deleted, and whether a final snapshot is taken.
**Note**
You can't create a final DB snapshot of your DB instance if it has a status of creating, failed, incompatible-create, incompatible-restore, or incompatible-network. For more information, see [Viewing Amazon RDS DB instance status](p. 684).

**Important**
When you choose to take a final snapshot, we recommend that you avoid writing data to your DB instance while the DB instance deletion is in progress. Once the DB instance deletion is initiated, data changes are not guaranteed to be captured by the final snapshot.

**Console**

**To delete an RDS Custom DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Databases, and then choose the RDS Custom for SQL Server DB instance that you want to delete. RDS Custom for SQL Server DB instances show the role Instance (RDS Custom for SQL Server).
3. For Actions, choose Delete.
4. To take a final snapshot, choose Create final snapshot, and provide a name for the Final snapshot name.
5. To retain automated backups, choose Retain automated backups.
6. Enter delete me in the box.
7. Choose Delete.

**AWS CLI**

You delete an RDS Custom for SQL Server DB instance by using the `delete-db-instance` AWS CLI command. Identify the DB instance using the required parameter `--db-instance-identifier`. The remaining parameters are the same as for an Amazon RDS DB instance.

The following example deletes the RDS Custom for SQL Server DB instance named my-custom-instance, takes a final snapshot, and retains automated backups.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds delete-db-instance
   --db-instance-identifier my-custom-instance
   --no-skip-final-snapshot
   --final-db-snapshot-identifier my-custom-instance-final-snapshot
   --no-delete-automated-backups
```

For Windows:

```bash
aws rds delete-db-instance
   --db-instance-identifier my-custom-instance
   --no-skip-final-snapshot
   --final-db-snapshot-identifier my-custom-instance-final-snapshot
   --no-delete-automated-backups
```

To take a final snapshot, the `--final-db-snapshot-identifier` option is required and must be specified.
To skip the final snapshot, specify the --skip-final-snapshot option instead of the --no-skip-final-snapshot and --final-db-snapshot-identifier options in the command.

To delete automated backups, specify the --delete-automated-backups option instead of the --no-delete-automated-backups option in the command.

**Starting and stopping an RDS Custom for SQL Server DB instance**

You can start and stop your RDS Custom for SQL Server DB instance. The same general requirements and limitations for RDS for SQL Server DB instances apply to stopping and starting your RDS Custom for SQL Server DB instances. For more information, see [Stopping an Amazon RDS DB instance temporarily](p. 381).

The following considerations also apply to starting and stopping your RDS Custom for SQL Server DB instance:

- Modifying an EC2 instance attribute of an RDS Custom for SQL Server DB instance while the DB instance is STOPPED isn't supported.
- You can stop and start an RDS Custom for SQL Server DB instance only if it's configured for a single Availability Zone. You can't stop an RDS Custom for SQL Server DB instance in a Multi-AZ configuration.
- A SYSTEM snapshot will be created when you stop an RDS Custom for SQL Server DB instance. The snapshot will be automatically deleted when you start the RDS Custom for SQL Server DB instance again.
- If you delete your EC2 instance while your RDS Custom for SQL Server DB instance is stopped, the C: drive will be replaced when you start the RDS Custom for SQL Server DB instance again.
- The C:\ drive, hostname, and your custom configurations are persisted when you stop an RDS Custom for SQL Server DB instance, as long as you don't modify the instance type.
- The following actions will result in RDS Custom placing the DB instance outside the support perimeter, and you're still charged for DB instance hours:
  - Starting the underlying EC2 instance while Amazon RDS is stopped. To resolve, you can call the start-db-instance Amazon RDS API, or stop the EC2 so the RDS Custom instance returns to STOPPED.
  - Stopping underlying EC2 instance when the RDS Custom for SQL Server DB instance is ACTIVE.

For more details about stopping and starting DB instances, see [Stopping an Amazon RDS DB instance temporarily](p. 381), and [Starting an Amazon RDS DB instance that was previously stopped](p. 384).
Managing a Multi-AZ deployment for RDS Custom for SQL Server

In a Multi-AZ DB instance deployment for RDS Custom for SQL Server, Amazon RDS automatically provisions and maintains a synchronous standby replica in a different Availability Zone (AZ). The primary DB instance is synchronously replicated across Availability Zones to a standby replica to provide data redundancy.

**Important**
A Multi-AZ deployment for RDS Custom for SQL Server is different than Multi-AZ for RDS for SQL Server. Unlike Multi-AZ for RDS for SQL Server, you must set up prerequisites for RDS Custom for SQL Server before creating your Multi-AZ DB instance because RDS Custom runs inside your own account, which requires permissions. If you don't complete the prerequisites, your Multi-AZ DB instance might fail to run, or automatically revert to a Single-AZ DB instance. For more information about prerequisites, see Prerequisites for a Multi-AZ deployment with RDS Custom for SQL Server (p. 1165).

Running a DB instance with high availability can enhance availability during planned system maintenance. In the event of planned database maintenance or unplanned service disruption, Amazon RDS automatically fails over to the up-to-date secondary DB instance. This functionality lets database operations resume quickly without manual intervention. The primary and standby instances use the same endpoint, whose physical network address transitions to the secondary replica as part of the failover process. You don't have to reconfigure your application when a failover occurs.

You can create an RDS Custom for SQL Server Multi-AZ deployment by specifying Multi-AZ when creating an RDS Custom DB instance. You can use the console to convert existing RDS Custom for SQL
Server DB instances to Multi-AZ deployments by modifying the DB instance and specifying the Multi-AZ option. You can also specify a Multi-AZ DB instance deployment with the AWS CLI or Amazon RDS API.

The RDS console shows the Availability Zone of the standby replica (the secondary AZ). You can also use the describe-db-instances CLI command or the DescribeDBInstances API operation to find the secondary AZ.

RDS Custom for SQL Server DB instances with Multi-AZ deployment can have increased write and commit latency compared to a Single-AZ deployment. This increase can happen because of the synchronous data replication between DB instances. You might have a change in latency if your deployment fails over to the standby replica, although AWS is engineered with low-latency network connectivity between Availability Zones.

**Note**
For production workloads, we recommend that you use a DB instance class with Provisioned IOPS (input/output operations per second) for fast, consistent performance. For more information about DB instance classes, see Requirements and limitations for Amazon RDS Custom for SQL Server (p. 1089).

**Topics**
- Region and version availability (p. 1164)
- Limitations for a Multi-AZ deployment with RDS Custom for SQL Server (p. 1164)
- Prerequisites for a Multi-AZ deployment with RDS Custom for SQL Server (p. 1165)
- Creating an RDS Custom for SQL Server Multi-AZ deployment (p. 1165)
- Modifying an RDS Custom for SQL Server Single-AZ deployment to a Multi-AZ deployment (p. 1165)
- Modifying an RDS Custom for SQL Server Multi-AZ deployment to a Single-AZ deployment (p. 1169)
- Failover process for an RDS Custom for SQL Server Multi-AZ deployment (p. 1170)
- Time to live (TTL) settings with applications using an RDS Custom for SQL Server Multi-AZ deployment (p. 1172)

**Region and version availability**

Multi-AZ deployments for RDS Custom for SQL Server are supported for the following SQL Server editions:

- SQL Server 2019 Enterprise Edition
- SQL Server 2019 Standard Edition
- SQL Server 2019 Web Edition

Multi-AZ deployments for RDS Custom for SQL Server are supported for the following SQL Server versions:

- SQL Server 2019 CU18 (15.0.4261.1)
- SQL Server 2019 CU17 (15.0.4249.2)

Multi-AZ deployments for RDS Custom for SQL Server are available in all Regions where RDS Custom for SQL Server is available. For more information on Region availability of Multi-AZ deployments for RDS Custom for SQL Server, see RDS Custom for SQL Server (p. 153).

**Limitations for a Multi-AZ deployment with RDS Custom for SQL Server**

Multi-AZ deployments with RDS Custom for SQL Server have the following limitations:
• Cross-Region Multi-AZ deployments aren't supported.
• You can't configure the secondary DB instance to accept database read activity.
• When you use a Custom Engine Version (CEV) with a Multi-AZ deployment, your secondary DB instance will also use the same CEV. The secondary DB instance can't use a different CEV.

Prerequisites for a Multi-AZ deployment with RDS Custom for SQL Server

If you have an existing RDS Custom for SQL Server Single-AZ deployment, the following additional prerequisites are required before modifying it to a Multi-AZ deployment. You can choose to complete the prerequisites manually or with the provided CloudFormation template. The latest CloudFormation template contains the prerequisites for both Single-AZ and Multi-AZ deployments.

**Important**
To simplify setup, we recommend that you use the latest AWS CloudFormation template file provided in the network setup instructions to create the prerequisites. For more information, see Configuring with AWS CloudFormation (p. 1117).

**Note**
When you modify an existing RDS Custom for SQL Server Single-AZ deployment to a Multi-AZ deployment, you must complete these prerequisites. If you don't complete the prerequisites, the Multi-AZ setup will fail. To complete the prerequisites, follow the steps in Modifying an RDS Custom for SQL Server Single-AZ deployment to a Multi-AZ deployment (p. 1165).

• Update the RDS security group inbound and outbound rules to allow port 1120.
• Add a rule in your private network Access Control List (ACL) that allows TCP ports 0-65535 for the DB instance VPC.
• Create new Amazon SQS VPC endpoints that allow the RDS Custom for SQL Server DB instance to communicate with SQS.
• Update the SQS permissions in the instance profile role.

Creating an RDS Custom for SQL Server Multi-AZ deployment

To create an RDS Custom for SQL Server Multi-AZ deployment, follow the steps in Creating and connecting to a DB instance for Amazon RDS Custom for SQL Server (p. 1146).

**Important**
To simplify setup, we recommend that you use the latest AWS CloudFormation template file provided in the network setup instructions. For more information, see Configuring with AWS CloudFormation (p. 1117).

Creating a Multi-AZ deployment takes a few minutes to complete.

Modifying an RDS Custom for SQL Server Single-AZ deployment to a Multi-AZ deployment

You can modify an existing RDS Custom for SQL Server DB instance from a Single-AZ deployment to a Multi-AZ deployment. When you modify the DB instance, Amazon RDS performs several actions:

• Takes a snapshot of the primary DB instance.
• Creates new volumes for the standby replica from the snapshot. These volumes initialize in the background, and maximum volume performance is achieved after the data is fully initialized.
• Turns on synchronous block-level replication between the primary and secondary DB instances.
Important
We recommend that you avoid modifying your RDS Custom for SQL Server DB instance from a Single-AZ to a Multi-AZ deployment on a production DB instance during periods of peak activity.

AWS uses a snapshot to create the standby instance to avoid downtime when you convert from Single-AZ to Multi-AZ, but performance might be impacted during and after converting to Multi-AZ. This impact can be significant for workloads that are sensitive to write latency. While this capability allows large volumes to quickly be restored from snapshots, it can cause increase in the latency of I/O operations because of the synchronous replication. This latency can impact your database performance.

Topics
- Configuring prerequisites to modify a Single-AZ to a Multi-AZ deployment using CloudFormation (p. 1166)
- Configuring prerequisites to modify a Single-AZ to a Multi-AZ deployment manually (p. 1167)
- Modify using the RDS console, AWS CLI, or RDS API. (p. 1168)

Configuring prerequisites to modify a Single-AZ to a Multi-AZ deployment using CloudFormation

To use a Multi-AZ deployment, you must ensure you've applied the latest CloudFormation template with prerequisites, or manually configure the latest prerequisites. If you've already applied the latest CloudFormation prerequisite template, you can skip these steps.

To configure the RDS Custom for SQL Server Multi-AZ deployment prerequisites using CloudFormation

2. To start the Create Stack wizard, select the existing stack you used to create a Single-AZ deployment and choose Update.
   The Update stack page appears.
3. For Prerequisite - Prepare template, choose Replace current template.
4. For Specify template, do the following:
   a. Download the latest AWS CloudFormation template file. Open the context (right-click) menu for the link custom-sqlserver-onboard.zip and choose Save Link As.
   b. Save and extract the custom-sqlserver-onboard.json file to your computer.
   c. For Template source, choose Upload a template file.
   d. For Choose file, navigate to and then choose custom-sqlserver-onboard.json.
5. Choose Next.
   The Specify stack details page appears.
6. To keep the default options, choose Next.
   The Advanced Options page appears.
7. To keep the default options, choose Next.
8. To keep the default options, choose Next.
9. On the Review Changes page, do the following:
   a. For Capabilities, select the I acknowledge that AWS CloudFormation might create IAM resources with custom names check box.
   b. Choose Submit.
10. Verify the update is successful. The status of a successful operation shows UPDATE_COMPLETE.
If the update fails, any new configuration specified in the update process will be rolled back. The existing resource will still be usable. For example, if you add network ACL rules numbered 18 and 19, but there were existing rules with same numbers, the update would return the following error: Resource handler returned message: "The network acl entry identified by 18 already exists. In this scenario you can modify the existing ACL rules to use a number lower than 18, then retry the update.

Configuring prerequisites to modify a Single-AZ to a Multi-AZ deployment manually

**Important**
To simplify setup, we recommend that you use the latest AWS CloudFormation template file provided in the network setup instructions. For more information, see Configuring prerequisites to modify a Single-AZ to a Multi-AZ deployment using CloudFormation (p. 1166).

If you choose to configure the prerequisites manually, perform the following tasks.

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose **Endpoint**. The **Create Endpoint** page appears.
3. For **Service Category**, choose **AWS services**.
4. In **Services**, search for **SQS**
5. In **VPC**, choose the VPC where your RDS Custom for SQL Server DB instance is deployed.
6. In **Subnets**, choose the subnets where your RDS Custom for SQL Server DB instance is deployed.
7. In **Security Groups**, choose the **-vpc-endpoint-sg** group.
8. For **Policy**, choose **Custom**
9. In your custom policy, replace the **AWS partition**, **Region**, **accountId**, and **IAM-Instance-role** with your own values.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Condition": {
                "StringLike": {
                    "aws:ResourceTag/AWSRDSCustom": "custom-sqlserver"
                }
            },
            "Action": [
                "SQS:SendMessage",
                "SQS:ReceiveMessage",
                "SQS:DeleteMessage",
                "SQS:GetQueueUrl"
            ],
            "Resource": "arn:${AWS::Partition}:sqs:${AWS::Region}:${AWS::AccountId}:do-not-delete-rds-custom-*",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:${AWS::Partition}:iam:${AWS::AccountId}:role/{IAM-Instance-role}"
            }
        }
    ]
}
```

10. Update the **Instance profile** with permission to access Amazon SQS. Replace the **AWS partition**, **Region**, and **accountId** with your own values.
11. Update the Amazon RDS security group inbound and outbound rules to allow port 1120.
   
   b. For Inbound Rules, create a Custom TCP rule to allow port 1120 from the source -rds-custom-instance-sg group.
   c. For Outbound Rules, create a Custom TCP rule to allow port 1120 to the destination -rds-custom-instance-sg group.

12. Add a rule in your private network Access Control List (ACL) that allows TCP ports 0-65535 for the source subnet of the DB instance.

   Note
   When creating an Inbound Rule and Outbound Rule, take note of the highest existing Rule number. The new rules you create must have a Rule number lower than 100 and not match any existing Rule number.

   a. In Network ACLs, choose the -private-network-acl group.
   b. For Inbound Rules, create an All TCP rule to allow TCP ports 0-65535 with a source from privatesubnet1 and privatesubnet2.
   c. For Outbound Rules, create an All TCP rule to allow TCP ports 0-65535 to destination privatesubnet1 and privatesubnet2.

Modify using the RDS console, AWS CLI, or RDS API.

After you've completed the prerequisites, you can modify an RDS Custom for SQL Server DB instance from a Single-AZ to Multi-AZ deployment using the RDS console, AWS CLI, or RDS API.

Console

To modify an existing RDS Custom for SQL Server Single-AZ to Multi-AZ deployment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the Amazon RDS console, choose **Databases**.

   The **Databases** pane appears.

3. Choose the RDS Custom for SQL Server DB instance that you want to modify.

4. For **Actions**, choose **Convert to Multi-AZ deployment**.

5. On the **Confirmation** page, choose **Apply immediately** to apply the changes immediately. Choosing this option doesn't cause downtime, but there is a possible performance impact. Alternatively, you can choose to apply the update during the next maintenance window. For more information, see **Using the Apply Immediately setting** (p. 402).

6. On the **Confirmation** page, choose **Convert to Multi-AZ**.

**AWS CLI**

To convert to a Multi-AZ DB instance deployment by using the AWS CLI, call the `modify-db-instance` command and set the `--multi-az` option. Specify the DB instance identifier and the values for other options that you want to modify. For information about each option, see **Settings for DB instances** (p. 402).

**Example**

The following code modifies `mycustomdbinstance` by including the `--multi-az` option. The changes are applied during the next maintenance window by using `--no-apply-immediately`. Use `--apply-immediately` to apply the changes immediately. For more information, see **Using the Apply Immediately setting** (p. 402).

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
   --db-instance-identifier mycustomdbinstance \
   --multi-az \
   --no-apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
   --db-instance-identifier mycustomdbinstance ^
   --multi-az ^
   --no-apply-immediately
```

**RDS API**

To convert to a Multi-AZ DB instance deployment with the RDS API, call the `ModifyDBInstance` operation and set the `MultiAZ` parameter to true.

**Modifying an RDS Custom for SQL Server Multi-AZ deployment to a Single-AZ deployment**

You can modify an existing RDS Custom for SQL Server DB instance from a Multi-AZ to a Single-AZ deployment.

**Console**

**To modify an RDS Custom for SQL Server DB instance from a Multi-AZ to Single-AZ deployment.**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the Amazon RDS console, choose **Databases**.

   The **Databases** pane appears.

3. Choose the RDS Custom for SQL Server DB instance that you want to modify.

4. For **Multi-AZ deployment**, choose **No**.

5. On the **Confirmation** page, choose **Apply immediately** to apply the changes immediately. Choosing this option doesn't cause downtime, but there is a possible performance impact. Alternatively, you can choose to apply the update during the next maintenance window. For more information, see **Using the Apply Immediately setting** (p. 402).

6. On the **Confirmation** page, choose **Modify DB Instance**.

**AWS CLI**

To modify a Multi-AZ deployment to a Single-AZ deployment by using the AWS CLI, call the `modify-db-instance` command and include the `--no-multi-az` option. Specify the DB instance identifier and the values for other options that you want to modify. For information about each option, see **Settings for DB instances** (p. 402).

**Example**

The following code modifies `mycustomdbinstance` by including the `--no-multi-az` option. The changes are applied during the next maintenance window by using `--no-apply-immediately`. Use `--apply-immediately` to apply the changes immediately. For more information, see **Using the Apply Immediately setting** (p. 402).

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier mycustomdbinstance \ 
  --no-multi-az \ 
  --no-apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier mycustomdbinstance ^
  --no-multi-az \ ^
  --no-apply-immediately
```

**RDS API**

To modify a Multi-AZ deployment to a Single-AZ deployment by using the RDS API, call the `ModifyDBInstance` operation and set the `MultiAZ` parameter to `false`.

**Failover process for an RDS Custom for SQL Server Multi-AZ deployment**

If a planned or unplanned outage of your DB instance results from an infrastructure defect, Amazon RDS automatically switches to a standby replica in another Availability Zone if you have turned on Multi-AZ. The time that it takes for the failover to complete depends on the database activity and other conditions at the time that the primary DB instance became unavailable. Failover times are typically 60 – 120 seconds. However, large transactions or a lengthy recovery process can increase failover time. When the failover is complete, it can take additional time for the RDS console to show the new Availability Zone.
### Note

You can force a failover manually when you reboot a DB instance with failover. For more information on rebooting a DB instance, see [Rebooting a DB instance](p. 436)

Amazon RDS handles failovers automatically so you can resume database operations as quickly as possible without administrative intervention. The primary DB instance switches over automatically to the standby replica if any of the conditions described in the following table occurs. You can view these failover reasons in the RDS event log.

<table>
<thead>
<tr>
<th>Failover reason</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>The operating system for the RDS Custom for SQL Server Multi-AZ DB instance is being patched in an offline operation</td>
<td>A failover was triggered during the maintenance window for an OS patch or a security update. For more information, see [Maintaining a DB instance](p. 418).</td>
</tr>
<tr>
<td>The primary host of the RDS Custom for SQL Server Multi-AZ DB instance is unhealthy.</td>
<td>The Multi-AZ DB instance deployment detected an impaired primary DB instance and failed over.</td>
</tr>
<tr>
<td>The primary host of the RDS Custom for SQL Server Multi-AZ DB instance is unreachable due to loss of network connectivity.</td>
<td>RDS monitoring detected a network reachability failure to the primary DB instance and triggered a failover.</td>
</tr>
<tr>
<td>The RDS Custom for SQL Server Multi-AZ DB instance was modified by the customer.</td>
<td>A DB instance modification triggered a failover. For more information, see [Modifying an RDS Custom for SQL Server DB instance](p. 1157).</td>
</tr>
<tr>
<td>The storage volume of the primary host of the RDS Custom for SQL Server Multi-AZ DB instance experienced a failure.</td>
<td>The Multi-AZ DB instance deployment detected a storage issue on the primary DB instance and failed over.</td>
</tr>
<tr>
<td>The user requested a failover of the RDS Custom for SQL Server Multi-AZ DB instance.</td>
<td>The RDS Custom for SQL Server Multi-AZ DB instance was rebooted with failover. For more information, see [Rebooting a DB instance](p. 436).</td>
</tr>
<tr>
<td>The RDS Custom for SQL Server Multi-AZ primary DB instance is busy or unresponsive.</td>
<td>The primary DB instance is unresponsive. We recommend that you try the following steps:</td>
</tr>
<tr>
<td></td>
<td>• Examine the event logs and CloudWatch logs for excessive CPU, memory, or swap space usage. For more information, see [Working with Amazon RDS event notification](p. 855).</td>
</tr>
<tr>
<td></td>
<td>• Create a rule that triggers on an Amazon RDS event. For more information, see [Creating a rule that triggers on an Amazon RDS event](p. 870).</td>
</tr>
<tr>
<td>Failover reason</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------</td>
</tr>
<tr>
<td></td>
<td>- Evaluate your workload to determine whether you’re using the appropriate DB instance class. For more information, see DB instance classes (p. 11).</td>
</tr>
</tbody>
</table>

To determine if your Multi-AZ DB instance has failed over, you can do the following:

- Set up DB event subscriptions to notify you by email or SMS that a failover has been initiated. For more information about events, see Working with Amazon RDS event notification (p. 855).
- View your DB events by using the RDS console or API operations.
- View the current state of your RDS Custom for SQL Server Multi-AZ DB instance deployment by using the RDS console, CLI, or API operations.

**Time to live (TTL) settings with applications using an RDS Custom for SQL Server Multi-AZ deployment**

The failover mechanism automatically changes the Domain Name System (DNS) record of the DB instance to point to the standby DB instance. As a result, you need to re-establish any existing connections to your DB instance. Ensure that any DNS cache time-to-live (TTL) configuration value is low, and validate that your application will not cache DNS for an extended time. A high TTL value might prevent your application from quickly reconnecting to the DB instance after failover.
Backing up and restoring an Amazon RDS Custom for SQL Server DB instance

Like Amazon RDS, RDS Custom creates and saves automated backups of your RDS Custom for SQL Server DB instance during the backup window of your DB instance. You can also back up your DB instance manually.

The procedure is identical to taking a snapshot of an Amazon RDS DB instance. The first snapshot of an RDS Custom DB instance contains the data for the full DB instance. Subsequent snapshots are incremental.

Restore DB snapshots using either the AWS Management Console or the AWS CLI.

Topics
- Creating an RDS Custom for SQL Server snapshot (p. 1173)
- Restoring from an RDS Custom for SQL Server DB snapshot (p. 1174)
- Restoring an RDS Custom for SQL Server instance to a point in time (p. 1175)
- Deleting an RDS Custom for SQL Server snapshot (p. 1178)
- Deleting RDS Custom for SQL Server automated backups (p. 1179)

Creating an RDS Custom for SQL Server snapshot

RDS Custom for SQL Server creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases. When you create a snapshot, specify which RDS Custom for SQL Server DB instance to back up. Give your snapshot a name so you can restore from it later.

When you create a snapshot, RDS Custom for SQL Server creates an Amazon EBS snapshot for every volume attached to the DB instance. RDS Custom for SQL Server uses the EBS snapshot of the root volume to register a new Amazon Machine Image (AMI). To make snapshots easy to associate with a specific DB instance, they're tagged with DBSnapshotIdentifier, DbiResourceId, and VolumeType.

Creating a DB snapshot results in a brief I/O suspension. This suspension can last from a few seconds to a few minutes, depending on the size and class of your DB instance. The snapshot creation time varies with the size of your database. Because the snapshot includes the entire storage volume, the size of files, such as temporary files, also affects snapshot creation time. To learn more about creating snapshots, see Creating a DB snapshot (p. 613).

Create an RDS Custom for SQL Server snapshot using the console or the AWS CLI.

Console

To create an RDS Custom snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. In the list of RDS Custom DB instances, choose the instance for which you want to take a snapshot.
4. For Actions, choose Take snapshot.
   The Take DB snapshot window appears.
5. For Snapshot name, enter the name of the snapshot.
6. Choose Take snapshot.
AWS CLI

You create a snapshot of an RDS Custom DB instance by using the `create-db-snapshot` AWS CLI command.

Specify the following options:

- `--db-instance-identifier` – Identifies which RDS Custom DB instance you are going to back up
- `--db-snapshot-identifier` – Names your RDS Custom snapshot so you can restore from it later

In this example, you create a DB snapshot called `my-custom-snapshot` for an RDS Custom DB instance called `my-custom-instance`.

Example

For Linux, macOS, or Unix:

```bash
aws rds create-db-snapshot \
  --db-instance-identifier my-custom-instance \
  --db-snapshot-identifier my-custom-snapshot
```

For Windows:

```bash
aws rds create-db-snapshot ^
  --db-instance-identifier my-custom-instance ^
  --db-snapshot-identifier my-custom-snapshot
```

Restoring from an RDS Custom for SQL Server DB snapshot

When you restore an RDS Custom for SQL Server DB instance, you provide the name of the DB snapshot and a name for the new instance. You can't restore from a snapshot to an existing RDS Custom DB instance. A new RDS Custom for SQL Server DB instance is created when you restore.

The restore process differs in the following ways from restore in Amazon RDS:

- Before restoring a snapshot, RDS Custom for SQL Server backs up existing configuration files. These files are available on the restored instance in the directory `/rdsdbdata/config/backup`. RDS Custom for SQL Server restores the DB snapshot with default parameters and overwrites the previous database configuration files with existing ones. Thus, the restored instance doesn't preserve custom parameters and changes to database configuration files.
- The restored database has the same name as in the snapshot. You can't specify a different name.

Console

To restore an RDS Custom DB instance from a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Snapshots.
3. Choose the DB snapshot that you want to restore from.
4. For Actions, choose Restore snapshot.
5. On the Restore DB instance page, for DB instance identifier, enter the name for your restored RDS Custom DB instance.
6. Choose **Restore DB instance**.

**AWS CLI**

You restore an RDS Custom DB snapshot by using the `restore-db-instance-from-db-snapshot` AWS CLI command.

If the snapshot you are restoring from is for a private DB instance, make sure to specify both the correct `db-subnet-group-name` and `no-publicly-accessible`. Otherwise, the DB instance defaults to publicly accessible. The following options are required:

- `db-snapshot-identifier` – Identifies the snapshot from which to restore
- `db-instance-identifier` – Specifies the name of the RDS Custom DB instance to create from the DB snapshot
- `custom-iam-instance-profile` – Specifies the instance profile associated with the underlying Amazon EC2 instance of an RDS Custom DB instance.

The following code restores the snapshot named `my-custom-snapshot` for `my-custom-instance`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds restore-db-instance-from-db-snapshot \
  --db-snapshot-identifier my-custom-snapshot \
  --db-instance-identifier my-custom-instance \
  --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance \
  --no-publicly-accessible
```

For Windows:

```bash
aws rds restore-db-instance-from-db-snapshot ^
  --db-snapshot-identifier my-custom-snapshot ^
  --db-instance-identifier my-custom-instance ^
  --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance ^
  --no-publicly-accessible
```

**Restoring an RDS Custom for SQL Server instance to a point in time**

You can restore a DB instance to a specific point in time (PITR), creating a new DB instance. To support PITR, your DB instances must have backup retention set to a nonzero value.

The latest restorable time for an RDS Custom for SQL Server DB instance depends on several factors, but is typically within 5 minutes of the current time. To see the latest restorable time for a DB instance, use the AWS CLI `describe-db-instances` command and look at the value returned in the `LatestRestorableTime` field for the DB instance. To see the latest restorable time for each DB instance in the Amazon RDS console, choose **Automated backups**.

You can restore to any point in time within your backup retention period. To see the earliest restorable time for each DB instance, choose **Automated backups** in the Amazon RDS console.

For general information about PITR, see **Restoring a DB instance to a specified time** (p. 660).

**Topics**

- [PITR considerations for RDS Custom for SQL Server](p. 1176)
PITR considerations for RDS Custom for SQL Server

In RDS Custom for SQL Server, PITR differs in the following important ways from PITR in Amazon RDS:

- PITR only restores the databases in the DB instance. It doesn't restore the operating system or files on the C: drive.
- For an RDS Custom for SQL Server DB instance, a database is backed up automatically and is eligible for PITR only under the following conditions:
  - The database is online.
  - Its recovery model is set to FULL.
  - It's writable.
  - It has its physical files on the D: drive.
  - It's not listed in the rds_pitr_blocked_databases table. For more information, see Making databases ineligible for PITR (p. 1176).
- RDS Custom for SQL Server allows up to 5,000 databases per DB instance. However, the maximum number of databases restored by a PITR operation for an RDS Custom for SQL Server DB instance is 100. The 100 databases are determined by the order of their database ID.

Other databases that aren't part of PITR can be restored from DB snapshots, including the automated backups used for PITR.

- Adding a new database, renaming a database, or restoring a database that is eligible for PITR initiates a snapshot of the DB instance.
- Restored databases have the same name as in the source DB instance. You can't specify a different name.
- AWSRDSCustomSQLServerIamRolePolicy requires new permissions. For more information, see Add an access policy to AWSRDSCustomSQLServerInstanceRole (p. 1121).
- Time zone changes aren't supported for RDS Custom for SQL Server. If you change the operating system or DB instance time zone, PITR (and other automation) doesn't work.

Making databases ineligible for PITR

You can specify that certain RDS Custom for SQL Server databases aren't part of automated backups and PITR. To do this, put their database_id values into a rds_pitr_blocked_databases table. Use the following SQL script to create the table.

To create the rds_pitr_blocked_databases table

- Run the following SQL script.

```sql
create table msdb..rds_pitr_blocked_databases
(
database_id INT NOT NULL,
database_name SYSNAME NOT NULL,
db_entry_updated_date datetime NOT NULL DEFAULT GETDATE(),
db_entry_updated_by SYSNAME NOT NULL DEFAULT CURRENT_USER,
PRIMARY KEY (database_id)
);
```

For the list of eligible and ineligible databases, see the RI.End file in the RDSCustomForSQLServer/Instances/DB_instance_resource_ID/TransactionLogMetadata directory in the Amazon S3 bucket do-not-delete-rds-custom-$ACCOUNT_ID-$REGION-unique_identifier. For more information about the RI.End file, see Transaction logs in Amazon S3 (p. 1177).
Transaction logs in Amazon S3

The backup retention period determines whether transaction logs for RDS Custom for SQL Server DB instances are automatically extracted and uploaded to Amazon S3. A nonzero value means that automatic backups are created, and that the RDS Custom agent uploads the transaction logs to S3 every 5 minutes.

Transaction log files on S3 are encrypted at rest using the AWS KMS key that you provided when you created your DB instance. For more information, see Protecting data using server-side encryption in the Amazon Simple Storage Service User Guide.

The transaction logs for each database are uploaded to an S3 bucket named do-not-delete-ids-custom-$ACCOUNT_ID-$REGION-unique_identifier. The RDSCustomForSQLServer/Instances/DB_instance_resource_ID directory in the S3 bucket contains two subdirectories:

- **TransactionLogs** – Contains the transaction logs for each database and their respective metadata.

  The transaction log file name follows the pattern `yyyyMMddHHmm.database_id.timestamp`, for example:

  ```
  202110202230.11.1634769287
  ```

  The same file name with the suffix _metadata contains information about the transaction log such as log sequence numbers, database name, and RdsChunkCount. RdsChunkCount determines how many physical files represent a single transaction log file. You might see files with suffixes _0001, _0002, and so on, which mean the physical chunks of a transaction log file. If you want to use a chunked transaction log file, make sure to merge the chunks after downloading them.

  Consider a scenario where you have the following files:

  - `202110202230.11.1634769287`
  - `202110202230.11.1634769287_0001`
  - `202110202230.11.1634769287_0002`
  - `202110202230.11.1634769287_metadata`

  The RdsChunkCount is 3. The order for merging the files is the following:

  ```
  202110202230.11.1634769287, 202110202230.11.1634769287_0001, 202110202230.11.1634769287_0002.
  ```

- **TransactionLogMetadata** – Contains metadata information about each iteration of transaction log extraction.

  The RI.End file contains information for all databases that had their transaction logs extracted, and all databases that exist but didn't have their transaction logs extracted. The RI.End file name follows the pattern `yyyyMMddMMHHmm.RI.End.timestamp`, for example:

  ```
  202110202230.RI.End.1634769281
  ```

You can restore an RDS Custom for SQL Server DB instance to a point in time using the AWS Management Console, the AWS CLI, or the RDS API.

Console

**To restore an RDS Custom DB instance to a specified time**

1. Sign in to the AWS Management Console and open the Amazon RDS console at `https://console.aws.amazon.com/rds/`. 
2. In the navigation pane, choose **Automated backups**.
3. Choose the RDS Custom DB instance that you want to restore.
4. For **Actions**, choose **Restore to point in time**.
   
   The **Restore to point in time** window appears.
5. Choose **Latest restorable time** to restore to the latest possible time, or choose **Custom** to choose a time.
   
   If you chose **Custom**, enter the date and time to which you want to restore the instance.

   Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/Central Daylight Time.
6. For **DB instance identifier**, enter the name of the target restored RDS Custom DB instance. The name must be unique.
7. Choose other options as needed, such as DB instance class.
8. Choose **Restore to point in time**.

**AWS CLI**

You restore a DB instance to a specified time by using the `restore-db-instance-to-point-in-time` AWS CLI command to create a new RDS Custom DB instance.

Use one of the following options to specify the backup to restore from:

- `--source-db-instance-identifier` *mysourcedbinstance*
- `--source-db-instance-automated-backups-arn` *backupARN*
- `--source-dbi-resource-id` *dbinstanceresourceID*

The `custom-iam-instance-profile` option is required.

The following example restores `my-custom-db-instance` to a new DB instance named `my-restored-custom-db-instance`, as of the specified time.

**Example**

For Linux, macOS, or Unix:

```shell
cmd
aws rds restore-db-instance-to-point-in-time \
   --source-db-instance-identifier my-custom-db-instance \
   --target-db-instance-identifier my-restored-custom-db-instance \ 
   --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance \ 
   --restore-time 2022-10-14T23:45:00.000Z
```

For Windows:

```shell
cmd
aws rds restore-db-instance-to-point-in-time ^
   --source-db-instance-identifier my-custom-db-instance ^
   --target-db-instance-identifier my-restored-custom-db-instance ^
   --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance ^
   --restore-time 2022-10-14T23:45:00.000Z
```

**Deleting an RDS Custom for SQL Server snapshot**

You can delete DB snapshots managed by RDS Custom for SQL Server when you no longer need them. The deletion procedure is the same for both Amazon RDS and RDS Custom DB instances.
The Amazon EBS snapshots for the binary and root volumes remain in your account for a longer time because they might be linked to some instances running in your account or to other RDS Custom for SQL Server snapshots. These EBS snapshots are automatically deleted after they’re no longer related to any existing RDS Custom for SQL Server resources (DB instances or backups).

**Console**

**To delete a snapshot of an RDS Custom DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Snapshots**.
3. Choose the DB snapshot that you want to delete.
4. For **Actions**, choose **Delete snapshot**.
5. Choose **Delete** on the confirmation page.

**AWS CLI**

To delete an RDS Custom snapshot, use the AWS CLI command `delete-db-snapshot`.

The following option is required:

- `--db-snapshot-identifier` – The snapshot to be deleted

The following example deletes the `my-custom-snapshot` DB snapshot.

**Example**

For Linux, macOS, or Unix:

```
aws rds delete-db-snapshot \
    --db-snapshot-identifier my-custom-snapshot
```

For Windows:

```
aws rds delete-db-snapshot ^
    --db-snapshot-identifier my-custom-snapshot
```

**Deleting RDS Custom for SQL Server automated backups**

You can delete retained automated backups for RDS Custom for SQL Server when they are no longer needed. The procedure is the same as the procedure for deleting Amazon RDS backups.

**Console**

**To delete a retained automated backup**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Automated backups**.
3. Choose **Retained**.
4. Choose the retained automated backup that you want to delete.
5. For **Actions**, choose **Delete**.
6. On the confirmation page, enter delete me and choose Delete.

**AWS CLI**

You can delete a retained automated backup by using the AWS CLI command `delete-db-instance-automated-backup`.

The following option is used to delete a retained automated backup:

- `--dbi-resource-id` – The resource identifier for the source RDS Custom DB instance.

You can find the resource identifier for the source DB instance of a retained automated backup by using the AWS CLI command `describe-db-instance-automated-backups`.

The following example deletes the retained automated backup with source DB instance resource identifier `custom-db-123ABCE.example`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds delete-db-instance-automated-backup \  
--dbi-resource-id custom-db-123ABCE.example
```

For Windows:

```bash
aws rds delete-db-instance-automated-backup ^  
--dbi-resource-id custom-db-123ABCE.example
```
Migrating an on-premises database to Amazon RDS Custom for SQL Server

You can use the following process to migrate an on-premises Microsoft SQL Server database to Amazon RDS Custom for SQL Server using native backup and restore:

1. Take a full backup of the database on the on-premises DB instance.
2. Upload the backup file to Amazon S3.
3. Download the backup file from S3 to your RDS Custom for SQL Server DB instance.
4. Restore a database using the downloaded backup file on the RDS Custom for SQL Server DB instance.

This process explains the migration of a database from on-premises to RDS Custom for SQL Server, using native full backup and restore. To reduce the cutover time during the migration process, you might also consider using differential or log backups.

For general information about native backup and restore for RDS for SQL Server, see [Importing and exporting SQL Server databases using native backup and restore](p. 1435).

Topics

- Prerequisites (p. 1181)
- Backing up the on-premises database (p. 1181)
- Uploading the backup file to Amazon S3 (p. 1182)
- Downloading the backup file from Amazon S3 (p. 1182)
- Restoring the backup file to the RDS Custom for SQL Server DB instance (p. 1182)

Prerequisites

Perform the following tasks before migrating the database:

1. Configure Remote Desktop Connection (RDP) for your RDS Custom for SQL Server DB instance. For more information, see [Connecting to your RDS Custom DB instance using RDP](p. 1151).
2. Configure access to Amazon S3 so you can upload and download the database backup file. For more information, see [Integrating an Amazon RDS for SQL Server DB instance with Amazon S3](p. 1480).

Backing up the on-premises database

You use SQL Server native backup to take a full backup of the database on the on-premises DB instance.

The following example shows a backup of a database called mydatabase, with the COMPRESSION option specified to reduce the backup file size.

To back up the on-premises database

1. Using SQL Server Management Studio (SSMS), connect to the on-premises SQL Server instance.
2. Run the following T-SQL command.

```sql
backup database mydatabase to
disk = 'C:\Program Files\Microsoft SQL Server\MSSQL13.MSSQLSERVER\MSSQL\Backup\mydb-full-compressed.bak'
with compression;
```
Uploading the backup file to Amazon S3

You use the AWS Management Console to upload the backup file `mydb-full-compressed.bak` to Amazon S3.

**To upload the backup file to S3**

1. Sign in to the AWS Management Console and open the Amazon S3 console at [https://console.aws.amazon.com/s3/](https://console.aws.amazon.com/s3/).
2. For **Buckets**, choose the name of the bucket to which you want to upload your backup file.
3. Choose **Upload**.
4. In the **Upload** window, do one of the following:
   - Drag and drop `mydb-full-compressed.bak` to the **Upload** window.
   - Choose **Add file**, choose `mydb-full-compressed.bak`, and then choose **Open**.

Amazon S3 uploads your backup file as an S3 object. When the upload completes, you can see a success message on the **Upload: status** page.

Downloading the backup file from Amazon S3

You use the console to download the backup file from S3 to the RDS Custom for SQL Server DB instance.

**To download the backup file from S3**

1. Using RDP, connect to your RDS Custom for SQL Server DB instance.
2. Sign in to the AWS Management Console and open the Amazon S3 console at [https://console.aws.amazon.com/s3/](https://console.aws.amazon.com/s3/).
3. In the **Buckets** list, choose the name of the bucket that contains your backup file.
4. Choose the backup file `mydb-full-compressed.bak`.
5. For **Actions**, choose **Download as**.
6. Open the context (right-click) menu for the link provided, then choose **Save As**.
7. Save `mydb-full-compressed.bak` to the `D:\rdsdbdata\BACKUP` directory.

Restoring the backup file to the RDS Custom for SQL Server DB instance

You use SQL Server native restore to restore the backup file to your RDS Custom for SQL Server DB instance.

In this example, the **MOVE** option is specified because the data and log file directories are different from the on-premises DB instance.

**To restore the backup file**

1. Using SSMS, connect to your RDS Custom for SQL Server DB instance.
2. Run the following T-SQL command.

   ```sql
   restore database mydatabase from disk='D:\rdsdbdata\BACKUP\mydb-full-compressed.bak'
   with move 'mydatabase' to 'D:\rdsdbdata\DATA\mydatabase.mdf',
   move 'mydatabase_log' to 'D:\rdsdbdata\DATA\mydatabase_log.ldf';
   ```
Upgrading a DB instance for Amazon RDS Custom for SQL Server

You can upgrade an Amazon RDS Custom for SQL Server DB instance by modifying it to use a new DB engine version, the same as you do for Amazon RDS.

The same limitations for upgrading an RDS Custom for SQL Server DB instance apply as for modifying an RDS Custom for SQL Server DB instance in general. For more information, see Modifying an RDS Custom for SQL Server DB instance (p. 1157).

For general information about upgrading DB instances, see Upgrading a DB instance engine version (p. 429).
Troubleshooting DB issues for Amazon RDS Custom for SQL Server

The shared responsibility model of RDS Custom provides OS shell-level access and database administrator access. RDS Custom runs resources in your account, unlike Amazon RDS, which runs resources in a system account. With greater access comes greater responsibility. In the following sections, you can learn how to troubleshoot issues with Amazon RDS Custom for SQL Server DB instances.

Note
This section explains how to troubleshoot RDS Custom for SQL Server. For troubleshooting RDS Custom for Oracle, see Troubleshooting DB issues for Amazon RDS Custom for Oracle (p. 1078).

Topics
- Viewing RDS Custom events (p. 1185)
- Viewing RDS Custom events (p. 1185)
- Troubleshooting CEV errors for RDS Custom for SQL Server (p. 1186)
- Fixing unsupported configurations in RDS Custom for SQL Server (p. 1188)

Viewing RDS Custom events

The procedure for viewing events is the same for RDS Custom and Amazon RDS DB instances. For more information, see Viewing Amazon RDS events (p. 852).

To view RDS Custom event notification using the AWS CLI, use the `describe-events` command. RDS Custom introduces several new events. The event categories are the same as for Amazon RDS. For the list of events, see Amazon RDS event categories and event messages (p. 874).

The following example retrieves details for the events that have occurred for the specified RDS Custom DB instance.

```
aws rds describe-events \
  --source-identifier my-custom-instance \
  --source-type db-instance
```

Viewing RDS Custom events

The procedure for subscribing to events is the same for RDS Custom and Amazon RDS DB instances. For more information, see Subscribing to Amazon RDS event notification (p. 860).

To subscribe to RDS Custom event notification using the CLI, use the `create-event-subscription` command. Include the following required parameters:

- `--subscription-name`
- `--sns-topic-arn`

The following example creates a subscription for backup and recovery events for an RDS Custom DB instance in the current AWS account. Notifications are sent to an Amazon Simple Notification Service (Amazon SNS) topic, specified by `--sns-topic-arn`.

```
aws rds create-event-subscription \
  --subscription-name my-instance-events \
  --source-type db-instance \
  --event-categories ['"backup","recovery"] \
  --sns-topic-arn arn:aws:sns:us-east-1:123456789012:interesting-events
```
Troubleshooting CEV errors for RDS Custom for SQL Server

When you try to create a CEV, it might fail. In this case, RDS Custom issues the RDS-EVENT-0198 event message. For more information on viewing RDS events, see Amazon RDS event categories and event messages (p. 874).

Use the following information to help you address possible causes.

<table>
<thead>

**Fixing unsupported configurations in RDS Custom for SQL Server**

Because of the shared responsibility model, it’s your responsibility to fix configuration issues that put your RDS Custom for SQL Server DB instance into the unsupported-configuration state. If the issue is with the AWS infrastructure, you can use the console or the AWS CLI to fix it. If the issue is with the operating system or the database configuration, you can log in to the host to fix it.

**Note**

This section explains how to fix unsupported configurations in RDS Custom for SQL Server. For information about RDS Custom for Oracle, see Fixing unsupported configurations in RDS Custom for Oracle (p. 1080).

In the following table, you can find descriptions of the notifications and events that the support perimeter sends and how to fix them. These notifications and the support perimeter are subject to
change. For background on the support perimeter, see [RDS Custom support perimeter (p. 985)](https://docs.aws.amazon.com/rds-custom/latest/userguide/troubleshooting.html). For event descriptions, see [Amazon RDS event categories and event messages (p. 874)](https://docs.aws.amazon.com/rds-custom/latest/userguide/troubleshooting.html).

<table>
<thead>
<tr>
<th>Configuration area</th>

### AWS resources

<p>| Amazon EC2 instance state | The state of the EC2 instance [i-xxxxxxxxxxxxxxxxx] has changed from [RUNNING] to [STOPPING]. The Amazon EC2 instance [i-xxxxxxxxxxxxxxxxx] has been terminated and can't be found. Delete the database instance to clean up resources. The Amazon EC2 instance [i-xxxxxxxxxxxxxxxxx] has been stopped. Start the instance, and restore the host configuration. For more information, see the troubleshooting documentation. | The support perimeter monitors EC2 instance state-change notifications. The EC2 instance must always be running. AMI associated with a CEV should always be active and available. | If the EC2 instance is stopped, start it and remount the binary and data volumes. If the EC2 instance is terminated, RDS Custom performs an automated recovery to provision a new EC2 instance. |</p>
<table>
<thead>
<tr>
<th>Configuration area</th>
<th>RDS event message</th>
<th>Description</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon EC2 instance attributes</td>
<td>The RDS Custom instance is going out of perimeter because an unsupported configuration was used for EC2 instance metadata.</td>
<td>The support perimeter monitors the instance type of the EC2 instance where the RDS Custom DB instance is running. The EC2 instance type must stay the same as when you set it up during RDS Custom DB instance creation.</td>
<td>Change the EC2 instance type back to the original type using the EC2 console or CLI. To change the instance type because of scaling requirements, do a PITR and specify the new instance type and class. However, doing this results in a new RDS Custom DB instance with a new host and Domain Name System (DNS) name.</td>
</tr>
</tbody>
</table>
| Amazon Elastic Block Store (Amazon EBS) volumes | The RDS Custom instance is going out of perimeter because an unsupported configuration was used for EBS volume metadata. | RDS Custom creates two types of EBS volume, besides the root volume created from the Amazon Machine Image (AMI), and associates them with the EC2 instance. The binary volume is where the database software binaries are located. The data volumes are where database files are located. The storage configurations that you set when creating the DB instance are used to configure the data volumes. The support perimeter monitors the following:  
  - The initial EBS volumes created with the DB instance are still associated.  
  - The initial EBS volumes still have the same configurations as initially set: storage type, size, Provisioned IOPS, and storage throughput. | If you detached any initial EBS volumes, contact AWS Support. If you modified the storage type, Provisioned IOPS, or storage throughput of an EBS volume, revert the modification to the original value. If you modified the storage size of an EBS volume, contact AWS Support. |
Working with Amazon RDS on AWS Outposts

Amazon RDS on AWS Outposts extends RDS for SQL Server, RDS for MySQL, and RDS for PostgreSQL databases to AWS Outposts environments. AWS Outposts uses the same hardware as in public AWS Regions to bring AWS services, infrastructure, and operation models on-premises. With RDS on Outposts, you can provision managed DB instances close to the business applications that must run on-premises. For more information about AWS Outposts, see AWS Outposts.

You use the same AWS Management Console, AWS CLI, and RDS API to provision and manage on-premises RDS on Outposts DB instances as you do for RDS DB instances running in the AWS Cloud. RDS on Outposts automates tasks, such as database provisioning, operating system and database patching, backup, and long-term archival in Amazon S3.

RDS on Outposts supports automated backups of DB instances. Network connectivity between your Outpost and your AWS Region is required to back up and restore DB instances. All DB snapshots and transaction logs from an Outpost are stored in your AWS Region. From your AWS Region, you can restore a DB instance from a DB snapshot to a different Outpost. For more information, see Working with backups (p. 591).

RDS on Outposts supports automated maintenance and upgrades of DB instances. For more information, see Maintaining a DB instance (p. 418).

RDS on Outposts uses encryption at rest for DB instances and DB snapshots using your AWS KMS key. For more information about encryption at rest, see Encrypting Amazon RDS resources (p. 2603).

By default, EC2 instances in Outposts subnets can use the Amazon Route 53 DNS Service to resolve domain names to IP addresses. You might encounter longer DNS resolution times with Route 53, depending on the path latency between your Outpost and the AWS Region. In such cases, you can use the DNS servers installed locally in your on-premises environment. For more information, see DNS in the AWS Outposts User Guide.

When network connectivity to the AWS Region isn't available, your DB instance continues to run locally. You can continue to access DB instances using DNS name resolution by configuring a local DNS server as a secondary server. However, you can't create new DB instances or take new actions on existing DB instances. Automatic backups don't occur when there is no connectivity. If there is a DB instance failure, the DB instance isn't automatically replaced until connectivity is restored. We recommend restoring network connectivity as soon as possible.

Topics
- Prerequisites for Amazon RDS on AWS Outposts (p. 1194)
- Amazon RDS on AWS Outposts support for Amazon RDS features (p. 1195)
- Supported DB instance classes for Amazon RDS on AWS Outposts (p. 1198)
- Customer-owned IP addresses for Amazon RDS on AWS Outposts (p. 1200)
- Working with Multi-AZ deployments for Amazon RDS on AWS Outposts (p. 1202)
- Creating DB instances for Amazon RDS on AWS Outposts (p. 1205)
- Creating read replicas for Amazon RDS on AWS Outposts (p. 1212)
- Considerations for restoring DB instances on Amazon RDS on AWS Outposts (p. 1214)
Prerequisites for Amazon RDS on AWS Outposts

The following are prerequisites for using Amazon RDS on AWS Outposts:

- Install AWS Outposts in your on-premises data center. For more information about AWS Outposts, see AWS Outposts.
- Make sure that you have at least one subnet available for RDS on Outposts. You can use the same subnet for other workloads.
- Make sure that you have a reliable network connection between your Outpost and an AWS Region.
Amazon RDS on AWS Outposts support for Amazon RDS features

The following table describes the Amazon RDS features supported by Amazon RDS on AWS Outposts.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Supported</th>
<th>Notes</th>
<th>More information</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB instance provisioning</td>

</tr>
</tbody>
</table>
• General purpose DB instance classes
  • db.m5.24xlarge
  • db.m5.12xlarge
  • db.m5.4xlarge
  • db.m5.2xlarge
  • db.m5.xlarge
  • db.m5.large
• Memory optimized DB instance classes
  • db.r5.24xlarge
  • db.r5.12xlarge
  • db.r5.4xlarge
  • db.r5.2xlarge
  • db.r5.xlarge
  • db.r5.large

Depending on how you've configured your Outpost, you might not have all of these classes available. For example, if you haven't purchased the db.r5 classes for your Outpost, you can't use them with RDS on Outposts.

Only general purpose SSD storage is supported for RDS on Outposts DB instances. For more information about DB instance classes, see DB instance classes (p. 11).

Amazon RDS manages maintenance and recovery for your DB instances and requires active capacity on the Outpost to do so. We recommend that you configure N+1 EC2 instances for each DB instance class in your production environments. RDS on Outposts can use the extra capacity of these EC2 instances for maintenance and repair operations. For example, if your production environments have 3 db.m5.large and 5 db.r5.xlarge DB instance classes, then we recommend that they have at least 4 m5.large EC2 instances and 6 r5.xlarge EC2 instances. For more information, see Resilience in AWS Outposts in the AWS Outposts User Guide.
Customer-owned IP addresses for Amazon RDS on AWS Outposts

Amazon RDS on AWS Outposts uses information that you provide about your on-premises network to create an address pool. This pool is known as a customer-owned IP address pool (CoIP pool). Customer-owned IP addresses (CoIPs) provide local or external connectivity to resources in your Outpost subnets through your on-premises network. For more information about CoIPs, see Customer-owned IP addresses in the AWS Outposts User Guide.

Each RDS on Outposts DB instance has a private IP address for traffic inside its virtual private cloud (VPC). This private IP address isn't publicly accessible. You can use the Public option to set whether the DB instance also has a public IP address in addition to the private IP address. Using the public IP address for connections routes them through the internet and can result in high latencies in some cases.

Instead of using these private and public IP addresses, RDS on Outposts supports using CoIPs for DB instances through their subnets. When you use a CoIP for an RDS on Outposts DB instance, you connect to the DB instance with the DB instance endpoint. RDS on Outposts then automatically uses the CoIP for all connections from both inside and outside of the VPC.

CoIPs can provide the following benefits for RDS on Outposts DB instances:

- Lower connection latency
- Enhanced security

Using CoIPs

You can turn CoIPs on or off for an RDS on Outposts DB instance using the AWS Management Console, the AWS CLI, or the RDS API:

- With the AWS Management Console, choose the Customer-owned IP address (CoIP) setting in Access type to use CoIPs. Choose one of the other settings to turn them off.

```
Access type Info

Private
RDS will not assign a public IP address to the database. Amazon EC2 instances and devices inside the VPC can connect to your database. EC2 instances and devices outside your VPC can’t connect unless they use AWS Site-to-Site VPN or AWS Direct Connect.

Customer-owned IP address (CoIP)
Devices on your on-premises network can connect to your database through a CoIP.

Public
Amazon EC2 instances and devices outside the VPC can connect to your database. Choose one or more VPC security groups that specify which EC2 instances and devices can connect to the database.
```

Database port
TCP/IP port that the database will use for application connections.

3306
Limitations

• With the AWS CLI, use the `--enable-customer-owned-ip` or `--no-enable-customer-owned-ip` option.
• With the RDS API, use the `EnableCustomerOwnedIp` parameter.

You can turn CoIPs on or off when you perform any of the following actions:

• Create a DB instance
  For more information, see [Creating DB instances for Amazon RDS on AWS Outposts](p. 1205).
• Modify a DB instance
  For more information, see [Modifying an Amazon RDS DB instance](p. 401).
• Create a read replica
  For more information, see [Creating read replicas for Amazon RDS on AWS Outposts](p. 1212).
• Restore a DB instance from a snapshot
  For more information, see [Restoring from a DB snapshot](p. 615).
• Restore a DB instance to a specified time
  For more information, see [Restoring a DB instance to a specified time](p. 660).

**Note**
In some cases, you might turn on CoIPs for a DB instance but Amazon RDS isn't able to allocate a CoIP for the DB instance. In such cases, the DB instance status is changed to `incompatible-network`. For more information about the DB instance status, see [Viewing Amazon RDS DB instance status](p. 684).

Limitations

The following limitations apply to CoIP support for RDS on Outposts DB instances:

• When using a CoIP for a DB instance, make sure that public accessibility is turned off for that DB instance.
• Make sure that the inbound rules for your VPC security groups include the CoIP address range (CIDR block). For more information about setting up security groups, see [Provide access to your DB instance in your VPC by creating a security group](p. 177).
• You can't assign a CoIP from a CoIP pool to a DB instance. When you use a CoIP for a DB instance, Amazon RDS automatically assigns a CoIP from a CoIP pool to the DB instance.
• You must use the AWS account that owns the Outpost resources (owner) or share the following resources with other AWS accounts (consumers) in the same organization:
  • The Outpost
  • The local gateway (LGW) route table for the DB instance's VPC
  • The CoIP pool or pools for the LGW route table

For more information, see [Working with shared AWS Outposts resources](in the AWS Outposts User Guide).
Working with Multi-AZ deployments for Amazon RDS on AWS Outposts

For Multi-AZ deployments, Amazon RDS creates a primary DB instance on one AWS Outpost. RDS synchronously replicates the data to a standby DB instance on a different Outpost.

Multi-AZ deployments on AWS Outposts operate like Multi-AZ deployments in AWS Regions, but with the following differences:

- They require a local connection between two or more Outposts.
- They require customer-owned IP (CoIP) pools. For more information, see Customer-owned IP addresses for Amazon RDS on AWS Outposts (p. 1200).
- Replication runs on your local network.

Multi-AZ on AWS Outposts is available for all supported versions of MySQL and PostgreSQL on RDS on Outposts. Local backups aren’t supported for Multi-AZ deployments. For more information, see Creating DB instances for Amazon RDS on AWS Outposts (p. 1205).

Working with the shared responsibility model

Although AWS uses commercially reasonable efforts to provide DB instances configured for high availability, the availability uses a shared responsibility model. The ability of RDS on Outposts to fail over and repair DB instances requires each of your Outposts to be connected to its AWS Region.

RDS on Outposts also requires connectivity between the Outpost that is hosting the primary DB instance and the Outpost that is hosting the standby DB instance for synchronous replication. Any impact to this connection can prevent RDS on Outposts from performing a failover.

You might see elevated latencies for a standard DB instance deployment as a result of the synchronous data replication. The bandwidth and latency of the connection between the Outpost hosting the primary DB instance and the Outpost hosting the standby DB instance directly affect latencies. For more information, see Prerequisites (p. 1203).

Improving availability

We recommend the following actions to improve availability:

- Allocate enough additional capacity for your mission-critical applications to allow recovery and failover if there is an underlying host issue. This applies to all Outposts that contain subnets in your DB subnet group. For more information, see Resilience in AWS Outposts.
- Provide redundant network connectivity for your Outposts.
- Use more than two Outposts. Having more than two Outposts allows Amazon RDS to recover a DB instance. RDS does this recovery by moving the DB instance to another Outpost if the current Outpost experiences a failure.
- Provide dual power sources and redundant network connectivity for your Outpost.

We recommend the following for your local networks:

- The round trip time (RTT) latency between the Outpost hosting your primary DB instance and the Outpost hosting your standby DB instance directly affects write latency. Keep the RTT latency between the AWS Outposts in the low single-digit milliseconds. We recommend not more than 5 milliseconds, but your requirements might vary.
You can find the net impact to network latency in the Amazon CloudWatch metrics for WriteLatency. For more information, see Amazon CloudWatch metrics for Amazon RDS (p. 806).

- The availability of the connection between the Outposts affects the overall availability of your DB instances. Have redundant network connectivity between the Outposts.

**Prerequisites**

Multi-AZ deployments on RDS on Outposts have the following prerequisites:

- Have at least two Outposts, connected over local connections and attached to different Availability Zones in an AWS Region.
- Make sure that your DB subnet groups contain the following:
  - At least two subnets in at least two Availability Zones in a given AWS Region.
  - Subnets only in Outposts.
  - At least two subnets in at least two Outposts within the same virtual private cloud (VPC).
- Associate your DB instance's VPC with all of your local gateway route tables. This association is necessary because replication runs over your local network using your Outposts' local gateways.

For example, suppose that your VPC contains subnet-A in Outpost-A and subnet-B in Outpost-B. Outpost-A uses LocalGateway-A (LGW-A), and Outpost-B uses LocalGateway-B (LGW-B). LGW-A has RouteTable-A, and LGW-B has RouteTable-B. You want to use both RouteTable-A and RouteTable-B for replication traffic. To do this, associate your VPC with both RouteTable-A and RouteTable-B.

For more information about how to create an association, see the Amazon EC2 create-local-gateway-route-table-vpc-association AWS CLI command.

- Make sure that your Outposts use customer-owned IP (CoIP) routing. Each route table must also each have at least one address pool. Amazon RDS allocates an additional IP address each for the primary and standby DB instances for data synchronization.
- Make sure that the AWS account that owns the RDS DB instances owns the local gateway route tables and CoIP pools. Or make sure it's part of a Resource Access Manager share with access to the local gateway route tables and CoIP pools.
- Make sure that the IP addresses in your CoIP pools can be routed from one Outpost local gateway to the others.
- Make sure that the VPC's CIDR blocks (for example, 10.0.0.0/4) and your CoIP pool CIDR blocks don't contain IP addresses from Class E (240.0.0.0/4). RDS uses these IP addresses internally.
- Make sure that you correctly set up outbound and related inbound traffic.

RDS on Outposts establishes a virtual private network (VPN) connection between the primary and standby DB instances. For this to work correctly, your local network must allow outbound and related inbound traffic for Internet Security Association and Key Management Protocol (ISAKMP). It does so using User Datagram Protocol (UDP) port 500 and IP Security (IPsec) Network Address Translation Traversal (NAT-T) using UDP port 4500.

For more information on CoIPs, see Customer-owned IP addresses for Amazon RDS on AWS Outposts (p. 1200) in this guide, and Customer-owned IP addresses in the AWS Outposts User Guide.
Working with API operations for Amazon EC2 permissions

Regardless of whether you use CoIPs for your DB instance on AWS Outposts, RDS requires access to your CoIP pool resources. RDS can call the following EC2 permissions API operations for CoIPs on your behalf for Multi-AZ deployments:

- **CreateCoipPoolPermission** – When you create a Multi-AZ DB instance on RDS on Outposts
- **DeleteCoipPoolPermission** – When you delete a Multi-AZ DB instance on RDS on Outposts

These API operations grant to, or remove from, internal RDS accounts the permission to allocate elastic IP addresses from the CoIP pool specified by the permission. You can view these IP addresses using the **DescribeCoipPoolUsage** API operation. For more information on CoIPs, see Customer-owned IP addresses for Amazon RDS on AWS Outposts (p. 1200) and Customer-owned IP addresses in the AWS Outposts User Guide.

RDS can also call the following EC2 permission API operations for local gateway route tables on your behalf for Multi-AZ deployments:

- **CreateLocalGatewayRouteTablePermission** – When you create a Multi-AZ DB instance on RDS on Outposts
- **DeleteLocalGatewayRouteTablePermission** – When you delete a Multi-AZ DB instance on RDS on Outposts

These API operations grant to, or remove from, internal RDS accounts the permission to associate internal RDS VPCs with your local gateway route tables. You can view these route table–VPC associations using the **DescribeLocalGatewayRouteTableVpcAssociations** API operations.
Creating an Amazon RDS on AWS Outposts DB instance is similar to creating an Amazon RDS DB instance in the AWS Cloud. However, make sure that you specify a DB subnet group that is associated with your Outpost.

A virtual private cloud (VPC) based on the Amazon VPC service can span all of the Availability Zones in an AWS Region. You can extend any VPC in the AWS Region to your Outpost by adding an Outpost subnet. To add an Outpost subnet to a VPC, specify the Amazon Resource Name (ARN) of the Outpost when you create the subnet.

Before you create an RDS on Outposts DB instance, you can create a DB subnet group that includes one subnet that is associated with your Outpost. When you create an RDS on Outposts DB instance, specify this DB subnet group. You can also choose to create a new DB subnet group when you create your DB instance.

For information about configuring AWS Outposts, see the AWS Outposts User Guide.

**Console**

**Creating a DB subnet group**

Create a DB subnet group with one subnet that is associated with your Outpost.

You can also create a new DB subnet group for the Outpost when you create your DB instance. If you want to do so, then skip this procedure.

**Note**

To create a DB subnet group for the AWS Cloud, specify at least two subnets.

**To create a DB subnet group for your Outpost**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where you want to create the DB subnet group.
3. Choose Subnet groups, and then choose Create DB Subnet Group.

The Create DB subnet group page appears.
4. For **Name**, choose the name of the DB subnet group.
5. For **Description**, choose a description for the DB subnet group.
6. For **VPC**, choose the VPC that you're creating the DB subnet group for.
7. For **Availability Zones**, choose the Availability Zone for your Outpost.
8. For **Subnets**, choose the subnet for use by RDS on Outposts.
9. Choose **Create** to create the DB subnet group.

**Creating the RDS on Outposts DB instance**

Create the DB instance, and choose the Outpost for your DB instance.
To create an RDS on Outposts DB instance using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where the Outpost on which you want to create the DB instance is attached.
3. In the navigation pane, choose Databases.
4. Choose Create database.

The AWS Management Console detects available Outposts that you have configured and presents the On-premises option in the Database location section.

Note
If you haven't configured any Outposts, either the Database location section doesn't appear or the RDS on Outposts option isn't available in the Choose an on-premises creation method section.

5. For Database location, choose On-premises.
6. For On-premises creation method, choose RDS on Outposts.
7. Specify your settings for Outposts Connectivity. These settings are for the Outpost that uses the VPC that has the DB subnet group for your DB instance. Your VPC must be based on the Amazon VPC service.

   a. For Virtual Private Cloud (VPC), choose the VPC that contains the DB subnet group for your DB instance.
   b. For VPC security group, choose the Amazon VPC security group for your DB instance.
   c. For DB subnet group, choose the DB subnet group for your DB instance.

     You can choose an existing DB subnet group that's associated with the Outpost—for example, if you performed the procedure in Creating a DB subnet group (p. 1205).

     You can also create a new DB subnet group for the Outpost.

8. For Multi-AZ deployment, choose Create a standby instance (recommended for production usage) to create a standby DB instance in another Outpost.

   Note
   This option isn't available for Microsoft SQL Server.
   If you choose to create a Multi-AZ deployment, you can't store backups on your Outpost.

9. Under Backup, do the following:
   a. For Backup target, choose one of the following:
      • AWS Cloud to store automated backups and manual snapshots in the parent AWS Region.
      • Outposts (on-premises) to create local backups.

         Note
         To store backups on your Outpost, your Outpost must have Amazon S3 capability.
         For more information, see Amazon S3 on Outposts.
         Local backups aren't supported for Multi-AZ deployments or read replicas.
      
   b. Choose Enable automated backups to create point-in-time snapshots of your DB instance.

      If you turn on automated backups, then you can choose values for Backup retention period and Backup window, or leave the default values.

10. Specify other DB instance settings as needed.

    For information about each setting when creating a DB instance, see Settings for DB instances (p. 308).
11. Choose **Create database**.

   The **Databases** page appears. A banner tells you that your DB instance is being created, and displays the **View credential details** button.

**Viewing DB instance details**

After you create your DB instance, you can view credentials and other details for it.

**To view DB instance details**

1. To view the master user name and password for the DB instance, choose **View credential details** on the **Databases** page.

   You can connect to the DB instance as the master user by using these credentials.

   **Important**
   
   You can’t view the master user password again. If you don’t record it, you might have to change it. To change the master user password after the DB instance is available, modify the DB instance. For more information about modifying a DB instance, see *Modifying an Amazon RDS DB instance* (p. 401).

2. Choose the name of the new DB instance on the **Databases** page.

   On the RDS console, the details for the new DB instance appear. The DB instance has a status of **Creating** until the DB instance is created and ready for use. When the state changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and storage allocated, it can take several minutes for the new DB instance to be available.

![Database instance status](image)

   After the DB instance is available, you can manage it the same way that you manage RDS DB instances in the AWS Cloud.

**AWS CLI**

Before you create a new DB instance in an Outpost with the AWS CLI, first create a DB subnet group for use by RDS on Outposts.
To create a DB subnet group for your Outpost

- Use the `create-db-subnet-group` command. For `--subnet-ids`, specify the subnet group in the Outpost for use by RDS on Outposts.

For Linux, macOS, or Unix:

```
aws rds create-db-subnet-group
   --db-subnet-group-name myoutpostdbsubnetgr
   --db-subnet-group-description "DB subnet group for RDS on Outposts"
   --subnet-ids subnet-abc123
```

For Windows:

```
aws rds create-db-subnet-group ^
   --db-subnet-group-name myoutpostdbsubnetgr ^
   --db-subnet-group-description "DB subnet group for RDS on Outposts" ^
   --subnet-ids subnet-abc123
```

To create an RDS on Outposts DB instance using the AWS CLI

- Use the `create-db-instance` command. Specify an Availability Zone for the Outpost, an Amazon VPC security group associated with the Outpost, and the DB subnet group you created for the Outpost. You can include the following options:
  - `--db-instance-identifier`
  - `--db-instance-class`
  - `--engine` – The database engine. Use one of the following values:
    - MySQL – Specify `mysql`.
    - PostgreSQL – Specify `postgres`.
    - Microsoft SQL Server – Specify `sqlserver-ee`, `sqlserver-se`, or `sqlserver-web`.
  - `--availability-zone`
  - `--vpc-security-group-ids`
  - `--db-subnet-group-name`
  - `--allocated-storage`
  - `--max-allocated-storage`
  - `--master-username`
  - `--master-user-password`
  - `--multi-az | --no-multi-az` – (Optional) Whether to create a standby DB instance in a different Availability Zone. The default is `--no-multi-az`.
    - The `--multi-az` option isn't available for SQL Server.
  - `--backup-retention-period`
  - `--backup-target` – (Optional) Where to store automated backups and manual snapshots. Use one of the following values:
    - `outposts` – Store them locally on your Outpost.
    - `region` – Store them in the parent AWS Region. This is the default value.

    If you use the `--multi-az` option, you can't use `outposts` for `--backup-target`. In addition, the DB instance can't have read replicas if you use `outposts` for `--backup-target`.

- `--storage-encrypted`
• --kms-key-id

Example

The following example creates a MySQL DB instance named myoutpostdbinstance with backups stored on your Outpost.

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance \
--db-instance-identifier myoutpostdbinstance \
--engine-version 8.0.17 \
--db-instance-class db.m5.large \
--engine mysql \
--availability-zone us-east-1d \
--vpc-security-group-ids outpost-sg \
--db-subnet-group-name myoutpostdsubnetgr \
--allocated-storage 100 \
--max-allocated-storage 1000 \
--master-username masterawsuser \
--manage-master-user-password \
--backup-retention-period 3 \
--backup-target outposts \
--storage-encrypted \
--kms-key-id mykey
```

For Windows:

```bash
aws rds create-db-instance ^
--db-instance-identifier myoutpostdbinstance ^
--engine-version 8.0.17 ^
--db-instance-class db.m5.large ^
--engine mysql ^
--availability-zone us-east-1d ^
--vpc-security-group-ids outpost-sg ^
--db-subnet-group-name myoutpostdsubnetgr ^
--allocated-storage 100 ^
--max-allocated-storage 1000 ^
--master-username masterawsuser ^
--manage-master-user-password ^
--backup-retention-period 3 ^
--backup-target outposts ^
--storage-encrypted ^
--kms-key-id mykey
```

For information about each setting when creating a DB instance, see Settings for DB instances (p. 308).

RDS API

To create a new DB instance in an Outpost with the RDS API, first create a DB subnet group for use by RDS on Outposts by calling the CreateDBSubnetGroup operation. For SubnetIds, specify the subnet group in the Outpost for use by RDS on Outposts.

Next, call the CreateDBInstance operation with the following parameters. Specify an Availability Zone for the Outpost, an Amazon VPC security group associated with the Outpost, and the DB subnet group you created for the Outpost.

- AllocatedStorage
- AvailabilityZone
• **BackupRetentionPeriod**
• **BackupTarget**

If you are creating a Multi-AZ DB instance deployment, you can't use outposts for BackupTarget. In addition, the DB instance can't have read replicas if you use outposts for BackupTarget.

• **DBInstanceClass**
• **DBInstanceIdentifier**
• **VpcSecurityGroupIds**
• **DBSubnetGroupName**
• **Engine**
• **EngineVersion**
• **MasterUsername**
• **MasterUserPassword**
• **MaxAllocatedStorage (optional)**
• **MultiAZ (optional)**
• **StorageEncrypted**
• **KmsKeyID**

For information about each setting when creating a DB instance, see [Settings for DB instances (p. 308)](#).
Creating read replicas for Amazon RDS on AWS Outposts

Amazon RDS on AWS Outposts uses the MySQL and PostgreSQL DB engines’ built-in replication functionality to create a read replica from a source DB instance. The source DB instance becomes the primary DB instance. Updates made to the primary DB instance are asynchronously copied to the read replica. You can reduce the load on your primary DB instance by routing read queries from your applications to the read replica. Using read replicas, you can elastically scale out beyond the capacity constraints of a single DB instance for read-heavy database workloads.

When you create a read replica from an RDS on Outposts DB instance, the read replica uses a customer-owned IP address (CoIP). For more information, see Customer-owned IP addresses for Amazon RDS on AWS Outposts (p. 1200).

Read replicas on RDS on Outposts have the following limitations:

• You can't create read replicas for RDS for SQL Server on RDS on Outposts DB instances.
• Cross-Region read replicas aren't supported on RDS on Outposts.
• Cascading read replicas aren't supported on RDS on Outposts.
• The source RDS on Outposts DB instance can’t have local backups. The backup target for the source DB instance must be your AWS Region.
• Read replicas require customer-owned IP (CoIP) pools. For more information, see Customer-owned IP addresses for Amazon RDS on AWS Outposts (p. 1200).

You can create a read replica from an RDS on Outposts DB instance using the AWS Management Console, AWS CLI, or RDS API. For more information on read replicas, see Working with DB instance read replicas (p. 438).

Console

To create a read replica from a source DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB instance that you want to use as the source for a read replica.
4. For Actions, choose Create read replica.
5. For DB instance identifier, enter a name for the read replica.
6. Specify your settings for Outposts Connectivity. These settings are for the Outpost that uses the virtual private cloud (VPC) that has the DB subnet group for your DB instance. Your VPC must be based on the Amazon VPC service.
7. Choose your DB instance class. We recommend that you use the same or larger DB instance class and storage type as the source DB instance for the read replica.
8. For Multi-AZ deployment, choose Create a standby instance (recommended for production usage) to create a standby DB instance in a different Availability Zone.

Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.
9. (Optional) Under Connectivity, set values for Subnet Group and Availability Zone.

If you specify values for both Subnet Group and Availability Zone, the read replica is created on an Outpost that is associated with the Availability Zone in the DB subnet group.
If you specify a value for Subnet Group and No preference for Availability Zone, the read replica is created on a random Outpost in the DB subnet group.

10. For AWS KMS key, choose the AWS KMS key identifier of the KMS key.

   The read replica must be encrypted.

11. Choose other options as needed.

12. Choose Create read replica.

After the read replica is created, you can see it on the Databases page in the RDS console. It shows Replica in the Role column.

AWS CLI

To create a read replica from a source MySQL or PostgreSQL DB instance, use the AWS CLI command create-db-instance-read-replica.

You can control where the read replica is created by specifying the --db-subnet-group-name and --availability-zone options:

- If you specify both the --db-subnet-group-name and --availability-zone options, the read replica is created on an Outpost that is associated with the Availability Zone in the DB subnet group.
- If you specify the --db-subnet-group-name option and don't specify the --availability-zone option, the read replica is created on a random Outpost in the DB subnet group.
- If you don't specify either option, the read replica is created on the same Outpost as the source RDS on Outposts DB instance.

The following example creates a replica and specifies the location of the read replica by including --db-subnet-group-name and --availability-zone options.

Example

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance-read-replica \
    --db-instance-identifier myreadreplica \
    --source-db-instance-identifier mydbinstance \
    --db-subnet-group-name myoutpostdbsubnetgr \
    --availability-zone us-west-2a
```

For Windows:

```bash
aws rds create-db-instance-read-replica ^
    --db-instance-identifier myreadreplica ^
    --source-db-instance-identifier mydbinstance ^
    --db-subnet-group-name myoutpostdbsubnetgr ^
    --availability-zone us-west-2a
```

RDS API

To create a read replica from a source MySQL or PostgreSQL DB instance, call the Amazon RDS API CreateDBInstanceReadReplica operation with the following required parameters:

- DBInstanceIdentifier
- SourceDBInstanceIdentifier
You can control where the read replica is created by specifying the DBSubnetGroupName and AvailabilityZone parameters:

- If you specify both the DBSubnetGroupName and AvailabilityZone parameters, the read replica is created on an Outpost that is associated with the Availability Zone in the DB subnet group.
- If you specify the DBSubnetGroupName parameter and don't specify the AvailabilityZone parameter, the read replica is created on a random Outpost in the DB subnet group.
- If you don't specify either parameter, the read replica is created on the same Outpost as the source RDS on Outposts DB instance.

Considerations for restoring DB instances on Amazon RDS on AWS Outposts

When you restore a DB instance in Amazon RDS on AWS Outposts, you can generally choose the storage location for automated backups and manual snapshots of the restored DB instance.

- When restoring from a manual DB snapshot, you can store backups either in the parent AWS Region or locally on your Outpost.
- When restoring from an automated backup (point-in-time recovery), you have fewer choices:
  - If restoring from the parent AWS Region, you can store backups either in the AWS Region or on your Outpost.
  - If restoring from your Outpost, you can store backups only on your Outpost.
Using Amazon RDS Proxy

By using Amazon RDS Proxy, you can allow your applications to pool and share database connections to improve their ability to scale. RDS Proxy makes applications more resilient to database failures by automatically connecting to a standby DB instance while preserving application connections. By using RDS Proxy, you can also enforce AWS Identity and Access Management (IAM) authentication for databases, and securely store credentials in AWS Secrets Manager.

Using RDS Proxy, you can handle unpredictable surges in database traffic. Otherwise, these surges might cause issues due to oversubscribing connections or creating new connections at a fast rate. RDS Proxy establishes a database connection pool and reuses connections in this pool. This approach avoids the memory and CPU overhead of opening a new database connection each time. To protect the database against oversubscription, you can control the number of database connections that are created.

RDS Proxy queues or throttles application connections that can’t be served immediately from the pool of connections. Although latencies might increase, your application can continue to scale without abruptly failing or overwhelming the database. If connection requests exceed the limits you specify, RDS Proxy rejects application connections (that is, it sheds load). At the same time, it maintains predictable performance for the load that can be served with the available capacity.

You can reduce the overhead to process credentials and establish a secure connection for each new connection. RDS Proxy can handle some of that work on behalf of the database.

RDS Proxy is fully compatible with the engine versions that it supports. You can enable RDS Proxy for most applications with no code changes.

Topics
- Region and version availability (p. 1215)

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of Amazon RDS with RDS Proxy, see Amazon RDS Proxy (p. 155).

Quotas and limitations for RDS Proxy

The following quotas and limitations apply to RDS Proxy:
You can have up to 20 proxies for each AWS account ID. If your application requires more proxies, you can request additional proxies by opening a ticket with the AWS Support organization.

Each proxy can have up to 200 associated Secrets Manager secrets. Thus, each proxy can connect to with up to 200 different user accounts at any given time.

You can create, view, modify, and delete up to 20 endpoints for each proxy. These endpoints are in addition to the default endpoint that's automatically created for each proxy.

For RDS DB instances in replication configurations, you can associate a proxy only with the writer DB instance, not a read replica.

Your RDS Proxy must be in the same virtual private cloud (VPC) as the database. The proxy can't be publicly accessible, although the database can be. For example, if you're prototyping on a local host, you can't connect to your RDS Proxy unless you set up dedicated networking. This is the case because your local host is outside of the proxy's VPC.

You can't use RDS Proxy with a VPC that has its tenancy set to dedicated.

If you use RDS Proxy with an RDS DB instance that has IAM authentication enabled, check user authentication. Users who connect through a proxy must authenticate through sign-in credentials. For details about Secrets Manager and IAM support in RDS Proxy, see Setting up database credentials in AWS Secrets Manager (p. 1225) and Setting up AWS Identity and Access Management (IAM) policies (p. 1226).

You can't use RDS Proxy with custom DNS when using SSL hostname validation.

Each proxy can be associated with a single target DB instance. However, you can associate multiple proxies with the same DB instance.

Any statement with a text size greater than 16 KB causes the proxy to pin the session to the current connection.

For additional limitations for each DB engine, see the following sections:

- Additional limitations for RDS for MariaDB (p. 1216)
- Additional limitations for RDS for Microsoft SQL Server (p. 1217)
- Additional limitations for RDS for MySQL (p. 1217)
- Additional limitations for RDS for PostgreSQL (p. 1217)

### Additional limitations for RDS for MariaDB

The following additional limitations apply to RDS Proxy with RDS for MariaDB databases:

- Currently, all proxies listen on port 3306 for MariaDB. The proxies still connect to your database using the port that you specified in the database settings.
- You can't use RDS Proxy with self-managed MariaDB databases in Amazon EC2 instances.
- You can't use RDS Proxy with an RDS for MariaDB DB instance that has the read_only parameter in its DB parameter group set to 1.
- RDS Proxy doesn't support compressed mode. For example, it doesn't support the compression used by the --compress or -C options of the mysql command.
- Some SQL statements and functions can change the connection state without causing pinning. For the most current pinning behavior, see Avoiding pinning (p. 1244).
- RDS Proxy doesn't support the MariaDB auth_ed25519 plugin.
- RDS Proxy doesn't support Transport Layer Security (TLS) version 1.3 for MariaDB databases.
- Database connections processing a GET DIAGNOSTIC command might return inaccurate information when RDS Proxy reuses the same database connection to run another query. This can happen when RDS Proxy multiplexes database connections.
Important
For proxies associated with MariaDB databases, don't set the configuration parameter `sql_auto_is_null` to `true` or a nonzero value in the initialization query. Doing so might cause incorrect application behavior.

Additional limitations for RDS for Microsoft SQL Server

The following additional limitations apply to RDS Proxy with RDS for Microsoft SQL Server databases:

- The number of Secrets Manager secrets that you need to create for a proxy depends on the collation that your DB instance uses. For example, suppose that your DB instance uses case-sensitive collation. If your application accepts both “Admin” and “admin,” then your proxy needs two separate secrets. For more information about collation in SQL Server, see the [Microsoft SQL Server](https://docs.microsoft.com/en-us/sql-server) documentation.
- RDS Proxy doesn't support connections that use Active Directory.
- You can't use IAM authentication with clients that don't support token properties. For more information, see [Considerations for connecting to a proxy with Microsoft SQL Server](https://docs.aws.amazon.com/autoscaling/documentation/rds/proxies/mssql-proxies.html#considerations-mssql-proxies).
- The results of `@@IDENTITY`, `@@ROWCOUNT`, and `SCOPE_IDENTITY` aren't always accurate. As a workaround, retrieve their values in the same session statement to ensure that they return the correct information.
- If the connection uses multiple active result sets (MARS), RDS Proxy doesn't run the initialization queries. For information about MARS, see the [Microsoft SQL Server](https://docs.microsoft.com/en-us/sql-server) documentation.

Additional limitations for RDS for MySQL

The following additional limitations apply to RDS Proxy with RDS for MySQL databases:

- RDS Proxy doesn't support the MySQL `sha256_password` and `caching_sha2_password` authentication plugins. These plugins implement SHA-256 hashing for user account passwords.
- Currently, all proxies listen on port 3306 for MySQL. The proxies still connect to your database using the port that you specified in the database settings.
- You can't use RDS Proxy with self-managed MySQL databases in EC2 instances.
- You can't use RDS Proxy with an RDS for MySQL DB instance that has the `read_only` parameter in its DB parameter group set to `1`.
- RDS Proxy doesn't support MySQL compressed mode. For example, it doesn't support the compression used by the `--compress` or `-C` options of the `mysql` command.
- Database connections processing a `GET DIAGNOSTIC` command might return inaccurate information when RDS Proxy reuses the same database connection to run another query. This can happen when RDS Proxy multiplexes database connections.
- Some SQL statements and functions such as `SET LOCAL` can change the connection state without causing pinning. For the most current pinning behavior, see [Avoiding pinning](https://docs.aws.amazon.com/autoscaling/documentation/rds/proxies/mysql-proxies.html#avoiding-pinning).

Important
For proxies associated with MySQL databases, don't set the configuration parameter `sql_auto_is_null` to `true` or a nonzero value in the initialization query. Doing so might cause incorrect application behavior.

Additional limitations for RDS for PostgreSQL

The following additional limitations apply to RDS Proxy with RDS for PostgreSQL databases:
• RDS Proxy doesn't support session pinning filters for PostgreSQL.
• Currently, all proxies listen on port 5432 for PostgreSQL.
• For PostgreSQL, RDS Proxy doesn't currently support canceling a query from a client by issuing a CancelRequest. This is the case, for example, when you cancel a long-running query in an interactive psql session by using Ctrl+C.
• The results of the PostgreSQL function lastval aren't always accurate. As a work-around, use the INSERT statement with the RETURNING clause.
• RDS Proxy doesn't multiplex connections when your client application drivers use the PostgreSQL extended query protocol.
• RDS Proxy currently doesn't support streaming replication mode.

Important
For existing proxies with PostgreSQL databases, if you modify the database authentication to use SCRAM only, the proxy becomes unavailable for up to 60 seconds. To avoid the issue, do one of the following:

• Ensure that the database allows both SCRAM and MD5 authentication.
• To use only SCRAM authentication, create a new proxy, migrate your application traffic to the new proxy, then delete the proxy previously associated with the database.

Planning where to use RDS Proxy

You can determine which of your DB instances, clusters, and applications might benefit the most from using RDS Proxy. To do so, consider these factors:

• Any DB instance that encounters "too many connections" errors is a good candidate for associating with a proxy. This is often characterized by a high value of the ConnectionAttempts CloudWatch metric. The proxy enables applications to open many client connections, while the proxy manages a smaller number of long-lived connections to the DB instance.
• For DB instances that use smaller AWS instance classes, such as T2 or T3, using a proxy can help avoid out-of-memory conditions. It can also help reduce the CPU overhead for establishing connections. These conditions can occur when dealing with large numbers of connections.
• You can monitor certain Amazon CloudWatch metrics to determine whether a DB instance is approaching certain types of limit. These limits are for the number of connections and the memory associated with connection management. You can also monitor certain CloudWatch metrics to determine whether a DB instance is handling many short-lived connections. Opening and closing such connections can impose performance overhead on your database. For information about the metrics to monitor, see Monitoring RDS Proxy metrics with Amazon CloudWatch (p. 1255).
• AWS Lambda functions can also be good candidates for using a proxy. These functions make frequent short database connections that benefit from connection pooling offered by RDS Proxy. You can take advantage of any IAM authentication you already have for Lambda functions, instead of managing database credentials in your Lambda application code.
• Applications that typically open and close large numbers of database connections and don't have built-in connection pooling mechanisms are good candidates for using a proxy.
• Applications that keep a large number of connections open for long periods are typically good candidates for using a proxy. Applications in industries such as software as a service (SaaS) or ecommerce often minimize the latency for database requests by leaving connections open. With RDS Proxy, an application can keep more connections open than it can when connecting directly to the DB instance.
• You might not have adopted IAM authentication and Secrets Manager due to the complexity of setting up such authentication for all DB instances. If so, you can leave the existing authentication methods
in place and delegate the authentication to a proxy. The proxy can enforce the authentication policies for client connections for particular applications. You can take advantage of any IAM authentication you already have for Lambda functions, instead of managing database credentials in your Lambda application code.

- RDS Proxy can help make applications more resilient and transparent to database failures. RDS Proxy bypasses Domain Name System (DNS) caches to reduce failover times by up to 66% for Amazon RDS Multi-AZ databases. RDS Proxy also automatically routes traffic to a new database instance while preserving application connections. This makes failovers more transparent for applications.

## RDS Proxy concepts and terminology

You can simplify connection management for your Amazon RDS DB instances and Amazon Aurora DB clusters by using RDS Proxy.

RDS Proxy handles the network traffic between the client application and the database. It does so in an active way first by understanding the database protocol. It then adjusts its behavior based on the SQL operations from your application and the result sets from the database.

RDS Proxy reduces the memory and CPU overhead for connection management on your database. The database needs less memory and CPU resources when applications open many simultaneous connections. It also doesn't require logic in your applications to close and reopen connections that stay idle for a long time. Similarly, it requires less application logic to reestablish connections in case of a database problem.

The infrastructure for RDS Proxy is highly available and deployed over multiple Availability Zones (AZs). The computation, memory, and storage for RDS Proxy are independent of your RDS DB instances and Aurora DB clusters. This separation helps lower overhead on your database servers, so that they can devote their resources to serving database workloads. The RDS Proxy compute resources are serverless, automatically scaling based on your database workload.

### Topics

- Overview of RDS Proxy concepts (p. 1219)
- Connection pooling (p. 1220)
- RDS Proxy security (p. 1220)
- Failover (p. 1222)
- Transactions (p. 1222)

### Overview of RDS Proxy concepts

RDS Proxy handles the infrastructure to perform connection pooling and the other features described in the sections that follow. You see the proxies represented in the RDS console on the Proxies page.

Each proxy handles connections to a single RDS DB instance or Aurora DB cluster. The proxy automatically determines the current writer instance for RDS Multi-AZ DB instances and Aurora provisioned clusters.

The connections that a proxy keeps open and available for your database application to use make up the connection pool.

By default, RDS Proxy can reuse a connection after each transaction in your session. This transaction-level reuse is called multiplexing. When RDS Proxy temporarily removes a connection from the connection pool to reuse it, that operation is called borrowing the connection. When it's safe to do so, RDS Proxy returns that connection to the connection pool.
In some cases, RDS Proxy can't be sure that it's safe to reuse a database connection outside of the current session. In these cases, it keeps the session on the same connection until the session ends. This fallback behavior is called *pinning*.

A proxy has a default endpoint. You connect to this endpoint when you work with an RDS DB instance or Aurora DB cluster. You do so instead of connecting to the read/write endpoint that connects directly to the instance or cluster. The special-purpose endpoints for an Aurora cluster remain available for you to use. For Aurora DB clusters, you can also create additional read/write and read-only endpoints. For more information, see [Overview of proxy endpoints](p. 1249).

For example, you can still connect to the cluster endpoint for read/write connections without connection pooling. You can still connect to the reader endpoint for load-balanced read-only connections. You can still connect to the instance endpoints for diagnosis and troubleshooting of specific DB instances within an Aurora cluster. If you use other AWS services such as AWS Lambda to connect to RDS databases, change their connection settings to use the proxy endpoint. For example, you specify the proxy endpoint to allow Lambda functions to access your database while taking advantage of RDS Proxy functionality.

Each proxy contains a target group. This *target group* embodies the RDS DB instance or Aurora DB cluster that the proxy can connect to. For an Aurora cluster, by default the target group is associated with all the DB instances in that cluster. That way, the proxy can connect to whichever Aurora DB instance is promoted to be the writer instance in the cluster. The RDS DB instance associated with a proxy, or the Aurora DB cluster and its instances, are called the *targets* of that proxy. For convenience, when you create a proxy through the console, RDS Proxy also creates the corresponding target group and registers the associated targets automatically.

An *engine family* is a related set of database engines that use the same DB protocol. You choose the engine family for each proxy that you create.

**Connection pooling**

Each proxy performs connection pooling for the writer instance of its associated RDS or Aurora database. *Connection pooling* is an optimization that reduces the overhead associated with opening and closing connections and with keeping many connections open simultaneously. This overhead includes memory needed to handle each new connection. It also involves CPU overhead to close each connection and open a new one. Examples include Transport Layer Security/Secure Sockets Layer (TLS/SSL) handshaking, authentication, negotiating capabilities, and so on. Connection pooling simplifies your application logic. You don't need to write application code to minimize the number of simultaneous open connections.

Each proxy also performs connection multiplexing, also known as connection reuse. With *multiplexing*, RDS Proxy performs all the operations for a transaction using one underlying database connection. RDS then can use a different connection for the next transaction. You can open many simultaneous connections to the proxy, and the proxy keeps a smaller number of connections open to the DB instance or cluster. Doing so further minimizes the memory overhead for connections on the database server. This technique also reduces the chance of “too many connections” errors.

**RDS Proxy security**

RDS Proxy uses the existing RDS security mechanisms such as TLS/SSL and AWS Identity and Access Management (IAM). For general information about those security features, see [Security in Amazon RDS](p. 2582). Also, make sure to familiarize yourself with how RDS and Aurora work with authentication, authorization, and other areas of security.

RDS Proxy can act as an additional layer of security between client applications and the underlying database. For example, you can connect to the proxy using TLS 1.2, even if the underlying DB instance supports an older version of TLS. You can connect to the proxy using an IAM role. This is so even if the proxy connects to the database using the native user and password authentication method. By using this technique, you can enforce strong authentication requirements for database applications without a costly migration effort for the DB instances themselves.
You store the database credentials used by RDS Proxy in AWS Secrets Manager. Each database user for the RDS DB instance or Aurora DB cluster accessed by a proxy must have a corresponding secret in Secrets Manager. You can also set up IAM authentication for users of RDS Proxy. By doing so, you can enforce IAM authentication for database access even if the databases use native password authentication. We recommend using these security features instead of embedding database credentials in your application code.

**Using TLS/SSL with RDS Proxy**

You can connect to RDS Proxy using the TLS/SSL protocol.

**Note**

RDS Proxy uses certificates from the AWS Certificate Manager (ACM). If you are using RDS Proxy, you don’t need to download Amazon RDS certificates or update applications that use RDS Proxy connections.

To enforce TLS for all connections between the proxy and your database, you can specify a setting **Require Transport Layer Security** when you create or modify a proxy.

RDS Proxy can also ensure that your session uses TLS/SSL between your client and the RDS Proxy endpoint. To have RDS Proxy do so, specify the requirement on the client side. SSL session variables are not set for SSL connections to a database using RDS Proxy.

- For RDS for MySQL and Aurora MySQL, specify the requirement on the client side with the **--ssl-mode** parameter when you run the `mysql` command.
- For Amazon RDS PostgreSQL and Aurora PostgreSQL, specify `sslmode=require` as part of the `conninfo` string when you run the `psql` command.

RDS Proxy supports TLS protocol version 1.0, 1.1, and 1.2. You can connect to the proxy using a higher version of TLS than you use in the underlying database.

By default, client programs establish an encrypted connection with RDS Proxy, with further control available through the **--ssl-mode** option. From the client side, RDS Proxy supports all SSL modes.

For the client, the SSL modes are the following:

**PREFERRED**

SSL is the first choice, but it isn't required.

**DISABLED**

No SSL is allowed.

**REQUIRED**

Enforce SSL.

**VERIFY_CA**

Enforce SSL and verify the certificate authority (CA).

**VERIFY_IDENTITY**

Enforce SSL and verify the CA and CA hostname.

When using a client with **--ssl-mode VERIFY_CA** or **VERIFY_IDENTITY**, specify the **--ssl-ca** option pointing to a CA in .pem format. For the .pem file to use, download all root CA PEMs from Amazon Trust Services and place them into a single .pem file.

RDS Proxy uses wildcard certificates, which apply to a both a domain and its subdomains. If you use the `mysql` client to connect with SSL mode **VERIFY_IDENTITY**, currently you must use the MySQL 8.0-compatible `mysql` command.
Failover

Failover is a high-availability feature that replaces a database instance with another one when the original instance becomes unavailable. A failover might happen because of a problem with a database instance. It might also be part of normal maintenance procedures, such as during a database upgrade. Failover applies to RDS DB instances in a Multi-AZ configuration. Failover applies to Aurora DB clusters with one or more reader instances in addition to the writer instance.

Connecting through a proxy makes your application more resilient to database failovers. When the original DB instance becomes unavailable, RDS Proxy connects to the standby database without dropping idle application connections. Doing so helps to speed up and simplify the failover process. The result is faster failover that's less disruptive to your application than a typical reboot or database problem.

Without RDS Proxy, a failover involves a brief outage. During the outage, you can't perform write operations on that database. Any existing database connections are disrupted, and your application must reopen them. The database becomes available for new connections and write operations when a read-only DB instance is promoted in place of one that's unavailable.

During DB failovers, RDS Proxy continues to accept connections at the same IP address and automatically directs connections to the new primary DB instance. Clients connecting through RDS Proxy are not susceptible to the following:

- Domain Name System (DNS) propagation delays on failover.
- Local DNS caching.
- Connection timeouts.
- Uncertainty about which DB instance is the current writer.
- Waiting for a query response from a former writer that became unavailable without closing connections.

For applications that maintain their own connection pool, going through RDS Proxy means that most connections stay alive during failovers or other disruptions. Only connections that are in the middle of a transaction or SQL statement are canceled. RDS Proxy immediately accepts new connections. When the database writer is unavailable, RDS Proxy queues up incoming requests.

For applications that don't maintain their own connection pools, RDS Proxy offers faster connection rates and more open connections. It offloads the expensive overhead of frequent reconnects from the database. It does so by reusing database connections maintained in the RDS Proxy connection pool. This approach is particularly important for TLS connections, where setup costs are significant.

Transactions

All the statements within a single transaction always use the same underlying database connection. The connection becomes available for use by a different session when the transaction ends. Using the transaction as the unit of granularity has the following consequences:

- Connection reuse can happen after each individual statement when the RDS for MySQL or Aurora MySQL autocommit setting is turned on.
- Conversely, when the autocommit setting is turned off, the first statement you issue in a session begins a new transaction. For example, suppose that you enter a sequence of SELECT, INSERT, UPDATE, and other data manipulation language (DML) statements. In this case, connection reuse doesn't happen until you issue a COMMIT, ROLLBACK, or otherwise end the transaction.
- Entering a data definition language (DDL) statement causes the transaction to end after that statement completes.
RDS Proxy detects when a transaction ends through the network protocol used by the database client application. Transaction detection doesn't rely on keywords such as COMMIT or ROLLBACK appearing in the text of the SQL statement.

In some cases, RDS Proxy might detect a database request that makes it impractical to move your session to a different connection. In these cases, it turns off multiplexing for that connection the remainder of your session. The same rule applies if RDS Proxy can't be certain that multiplexing is practical for the session. This operation is called pinning. For ways to detect and minimize pinning, see Avoiding pinning (p. 1244).

Getting started with RDS Proxy

In the following sections, you can find how to set up RDS Proxy. You can also find how to set related security options. These control who can access each proxy and how each proxy connects to DB instances.

Topics
- Setting up network prerequisites (p. 1223)
- Setting up database credentials in AWS Secrets Manager (p. 1225)
- Setting up AWS Identity and Access Management (IAM) policies (p. 1226)
- Creating an RDS Proxy (p. 1228)
- Viewing an RDS Proxy (p. 1233)
- Connecting to a database through RDS Proxy (p. 1234)

Setting up network prerequisites

Using RDS Proxy requires you to have a common virtual private cloud (VPC) between your Aurora DB cluster or RDS DB instance and RDS Proxy. This VPC should have a minimum of two subnets that are in different Availability Zones. Your account can either own these subnets or share them with other accounts. For information about VPC sharing, see Work with shared VPCs. Your client application resources such as Amazon EC2, Lambda, or Amazon ECS can be in the same VPC as the proxy. Or they can be in a separate VPC from the proxy. If you successfully connected to any RDS DB instances or Aurora DB clusters, you already have the required network resources.

Topics
- Getting information about your subnets (p. 1223)
- Planning for IP address capacity (p. 1224)

Getting information about your subnets

The following Linux example shows AWS CLI commands that examine the VPCs and subnets owned by your AWS account. In particular, you pass subnet IDs as parameters when you create a proxy using the CLI.

```
aws ec2 describe-vpcs
aws ec2 describe-internet-gateways
aws ec2 describe-subnets --query '*'[.].[VpcId,SubnetId]' --output text | sort
```

The following example shows AWS CLI commands to determine the subnet IDs corresponding to a specific Aurora DB cluster or RDS DB instance. For an Aurora cluster, first you find the ID for one of the associated DB instances. You can extract the subnet IDs used by that DB instance. To do so, examine the nested fields within the DBSubnetGroup and Subnets attributes in the describe output for the DB instance. You specify some or all of those subnet IDs when setting up a proxy for that database server.
## Setting up network prerequisites

$ # Optional first step, only needed if you're starting from an Aurora cluster. Find the ID of any DB instance in the cluster.
$ `aws rds describe-db-clusters --db-cluster-identifier my_cluster_id --query 'DBClusterMembers[0][0][*].DBInstanceIdentifier'` --output text

my_instance_id  
instance_id_2  
instance_id_3
...

$ # From the DB instance, trace through the DBSubnetGroup and Subnets to find the subnet IDs.
$ `aws rds describe-db-instances --db-instance-identifier my_instance_id --query 'DBSubnetGroup[0][0][Subnets][0][*].SubnetIdentifier'` --output text

subnet_id_1  
subnet_id_2  
subnet_id_3
...

Or you can first find the VPC ID for the DB instance. Then you can examine the VPC to find its subnets. The following Linux example shows how.

$ # From the DB instance, find the VPC.
$ `aws rds describe-db-instances --db-instance-identifier my_instance_id --query 'DBSubnetGroup[0][0].VpcId'` --output text

my_vpc_id

$ `aws ec2 describe-subnets --filters Name=vpc-id,Values=my_vpc_id --query '[SubnetId]'` --output text

subnet_id_1  
subnet_id_2  
subnet_id_3  
subnet_id_4  
subnet_id_5  
subnet_id_6

### Planning for IP address capacity

An RDS Proxy automatically adjusts its capacity as needed based on the size and number of DB instances registered with it. Certain operations might also require additional proxy capacity. Some examples are increasing the size of a registered database or internal RDS Proxy maintenance operations. During these operations, your proxy might need more IP addresses to provision the extra capacity. These additional addresses allow your proxy to scale without affecting your workload. A lack of free IP addresses in your subnets prevents a proxy from scaling up. This can lead to higher query latencies or client connection failures. RDS notifies you through event RDS-EVENT-0243 when there aren't enough free IP addresses in your subnets. For information about this event, see [Working with RDS Proxy events](p. 1260).

Following are the recommended minimum number of IP addresses to leave free in your subnets for your proxy based on DB instance class sizes.

<table>
<thead>
<tr>
<th>DB instance class</th>
<th>Minimum free IP addresses</th>
</tr>
</thead>
<tbody>
<tr>
<td>db.*.xlarge or smaller</td>
<td>10</td>
</tr>
<tr>
<td>db.*.2xlarge</td>
<td>15</td>
</tr>
<tr>
<td>db.*.4xlarge</td>
<td>25</td>
</tr>
<tr>
<td>db.*.8xlarge</td>
<td>45</td>
</tr>
</tbody>
</table>
Amazon Relational Database Service User Guide
Setting up database credentials in Secrets Manager

<table>
<thead>
<tr>
<th>DB instance class</th>
<th>Minimum free IP addresses</th>
</tr>
</thead>
<tbody>
<tr>
<td>db.*.12xlarge</td>
<td>60</td>
</tr>
<tr>
<td>db.*.16xlarge</td>
<td>75</td>
</tr>
<tr>
<td>db.*.24xlarge</td>
<td>110</td>
</tr>
</tbody>
</table>

These numbers of recommended IP addresses are estimates for a proxy with only the default endpoint. A proxy with additional endpoints or read replicas might need more free IP addresses. For each additional endpoint, we recommend that you reserve three more IP addresses. For each read replica, we recommend that you reserve additional IP addresses as specified in the table based on that read replica's size.

**Note**
RDS Proxy never uses more than 215 IP addresses in a VPC.

**Setting up database credentials in AWS Secrets Manager**

For each proxy that you create, you first use the Secrets Manager service to store sets of user name and password credentials. You create a separate Secrets Manager secret for each database user account that the proxy connects to on the RDS DB instance or Aurora DB cluster.

In Secrets Manager, you create these secrets with values for the `username` and `password` fields. Doing so allows the proxy to connect to the corresponding database users on RDS DB instances or Aurora DB clusters that you associate with the proxy. To do this, you can use the setting **Credentials for other database, Credentials for RDS database, or Other type of secrets**. Fill in the appropriate values for the **User name** and **Password** fields, and placeholder values for any other required fields. The proxy ignores other fields such as **Host** and **Port** if they're present in the secret. Those details are automatically supplied by the proxy.

You can also choose **Other type of secrets**. In this case, you create the secret with keys named `username` and `password`.

Because the secrets used by your proxy aren't tied to a specific database server, you can reuse a secret across multiple proxies. To do so, use the same credentials across multiple database servers. For example, you might use the same credentials across a group of development and test servers.

To connect through the proxy as a specific user, make sure that the password associated with a secret matches the database password for that user. If there's a mismatch, you can update the associated secret in Secrets Manager. In this case, you can still connect to other accounts where the secret credentials and the database passwords do match.

**Note**
For RDS for SQL Server, the number of Secrets Manager secrets that you need to create for a proxy depends on the collation that your DB instance uses. For example, suppose that your DB instance uses case-sensitive collation. If your application accepts both "Admin" and "admin," then your proxy needs two separate secrets. For more information about collation in SQL Server, see the [Microsoft SQL Server](https://docs.microsoft.com/en-us/sql/database-engine/configure-and-manage-server-collation) documentation.

When you create a proxy through the AWS CLI or RDS API, you specify the Amazon Resource Names (ARNs) of the corresponding secrets. You do so for all the DB user accounts that the proxy can access. In the AWS Management Console, you choose the secrets by their descriptive names.

For instructions about creating secrets in Secrets Manager, see the [Creating a secret](https://docs.aws.amazon.com/secretsmanager/latest/userguide/create-secret.html) page in the Secrets Manager documentation. Use one of the following techniques:
• Use Secrets Manager in the console.
• To use the CLI to create a Secrets Manager secret for use with RDS Proxy, use a command such as the following.

```bash
aws secretsmanager create-secret
  --name "secret_name"
  --description "secret_description"
  --region region_name
  --secret-string '{"username":"db_user","password":"db_user_password"}'
```

For example, the following commands create Secrets Manager secrets for two database users, one named admin and the other named app-user.

```bash
aws secretsmanager create-secret
  --name admin_secret_name --description "db admin user"
  --secret-string '{"username":"admin","password":"choose_your_own_password"}"

aws secretsmanager create-secret
  --name proxy_secret_name --description "application user"
  --secret-string '{"username":"app-user","password":"choose_your_own_password"}"
```

To see the secrets owned by your AWS account, use a command such as the following.

```bash
aws secretsmanager list-secrets
```

When you create a proxy using the CLI, you pass the Amazon Resource Names (ARNs) of one or more secrets to the --auth parameter. The following Linux example shows how to prepare a report with only the name and ARN of each secret owned by your AWS account. This example uses the --output table parameter that is available in AWS CLI version 2. If you are using AWS CLI version 1, use --output text instead.

```bash
aws secretsmanager list-secrets --query '*[].[Name,ARN]' --output table
```

To verify that you stored the correct credentials and in the right format in a secret, use a command such as the following. Substitute the short name or the ARN of the secret for `your_secret_name`.

```bash
aws secretsmanager get-secret-value --secret-id your_secret_name
```

The output should include a line displaying a JSON-encoded value like the following.

```
"SecretString": "{\"username\":\"your_username\",\"password\":\"your_password\"}",
```

**Setting up AWS Identity and Access Management (IAM) policies**

After you create the secrets in Secrets Manager, you create an IAM policy that can access those secrets. For general information about using IAM with RDS and Aurora, see Identity and access management for Amazon RDS (p. 2623).

**Tip**

The following procedure applies if you use the IAM console. If you use the AWS Management Console for RDS, RDS can create the IAM policy for you automatically. In that case, you can skip the following procedure.
To create an IAM policy that accesses your Secrets Manager secrets for use with your proxy

1. Sign in to the IAM console. Follow the Create role process, as described in Creating IAM roles, choosing Creating a role to delegate permissions to an AWS service.

   Choose AWS service for the Trusted entity type. Under Use case, select RDS from Use cases for other AWS services dropdown. Select RDS - Add Role to Database.

2. For the new role, perform the Add inline policy step. Use the same general procedures as in Editing IAM policies. Paste the following JSON into the JSON text box. Substitute your own account ID. Substitute your AWS Region for us-east-2. Substitute the Amazon Resource Names (ARNs) for the secrets that you created, see Specifying KMS keys in IAM policy statements. For the kms:Decrypt action, substitute the ARN of the default AWS KMS key or your own KMS key. Which one you use depends on which one you used to encrypt the Secrets Manager secrets.

   ```json
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Sid": "VisualEditor0",
   "Effect": "Allow",
   "Action": "secretsmanager:GetSecretValue",
   "Resource": [
   "arn:aws:secretsmanager:us-east-2:account_id:secret:secret_name_1",
   "arn:aws:secretsmanager:us-east-2:account_id:secret:secret_name_2"
   ],
   },
   {
   "Sid": "VisualEditor1",
   "Effect": "Allow",
   "Action": "kms:Decrypt",
   "Condition": {
   "StringEquals": {
   "kms:ViaService": "secretsmanager.us-east-2.amazonaws.com"
   }
   },
   }
   ]
   }
   }
   }
   ```

3. Edit the trust policy for this IAM role. Paste the following JSON into the JSON text box.

   ```json
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Sid": "",
   "Effect": "Allow",
   "Principal": {
   "Service": "rds.amazonaws.com"
   },
   "Action": "sts:AssumeRole"
   }
   ]
   }
   ```

The following commands perform the same operation through the AWS CLI.

```
PREFIX=my_identifier
```
Creating an RDS Proxy

To manage connections for a specified set of DB instances, you can create a proxy. You can associate a proxy with an RDS for MariaDB, RDS for Microsoft SQL Server, RDS for MySQL, or RDS for PostgreSQL DB instance.
AWS Management Console

To create a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Proxies.
3. Choose Create proxy.
4. Choose all the settings for your proxy.

For Proxy configuration, provide information for the following:

- **Engine family.** This setting determines which database network protocol the proxy recognizes when it interprets network traffic to and from the database. For RDS for MariaDB or RDS for MySQL, choose MariaDB and MySQL. For RDS for PostgreSQL, choose PostgreSQL. For RDS for SQL Server, choose SQL Server.
- **Proxy identifier.** Specify a name of your choosing, unique within your AWS account ID and current AWS Region.
- **Idle client connection timeout.** Choose a time period that a client connection can be idle before the proxy can close it. The default is 1,800 seconds (30 minutes). A client connection is considered idle when the application doesn't submit a new request within the specified time after the previous request completed. The underlying database connection stays open and is returned to the connection pool. Thus, it's available to be reused for new client connections.

Consider lowering the idle client connection timeout if you want the proxy to proactively remove stale connections. If your workload is spiking, consider raising the idle client connection timeout to save the cost of establishing connections.

For Target group configuration, provide information for the following:

- **Database.** Choose one RDS DB instance or Aurora DB cluster to access through this proxy. The list only includes DB instances and clusters with compatible database engines, engine versions, and other settings. If the list is empty, create a new DB instance or cluster that's compatible with RDS Proxy. To do so, follow the procedure in Creating an Amazon RDS DB instance (p. 300). Then try creating the proxy again.
- **Connection pool maximum connections.** Specify a value from 1 through 100. This setting represents the percentage of the max_connections value that RDS Proxy can use for its connections. If you only intend to use one proxy with this DB instance or cluster, you can set this value to 100. For details about how RDS Proxy uses this setting, see MaxConnectionsPercent (p. 1242).
- **Session pinning filters.** (Optional) This option allows you to force RDS Proxy to not pin for certain types of detected session states. This circumvents the default safety measures for multiplexing database connections across client connections. Currently, the setting isn't supported for PostgreSQL and the only choice is EXCLUDE_VARIABLE_SETS.

Enabling this setting can cause variables of one connection to impact other connections. This can cause errors or correctness issues if your queries depend on session variable values set outside of the current transaction. Consider using this option after verifying it is safe for your applications to share database connections across client connections.

The following patterns can be considered safe:

- SET statements where there is no change to the effective session variable value, i.e., there is no change to the session variable.
- You change the session variable value and execute a statement in the same transaction.
For more information, see Avoiding pinning (p. 1244).

- **Connection borrow timeout.** In some cases, you might expect the proxy to sometimes use all available database connections. In such cases, you can specify how long the proxy waits for a database connection to become available before returning a timeout error. You can specify a period up to a maximum of five minutes. This setting only applies when the proxy has the maximum number of connections open and all connections are already in use.

- **Initialization query.** (Optional) You can specify one or more SQL statements for the proxy to run when opening each new database connection. The setting is typically used with SET statements to make sure that each connection has identical settings such as time zone and character set. For multiple statements, use semicolons as the separator. You can also include multiple variables in a single SET statement, such as SET $x=1$, $y=2$.

For Authentication, provide information for the following:

- **IAM role.** Choose an IAM role that has permission to access the Secrets Manager secrets that you chose earlier. You can also choose for the AWS Management Console to create a new IAM role for you and use that.

- **Secrets Manager secrets.** Choose at least one Secrets Manager secret that contains database user credentials for the RDS DB instance or Aurora DB cluster to access with this proxy.

- **Client authentication type.** Choose the type of authentication the proxy uses for connections from clients. Your choice applies to all Secrets Manager secrets that you associate with this proxy. If you need to specify a different client authentication type for each secret, create your proxy by using the AWS CLI or the API instead.

- **IAM authentication.** Choose whether to require, allow, or disallow IAM authentication for connections to your proxy. The allow option is only valid for proxies for RDS for SQL Server. Your choice applies to all Secrets Manager secrets that you associate with this proxy. If you need to specify a different IAM authentication for each secret, create your proxy by using the AWS CLI or the API instead.

For Connectivity, provide information for the following:

- **Require Transport Layer Security.** Choose this setting if you want the proxy to enforce TLS/SSL for all client connections. For an encrypted or unencrypted connection to a proxy, the proxy uses the same encryption setting when it makes a connection to the underlying database.

- **Subnets.** This field is prepopulated with all the subnets associated with your VPC. You can remove any subnets that you don't need for this proxy. You must leave at least two subnets.

Provide additional connectivity configuration:

- **VPC security group.** Choose an existing VPC security group. You can also choose for the AWS Management Console to create a new security group for you and use that. You must configure the Inbound rules to allow your applications to access the proxy. You must also configure the Outbound rules to allow traffic from your DB targets.

  **Note**
  This security group must allow connections from the proxy to the database. The same security group is used for ingress from your applications to the proxy, and for egress from the proxy to the database. For example, suppose that you use the same security group for your database and your proxy. In this case, make sure that you specify that resources in that security group can communicate with other resources in the same security group. When using a shared VPC, you can't use the default security group for the VPC, or one that belongs to another account. Choose a security group that belongs to your account. If one doesn't exist, create one. For more information about this limitation, see Work with shared VPCs.
(Optional) Provide advanced configuration:

- **Enable enhanced logging.** You can enable this setting to troubleshoot proxy compatibility or performance issues.

  When this setting is enabled, RDS Proxy includes detailed information about SQL statements in its logs. This information helps you to debug issues involving SQL behavior or the performance and scalability of the proxy connections. The debug information includes the text of SQL statements that you submit through the proxy. Thus, only enable this setting when needed for debugging. Also, only enable it when you have security measures in place to safeguard any sensitive information that appears in the logs.

  To minimize overhead associated with your proxy, RDS Proxy automatically turns this setting off 24 hours after you enable it. Enable it temporarily to troubleshoot a specific issue.

5. Choose **Create Proxy**.

**AWS CLI**

To create a proxy by using the AWS CLI, call the `create-db-proxy` command with the following required parameters:

- `--db-proxy-name`
- `--engine-family`
- `--role-arn`
- `--auth`
- `--vpc-subnet-ids`

The `--engine-family` value is case-sensitive.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-proxy
   --db-proxy-name proxy_name
   --engine-family { MYSQL | POSTGRESQL | SQLSERVER }
   --auth ProxyAuthenticationConfig_JSON_string
   --role-arn iam_role
   --vpc-subnet-ids space_separated_list
   [--vpc-security-group-ids space_separated_list]
   [--require-tls | --no-require-tls]
   [--idle-client-timeout value]
   [--debug-logging | --no-debug-logging]
   [--tags comma_separated_list]
```

For Windows:

```bash
aws rds create-db-proxy
   --db-proxy-name proxy_name
   --engine-family { MYSQL | POSTGRESQL | SQLSERVER }
   --auth ProxyAuthenticationConfig_JSON_string
   --role-arn iam_role
   --vpc-subnet-ids space_separated_list
   [--vpc-security-group-ids space_separated_list]
```

1231
The following is an example of the JSON value for the --auth option. This example applies a different client authentication type to each secret.

```json
[
    {
        "Description": "proxy description 1",
        "AuthScheme": "SECRETS",
        "IAMAuth": "DISABLED",
        "ClientPasswordAuthType": "POSTGRES_SCRAM_SHA_256"
    },
    {
        "Description": "proxy description 2",
        "AuthScheme": "SECRETS",
        "IAMAuth": "DISABLED",
        "ClientPasswordAuthType": "POSTGRES_MD5"
    },
    {
        "Description": "proxy description 3",
        "AuthScheme": "SECRETS",
        "IAMAuth": "REQUIRED"
    }
]
```

**Tip**

If you don't already know the subnet IDs to use for the --vpc-subnet-ids parameter, see Setting up network prerequisites (p. 1223) for examples of how to find them.

**Note**

The security group must allow access to the database the proxy connects to. The same security group is used for ingress from your applications to the proxy, and for egress from the proxy to the database. For example, suppose that you use the same security group for your database and your proxy. In this case, make sure that you specify that resources in that security group can communicate with other resources in the same security group.

When using a shared VPC, you can't use the default security group for the VPC, or one that belongs to another account. Choose a security group that belongs to your account. If one doesn't exist, create one. For more information about this limitation, see Work with shared VPCs.

To create the required information and associations for the proxy, you also use the register-db-proxy-targets command. Specify the target group name default. RDS Proxy automatically creates a target group with this name when you create each proxy.

```bash
aws rds register-db-proxy-targets
  --db-proxy-name value
  [--target-group-name target_group_name]
  [--db-instance-identifiers space_separated_list] # rds db instances, or
  [--db-cluster-identifiers cluster_id] # rds db cluster (all instances)
```

1232
RDS API

To create an RDS proxy, call the Amazon RDS API operation CreateDBProxy. You pass a parameter with the AuthConfig data structure.

RDS Proxy automatically creates a target group named default when you create each proxy. You associate an RDS DB instance or Aurora DB cluster with the target group by calling the function RegisterDBProxyTargets.

Viewing an RDS Proxy

After you create one or more RDS proxies, you can view them all. Doing so makes it possible to examine their configuration details and choose which ones to modify, delete, and so on.

Any database applications that use the proxy require the proxy endpoint to use in the connection string.

AWS Management Console

To view your proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you created the RDS Proxy.
3. In the navigation pane, choose Proxies.
4. Choose the name of an RDS proxy to display its details.
5. On the details page, the Target groups section shows how the proxy is associated with a specific RDS DB instance or Aurora DB cluster. You can follow the link to the default target group page to see more details about the association between the proxy and the database. This page is where you see settings that you specified when creating the proxy. These include maximum connection percentage, connection borrow timeout, engine family, and session pinning filters.

CLI

To view your proxy using the CLI, use the describe-db-proxies command. By default, it displays all proxies owned by your AWS account. To see details for a single proxy, specify its name with the --db-proxy-name parameter.

```
aws rds describe-db-proxies [--db-proxy-name proxy_name]
```

To view the other information associated with the proxy, use the following commands.

```
aws rds describe-db-proxy-target-groups --db-proxy-name proxy_name
aws rds describe-db-proxy-targets --db-proxy-name proxy_name
```

Use the following sequence of commands to see more detail about the things that are associated with the proxy:

1. To get a list of proxies, run describe-db-proxies.
2. To show connection parameters such as the maximum percentage of connections that the proxy can use, run describe-db-proxy-target-groups --db-proxy-name. Use the name of the proxy as the parameter value.
3. To see the details of the RDS DB instance or Aurora DB cluster associated with the returned target group, run `describe-db-proxy-targets`.

**RDS API**

To view your proxies using the RDS API, use the `DescribeDBProxies` operation. It returns values of the `DBProxy` data type.

To see details of the connection settings for the proxy, use the `DescribeDBProxyTargetGroups` operation. It returns values of the `DBProxyTargetGroup` data type.

To see the RDS instance or Aurora DB cluster associated with the proxy, use the `DescribeDBProxyTargets` operation. It returns values of the `DBProxyTarget` data type.

**Connecting to a database through RDS Proxy**

You connect to an RDS DB instance through a proxy in generally the same way as you connect directly to the database. The main difference is that you specify the proxy endpoint instead of the instance endpoint. For more information, see [Overview of proxy endpoints](p. 1249).

**Topics**

- Connecting to a proxy using native authentication (p. 1234)
- Connecting to a proxy using IAM authentication (p. 1235)
- Considerations for connecting to a proxy with Microsoft SQL Server (p. 1235)
- Considerations for connecting to a proxy with PostgreSQL (p. 1236)

**Connecting to a proxy using native authentication**

Use the following basic steps to connect to a proxy using native authentication:

1. Find the proxy endpoint. In the AWS Management Console, you can find the endpoint on the details page for the corresponding proxy. With the AWS CLI, you can use the `describe-db-proxies` command. The following example shows how.

```bash
# Add --output text to get output as a simple tab-separated list.
$ aws rds describe-db-proxies --query '[*].{DBProxyName:DBProxyName,Endpoint:Endpoint}'
[
  {
    "Endpoint": "the-proxy.proxy-demo.us-east-1.rds.amazonaws.com",
    "DBProxyName": "the-proxy"
  },
  {
    "Endpoint": "the-proxy-other-secret.proxy-demo.us-east-1.rds.amazonaws.com",
    "DBProxyName": "the-proxy-other-secret"
  },
  {
    "Endpoint": "the-proxy-rds-secret.proxy-demo.us-east-1.rds.amazonaws.com",
    "DBProxyName": "the-proxy-rds-secret"
  },
  {
    "Endpoint": "the-proxy-t3.proxy-demo.us-east-1.rds.amazonaws.com",
    "DBProxyName": "the-proxy-t3"
  }
]
```
2. Specify that endpoint as the host parameter in the connection string for your client application. For example, specify the proxy endpoint as the value for the `mysql -h` option or `psql -h` option.
3. Supply the same database user name and password as you usually do.

Connecting to a proxy using IAM authentication

When you use IAM authentication with RDS Proxy, set up your database users to authenticate with regular user names and passwords. The IAM authentication applies to RDS Proxy retrieving the user name and password credentials from Secrets Manager. The connection from RDS Proxy to the underlying database doesn't go through IAM.

To connect to RDS Proxy using IAM authentication, use the same general connection procedure as for IAM authentication with an RDS DB instance or Aurora cluster. For general information about using IAM with RDS and Aurora, see Security in Amazon RDS (p. 2582).

The major differences in IAM usage for RDS Proxy include the following:

- You don’t configure each individual database user with an authorization plugin. The database users still have regular user names and passwords within the database. You set up Secrets Manager secrets containing these user names and passwords, and authorize RDS Proxy to retrieve the credentials from Secrets Manager.

  The IAM authentication applies to the connection between your client program and the proxy. The proxy then authenticates to the database using the user name and password credentials retrieved from Secrets Manager.

- Instead of the instance, cluster, or reader endpoint, you specify the proxy endpoint. For details about the proxy endpoint, see Connecting to your DB instance using IAM authentication (p. 2667).

- In the direct database IAM authentication case, you selectively choose database users and configure them to be identified with a special authentication plugin. You can then connect to those users using IAM authentication.

  In the proxy use case, you provide the proxy with Secrets that contain some user's user name and password (native authentication). You then connect to the proxy using IAM authentication. Here, you do this by generating an authentication token with the proxy endpoint, not the database endpoint. You also use a user name that matches one of the user names for the secrets that you provided.

- Make sure that you use Transport Layer Security (TLS)/Secure Sockets Layer (SSL) when connecting to a proxy using IAM authentication.

You can grant a specific user access to the proxy by modifying the IAM policy. An example follows.

```
```

Considerations for connecting to a proxy with Microsoft SQL Server

For connecting to a proxy using IAM authentication, you don't use the password field. Instead, you provide the appropriate token property for each type of database driver in the token field. For example, use the `accessToken` property for JDBC, or the `sql_copt_ss_access_token` property for ODBC. Or use the `AccessToken` property for the .NET SqlClient driver. You can't use IAM authentication with clients that don't support token properties.

Under some conditions, a proxy can't share a database connection and instead pins the connection from your client application to the proxy to a dedicated database connection. For more information about these conditions, see Avoiding pinning (p. 1244).
Considerations for connecting to a proxy with PostgreSQL

For PostgreSQL, when a client starts a connection to a PostgreSQL database, it sends a startup message. This message includes pairs of parameter name and value strings. For details, see the StartupMessage in PostgreSQL message formats in the PostgreSQL documentation.

When connecting through an RDS proxy, the startup message can include the following currently recognized parameters:

- user
- database
- replication

The startup message can also include the following additional runtime parameters:

- application_name
- client_encoding
- DateStyle
- TimeZone
- extra_float_digits

For more information about PostgreSQL messaging, see the Frontend/Backend protocol in the PostgreSQL documentation.

For PostgreSQL, if you use JDBC we recommend the following to avoid pinning:

- Set the JDBC connection parameter assumeMinServerVersion to at least 9.0 to avoid pinning. Doing this prevents the JDBC driver from performing an extra round trip during connection startup when it runs SET extra_float_digits = 3.
- Set the JDBC connection parameter ApplicationName to any/your-application-name to avoid pinning. Doing this prevents the JDBC driver from performing an extra round trip during connection startup when it runs SET application_name = "PostgreSQL JDBC Driver". Note the JDBC parameter is ApplicationName but the PostgreSQL StartupMessage parameter is application_name.
- Set the JDBC connection parameter preferQueryMode to extendedForPrepared to avoid pinning. The extendedForPrepared ensures that the extended mode is used only for prepared statements.

The default for the preferQueryMode parameter is extended, which uses the extended mode for all queries. The extended mode uses a series of Prepare, Bind, Execute, and Sync requests and corresponding responses. This type of series causes connection pinning in an RDS proxy.

For more information, see Avoiding pinning (p. 1244). For more information about connecting using JDBC, see Connecting to the database in the PostgreSQL documentation.

Managing an RDS Proxy

Following, you can find an explanation of how to manage RDS Proxy operation and configuration. These procedures help your application make the most efficient use of database connections and achieve maximum connection reuse. The more that you can take advantage of connection reuse, the more CPU and memory overhead that you can save. This in turn reduces latency for your application and enables the database to devote more of its resources to processing application requests.
Modifying an RDS Proxy

You can change specific settings associated with a proxy after you create the proxy. You do so by modifying the proxy itself, its associated target group, or both. Each proxy has an associated target group.

AWS Management Console

Important

The values in the **Client authentication type** and **IAM authentication** fields apply to all Secrets Manager secrets that are associated with this proxy. To specify different values for each secret, modify your proxy by using the AWS CLI or the API instead.

To modify the settings for a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Proxies**.
3. In the list of proxies, choose the proxy whose settings you want to modify or go to its details page.
4. For **Actions**, choose **Modify**.
5. Enter or choose the properties to modify. You can modify the following:
   - **Proxy identifier** – Rename the proxy by entering a new identifier.
   - **Idle client connection timeout** – Enter a time period for the idle client connection timeout.
   - **IAM role** – Change the IAM role used to retrieve the secrets from Secrets Manager.
   - **Secrets Manager secrets** – Add or remove Secrets Manager secrets. These secrets correspond to database user names and passwords.
   - **Client authentication type** – (PostgreSQL only) Change the type of authentication for client connections to the proxy.
   - **IAM authentication** – Require or disallow IAM authentication for connections to the proxy.
   - **Require Transport Layer Security** – Turn the requirement for Transport layer Security (TLS) on or off.
   - **VPC security group** – Add or remove VPC security groups for the proxy to use.
   - **Enable enhanced logging** – Enable or disable enhanced logging.
6. Choose **Modify**.

If you didn't find the settings listed that you want to change, use the following procedure to update the target group for the proxy. The **target group** associated with a proxy controls the settings related to the physical database connections. Each proxy has one associated target group named **default**, which is created automatically along with the proxy.

You can only modify the target group from the proxy details page, not from the list on the **Proxies** page.
To modify the settings for a proxy target group

1. On the Proxies page, go to the details page for a proxy.
2. For Target groups, choose the default link. Currently, all proxies have a single target group named default.
3. On the details page for the default target group, choose Modify.
4. Choose new settings for the properties that you can modify:

   - **Database** – Choose a different RDS DB instance or Aurora cluster.
   - **Connection pool maximum connections** – Adjust what percentage of the maximum available connections the proxy can use.
   - **Session pinning filters** – (Optional) Choose a session pinning filter. Doing this can help reduce performance issues due to insufficient transaction-level reuse for connections. Using this setting requires understanding of application behavior and the circumstances under which RDS Proxy pins a session to a database connection. Currently, the setting isn't supported for PostgreSQL and the only choice is EXCLUDE_VARIABLE_SETS.
   - **Connection borrow timeout** – Adjust the connection borrow timeout interval. This setting applies when the maximum number of connections is already being used for the proxy. The setting determines how long the proxy waits for a connection to become available before returning a timeout error.
   - **Initialization query** – (Optional) Add an initialization query, or modify the current one. You can specify one or more SQL statements for the proxy to run when opening each new database connection. The setting is typically used with SET statements to make sure that each connection has identical settings such as time zone and character set. For multiple statements, use semicolons as the separator. You can also include multiple variables in a single SET statement, such as SET x=1, y=2. Initialization query is not currently supported for PostgreSQL.

You can't change certain properties, such as the target group identifier and the database engine.

5. Choose Modify target group.

AWS CLI

To modify a proxy using the AWS CLI, use the commands modify-db-proxy, modify-db-proxy-target-group, deregister-db-proxy-targets, and register-db-proxy-targets.

With the modify-db-proxy command, you can change properties such as the following:

- The set of Secrets Manager secrets used by the proxy.
- Whether TLS is required.
- The idle client timeout.
- Whether to log additional information from SQL statements for debugging.
- The IAM role used to retrieve Secrets Manager secrets.
- The security groups used by the proxy.

The following example shows how to rename an existing proxy.

```
aws rds modify-db-proxy --db-proxy-name the-proxy --new-db-proxy-name the_new_name
```

To modify connection-related settings or rename the target group, use the modify-db-proxy-target-group command. Currently, all proxies have a single target group named default. When working with this target group, you specify the name of the proxy and default for the name of the target group.
The following example shows how to first check the MaxIdleConnectionsPercent setting for a proxy and then change it, using the target group.

```bash
aws rds describe-db-proxy-target-groups --db-proxy-name the-proxy
{
  "TargetGroups": [
    {
      "Status": "available",
      "UpdatedDate": "2019-11-30T16:49:30.342Z",
      "ConnectionPoolConfig": {
        "MaxIdleConnectionsPercent": 50,
        "ConnectionBorrowTimeout": 120,
        "MaxConnectionsPercent": 100,
        "SessionPinningFilters": []
      },
      "TargetGroupName": "default",
      "CreatedDate": "2019-11-30T16:49:27.940Z",
      "DBProxyName": "the-proxy",
      "IsDefault": true
    }
  ]
}
aws rds modify-db-proxy-target-group --db-proxy-name the-proxy --target-group-name default --connection-pool-config '{ "MaxIdleConnectionsPercent": 75 }'
{
  "DBProxyTargetGroup": {
    "Status": "available",
    "UpdatedDate": "2019-12-02T04:09:50.420Z",
    "ConnectionPoolConfig": {
      "MaxIdleConnectionsPercent": 75,
      "ConnectionBorrowTimeout": 120,
      "MaxConnectionsPercent": 100,
      "SessionPinningFilters": []
    },
    "TargetGroupName": "default",
    "CreatedDate": "2019-11-30T16:49:27.940Z",
    "DBProxyName": "the-proxy",
    "IsDefault": true
  }
}
```

With the deregister-db-proxy-targets and register-db-proxy-targets commands, you change which RDS DB instance or Aurora DB cluster the proxy is associated with through its target group. Currently, each proxy can connect to one RDS DB instance or Aurora DB cluster. The target group tracks the connection details for all the RDS DB instances in a Multi-AZ configuration. Or the target group tracks the connection details for all the DB instances in an Aurora cluster.

The following example starts with a proxy that is associated with an Aurora MySQL cluster named cluster-56-2020-02-25-1399. The example shows how to change the proxy so that it can connect to a different cluster named provisioned-cluster.

When you work with an RDS DB instance, you specify the --db-instance-identifier option. When you work with an Aurora DB cluster, you specify the --db-cluster-identifier option instead.

The following example modifies an Aurora MySQL proxy. An Aurora PostgreSQL proxy has port 5432.

```bash
aws rds describe-db-proxy-targets --db-proxy-name the-proxy
```
```json
{
  "Targets": [
    {
      "Endpoint": "instance-9814.demo.us-east-1.rds.amazonaws.com",
      "Type": "RDS_INSTANCE",
      "Port": 3306,
      "RdsResourceId": "instance-9814"
    },
    {
      "Endpoint": "instance-8898.demo.us-east-1.rds.amazonaws.com",
      "Type": "RDS_INSTANCE",
      "Port": 3306,
      "RdsResourceId": "instance-8898"
    },
    {
      "Endpoint": "instance-1018.demo.us-east-1.rds.amazonaws.com",
      "Type": "RDS_INSTANCE",
      "Port": 3306,
      "RdsResourceId": "instance-1018"
    },
    {
      "Type": "TRACKED_CLUSTER",
      "Port": 0,
      "RdsResourceId": "cluster-56-2020-02-25-1399"
    },
    {
      "Endpoint": "instance-4330.demo.us-east-1.rds.amazonaws.com",
      "Type": "RDS_INSTANCE",
      "Port": 3306,
      "RdsResourceId": "instance-4330"
    }
  ]
}
```

```bash
aws rds deregister-db-proxy-targets --db-proxy-name the-proxy --db-cluster-identifier cluster-56-2020-02-25-1399

aws rds describe-db-proxy-targets --db-proxy-name the-proxy

[ "Targets": [] ]
```

```bash
aws rds register-db-proxy-targets --db-proxy-name the-proxy --db-cluster-identifier provisioned-cluster

[ "DBProxyTargets": [
  {
    "Type": "TRACKED_CLUSTER",
    "Port": 0,
    "RdsResourceId": "provisioned-cluster"
  },
  {
    "Endpoint": "gkldje.demo.us-east-1.rds.amazonaws.com",
    "Type": "RDS_INSTANCE",
    "Port": 3306,
    "RdsResourceId": "gkldje"
  },
  {
    "Endpoint": "provisioned-1.demo.us-east-1.rds.amazonaws.com",
    "Type": "RDS_INSTANCE",
    "Port": 3306,
    "RdsResourceId": "provisioned-1"
  }
]
```
To modify a proxy using the RDS API, you use the operations `ModifyDBProxy`, `ModifyDBProxyTargetGroup`, `DeregisterDBProxyTargets`, and `RegisterDBProxyTargets` operations.

With `ModifyDBProxy`, you can change properties such as the following:

- The set of Secrets Manager secrets used by the proxy.
- Whether TLS is required.
- The idle client timeout.
- Whether to log additional information from SQL statements for debugging.
- The IAM role used to retrieve Secrets Manager secrets.
- The security groups used by the proxy.

With `ModifyDBProxyTargetGroup`, you can modify connection-related settings or rename the target group. Currently, all proxies have a single target group named default. When working with this target group, you specify the name of the proxy and default for the name of the target group.

With `DeregisterDBProxyTargets` and `RegisterDBProxyTargets`, you change which RDS DB instance or Aurora DB cluster the proxy is associated with through its target group. Currently, each proxy can connect to one RDS DB instance or Aurora DB cluster. The target group tracks the connection details for all the RDS DB instances in a Multi-AZ configuration, or all the DB instances in an Aurora cluster.

### Adding a new database user

In some cases, you might add a new database user to an RDS DB instance or Aurora cluster that's associated with a proxy. If so, add or repurpose a Secrets Manager secret to store the credentials for that user. To do this, choose one of the following options:

1. Create a new Secrets Manager secret, using the procedure described in Setting up database credentials in AWS Secrets Manager (p. 1225).
2. Update the IAM role to give RDS Proxy access to the new Secrets Manager secret. To do so, update the resources section of the IAM role policy.
3. Modify the RDS Proxy to add the new Secrets Manager secret under Secrets Manager secrets.
4. If the new user takes the place of an existing one, update the credentials stored in the proxy's Secrets Manager secret for the existing user.

If you have you have the run the following command for your PostgreSQL databases:

```bash
REVOKE CONNECT ON DATABASE postgres FROM PUBLIC;
```

Grant the `rdsproxyadmin` user the CONNECT privilege so the user can monitor connections on the target database.

```bash
GRANT CONNECT ON DATABASE postgres TO rdsproxyadmin;
```

You can also allow other target database users to perform health checks by changing `rdsproxyadmin` to the database user in the command above.
Changing the password for a database user

In some cases, you might change the password for a database user in an RDS DB instance or Aurora cluster that's associated with a proxy. If so, update the corresponding Secrets Manager secret with the new password.

Configuring connection settings

To adjust RDS Proxy's connection pooling, you can modify the following settings:

- **IdleClientTimeout** (p. 1242)
- **MaxConnectionsPercent** (p. 1242)
- **MaxIdleConnectionsPercent** (p. 1243)
- **ConnectionBorrowTimeout** (p. 1243)

**IdleClientTimeout**

You can specify how long a client connection can be idle before the proxy can close it. The default is 1,800 seconds (30 minutes).

A client connection is considered *idle* when the application doesn't submit a new request within the specified time after the previous request completed. The underlying database connection stays open and is returned to the connection pool. Thus, it's available to be reused for new client connections. If you want the proxy to proactively remove stale connections, consider lowering the idle client connection timeout. If your workload establishes frequent connections with the proxy, consider raising the idle client connection timeout to save the cost of establishing connections.

This setting is represented by the *idle client connection timeout* field in the RDS console and the `IdleClientTimeout` setting in the AWS CLI and the API. To learn how to change the value of the *idle client connection timeout* field in the RDS console, see [AWS Management Console](p. 1237). To learn how to change the value of the `IdleClientTimeout` setting, see the CLI command `modify-db-proxy` or the API operation `ModifyDBProxy`.

**MaxConnectionsPercent**

You can limit the number of connections that an RDS Proxy can establish with the target database. You specify the limit as a percentage of the maximum connections available for your database. This setting is represented by the *Connection pool maximum connections* field in the RDS console and the `MaxConnectionsPercent` setting in the AWS CLI and the API.

The `MaxConnectionsPercent` value is expressed as a percentage of the `max_connections` setting for the RDS DB instance used by the target group. The proxy doesn't create all of these connections in advance. This setting reserves the right for the proxy to establish these connections as the workload needs them.

For example, for a registered database target with `max_connections` set to 1000, and `MaxConnectionsPercent` set to 95, RDS Proxy sets 950 connections as the upper limit for concurrent connections to that database target.

A common side-effect of your workload reaching the maximum number of allowed database connections is an increase in overall query latency, along with an increase in the `DatabaseConnectionsBorrowLatency` metric. You can monitor currently used and total allowed database connections by comparing the `DatabaseConnections` and `MaxDatabaseConnectionsAllowed` metrics.

When setting this parameter, note the following best practices:
- Allow sufficient connection headroom for changes in workload pattern. It is recommended to set the parameter at least 30% above your maximum recent monitored usage. As RDS Proxy redistributes database connection quotas across multiple nodes, internal capacity changes might require at least 30% headroom for additional connections to avoid increased borrow latencies.

- RDS Proxy reserves a certain number of connections for active monitoring to support fast failover, traffic routing and internal operations. The MaxDatabaseConnectionsAllowed metric does not include these reserved connections. It represents the number of connections available to serve the workload, and can be lower than the value derived from the MaxConnectionsPercent setting.

  Minimal recommended MaxConnectionsPercent values
  - db.t3.small: 30
  - db.t3.medium or above: 20

To learn how to change the value of the Connection pool maximum connections field in the RDS console, see AWS Management Console (p. 1237). To learn how to change the value of the MaxConnectionsPercent setting, see the CLI command modify-db-proxy-target-group or the API operation ModifyDBProxyTargetGroup.

For information on database connection limits, see Maximum number of database connections.

**MaxIdleConnectionsPercent**

You can control the number of idle database connections that RDS Proxy can keep in the connection pool. RDS Proxy considers a database connection in its pool to be *idle* when there's been no activity on the connection for five minutes.

You specify the limit as a percentage of the maximum connections available for your database. The default value is 50 percent of MaxConnectionsPercent, and the upper limit is the value of MaxConnectionsPercent. With a high value, the proxy leaves a high percentage of idle database connections open. With a low value, the proxy closes a high percentage of idle database connections. If your workloads are unpredictable, consider setting a high value for MaxIdleConnectionsPercent. Doing so means that RDS Proxy can accommodate surges in activity without opening a lot of new database connections.

This setting is represented by the MaxIdleConnectionsPercent setting of DBProxyTargetGroup in the AWS CLI and the API. To learn how to change the value of the MaxIdleConnectionsPercent setting, see the CLI command modify-db-proxy-target-group or the API operation ModifyDBProxyTargetGroup.

**Note**

RDS Proxy closes database connections some time after 24 hours when they are no longer in use. The proxy performs this action regardless of the value of the maximum idle connections setting.

For information on database connection limits, see Maximum number of database connections.

**ConnectionBorrowTimeout**

You can choose how long RDS Proxy waits for a database connection in the connection pool to become available for use before returning a timeout error. The default is 120 seconds. This setting applies when the number of connections is at the maximum, and so no connections are available in the connection pool. It also applies if no appropriate database instance is available to handle the request because, for example, a failover operation is in process. Using this setting, you can set the best wait period for your application without having to change the query timeout in your application code.

This setting is represented by the Connection borrow timeout field in the RDS console or the ConnectionBorrowTimeout setting of DBProxyTargetGroup in the AWS CLI or API. To learn how to change the value of the Connection borrow timeout field in the RDS console, see AWS Management Console.
Avoiding pinning

Multiplexing is more efficient when database requests don't rely on state information from previous requests. In that case, RDS Proxy can reuse a connection at the conclusion of each transaction. Examples of such state information include most variables and configuration parameters that you can change through SET or SELECT statements. SQL transactions on a client connection can multiplex between underlying database connections by default.

Your connections to the proxy can enter a state known as pinning. When a connection is pinned, each later transaction uses the same underlying database connection until the session ends. Other client connections also can't reuse that database connection until the session ends. The session ends when the client connection is dropped.

RDS Proxy automatically pins a client connection to a specific DB connection when it detects a session state change that isn't appropriate for other sessions. Pinning reduces the effectiveness of connection reuse. If all or almost all of your connections experience pinning, consider modifying your application code or workload to reduce the conditions that cause the pinning.

For example, suppose that your application changes a session variable or configuration parameter. In this case, later statements can rely on the new variable or parameter to be in effect. Thus, when RDS Proxy processes requests to change session variables or configuration settings, it pins that session to the DB connection. That way, the session state remains in effect for all later transactions in the same session.

For some database engines, this rule doesn't apply to all parameters that you can set. RDS Proxy tracks certain statements and variables. Thus RDS Proxy doesn't pin the session when you modify them. In this case, RDS Proxy only reuses the connection for other sessions that have the same values for those settings. For details about what RDS Proxy tracks for a database engine, see the following:

- What RDS Proxy tracks for RDS for SQL Server databases (p. 1244)
- What RDS Proxy tracks for RDS for MariaDB and RDS for MySQL databases (p. 1245)

What RDS Proxy tracks for RDS for SQL Server databases

Following are the SQL Server statements that RDS Proxy tracks:

- USE
- SET ANSI_NULLS
- SET ANSI_PADDING
- SET ANSI_WARNINGS
- SET ARITHABORT
- SET CONCAT_NULL_YIELDS_NULL
- SET CURSOR_CLOSE_ON_COMMIT
- SET DATEFIRST
- SET DATEFORMAT
- SET LANGUAGE
- SET LOCK_TIMEOUT
- SET NUMERIC_ROUNDABORT
- SET QUOTED_IDENTIFIER
- SET TEXTSIZE
- SET TRANSACTION ISOLATION LEVEL
What RDS Proxy tracks for RDS for MariaDB and RDS for MySQL databases

Following are the MySQL and MariaDB statements that RDS Proxy tracks:

- DROP DATABASE
- DROP SCHEMA
- USE

Following are the MySQL and MariaDB variables that RDS Proxy tracks:

- AUTOCOMMIT
- AUTO_INCREMENT_INCREMENT
- CHARACTER SET (or CHAR SET)
- CHARACTER_SET_CLIENT
- CHARACTER_SET_DATABASE
- CHARACTER_SET_FILES
- CHARACTER_SET_FILESYSTEM
- CHARACTER_SET_CONNECTION
- CHARACTER_SET_RESULTS
- CHARACTER_SET_SERVER
- COLLATION_CONNECTION
- COLLATION_DATABASE
- COLLATION_FILES
- COLLATION_SERVER
- INTERACTIVE_TIMEOUT
- NAMES
- NET_WRITE_TIMEOUT
- QUERY_CACHE_TYPE
- SESSION_TRACK_SCHEMA
- SQL_MODE
- TIME_ZONE
- TRANSACTION_ISOLATION (or TX_ISOLATION)
- TRANSACTION_READ_ONLY (or TX_READ_ONLY)
- WAIT_TIMEOUT

Minimizing pinning

Performance tuning for RDS Proxy involves trying to maximize transaction-level connection reuse (multiplexing) by minimizing pinning.

In some cases, RDS Proxy can't be sure that it's safe to reuse a database connection outside of the current session. In these cases, it keeps the session on the same connection until the session ends. This fallback behavior is called pinning.

You can minimize pinning by doing the following:

- Avoid unnecessary database requests that might cause pinning.
- Set variables and configuration settings consistently across all connections. That way, later sessions are more likely to reuse connections that have those particular settings.
However, for PostgreSQL setting a variable leads to session pinning.

- For a MySQL engine family database, apply a session pinning filter to the proxy. You can exempt certain kinds of operations from pinning the session if you know that doing so doesn’t affect the correct operation of your application.
- See how frequently pinning occurs by monitoring the Amazon CloudWatch metric `DatabaseConnectionsCurrentlySessionPinned`. For information about this and other CloudWatch metrics, see Monitoring RDS Proxy metrics with Amazon CloudWatch (p. 1255).
- If you use `SET` statements to perform identical initialization for each client connection, you can do so while preserving transaction-level multiplexing. In this case, you move the statements that set up the initial session state into the initialization query used by a proxy. This property is a string containing one or more SQL statements, separated by semicolons.

For example, you can define an initialization query for a proxy that sets certain configuration parameters. Then, RDS Proxy applies those settings whenever it sets up a new connection for that proxy. You can remove the corresponding `SET` statements from your application code, so that they don’t interfere with transaction-level multiplexing.

For metrics about how often pinning occurs for a proxy, see Monitoring RDS Proxy metrics with Amazon CloudWatch (p. 1255).

**Conditions that cause pinning for all engine families**

The proxy pins the session to the current connection in the following situations where multiplexing might cause unexpected behavior:

- Any statement with a text size greater than 16 KB causes the proxy to pin the session.
- Prepared statements cause the proxy to pin the session. This rule applies whether the prepared statement uses SQL text or the binary protocol.

**Conditions that cause pinning for RDS for Microsoft SQL Server**

For RDS for SQL Server, the following interactions also cause pinning:

- Using multiple active result sets (MARS). For information about MARS, see the SQL Server documentation.
- Using distributed transaction coordinator (DTC) communication.
- Creating temporary tables, transactions, cursors, or prepared statements.
- Using the following `SET` statements:
  - `SET ANSI_DEFAULTS`
  - `SET ANSI_NULL_DFLT`
  - `SET ARITHIGNORE`
  - `SET DEADLOCK_PRIORITY`
  - `SET FIPS_FLAGGER`
  - `SET FMTONLY`
  - `SET FORCEPLAN`
  - `SET IDENTITY_INSERT`
  - `SET NOCOUNT`
  - `SET NOEXEC`
  - `SET OFFSETS`
  - `SET PARSEONLY`
Conditions that cause pinning for RDS for MariaDB and RDS for MySQL

For MySQL and MariaDB, the following interactions also cause pinning:

- Explicit table lock statements LOCK TABLE, LOCK TABLES, or FLUSH TABLES WITH READ LOCK cause the proxy to pin the session.
- Creating named locks by using GET_LOCK causes the proxy to pin the session.
- Setting a user variable or a system variable (with some exceptions) causes the proxy to pin the session. If this situation reduces your connection reuse too much, you can choose for SET operations not to cause pinning. For information about how to do so by setting the session pinning filters property, see Creating an RDS Proxy (p. 1228) and Modifying an RDS Proxy (p. 1237).
- RDS Proxy does not pin connections when you use SET LOCAL.
- Creating a temporary table causes the proxy to pin the session. That way, the contents of the temporary table are preserved throughout the session regardless of transaction boundaries.
- Calling the functions ROW_COUNT, FOUND_ROWS, and LAST_INSERT_ID sometimes causes pinning.

Calling stored procedures and stored functions doesn't cause pinning. RDS Proxy doesn't detect any session state changes resulting from such calls. Therefore, make sure that your application doesn't change session state inside stored routines and rely on that session state to persist across transactions. For example, if a stored procedure creates a temporary table that is intended to persist across transactions, that application currently isn't compatible with RDS Proxy.

If you have expert knowledge about your application behavior, you can skip the pinning behavior for certain application statements. To do so, choose the Session pinning filters option when creating the proxy. Currently, you can opt out of session pinning for setting session variables and configuration settings.

Conditions that cause pinning for RDS for PostgreSQL

For PostgreSQL, the following interactions also cause pinning:

- Using SET commands
- Using the PostgreSQL extended query protocol such as by using JDBC default settings
- Creating temporary sequences, tables, or views
- Declaring cursors
- Discarding the session state
- Listening on a notification channel
- Loading a library module such as auto_explain
- Manipulating sequences using functions such as nextval and setval
- Interacting with locks using functions such as pg_advisory_lock and pg_try_advisory_lock
- Using prepared statements, setting parameters, or resetting a parameter to its default
Deleting an RDS Proxy

You can delete a proxy if you no longer need it. You might delete a proxy because the application that was using it is no longer relevant. Or you might delete a proxy if you take the DB instance or cluster associated with it out of service.

AWS Management Console

To delete a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Proxies.
3. Choose the proxy to delete from the list.

AWS CLI

To delete a DB proxy, use the AWS CLI command delete-db-proxy. To remove related associations, also use the deregister-db-proxy-targets command.

aws rds delete-db-proxy --name proxy_name

aws rds deregister-db-proxy-targets
   --db-proxy-name proxy_name
   [--target-group-name target_group_name]
   [--target-ids comma_separated_list] # or
   [--target-ids comma_separated_list] # or
   [--db-instance-identifiers instance_id]
   [--db-instance-identifiers instance_id]
   [--db-cluster-identifiers cluster_id]
   [--db-cluster-identifiers cluster_id]

RDS API

To delete a DB proxy, call the Amazon RDS API function DeleteDBProxy. To delete related items and associations, you also call the functions DeleteDBProxyTargetGroup and DeregisterDBProxyTargetGroup.

Working with Amazon RDS Proxy endpoints

Following, you can learn about endpoints for RDS Proxy and how to use them. By using endpoints, you can take advantage of the following capabilities:

- You can use multiple endpoints with a proxy to monitor and troubleshoot connections from different applications independently.
- You can use reader endpoints with Aurora DB clusters to improve read scalability and high availability for your query-intensive applications.
- You can use a cross-VPC endpoint to allow access to databases in one VPC from resources such as Amazon EC2 instances in a different VPC.

Topics

- Overview of proxy endpoints (p. 1249)
- Reader endpoints (p. 1249)
- Accessing Aurora and RDS databases across VPCs (p. 1249)
- Creating a proxy endpoint (p. 1250)
Overview of proxy endpoints

Working with RDS Proxy endpoints involves the same kinds of procedures as with Aurora DB cluster and reader endpoints and RDS instance endpoints. If you aren’t familiar with RDS endpoints, find more information in Connecting to a DB instance running the MySQL database engine and Connecting to a DB instance running the PostgreSQL database engine.

By default, the endpoint that you connect to when you use RDS Proxy with an Aurora cluster has read/write capability. As a result, this endpoint sends all requests to the writer instance of the cluster. All of those connections count against the max_connections value for the writer instance. If your proxy is associated with an Aurora DB cluster, you can create additional read/write or read-only endpoints for that proxy.

You can use a read-only endpoint with your proxy for read-only queries. You do this the same way that you use the reader endpoint for an Aurora provisioned cluster. Doing so helps you to take advantage of the read scalability of an Aurora cluster with one or more reader DB instances. You can run more simultaneous queries and make more simultaneous connections by using a read-only endpoint and adding more reader DB instances to your Aurora cluster as needed.

For a proxy endpoint that you create, you can also associate the endpoint with a different virtual private cloud (VPC) than the proxy itself uses. By doing so, you can connect to the proxy from a different VPC, for example a VPC used by a different application within your organization.

For information about limits associated with proxy endpoints, see Limitations for proxy endpoints (p. 1255).

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name you specified for a user-defined endpoint. Or it can be the special name default for read/write requests using the default endpoint of a proxy.

Each proxy endpoint has its own set of CloudWatch metrics. You can monitor the metrics for all endpoints of a proxy. You can also monitor metrics for a specific endpoint, or for all the read/write or read-only endpoints of a proxy. For more information, see Monitoring RDS Proxy metrics with Amazon CloudWatch (p. 1255).

A proxy endpoint uses the same authentication mechanism as its associated proxy. RDS Proxy automatically sets up permissions and authorizations for the user-defined endpoint, consistent with the properties of the associated proxy.

Reader endpoints

With RDS Proxy, you can create and use reader endpoints. However, these endpoints only work for proxies associated with Aurora DB clusters. You might see references to reader endpoints in the AWS Management Console. If you use the RDS CLI or API, you might see the TargetRole attribute with a value of READ_ONLY. You can take advantage of these features by changing the target of a proxy from an RDS DB instance to an Aurora DB cluster. To learn about reader endpoints, see Managing connections with Amazon RDS Proxy in the Aurora User Guide.

Accessing Aurora and RDS databases across VPCs

By default, the components of your RDS and Aurora technology stack are all in the same Amazon VPC. For example, suppose that an application running on an Amazon EC2 instance connects to an Amazon
Creating a proxy endpoint

The following steps explain how to create and access a cross-VPC endpoint through RDS Proxy:

1. Create two VPCs, or choose two VPCs that you already use for Aurora and RDS work. Each VPC should have its own associated network resources such as an Internet gateway, route tables, subnets, and security groups. If you only have one VPC, you can consult Getting started with Amazon RDS (p. 180) for the steps to set up another VPC to use RDS successfully. You can also examine your existing VPC in the Amazon EC2 console to see what kinds of resources to connect together.

2. Create a DB proxy associated with the Aurora DB cluster or RDS instance that you want to connect to. Follow the procedure in Creating an RDS Proxy (p. 1228).

3. On the Details page for your proxy in the RDS console, under the Proxy endpoints section, choose Create endpoint. Follow the procedure in Creating a proxy endpoint (p. 1250).

4. Choose whether to make the cross-VPC endpoint read/write or read-only.

5. Instead of accepting the default of the same VPC as the Aurora DB cluster or RDS instance, choose a different VPC. This VPC must be in the same AWS Region as the VPC where the proxy resides.

6. Now instead of accepting the defaults for subnets and security groups from the same VPC as the Aurora DB cluster or RDS instance, make new selections. Make these based on the subnets and security groups from the VPC that you chose.

7. You don't need to change any of the settings for the Secrets Manager secrets. The same credentials work for all endpoints for your proxy, regardless of which VPC each endpoint is in.

8. Wait for the new endpoint to reach the Available state.

9. Make a note of the full endpoint name. This is the value ending in Region_name.rds.amazonaws.com that you supply as part of the connection string for your database application.

10. Access the new endpoint from a resource in the same VPC as the endpoint. A simple way to test this process is to create a new EC2 instance in this VPC. Then you can log into the EC2 instance and run the mysql or psql commands to connect by using the endpoint value in your connection string.

Creating a proxy endpoint

Console

To create a proxy endpoint

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Proxies.
3. Click the name of the proxy that you want to create a new endpoint for.
The details page for that proxy appears.

4. In the **Proxy endpoints** section, choose **Create proxy endpoint**.

The **Create proxy endpoint** window appears.

5. For **Proxy endpoint name**, enter a descriptive name of your choice.

6. For **Target role**, choose whether to make the endpoint read/write or read-only.

Connections that use a read/write endpoint can perform any kind of operation: data definition language (DDL) statements, data manipulation language (DML) statements, and queries. These endpoints always connect to the primary instance of the Aurora cluster. You can use read/write endpoints for general database operations when you only use a single endpoint in your application. You can also use read/write endpoints for administrative operations, online transaction processing (OLTP) applications, and extract-transform-load (ETL) jobs.

Connections that use a read-only endpoint can only perform queries. When there are multiple reader instances in the Aurora cluster, RDS Proxy can use a different reader instance for each connection to the endpoint. That way, a query-intensive application can take advantage of Aurora's clustering capability. You can add more query capacity to the cluster by adding more reader DB instances. These read-only connections don't impose any overhead on the primary instance of the cluster. That way, your reporting and analysis queries don't slow down the write operations of your OLTP applications.

7. For **Virtual Private Cloud (VPC)**, choose the default to access the endpoint from the same EC2 instances or other resources where you normally access the proxy or its associated database. To set up cross-VPC access for this proxy, choose a VPC other than the default. For more information about cross-VPC access, see [Accessing Aurora and RDS databases across VPCs](p. 1249).

8. For **Subnets**, RDS Proxy fills in the same subnets as the associated proxy by default. To restrict access to the endpoint so only a portion of the VPC's address range can connect to it, remove one or more subnets.

9. For **VPC security group**, you can choose an existing security group or create a new one. RDS Proxy fills in the same security group or groups as the associated proxy by default. If the inbound and outbound rules for the proxy are appropriate for this endpoint, you can leave the default choice.

   If you choose to create a new security group, specify a name for the security group on this page. Then edit the security group settings from the EC2 console afterward.

10. Choose **Create proxy endpoint**.

**AWS CLI**

To create a proxy endpoint, use the AWS CLI `create-db-proxy-endpoint` command.

Include the following required parameters:

- `--db-proxy-name value`
- `--db-proxy-endpoint-name value`
- `--vpc-subnet-ids list_of_ids`. Separate the subnet IDs with spaces. You don't specify the ID of the VPC itself.

You can also include the following optional parameters:

- `--target-role { READ_WRITE | READ_ONLY }`. This parameter defaults to `READ_WRITE`. The `READ_ONLY` value only has an effect on Aurora provisioned clusters that contain one or more reader DB instances. When the proxy is associated with an RDS instance or with an Aurora cluster that only contains a writer DB instance, you can't specify `READ_ONLY`. 1251
• `--vpc-security-group-ids value`. Separate the security group IDs with spaces. If you omit this parameter, RDS Proxy uses the default security group for the VPC. RDS Proxy determines the VPC based on the subnet IDs that you specify for the `--vpc-subnet-ids` parameter.

**Example**

The following example creates a proxy endpoint named `my-endpoint`.

For Linux, macOS, or Unix:

```bash
aws rds create-db-proxy-endpoint \
  --db-proxy-name my-proxy \
  --db-proxy-endpoint-name my-endpoint \
  --vpc-subnet-ids subnet_id subnet_id subnet_id ... \
  --target-role READ_ONLY \
  --vpc-security-group-ids security_group_id
```

For Windows:

```bash
aws rds create-db-proxy-endpoint ^
  --db-proxy-name my-proxy ^
  --db-proxy-endpoint-name my-endpoint ^
  --vpc-subnet-ids subnet_id_1 subnet_id_2 subnet_id_3 ... ^
  --target-role READ_ONLY ^
  --vpc-security-group-ids security_group_id
```

**RDS API**

To create a proxy endpoint, use the RDS API `CreateDBProxyEndpoint` action.

**Viewing proxy endpoints**

**Console**

**To view the details for a proxy endpoint**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Proxies**.
3. In the list, choose the proxy whose endpoint you want to view. Click the proxy name to view its details page.
4. In the **Proxy endpoints** section, choose the endpoint that you want to view. Click its name to view the details page.
5. Examine the parameters whose values you're interested in. You can check properties such as the following:
   - Whether the endpoint is read/write or read-only.
   - The endpoint address that you use in a database connection string.
   - The VPC, subnets, and security groups associated with the endpoint.

**AWS CLI**

To view one or more DB proxy endpoints, use the AWS CLI `describe-db-proxy-endpoints` command.
You can include the following optional parameters:

- `--db-proxy-endpoint-name`
- `--db-proxy-name`

The following example describes the `my-endpoint` proxy endpoint.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds describe-db-proxy-endpoints \
   --db-proxy-endpoint-name my-endpoint
```

For Windows:

```bash
aws rds describe-db-proxy-endpoints ^
   --db-proxy-endpoint-name my-endpoint
```

**RDS API**

To describe one or more proxy endpoints, use the RDS API [DescribeDBProxyEndpoints](https://docs.aws.amazon.com/AmazonRDS/latest/userguide/API_DescribeDBProxyEndpoints.html) operation.

**Modifying a proxy endpoint**

**Console**

**To modify one or more proxy endpoints**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Proxies**.
3. In the list, choose the proxy whose endpoint you want to modify. Click the proxy name to view its details page.
4. In the **Proxy endpoints** section, choose the endpoint that you want to modify. You can select it in the list, or click its name to view the details page.
5. On the proxy details page, under the **Proxy endpoints** section, choose **Edit**. Or on the proxy endpoint details page, for **Actions**, choose **Edit**.
6. Change the values of the parameters that you want to modify.
7. Choose **Save changes**.

**AWS CLI**

To modify a DB proxy endpoint, use the AWS CLI [modify-db-proxy-endpoint](https://docs.aws.amazon.com/AmazonRDS/latest/userguide/CLI-CreatingStagingS3.html) command with the following required parameters:

- `--db-proxy-endpoint-name`

Specify changes to the endpoint properties by using one or more of the following parameters:

- `--new-db-proxy-endpoint-name`
- `--vpc-security-group-ids`. Separate the security group IDs with spaces.
The following example renames the `my-endpoint` proxy endpoint to `new-endpoint-name`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-proxy-endpoint \
   --db-proxy-endpoint-name my-endpoint \ 
   --new-db-proxy-endpoint-name new-endpoint-name
```

For Windows:

```bash
aws rds modify-db-proxy-endpoint ^
   --db-proxy-endpoint-name my-endpoint ^
   --new-db-proxy-endpoint-name new-endpoint-name
```

**RDS API**

To modify a proxy endpoint, use the RDS API [ModifyDBProxyEndpoint](https://docs.aws.amazon.com/AmazonRDS/latest/userguide/RDS-DBProxy.html) operation.

**Deleting a proxy endpoint**

You can delete an endpoint for your proxy using the console as described following.

**Note**

You can't delete the default endpoint that RDS Proxy automatically creates for each proxy. When you delete a proxy, RDS Proxy automatically deletes all the associated endpoints.

**Console**

**To delete a proxy endpoint using the AWS Management Console**

1. In the navigation pane, choose Proxies.
2. In the list, choose the proxy whose endpoint you want to endpoint. Click the proxy name to view its details page.
3. In the **Proxy endpoints** section, choose the endpoint that you want to delete. You can select one or more endpoints in the list, or click the name of a single endpoint to view the details page.
4. On the proxy details page, under the **Proxy endpoints** section, choose Delete. Or on the proxy endpoint details page, for **Actions**, choose Delete.

**AWS CLI**

To delete a proxy endpoint, run the `delete-db-proxy-endpoint` command with the following required parameters:

- `--db-proxy-endpoint-name`

The following command deletes the proxy endpoint named `my-endpoint`.

For Linux, macOS, or Unix:

```bash
aws rds delete-db-proxy-endpoint \ 
   --db-proxy-endpoint-name my-endpoint
```

For Windows:
RDS API

To delete a proxy endpoint with the RDS API, run the `DeleteDBProxyEndpoint` operation. Specify the name of the proxy endpoint for the `DBProxyEndpointName` parameter.

**Limitations for proxy endpoints**

Each proxy has a default endpoint that you can modify but not create or delete.

The maximum number of user-defined endpoints for a proxy is 20. Thus, a proxy can have up to 21 endpoints: the default endpoint, plus 20 that you create.

When you associate additional endpoints with a proxy, RDS Proxy automatically determines which DB instances in your cluster to use for each endpoint. You can't choose specific instances the way that you can with Aurora custom endpoints.

Reader endpoints aren't available for Aurora multi-writer clusters.

**Monitoring RDS Proxy metrics with Amazon CloudWatch**

You can monitor RDS Proxy by using Amazon CloudWatch. CloudWatch collects and processes raw data from the proxies into readable, near-real-time metrics. To find these metrics in the CloudWatch console, choose **Metrics**, then choose **RDS**, and choose **Per-Proxy Metrics**. For more information, see **Using Amazon CloudWatch metrics** in the Amazon CloudWatch User Guide.

**Note**

RDS publishes these metrics for each underlying Amazon EC2 instance associated with a proxy. A single proxy might be served by more than one EC2 instance. Use CloudWatch statistics to aggregate the values for a proxy across all the associated instances.

Some of these metrics might not be visible until after the first successful connection by a proxy.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name you specified for a user-defined endpoint, or the special name `default` for read/write requests using the default endpoint of a proxy.

All RDS Proxy metrics are in the group `proxy`.

Each proxy endpoint has its own CloudWatch metrics. You can monitor the usage of each proxy endpoint independently. For more information about proxy endpoints, see **Working with Amazon RDS Proxy endpoints (p. 1248)**.

You can aggregate the values for each metric using one of the following dimension sets. For example, by using the `ProxyName` dimension set, you can analyze all the traffic for a particular proxy. By using the other dimension sets, you can split the metrics in different ways. You can split the metrics based on the different endpoints or target databases of each proxy, or the read/write and read-only traffic to each database.

- Dimension set 1: `ProxyName`
- Dimension set 2: `ProxyName`, `EndpointName`
- Dimension set 3: ProxyName, TargetGroup, Target
- Dimension set 4: ProxyName, TargetGroup, TargetRole

</tr>
</tbody>
</table>

You can find logs of RDS Proxy activity under CloudWatch in the AWS Management Console. Each proxy has an entry in the Log groups page.

Important
These logs are intended for human consumption for troubleshooting purposes and not for programmatic access. The format and content of the logs is subject to change.
In particular, older logs don't contain any prefixes indicating the endpoint for each request. In newer logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name that you specified for a user-defined endpoint, or the special name default for requests using the default endpoint of a proxy.
Working with RDS Proxy events

An event indicates a change in an environment. This can be an AWS environment or a service or application from a software as a service (SaaS) partner. Or it can be one of your own custom applications or services. For example, Amazon RDS generates an event when you create or modify an RDS Proxy. Amazon RDS delivers events to CloudWatch Events and Amazon EventBridge in near-real time. Following, you can find a list of RDS Proxy events that you can subscribe to and an example of an RDS Proxy event.

For more information about working with events, see the following:

- For instructions on how to view events by using the AWS Management Console, AWS CLI, or RDS API, see Viewing Amazon RDS events (p. 852).
- To learn how to configure Amazon RDS to send events to EventBridge, see Creating a rule that triggers on an Amazon RDS event (p. 870).

RDS Proxy events

The following table shows the event category and a list of events when an RDS Proxy is the source type.

<table>
<thead>
<tr>
<th>Category</th>
<th>RDS event ID</th>
<th>Message</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>configuration change</td>
<td>RDS-EVENT-0204</td>
<td>RDS modified DB proxy name.</td>
<td></td>

```

**RDS Proxy command-line examples**

To see how combinations of connection commands and SQL statements interact with RDS Proxy, look at the following examples.
Examples

- Preserving Connections to a MySQL Database Across a Failover
- Adjusting the max_connections Setting for an Aurora DB Cluster

Example  Preserving connections to a MySQL database across a failover

This MySQL example demonstrates how open connections continue working during a failover. An example is when you reboot a database or it becomes unavailable due to a problem. This example uses a proxy named the-proxy and an Aurora DB cluster with DB instances instance-8898 and instance-9814. When you run the failover-db-cluster command from the Linux command line, the writer instance that the proxy is connected to changes to a different DB instance. You can see that the DB instance associated with the proxy changes while the connection remains open.

```
$ mysql -h the-proxy.proxy-demo.us-east-1.rds.amazonaws.com -u admin_user -p

Example  Adjusting the max_connections setting for an Aurora DB cluster

This example demonstrates how you can adjust the max_connections setting for an Aurora MySQL DB cluster. To do so, you create your own DB cluster parameter group based on the default parameter settings for clusters that are compatible with MySQL 5.7. You specify a value for the max_connections setting, overriding the formula that sets the default value. You associate the DB cluster parameter group with your DB cluster.

```sh
export REGION=us-east-1
export CLUSTER_PARAM_GROUP=rds-proxy-mysql-57-max-connections-demo
export CLUSTER_NAME=rds-proxy-mysql-57

aws rds create-db-parameter-group --region $REGION --db-parameter-group-family aurora-mysql5.7 --db-parameter-group-name $CLUSTER_PARAM_GROUP --description "Aurora MySQL 5.7 cluster parameter group for RDS Proxy demo."

aws rds modify-db-cluster --region $REGION --db-cluster-identifier $CLUSTER_NAME --db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP

echo "New cluster param group is assigned to cluster:"
aws rds describe-db-clusters --region $REGION --db-cluster-identifier $CLUSTER_NAME --query '*[].{DBClusterParameterGroup:DBClusterParameterGroup}'

echo "Current value for max_connections:"
aws rds describe-db-cluster-parameters --region $REGION --db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP --query '*[ParameterName:ParameterName,ParameterValue:ParameterValue]' --output text | grep ^max_connections

echo -n "Enter number for max_connections setting: "
read answer

aws rds modify-db-cluster-parameter-group --region $REGION --db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP --parameters "ParameterName=max_connections,ParameterValue=$answer,ApplyMethod=immediate"

echo "Updated value for max_connections:"
aws rds describe-db-cluster-parameters --region $REGION --db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP --query '*[ParameterName:ParameterName,ParameterValue:ParameterValue]' --output text | grep ^max_connections
```

Troubleshooting for RDS Proxy

Following, you can find troubleshooting ideas for some common RDS Proxy issues and information on CloudWatch logs for RDS Proxy.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name that you specified for a user-defined endpoint. Or it can be the special name

```
+---------------+---------------+
| Variable_name | Value         |
+---------------+---------------+
| hostname      | ip-10-1-3-178 |
+---------------+---------------+
```
default for read/write requests using the default endpoint of a proxy. For more information about proxy endpoints, see Working with Amazon RDS Proxy endpoints (p. 1248).

Topics

- Verifying connectivity for a proxy (p. 1264)
- Common issues and solutions (p. 1265)

Verifying connectivity for a proxy

You can use the following commands to verify that all components of the connection mechanism can communicate with the other components.

Examine the proxy itself using the `describe-db-proxies` command. Also examine the associated target group using the `describe-db-proxy-target-groups` command. Check that the details of the targets match the RDS DB instance or Aurora DB cluster that you intend to associate with the proxy. Use commands such as the following.

```bash
aws rds describe-db-proxies --db-proxy-name $DB_PROXY_NAME
aws rds describe-db-proxy-target-groups --db-proxy-name $DB_PROXY_NAME
```

To confirm that the proxy can connect to the underlying database, examine the targets specified in the target groups using the `describe-db-proxy-targets` command. Use a command such as the following.

```bash
aws rds describe-db-proxy-targets --db-proxy-name $DB_PROXY_NAME
```

The output of the `describe-db-proxy-targets` command includes a `TargetHealth` field. You can examine the fields `State`, `Reason`, and `Description` inside `TargetHealth` to check if the proxy can communicate with the underlying DB instance.

- A `State` value of `AVAILABLE` indicates that the proxy can connect to the DB instance.
- A `State` value of `UNAVAILABLE` indicates a temporary or permanent connection problem. In this case, examine the `Reason` and `Description` fields. For example, if `Reason` has a value of `PENDING_PROXY_CAPACITY`, try connecting again after the proxy finishes its scaling operation. If `Reason` has a value of `UNREACHABLE`, `CONNECTION_FAILED`, or `AUTH_FAILURE`, use the explanation from the `Description` field to help you diagnose the issue.
- The `State` field might have a value of `REGISTERING` for a brief time before changing to `AVAILABLE` or `UNAVAILABLE`.

If the following Netcat command (`nc`) is successful, you can access the proxy endpoint from the EC2 instance or other system where you're logged in. This command reports failure if you're not in the same VPC as the proxy and the associated database. You might be able to log directly in to the database without being in the same VPC. However, you can't log into the proxy unless you're in the same VPC.

```bash
nc -zx MySQL_proxy_endpoint 3306
nc -zx PostgreSQL_proxy_endpoint 5432
```

You can use the following commands to make sure that your EC2 instance has the required properties. In particular, the VPC for the EC2 instance must be the same as the VPC for the RDS DB instance or Aurora DB cluster that the proxy connects to.

```bash
aws ec2 describe-instances --instance-ids your_ec2_instance_id
```

Examine the Secrets Manager secrets used for the proxy.
Make sure that the SecretString field displayed by get-secret-value is encoded as a JSON string that includes username and password fields. The following example shows the format of the SecretString field.

```
{
    "ARN": "some_arn",
    "Name": "some_name",
    "VersionId": "some_version_id",
    "SecretString": '{"username":"some_username","password":"some_password"}',
    "VersionStages": [ "some_stage" ],
    "CreatedDate": some_timestamp
}
```

### Common issues and solutions

For possible causes and solutions to some common problems that you might encounter using RDS Proxy, see the following.

After running `aws rds describe-db-proxy-targets`, if the TargetHealth description states Proxy does not have any registered credentials, verify the following:

- There are credentials registered for the user to access the proxy.
- The IAM role to access the proxy secret from Secrets Manager is valid.
- The DB proxy is using an authentication method.

You might encounter the following RDS events while creating or connecting to a DB proxy.

<table>
<thead>
<tr>
<th>Category</th>
<th>RDS event ID</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>failure</td>
<td>RDS-EVENT-0243</td>
<td>RDS couldn't provision capacity for the proxy because there aren't enough IP addresses available in your subnets. To fix the issue, make sure that your subnets have the minimum number of unused IP addresses. To determine the recommended number for your instance class, see Planning for IP address capacity (p. 1224).</td>
</tr>
<tr>
<td>failure</td>
<td>RDS-EVENT-0275</td>
<td>RDS throttled some connections to DB proxy (RDS Proxy).</td>
</tr>
</tbody>
</table>

You might encounter the following issues while creating a new proxy or connecting to a proxy.

<table>
<thead>
<tr>
<th>Error</th>
<th>Causes or workarounds</th>
</tr>
</thead>
<tbody>
<tr>
<td>403: The security token included</td>
<td>Select an existing IAM role instead of choosing to create a new one.</td>
</tr>
</tbody>
</table>
### Error Causes or workarounds

You might encounter the following issues while connecting to a MySQL proxy.

<table>
<thead>
<tr>
<th>Error</th>
<th>Causes or workarounds</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>in the request is invalid</strong></td>
<td></td>
</tr>
<tr>
<td><strong>ERROR 1040 (HY000): Connections rate limit exceeded</strong> <em>(limit_value)</em></td>
<td>The rate of connection requests from the client to the proxy has exceeded the limit.</td>
</tr>
<tr>
<td><strong>ERROR 1040 (HY000): IAM authentication rate limit exceeded</strong></td>
<td>The number of simultaneous requests with IAM authentication from the client to the proxy has exceeded the limit.</td>
</tr>
<tr>
<td><strong>ERROR 1040 (HY000): Number simultaneous connections exceeded</strong> <em>(limit_value)</em></td>
<td>The number of simultaneous connection requests from the client to the proxy exceeded the limit.</td>
</tr>
</tbody>
</table>
| **ERROR 1045 (28000): Access denied for user 'DB_USER'@'%' (using password: YES)** | Some possible reasons include the following:  
  - The Secrets Manager secret used by the proxy doesn't match the user name and password of an existing database user. Either update the credentials in the Secrets Manager secret, or make sure the database user exists and has the same password as in the secret. |
| **ERROR 1105 (HY000): Unknown error** | An unknown error occurred. |
| **ERROR 1231 (42000): Variable 'character_set_client' can't be set to the value of value** | The value set for the character_set_client parameter is not valid. For example, the value ucs2 is not valid because it can crash the MySQL server. |
| **ERROR 3159 (HY000): This RDS Proxy requires TLS connections.** | You enabled the setting **Require Transport Layer Security** in the proxy but your connection included the parameter ssl-mode=DISABLED in the MySQL client. Do either of the following:  
  - Disable the setting **Require Transport Layer Security** for the proxy.  
  - Connect to the database using the minimum setting of ssl-mode=REQUIRED in the MySQL client. |
| **ERROR 2026 (HY000): SSL connection error:** | The TLS handshake to the proxy failed. Some possible reasons include the following:  
  - SSL is required but the server doesn't support it. |
### Error | Causes or workarounds
--- | ---
Internal Server Error | • An internal server error occurred.  
• A bad handshake occurred.

**ERROR 9501 (HY000): Timed-out waiting to acquire database connection** | The proxy timed-out waiting to acquire a database connection. Some possible reasons include the following:  
• The proxy is unable to establish a database connection because the maximum connections have been reached  
• The proxy is unable to establish a database connection because the database is unavailable.

You might encounter the following issues while connecting to a PostgreSQL proxy.

<table>
<thead>
<tr>
<th>Error</th>
<th>Cause</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>IAM authentication is allowed only with SSL connections.</td>
<td>The user tried to connect to the database using IAM authentication with the setting <code>sslmode=disable</code> in the PostgreSQL client.</td>
<td>The user needs to connect to the database using the minimum setting of <code>sslmode=require</code> in the PostgreSQL client. For more information, see the PostgreSQL SSL support documentation.</td>
</tr>
</tbody>
</table>
| This RDS Proxy requires TLS connections. | The user enabled the option **Require Transport Layer Security** but tried to connect with `sslmode=disable` in the PostgreSQL client. | To fix this error, do one of the following:  
• Disable the proxy's **Require Transport Layer Security** option.  
• Connect to the database using the minimum setting of `sslmode=allow` in the PostgreSQL client. |
| IAM authentication failed for user **user_name**. Check the IAM token for this user and try again. | This error might be due to the following reasons:  
• The client supplied the incorrect IAM user name.  
• The client supplied an incorrect IAM authorization token for the user.  
• The client is using an IAM policy that does not have the necessary permissions.  
• The client supplied an expired IAM authorization token for the user. | To fix this error, do the following:  
1. Confirm that the provided IAM user exists.  
2. Confirm that the IAM authorization token belongs to the provided IAM user.  
3. Confirm that the IAM policy has adequate permissions for RDS.  
4. Check the validity of the IAM authorization token used. |
<p>| This RDS proxy has no credentials for the role <strong>role_name</strong>. Check the credentials for this role and try again. | There is no Secrets Manager secret for this role. | Add a Secrets Manager secret for this role. For more information, see Setting up AWS Identity and Access Management (IAM) policies (p. 1226). |</p>

<tr>
<td>IAM is allowed only with SSL connections.</td>
<td>A client tried to connect using IAM authentication, but SSL wasn't enabled.</td>
<td>Enable SSL in the PostgreSQL client.</td>
</tr>
<tr>
<td>Unknown error.</td>
<td>An unknown error occurred.</td>
<td>Reach out to AWS Support to investigate the issue.</td>
</tr>
<tr>
<td>Timed-out waiting to acquire database connection.</td>
<td>The proxy timed-out waiting to acquire a database connection. Some possible reasons include the following:</td>
<td>Possible solutions are the following:</td>
</tr>
<tr>
<td></td>
<td>• The proxy can't establish a database connection because the maximum connections have been reached.</td>
<td>• Check the target of the RDS DB instance or Aurora DB cluster status to see if it's unavailable.</td>
</tr>
<tr>
<td></td>
<td>• The proxy can't establish a database connection because the database is unavailable.</td>
<td>• Check if there are long-running transactions and/or queries being executed. They can use database connections from the connection pool for a long time.</td>
</tr>
<tr>
<td>Request returned an error: database_error.</td>
<td>The database connection established from the proxy returned an error.</td>
<td>The solution depends on the specific database error. One example is: Request returned an error: database &quot;your-database-name&quot; does not exist. This means that the specified database name doesn't exist on the database server. Or it means that the user name used as a database name (if a database name isn't specified) doesn't exist on the server.</td>
</tr>
</tbody>
</table>

### Using RDS Proxy with AWS CloudFormation

You can use RDS Proxy with AWS CloudFormation. Doing so helps you to create groups of related resources. Such a group can include a proxy that can connect to a newly created Amazon RDS DB instance or Aurora DB cluster. RDS Proxy support in AWS CloudFormation involves two new registry types: DBProxy and DBProxyTargetGroup.

The following listing shows a sample AWS CloudFormation template for RDS Proxy.

```yaml
Resources:
  DBProxy:
    Type: AWS::RDS::DBProxy
    Properties:
```
DBProxyName: CanaryProxy
EngineFamily: MYSQL
RoleArn:
  Fn::ImportValue: SecretReaderRoleArn
Auth:
  - {AuthScheme: SECRETS, SecretArn: !ImportValue ProxySecret, IAMAuth: DISABLED}
VpcSubnetIds:
  Fn::Split: [",", "Fn::ImportValue": SubnetIds]

ProxyTargetGroup:
  Type: AWS::RDS::DBProxyTargetGroup
  Properties:
    DBProxyName: CanaryProxy
    TargetGroupName: default
    DBInstanceIdentifiers:
      - Fn::ImportValue: DBInstanceName
DependsOn: DBProxy

For more information about the resources in this sample, see DBProxy and DBProxyTargetGroup.
For more information about the Amazon RDS and Aurora resources that you can create using AWS CloudFormation, see RDS resource type reference.
Amazon RDS for MariaDB

Amazon RDS supports DB instances that run the following versions of MariaDB:

- MariaDB 10.11
- MariaDB 10.6
- MariaDB 10.5
- MariaDB 10.4
- MariaDB 10.3 (RDS end of standard support scheduled for October 23, 2023)

For more information about minor version support, see [MariaDB on Amazon RDS versions](#).

To create a MariaDB DB instance, use the Amazon RDS management tools or interfaces. You can then use the Amazon RDS tools to perform management actions for the DB instance. These include actions such as the following:

- Reconfiguring or resizing the DB instance
- Authorizing connections to the DB instance
- Creating and restoring from backups or snapshots
- Creating Multi-AZ secondaries
- Creating read replicas
- Monitoring the performance of your DB instance

To store and access the data in your DB instance, use standard MariaDB utilities and applications.

MariaDB is available in all of the AWS Regions. For more information about AWS Regions, see [Regions, Availability Zones, and Local Zones](#).

You can use Amazon RDS for MariaDB databases to build HIPAA-compliant applications. You can store healthcare-related information, including protected health information (PHI), under a Business Associate Agreement (BAA) with AWS. For more information, see [HIPAA compliance](#). AWS Services in Scope have been fully assessed by a third-party auditor and result in a certification, attestation of compliance, or Authority to Operate (ATO). For more information, see [AWS services in scope by compliance program](#).

Before creating a DB instance, complete the steps in [Setting up for Amazon RDS](#). When you create a DB instance, the RDS master user gets DBA privileges, with some limitations. Use this account for administrative tasks such as creating additional database accounts.

You can create the following:

- DB instances
- DB snapshots
- Point-in-time restores
- Automated backups
- Manual backups

You can use DB instances running MariaDB inside a virtual private cloud (VPC) based on Amazon VPC. You can also add features to your MariaDB DB instance by enabling various options. Amazon RDS supports Multi-AZ deployments for MariaDB as a high-availability, failover solution.

**Important**

To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that need advanced...
privileges. You can access your database using standard SQL clients such as the mysql client. However, you can't access the host directly by using Telnet or Secure Shell (SSH).

**Topics**
- MariaDB feature support on Amazon RDS (p. 1272)
- MariaDB on Amazon RDS versions (p. 1281)
- Connecting to a DB instance running the MariaDB database engine (p. 1285)
- Securing MariaDB DB instance connections (p. 1290)
- Improving query performance for RDS for MariaDB with Amazon RDS Optimized Reads (p. 1297)
- Improving write performance with Amazon RDS Optimized Writes for MariaDB (p. 1300)
- Upgrading the MariaDB DB engine (p. 1305)
- Importing data into a MariaDB DB instance (p. 1312)
- Working with MariaDB replication in Amazon RDS (p. 1334)
- Options for MariaDB database engine (p. 1350)
- Parameters for MariaDB (p. 1354)
- Migrating data from a MySQL DB snapshot to a MariaDB DB instance (p. 1357)
- MariaDB on Amazon RDS SQL reference (p. 1360)
- Local time zone for MariaDB DB instances (p. 1365)
- Known issues and limitations for RDS for MariaDB (p. 1368)

**MariaDB feature support on Amazon RDS**

RDS for MariaDB supports most of the features and capabilities of MariaDB. Some features might have limited support or restricted privileges.

You can filter new Amazon RDS features on the What’s New with Database? page. For Products, choose Amazon RDS. Then search using keywords such as MariaDB 2023.

**Note**
The following lists are not exhaustive.

**Topics**
- MariaDB feature support on Amazon RDS for MariaDB major versions (p. 1272)
- Supported storage engines for MariaDB on Amazon RDS (p. 1277)
- Cache warming for MariaDB on Amazon RDS (p. 1278)
- MariaDB features not supported by Amazon RDS (p. 1279)

**MariaDB feature support on Amazon RDS for MariaDB major versions**

In the following sections, find information about MariaDB feature support on Amazon RDS for MariaDB major versions:

**Topics**
- MariaDB 10.11 support on Amazon RDS (p. 1273)
- MariaDB 10.6 support on Amazon RDS (p. 1274)
- MariaDB 10.5 support on Amazon RDS (p. 1275)
- MariaDB 10.4 support on Amazon RDS (p. 1276)
MariaDB major versions

• MariaDB 10.3 support on Amazon RDS (p. 1277)

For information about supported minor versions of Amazon RDS for MariaDB, see MariaDB on Amazon RDS versions (p. 1281).

MariaDB 10.11 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.11 or higher.

• Password Reuse Check plugin – You can use the MariaDB Password Reuse Check plugin to prevent users from reusing passwords and to set the retention period of passwords. For more information, see Password Reuse Check Plugin.

• GRANT TO PUBLIC authorization – You can grant privileges to all users who have access to your server. For more information, see GRANT TO PUBLIC.

• Separation of SUPER and READ ONLY ADMIN privileges – You can remove READ ONLY ADMIN privileges from all users, even users that previously had SUPER privileges.

• Security – You can now set option --ssl as the default for your MariaDB client. MariaDB no longer silently disables SSL if the configuration is incorrect.

• SQL commands and functions – You can now use the SHOW ANALYZE FORMAT=JSON command and the functions ROW_NUMBER, SFORMAT, and RANDOM_BYTES. SFORMAT allows string formatting and is enabled by default. You can convert partition to table and table to partition in a single command. There are also several improvements around JSON_*() functions. DES_ENCRYPT and DES_DECRYPT functions were deprecated for version 10.10 and higher. For more information, see SFORMAT.

• InnoDB enhancements – These enhancements include the following items:
  • Performance improvements in the redo log to reduce write amplification and to improve concurrency.
  • The ability for you to change the undo tablespace without reinitializing the data directory. This enhancement reduces control plane overhead. It requires restarting but it doesn't require reinitialization after changing undo tablespace.
  • Support for CHECK TABLE … EXTENDED and for descending indexes internally.
  • Improvements to bulk insert.

• Binlog changes – These changes include the following items:
  • Logging ALTER in two phases to decrease replication latency. The binlog_alter_two_phase parameter is disabled by default, but can be enabled through parameter groups.
  • Logging explicit_defaults_for_timestamp.
  • No longer logging INCIDENT_EVENT if the transaction can be safely rolled back.

• Replication improvements – MariaDB version 10.11 DB instances use GTID replication by default if the master supports it. Also, Seconds_Behind_Master is more precise.

• Clients – You can use new command-line options for mysqlbinlog and mariadb-dump. You can use mariadb-dump to dump and restore historical data.

• System versioning – You can modify history. MariaDB automatically creates new partitions.

• Atomic DDL – CREATE OR REPLACE is now atomic. Either the statement succeeds or it's completely reversed.

• Redo log write – Redo log writes asynchronously.

• Stored functions – Stored functions now support the same IN, OUT, and INOUT parameters as in stored procedures.

• Deprecated or removed parameters – The following parameters have been deprecated or removed for MariaDB version 10.11 DB instances:
  • innodb_change_buffering
  • innodb_disallow_writes
*innodb_log_write_ahead_size*
*innodb_prefix_index_cluster_optimization*
*keep_files_on_create*
*old*

**Dynamic parameters** – The following parameters are now dynamic for MariaDB version 10.11 DB instances:
*innodb_log_file_size*
*innodb_write_io_threads*
*innodb_read_io_threads*

**New default values for parameters** – The following parameters have new default values for MariaDB version 10.11 DB instances:
- The default value of the `explicit_defaults_for_timestamp` parameter changed from OFF to ON.
- The default value of the `optimizer_prune_level` parameter changed from 1 to 2.

**New valid values for parameters** – The following parameters have new valid values for MariaDB version 10.11 DB instances:
- The valid values for the `old` parameter were merged into those for the `old_mode` parameter.
- The valid values for the `histogram_type` parameter now include `JSON_HB`.
- The valid value range for the `innodb_log_buffer_size` parameter is now `262144` to `4294967295` (256KB to 4096MB).
- The valid value range for the `innodb_log_file_size` parameter is now `4194304` to `512GB` (4MB to 512GB).
- The valid values for the `optimizer_prune_level` parameter now include 2.

**New parameters** – The following parameters are new for MariaDB version 10.11 DB instances:
- The `binlog_alter_two_phase` parameter can improve replication performance.
- The `log_slow_min_examined_row_limit` parameter can improve performance.
- The `log_slow_query` parameter and the `log_slow_query_file` parameter are aliases for `slow_query_log` and `slow_query_log_file`, respectively.
- `optimizer_extra_pruning_depth`
- `system_versioning_insert_history`

For a list of all features and documentation, see the following information on the MariaDB website.

For a list of unsupported features, see [MariaDB features not supported by Amazon RDS (p. 1279)](amazonrds unsupportedfeatures).

**MariaDB 10.6 support on Amazon RDS**

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.6 or higher:
• **MyRocks storage engine** – You can use the MyRocks storage engine with RDS for MariaDB to optimize storage consumption of your write-intensive, high-performance web applications. For more information, see Supported storage engines for MariaDB on Amazon RDS (p. 1277) and MyRocks.

• **AWS Identity and Access Management (IAM) DB authentication** – You can use IAM DB authentication for better security and central management of connections to your MariaDB DB instances. For more information, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 2659).

• **Upgrade options** – You can now upgrade to RDS for MariaDB version 10.6 from any prior major release (10.3, 10.4, 10.5). You can also restore a snapshot of an existing MySQL 5.6 or 5.7 DB instance to a MariaDB 10.6 instance. For more information, see Upgrading the MariaDB DB engine (p. 1305).

• **Delayed replication** – You can now set a configurable time period for which a read replica lags behind the source database. In a standard MariaDB replication configuration, there is minimal replication delay between the source and the replica. With delayed replication, you can set an intentional delay as a strategy for disaster recovery. For more information, see Configuring delayed replication with MariaDB (p. 1340).

• **Oracle PL/SQL compatibility** – By using RDS for MariaDB version 10.6, you can more easily migrate your legacy Oracle applications to Amazon RDS. For more information, see SQL_MODE=ORACLE.

• **Atomic DDL** – Your dynamic data language (DDL) statements can be relatively crash-safe with RDS for MariaDB version 10.6. CREATE TABLE, ALTER TABLE, RENAME TABLE, DROP TABLE, DROP DATABASE and related DDL statements are now atomic. Either the statement succeeds, or it's completely reversed. For more information, see Atomic DDL.

• **Other enhancements** – These enhancements include a JSON_TABLE function for transforming JSON data to relational format within SQL, and faster empty table data load with InnoDB. They also include new sys_schema for analysis and troubleshooting, optimizer enhancement for ignoring unused indexes, and performance improvements. For more information, see JSON_TABLE.

• **New default values for parameters** – The following parameters have new default values for MariaDB version 10.6 DB instances:
  - The default value for the following parameters has changed from utf8 to utf8mb3:
    - `character_set_client`
    - `character_set_connection`
    - `character_set_results`
    - `character_set_system`
  - Although the default values have changed for these parameters, there is no functional change. For more information, see Supported Character Sets and Collations in the MariaDB documentation.
  - The default value of the `collation_connection` parameter has changed from `utf8_general_ci` to `utf8mb3_general_ci`. Although the default value has changed for this parameter, there is no functional change.
  - The default value of the `old_mode` parameter has changed from unset to UTF8_IS_UTF8MB3. Although the default value has changed for this parameter, there is no functional change.

For a list of all MariaDB 10.6 features and their documentation, see Changes and improvements in MariaDB 10.6 and Release notes - MariaDB 10.6 series on the MariaDB website.

For a list of unsupported features, see MariaDB features not supported by Amazon RDS (p. 1279).

**MariaDB 10.5 support on Amazon RDS**

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.5 or later:

• **InnoDB enhancements** – MariaDB version 10.5 includes InnoDB enhancements. For more information, see InnoDB: Performance Improvements etc. in the MariaDB documentation.
• **Performance schema updates** – MariaDB version 10.5 includes performance schema updates. For more information, see [Performance Schema Updates to Match MySQL 5.7 Instrumentation and Tables](https://mariadb.com/kb/en/docs/mysql-57-instrumentation-and-tables/) in the MariaDB documentation.

• **One file in the InnoDB redo log** – In versions of MariaDB before version 10.5, the value of the `innodb_log_files_in_group` parameter was set to 2. In MariaDB version 10.5, the value of this parameter is set to 1.

  If you are upgrading from a prior version to MariaDB version 10.5, and you don't modify the parameters, the `innodb_log_file_size` parameter value is unchanged. However, it applies to one log file instead of two. The result is that your upgraded MariaDB version 10.5 DB instance uses half of the redo log size that it was using before the upgrade. This change can have a noticeable performance impact. To address this issue, you can double the value of the `innodb_log_file_size` parameter. For information about modifying parameters, see [Modifying parameters in a DB parameter group](https://mariadb.com/kb/en/modifying-parameters-in-a-db-parameter-group/).

• **SHOW SLAVE STATUS command not supported** – In versions of MariaDB before version 10.5, the SHOW SLAVE STATUS command required the REPLICATION SLAVE privilege. In MariaDB version 10.5, the equivalent SHOW REPLICATION STATUS command requires the REPLICATION REPLICA ADMIN privilege. This new privilege isn't granted to the RDS master user.

  Instead of using the SHOW REPLICATION STATUS command, run the new `mysql.rds_replica_status` stored procedure to return similar information. For more information, see [mysql.rds_replica_status](https://mariadb.com/kb/en/mysql-rds_replica_status/).

• **SHOW RELAYLOG EVENTS command not supported** – In versions of MariaDB before version 10.5, the SHOW RELAYLOG EVENTS command required the REPLICATION SLAVE privilege. In MariaDB version 10.5, this command requires the REPLICATION REPLICA ADMIN privilege. This new privilege isn't granted to the RDS master user.

• **New default values for parameters** – The following parameters have new default values for MariaDB version 10.5 DB instances:
  - The default value of the `max_connections` parameter has changed to `LEAST({DBInstanceClassMemory/25165760},12000)`. For information about the LEAST parameter function, see [DB parameter functions](https://mariadb.com/kb/en/db-parameter-functions/).
  - The default value of the `innodb_adaptive_hash_index` parameter has changed to `OFF` (0).
  - The default value of the `innodb_checksum_algorithm` parameter has changed to `full_crc32`.
  - The default value of the `innodb_log_file_size` parameter has changed to 2 GB.

For a list of all MariaDB 10.5 features and their documentation, see [Changes and improvements in MariaDB 10.5](https://mariadb.com/kb/en/changes-and-improvements-in-mariadb-10-5/) and [Release notes - MariaDB 10.5 series](https://mariadb.com/kb/en/release-notes-mariadb-10-5-series/) on the MariaDB website.

For a list of unsupported features, see [MariaDB features not supported by Amazon RDS](https://aws.amazon.com/rds/mariadb/unsupported-features/). (p. 1279)

**MariaDB 10.4 support on Amazon RDS**

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.4 or later:

• **User account security enhancements** – Password expiration and account locking improvements

• **Optimizer enhancements** – Optimizer trace feature

• **InnoDB enhancements** – Instant DROP COLUMN support and instant VARCHAR extension for ROW_FORMAT=DYNAMIC and ROW_FORMAT=COMPACT

• **New parameters** – Including `tcp_nodelay`, `tls_version`, and `gtid_cleanup_batch_size`

For a list of all MariaDB 10.4 features and their documentation, see [Changes and improvements in MariaDB 10.4](https://mariadb.com/kb/en/changes-and-improvements-in-mariadb-10-4/) and [Release notes - MariaDB 10.4 series](https://mariadb.com/kb/en/release-notes-mariadb-10-4-series/) on the MariaDB website.
For a list of unsupported features, see MariaDB features not supported by Amazon RDS (p. 1279).

MariaDB 10.3 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.3 or later:

- **Oracle compatibility** – PL/SQL compatibility parser, sequences, INTERSECT and EXCEPT to complement UNION, new TYPE OF and ROW TYPE OF declarations, and invisible columns
- **Temporal data processing** – System versioned tables for querying of past and present states of the database
- **Flexibility** – User-defined aggregates, storage-independent column compression, and proxy protocol support to relay the client IP address to the server
- **Manageability** – Instant ADD COLUMN operations and fast-fail data definition language (DDL) operations

For a list of all MariaDB 10.3 features and their documentation, see Changes & improvements in MariaDB 10.3 and Release notes - MariaDB 10.3 series on the MariaDB website.

For a list of unsupported features, see MariaDB features not supported by Amazon RDS (p. 1279).

Supported storage engines for MariaDB on Amazon RDS

RDS for MariaDB supports the following storage engines.

**Topics**

- The InnoDB storage engine (p. 1277)
- The MyRocks storage engine (p. 1277)

Other storage engines aren’t currently supported by RDS for MariaDB.

The InnoDB storage engine

Although MariaDB supports multiple storage engines with varying capabilities, not all of them are optimized for recovery and data durability. InnoDB is the recommended storage engine for MariaDB DB instances on Amazon RDS. Amazon RDS features such as point-in-time restore and snapshot restore require a recoverable storage engine and are supported only for the recommended storage engine for the MariaDB version.

For more information, see InnoDB.

The MyRocks storage engine

The MyRocks storage engine is available in RDS for MariaDB version 10.6 and higher. Before using the MyRocks storage engine in a production database, we recommend that you perform thorough benchmarking and testing to verify any potential benefits over InnoDB for your use case.

The default parameter group for MariaDB version 10.6 includes MyRocks parameters. For more information, see Parameters for MariaDB (p. 1354) and Working with parameter groups (p. 347).

To create a table that uses the MyRocks storage engine, specify ENGINE=RocksDB in the CREATE TABLE statement. The following example creates a table that uses the MyRocks storage engine.
CREATE TABLE test (a INT NOT NULL, b CHAR(10)) ENGINE=RocksDB;

We strongly recommend that you don't run transactions that span both InnoDB and MyRocks tables. MariaDB doesn't guarantee ACID (atomicity, consistency, isolation, durability) for transactions across storage engines. Although it is possible to have both InnoDB and MyRocks tables in a DB instance, we don't recommend this approach except during a migration from one storage engine to the other. When both InnoDB and MyRocks tables exist in a DB instance, each storage engine has its own buffer pool, which might cause performance to degrade.

MyRocks doesn't support SERIALIZABLE isolation or gap locks. So, generally you can't use MyRocks with statement-based replication. For more information, see MyRocks and Replication.

Currently, you can modify only the following MyRocks parameters:

- rocksdb_block_cache_size
- rocksdb_bulk_load
- rocksdb_bulk_load_size
- rocksdb_deadlock_detect
- rocksdb_deadlock_detect_depth
- rocksdb_max_latest_deadlocks

The MyRocks storage engine and the InnoDB storage engine can compete for memory based on the settings for the rocksdb_block_cache_size and innodb_buffer_pool_size parameters. In some cases, you might only intend to use the MyRocks storage engine on a particular DB instance. If so, we recommend setting the innodb_buffer_pool_size minimal parameter to a minimal value and setting the rocksdb_block_cache_size as high as possible.

You can access MyRocks log files by using the DescribeDBLogFiles and DownloadDBLogFilePortion operations.

For more information about MyRocks, see MyRocks on the MariaDB website.

Cache warming for MariaDB on Amazon RDS

InnoDB cache warming can provide performance gains for your MariaDB DB instance by saving the current state of the buffer pool when the DB instance is shut down, and then reloading the buffer pool from the saved information when the DB instance starts up. This approach bypasses the need for the buffer pool to “warm up” from normal database use and instead preloads the buffer pool with the pages for known common queries. For more information on cache warming, see Dumping and restoring the buffer pool in the MariaDB documentation.

Cache warming is enabled by default on MariaDB 10.3 and higher DB instances. To enable it, set the innodb_buffer_pool_dump_at_shutdown and innodb_buffer_pool_load_at_startup parameters to 1 in the parameter group for your DB instance. Changing these parameter values in a parameter group affects all MariaDB DB instances that use that parameter group. To enable cache warming for specific MariaDB DB instances, you might need to create a new parameter group for those DB instances. For information on parameter groups, see Working with parameter groups (p. 347).

Cache warming primarily provides a performance benefit for DB instances that use standard storage. If you use PIOPS storage, you don’t commonly see a significant performance benefit.

Important

If your MariaDB DB instance doesn’t shut down normally, such as during a failover, then the buffer pool state isn’t saved to disk. In this case, MariaDB loads whatever buffer pool file is available when the DB instance is restarted. No harm is done, but the restored buffer pool might
not reflect the most recent state of the buffer pool before the restart. To ensure that you have
a recent state of the buffer pool available to warm the cache on startup, we recommend that
you periodically dump the buffer pool "on demand." You can dump or load the buffer pool on
demand.
You can create an event to dump the buffer pool automatically and at a regular interval. For
example, the following statement creates an event named periodic_buffer_pool_dump that
dumps the buffer pool every hour.

```
CREATE EVENT periodic_buffer_pool_dump
  ON SCHEDULE EVERY 1 HOUR
  DO CALL mysql.rds_innodb_buffer_pool_dump_now();
```

For more information, see Events in the MariaDB documentation.

**Dumping and loading the buffer pool on demand**

You can save and load the cache on demand using the following stored procedures:

- To dump the current state of the buffer pool to disk, call the
  `mysql.rds_innodb_buffer_pool_dump_now` stored procedure.
- To load the saved state of the buffer pool from disk, call the
  `mysql.rds_innodb_buffer_pool_load_now` stored procedure.
- To cancel a load operation in progress, call the `mysql.rds_innodb_buffer_pool_load_abort` stored procedure.

**MariaDB features not supported by Amazon RDS**

The following MariaDB features are not supported on Amazon RDS:

- S3 storage engine
- Authentication plugin – GSSAPI
- Authentication plugin – Unix Socket
- AWS Key Management encryption plugin
- Delayed replication for MariaDB versions lower than 10.6
- Native MariaDB encryption at rest for InnoDB and Aria

You can enable encryption at rest for a MariaDB DB instance by following the instructions in
Encrypting Amazon RDS resources.

- HandlerSocket
- JSON table type for MariaDB versions lower than 10.6
- MariaDB ColumnStore
- MariaDB Galera Cluster
- Multisource replication
- MyRocks storage engine for MariaDB versions lower than 10.6
- Password validation plugin, `simple_password_check`, and `cracklib_password_check`
- Spider storage engine
- Sphinx storage engine
- TokuDB storage engine
- Storage engine-specific object attributes, as described in Engine-defined new Table/Field/Index
  attributes in the MariaDB documentation
- Table and tablespace encryption
• Hashicorp Key Management plugin
• Running two upgrades in parallel

To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and it restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application. Amazon RDS doesn't allow direct host access to a DB instance by using Telnet, Secure Shell (SSH), or Windows Remote Desktop Connection.
MariaDB on Amazon RDS versions

For MariaDB, version numbers are organized as version X.Y.Z. In Amazon RDS terminology, X.Y denotes the major version, and Z is the minor version number. For Amazon RDS implementations, a version change is considered major if the major version number changes, for example going from version 10.5 to 10.6. A version change is considered minor if only the minor version number changes, for example going from version 10.6.10 to 10.6.12.

Topics

• Supported MariaDB minor versions on Amazon RDS (p. 1281)
• Supported MariaDB major versions on Amazon RDS (p. 1283)
• MariaDB 10.3 RDS end of standard support (p. 1283)
• MariaDB 10.2 RDS end of standard support (p. 1284)
• Deprecated versions for Amazon RDS for MariaDB (p. 1284)

Supported MariaDB minor versions on Amazon RDS

Amazon RDS currently supports the following minor versions of MariaDB.

Note
Dates with only a month and a year are approximate and are updated with an exact date when it's known.

<table>
<thead>
<tr>
<th>MariaDB engine version</th>

<tr>
<td>10.5.21</td>
<td>7 June 2023</td>
<td>22 June 2023</td>
<td>September 2024</td>
</tr>
<tr>
<td>10.5.20</td>
<td>10 May 2023</td>
<td>15 June 2023</td>
<td>September 2024</td>
</tr>
</tbody>
</table>
You can specify any currently supported MariaDB version when creating a new DB instance. You can specify the major version (such as MariaDB 10.5), and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified. To see a list of supported versions, as well as defaults for newly created DB instances, use the `describe-db-engine-versions` AWS CLI command.

For example, to list the supported engine versions for RDS for MariaDB, run the following CLI command:

```
```

The default MariaDB version might vary by AWS Region. To create a DB instance with a specific minor version, specify the minor version during DB instance creation. You can determine the default minor version for an AWS Region using the following AWS CLI command:

```
```
Replace `major-engine-version` with the major engine version, and replace `region` with the AWS Region. For example, the following AWS CLI command returns the default MariaDB minor engine version for the 10.5 major version and the US West (Oregon) AWS Region (us-west-2):

```
```

### Supported MariaDB major versions on Amazon RDS

RDS for MariaDB major versions remain available at least until community end of life for the corresponding community version. You can use the following dates to plan your testing and upgrade cycles. If Amazon extends support for an RDS for MariaDB version for longer than originally stated, we plan to update this table to reflect the later date.

**Note**

Dates with only a month and a year are approximate and are updated with an exact date when it’s known.

<table>
<thead>
<tr>
<th>MariaDB major version</th>
<th>Community release date</th>
<th>RDS release date</th>

### MariaDB 10.3 RDS end of standard support

On October 23, 2023, Amazon RDS is starting the RDS end of standard support process for MariaDB version 10.3 using the following schedule, which includes upgrade recommendations. We recommend that you upgrade all MariaDB 10.3 DB instances to MariaDB 10.6 as soon as possible. For more information, see [Upgrading the MariaDB DB engine](p. 1305).

<table>
<thead>
<tr>
<th>Action or recommendation</th>
<th>Dates</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>We recommend that you manually upgrade MariaDB 10.3 DB instances to the version of your choice. You can upgrade directly to MariaDB version 10.6 or higher.</td>
<td>Now–October 23, 2023</td>
<td></td>
</tr>
<tr>
<td>We recommend that you manually upgrade MariaDB 10.3 snapshots to the version of your choice.</td>
<td>Now–October 23, 2023</td>
<td></td>
</tr>
<tr>
<td>You can no longer create new MariaDB 10.3 DB instances. You can still create read replicas of existing MariaDB 10.3 DB instances and change them from Single-AZ deployments to Multi-AZ deployments.</td>
<td>August 23, 2023</td>
<td></td>
</tr>
</tbody>
</table>
### MariaDB 10.2 RDS end of standard support

On October 15, 2022, Amazon RDS is starting the RDS end of standard support process for MariaDB version 10.2 using the following schedule, which includes upgrade recommendations. We recommend that you upgrade all MariaDB 10.2 DB instances to MariaDB 10.3 or higher as soon as possible. For more information, see Upgrading the MariaDB DB engine (p. 1305).

<table>
<thead>
<tr>
<th>Action or recommendation</th>
<th>Dates</th>
</tr>
</thead>
<tbody>
<tr>
<td>We recommend that you upgrade MariaDB 10.2 DB instances manually to the version of your choice. You can upgrade directly to MariaDB version 10.3 or 10.6.</td>
<td>Now–October 15, 2022</td>
</tr>
<tr>
<td>We recommend that you upgrade MariaDB 10.2 snapshots manually to the version of your choice.</td>
<td>Now–October 15, 2022</td>
</tr>
<tr>
<td>You can no longer create new MariaDB 10.2 DB instances. You can still create read replicas of existing MariaDB 10.2 DB instances and change them from Single-AZ deployments to Multi-AZ deployments.</td>
<td>July 15, 2022</td>
</tr>
<tr>
<td>Amazon RDS starts automatic upgrades of your MariaDB 10.2 DB instances to version 10.3.</td>
<td>October 15, 2022</td>
</tr>
<tr>
<td>Amazon RDS starts automatic upgrades to version 10.3 for any MariaDB 10.2 DB instances restored from snapshots.</td>
<td>October 15, 2022</td>
</tr>
<tr>
<td>Amazon RDS automatically upgrades any remaining MariaDB 10.2 DB instances to version 10.3 whether or not they are in a scheduled maintenance window.</td>
<td>January 15, 2023</td>
</tr>
</tbody>
</table>

For more information about Amazon RDS for MariaDB 10.2 RDS end of standard support, see Announcement: Amazon Relational Database Service (Amazon RDS) for MariaDB 10.2 End-of-Life date is October 15, 2022.

### Deprecated versions for Amazon RDS for MariaDB

Amazon RDS for MariaDB version 10.0, 10.1, and 10.2 are deprecated.

For information about the Amazon RDS depreciation policy for MariaDB, see Amazon RDS FAQs.
Connecting to a DB instance running the MariaDB database engine

After Amazon RDS provisions your DB instance, you can use any standard MariaDB client application or utility to connect to the instance. In the connection string, you specify the Domain Name System (DNS) address from the DB instance endpoint as the host parameter. You also specify the port number from the DB instance endpoint as the port parameter.

You can connect to an Amazon RDS for MariaDB DB instance by using tools like the MySQL command-line client. For more information on using the MySQL command-line client, see [mysql command-line client](#) in the MariaDB documentation. One GUI-based application that you can use to connect is Heidi. For more information, see the [Download HeidiSQL](#) page. For information about installing MySQL (including the MySQL command-line client), see [Installing and upgrading MySQL](#).

Most Linux distributions include the MariaDB client instead of the Oracle MySQL client. To install the MySQL command-line client on Amazon Linux 2023, run the following command:

```bash
sudo dnf install mariadb105
```

To install the MySQL command-line client on Amazon Linux 2, run the following command:

```bash
sudo yum install mariadb
```

To install the MySQL command-line client on most DEB-based Linux distributions, run the following command.

```bash
apt-get install mariadb-client
```

To check the version of your MySQL command-line client, run the following command.

```bash
mysql --version
```

To read the MySQL documentation for your current client version, run the following command.

```bash
man mysql
```

To connect to a DB instance from outside of a virtual private cloud (VPC) based on Amazon VPC, the DB instance must be publicly accessible. Also, access must be granted using the inbound rules of the DB instance's security group, and other requirements must be met. For more information, see [Can't connect to Amazon RDS DB instance](#).

You can use SSL encryption on connections to a MariaDB DB instance. For information, see [Using SSL/TLS with a MariaDB DB instance](#).

**Topics**

- [Connecting from the MySQL command-line client (unencrypted)](#)
- [Troubleshooting connections to your MariaDB DB instance](#)
Finding the connection information for a MariaDB DB instance

The connection information for a DB instance includes its endpoint, port, and a valid database user, such as the master user. For example, suppose that an endpoint value is mydb.123456789012.us-east-1.rds.amazonaws.com. In this case, the port value is 3306, and the database user is admin. Given this information, you specify the following values in a connection string:

- For host or host name or DNS name, specify mydb.123456789012.us-east-1.rds.amazonaws.com.
- For port, specify 3306.
- For user, specify admin.

To connect to a DB instance, use any client for the MariaDB DB engine. For example, you might use the MySQL command-line client or MySQL Workbench.

To find the connection information for a DB instance, you can use the AWS Management Console, the AWS Command Line Interface (AWS CLI) describe-db-instances command, or the Amazon RDS API DescribeDBInstances operation to list its details.

Console

To find the connection information for a DB instance in the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases to display a list of your DB instances.
3. Choose the name of the MariaDB DB instance to display its details.
4. On the Connectivity & security tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.
5. If you need to find the master user name, choose the Configuration tab and view the Master username value.

**AWS CLI**

To find the connection information for a MariaDB DB instance by using the AWS CLI, call the `describe-db-instances` command. In the call, query for the DB instance ID, endpoint, port, and master user name.
For Linux, macOS, or Unix:

```bash
aws rds describe-db-instances \
   --filters "Name=engine,Values=mariadb" \
   --query "*[].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

For Windows:

```bash
aws rds describe-db-instances ^
   --filters "Name=engine,Values=mariadb" ^
   --query "*[].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

Your output should be similar to the following.

```
[
  [
    "mydb1",
    "mydb1.123456789012.us-east-1.rds.amazonaws.com",
    3306,
    "admin"
  ],
  [
    "mydb2",
    "mydb2.123456789012.us-east-1.rds.amazonaws.com",
    3306,
    "admin"
  ]
]
```

**RDS API**

To find the connection information for a DB instance by using the Amazon RDS API, call the `DescribeDBInstances` operation. In the output, find the values for the endpoint address, endpoint port, and master user name.

**Connecting from the MySQL command-line client (unencrypted)**

**Important**

Only use an unencrypted MySQL connection when the client and server are in the same VPC and the network is trusted. For information about using encrypted connections, see Connecting from the MySQL command-line client with SSL/TLS (encrypted) (p. 1292).

To connect to a DB instance using the MySQL command-line client, enter the following command at a command prompt on a client computer. Doing this connects you to a database on a MariaDB DB instance. Substitute the DNS name (endpoint) for `<endpoint>` and the master user name that you used for `<mymasteruser>`. Provide the master password that you used when prompted for a password.

```bash
mysql -h <endpoint> -P 3306 -u <mymasteruser> -p
```

After you enter the password for the user, you see output similar to the following.

```
Welcome to the MariaDB monitor. Commands end with ; or \g.
Your MariaDB connection id is 31
Server version: 10.6.10-MariaDB-log Source distribution
```
Troubleshooting connections to your MariaDB DB instance

Two common causes of connection failures to a new DB instance are the following:

- The DB instance was created using a security group that doesn't authorize connections from the device or Amazon EC2 instance where the MariaDB application or utility is running. The DB instance must have a VPC security group that authorizes the connections. For more information, see Amazon VPC VPCs and Amazon RDS (p. 2705).
  
  You can add or edit an inbound rule in the security group. For Source, choose My IP. This allows access to the DB instance from the IP address detected in your browser.

- The DB instance was created using the default port of 3306, and your company has firewall rules blocking connections to that port from devices in your company network. To fix this failure, recreate the instance with a different port.

For more information on connection issues, see Can't connect to Amazon RDS DB instance (p. 2744).
Securing MariaDB DB instance connections

You can manage the security of your MariaDB DB instances.

Topics

- MariaDB security on Amazon RDS (p. 1290)
- Encrypting client connections to MariaDB DB instances with SSL/TLS (p. 1291)
- Updating applications to connect to MariaDB instances using new SSL/TLS certificates (p. 1293)

MariaDB security on Amazon RDS

Security for MariaDB DB instances is managed at three levels:

- AWS Identity and Access Management controls who can perform Amazon RDS management actions on DB instances. When you connect to AWS using IAM credentials, your IAM account must have IAM policies that grant the permissions required to perform Amazon RDS management operations. For more information, see Identity and access management for Amazon RDS (p. 2623).

- When you create a DB instance, you use a VPC security group to control which devices and Amazon EC2 instances can open connections to the endpoint and port of the DB instance. These connections can be made using Secure Socket Layer (SSL) and Transport Layer Security (TLS). In addition, firewall rules at your company can control whether devices running at your company can open connections to the DB instance.

- Once a connection has been opened to a MariaDB DB instance, authentication of the login and permissions are applied the same way as in a stand-alone instance of MariaDB. Commands such as CREATE USER, RENAME USER, GRANT, REVOKE, and SET PASSWORD work just as they do in stand-alone databases, as does directly modifying database schema tables.

When you create an Amazon RDS DB instance, the master user has the following default privileges:

- alter
- alter routine
- create
- create routine
- create temporary tables
- create user
- create view
- delete
- drop
- event
- execute
- grant option
- index
- insert
- lock tables
- process
- references
- reload
This privilege is limited on MariaDB DB instances. It doesn't grant access to the FLUSH LOGS or FLUSH TABLES WITH READ LOCK operations.

- replication client
- replication slave
- select
- show databases
- show view
- trigger
- update

For more information about these privileges, see User account management in the MariaDB documentation.

**Note**
Although you can delete the master user on a DB instance, we don't recommend doing so. To recreate the master user, use the ModifyDBInstance API or the modify-db-instance AWS CLI and specify a new master user password with the appropriate parameter. If the master user does not exist in the instance, the master user is created with the specified password.

To provide management services for each DB instance, the rdsadmin user is created when the DB instance is created. Attempting to drop, rename, change the password for, or change privileges for the rdsadmin account results in an error.

To allow management of the DB instance, the standard kill and kill_query commands have been restricted. The Amazon RDS commands mysql.rds_kill, mysql.rds_kill_query, and mysql.rds_kill_query_id are provided for use in MariaDB and also MySQL so that you can end user sessions or queries on DB instances.

### Encrypting client connections to MariaDB DB instances with SSL/TLS

Secure Sockets Layer (SSL) is an industry-standard protocol for securing network connections between client and server. After SSL version 3.0, the name was changed to Transport Layer Security (TLS). Amazon RDS supports SSL/TLS encryption for MariaDB DB instances. Using SSL/TLS, you can encrypt a connection between your application client and your MariaDB DB instance. SSL/TLS support is available in all AWS Regions.

**Topics**
- Using SSL/TLS with a MariaDB DB instance (p. 1291)
- Requiring SSL/TLS for all connections to a MariaDB DB instance (p. 1292)
- Connecting from the MySQL command-line client with SSL/TLS (encrypted) (p. 1292)

### Using SSL/TLS with a MariaDB DB instance

Amazon RDS creates an SSL/TLS certificate and installs the certificate on the DB instance when Amazon RDS provisions the instance. These certificates are signed by a certificate authority. The SSL/TLS certificate includes the DB instance endpoint as the Common Name (CN) for the SSL/TLS certificate to guard against spoofing attacks.

An SSL/TLS certificate created by Amazon RDS is the trusted root entity and should work in most cases but might fail if your application does not accept certificate chains. If your application does not accept certificate chains, you might need to use an intermediate certificate to connect to your AWS Region. For
example, you must use an intermediate certificate to connect to the AWS GovCloud (US) Regions using
SSL/TLS.

For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB
instance (p. 2608). For more information about using SSL/TLS with MySQL, see Updating applications to
connect to MariaDB instances using new SSL/TLS certificates (p. 1293).

Amazon RDS for MariaDB supports Transport Layer Security (TLS) versions 1.0, 1.1, 1.2, and 1.3 for all
MariaDB versions.

You can require SSL/TLS connections for specific users accounts. For example, you can use one of the
following statements, depending on your MariaDB version, to require SSL/TLS connections on the user
account encrypted_user.

Use the following statement.

```
ALTER USER 'encrypted_user'@'%' REQUIRE SSL;
```

For more information on SSL/TLS connections with MariaDB, see Securing Connections for Client and
Server in the MariaDB documentation.

**Requiring SSL/TLS for all connections to a MariaDB DB instance**

Use the require_secure_transport parameter to require that all user connections to your MariaDB
DB instance use SSL/TLS. By default, the require_secure_transport parameter is set to OFF. You
can set the require_secure_transport parameter to ON to require SSL/TLS for connections to your
DB instance.

**Note**
The require_secure_transport parameter is only supported for MariaDB version 10.5 and
higher.

You can set the require_secure_transport parameter value by updating the DB parameter group
for your DB instance. You don't need to reboot your DB instance for the change to take effect.

When the require_secure_transport parameter is set to ON for a DB instance, a database client
can connect to it if it can establish an encrypted connection. Otherwise, an error message similar to the
following is returned to the client:

```
ERROR 1045 (28000): Access denied for user 'USER'@'localhost' (using password: YES | NO)
```

For more information about setting parameters, see Modifying parameters in a DB parameter group (p. 352).

For more information about the require_secure_transport parameter, see the MariaDB
documentation.

**Connecting from the MySQL command-line client with SSL/TLS (encrypted)**

The mysql client program parameters are slightly different if you are using the MySQL 5.7 version, the
MySQL 8.0 version, or the MariaDB version.

To find out which version you have, run the mysql command with the --version option. In the
following example, the output shows that the client program is from MariaDB.

```
$ mysql --version
mysql Ver 15.1 Distrib 10.5.15-MariaDB, for osx10.15 (x86_64) using readline 5.1
```
Most Linux distributions, such as Amazon Linux, CentOS, SUSE, and Debian have replaced MySQL with MariaDB, and the mysql version in them is from MariaDB.

To connect to your DB instance using SSL/TLS, follow these steps:

**To connect to a DB instance with SSL/TLS using the MySQL command-line client**

1. **Download a root certificate that works for all AWS Regions.**
   
   For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2608).

2. **Use a MySQL command-line client to connect to a DB instance with SSL/TLS encryption.** For the `-h` parameter, substitute the DNS name (endpoint) for your DB instance. For the `--ssl-ca` parameter, substitute the SSL/TLS certificate file name. For the `-P` parameter, substitute the port for your DB instance. For the `-u` parameter, substitute the user name of a valid database user, such as the master user. Enter the master user password when prompted.

   The following example shows how to launch the client using the `--ssl-ca` parameter using the MariaDB client:

   ```
   mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl -P 3306 -u myadmin -p
   ```

   To require that the SSL/TLS connection verifies the DB instance endpoint against the endpoint in the SSL/TLS certificate, enter the following command:

   ```
   mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl-verify-server-cert -P 3306 -u myadmin -p
   ```

   The following example shows how to launch the client using the `--ssl-ca` parameter using the MySQL 5.7 client or later:

   ```
   mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl-mode=REQUIRED -P 3306 -u myadmin -p
   ```

3. **Enter the master user password when prompted.**

   You should see output similar to the following.

   Welcome to the MariaDB monitor. Commands end with ; or \g.
   Your MariaDB connection id is 31
   Server version: 10.6.10-MariaDB-log Source distribution
   Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.
   Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.
   MariaDB [(none)]>

**Updating applications to connect to MariaDB instances using new SSL/TLS certificates**

As of January 13, 2023, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.
This topic can help you to determine whether your applications require certificate verification to connect to your DB instances.

**Note**
Some applications are configured to connect to MariaDB only if they can successfully verify the certificate on the server. For such applications, you must update your client application trust stores to include the new CA certificates.

You can specify the following SSL modes: disabled, preferred, and required. When you use the preferred SSL mode and the CA certificate doesn't exist or isn't up to date, the connection falls back to not using SSL and still connects successfully.

We recommend avoiding preferred mode. In preferred mode, if the connection encounters an invalid certificate, it stops using encryption and proceeds unencrypted.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate (p. 2613). For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2608). For information about using SSL/TLS with MariaDB DB instances, see Using SSL/TLS with a MariaDB DB instance (p. 1291).

**Topics**
- Determining whether a client requires certificate verification in order to connect (p. 1294)
- Updating your application trust store (p. 1295)
- Example Java code for establishing SSL connections (p. 1296)

**Determining whether a client requires certificate verification in order to connect**

You can check whether JDBC clients and MySQL clients require certificate verification to connect.

**JDBC**

The following example with MySQL Connector/J 8.0 shows one way to check an application's JDBC connection properties to determine whether successful connections require a valid certificate. For more information on all of the JDBC connection options for MySQL, see Configuration properties in the MySQL documentation.

When using the MySQL Connector/J 8.0, an SSL connection requires verification against the server CA certificate if your connection properties have sslMode set to VERIFY_CA or VERIFY_IDENTITY, as in the following example.

```java
Properties properties = new Properties();
properties.setProperty("sslMode", "VERIFY_IDENTITY");
properties.put("user", DB_USER);
properties.put("password", DB_PASSWORD);
```

**Note**
If you use either the MySQL Java Connector v5.1.38 or later, or the MySQL Java Connector v8.0.9 or later to connect to your databases, even if you haven't explicitly configured your applications to use SSL/TLS when connecting to your databases, these client drivers default to using SSL/TLS. In addition, when using SSL/TLS, they perform partial certificate verification and fail to connect if the database server certificate is expired.
Specify a password other than the prompt shown here as a security best practice.

**MySQL**

The following examples with the MySQL Client show two ways to check a script’s MySQL connection to determine whether successful connections require a valid certificate. For more information on all of the connection options with the MySQL Client, see [Client-side configuration for encrypted connections](#) in the MySQL documentation.

When using the MySQL 5.7 or MySQL 8.0 Client, an SSL connection requires verification against the server CA certificate if for the `--ssl-mode` option you specify `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```bash
code
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem --ssl-mode=VERIFY_CA
```

When using the MySQL 5.6 Client, an SSL connection requires verification against the server CA certificate if you specify the `--ssl-verify-server-cert` option, as in the following example.

```bash
code
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem --ssl-verify-server-cert
```

**Updating your application trust store**

For information about updating the trust store for MySQL applications, see [Using TLS/SSL with MariaDB Connector/J](#) in the MariaDB documentation.

For information about downloading the root certificate, see [Using SSL/TLS to encrypt a connection to a DB instance (p. 2608)](#).

For sample scripts that import certificates, see [Sample script for importing certificates into your trust store (p. 2620)](#).

**Note**

When you update the trust store, you can retain older certificates in addition to adding the new certificates.

If you are using the MariaDB Connector/J JDBC driver in an application, set the following properties in the application.

```java
code
System.setProperty("javax.net.ssl.trustStore", certs);
System.setProperty("javax.net.ssl.trustStorePassword", "password");
```

When you start the application, set the following properties.

```java
code
java -Djavax.net.ssl.trustStore=/path_to_truststore/MyTruststore.jks -Djavax.net.ssl.trustStorePassword=my_truststore_password com.companyName.MyApplication
```
Note
Specify passwords other than the prompts shown here as a security best practice.

Example Java code for establishing SSL connections

The following code example shows how to set up the SSL connection using JDBC.

```java
private static final String DB_USER = "admin";
private static final String DB_USER = "user name";
private static final String DB_PASSWORD = "password";
private static final String KEY_STORE_FILE_PATH = "file-path-to-keystore";
private static final String KEY_STORE_PASS = "keystore-password";

public static void main(String[] args) throws Exception {
    Class.forName("org.mariadb.jdbc.Driver");
    System.setProperty("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
    System.setProperty("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);
    Properties properties = new Properties();
    properties.put("user", DB_USER);
    properties.put("password", DB_PASSWORD);
    Connection connection = DriverManager.getConnection("jdbc:mysql://ssl-mariadb-public.cni62e2e7kwh.us-east-1.rds.amazonaws.com:3306?useSSL=true", properties);
    Statement stmt = connection.createStatement();
    ResultSet rs = stmt.executeQuery("SELECT 1 from dual");
    return;
}
```

Important
After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-rsa2048-g1 certificates. For instructions, see step 3 in Updating your CA certificate by modifying your DB instance (p. 2614).
Specify a password other than the prompt shown here as a security best practice.
You can achieve faster query processing for RDS for MariaDB with Amazon RDS Optimized Reads. An RDS for MariaDB DB instance that uses RDS Optimized Reads can achieve up to 2x faster query processing compared to a DB instance that doesn't use it.

Topics

- Overview of RDS Optimized Reads (p. 1297)
- Use cases for RDS Optimized Reads (p. 1297)
- Best practices for RDS Optimized Reads (p. 1298)
- Using RDS Optimized Reads (p. 1298)
- Monitoring DB instances that use RDS Optimized Reads (p. 1299)
- Limitations for RDS Optimized Reads (p. 1299)

Overview of RDS Optimized Reads

When you use an RDS for MariaDB DB instance that has RDS Optimized Reads turned on, your DB instance achieves faster query performance through the use of an instance store. An instance store provides temporary block-level storage for your DB instance. The storage is located on Non-Volatile Memory Express (NVMe) solid state drives (SSDs) that are physically attached to the host server. This storage is optimized for low latency, high random I/O performance, and high sequential read throughput.

RDS Optimized Reads is turned on by default when a DB instance uses a DB instance class with an instance store, such as db.m5d or db.m6gd. With RDS Optimized Reads, some temporary objects are stored on the instance store. These temporary objects include internal temporary files, internal on-disk temp tables, memory map files, and binary log (binlog) cache files. For more information about the instance store, see Amazon EC2 instance store in the Amazon Elastic Compute Cloud User Guide for Linux Instances.

The workloads that generate temporary objects in MariaDB for query processing can take advantage of the instance store for faster query processing. This type of workload includes queries involving sorts, hash aggregations, high-load joins, Common Table Expressions (CTEs), and queries on unindexed columns. These instance store volumes provide higher IOPS and performance, regardless of the storage configurations used for persistent Amazon EBS storage. Because RDS Optimized Reads offloads operations on temporary objects to the instance store, the input/output operations per second (IOPS) or throughput of the persistent storage (Amazon EBS) can now be used for operations on persistent objects. These operations include regular data file reads and writes and background engine operations, such as flushing and insert buffer merges.

Note

Both manual and automated RDS snapshots contain only the engine files for persistent objects. The temporary objects created in the instance store aren't included in RDS snapshots.

Use cases for RDS Optimized Reads

If you have workloads that rely heavily on temporary objects, such as internal tables or files, for their query execution, then you can benefit from turning on RDS Optimized Reads. The following use cases are candidates for RDS Optimized Reads:

- Applications that run analytical queries with complex common table expressions (CTEs), derived tables, and grouping operations
• Read replicas that serve heavy read traffic with unoptimized queries
• Applications that run on-demand or dynamic reporting queries that involve complex operations, such as queries with GROUP BY and ORDER BY clauses
• Workloads that use internal temporary tables for query processing

You can monitor the engine status variable `created_tmp_disk_tables` to determine the number of disk-based temporary tables created on your DB instance.

• Applications that create large temporary tables, either directly or in procedures, to store intermediate results
• Database queries that perform grouping or ordering on non-indexed columns

Best practices for RDS Optimized Reads

Use the following best practices for RDS Optimized Reads:

• Add retry logic for read-only queries in case they fail because the instance store is full during the execution.
• Monitor the storage space available on the instance store with the CloudWatch metric `FreeLocalStorage`. If the instance store is reaching its limit because of workload on the DB instance, modify the DB instance to use a larger DB instance class.
• When your DB instance has sufficient memory but is still reaching the storage limit on the instance store, increase the `binlog_cache_size` value to maintain the session-specific binlog entries in memory. This configuration prevents writing the binlog entries to temporary binlog cache files on disk.

The `binlog_cache_size` parameter is session-specific. You can change the value for each new session. The setting for this parameter can increase the memory utilization on the DB instance during peak workload. Therefore, consider increasing the parameter value based on the workload pattern of your application and available memory on the DB instance.

• Use the default value of MIXED for the `binlog_format`. Depending on the size of the transactions, setting `binlog_format` to ROW can result in large binlog cache files on the instance store.
• Avoid performing bulk changes in a single transaction. These types of transactions can generate large binlog cache files on the instance store and can cause issues when the instance store is full. Consider splitting writes into multiple small transactions to minimize storage use for binlog cache files.

Using RDS Optimized Reads

When you provision an RDS for MariaDB DB instance with one of the following DB instance classes in a Single-AZ DB instance deployment or Multi-AZ DB instance deployment, the DB instance automatically uses RDS Optimized Reads.

To turn on RDS Optimized Reads, do one of the following:

• Create an RDS for MariaDB DB instance using one of these DB instance classes. For more information, see [Creating an Amazon RDS DB instance](p. 300).
• Modify an existing RDS for MariaDB DB instance to use one of these DB instance classes. For more information, see [Modifying an Amazon RDS DB instance](p. 401).

RDS Optimized Reads is available in all AWS Regions where one or more of the DB instance classes with local NVMe SSD storage are supported. For information about DB instance classes, see the section called "DB instance classes" (p. 11).
DB instance class availability differs for AWS Regions. To determine whether a DB instance class is supported in a specific AWS Region, see the section called “Determining DB instance class support in AWS Regions” (p. 68).

If you don’t want to use RDS Optimized Reads, modify your DB instance so that it doesn’t use a DB instance class that supports the feature.

**Monitoring DB instances that use RDS Optimized Reads**

You can monitor DB instances that use RDS Optimized Reads with the following CloudWatch metrics:

- FreeLocalStorage
- ReadIOPSLocalStorage
- ReadLatencyLocalStorage
- ReadThroughputLocalStorage
- WriteIOPSLocalStorage
- WriteLatencyLocalStorage
- WriteThroughputLocalStorage

These metrics provide data about available instance store storage, IOPS, and throughput. For more information about these metrics, see *Amazon CloudWatch instance-level metrics for Amazon RDS* (p. 806).

**Limitations for RDS Optimized Reads**

The following limitations apply to RDS Optimized Reads:

- RDS Optimized Reads is supported for the following RDS for MariaDB versions:
  - 10.11.4 and higher 10.11 versions
  - 10.6.7 and higher 10.6 versions
  - 10.5.16 and higher 10.5 versions
  - 10.4.25 and higher 10.4 versions

  For information about RDS for MariaDB versions, see *MariaDB on Amazon RDS versions* (p. 1281).

- You can’t change the location of temporary objects to persistent storage (Amazon EBS) on the DB instance classes that support RDS Optimized Reads.

- When binary logging is enabled on a DB instance, the maximum transaction size is limited by the size of the instance store. In MariaDB, any session that requires more storage than the value of binlog_cache_size writes transaction changes to temporary binlog cache files, which are created on the instance store.

- Transactions can fail when the instance store is full.
Improving write performance with Amazon RDS Optimized Writes for MariaDB

You can improve the performance of write transactions with Amazon RDS Optimized Writes for MariaDB. When your RDS for MariaDB database uses RDS Optimized Writes, it can achieve up to two times higher write transaction throughput.

Topics
- Overview of RDS Optimized Writes (p. 1300)
- Using RDS Optimized Writes (p. 1301)
- Limitations for RDS Optimized Writes (p. 1304)

Overview of RDS Optimized Writes

When you turn on Amazon RDS Optimized Writes, your RDS for MariaDB databases write only once when flushing data to durable storage without the need for the doublewrite buffer. The databases continue to provide ACID property protections for reliable database transactions, along with improved performance.

Relational databases, like MariaDB, provide the ACID properties of atomicity, consistency, isolation, and durability for reliable database transactions. To help provide these properties, MariaDB uses a data storage area called the doublewrite buffer that prevents partial page write errors. These errors occur when there is a hardware failure while the database is updating a page, such as in the case of a power outage. A MariaDB database can detect partial page writes and recover with a copy of the page in the doublewrite buffer. While this technique provides protection, it also results in extra write operations. For more information about the MariaDB doublewrite buffer, see InnoDB Doublewrite Buffer in the MariaDB documentation.

With RDS Optimized Writes turned on, RDS for MariaDB databases write only once when flushing data to durable storage without using the doublewrite buffer. RDS Optimized Writes is useful if you run write-heavy workloads on your RDS for MariaDB databases. Examples of databases with write-heavy workloads include ones that support digital payments, financial trading, and gaming applications.

These databases run on DB instance classes that use the AWS Nitro System. Because of the hardware configuration in these systems, the database can write 16-KiB pages directly to data files reliably and durably in one step. The AWS Nitro System makes RDS Optimized Writes possible.

You can set the new database parameter rds.optimized_writes to control the RDS Optimized Writes feature for RDS for MariaDB databases. Access this parameter in the DB parameter groups of RDS for MariaDB for the following versions:

- 10.11.4 and higher 10.11 versions
- 10.6.10 and higher 10.6 versions

Set the parameter using the following values:

- AUTO – Turn on RDS Optimized Writes if the database supports it. Turn off RDS Optimized Writes if the database doesn't support it. This setting is the default.
- OFF – Turn off RDS Optimized Writes even if the database supports it.

If you migrate an RDS for MariaDB database that is configured to use RDS Optimized Writes to a DB instance class that doesn't support the feature, RDS automatically turns off RDS Optimized Writes for the database.
When RDS Optimized Writes is turned off, the database uses the MariaDB doublewrite buffer.

To determine whether an RDS for MariaDB database is using RDS Optimized Writes, view the current value of the innodb_doublewrite parameter for the database. If the database is using RDS Optimized Writes, this parameter is set to FALSE (0).

## Using RDS Optimized Writes

You can turn on RDS Optimized Writes when you create an RDS for MariaDB database with the RDS console, the AWS CLI, or the RDS API. RDS Optimized Writes is turned on automatically when both of the following conditions apply during database creation:

- You specify a DB engine version and DB instance class that support RDS Optimized Writes.
- RDS Optimized Writes is supported for the following RDS for MariaDB versions:
  - 10.11.4 and higher 10.11 versions
  - 10.6.10 and higher 10.6 versions

For information about RDS for MariaDB versions, see [MariaDB on Amazon RDS versions](p. 1281).

- RDS Optimized Writes is supported for RDS for MariaDB databases that use the following DB instance classes:
  - db.m7g
  - db.m6g
  - db.m6gd
  - db.m6i
  - db.m5d
  - db.r7g
  - db.r6g
  - db.r6gd
  - db.r6i
  - db.r5
  - db.r5b
  - db.r5d
  - db.x2idn
  - db.x2iedn

For information about DB instance classes, see [the section called “DB instance classes”](p. 11).

DB instance class availability differs for AWS Regions. To determine whether a DB instance class is supported in a specific AWS Region, see [the section called “Determining DB instance class support in AWS Regions”](p. 68).

- In the parameter group associated with the database, the rds.optimized_writes parameter is set to AUTO. In default parameter groups, this parameter is always set to AUTO.

If you want to use a DB engine version and DB instance class that support RDS Optimized Writes, but you don't want to use this feature, then specify a custom parameter group when you create the database. In this parameter group, set the rds.optimized_writes parameter to OFF. If you want the database to use RDS Optimized Writes later, you can set the parameter to AUTO to turn it on. For information about creating custom parameter groups and setting parameters, see [Working with parameter groups](p. 347).

For information about creating a DB instance, see [Creating an Amazon RDS DB instance](p. 300).
Console

When you use the RDS console to create an RDS for MariaDB database, you can filter for the DB engine versions and DB instance classes that support RDS Optimized Writes. After you turn on the filters, you can choose from the available DB engine versions and DB instance classes.

To choose a DB engine version that supports RDS Optimized Writes, filter for the RDS for MariaDB DB engine versions that support it in **Engine version**, and then choose a version.

In the **Instance configuration** section, filter for the DB instance classes that support RDS Optimized Writes, and then choose a DB instance class.
After you make these selections, you can choose other settings that meet your requirements and finish creating the RDS for MariaDB database with the console.

**AWS CLI**

To create a DB instance by using the AWS CLI, use the `create-db-instance` command. Make sure the `--engine-version` and `--db-instance-class` values support RDS Optimized Writes. In addition, make sure the parameter group associated with the DB instance has the `rds.optimized_writes` parameter set to AUTO. This example associates the default parameter group with the DB instance.

**Example Creating a DB instance that uses RDS Optimized Writes**

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance \
  --db-instance-identifier mydbinstance \
  --engine mariadb \
  --engine-version 10.6.10 \
  --db-instance-class db.r5b.large \
  --manage-master-user-password \
  --master-username admin \
  --allocated-storage 200
```

For Windows:

```bash
aws rds create-db-instance ^
  --db-instance-identifier mydbinstance ^
  --engine mariadb ^
  --engine-version 10.6.10 ^
  --db-instance-class db.r5b.large ^
  --manage-master-user-password ^
  --master-username admin ^
  --allocated-storage 200
```

**RDS API**

You can create a DB instance using the CreateDBInstance operation. When you use this operation, make sure the EngineVersion and DBInstanceClass values support RDS Optimized Writes. In addition, make sure the parameter group associated with the DB instance has the `rds.optimized_writes` parameter set to AUTO.
Limitations for RDS Optimized Writes

The following limitations apply to RDS Optimized Writes:

- You can only modify a database to turn on RDS Optimized Writes if the database was created with a DB engine version and DB instance class that support the feature. In this case, if RDS Optimized Writes is turned off for the database, you can turn it on by setting the `rds.optimized_writes` parameter to AUTO. For more information, see Using RDS Optimized Writes (p. 1301).

- You can only modify a database to turn on RDS Optimized Writes if the database was created after the feature was released. The underlying file system format and organization that RDS Optimized Writes needs is incompatible with the file system format of databases created before the feature was released. By extension, you can't use any snapshots of previously created instances with this feature because the snapshots use the older, incompatible file system.

  **Important**
  
  To convert from the old format to the new format, you need to perform a full database migration. If you want to use this feature on DB instances that were created before the feature was released, create a new empty DB instance and manually migrate your older DB instance to the newer DB instance. You can migrate your older DB instance using the native `mysqldump` tool, replication, or AWS Database Migration Service. For more information, see `mariadb-dump/mysqldump` in the MariaDB documentation, Working with MariaDB replication in Amazon RDS (p. 1334), and the AWS Database Migration Service User Guide. For help with migrating using AWS tools, contact support.

- When you are restoring an RDS for MariaDB database from a snapshot, you can only turn on RDS Optimized Writes for the database if all of the following conditions apply:
  - The snapshot was created from a database that supports RDS Optimized Writes.
  - The snapshot was created from a database that was created after RDS Optimized Writes was released.
  - The snapshot is restored to a database that supports RDS Optimized Writes.
  - The restored database is associated with a parameter group that has the `rds.optimized_writes` parameter set to AUTO.
Upgrading the MariaDB DB engine

When Amazon RDS supports a new version of a database engine, you can upgrade your DB instances to the new version. There are two kinds of upgrades for MariaDB DB instances: major version upgrades and minor version upgrades.

**Major version upgrades** can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your DB instances. You can initiate a major version upgrade by modifying your DB instance. However, before you perform a major version upgrade, we recommend that you follow the instructions in [Major version upgrades for MariaDB](p. 1306).

In contrast, **minor version upgrades** include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your DB instance. Or you can enable the **Auto minor version upgrade** option when creating or modifying a DB instance. Doing so means that your DB instance is automatically upgraded after Amazon RDS tests and approves the new version. For information about performing an upgrade, see [Upgrading a DB instance engine version](p. 429).

If your MariaDB DB instance is using read replicas, you must upgrade all of the read replicas before upgrading the source instance. If your DB instance is in a Multi-AZ deployment, both the writer and standby replicas are upgraded. Your DB instance might not be available until the upgrade is complete.

For more information about MariaDB supported versions and version management, see [MariaDB on Amazon RDS versions](p. 1281).

Database engine upgrades require downtime. The duration of the downtime varies based on the size of your DB instance.

**Tip**
You can minimize the downtime required for DB instance upgrade by using a blue/green deployment. For more information, see [Using Amazon RDS Blue/Green Deployments for database updates](p. 566).

Topics
- Overview of upgrading (p. 1305)
- Major version upgrades for MariaDB (p. 1306)
- Upgrading a MariaDB DB instance (p. 1307)
- Automatic minor version upgrades for MariaDB (p. 1307)
- Using a read replica to reduce downtime when upgrading a MariaDB database (p. 1309)

Overview of upgrading

When you use the AWS Management Console to upgrade a DB instance, it shows the valid upgrade targets for the DB instance. You can also use the following AWS CLI command to identify the valid upgrade targets for a DB instance:

For Linux, macOS, or Unix:

```bash
cmd aws rds describe-db-engine-versions
  --engine mariadb
  --engine-version version-number
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

For Windows:

```
```
For example, to identify the valid upgrade targets for a MariaDB version 10.5.17 DB instance, run the following AWS CLI command:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions
  --engine mariadb
  --engine-version 10.5.17
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

For Windows:

```
aws rds describe-db-engine-versions
  --engine mariadb
  --engine-version 10.5.17
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

Amazon RDS takes two or more DB snapshots during the upgrade process. Amazon RDS takes up to two snapshots of the DB instance before making any upgrade changes. If the upgrade doesn't work for your databases, you can restore one of these snapshots to create a DB instance running the old version. Amazon RDS takes another snapshot of the DB instance when the upgrade completes. Amazon RDS takes these snapshots regardless of whether AWS Backup manages the backups for the DB instance.

**Note**

Amazon RDS only takes DB snapshots if you have set the backup retention period for your DB instance to a number greater than 0. To change your backup retention period, see [Modifying an Amazon RDS DB instance](p. 401).

After the upgrade is complete, you can't revert to the previous version of the database engine. If you want to return to the previous version, restore the first DB snapshot taken to create a new DB instance.

You control when to upgrade your DB instance to a new version supported by Amazon RDS. This level of control helps you maintain compatibility with specific database versions and test new versions with your application before deploying in production. When you are ready, you can perform version upgrades at the times that best fit your schedule.

If your DB instance is using read replication, you must upgrade all of the Read Replicas before upgrading the source instance.

If your DB instance is in a Multi-AZ deployment, both the primary and standby DB instances are upgraded. The primary and standby DB instances are upgraded at the same time and you will experience an outage until the upgrade is complete. The time for the outage varies based on your database engine, engine version, and the size of your DB instance.

**Major version upgrades for MariaDB**

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, Amazon RDS doesn't apply major version upgrades automatically. You must manually modify your DB instance. We recommend that you thoroughly test any upgrade before applying it to your production instances.
Amazon RDS supports the following in-place upgrades for major versions of the MariaDB database engine:

- Any MariaDB version to MariaDB 10.11
- Any MariaDB version to MariaDB 10.6
- MariaDB 10.4 to MariaDB 10.5
- MariaDB 10.3 to MariaDB 10.4

To perform a major version upgrade to a MariaDB version lower than 10.6, upgrade to each major version in order. For example, to upgrade from version 10.3 to version 10.5, upgrade in the following order: 10.3 to 10.4 and then 10.4 to 10.5.

If you are using a custom parameter group, and you perform a major version upgrade, you must specify either a default parameter group for the new DB engine version or create your own custom parameter group for the new DB engine version. Associating the new parameter group with the DB instance requires a customer-initiated database reboot after the upgrade completes. The instance's parameter group status will show pending-reboot if the instance needs to be rebooted to apply the parameter group changes. An instance's parameter group status can be viewed in the AWS Management Console or by using a "describe" call such as describe-db-instances.

Upgrading a MariaDB DB instance

For information about manually or automatically upgrading a MariaDB DB instance, see Upgrading a DB instance engine version (p. 429).

Automatic minor version upgrades for MariaDB

If you specify the following settings when creating or modifying a DB instance, you can have your DB instance automatically upgraded.

- The Auto minor version upgrade setting is enabled.
- The Backup retention period setting is greater than 0.

In the AWS Management Console, these settings are under Additional configuration. The following image shows the Auto minor version upgrade setting.
For more information about these settings, see Settings for DB instances (p. 402).

For some RDS for MariaDB major versions in some AWS Regions, one minor version is designated by RDS as the automatic upgrade version. After a minor version has been tested and approved by Amazon RDS, the minor version upgrade occurs automatically during your maintenance window. RDS doesn't automatically set newer released minor versions as the automatic upgrade version. Before RDS designates a newer automatic upgrade version, several criteria are considered, such as the following:

- Known security issues
- Bugs in the MariaDB community version
- Overall fleet stability since the minor version was released

You can use the following AWS CLI command to determine the current automatic minor upgrade target version for a specified MariaDB minor version in a specific AWS Region.

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions
  --engine mariadb
  --engine-version minor-version
  --region region
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].
  {AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}"
  --output text
```

For Windows:

```bash
aws rds describe-db-engine-versions
  --engine mariadb
  --engine-version minor-version
  --region region
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].
  {AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}"
  --output text
```

For example, the following AWS CLI command determines the automatic minor upgrade target for MariaDB minor version 10.5.16 in the US East (Ohio) AWS Region (us-east-2).

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions
  --engine mariadb
  --engine-version 10.5.16
  --region us-east-2
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].
  {AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}"
  --output table
```

For Windows:

```bash
aws rds describe-db-engine-versions
  --engine mariadb
  --engine-version 10.5.16
  --region us-east-2
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].
  {AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}"
  --output table
```
In this example, the AutoUpgrade value is True for MariaDB version 10.5.17. So, the automatic minor upgrade target is MariaDB version 10.5.17, which is highlighted in the output.

A MariaDB DB instance is automatically upgraded during your maintenance window if the following criteria are met:

- The **Auto minor version upgrade** setting is enabled.
- The **Backup retention period** setting is greater than 0.
- The DB instance is running a minor DB engine version that is less than the current automatic upgrade minor version.

For more information, see Automatically upgrading the minor engine version (p. 431).

### Using a read replica to reduce downtime when upgrading a MariaDB database

In most cases, a blue/green deployment is the best option to reduce downtime when upgrading a MariaDB DB instance. For more information, see Using Amazon RDS Blue/Green Deployments for database updates (p. 566).

If you can't use a blue/green deployment and your MariaDB DB instance is currently in use with a production application, you can use the following procedure to upgrade the database version for your DB instance. This procedure can reduce the amount of downtime for your application.

By using a read replica, you can perform most of the maintenance steps ahead of time and minimize the necessary changes during the actual outage. With this technique, you can test and prepare the new DB instance without making any changes to your existing DB instance.

The following procedure shows an example of upgrading from MariaDB version 10.5 to MariaDB version 10.6. You can use the same general steps for upgrades to other major versions.

#### To upgrade a MariaDB database while a DB instance is in use

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Create a read replica of your MariaDB 10.5 DB instance. This process creates an upgradable copy of your database. Other read replicas of the DB instance might also exist.
   
   a. In the console, choose **Databases**, and then choose the DB instance that you want to upgrade.
b. For Actions, choose Create read replica.

c. Provide a value for DB instance identifier for your read replica and ensure that the DB instance class and other settings match your MariaDB 10.5 DB instance.

d. Choose Create read replica.

3. (Optional) When the read replica has been created and Status shows Available, convert the read replica into a Multi-AZ deployment and enable backups.

By default, a read replica is created as a Single-AZ deployment with backups disabled. Because the read replica ultimately becomes the production DB instance, it is a best practice to configure a Multi-AZ deployment and enable backups now.

a. In the console, choose Databases, and then choose the read replica that you just created.

b. Choose Modify.

c. For Multi-AZ deployment, choose Create a standby instance.

d. For Backup Retention Period, choose a positive nonzero value, such as 3 days, and then choose Continue.

e. For Scheduling of modifications, choose Apply immediately.

f. Choose Modify DB instance.

4. When the read replica Status shows Available, upgrade the read replica to MariaDB 10.6.

a. In the console, choose Databases, and then choose the read replica that you just created.

b. Choose Modify.

c. For DB engine version, choose the MariaDB 10.6 version to upgrade to, and then choose Continue.

d. For Scheduling of modifications, choose Apply immediately.

e. Choose Modify DB instance to start the upgrade.

5. When the upgrade is complete and Status shows Available, verify that the upgraded read replica is up-to-date with the source MariaDB 10.5 DB instance. To verify, connect to the read replica and run the SHOW REPLICA STATUS command. If the Seconds_Behind_Master field is 0, then replication is up-to-date.

Note
Previous versions of MariaDB used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MariaDB version before 10.6, then use SHOW SLAVE STATUS.

6. (Optional) Create a read replica of your read replica.

If you want the DB instance to have a read replica after it is promoted to a standalone DB instance, you can create the read replica now.

a. In the console, choose Databases, and then choose the read replica that you just upgraded.

b. For Actions, choose Create read replica.

c. Provide a value for DB instance identifier for your read replica and ensure that the DB instance class and other settings match your MariaDB 10.5 DB instance.

d. Choose Create read replica.

7. (Optional) Configure a custom DB parameter group for the read replica.

If you want the DB instance to use a custom parameter group after it is promoted to a standalone DB instance, you can create the DB parameter group now and associate it with the read replica.

a. Create a custom DB parameter group for MariaDB 10.6. For instructions, see Creating a DB parameter group (p. 350).

b. Modify the parameters that you want to change in the DB parameter group you just created. For instructions, see Modifying parameters in a DB parameter group (p. 352).
c. In the console, choose **Databases**, and then choose the read replica.
d. Choose **Modify**.
e. For **DB parameter group**, choose the MariaDB 10.6 DB parameter group you just created, and then choose **Continue**.
f. For **Scheduling of modifications**, choose **Apply immediately**.
g. Choose **Modify DB instance** to start the upgrade.

8. Make your MariaDB 10.6 read replica a standalone DB instance.

**Important**
When you promote your MariaDB 10.6 read replica to a standalone DB instance, it is no longer a replica of your MariaDB 10.5 DB instance. We recommend that you promote your MariaDB 10.6 read replica during a maintenance window when your source MariaDB 10.5 DB instance is in read-only mode and all write operations are suspended. When the promotion is completed, you can direct your write operations to the upgraded MariaDB 10.6 DB instance to ensure that no write operations are lost.
In addition, we recommend that, before promoting your MariaDB 10.6 read replica, you perform all necessary data definition language (DDL) operations on your MariaDB 10.6 read replica. An example is creating indexes. This approach avoids negative effects on the performance of the MariaDB 10.6 read replica after it has been promoted. To promote a read replica, use the following procedure.

a. In the console, choose **Databases**, and then choose the read replica that you just upgraded.
b. For **Actions**, choose **Promote**.
c. Choose **Yes** to enable automated backups for the read replica instance. For more information, see **Working with backups** (p. 591).
d. Choose **Continue**.
e. Choose **Promote Read Replica**.

9. You now have an upgraded version of your MariaDB database. At this point, you can direct your applications to the new MariaDB 10.6 DB instance.
## Importing data into a MariaDB DB instance

You can use several different techniques to import data into an RDS for MariaDB DB instance. The best approach depends on the source of the data, the amount of data, and whether the import is done one time or is ongoing. If you are migrating an application along with the data, also consider the amount of downtime that you are willing to experience.

Find techniques to import data into an RDS for MariaDB DB instance in the following table.

<table>
<thead>
<tr>
<th>Source</th>
<th>Amount of data</th>
<th>One time or ongoing</th>
<th>Application downtime</th>
<th>Technique</th>
<th>More information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Existing MariaDB DB instance</td>
<td>Any</td>
<td>One time or ongoing</td>
<td>Minimal</td>
<td>Create a read replica for ongoing replication. Promote the read replica for one-time creation of a new DB instance.</td>
<td>Working with DB instance read replicas (p. 438)</td>
</tr>
<tr>
<td>Existing MariaDB or MySQL database</td>
<td>Small</td>
<td>One time</td>
<td>Some</td>
<td>Copy the data directly to your MySQL DB instance using a command-line utility.</td>
<td>Importing data from a MariaDB or MySQL database to a MariaDB or MySQL DB instance (p. 1313)</td>
</tr>
<tr>
<td>Data not stored in an existing database</td>
<td>Medium</td>
<td>One time</td>
<td>Some</td>
<td>Create flat files and import them using the mysqlimport utility.</td>
<td>Importing data from any source to a MariaDB or MySQL DB instance (p. 1329)</td>
</tr>
<tr>
<td>Existing MariaDB or MySQL database on premises or on Amazon EC2</td>
<td>Any</td>
<td>Ongoing</td>
<td>Minimal</td>
<td>Configure replication with an existing MariaDB or MySQL database as the replication source.</td>
<td>Configuring binary log file position replication with an external source instance (p. 1347)</td>
</tr>
</tbody>
</table>

You can configure replication into a MariaDB DB instance using MariaDB global transaction identifiers (GTIDs) when the external instance is MariaDB version 10.0.24 or higher, or using binary log coordinates for MySQL instances or MariaDB instances on earlier versions than 10.0.24. MariaDB GTIDs are implemented differently than MySQL.
Importing data from an external database

<table>
<thead>
<tr>
<th>Source</th>
<th>Amount of data</th>
<th>One time or ongoing</th>
<th>Applicationdown</th>
<th>Technique</th>
<th>More information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon RDS</td>
<td></td>
<td></td>
<td>GTIDs, which aren't supported by Amazon RDS.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Any existing database</td>
<td>Any</td>
<td>One time or ongoing</td>
<td>Minimal</td>
<td>Use AWS Database Migration Service to migrate the database with minimal downtime and, for many database DB engines, continue ongoing replication.</td>
<td>What is AWS Database Migration Service and Using a MySQL-compatible database as a target for AWS DMS in the AWS Database Migration Service User Guide</td>
</tr>
</tbody>
</table>

**Note**
The mysql system database contains authentication and authorization information required to log into your DB instance and access your data. Dropping, altering, renaming, or truncating tables, data, or other contents of the mysql database in your DB instance can result in errors and might render the DB instance and your data inaccessible. If this occurs, the DB instance can be restored from a snapshot using the AWS CLI `restore-db-instance-from-db-snapshot` or recovered using `restore-db-instance-to-point-in-time` commands.

**Importing data from a MariaDB or MySQL database to a MariaDB or MySQL DB instance**

You can also import data from an existing MariaDB or MySQL database to a MySQL or MariaDB DB instance. You do so by copying the database with `mysqldump` and piping it directly into the MariaDB or MySQL DB instance. The `mysqldump` command line utility is commonly used to make backups and transfer data from one MariaDB or MySQL server to another. It's included with MySQL and MariaDB client software.
### Note
If you are using a MySQL DB instance and your scenario supports it, it's easier to move data in and out of Amazon RDS by using backup files and Amazon S3. For more information, see Restoring a backup into a MySQL DB instance (p. 1696).

A typical `mysqldump` command to move data from an external database to an Amazon RDS DB instance looks similar to the following.

```
mysqldump -u local_user \
   --databases database_name \
   --single-transaction \
   --compress \
   --order-by-primary \
   -plocal_password | mysql -u RDS_user \
   --port=port_number \
   --host=host_name \
   -pRDS_password
```

### Important
Make sure not to leave a space between the `-p` option and the entered password. Specify credentials other than the prompts shown here as a security best practice.

Make sure that you're aware of the following recommendations and considerations:

- Exclude the following schemas from the dump file: `sys`, `performance_schema`, and `information_schema`. The `mysqldump` utility excludes these schemas by default.
- If you need to migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the `pt-show-grants` utility.
- To perform the import, make sure the user doing so has access to the DB instance. For more information, see Controlling access with security groups (p. 2697).

The parameters used are as follows:

- `-u local_user` – Use to specify a user name. In the first usage of this parameter, you specify the name of a user account on the local MariaDB or MySQL database identified by the `--databases` parameter.
- `--databases database_name` – Use to specify the name of the database on the local MariaDB or MySQL instance that you want to import into Amazon RDS.
- `--single-transaction` – Use to ensure that all of the data loaded from the local database is consistent with a single point in time. If there are other processes changing the data while `mysqldump` is reading it, using this parameter helps maintain data integrity.
- `--compress` – Use to reduce network bandwidth consumption by compressing the data from the local database before sending it to Amazon RDS.
- `--order-by-primary` – Use to reduce load time by sorting each table's data by its primary key.
- `-plocal_password` – Use to specify a password. In the first usage of this parameter, you specify the password for the user account identified by the first `-u` parameter.
- `-u RDS_user` – Use to specify a user name. In the second usage of this parameter, you specify the name of a user account on the default database for the MariaDB or MySQL DB instance identified by the `--host` parameter.
- `--port port_number` – Use to specify the port for your MariaDB or MySQL DB instance. By default, this is 3306 unless you changed the value when creating the instance.
- `--host host_name` – Use to specify the Domain Name System (DNS) name from the Amazon RDS DB instance endpoint, for example, `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the Amazon RDS Management Console.
- `RDS_password` – Use to specify a password. In the second usage of this parameter, you specify the password for the user account identified by the second `-u` parameter.

Make sure to create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, then exclude them when you run `mysqldump`. To do so, include the following parameters with your `mysqldump` command: `--routines=0 --triggers=0 --events=0`.

The following example copies the `world` sample database on the local host to a MySQL DB instance.

For Linux, macOS, or Unix:

```
sudo mysqldump -u localuser \
   --databases world \
   --single-transaction \
   --compress \
   --order-by-primary \
   --routines=0 \
   --triggers=0 \
   --events=0 \
   -p localpassword | mysql -u rdsuser \
   --port=3306 \
   --host=myinstance.123456789012.us-east-1.rds.amazonaws.com \
   -prdspassword
```

For Windows, run the following command in a command prompt that has been opened by right-clicking `Command Prompt` on the Windows programs menu and choosing `Run as administrator`:

```
mysqldump -u localuser ^
   --databases world ^
   --single-transaction ^
   --compress ^
   --order-by-primary ^
   --routines=0 ^
   --triggers=0 ^
   --events=0 ^
   -p localpassword | mysql -u rdsuser ^
   --port=3306 ^
   --host=myinstance.123456789012.us-east-1.rds.amazonaws.com ^
   -prdspassword
```

**Note**

Specify credentials other than the prompts shown here as a security best practice.

## Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime

In some cases, you might need to import data from an external MariaDB or MySQL database that supports a live application to a MariaDB DB instance, a MySQL DB instance, or a MySQL Multi-AZ DB cluster. Use the following procedure to minimize the impact on availability of applications. This procedure can also help if you are working with a very large database. Using this procedure, you can reduce the cost of the import by reducing the amount of data that is passed across the network to AWS.

In this procedure, you transfer a copy of your database data to an Amazon EC2 instance and import the data into a new Amazon RDS database. You then use replication to bring the Amazon RDS database up-to-date with your live external instance, before redirecting your application to the Amazon RDS
database. Configure MariaDB replication based on global transaction identifiers (GTIDs) if the external instance is MariaDB 10.0.24 or higher and the target instance is RDS for MariaDB. Otherwise, configure replication based on binary log coordinates. We recommend GTID-based replication if your external database supports it because GTID-based replication is a more reliable method. For more information, see Global transaction ID in the MariaDB documentation.

**Note**
If you want to import data into a MySQL DB instance and your scenario supports it, we recommend moving data in and out of Amazon RDS by using backup files and Amazon S3. For more information, see Restoring a backup into a MySQL DB instance (p. 1696).

Create a copy of your existing database

The first step in the process of migrating a large amount of data to an RDS for MariaDB or RDS for MySQL database with minimal downtime is to create a copy of the source data.
You can use the mysqldump utility to create a database backup in either SQL or delimited-text format. We recommend that you do a test run with each format in a non-production environment to see which method minimizes the amount of time that mysqldump runs.

We also recommend that you weigh mysqldump performance against the benefit offered by using the delimited-text format for loading. A backup using delimited-text format creates a tab-separated text file for each table being dumped. To reduce the amount of time required to import your database, you can load these files in parallel using the `LOAD DATA LOCAL INFILE` command. For more information about choosing a mysqldump format and then loading the data, see "Using mysqldump for backups" in the MySQL documentation.

Before you start the backup operation, make sure to set the replication options on the MariaDB or MySQL database that you are copying to Amazon RDS. The replication options include turning on binary logging and setting a unique server ID. Setting these options causes your server to start logging database transactions and prepares it to be a source replication instance later in this process.

**Note**

Use the `--single-transaction` option with mysqldump because it dumps a consistent state of the database. To ensure a valid dump file, don't run data definition language (DDL) statements while mysqldump is running. You can schedule a maintenance window for these operations.

Exclude the following schemas from the dump file: `sys`, `performance_schema`, and `information_schema`. The mysqldump utility excludes these schemas by default.

To migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the `pt-show-grants` utility.

**To set replication options**

1. Edit the `my.cnf` file (this file is usually under `/etc`).

```
sudo vi /etc/my.cnf
```
Add the log_bin and server_id options to the [mysqld] section. The log_bin option provides a file name identifier for binary log files. The server_id option provides a unique identifier for the server in source-replica relationships.

The following example shows the updated [mysqld] section of a my.cnf file.

```
[mysqld]
log-bin=mysql-bin
server-id=1
```

For more information, see the MySQL documentation.

2. For replication with a Multi-AZ DB cluster, set the ENFORCE_GTID_CONSISTENCY and the GTID_MODE parameter to ON.

```
mysql> SET @@GLOBAL.ENFORCE_GTID_CONSISTENCY = ON;
```

```
mysql> SET @@GLOBAL.GTID_MODE = ON;
```

These settings aren't required for replication with a DB instance.

3. Restart the mysql service.

```
sudo service mysqld restart
```

To create a backup copy of your existing database

1. Create a backup of your data using the mysqldump utility, specifying either SQL or delimited-text format.

   Specify --master-data=2 to create a backup file that can be used to start replication between servers. For more information, see the mysqldump documentation.

   To improve performance and ensure data integrity, use the --order-by-primary and --single-transaction options of mysqldump.

   To avoid including the MySQL system database in the backup, do not use the --all-databases option with mysqldump. For more information, see Creating a data snapshot using mysqldump in the MySQL documentation.

   Use chmod if necessary to make sure that the directory where the backup file is being created is writable.

   **Important**
   
   On Windows, run the command window as an administrator.

   • To produce SQL output, use the following command.

   For Linux, macOS, or Unix:

   ```
sudo mysqldump
   --databases database_name
   --master-data=2
   --single-transaction
   --order-by-primary
   -r backup.sql
   -u local_user
   ```
-p password

Note
Specify credentials other than the prompts shown here as a security best practice.

For Windows:

```
mysqldump ^
  --databases database_name ^
  --master-data=2 ^
  --single-transaction ^
  --order-by-primary ^
  -r backup.sql ^
  -u local_user ^
  -p password
```

Note
Specify credentials other than the prompts shown here as a security best practice.

- To produce delimited-text output, use the following command.

For Linux, macOS, or Unix:

```
sudo mysqldump \
  --tab=target_directory \ 
  --fields-terminated-by ',' \ 
  --fields-enclosed-by '"""' \ 
  --lines-terminated-by 0x0d0a \ 
  database_name \ 
  --master-data=2 \ 
  --single-transaction \ 
  --order-by-primary \ 
  -p password
```

For Windows:

```
mysqldump ^
  --tab=target_directory ^
  --fields-terminated-by ',' ^
  --fields-enclosed-by '"""' ^
  --lines-terminated-by 0x0d0a ^
  database_name ^
  --master-data=2 ^
  --single-transaction ^
  --order-by-primary ^
  -p password
```

Note
Specify credentials other than the prompts shown here as a security best practice. Make sure to create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, exclude them when you run mysqldump. To do so, include the following arguments with your mysqldump command: --routines=0 --triggers=0 --events=0.

When using the delimited-text format, a CHANGE MASTER TO comment is returned when you run mysqldump. This comment contains the master log file name and position. If the external instance is other than MariaDB version 10.0.24 or higher, note the values for MASTER_LOG_FILE and MASTER_LOG_POS. You need these values when setting up replication.
If you are using SQL format, you can get the master log file name and position in the CHANGE MASTER TO comment in the backup file. If the external instance is MariaDB version 10.0.24 or higher, you can get the GTID in the next step.

2. If the external instance you are using is MariaDB version 10.0.24 or higher, you use GTID-based replication. Run `SHOW MASTER STATUS` on the external MariaDB instance to get the binary log file name and position, then convert them to a GTID by running `BINLOG_GTID_POS` on the external MariaDB instance.

   ```sql
   SELECT BINLOG_GTID_POS('binary log file name', binary log file position);
   ```

   Note the GTID returned; you need it to configure replication.

3. Compress the copied data to reduce the amount of network resources needed to copy your data to the Amazon RDS database. Note the size of the backup file. You need this information when determining how large an Amazon EC2 instance to create. When you are done, compress the backup file using GZIP or your preferred compression utility.

   - To compress SQL output, use the following command.

   ```bash
   gzip backup.sql
   ```

   - To compress delimited-text output, use the following command.

   ```bash
   tar -zcvf backup.tar.gz target_directory
   ```

Create an Amazon EC2 instance and copy the compressed database

Copying your compressed database backup file to an Amazon EC2 instance takes fewer network resources than doing a direct copy of uncompressed data between database instances. After your data is in Amazon EC2, you can copy it from there directly to your MariaDB or MySQL database. For you to save on the cost of network resources, your Amazon EC2 instance must be in the same AWS Region as your Amazon RDS DB instance. Having the Amazon EC2 instance in the same AWS Region as your Amazon RDS database also reduces network latency during the import.
To create an Amazon EC2 instance and copy your data

1. In the AWS Region where you plan to create the RDS database, create a virtual private cloud (VPC), a VPC security group, and a VPC subnet. Ensure that the inbound rules for your VPC security group allow the IP addresses required for your application to connect to AWS. You can specify a range of IP addresses (for example, 203.0.113.0/24), or another VPC security group. You can use the Amazon VPC Management Console to create and manage VPCs, subnets, and security groups. For more information, see Getting started with Amazon VPC in the Amazon Virtual Private Cloud Getting Started Guide.

2. Open the Amazon EC2 Management Console and choose the AWS Region to contain both your Amazon EC2 instance and your Amazon RDS database. Launch an Amazon EC2 instance using the VPC, subnet, and security group that you created in Step 1. Ensure that you select an instance type with enough storage for your database backup file when it is uncompressed. For details on Amazon EC2 instances, see Getting started with Amazon EC2 Linux instances in the Amazon Elastic Compute Cloud User Guide for Linux.

3. To connect to your Amazon RDS database from your Amazon EC2 instance, edit your VPC security group. Add an inbound rule specifying the private IP address of your EC2 instance. You can find the private IP address on the Details tab of the Instance pane in the EC2 console window. To edit the VPC security group and add an inbound rule, choose Security Groups in the EC2 console navigation pane, choose your security group, and then add an inbound rule for MySQL or Aurora specifying the private IP address of your EC2 instance. To learn how to add an inbound rule to a VPC security group, see Adding and removing rules in the Amazon VPC User Guide.

4. Copy your compressed database backup file from your local system to your Amazon EC2 instance. Use chmod if necessary to make sure that you have write permission for the target directory of the Amazon EC2 instance. You can use scp or a Secure Shell (SSH) client to copy the file. The following is an example.

   `$ scp -i key pair.pem backup.sql.gz ec2-user@EC2 DNS:/target_directory/backup.sql.gz`

   **Important**
   Be sure to copy sensitive data using a secure network transfer protocol.
5. Connect to your Amazon EC2 instance and install the latest updates and the MySQL client tools using the following commands.

```
sudo yum update -y
sudo yum install mysql -y
```

For more information, see Connect to your instance in the Amazon Elastic Compute Cloud User Guide for Linux.

**Important**
This example installs the MySQL client on an Amazon Machine Image (AMI) for an Amazon Linux distribution. To install the MySQL client on a different distribution, such as Ubuntu or Red Hat Enterprise Linux, this example doesn’t work. For information about installing MySQL, see Installing and Upgrading MySQL in the MySQL documentation.

6. While connected to your Amazon EC2 instance, decompress your database backup file. The following are examples.

- To decompress SQL output, use the following command.

```
gzip backup.sql.gz -d
```

- To decompress delimited-text output, use the following command.

```
tar xzvf backup.tar.gz
```

**Create a MySQL or MariaDB database and import data from your Amazon EC2 instance**

By creating a MariaDB DB instance, a MySQL DB instance, or a MySQL Multi-AZ DB cluster in the same AWS Region as your Amazon EC2 instance, you can import the database backup file from EC2 faster than over the internet.
To create a MariaDB or MySQL database and import your data

1. Determine which DB instance class and what amount of storage space is required to support the expected workload for this Amazon RDS database. As part of this process, decide what is sufficient space and processing capacity for your data load procedures. Also decide what is required to handle the production workload. You can estimate this based on the size and resources of the source MariaDB or MySQL database. For more information, see DB instance classes (p. 11).

2. Create a DB instance or Multi-AZ DB cluster in the AWS Region that contains your Amazon EC2 instance.

To create a MySQL Multi-AZ DB cluster, follow the instructions in Creating a Multi-AZ DB cluster (p. 508).

To create a MariaDB or MySQL DB instance, follow the instructions in Creating an Amazon RDS DB instance (p. 300) and use the following guidelines:

- Specify a DB engine version that is compatible with your source DB instance, as follows:
  - If your source instance is MySQL 5.5.x, the Amazon RDS DB instance must be MySQL.
  - If your source instance is MySQL 5.6.x or 5.7.x, the Amazon RDS DB instance must be MySQL or MariaDB.
  - If your source instance is MySQL 8.0.x, the Amazon RDS DB instance must be MySQL 8.0.x.
  - If your source instance is MariaDB 5.5 or higher, the Amazon RDS DB instance must be MariaDB.

- Specify the same virtual private cloud (VPC) and VPC security group as for your Amazon EC2 instance. This approach ensures that your Amazon EC2 instance and your Amazon RDS instance are visible to each other over the network. Make sure your DB instance is publicly accessible. To set up replication with your source database as described later, your DB instance must be publicly accessible.

- Don't configure multiple Availability Zones, backup retention, or read replicas until after you have imported the database backup. When that import is completed, you can configure Multi-AZ and backup retention for the production instance.

3. Review the default configuration options for the Amazon RDS database. If the default parameter group for the database doesn't have the configuration options that you want, find a different one that does or create a new parameter group. For more information on creating a parameter group, see Working with parameter groups (p. 347).

4. Connect to the new Amazon RDS database as the master user. Create the users required to support the administrators, applications, and services that need to access the instance. The hostname for the Amazon RDS database is the Endpoint value for this instance without including the port number. An example is mysampledb.123456789012.us-west-2.rds.amazonaws.com. You can find the endpoint value in the database details in the Amazon RDS Management Console.

5. Connect to your Amazon EC2 instance. For more information, see Connect to your instance in the Amazon Elastic Compute Cloud User Guide for Linux.

6. Connect to your Amazon RDS database as a remote host from your Amazon EC2 instance using the mysql command. The following is an example.

```
mysql -h host_name -P 3306 -u db_master_user -p
```

The hostname is the Amazon RDS database endpoint.

7. At the mysql prompt, run the source command and pass it the name of your database dump file to load the data into the Amazon RDS DB instance:

- For SQL format, use the following command.

```
mysql> source backup.sql;
```
For delimited-text format, first create the database, if it isn't the default database you created when setting up the Amazon RDS database.

```
mysql> create database database_name;
$ mysql> use database_name;
```

Then create the tables.

```
mysql> source table1.sql
$ mysql> source table2.sql
etc...
```

Then import the data.

```
mysql> LOAD DATA LOCAL INFILE 'table1.txt' INTO TABLE table1 FIELDS TERMINATED BY ',' ENCLOSED BY '"' LINES TERMINATED BY '0x0d0a';
$ mysql> LOAD DATA LOCAL INFILE 'table2.txt' INTO TABLE table2 FIELDS TERMINATED BY ',' ENCLOSED BY '"' LINES TERMINATED BY '0x0d0a';
etc...
```

To improve performance, you can perform these operations in parallel from multiple connections so that all of your tables are created and then loaded at the same time.

**Note**

If you used any data-formatting options with mysqldump when you initially dumped the table, make sure to use the same options with mysqlimport or LOAD DATA LOCAL INFILE to ensure proper interpretation of the data file contents.

8. Run a simple SELECT query against one or two of the tables in the imported database to verify that the import was successful.

If you no longer need the Amazon EC2 instance used in this procedure, terminate the EC2 instance to reduce your AWS resource usage. To terminate an EC2 instance, see [Terminating an instance](#) in the Amazon EC2 User Guide.

**Replicate between your external database and new Amazon RDS database**

Your source database was likely updated during the time that it took to copy and transfer the data to the MariaDB or MySQL database. Thus, you can use replication to bring the copied database up-to-date with the source database.
The permissions required to start replication on an Amazon RDS database are restricted and not available to your Amazon RDS master user. Because of this, make sure to use either the Amazon RDS `mysql.rds_set_external_master` command or the `mysql.rds_set_external_master_gtid` command to configure replication, and the `mysql.rds_start_replication` command to start replication between your live database and your Amazon RDS database.

To start replication

Earlier, you turned on binary logging and set a unique server ID for your source database. Now you can set up your Amazon RDS database as a replica with your live database as the source replication instance.

1. In the Amazon RDS Management Console, add the IP address of the server that hosts the source database to the VPC security group for the Amazon RDS database. For more information on modifying a VPC security group, see Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

   You might also need to configure your local network to permit connections from the IP address of your Amazon RDS database, so that it can communicate with your source instance. To find the IP address of the Amazon RDS database, use the `host` command.

   ```
   host rds_db_endpoint
   ```

   The hostname is the DNS name from the Amazon RDS database endpoint, for example `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the Amazon RDS Management Console.

2. Using the client of your choice, connect to the source instance and create a user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following is an example.

   **MySQL 5.5, 5.6, and 5.7**

   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
   ```

   **MySQL 8.0**
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY 'password';

**Note**
Specify credentials other than the prompts shown here as a security best practice.

3. For the source instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. For example, to grant the REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain, issue the following command.

MySQL 5.5, 5.6, and 5.7

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
IDENTIFIED BY 'password';
```

MySQL 8.0

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

**Note**
Specify credentials other than the prompts shown here as a security best practice.

4. If you used SQL format to create your backup file and the external instance is not MariaDB 10.0.24 or higher, look at the contents of that file.

```
cat backup.sql
```

The file includes a CHANGE MASTER TO comment that contains the master log file name and position. This comment is included in the backup file when you use the --master-data option with mysqldump. Note the values for MASTER_LOG_FILE and MASTER_LOG_POS.

```
---- Position to start replication or point-in-time recovery from
--
-- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031', MASTER_LOG_POS=107;
```

If you used delimited text format to create your backup file and the external instance isn't MariaDB 10.0.24 or higher, you should already have binary log coordinates from step 1 of the procedure at "To create a backup copy of your existing database" in this topic.

If the external instance is MariaDB 10.0.24 or higher, you should already have the GTID from which to start replication from step 2 of the procedure at "To create a backup copy of your existing database" in this topic.

5. Make the Amazon RDS database the replica. If the external instance isn't MariaDB 10.0.24 or higher, connect to the Amazon RDS database as the master user and identify the source database as the source replication instance by using the `mysql.rds_set_external_master` command. Use the master log file name and master log position that you determined in the previous step if you have a SQL format backup file. Or use the name and position that you determined when creating the backup files if you used delimited-text format. The following is an example.

```
CALL `mysql.rds_set_external_master` ('myserver.mydomain.com', 3306, 'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0);
```
Note
Specify credentials other than the prompts shown here as a security best practice.

If the external instance is MariaDB 10.0.24 or higher, connect to the Amazon RDS database as the master user and identify the source database as the source replication instance by using the `mysql.rds_set_external_master_gtid` command. Use the GTID that you determined in step 2 of the procedure at "To create a backup copy of your existing database" in this topic. The following is an example.

```sql
CALL mysql.rds_set_external_master_gtid ('source_server_ip_address', 3306, 'ReplicationUser', 'password', 'GTID', 0);
```

The `source_server_ip_address` is the IP address of source replication instance. An EC2 private DNS address is currently not supported.

Note
Specify credentials other than the prompts shown here as a security best practice.

6. On the Amazon RDS database, issue the `mysql.rds_start_replication` command to start replication.

```sql
CALL mysql.rds_start_replication;
```

7. On the Amazon RDS database, run the `SHOW REPLICA STATUS` command to determine when the replica is up-to-date with the source replication instance. The results of the `SHOW REPLICA STATUS` command include the `Seconds_Behind_Master` field. When the `Seconds_Behind_Master` field returns 0, then the replica is up-to-date with the source replication instance.

Note
Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

For a MariaDB 10.5, 10.6, or 10.11 DB instance, run the `mysql.rds_replica_status` procedure instead of the MySQL command.

8. After the Amazon RDS database is up-to-date, turn on automated backups so you can restore that database if needed. You can turn on or modify automated backups for your Amazon RDS database using the Amazon RDS Management Console. For more information, see Working with backups (p. 591).

Redirect your live application to your Amazon RDS instance

After the MariaDB or MySQL database is up-to-date with the source replication instance, you can now update your live application to use the Amazon RDS instance.
To redirect your live application to your MariaDB or MySQL database and stop replication

1. To add the VPC security group for the Amazon RDS database, add the IP address of the server that hosts the application. For more information on modifying a VPC security group, see Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

2. Verify that the Seconds_Behind_Master field in the SHOW REPLICA STATUS command results is 0, which indicates that the replica is up-to-date with the source replication instance.

   ```sql
   SHOW REPLICA STATUS;
   ```

   **Note**
   Previous versions of MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

   For a MariaDB 10.5, 10.6, or 10.11 DB instance, run the `mysql.rds_replica_status` procedure instead of the MySQL command.

3. Close all connections to the source when their transactions complete.

4. Update your application to use the Amazon RDS database. This update typically involves changing the connection settings to identify the hostname and port of the Amazon RDS database, the user account and password to connect with, and the database to use.

5. Connect to the DB instance.

   For a Multi-AZ DB cluster, connect to the writer DB instance.

6. Stop replication for the Amazon RDS instance using the `mysql.rds_stop_replication` command.

   ```sql
   CALL mysql.rds_stop_replication;
   ```

7. Run the `mysqlrds_reset_external_master` command on your Amazon RDS database to reset the replication configuration so this instance is no longer identified as a replica.
CALL mysql.rds_reset_external_master;

8. Turn on additional Amazon RDS features such as Multi-AZ support and read replicas. For more information, see Configuring and managing a Multi-AZ deployment (p. 492) and Working with DB instance read replicas (p. 438).

Importing data from any source to a MariaDB or MySQL DB instance

If you have more than 1 GiB of data to load, or if your data is coming from somewhere other than a MariaDB or MySQL database, we recommend creating flat files and loading them with mysqlimport. The mysqlimport utility is another command line utility bundled with the MySQL and MariaDB client software. Its purpose is to load flat files into MySQL or MariaDB. For information about mysqlimport, see mysqlimport - a data import program in the MySQL documentation.

We also recommend creating DB snapshots of the target Amazon RDS DB instance before and after the data load. Amazon RDS DB snapshots are complete backups of your DB instance that can be used to restore your DB instance to a known state. When you initiate a DB snapshot, I/O operations to your DB instance are momentarily suspended while your database is backed up.

Creating a DB snapshot immediately before the load makes it possible for you to restore the database to its state before the load, if you need to. A DB snapshot taken immediately after the load protects you from having to load the data again in case of a mishap and can also be used to seed new database instances.

The following list shows the steps to take. Each step is discussed in more detail following.

1. Create flat files containing the data to be loaded.
2. Stop any applications accessing the target DB instance.
3. Create a DB snapshot.
4. Consider turning off Amazon RDS automated backups.
5. Load the data using mysqlimport.
6. Enable automated backups again.

Step 1: Create flat files containing the data to be loaded

Use a common format, such as comma-separated values (CSV), to store the data to be loaded. Each table must have its own file; you can’t combine data for multiple tables in the same file. Give each file the same name as the table it corresponds to. The file extension can be anything you like. For example, if the table name is sales, the file name might be sales.csv or sales.txt, but not sales_01.csv.

Whenever possible, order the data by the primary key of the table being loaded. Doing this drastically improves load times and minimizes disk storage requirements.

The speed and efficiency of this procedure depends on keeping the size of the files small. If the uncompressed size of any individual file is larger than 1 GiB, split it into multiple files and load each one separately.

On Unix-like systems (including Linux), use the split command. For example, the following command splits the sales.csv file into multiple files of less than 1 GiB, splitting only at line breaks (-C 1024m). The new files are named sales.part_00, sales.part_01, and so on.
split -C 1024m -d sales.csv sales.part_

Similar utilities are available for other operating systems.

**Step 2: Stop any applications accessing the target DB instance**

Before starting a large load, stop all application activity accessing the target DB instance that you plan to load to. We recommend this particularly if other sessions will be modifying the tables being loaded or tables that they reference. Doing this reduces the risk of constraint violations occurring during the load and improves load performance. It also makes it possible to restore the DB instance to the point just before the load without losing changes made by processes not involved in the load.

Of course, this might not be possible or practical. If you can't stop applications from accessing the DB instance before the load, take steps to ensure the availability and integrity of your data. The specific steps required vary greatly depending upon specific use cases and site requirements.

**Step 3: Create a DB snapshot**

If you plan to load data into a new DB instance that contains no data, you can skip this step. Otherwise, creating a DB snapshot of your DB instance makes it possible for you to restore the DB instance to the point just before the load, if it becomes necessary. As previously mentioned, when you initiate a DB snapshot, I/O operations to your DB instance are suspended for a few minutes while the database is backed up.

The example following uses the AWS CLI `create-db-snapshot` command to create a DB snapshot of the AcmeRDS instance and give the DB snapshot the identifier "preload".

For Linux, macOS, or Unix:

```
aws rds create-db-snapshot \
   --db-instance-identifier AcmeRDS \
   --db-snapshot-identifier preload
```

For Windows:

```
aws rds create-db-snapshot ^
   --db-instance-identifier AcmeRDS ^
   --db-snapshot-identifier preload
```

You can also use the restore from DB snapshot functionality to create test DB instances for dry runs or to undo changes made during the load.

Keep in mind that restoring a database from a DB snapshot creates a new DB instance that, like all DB instances, has a unique identifier and endpoint. To restore the DB instance without changing the endpoint, first delete the DB instance so that you can reuse the endpoint.

For example, to create a DB instance for dry runs or other testing, you give the DB instance its own identifier. In the example, AcmeRDS-2* is the identifier. The example connects to the DB instance using the endpoint associated with AcmeRDS-2.

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-db-snapshot \
   --db-instance-identifier AcmeRDS-2 \
   --db-snapshot-identifier preload
```
For Windows:

```bash
aws rds restore-db-instance-from-db-snapshot
    --db-instance-identifier AcmeRDS-2
    --db-snapshot-identifier preload
```

To reuse the existing endpoint, first delete the DB instance and then give the restored database the same identifier.

For Linux, macOS, or Unix:

```bash
aws rds delete-db-instance
    --db-instance-identifier AcmeRDS
    --final-db-snapshot-identifier AcmeRDS-Final

aws rds restore-db-instance-from-db-snapshot
    --db-instance-identifier AcmeRDS
    --db-snapshot-identifier preload
```

For Windows:

```bash
aws rds delete-db-instance
    --db-instance-identifier AcmeRDS
    --final-db-snapshot-identifier AcmeRDS-Final

aws rds restore-db-instance-from-db-snapshot
    --db-instance-identifier AcmeRDS
    --db-snapshot-identifier preload
```

The preceding example takes a final DB snapshot of the DB instance before deleting it. This is optional but recommended.

### Step 4: Consider turning off Amazon RDS automated backups

**Warning**

Do not turn off automated backups if you need to perform point-in-time recovery.

Turning off automated backups erases all existing backups, so point-in-time recovery isn't possible after automated backups have been turned off. Disabling automated backups is a performance optimization and isn't required for data loads. Manual DB snapshots aren't affected by turning off automated backups. All existing manual DB snapshots are still available for restore.

Turning off automated backups reduces load time by about 25 percent and reduces the amount of storage space required during the load. If you plan to load data into a new DB instance that contains no data, turning off backups is an easy way to speed up the load and avoid using the additional storage needed for backups. However, in some cases you might plan to load into a DB instance that already contains data. If so, weigh the benefits of turning off backups against the impact of losing the ability to perform point-in-time-recovery.

DB instances have automated backups turned on by default (with a one day retention period). To turn off automated backups, set the backup retention period to zero. After the load, you can turn backups back on by setting the backup retention period to a nonzero value. To turn on or turn off backups, Amazon RDS shuts the DB instance down and restarts it to turn MariaDB or MySQL logging on or off.

Use the AWS CLI `modify-db-instance` command to set the backup retention to zero and apply the change immediately. Setting the retention period to zero requires a DB instance restart, so wait until the restart has completed before proceeding.

For Linux, macOS, or Unix:
aws rds modify-db-instance \  
--db-instance-identifier AcmeRDS \  
--apply-immediately \  
--backup-retention-period 0

For Windows:

aws rds modify-db-instance ^  
--db-instance-identifier AcmeRDS ^  
--apply-immediately ^  
--backup-retention-period 0

You can check the status of your DB instance with the AWS CLI describe-db-instances command. The following example displays the DB instance status of the AcmeRDS DB instance.

aws rds describe-db-instances --db-instance-identifier AcmeRDS --query "[].{DBInstanceStatus:DBInstanceStatus}"  

When the DB instance status is available, you're ready to proceed.

**Step 5: Load the data**

Use the mysqlimport utility to load the flat files into Amazon RDS. The following example tells mysqlimport to load all of the files named "sales" with an extension starting with "part_". This is a convenient way to load all of the files created in the "split" example.

Use the --compress option to minimize network traffic. The --fields-terminated-by=',' option is used for CSV files, and the --local option specifies that the incoming data is located on the client. Without the --local option, the Amazon RDS DB instance looks for the data on the database host, so always specify the --local option. For the --host option, specify the DB instance endpoint of the RDS for MySQL DB instance.

In the following examples, replace `master_user` with the master username for your DB instance.

Replace `hostname` with the endpoint for your DB instance. An example of a DB instance endpoint is `my-db-instance.123456789012.us-west-2.rds.amazonaws.com`.

For RDS for MySQL version 8.0.15 and higher, run the following statement before using the mysqlimport utility:

GRANT SESSION_VARIABLES_ADMIN ON *.* TO `master_user`;

For Linux, macOS, or Unix:

mysqlimport --local \  
--compress \  
--user=`master_user` \  
--password \  
--host=`hostname` \  
--fields-terminated-by=',' Acme sales.part_*

For Windows:

mysqlimport --local ^  
--compress ^  
--user=`master_user` ^  
--password ^
For very large data loads, take additional DB snapshots periodically between loading files and note which files have been loaded. If a problem occurs, you can easily resume from the point of the last DB snapshot, avoiding lengthy reloads.

**Step 6: Turn Amazon RDS automated backups back on**

After the load is finished, turn Amazon RDS automated backups on by setting the backup retention period back to its preload value. As noted earlier, Amazon RDS restarts the DB instance, so be prepared for a brief outage.

The following example uses the AWS CLI `modify-db-instance` command to turn on automated backups for the AcmeRDS DB instance and set the retention period to one day.

For Linux, macOS, or Unix:

```sql
aws rds modify-db-instance \
  --db-instance-identifier AcmeRDS \
  --backup-retention-period 1 \
  --apply-immediately
```

For Windows:

```sql
aws rds modify-db-instance ^
  --db-instance-identifier AcmeRDS ^
  --backup-retention-period 1 ^
  --apply-immediately
```
Working with MariaDB replication in Amazon RDS

You usually use read replicas to configure replication between Amazon RDS DB instances. For general information about read replicas, see Working with DB instance read replicas (p. 438). For specific information about working with read replicas on Amazon RDS for MariaDB, see Working with MariaDB read replicas (p. 1334).

You can also configure replication based on binary log coordinates for a MariaDB DB instance. For MariaDB instances, you can also configure replication based on global transaction IDs (GTIDs), which provides better crash safety. For more information, see Configuring GTID-based replication with an external source instance (p. 1344).

The following are other replication options available with RDS for MariaDB:

- You can set up replication between an RDS for MariaDB DB instance and a MySQL or MariaDB instance that is external to Amazon RDS. For information about configuring replication with an external source, see Configuring binary log file position replication with an external source instance (p. 1347).
- You can configure replication to import databases from a MySQL or MariaDB instance that is external to Amazon RDS, or to export databases to such instances. For more information, see Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime (p. 1315) and Exporting data from a MySQL DB instance by using replication (p. 1744).

For any of these replication options, you can use either row-based replication, statement-based, or mixed replication. Row-based replication only replicates the changed rows that result from a SQL statement. Statement-based replication replicates the entire SQL statement. Mixed replication uses statement-based replication when possible, but switches to row-based replication when SQL statements that are unsafe for statement-based replication are run. In most cases, mixed replication is recommended. The binary log format of the DB instance determines whether replication is row-based, statement-based, or mixed. For information about setting the binary log format, see Binary logging format (p. 907).

Topics
- Working with MariaDB read replicas (p. 1334)
- Configuring GTID-based replication with an external source instance (p. 1344)
- Configuring binary log file position replication with an external source instance (p. 1347)

Working with MariaDB read replicas

Following, you can find specific information about working with read replicas on Amazon RDS for MariaDB. For general information about read replicas and instructions for using them, see Working with DB instance read replicas (p. 438).

Topics
- Configuring read replicas with MariaDB (p. 1335)
- Configuring replication filters with MariaDB (p. 1335)
- Configuring delayed replication with MariaDB (p. 1340)
- Updating read replicas with MariaDB (p. 1341)
- Working with Multi-AZ read replica deployments with MariaDB (p. 1341)
- Using cascading read replicas with RDS for MariaDB (p. 1342)
- Monitoring MariaDB read replicas (p. 1342)
- Starting and stopping replication with MariaDB read replicas (p. 1343)
- Troubleshooting a MariaDB read replica problem (p. 1343)
Configuring read replicas with MariaDB

Before a MariaDB DB instance can serve as a replication source, make sure to turn on automatic backups on the source DB instance by setting the backup retention period to a value other than 0. This requirement also applies to a read replica that is the source DB instance for another read replica.

You can create up to 15 read replicas from one DB instance within the same Region. For replication to operate effectively, each read replica should have as the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, also scale the read replicas.

RDS for MariaDB supports cascading read replicas. To learn how to configure cascading read replicas, see Using cascading read replicas with RDS for MariaDB (p. 1342).

You can run multiple read replica create and delete actions at the same time that reference the same source DB instance. When you perform these actions, stay within the limit of 15 read replicas for each source instance.

Configuring replication filters with MariaDB

You can use replication filters to specify which databases and tables are replicated with a read replica. Replication filters can include databases and tables in replication or exclude them from replication.

The following are some use cases for replication filters:

- To reduce the size of a read replica. With replication filtering, you can exclude the databases and tables that aren't needed on the read replica.
- To exclude databases and tables from read replicas for security reasons.
- To replicate different databases and tables for specific use cases at different read replicas. For example, you might use specific read replicas for analytics or sharding.
- For a DB instance that has read replicas in different AWS Regions, to replicate different databases or tables in different AWS Regions.

Note
You can also use replication filters to specify which databases and tables are replicated with a primary MariaDB DB instance that is configured as a replica in an inbound replication topology. For more information about this configuration, see Configuring binary log file position replication with an external source instance (p. 1740).

Topics
- Setting replication filtering parameters for RDS for MariaDB (p. 1335)
- Replication filtering limitations for RDS for MariaDB (p. 1336)
- Replication filtering examples for RDS for MariaDB (p. 1336)
- Viewing the replication filters for a read replica (p. 1339)

Setting replication filtering parameters for RDS for MariaDB

To configure replication filters, set the following replication filtering parameters on the read replica:

- replicate-do-db – Replicate changes to the specified databases. When you set this parameter for a read replica, only the databases specified in the parameter are replicated.
- replicate-ignore-db – Don't replicate changes to the specified databases. When the replicate-do-db parameter is set for a read replica, this parameter isn't evaluated.
- replicate-do-table – Replicate changes to the specified tables. When you set this parameter for a read replica, only the tables specified in the parameter are replicated. Also, when the replicate-do-
db or replicate-ignore-db parameter is set, the database that includes the specified tables must be included in replication with the read replica.

- **replicate-ignore-table** – Don’t replicate changes to the specified tables. When the replicate-do-table parameter is set for a read replica, this parameter isn’t evaluated.

- **replicate-wild-do-table** – Replicate tables based on the specified database and table name patterns. The % and _ wildcard characters are supported. When the replicate-do-db or replicate-ignore-db parameter is set, make sure to include the database that includes the specified tables in replication with the read replica.

- **replicate-wild-ignore-table** – Don’t replicate tables based on the specified database and table name patterns. The % and _ wildcard characters are supported. When the replicate-do-table or replicate-wild-do-table parameter is set for a read replica, this parameter isn’t evaluated.

The parameters are evaluated in the order that they are listed. For more information about how these parameters work, see the MariaDB documentation.

By default, each of these parameters has an empty value. On each read replica, you can use these parameters to set, change, and delete replication filters. When you set one of these parameters, separate each filter from others with a comma.

You can use the % and _ wildcard characters in the replicate-wild-do-table and replicate-wild-ignore-table parameters. The % wildcard matches any number of characters, and the _ wildcard matches only one character.

The binary logging format of the source DB instance is important for replication because it determines the record of data changes. The setting of the binlog_format parameter determines whether the replication is row-based or statement-based. For more information, see Binary logging format (p. 907).

**Note**

All data definition language (DDL) statements are replicated as statements, regardless of the binlog_format setting on the source DB instance.

**Replication filtering limitations for RDS for MariaDB**

The following limitations apply to replication filtering for RDS for MariaDB:

- Each replication filtering parameter has a 2,000-character limit.
- Commas aren’t supported in replication filters.
- The MariaDB binlog_do_db and binlog_ignore_db options for binary log filtering aren’t supported.
- Replication filtering doesn’t support XA transactions.

For more information, see Restrictions on XA Transactions in the MySQL documentation.

**Replication filtering examples for RDS for MariaDB**

To configure replication filtering for a read replica, modify the replication filtering parameters in the parameter group associated with the read replica.

**Note**

You can’t modify a default parameter group. If the read replica is using a default parameter group, create a new parameter group and associate it with the read replica. For more information on DB parameter groups, see Working with parameter groups (p. 347).

You can set parameters in a parameter group using the AWS Management Console, AWS CLI, or RDS API. For information about setting parameters, see Modifying parameters in a DB parameter group (p. 352).
When you set parameters in a parameter group, all of the DB instances associated with the parameter group use the parameter settings. If you set the replication filtering parameters in a parameter group, make sure that the parameter group is associated only with read replicas. Leave the replication filtering parameters empty for source DB instances.

The following examples set the parameters using the AWS CLI. These examples set `ApplyMethod` to `immediate` so that the parameter changes occur immediately after the CLI command completes. If you want a pending change to be applied after the read replica is rebooted, set `ApplyMethod` to `pending-reboot`.

The following examples set replication filters:

- Including databases in replication
- Including tables in replication
- Including tables in replication with wildcard characters
- Escaping wildcard characters in names
- Excluding databases from replication
- Excluding tables from replication
- Excluding tables from replication using wildcard characters

**Example Including databases in replication**

The following example includes the `mydb1` and `mydb2` databases in replication. When you set `replicate-do-db` for a read replica, only the databases specified in the parameter are replicated.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group
   --db-parameter-group-name myparametergroup
   --parameters "["ParameterName": "replicate-do-db", "ParameterValue": "mydb1,mydb2",
   "ApplyMethod": "immediate"]"
```

For Windows:

```bash
aws rds modify-db-parameter-group
   --db-parameter-group-name myparametergroup
   --parameters "["ParameterName": "replicate-do-db", "ParameterValue": "mydb1,mydb2",
   "ApplyMethod": "immediate"]"
```

**Example Including tables in replication**

The following example includes the `table1` and `table2` tables in database `mydb1` in replication.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group
   --db-parameter-group-name myparametergroup
   --parameters "["ParameterName": "replicate-do-table", "ParameterValue": "mydb1.table1,mydb1.table2",
   "ApplyMethod": "immediate"]"
```

For Windows:

```bash
aws rds modify-db-parameter-group
   --db-parameter-group-name myparametergroup
   --parameters "["ParameterName": "replicate-do-table", "ParameterValue": "mydb1.table1,mydb1.table2",
   "ApplyMethod": "immediate"]"
```
### Example Including tables in replication using wildcard characters

The following example includes tables with names that begin with `orders` and `returns` in database `mydb` in replication.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group
  --db-parameter-group-name myparametergroup
  --parameters "["ParameterName": "replicate-do-table", "ParameterValue": "mydb1.table1,mydb1.table2", "ApplyMethod": "immediate"]"
```

For Windows:

```bash
aws rds modify-db-parameter-group
  --db-parameter-group-name myparametergroup
  --parameters "["ParameterName": "replicate-do-table", "ParameterValue": "mydb1.table1,mydb1.table2", "ApplyMethod": "immediate"]"
```

### Example Escaping wildcard characters in names

The following example shows you how to use the escape character `\` to escape a wildcard character that is part of a name.

Assume that you have several table names in database `mydb1` that start with `my_table`, and you want to include these tables in replication. The table names include an underscore, which is also a wildcard character, so the example escapes the underscore in the table names.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group
  --db-parameter-group-name myparametergroup
  --parameters "["ParameterName": "replicate-wild-do-table", "ParameterValue": "my\_table%,mydb.returns%", "ApplyMethod": "immediate"]"
```

For Windows:

```bash
aws rds modify-db-parameter-group
  --db-parameter-group-name myparametergroup
  --parameters "["ParameterName": "replicate-wild-do-table", "ParameterValue": "my\_table%,mydb.returns%", "ApplyMethod": "immediate"]"
```

### Example Excluding databases from replication

The following example excludes the `mydb1` and `mydb2` databases from replication.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group
  --db-parameter-group-name myparametergroup
```
--parameters "["ParameterName": "replicate-ignore-db", "ParameterValue": "mydb1,mydb2", "ApplyMethod": "immediate"]"

For Windows:

```bash
aws rds modify-db-parameter-group ^
   --db-parameter-group-name myparametergroup ^
   --parameters "["ParameterName": "replicate-ignore-db", "ParameterValue": "mydb1,mydb2", "ApplyMethod": "immediate"]"
```

### Example Excluding tables from replication

The following example excludes tables `table1` and `table2` in database `mydb1` from replication.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group \
   --db-parameter-group-name myparametergroup \
   --parameters "["ParameterName": "replicate-ignore-table", "ParameterValue": "mydb1.table1,mydb1.table2", "ApplyMethod": "immediate"]"
```

For Windows:

```bash
aws rds modify-db-parameter-group ^
   --db-parameter-group-name myparametergroup ^
   --parameters "["ParameterName": "replicate-ignore-table", "ParameterValue": "mydb1.table1,mydb1.table2", "ApplyMethod": "immediate"]"
```

### Example Excluding tables from replication using wildcard characters

The following example excludes tables with names that begin with `orders` and `returns` in database `mydb` from replication.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group \
   --db-parameter-group-name myparametergroup \
   --parameters "["ParameterName": "replicate-wildignore-table", "ParameterValue": "mydb.orders%,mydb.returns%", "ApplyMethod": "immediate"]"
```

For Windows:

```bash
aws rds modify-db-parameter-group ^
   --db-parameter-group-name myparametergroup ^
   --parameters "["ParameterName": "replicate-wildignore-table", "ParameterValue": "mydb.orders%,mydb.returns%", "ApplyMethod": "immediate"]"
```

### Viewing the replication filters for a read replica

You can view the replication filters for a read replica in the following ways:

- Check the settings of the replication filtering parameters in the parameter group associated with the read replica.

  For instructions, see [Viewing parameter values for a DB parameter group](p. 359).
• In a MariaDB client, connect to the read replica and run the SHOW REPLICA STATUS statement.

In the output, the following fields show the replication filters for the read replica:
• Replicate_Do_DB
• Replicate_Ignore_DB
• Replicate_Do_Table
• Replicate_Ignore_Table
• Replicate_Wild_Do_Table
• Replicate_Wild_Ignore_Table

For more information about these fields, see Checking Replication Status in the MySQL documentation.

Note
Previous versions of MariaDB used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MariaDB version before 10.5, then use SHOW SLAVE STATUS.

Configuring delayed replication with MariaDB

You can use delayed replication as a strategy for disaster recovery. With delayed replication, you specify the minimum amount of time, in seconds, to delay replication from the source to the read replica. In the event of a disaster, such as a table deleted unintentionally, you complete the following steps to recover from the disaster quickly:

• Stop replication to the read replica before the change that caused the disaster is sent to it.

To stop replication, use the mysql.rds_stop_replication(p. 1798) stored procedure.
• Promote the read replica to be the new source DB instance by using the instructions in Promoting a read replica to be a standalone DB instance (p. 447).

Note
• Delayed replication is supported for MariaDB 10.6 and higher.
• Use stored procedures to configure delayed replication. You can’t configure delayed replication with the AWS Management Console, the AWS CLI, or the Amazon RDS API.
• You can use replication based on global transaction identifiers (GTIDs) in a delayed replication configuration.

Topics
• Configuring delayed replication during read replica creation (p. 1340)
• Modifying delayed replication for an existing read replica (p. 1341)
• Promoting a read replica (p. 1341)

Configuring delayed replication during read replica creation

To configure delayed replication for any future read replica created from a DB instance, run the mysql.rds_set_configuration(p. 1774) stored procedure with the target delay parameter.

To configure delayed replication during read replica creation

1. Using a MariaDB client, connect to the MariaDB DB instance to be the source for read replicas as the master user.
2. Run the `mysql.rds_set_configuration` stored procedure with the `target delay` parameter.
   For example, run the following stored procedure to specify that replication is delayed by at least one hour (3,600 seconds) for any read replica created from the current DB instance.
   
   ```
   call mysql.rds_set_configuration('target delay', 3600);
   ```

   **Note**
   After running this stored procedure, any read replica you create using the AWS CLI or Amazon RDS API is configured with replication delayed by the specified number of seconds.

### Modifying delayed replication for an existing read replica

To modify delayed replication for an existing read replica, run the `mysql.rds_set_source_delay` stored procedure.

**To modify delayed replication for an existing read replica**

1. Using a MariaDB client, connect to the read replica as the master user.
2. Use the `mysql.rds_stop_replication` stored procedure to stop replication.
3. Run the `mysql.rds_set_source_delay` stored procedure.
   For example, run the following stored procedure to specify that replication to the read replica is delayed by at least one hour (3600 seconds).
   
   ```
   call mysql.rds_set_source_delay(3600);
   ```
4. Use the `mysql.rds_start_replication` stored procedure to start replication.

### Promoting a read replica

After replication is stopped, in a disaster recovery scenario, you can promote a read replica to be the new source DB instance. For information about promoting a read replica, see [Promoting a read replica to be a standalone DB instance](p. 447).

### Updating read replicas with MariaDB

Read replicas are designed to support read queries, but you might need occasional updates. For example, you might need to add an index to speed the specific types of queries accessing the replica. You can enable updates by setting the `read_only` parameter to 0 in the DB parameter group for the read replica.

### Working with Multi-AZ read replica deployments with MariaDB

You can create a read replica from either single-AZ or Multi-AZ DB instance deployments. You use Multi-AZ deployments to improve the durability and availability of critical data, but you can't use the Multi-AZ secondary to serve read-only queries. Instead, you can create read replicas from high-traffic Multi-AZ DB instances to offload read-only queries. If the source instance of a Multi-AZ deployment fails over to the secondary, any associated read replicas automatically switch to use the secondary (now primary) as their replication source. For more information, see [Configuring and managing a Multi-AZ deployment](p. 492).

You can create a read replica as a Multi-AZ DB instance. Amazon RDS creates a standby of your replica in another Availability Zone for failover support for the replica. Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.
Using cascading read replicas with RDS for MariaDB

RDS for MariaDB supports cascading read replicas. With cascading read replicas, you can scale reads without adding overhead to your source RDS for MariaDB DB instance.

With cascading read replicas, your RDS for MariaDB DB instance sends data to the first read replica in the chain. That read replica then sends data to the second replica in the chain, and so on. The end result is that all read replicas in the chain have the changes from the RDS for MariaDB DB instance, but without the overhead solely on the source DB instance.

You can create a series of up to three read replicas in a chain from a source RDS for MariaDB DB instance. For example, suppose that you have an RDS for MariaDB DB instance, mariadb-main. You can do the following:

• Starting with mariadb-main, create the first read replica in the chain, read-replica-1.
• Next, from read-replica-1, create the next read replica in the chain, read-replica-2.
• Finally, from read-replica-2, create the third read replica in the chain, read-replica-3.

You can't create another read replica beyond this third cascading read replica in the series for mariadb-main. A complete series of instances from an RDS for MariaDB source DB instance through to the end of a series of cascading read replicas can consist of at most four DB instances.

For cascading read replicas to work, each source RDS for MariaDB DB instance must have automated backups turned on. To turn on automatic backups on a read replica, first create the read replica, and then modify the read replica to turn on automatic backups. For more information, see Creating a read replica (p. 445).

As with any read replica, you can promote a read replica that's part of a cascade. Promoting a read replica from within a chain of read replicas removes that replica from the chain. For example, suppose that you want to move some of the workload from your mariadb-main DB instance to a new instance for use by the accounting department only. Assuming the chain of three read replicas from the example, you decide to promote read-replica-2. The chain is affected as follows:

• Promoting read-replica-2 removes it from the replication chain.
  • It is now a full read/write DB instance.
  • It continues replicating to read-replica-3, just as it was doing before promotion.
  • Your mariadb-main continues replicating to read-replica-1.

For more information about promoting read replicas, see Promoting a read replica to be a standalone DB instance (p. 447).

Monitoring MariaDB read replicas

For MariaDB read replicas, you can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS ReplicaLag metric. The ReplicaLag metric reports the value of the Seconds_Behind_Master field of the SHOW REPLICA STATUS command.

**Note**

Previous versions of MariaDB used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MariaDB version before 10.5, then use SHOW SLAVE STATUS.

Common causes for replication lag for MariaDB are the following:

• A network outage.
• Writing to tables with indexes on a read replica. If the read_only parameter is not set to 0 on the read replica, it can break replication.
Using a nontransactional storage engine such as MyISAM. Replication is only supported for the InnoDB storage engine on MariaDB.

When the ReplicaLag metric reaches 0, the replica has caught up to the source DB instance. If the ReplicaLag metric returns -1, then replication is currently not active. ReplicaLag = -1 is equivalent to Seconds_Behind_Master = NULL.

Starting and stopping replication with MariaDB read replicas

You can stop and restart the replication process on an Amazon RDS DB instance by calling the system stored procedures `mysql.rds_stop_replication` (p. 1798) and `mysql.rds_start_replication` (p. 1796). You can do this when replicating between two Amazon RDS instances for long-running operations such as creating large indexes. You also need to stop and start replication when importing or exporting databases. For more information, see Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime (p. 1706) and Exporting data from a MySQL DB instance by using replication (p. 1744).

If replication is stopped for more than 30 consecutive days, either manually or due to a replication error, Amazon RDS ends replication between the source DB instance and all read replicas. It does so to prevent increased storage requirements on the source DB instance and long failover times. The read replica DB instance is still available. However, replication can't be resumed because the binary logs required by the read replica are deleted from the source DB instance after replication is ended. You can create a new read replica for the source DB instance to reestablish replication.

Troubleshooting a MariaDB read replica problem

The replication technologies for MariaDB are asynchronous. Because they are asynchronous, occasional BinLogDiskUsage increases on the source DB instance and ReplicaLag on the read replica are to be expected. For example, a high volume of write operations to the source DB instance can occur in parallel. In contrast, write operations to the read replica are serialized using a single I/O thread, which can lead to a lag between the source instance and read replica. For more information about read-only replicas in the MariaDB documentation, go to Replication overview.

You can do several things to reduce the lag between updates to a source DB instance and the subsequent updates to the read replica, such as the following:

• Sizing a read replica to have a storage size and DB instance class comparable to the source DB instance.

• Ensuring that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the `max_allowed_packet` parameter later in this section.

Amazon RDS monitors the replication status of your read replicas and updates the Replication State field of the read replica instance to Error if replication stops for any reason. An example might be if DML queries run on your read replica conflict with the updates made on the source DB instance.

You can review the details of the associated error thrown by the MariaDB engine by viewing the Replication Error field. Events that indicate the status of the read replica are also generated, including RDS-EVENT-0045 (p. 887), RDS-EVENT-0046 (p. 888), and RDS-EVENT-0047 (p. 883). For more information about events and subscribing to events, see Working with Amazon RDS event notification (p. 855). If a MariaDB error message is returned, review the error in the MariaDB error message documentation.

One common issue that can cause replication errors is when the value for the `max_allowed_packet` parameter for a read replica is less than the `max_allowed_packet` parameter for the source DB.
instance. The `max_allowed_packet` parameter is a custom parameter that you can set in a DB parameter group that is used to specify the maximum size of DML code that can be run on the database. In some cases, the `max_allowed_packet` parameter value in the DB parameter group associated with a source DB instance is smaller than the `max_allowed_packet` parameter value in the DB parameter group associated with the source's read replica. In these cases, the replication process can throw an error (Packet bigger than 'max_allowed_packet' bytes) and stop replication. You can fix the error by having the source and read replica use DB parameter groups with the same `max_allowed_packet` parameter values.

Other common situations that can cause replication errors include the following:

- Writing to tables on a read replica. If you are creating indexes on a read replica, you need to have the `read_only` parameter set to 0 to create the indexes. If you are writing to tables on the read replica, it might break replication.
- Using a non-transactional storage engine such as MyISAM. read replicas require a transactional storage engine. Replication is only supported for the InnoDB storage engine on MariaDB.
- Using unsafe nondeterministic queries such as `SYSDATE()`. For more information, see Determination of safe and unsafe statements in binary logging.

If you decide that you can safely skip an error, you can follow the steps described in Skipping the current replication error (p. 1760). Otherwise, you can delete the read replica and create an instance using the same DB parameter group with the same `max_allowed_packet` parameter values. You can reduce the chance of this happening by setting the following parameter values: `sync_binlog=1` and `innodb_flush_log_at_trx_commit=1`. These settings might reduce performance, so test their impact before implementing the changes in a production environment.

**Configuring GTID-based replication with an external source instance**

You can set up replication based on global transaction identifiers (GTIDs) from an external MariaDB instance of version 10.0.24 or higher into an RDS for MariaDB DB instance. Follow these guidelines when you set up an external source instance and a replica on Amazon RDS:

- Monitor failover events for the RDS for MariaDB DB instance that is your replica. If a failover occurs, then the DB instance that is your replica might be recreated on a new host with a different network address. For information on how to monitor failover events, see Working with Amazon RDS event notification (p. 855).
- Maintain the binary logs (binlogs) on your source instance until you have verified that they have been applied to the replica. This maintenance ensures that you can restore your source instance in the event of a failure.
- Turn on automated backups on your MariaDB DB instance on Amazon RDS. Turning on automated backups ensures that you can restore your replica to a particular point in time if you need to resynchronize your source instance and replica. For information on backups and Point-In-Time Restore, see Backing up and restoring (p. 590).

**Note**
The permissions required to start replication on a MariaDB DB instance are restricted and not available to your Amazon RDS master user. Because of this, you must use the Amazon RDS `mysql.rds_set_external_master_gtid` (p. 1361) and `mysql.rds_start_replication` (p. 1796) commands to set up replication between your live database and your RDS for MariaDB database.
To start replication between an external source instance and a MariaDB DB instance on Amazon RDS, use the following procedure.

**To start replication**

1. Make the source MariaDB instance read-only:

   ```
   mysql> FLUSH TABLES WITH READ LOCK;
   mysql> SET GLOBAL read_only = ON;
   ```

2. Get the current GTID of the external MariaDB instance. You can do this by using `mysql` or the query editor of your choice to run `SELECT @@gtid_current_pos;`.

   The GTID is formatted as `<domain-id>-<server-id>-<sequence-id>`. A typical GTID looks something like `0-1234510749-1728`. For more information about GTIDs and their component parts, see Global transaction ID in the MariaDB documentation.

3. Copy the database from the external MariaDB instance to the MariaDB DB instance using `mysqldump`. For very large databases, you might want to use the procedure in Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime (p. 1706).

   For Linux, macOS, or Unix:

   ```
   mysqldump \
   --databases database_name \
   --single-transaction \n   --compress \
   --order-by-primary \n   -u local_user \n   -plocal_password | mysql \
   --host=hostname \
   --port=3306 \
   -u RDS_user_name \
   -pRDS_password
   ```

   For Windows:

   ```
   mysqldump ^
   --databases database_name ^
   --single-transaction ^
   --compress ^
   --order-by-primary \n   -u local_user ^
   -plocal_password | mysql ^
   --host=hostname ^
   --port=3306 ^
   -u RDS_user_name ^
   -pRDS_password
   ```

   **Note**
   Make sure that there isn’t a space between the `-p` option and the entered password. Specify a password other than the prompt shown here as a security best practice.

   Use the `--host`, `--user (-u)`, `--port` and `-p` options in the `mysql` command to specify the host name, user name, port, and password to connect to your MariaDB DB instance. The host name is the DNS name from the MariaDB DB instance endpoint, for example `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the Amazon RDS Management Console.

4. Make the source MariaDB instance writeable again.
Configuring GTID-based replication with an external source instance

5. In the Amazon RDS Management Console, add the IP address of the server that hosts the external MariaDB database to the VPC security group for the MariaDB DB instance. For more information on modifying a VPC security group, go to Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

The IP address can change when the following conditions are met:

- You are using a public IP address for communication between the external source instance and the DB instance.
- The external source instance was stopped and restarted.

If these conditions are met, verify the IP address before adding it.

You might also need to configure your local network to permit connections from the IP address of your MariaDB DB instance, so that it can communicate with your external MariaDB instance. To find the IP address of the MariaDB DB instance, use the `host` command.

6. Using the client of your choice, connect to the external MariaDB instance and create a MariaDB user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following is an example.

   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
   ```

   **Note**
   Specify a password other than the prompt shown here as a security best practice.

7. For the external MariaDB instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. For example, to grant the REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain, issue the following command.

   ```
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
   ```

8. Make the MariaDB DB instance the replica. Connect to the MariaDB DB instance as the master user and identify the external MariaDB database as the replication source instance by using the `mysql.rds_set_external_master_gtid` command. Use the GTID that you determined in Step 2. The following is an example.

   ```
   CALL mysql.rds_set_external_master_gtid ('mymasterserver.mydomain.com', 3306, 'repl_user', 'password', 'GTID', 0);
   ```

   **Note**
   Specify a password other than the prompt shown here as a security best practice.

9. On the MariaDB DB instance, issue the `mysql.rds_start_replication` command to start replication.

   ```
   CALL mysql.rds_start_replication;
   ```
Configuring binary log file position replication with an external source instance

You can set up replication between an RDS for MySQL or MariaDB DB instance and a MySQL or MariaDB instance that is external to Amazon RDS using binary log file replication.

Topics

• Before you begin (p. 1347)
• Configuring binary log file position replication with an external source instance (p. 1347)

Before you begin

You can configure replication using the binary log file position of replicated transactions.

The permissions required to start replication on an Amazon RDS DB instance are restricted and not available to your Amazon RDS master user. Because of this, make sure that you use the Amazon RDS mysql.rds_set_external_master (p. 1785) and mysql.rds_start_replication (p. 1796) commands to set up replication between your live database and your Amazon RDS database.

To set the binary logging format for a MySQL or MariaDB database, update the binlog_format parameter. If your DB instance uses the default DB instance parameter group, create a new DB parameter group to modify binlog_format settings. We recommend that you use the default setting for binlog_format, which is MIXED. However, you can also set binlog_format to ROW or STATEMENT if you need a specific binary log (binlog) format. Reboot your DB instance for the change to take effect.

For information about setting the binlog_format parameter, see Configuring MySQL binary logging (p. 921). For information about the implications of different MySQL replication types, see Advantages and disadvantages of statement-based and row-based replication in the MySQL documentation.

Configuring binary log file position replication with an external source instance

Follow these guidelines when you set up an external source instance and a replica on Amazon RDS:

• Monitor failover events for the Amazon RDS DB instance that is your replica. If a failover occurs, then the DB instance that is your replica might be recreated on a new host with a different network address. For information on how to monitor failover events, see Working with Amazon RDS event notification (p. 855).

• Maintain the binlogs on your source instance until you have verified that they have been applied to the replica. This maintenance makes sure that you can restore your source instance in the event of a failure.

• Turn on automated backups on your Amazon RDS DB instance. Turning on automated backups makes sure that you can restore your replica to a particular point in time if you need to re-synchronize your source instance and replica. For information on backups and point-in-time restore, see Backing up and restoring (p. 590).

To configure binary log file replication with an external source instance

1. Make the source MySQL or MariaDB instance read-only.

```sql
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```
2. Run the `SHOW MASTER STATUS` command on the source MySQL or MariaDB instance to determine the binlog location.

You receive output similar to the following example.

<table>
<thead>
<tr>
<th>File</th>
<th>Position</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql-bin-changelog.000031</td>
<td>107</td>
</tr>
</tbody>
</table>

3. Copy the database from the external instance to the Amazon RDS DB instance using `mysqldump`.
For very large databases, you might want to use the procedure in Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime (p. 1706).

For Linux, macOS, or Unix:

```bash
mysqldump --databases database_name \
    --single-transaction \ 
    --compress \ 
    --order-by-primary \ 
    -u local_user \ 
    -plocal_password | mysql \ 
    --host=hostname \ 
    --port=3306 \ 
    -u RDS_user_name \ 
    -pRDS_password
```

For Windows:

```bash
mysqldump --databases database_name ^
    --single-transaction ^
    --compress ^
    --order-by-primary ^
    -u local_user ^
    -plocal_password | mysql ^
    --host=hostname ^
    --port=3306 ^
    -u RDS_user_name ^
    -pRDS_password
```

**Note**
Make sure that there isn't a space between the `-p` option and the entered password.

To specify the host name, user name, port, and password to connect to your Amazon RDS DB instance, use the `--host`, `--user (-u)`, `--port` and `-p` options in the `mysql` command. The host name is the Domain Name Service (DNS) name from the Amazon RDS DB instance endpoint, for example `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the AWS Management Console.

4. Make the source MySQL or MariaDB instance writeable again.

```sql
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

For more information on making backups for use with replication, see the MySQL documentation.

5. In the AWS Management Console, add the IP address of the server that hosts the external database to the virtual private cloud (VPC) security group for the Amazon RDS DB instance. For more information on modifying a VPC security group, see Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.
Configuring binary log file position
replication with an external source instance

The IP address can change when the following conditions are met:

- You are using a public IP address for communication between the external source instance and the DB instance.
- The external source instance was stopped and restarted.

If these conditions are met, verify the IP address before adding it.

You might also need to configure your local network to permit connections from the IP address of your Amazon RDS DB instance. You do this so that your local network can communicate with your external MySQL or MariaDB instance. To find the IP address of the Amazon RDS DB instance, use the `host` command.

```
host db_instance_endpoint
```

The host name is the DNS name from the Amazon RDS DB instance endpoint.

6. Using the client of your choice, connect to the external instance and create a user to use for replication. Use this account solely for replication and restrict it to your domain to improve security. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

**Note**
Specify a password other than the prompt shown here as a security best practice.

7. For the external instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. For example, to grant the `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the `repl_user` user for your domain, issue the following command.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

8. Make the Amazon RDS DB instance the replica. To do so, first connect to the Amazon RDS DB instance as the master user. Then identify the external MySQL or MariaDB database as the source instance by using the `mysql.rds_set_external_master` (p. 1785) command. Use the master log file name and master log position that you determined in step 2. The following is an example.

```
CALL mysql.rds_set_external_master ('mymasterserver.mydomain.com', 3306, 'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0);
```

**Note**
On RDS for MySQL, you can choose to use delayed replication by running the `mysql.rds_set_external_master_with_delay` (p. 1790) stored procedure instead. On RDS for MySQL, one reason to use delayed replication is to turn on disaster recovery with the `mysql.rds_start_replication_until` (p. 1796) stored procedure. Currently, RDS for MariaDB supports delayed replication but doesn't support the `mysql.rds_start_replication_until` procedure.

9. On the Amazon RDS DB instance, issue the `mysql.rds_start_replication` (p. 1796) command to start replication.

```
CALL mysql.rds_start_replication;
```
Options for MariaDB database engine

Following, you can find descriptions for options, or additional features, that are available for Amazon RDS instances running the MariaDB DB engine. To turn on these options, you add them to a custom option group, and then associate the option group with your DB instance. For more information about working with option groups, see Working with option groups (p. 331).

Amazon RDS supports the following options for MariaDB:

<table>
<thead>
<tr>
<th>Option ID</th>
<th>Engine versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>MARIADB_AUDIT_PLUGIN</td>
<td>MariaDB 10.3 and higher</td>
</tr>
</tbody>
</table>

MariaDB Audit Plugin support

Amazon RDS supports using the MariaDB Audit Plugin on MariaDB database instances. The MariaDB Audit Plugin records database activity such as users logging on to the database, queries run against the database, and more. The record of database activity is stored in a log file.

Audit Plugin option settings

Amazon RDS supports the following settings for the MariaDB Audit Plugin option.

Note
If you don't configure an option setting in the RDS console, RDS uses the default setting.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SERVER_AUDIT_FILE_PATH</td>
<td>/rdsdbdata/log/audit/</td>
<td>/rdsdbdata/log/audit/</td>
<td>The location of the log file. The log file contains the record of the activity specified in SERVER_AUDIT_EVENTS. For more information, see Viewing and listing database log files (p. 895) and MariaDB database log files (p. 902).</td>
</tr>
<tr>
<td>SERVER_AUDIT_FILE_SIZE</td>
<td>1–1000000000</td>
<td>1000000</td>
<td>The size in bytes that when reached, causes the file to rotate. For more information, see Log file size (p. 906).</td>
</tr>
<tr>
<td>SERVER_AUDIT_FILE_ROTATIONS</td>
<td>0–100</td>
<td>9</td>
<td>The number of log rotations to save when server_audit_output_type=file. If set to 0, then the log file never rotates. For more information, see Log file size (p. 906) and Downloading a database log file (p. 896).</td>
</tr>
<tr>
<td>SERVER_AUDIT_EVENTS</td>
<td>CONNECT, QUERY, TABLE, QUERY_DDL, QUERY_DML, QUERY_DML_NO_SELECT, QUERY_DCL</td>
<td>CONNECT, QUERY</td>
<td>The types of activity to record in the log. Installing the MariaDB Audit Plugin is itself logged.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• CONNECT: Log successful and unsuccessful connections to the database, and disconnections from the database.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• QUERY: Log the text of all queries run against the database.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• TABLE: Log tables affected by queries when the queries are run against the database.</td>
</tr>
</tbody>
</table>

</tbody>
</table>

#### SERVER_AUDIT_INCL_USERS

- **Multiple comma-separated values**
- **None**

Include only activity from the specified users. By default, activity is recorded for all users. SERVER_AUDIT_INCL_USERS and SERVER_AUDIT_EXCL_USERS are mutually exclusive. If you add values to SERVER_AUDIT_INCL_USERS, make sure no values are added to SERVER_AUDIT_EXCL_USERS.

#### SERVER_AUDIT_EXCL_USERS

- **Multiple comma-separated values**
- **None**

Exclude activity from the specified users. By default, activity is recorded for all users. SERVER_AUDIT_INCL_USERS and SERVER_AUDIT_EXCL_USERS are mutually exclusive. If you add values to SERVER_AUDIT_EXCL_USERS, make sure no values are added to SERVER_AUDIT_INCL_USERS.

The rdsadmin user queries the database every second to check the health of the database. Depending on your other settings, this activity can possibly cause the size of your log file to grow very large, very quickly. If you don't need to record this activity, add the rdsadmin user to the SERVER_AUDIT_EXCL_USERS list.

**Note**

CONNECT activity is always recorded for all users, even if the user is specified for this option setting.

#### SERVER_AUDIT_LOGGING

- **ON**

Logging is active. The only valid value is ON. Amazon RDS does not support deactivating logging. If you want to deactivate logging, remove the MariaDB Audit Plugin. For more information, see [Removing the MariaDB Audit Plugin](p. 1352).

#### SERVER_AUDIT_QUERY_LOG_LIMIT

- **0–2147483647**
- **1024**

The limit on the length of the query string in a record.
Adding the MariaDB Audit Plugin

The general process for adding the MariaDB Audit Plugin to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

After you add the MariaDB Audit Plugin, you don't need to restart your DB instance. As soon as the option group is active, auditing begins immediately.

To add the MariaDB Audit Plugin

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group. Choose mariadb for Engine, and choose 10.3 or higher for Major engine version. For more information, see Creating an option group (p. 332).
2. Add the MARIADB_AUDIT_PLUGIN option to the option group, and configure the option settings. For more information about adding options, see Adding an option to an option group (p. 335). For more information about each setting, see Audit Plugin option settings (p. 1350).
3. Apply the option group to a new or existing DB instance.
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 300).
   - For an existing DB instance, you apply the option group by modifying the DB instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 401).

Viewing and downloading the MariaDB Audit Plugin log

After you enable the MariaDB Audit Plugin, you access the results in the log files the same way you access any other text-based log files. The audit log files are located at /rds/dbdata/log/audit/. For information about viewing the log file in the console, see Viewing and listing database log files (p. 895). For information about downloading the log file, see Downloading a database log file (p. 896).

Modifying MariaDB Audit Plugin settings

After you enable the MariaDB Audit Plugin, you can modify settings for the plugin. For more information about how to modify option settings, see Modifying an option setting (p. 340). For more information about each setting, see Audit Plugin option settings (p. 1350).

Removing the MariaDB Audit Plugin

Amazon RDS doesn't support turning off logging in the MariaDB Audit Plugin. However, you can remove the plugin from a DB instance. When you remove the MariaDB Audit Plugin, the DB instance is restarted automatically to stop auditing.

To remove the MariaDB Audit Plugin from a DB instance, do one of the following:

- Remove the MariaDB Audit Plugin option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 343).
- Modify the DB instance and specify a different option group that doesn't include the plugin. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 401).
Parameters for MariaDB

By default, a MariaDB DB instance uses a DB parameter group that is specific to a MariaDB database. This parameter group contains some but not all of the parameters contained in the Amazon RDS DB parameter groups for the MySQL database engine. It also contains a number of new, MariaDB-specific parameters. For information about working with parameter groups and setting parameters, see Working with parameter groups (p. 347).

Viewing MariaDB parameters

RDS for MariaDB parameters are set to the default values of the storage engine that you have selected. For more information about MariaDB parameters, see the MariaDB documentation. For more information about MariaDB storage engines, see Supported storage engines for MariaDB on Amazon RDS (p. 1277).

You can view the parameters available for a specific RDS for MariaDB version using the RDS console or the AWS CLI. For information about viewing the parameters in a MariaDB parameter group in the RDS console, see Viewing parameter values for a DB parameter group (p. 359).

Using the AWS CLI, you can view the parameters for an RDS for MariaDB version by running the describe-engine-default-parameters command. Specify one of the following values for the --db-parameter-group-family option:

- mariadb10.11
- mariadb10.6
- mariadb10.5
- mariadb10.4
- mariadb10.3

For example, to view the parameters for RDS for MariaDB version 10.6, run the following command.

```bash
aws rds describe-engine-default-parameters --db-parameter-group-family mariadb10.6
```

Your output looks similar to the following.

```json
{
  "EngineDefaults": {
    "Parameters": [
      {
        "ParameterName": "alter_algorithm",
        "Description": "Specify the alter table algorithm.",
        "Source": "engine-default",
        "ApplyType": "dynamic",
        "DataType": "string",
        "AllowedValues": "DEFAULT,COPY,INPLACE,NOCOPY,INSTANT",
        "IsModifiable": true
      },
      {
        "ParameterName": "analyze_sample_percentage",
        "Description": "Percentage of rows from the table ANALYZE TABLE will sample to collect table statistics.",
        "Source": "engine-default",
        "ApplyType": "dynamic",
        "DataType": "float",
        "AllowedValues": "0-100",
        "IsModifiable": true
      }
    ]
  }
}
```
MySQL parameters that aren't available

The following MySQL parameters are not available in MariaDB-specific DB parameter groups:

- bind_address
- binlog_error_action
- binlog_gtid_simple_recovery
- binlog_max_flush_queue_time
- binlog_order_commits
- binlog_row_image
- binlog_rows_query_log_events
- binlogging_impossible_mode
- block_encryption_mode
- core_file
- default_tmp_storage_engine
- div_precision_increment
- end_markers_in_json
- enforce_gtid_consistency
- eq_range_index_dive_limit
- explicit_defaults_for_timestamp
- gtid_executed
- gtid-mode

To list only the modifiable parameters for RDS for MariaDB version 10.6, run the following command.

For Linux, macOS, or Unix:

```
aws rds describe-engine-default-parameters --db-parameter-group-family mariadb10.6 \
  --query 'EngineDefaults.Parameters[?IsModifiable==`true`]'
```

For Windows:

```
aws rds describe-engine-default-parameters --db-parameter-group-family mariadb10.6 ^
  --query "EngineDefaults.Parameters[?IsModifiable==`true`]"
```
• gtid_next
• gtid_owned
• gtid_purged
• log_bin_basename
• log_bin_index
• log_bin_use_v1_row_events
• log_slow_admin_statements
• log_slow_slave_statements
• log_throttle_queries_not_using_indexes
• master-info-repository
• optimizer_trace
• optimizer_trace_features
• optimizer_trace_limit
• optimizer_trace_max_mem_size
• optimizer_trace_offset
• relay_log_info_repository
• rpl_stop_slave_timeout
• slave_parallel_workers
• slave_pending_jobs_size_max
• slave_rows_search_algorithms
• storage_engine
• table_open_cache_instances
• timed_mutexes
• transaction_allow_batching

• validate_password_dictionary_file
• validate_password_length
• validate_password_mixed_case_count
• validate_password_number_count
• validate_password_policy
• validate_password_special_char_count

For more information on MySQL parameters, see the MySQL documentation.
Migrating data from a MySQL DB snapshot to a MariaDB DB instance

You can migrate an RDS for MySQL DB snapshot to a new DB instance running MariaDB using the AWS Management Console, the AWS CLI, or Amazon RDS API. You must use a DB snapshot that was created from an Amazon RDS DB instance running MySQL 5.6 or 5.7. To learn how to create an RDS for MySQL DB snapshot, see Creating a DB snapshot (p. 613).

Migrating the snapshot doesn't affect the original DB instance from which the snapshot was taken. You can test and validate the new DB instance before diverting traffic to it as a replacement for the original DB instance.

After you migrate from MySQL to MariaDB, the MariaDB DB instance is associated with the default DB parameter group and option group. After you restore the DB snapshot, you can associate a custom DB parameter group with the new DB instance. However, a MariaDB parameter group has a different set of configurable system variables. For information about the differences between MySQL and MariaDB system variables, see System Variable Differences between MariaDB and MySQL. To learn about DB parameter groups, see Working with parameter groups (p. 347). To learn about option groups, see Working with option groups (p. 331).

Performing the migration

You can migrate an RDS for MySQL DB snapshot to a new MariaDB DB instance using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To migrate a MySQL DB snapshot to a MariaDB DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots, and then select the MySQL DB snapshot you want to migrate.
3. For Actions, choose Migrate snapshot. The Migrate database page appears.
4. For Migrate to DB Engine, choose mariadb.

Amazon RDS selects the DB engine version automatically. You can't change the DB engine version.
5. For the remaining sections, specify your DB instance settings. For information about each setting, see Settings for DB instances (p. 308).

6. Choose Migrate.

AWS CLI

To migrate data from a MySQL DB snapshot to a MariaDB DB instance, use the AWS CLI restore-db-instance-from-db-snapshot command with the following parameters:

- --db-instance-identifier – Name of the DB instance to create from the DB snapshot.
- --db-snapshot-identifier – The identifier for the DB snapshot to restore from.
- --engine – The database engine to use for the new instance.

Example

For Linux, macOS, or Unix:

```bash
aws rds restore-db-instance-from-db-snapshot
  --db-instance-identifier newmariadbinstance
  --db-snapshot-identifier mysqlsnapshot
  --engine mariadb
```

For Windows:

```bash
aws rds restore-db-instance-from-db-snapshot
  --db-instance-identifier newmariadbinstance
  --db-snapshot-identifier mysqlsnapshot
  --engine mariadb
```
To migrate data from a MySQL DB snapshot to a MariaDB DB instance, call the Amazon RDS API operation `RestoreDBInstanceFromDBSnapshot`.

### Incompatibilities between MariaDB and MySQL

Incompatibilities between MySQL and MariaDB include the following:

- You can't migrate a DB snapshot created with MySQL 8.0 to MariaDB.
- If the source MySQL database uses a SHA256 password hash, make sure to reset user passwords that are SHA256 hashed before you connect to the MariaDB database. The following code shows how to reset a password that is SHA256 hashed.

```sql
SET old_passwords = 0;
UPDATE mysql.user SET plugin = 'mysql_native_password',
    Password = PASSWORD('new_password')
WHERE (User, Host) = ('master_user_name', %);
FLUSH PRIVILEGES;
```

- If your RDS master user account uses the SHA-256 password hash, make sure to reset the password using the AWS Management Console, the `modify-db-instance` AWS CLI command, or the `ModifyDBInstance` RDS API operation. For information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 401).
- MariaDB doesn't support the Memcached plugin. However, the data used by the Memcached plugin is stored as InnoDB tables. After you migrate a MySQL DB snapshot, you can access the data used by the Memcached plugin using SQL. For more information about the innodb_memcache database, see InnoDB memcached Plugin Internals.
MariaDB on Amazon RDS SQL reference

Following, you can find descriptions of system stored procedures that are available for Amazon RDS instances running the MariaDB DB engine.

You can use the system stored procedures that are available for MySQL DB instances and MariaDB DB instances. These stored procedures are documented at RDS for MySQL stored procedure reference (p. 1773). MariaDB DB instances support all of the stored procedures, except for mysql.rds_start_replication_until and mysql.rds_start_replication_until_gtid.

Additionally, the following system stored procedures are supported only for Amazon RDS DB instances running MariaDB:

- mysql.rds_replica_status (p. 1360)
- mysql.rds_set_external_master_gtid (p. 1361)
- mysql.rds_kill_query_id (p. 1363)

mysql.rds_replica_status

Shows the replication status of a MariaDB read replica.

Call this procedure on the read replica to show status information on essential parameters of the replica threads.

Syntax

```
CALL mysql.rds_replica_status;
```

Usage notes

This procedure is only supported for MariaDB DB instances running MariaDB version 10.5 and higher.

This procedure is the equivalent of the SHOW REPLICA STATUS command. This command isn't supported for MariaDB version 10.5 and higher DB instances.

In prior versions of MariaDB, the equivalent SHOW SLAVE STATUS command required the REPLICATION SLAVE privilege. In MariaDB version 10.5 and higher, it requires the REPLICATION REPLICATION ADMIN privilege. To protect the RDS management of MariaDB 10.5 and higher DB instances, this new privilege isn't granted to the RDS master user.

Examples

The following example shows the status of a MariaDB read replica:

```
call mysql.rds_replica_status;
```

The response is similar to the following:

```
*************************** 1. row ***************************
Replica_IO_State: Waiting for master to send event
Source_Host: XX.XX.XX.XXX
Source_User: rdsrepladmin
Source_Port: 3306
```
mysql.rds_set_external_master_gtid

Configures GTID-based replication from a MariaDB instance running external to Amazon RDS to a MariaDB DB instance. This stored procedure is supported only where the external MariaDB instance is version 10.0.24 or higher. When setting up replication where one or both instances do not support MariaDB global transaction identifiers (GTIDs), use mysql.rds_set_external_master (p. 1785).

Using GTIDs for replication provides crash-safety features not offered by binary log replication, so we recommend it in cases where the replicating instances support it.
Syntax

CALL mysql.rds_set_external_master_gtid(
    host_name,
    host_port,
    replication_user_name,
    replication_user_password,
    gtid,
    ssl_encryption
);

Parameters

host_name

String. The host name or IP address of the MariaDB instance running external to Amazon RDS that will become the source instance.

host_port

Integer. The port used by the MariaDB instance running external to Amazon RDS to be configured as the source instance. If your network configuration includes SSH port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

String. The ID of a user with REPLICATION SLAVE permissions in the MariaDB DB instance to be configured as the read replica.

replication_user_password

String. The password of the user ID specified in replication_user_name.

gtid

String. The global transaction ID on the source instance that replication should start from.

You can use @@gtid_current_pos to get the current GTID if the source instance has been locked while you are configuring replication, so the binary log doesn't change between the points when you get the GTID and when replication starts.

Otherwise, if you are using mysqldump version 10.0.13 or greater to populate the replica instance prior to starting replication, you can get the GTID position in the output by using the --master-data or --dump-slave options. If you are not using mysqldump version 10.0.13 or greater, you can run the SHOW MASTER STATUS or use those same mysqldump options to get the binary log file name and position, then convert them to a GTID by running BINLOG_GTID_POS on the external MariaDB instance:

SELECT BINLOG_GTID_POS('<binary log file name>', <binary log file position>);

For more information about the MariaDB implementation of GTIDs, go to Global transaction ID in the MariaDB documentation.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

Note

The MASTER_SSL_VERIFY_SERVER_CERT option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.
Usage notes

The `mysql.rds_set_external_master_gtid` procedure must be run by the master user. It must be run on the MariaDB DB instance that you are configuring as the replica of a MariaDB instance running external to Amazon RDS. Before running `mysql.rds_set_external_master_gtid`, you must have configured the instance of MariaDB running external to Amazon RDS as a source instance. For more information, see [Importing data into a MariaDB DB instance](p. 1312).

**Warning**
Do not use `mysql.rds_set_external_master_gtid` to manage replication between two Amazon RDS DB instances. Use it only when replicating with a MariaDB instance running external to RDS. For information about managing replication between Amazon RDS DB instances, see [Working with DB instance read replicas](p. 438).

After calling `mysql.rds_set_external_master_gtid` to configure an Amazon RDS DB instance as a read replica, you can call `mysql.rds_start_replication` on the replica to start the replication process. You can call `mysql.rds_reset_external_master` to remove the read replica configuration.

When `mysql.rds_set_external_master_gtid` is called, Amazon RDS records the time, user, and an action of "set master" in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

Examples

When run on a MariaDB DB instance, the following example configures it as the replica of an instance of MariaDB running external to Amazon RDS.

```sql
CALL mysql.rds_set_external_master_gtid
('Sourcedb.some.com',3306,'ReplicationUser','SomePassW0rd','0-123-456',0);
```

`mysql.rds_kill_query_id`

Ends a query running against the MariaDB server.

**Syntax**

```sql
CALL mysql.rds_kill_query_id(queryID);
```

**Parameters**

`queryID`

Integer. The identity of the query to be ended.

**Usage notes**

To stop a query running against the MariaDB server, use the `mysql.rds_kill_query_id` procedure and pass in the ID of that query. To obtain the query ID, query the MariaDB `Information schema PROCESSLIST` table, as shown following:

```sql
SELECT USER, HOST, COMMAND, TIME, STATE, INFO, QUERY_ID FROM
INFORMATION_SCHEMA.PROCESSLIST WHERE USER = '<user name>';
```

The connection to the MariaDB server is retained.
Examples

The following example ends a query with a query ID of 230040:

```sql
CALL mysql.rds_kill_query_id(230040);
```
Local time zone for MariaDB DB instances

By default, the time zone for a MariaDB DB instance is Universal Time Coordinated (UTC). You can set the time zone for your DB instance to the local time zone for your application instead.

To set the local time zone for a DB instance, set the `time_zone` parameter in the parameter group for your DB instance to one of the supported values listed later in this section. When you set the `time_zone` parameter for a parameter group, all DB instances and read replicas that are using that parameter group change to use the new local time zone. For information on setting parameters in a parameter group, see `Working with parameter groups` (p. 347).

After you set the local time zone, all new connections to the database reflect the change. If you have any open connections to your database when you change the local time zone, you won't see the local time zone update until after you close the connection and open a new connection.

You can set a different local time zone for a DB instance and one or more of its read replicas. To do this, use a different parameter group for the DB instance and the replica or replicas and set the `time_zone` parameter in each parameter group to a different local time zone.

If you are replicating across AWS Regions, then the source DB instance and the read replica use different parameter groups (parameter groups are unique to an AWS Region). To use the same local time zone for each instance, you must set the `time_zone` parameter in the instance's and read replica's parameter groups.

When you restore a DB instance from a DB snapshot, the local time zone is set to UTC. You can update the time zone to your local time zone after the restore is complete. If you restore a DB instance to a point in time, then the local time zone for the restored DB instance is the time zone setting from the parameter group of the restored DB instance.

The Internet Assigned Numbers Authority (IANA) publishes new time zones at `https://www.iana.org/time-zones` several times a year. Every time RDS releases a new minor maintenance release of MariaDB, it ships with the latest time zone data at the time of the release. When you use the latest RDS for MariaDB versions, you have recent time zone data from RDS. To ensure that your DB instance has recent time zone data, we recommend upgrading to a higher DB engine version. Alternatively, you can modify the time zone tables in MariaDB DB instances manually. To do so, you can use SQL commands or run the `mysql_tzinfo_to_sql` tool in a SQL client. After updating the time zone data manually, reboot your DB instance so that the changes take effect. RDS doesn't modify or reset the time zone data of running DB instances. New time zone data is installed only when you perform a database engine version upgrade.

You can set your local time zone to one of the following values.

</table>
Known issues and limitations for RDS for MariaDB

The following items are known issues and limitations when using RDS for MariaDB.

Note
This list is not exhaustive.

Topics

- MariaDB file size limits in Amazon RDS (p. 1368)
- InnoDB reserved word (p. 1369)
- Custom ports (p. 1369)
- Performance Insights (p. 1369)

MariaDB file size limits in Amazon RDS

For MariaDB DB instances, the maximum size of a table is 16 TB when using InnoDB file-per-table tablespaces. This limit also constrains the system tablespace to a maximum size of 16 TB. InnoDB file-per-table tablespaces (with tables each in their own tablespace) are set by default for MariaDB DB instances. This limit isn't related to the maximum storage limit for MariaDB DB instances. For more information about the storage limit, see Amazon RDS DB instance storage (p. 101).

There are advantages and disadvantages to using InnoDB file-per-table tablespaces, depending on your application. To determine the best approach for your application, see File-per-table tablespaces in the MySQL documentation.

We don't recommend allowing tables to grow to the maximum file size. In general, a better practice is to partition data into smaller tables, which can improve performance and recovery times.

One option that you can use for breaking up a large table into smaller tables is partitioning. Partitioning distributes portions of your large table into separate files based on rules that you specify. For example, if you store transactions by date, you can create partitioning rules that distribute older transactions into separate files using partitioning. Then periodically, you can archive the historical transaction data that doesn't need to be readily available to your application. For more information, see Partitioning in the MySQL documentation.

To determine the size of all InnoDB tablespaces

- Use the following SQL command to determine if any of your tables are too large and are candidates for partitioning.

  SELECT SPACE, NAME, ROUND((((ALLOCATED_SIZE/1024)/1024)/1024), 2) as "Tablespace Size (GB)"
  FROM information_schema.INNODB_SYS_TABLESPACES ORDER BY 3 DESC;

  Note
  For MariaDB 10.6 and higher, this query also returns the size of the InnoDB system tablespace.
  For MariaDB versions earlier than 10.6, you can't determine the size of the InnoDB system tablespace by querying the system tables. We recommend that you upgrade to a later version.

To determine the size of non-InnoDB user tables

- Use the following SQL command to determine if any of your non-InnoDB user tables are too large.
SELECT TABLE_SCHEMA, TABLE_NAME, round(((DATA_LENGTH + INDEX_LENGTH + DATA_FREE) / 1024 / 1024 / 1024), 2) As "Approximate size (GB)" FROM information_schema.TABLES WHERE TABLE_SCHEMA NOT IN ('mysql', 'information_schema', 'performance_schema') and ENGINE <> 'InnoDB';

**To enable InnoDB file-per-table tablespaces**

- Set the `innodb_file_per_table` parameter to 1 in the parameter group for the DB instance.

**To disable InnoDB file-per-table tablespaces**

- Set the `innodb_file_per_table` parameter to 0 in the parameter group for the DB instance.

For information on updating a parameter group, see [Working with parameter groups (p. 347)].

When you have enabled or disabled InnoDB file-per-table tablespaces, you can issue an `ALTER TABLE` command. You can use this command to move a table from the global tablespace to its own tablespace. Or you can move a table from its own tablespace to the global tablespace. Following is an example.

```sql
ALTER TABLE table_name ENGINE=InnoDB, ALGORITHM=COPY;
```

**InnoDB reserved word**

InnoDB is a reserved word for RDS for MariaDB. You can't use this name for a MariaDB database.

**Custom ports**

Amazon RDS blocks connections to custom port 33060 for the MariaDB engine. Choose a different port for your MariaDB engine.

**Performance Insights**

InnoDB counters are not visible in Performance Insights for RDS for MariaDB version 10.11 because the MariaDB community no longer supports them.
Amazon RDS for Microsoft SQL Server

Amazon RDS supports several versions and editions of Microsoft SQL Server. The following table shows the most recent supported minor version of each major version. For the full list of supported versions, editions, and RDS engine versions, see Microsoft SQL Server versions on Amazon RDS (p. 1378).

<table>
<thead>

For information about licensing for SQL Server, see Licensing Microsoft SQL Server on Amazon RDS (p. 1395). For information about SQL Server builds, see this Microsoft support article about the latest SQL Server builds.

With Amazon RDS, you can create DB instances and DB snapshots, point-in-time restores, and automated or manual backups. DB instances running SQL Server can be used inside a VPC. You can also use Secure Sockets Layer (SSL) to connect to a DB instance running SQL Server, and you can use transparent data encryption (TDE) to encrypt data at rest. Amazon RDS currently supports Multi-AZ deployments for SQL Server using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs) as a high-availability, failover solution.

To deliver a managed service experience, Amazon RDS does not provide shell access to DB instances, and it restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application such as Microsoft SQL Server Management Studio. Amazon RDS does not allow direct host access to a DB instance via Telnet, Secure Shell (SSH), or Windows Remote Desktop Connection. When you create a DB instance, the master user is assigned to the db_owner role for all user databases on that instance, and has all database-level permissions except for those that are used for backups. Amazon RDS manages backups for you.

Before creating your first DB instance, you should complete the steps in the setting up section of this guide. For more information, see Setting up for Amazon RDS (p. 174).

</tbody>
</table>

There are also advanced administrative tasks for working with SQL Server DB instances. For more information, see the following documentation:

- Common DBA tasks for Microsoft SQL Server (p. 1618).
- Working with AWS Managed Active Directory with RDS for SQL Server (p. 1417)
- Accessing the tempdb database (p. 1619)
Limitations for Microsoft SQL Server DB instances

The Amazon RDS implementation of Microsoft SQL Server on a DB instance has some limitations that you should be aware of:

- The maximum number of databases supported on a DB instance depends on the instance class type and the availability mode—Single-AZ, Multi-AZ Database Mirroring (DBM), or Multi-AZ Availability Groups (AGs). The Microsoft SQL Server system databases don't count toward this limit.

The following table shows the maximum number of supported databases for each instance class type and availability mode. Use this table to help you decide if you can move from one instance class type to another, or from one availability mode to another. If your source DB instance has more databases than the target instance class type or availability mode can support, modifying the DB instance fails. You can see the status of your request in the Events pane.

<table>
<thead>
<tr>
<th>Instance class type</th>
<th>Single-AZ</th>
<th>Multi-AZ with DBM</th>
<th>Multi-AZ with Always On AGs</th>
</tr>
</thead>
<tbody>
<tr>
<td>db.<em>.micro to db.</em>.medium</td>
<td>30</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>db.*.large</td>
<td>30</td>
<td>30</td>
<td>30</td>
</tr>
<tr>
<td>db.<em>.xlarge to db.</em>.16xlarge</td>
<td>100</td>
<td>50</td>
<td>75</td>
</tr>
<tr>
<td>db.*.24xlarge</td>
<td>100</td>
<td>50</td>
<td>100</td>
</tr>
</tbody>
</table>

* Represents the different instance class types.

For example, let's say that your DB instance runs on a db.*.16xlarge with Single-AZ and that it has 76 databases. You modify the DB instance to upgrade to using Multi-AZ Always On AGs. This upgrade fails, because your DB instance contains more databases than your target configuration can support. If you upgrade your instance class type to db.*.24xlarge instead, the modification succeeds.

If the upgrade fails, you see events and messages similar to the following:

- Unable to modify database instance class. The instance has 76 databases, but after conversion it would only support 75.
- Unable to convert the DB instance to Multi-AZ: The instance has 76 databases, but after conversion it would only support 75.

If the point-in-time restore or snapshot restore fails, you see events and messages similar to the following:

- Database instance put into incompatible-restore. The instance has 76 databases, but after conversion it would only support 75.
- Some ports are reserved for Amazon RDS, and you can't use them when you create a DB instance.
- Client connections from IP addresses within the range 169.254.0.0/16 are not permitted. This is the Automatic Private IP Addressing Range (APIPA), which is used for local-link addressing.
- SQL Server Standard Edition uses only a subset of the available processors if the DB instance has more processors than the software limits (24 cores, 4 sockets, and 128GB RAM). Examples of this are the db.m5.24xlarge and db.r5.24xlarge instance classes.

For more information, see the table of scale limits under Editions and supported features of SQL Server 2019 (15.x) in the Microsoft documentation.
• Amazon RDS for SQL Server doesn't support importing data into the msdb database.
• You can't rename databases on a DB instance in a SQL Server Multi-AZ deployment.
• Make sure that you use these guidelines when setting the following DB parameters on RDS for SQL Server:
  • max server memory (mb) >= 256 MB
  • max worker threads >= (number of logical CPUs * 7)

For more information on setting DB parameters, see Working with parameter groups (p. 347).
• The maximum storage size for SQL Server DB instances is the following:
  • General Purpose (SSD) storage – 16 TiB for all editions
  • Provisioned IOPS storage – 16 TiB for all editions
  • Magnetic storage – 1 TiB for all editions

If you have a scenario that requires a larger amount of storage, you can use sharding across multiple DB instances to get around the limit. This approach requires data-dependent routing logic in applications that connect to the sharded system. You can use an existing sharding framework, or you can write custom code to enable sharding. If you use an existing framework, the framework can't install any components on the same server as the DB instance.
• The minimum storage size for SQL Server DB instances is the following:
  • General Purpose (SSD) storage – 20 GiB for Enterprise, Standard, Web, and Express Editions
  • Provisioned IOPS storage – 20 GiB for Enterprise, Standard, Web, and Express Editions
  • Magnetic storage – 20 GiB for Enterprise, Standard, Web, and Express Editions
• Amazon RDS doesn't support running these services on the same server as your RDS DB instance:
  • Data Quality Services
  • Master Data Services

To use these features, we recommend that you install SQL Server on an Amazon EC2 instance, or use an on-premises SQL Server instance. In these cases, the EC2 or SQL Server instance acts as the Master Data Services server for your SQL Server DB instance on Amazon RDS. You can install SQL Server on an Amazon EC2 instance with Amazon EBS storage, pursuant to Microsoft licensing policies.
• Because of limitations in Microsoft SQL Server, restoring to a point in time before successfully running DROP DATABASE might not reflect the state of that database at that point in time. For example, the dropped database is typically restored to its state up to 5 minutes before the DROP DATABASE command was issued. This type of restore means that you can't restore the transactions made during those few minutes on your dropped database. To work around this, you can reissue the DROP DATABASE command after the restore operation is completed. Dropping a database removes the transaction logs for that database.
• For SQL Server, you create your databases after you create your DB instance. Database names follow the usual SQL Server naming rules with the following differences:
  • Database names can't start with rdsadmin.
  • They can't start or end with a space or a tab.
  • They can't contain any of the characters that create a new line.
  • They can't contain a single quote (').

DB instance class support for Microsoft SQL Server

The computation and memory capacity of a DB instance is determined by its DB instance class. The DB instance class you need depends on your processing power and memory requirements. For more information, see DB instance classes (p. 11).
The following list of DB instance classes supported for Microsoft SQL Server is provided here for your convenience. For the most current list, see the RDS console: https://console.aws.amazon.com/rds/.

Not all DB instance classes are available on all supported SQL Server minor versions. For example, some newer DB instance classes such as db.r6i aren't available on older minor versions. You can use the `describe-orderable-db-instance-options` AWS CLI command to find out which DB instance classes are available for your SQL Server edition and version.

## Microsoft SQL Server security

The Microsoft SQL Server database engine uses role-based security. The master user name that you specify when you create a DB instance is a SQL Server Authentication login that is a member of the **processadmin**, **public**, and **setupadmin** fixed server roles.

Any user who creates a database is assigned to the **db_owner** role for that database and has all database-level permissions except for those that are used for backups. Amazon RDS manages backups for you.

The following server-level roles aren't available in Amazon RDS for SQL Server:

- bulkadmin
- dbcreador

### SQL Server edition

<table>
<thead>

</tr>
</tbody>
</table>
• diskadmin
• securityadmin
• serveradmin
• sysadmin

The following server-level permissions aren't available on RDS for SQL Server DB instances:

• ALTER ANY DATABASE
• ALTER ANY EVENT NOTIFICATION
• ALTER RESOURCES
• ALTER SETTINGS (you can use the DB parameter group API operations to modify parameters; for more information, see Working with parameter groups (p. 347))
• AUTHENTICATE SERVER
• CONTROL _ SERVER
• CREATE DDL EVENT NOTIFICATION
• CREATE ENDPOINT
• CREATE SERVER ROLE
• CREATE TRACE EVENT NOTIFICATION
• DROP ANY DATABASE
• EXTERNAL ACCESS ASSEMBLY
• SHUTDOWN (You can use the RDS reboot option instead)
• UNSAFE ASSEMBLY
• ALTER ANY AVAILABILITY GROUP
• CREATE ANY AVAILABILITY GROUP

Compliance program support for Microsoft SQL Server DB instances

AWS Services in scope have been fully assessed by a third-party auditor and result in a certification, attestation of compliance, or Authority to Operate (ATO). For more information, see AWS services in scope by compliance program.

HIPAA support for Microsoft SQL Server DB instances

You can use Amazon RDS for Microsoft SQL Server databases to build HIPAA-compliant applications. You can store healthcare-related information, including protected health information (PHI), under a Business Associate Agreement (BAA) with AWS. For more information, see HIPAA compliance.

Amazon RDS for SQL Server supports HIPAA for the following versions and editions:

• SQL Server 2019 Enterprise, Standard, and Web Editions
• SQL Server 2017 Enterprise, Standard, and Web Editions
• SQL Server 2016 Enterprise, Standard, and Web Editions
• SQL Server 2014 Enterprise, Standard, and Web Editions

To enable HIPAA support on your DB instance, set up the following three components.
SSL support

You can use SSL to encrypt connections between your applications and your Amazon RDS DB instances running Microsoft SQL Server. You can also force all connections to your DB instance to use SSL. If you force connections to use SSL, it happens transparently to the client, and the client doesn't have to do any work to use SSL.

SSL is supported in all AWS Regions and for all supported SQL Server editions. For more information, see Using SSL with a Microsoft SQL Server DB instance (p. 1472).

Microsoft SQL Server versions on Amazon RDS

You can specify any currently supported Microsoft SQL Server version when creating a new DB instance. You can specify the Microsoft SQL Server major version (such as Microsoft SQL Server 14.00), and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified.

The following table shows the supported versions for all editions and all AWS Regions, except where noted. You can also use the describe-db-engine-versions AWS CLI command to see a list of supported versions, as well as defaults for newly created DB instances.

### SQL Server versions supported in RDS

<table>
<thead>
<tr>
<th>Major version</th>
<th>Minor version</th>
<th>RDS API EngineVersion and CLI engine-version</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL Server 2019</td>
<td>15.00.4316.3 (CU21)</td>
<td>15.00.4316.3.v1</td>
</tr>
<tr>
<td></td>
<td>15.00.4236.7 (CU16)</td>
<td>15.00.4236.7.v1</td>
</tr>
<tr>
<td></td>
<td>15.00.4198.2 (CU15)</td>
<td>15.00.4198.2.v1</td>
</tr>
</tbody>
</table>
### Version management in Amazon RDS

Amazon RDS includes flexible version management that enables you to control when and how your DB instance is patched or upgraded. This enables you to do the following for your DB engine:

- Maintain compatibility with database engine patch versions.
- Test new patch versions to verify that they work with your application before you deploy them in production.
- Plan and perform version upgrades to meet your service level agreements and timing requirements.

#### Microsoft SQL Server engine patching in Amazon RDS

Amazon RDS periodically aggregates official Microsoft SQL Server database patches into a DB instance engine version that's specific to Amazon RDS. For more information about the Microsoft SQL Server patches in each engine version, see [Version and feature support on Amazon RDS](#).

<table>
<thead>
<tr>
<th>Major version</th>
<th>Minor version</th>
<th>RDS API EngineVersion and CLI engine-version</th>

<td>12.00.6439.10 (SP3 CU4 SU)</td>
<td>12.00.6439.10.v1</td>
</tr>
<tr>
<td></td>
<td>12.00.6433.1 (SP3 CU4 SU)</td>
<td>12.00.6433.1.v1</td>
</tr>
<tr>
<td></td>
<td>12.00.6329.1 (SP3 CU4)</td>
<td>12.00.6329.1.v1</td>
</tr>
<tr>
<td></td>
<td>12.00.6293.0 (SP3 CU3)</td>
<td>12.00.6293.0.v1</td>
</tr>
</tbody>
</table>
Currently, you manually perform all engine upgrades on your DB instance. For more information, see Upgrading the Microsoft SQL Server DB engine (p. 1430).

Deprecation schedule for major engine versions of Microsoft SQL Server on Amazon RDS

The following table displays the planned schedule of deprecations for major engine versions of Microsoft SQL Server.

<table>
<thead>
<tr>
<th>Date</th>
<th>Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>July 9, 2024</td>
<td>Microsoft will stop critical patch updates for SQL Server 2014. For more information, see the Microsoft documentation.</td>
</tr>
<tr>
<td>June 1, 2024</td>
<td>Amazon RDS plans to end support of Microsoft SQL Server 2014 on RDS for SQL Server. ADB instances scheduled to migrate to SQL Server 2016 (latest minor version available). For more information, see Amazon RDS ending support for SQL Server 2014 major versions. To avoid an automatic upgrade from Microsoft SQL Server 2014, you can upgrade at a time convenient to you. For more information, see Upgrading a DB instance engine version (p. 429).</td>
</tr>
<tr>
<td>July 12, 2022</td>
<td>Microsoft will stop critical patch updates for SQL Server 2012. For more information, see the Microsoft documentation.</td>
</tr>
<tr>
<td>June 1, 2022</td>
<td>Amazon RDS plans to end support of Microsoft SQL Server 2012 on RDS for SQL Server. ADB instances scheduled to migrate to SQL Server 2014 (latest minor version available). For more information, see Amazon RDS ending support for SQL Server 2012 major versions. To avoid an automatic upgrade from Microsoft SQL Server 2012, you can upgrade at a time convenient to you. For more information, see Upgrading a DB instance engine version (p. 429).</td>
</tr>
<tr>
<td>September 1, 2021</td>
<td>Amazon RDS is starting to disable the creation of new RDS for SQL Server DB instances using Microsoft SQL Server 2012. For more information, see Announcement: Amazon RDS for SQL Server ending support for SQL Server 2012 major versions.</td>
</tr>
<tr>
<td>July 12, 2019</td>
<td>The Amazon RDS team deprecated support for Microsoft SQL Server 2008 R2 in June 2019. SQL Server 2008 R2 and SQL Server 2008 R2 are migrating to SQL Server 2012 (latest minor version available). To avoid an automatic upgrade from Microsoft SQL Server 2008 R2, you can upgrade at a time convenient to you. For more information, see Upgrading a DB instance engine version (p. 429).</td>
</tr>
<tr>
<td>April 25, 2019</td>
<td>Before the end of April 2019, you will no longer be able to create new Amazon RDS for SQL Server 2008R2.</td>
</tr>
</tbody>
</table>

Microsoft SQL Server features on Amazon RDS

The supported SQL Server versions on Amazon RDS include the following features. In general, a version also includes features from the previous versions, unless otherwise noted in the Microsoft documentation.

Topics

- Microsoft SQL Server 2019 features (p. 1381)
- Microsoft SQL Server 2017 features (p. 1381)
- Microsoft SQL Server 2016 features (p. 1382)
Microsoft SQL Server 2019 features

SQL Server 2019 includes many new features, such as the following:

- Accelerated database recovery (ADR) – Reduces crash recovery time after a restart or a long-running transaction rollback.
- Intelligent Query Processing (IQP):
  - Row mode memory grant feedback – Corrects excessive grants automatically, that would otherwise result in wasted memory and reduced concurrency.
  - Batch mode on rowstore – Enables batch mode execution for analytic workloads without requiring columnstore indexes.
  - Table variable deferred compilation – Improves plan quality and overall performance for queries that reference table variables.
- Intelligent performance:
  - OPTIMIZE_FOR_SEQUENTIAL_KEY index option – Improves throughput for high-concurrency inserts into indexes.
  - Improved indirect checkpoint scalability – Helps databases with heavy DML workloads.
  - Concurrent Page Free Space (PFS) updates – Enables handling as a shared latch rather than an exclusive latch.
- Monitoring improvements:
  - WAIT_ON_SYNC_STATISTICS_REFRESH wait type – Shows accumulated instance-level time spent on synchronous statistics refresh operations.
  - Database-scoped configurations – Include LIGHTWEIGHT_QUERY_PROFILING and LAST_QUERY_PLAN_STATS.
  - Dynamic management functions (DMFs) – Include sys.dm_exec_query_plan_stats and sys.dm_db_page_info.
  - Verbose truncation warnings – The data truncation error message defaults to include table and column names and the truncated value.
  - Resumable online index creation – In SQL Server 2017, only resumable online index rebuild is supported.

For the full list of SQL Server 2019 features, see What's new in SQL Server 2019 (15.x) in the Microsoft documentation.

For a list of unsupported features, see Features not supported and features with limited support (p. 1383).

Microsoft SQL Server 2017 features

SQL Server 2017 includes many new features, such as the following:

- Adaptive query processing
- Automatic plan correction (an automatic tuning feature)
- GraphDB
- Resumable index rebuilds
For the full list of SQL Server 2017 features, see What's new in SQL Server 2017 in the Microsoft documentation.

For a list of unsupported features, see Features not supported and features with limited support (p. 1383).

**Microsoft SQL Server 2016 features**

Amazon RDS supports the following features of SQL Server 2016:

- Always Encrypted
- JSON Support
- Operational Analytics
- Query Store
- Temporal Tables

For the full list of SQL Server 2016 features, see What's new in SQL Server 2016 in the Microsoft documentation.

**Microsoft SQL Server 2014 features**

In addition to supported features of SQL Server 2012, Amazon RDS supports the new query optimizer available in SQL Server 2014, and also the delayed durability feature.

For a list of unsupported features, see Features not supported and features with limited support (p. 1383).

SQL Server 2014 supports all the parameters from SQL Server 2012 and uses the same default values. SQL Server 2014 includes one new parameter, backup checksum default. For more information, see How to enable the CHECKSUM option if backup utilities do not expose the option in the Microsoft documentation.

**Microsoft SQL Server 2012 end of support on Amazon RDS**

SQL Server 2012 has reached its end of support on Amazon RDS.

RDS is upgrading all existing DB instances that are still using SQL Server 2012 to the latest minor version of SQL Server 2014. For more information, see Version management in Amazon RDS (p. 1379).

**Microsoft SQL Server 2008 R2 end of support on Amazon RDS**

SQL Server 2008 R2 has reached its end of support on Amazon RDS.

RDS is upgrading all existing DB instances that are still using SQL Server 2008 R2 to the latest minor version of SQL Server 2012. For more information, see Version management in Amazon RDS (p. 1379).
Change data capture support for Microsoft SQL Server DB instances

Amazon RDS supports change data capture (CDC) for your DB instances running Microsoft SQL Server. CDC captures changes that are made to the data in your tables, and stores metadata about each change that you can access later. For more information, see Change data capture in the Microsoft documentation.

Amazon RDS supports CDC for the following SQL Server editions and versions:

- Microsoft SQL Server Enterprise Edition (All versions)
- Microsoft SQL Server Standard Edition:
  - 2019
  - 2017
  - 2016 version 13.00.4422.0 SP1 CU2 and later

To use CDC with your Amazon RDS DB instances, first enable or disable CDC at the database level by using RDS-provided stored procedures. After that, any user that has the db_owner role for that database can use the native Microsoft stored procedures to control CDC on that database. For more information, see Using change data capture (p. 1630).

You can use CDC and AWS Database Migration Service to enable ongoing replication from SQL Server DB instances.

Features not supported and features with limited support

The following Microsoft SQL Server features aren't supported on Amazon RDS:

- Backing up to Microsoft Azure Blob Storage
- Buffer pool extension
- Custom password policies
- Data Quality Services
- Database Log Shipping
- Database snapshots (Amazon RDS supports only DB instance snapshots)
- Extended stored procedures, including xp_cmdshell
- FILESTREAM support
- File tables
- Machine Learning and R Services (requires OS access to install it)
- Maintenance plans
- Performance Data Collector
- Policy-Based Management
- PolyBase
- Replication
Multi-AZ deployments using Microsoft SQL Server

Database Mirroring or Always On availability groups

Amazon RDS supports Multi-AZ deployments for DB instances running Microsoft SQL Server by using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). Multi-AZ deployments provide increased availability, data durability, and fault tolerance for DB instances. In the event of planned database maintenance or unplanned service disruption, Amazon RDS automatically fails over to the up-to-date secondary replica so database operations can resume quickly without manual intervention. The primary and secondary instances use the same endpoint, whose physical network address transitions to the passive secondary replica as part of the failover process. You don't have to reconfigure your application when a failover occurs.

Amazon RDS manages failover by actively monitoring your Multi-AZ deployment and initiating a failover when a problem with your primary occurs. Failover doesn't occur unless the standby and primary are fully in sync. Amazon RDS actively maintains your Multi-AZ deployment by automatically repairing unhealthy DB instances and re-establishing synchronous replication. You don't have to manage anything. Amazon RDS handles the primary, the witness, and the standby instance for you. When you set up SQL Server Multi-AZ, RDS configures passive secondary instances for all of the databases on the instance.

For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server (p. 1466).

Using Transparent Data Encryption to encrypt data at rest

Amazon RDS supports Microsoft SQL Server Transparent Data Encryption (TDE), which transparently encrypts stored data. Amazon RDS uses option groups to enable and configure these features. For more information about the TDE option, see Support for Transparent Data Encryption in SQL Server (p. 1544).
## Functions and stored procedures for Amazon RDS for Microsoft SQL Server

Following, you can find a list of the Amazon RDS functions and stored procedures that help automate SQL Server tasks.

<table>

### Local time zone for Microsoft SQL Server DB instances

The time zone of an Amazon RDS DB instance running Microsoft SQL Server is set by default. The current default is Coordinated Universal Time (UTC). You can set the time zone of your DB instance to a local time zone instead, to match the time zone of your applications.

You set the time zone when you first create your DB instance. You can create your DB instance by using the **AWS Management Console**, the Amazon RDS API **CreateDBInstance** action, or the AWS CLI **create-db-instance** command.

If your DB instance is part of a Multi-AZ deployment (using SQL Server DBM or AGs), then when you fail over, your time zone remains the local time zone that you set. For more information, see [Multi-AZ deployments using Microsoft SQL Server Database Mirroring or Always On availability groups](p. 1384).

When you request a point-in-time restore, you specify the time to restore to. The time is shown in your local time zone. For more information, see [Restoring a DB instance to a specified time](p. 660).

The following are limitations to setting the local time zone on your DB instance:

- You can't modify the time zone of an existing SQL Server DB instance.
- You can't restore a snapshot from a DB instance in one time zone to a DB instance in a different time zone.
- We strongly recommend that you don't restore a backup file from one time zone to a different time zone. If you restore a backup file from one time zone to a different time zone, you must audit your queries and applications for the effects of the time zone change. For more information, see [Importing and exporting SQL Server databases using native backup and restore](p. 1435).

### Supported time zones

You can set your local time zone to one of the values listed in the following table.
## Supported time zones

<table>
<thead>
<tr>
<th>Time zone</th>

Licensing Microsoft SQL Server on Amazon RDS

When you set up an Amazon RDS DB instance for Microsoft SQL Server, the software license is included. This means that you don’t need to purchase SQL Server licenses separately. AWS holds the license for the SQL Server database software. Amazon RDS pricing includes the software license, underlying hardware resources, and Amazon RDS management capabilities.

Amazon RDS supports the following Microsoft SQL Server editions:

- Enterprise
- Standard
- Web
- Express

**Note**

Licensing for SQL Server Web Edition supports only public and internet-accessible webpages, websites, web applications, and web services. This level of support is required for compliance with Microsoft’s usage rights. For more information, see [AWS service terms](https://aws.amazon.com/terms).

Amazon RDS supports Multi-AZ deployments for DB instances running Microsoft SQL Server by using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). There are no additional licensing requirements for Multi-AZ deployments. For more information, see [Multi-AZ deployments for Amazon RDS for Microsoft SQL Server](p. 1466).

**Restoring license-terminated DB instances**

Amazon RDS takes snapshots of license-terminated DB instances. If your instance is terminated for licensing issues, you can restore it from the snapshot to a new DB instance. New DB instances have a license included.

For more information, see [Restoring license-terminated DB instances](p. 1630).

**Development and test**

Because of licensing requirements, we can’t offer SQL Server Developer Edition on Amazon RDS. You can use Express Edition for many development, testing, and other nonproduction needs. However, if you need the full feature capabilities of an enterprise-level installation of SQL Server for development, you can download and install SQL Server Developer Edition (and other MSDN products) on Amazon EC2. Dedicated infrastructure isn’t required for Developer Edition. By using your own host, you also gain access to other programmability features that are not accessible on Amazon RDS. For more information on the difference between SQL Server editions, see [Editions and supported features of SQL Server 2017](https://docs.microsoft.com/en-us/sql/sql-server-editions) in the Microsoft documentation.
Connecting to a DB instance running the Microsoft SQL Server database engine

After Amazon RDS provisions your DB instance, you can use any standard SQL client application to connect to the DB instance. In this topic, you connect to your DB instance by using either Microsoft SQL Server Management Studio (SSMS) or SQL Workbench/J.

For an example that walks you through the process of creating and connecting to a sample DB instance, see Creating and connecting to a Microsoft SQL Server DB instance (p. 194).

Before you connect

Before you can connect to your DB instance, it has to be available and accessible.

1. Make sure that its status is available. You can check this on the details page for your instance in the AWS Management Console or by using the describe-db-instances AWS CLI command.

2. Make sure that it is accessible to your source. Depending on your scenario, it may not need to be publicly accessible. For more information, see Amazon VPC VPCs and Amazon RDS (p. 2705).
3. Make sure that the inbound rules of your VPC security group allow access to your DB instance. For more information, see Can't connect to Amazon RDS DB instance (p. 2744).

Finding the DB instance endpoint and port number

You need both the endpoint and the port number to connect to the DB instance.

To find the endpoint and port

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.  

2. In the upper-right corner of the Amazon RDS console, choose the AWS Region of your DB instance.
3. Find the Domain Name System (DNS) name (endpoint) and port number for your DB instance:
   a. Open the RDS console and choose Databases to display a list of your DB instances.
   b. Choose the SQL Server DB instance name to display its details.
   c. On the Connectivity & security tab, copy the endpoint.
   d. Note the port number.

Connecting to your DB instance with Microsoft SQL Server Management Studio

In this procedure, you connect to your sample DB instance by using Microsoft SQL Server Management Studio (SSMS). To download a standalone version of this utility, see Download SQL Server Management Studio (SSMS) in the Microsoft documentation.

To connect to a DB instance using SSMS

1. Start SQL Server Management Studio.

   The Connect to Server dialog box appears.
2. Provide the information for your DB instance:
   
a. For **Server type**, choose **Database Engine**.

b. For **Server name**, enter the DNS name (endpoint) and port number of your DB instance, separated by a comma.

   **Important**
   Change the colon between the endpoint and port number to a comma.

   Your server name should look like the following example.

   `database-2.cg034itsfake.us-east-1.rds.amazonaws.com,1433`

c. For **Authentication**, choose **SQL Server Authentication**.

d. For **Login**, enter the master user name for your DB instance.

e. For **Password**, enter the password for your DB instance.

3. Choose **Connect**.

   After a few moments, SSMS connects to your DB instance.

   If you can't connect to your DB instance, see Security group considerations (p. 1401) and Troubleshooting connections to your SQL Server DB instance (p. 1401).

4. Your SQL Server DB instance comes with SQL Server's standard built-in system databases (**master**, **model**, **msdb**, and **tempdb**). To explore the system databases, do the following:

   a. In SSMS, on the **View** menu, choose **Object Explorer**.

   b. Expand your DB instance, expand **Databases**, and then expand **System Databases**.
5. Your SQL Server DB instance also comes with a database named rdsadmin. Amazon RDS uses this database to store the objects that it uses to manage your database. The rdsadmin database also includes stored procedures that you can run to perform advanced tasks. For more information, see Common DBA tasks for Microsoft SQL Server (p. 1618).

6. You can now start creating your own databases and running queries against your DB instance and databases as usual. To run a test query against your DB instance, do the following:

   a. In SSMS, on the File menu point to New and then choose Query with Current Connection.
   b. Enter the following SQL query.

     ```sql
     select @@VERSION
     ```
   c. Run the query. SSMS returns the SQL Server version of your Amazon RDS DB instance.
Connecting to your DB instance with SQL Workbench/J

This example shows how to connect to a DB instance running the Microsoft SQL Server database engine by using the SQL Workbench/J database tool. To download SQL Workbench/J, see SQL Workbench/J.

SQL Workbench/J uses JDBC to connect to your DB instance. You also need the JDBC driver for SQL Server. To download this driver, see Microsoft JDBC drivers 4.1 (preview) and 4.0 for SQL Server.

**To connect to a DB instance using SQL Workbench/J**

1. Open SQL Workbench/J. The Select Connection Profile dialog box appears, as shown following.

2. In the first box at the top of the dialog box, enter a name for the profile.

3. For **Driver**, choose SQL JDBC 4.0.

4. For **URL**, enter `jdbc:sqlserver://`, then enter the endpoint of your DB instance. For example, the URL value might be the following.

   ```
   ```

5. For **Username**, enter the master user name for the DB instance.

6. For **Password**, enter the password for the master user.

7. Choose the save icon in the dialog toolbar, as shown following.

8. Choose **OK**. After a few moments, SQL Workbench/J connects to your DB instance. If you can't connect to your DB instance, see Security group considerations (p. 1401) and Troubleshooting connections to your SQL Server DB instance (p. 1401).

9. In the query pane, enter the following SQL query.

   ```
   select @@VERSION
   ```

10. Choose the Execute icon in the toolbar, as shown following.
The query returns the version information for your DB instance, similar to the following.

Microsoft SQL Server 2017 (RTM-CU22) (KB4577467) - 14.0.3356.20 (X64)

Security group considerations

To connect to your DB instance, your DB instance must be associated with a security group. This security group contains the IP addresses and network configuration that you use to access the DB instance. You might have associated your DB instance with an appropriate security group when you created your DB instance. If you assigned a default, no-configured security group when you created your DB instance, your DB instance firewall prevents connections.

In some cases, you might need to create a new security group to make access possible. For instructions on creating a new security group, see Controlling access with security groups (p. 2697). For a topic that walks you through the process of setting up rules for your VPC security group, see Tutorial: Create a VPC for use with a DB instance (IPv4 only) (p. 2723).

After you have created the new security group, modify your DB instance to associate it with the security group. For more information, see Modifying an Amazon RDS DB instance (p. 401).

You can enhance security by using SSL to encrypt connections to your DB instance. For more information, see Using SSL with a Microsoft SQL Server DB instance (p. 1472).

Troubleshooting connections to your SQL Server DB instance

The following table shows error messages that you might encounter when you attempt to connect to your SQL Server DB instance.

<table>
<thead>
<tr>
<th>Issue</th>
<th>Troubleshooting suggestions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Could not open a connection to SQL Server – Microsoft SQL Server, Error: 53</td>
<td>Make sure that you specified the server name correctly. For <strong>Server name</strong>, enter the DNS name and port number of your sample DB instance, separated by a comma. <strong>Important</strong>&lt;br&gt; If you have a colon between the DNS name and port number, change the colon to a comma. Your server name should look like the following example. &lt;br&gt;sample-instance.cg034itsfake.us-east-1.rds.amazonaws.com,1433</td>
</tr>
<tr>
<td>No connection could be made because the target machine actively refused it –</td>
<td>You were able to reach the DB instance but the connection was refused. This issue is usually caused by specifying the user name or password incorrectly. Verify the user name and password, then retry.</td>
</tr>
<tr>
<td>Issue</td>
<td>Troubleshooting suggestions</td>
</tr>
<tr>
<td>----------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Microsoft SQL Server, Error: 10061</td>
<td>The access rules enforced by your local firewall and the IP addresses authorized to access your DB instance might not match. The problem is most likely the inbound rules in your security group. For more information, see Security in Amazon RDS (p. 2582).</td>
</tr>
<tr>
<td>A network-related or instance-specific error occurred while establishing a connection to SQL Server. The server was not found or was not accessible... The wait operation timed out – Microsoft SQL Server, Error: 258</td>
<td>Your database instance must be publicly accessible. To connect to it from outside of the VPC, the instance must have a public IP address assigned.</td>
</tr>
</tbody>
</table>

**Note**
For more information on connection issues, see Can't connect to Amazon RDS DB instance (p. 2744).
Working with Active Directory with RDS for SQL Server

You can join an RDS for SQL Server DB instance to a Microsoft Active Directory (AD) domain. Your AD domain can be hosted on AWS Managed AD within AWS, or on a Self Managed AD in a location of your choice, including your corporate data centers, on AWS EC2, or with other cloud providers.

You can authenticate domain users using NTLM authentication with Self Managed Active Directory. You can use Kerberos and NTLM authentication with AWS Managed Active Directory.

In the following sections, you can find information about working with Self Managed Active Directory and AWS Managed Active Directory for Microsoft SQL Server on Amazon RDS.

Topics
- Working with Self Managed Active Directory with an Amazon RDS for SQL Server DB instance (p. 1404)
- Working with AWS Managed Active Directory with RDS for SQL Server (p. 1417)
Working with Self Managed Active Directory with an Amazon RDS for SQL Server DB instance

You can join your RDS for SQL Server DB instances directly to your self-managed Active Directory (AD) domain, regardless of where your AD is hosted: in corporate data centers, on AWS EC2, or with other cloud providers. With self-managed AD, you use NTLM authentication to directly control authentication of users and services on your RDS for SQL Server DB instances without using intermediary domains and forest trusts. When users authenticate with an RDS for SQL Server DB instance joined to your self-managed AD domain, authentication requests are forwarded to a self-managed AD domain that you specify.

Topics
- Region and version availability (p. 1404)
- Requirements (p. 1404)
- Limitations (p. 1406)
- Overview of setting up Self Managed Active Directory (p. 1407)
- Setting up Self Managed Active Directory (p. 1407)
- Managing a DB instance in a self-managed Active Directory Domain (p. 1413)
- Understanding self-managed Active Directory Domain membership (p. 1414)
- Troubleshooting self-managed Active Directory (p. 1414)
- Restoring a SQL Server DB instance and then adding it to a self-managed Active Directory domain (p. 1416)

Region and version availability

Amazon RDS supports Self Managed AD for SQL Server using NTLM in all AWS Regions.

Requirements

Make sure you've met the following requirements before joining an RDS for SQL Server DB instance to your self-managed AD domain.

Topics
- Configure your on-premises AD (p. 1404)
- Configure your network connectivity (p. 1405)
- Configure your AD domain service account (p. 1406)

Configure your on-premises AD

Make sure that you have an on-premises or other self-managed Microsoft AD that you can join the Amazon RDS for SQL Server instance to. Your on-premises AD should have the following configuration:

- If you have Active Directory sites defined, make sure the subnets in the VPC associated with your RDS for SQL Server DB instance are defined in your Active Directory site. Confirm there aren't any conflicts between the subnets in your VPC and the subnets in your other AD sites.
- Your AD domain controller has a domain functional level of Windows Server 2008 R2 or higher.
- Your AD domain name can't be in Single Label Domain (SLD) format. RDS for SQL Server does not support SLD domains.
• The fully qualified domain name (FQDN) and organizational unit (OU) for your AD can't exceed 64 characters.

**Configure your network connectivity**

Make sure that you have met the following network configurations:

• Connectivity configured between the Amazon VPC where you want to create the RDS for SQL Server DB instance and your self-managed Active Directory. You can set up connectivity using AWS Direct Connect, AWS VPN, VPC peering, or AWS Transit Gateway.

• For VPC security groups, the default security group for your default Amazon VPC is already added to your RDS for SQL Server DB instance in the console. Ensure that the security group and the VPC network ACLs for the subnet(s) where you're creating your RDS for SQL Server DB instance allow traffic on the ports and in the directions shown in the following diagram.

The following table identifies the role of each port.

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Ports</th>
<th>Role</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP/UDP</td>
<td>53</td>
<td>Domain Name System (DNS)</td>
</tr>
<tr>
<td>TCP/UDP</td>
<td>88</td>
<td>Kerberos authentication</td>
</tr>
<tr>

<tr>
<td>TCP/UDP</td>
<td>389</td>
<td>Lightweight Directory Access Protocol (LDAP)</td>
</tr>
<tr>
<td>TCP</td>
<td>135</td>
<td>Distributed Computing Environment / End Point Mapper (DCE / EPMAP)</td>
</tr>
<tr>
<td>TCP</td>
<td>445</td>
<td>Directory Services SMB file sharing</td>
</tr>
<tr>
<td>TCP</td>
<td>636</td>
<td>Lightweight Directory Access Protocol over TLS/SSL (LDAPS)</td>
</tr>
<tr>
<td>Protocol</td>
<td>Ports</td>
<td>Role</td>
</tr>
<tr>
<td>----------</td>
<td>--------------------</td>
<td>-------------------------------</td>
</tr>
<tr>
<td>TCP</td>
<td>49152 - 65535</td>
<td>Ephemeral ports for RPC</td>
</tr>
</tbody>
</table>

- Generally, the domain DNS servers are located in the AD domain controllers. You do not need to configure the VPC DHCP option set to use this feature. For more information, see [DHCP option sets](#) in the [Amazon VPC User Guide](#).

**Important**

If you're using VPC network ACLs, you must also allow outbound traffic on dynamic ports (49152-65535) from your RDS for SQL Server DB instance. Ensure that these traffic rules are also mirrored on the firewalls that apply to each of the AD domain controllers, DNS servers, and RDS for SQL Server DB instances.

While VPC security groups require ports to be opened only in the direction that network traffic is initiated, most Windows firewalls and VPC network ACLs require ports to be open in both directions.

**Configure your AD domain service account**

Make sure that you have met the following requirements for an AD domain service account:

- Make sure that you have a service account in your self-managed AD domain with delegated permissions to join computers to the domain. A domain service account is a user account in your self-managed AD that has been delegated permission to perform certain tasks.

- The domain service account needs to be delegated the following permissions in the Organizational Unit (OU) that you're joining your RDS for SQL Server DB instance to:
  - Validated ability to write to the DNS host name
  - Validated ability to write to the service principal name
  - Create and delete computer objects

These represent the minimum set of permissions that are required to join computer objects to your self-managed Active Directory. For more information, see [Errors when attempting to join computers to a domain](#) in the Microsoft Windows Server documentation.

**Important**

Do not move computer objects that RDS for SQL Server creates in the Organizational Unit after your DB instance is created. Moving the associated objects will cause your RDS for SQL Server DB instance to become misconfigured. If you need to move the computer objects created by Amazon RDS, use the [ModifyDBInstance](#) RDS API operation to modify the domain parameters with the desired location of the computer objects.

**Limitations**

The following limitations apply for Self Managed AD for SQL Server.

- NTLM is the only supported authentication type. Kerberos authentication is not supported. If you need to use kerberos authentication, you can use AWS Managed AD instead of self-managed AD.

- The Microsoft Distributed Transaction Coordinator (MSDTC) service isn't supported, as it requires Kerberos authentication.

- Your RDS for SQL Server DB instances do not use the Network Time Protocol (NTP) server of your self-managed AD domain. They use an AWS NTP service instead.

- SQL Server linked servers must use SQL authentication to connect to other RDS for SQL Server DB instances joined to your self-managed AD domain.
Microsoft Group Policy Object (GPO) settings from your self-managed AD domain are not applied to RDS for SQL Server DB instances.

Overview of setting up Self Managed Active Directory

To set up self-managed AD for an RDS for SQL Server DB instance, take the following steps, explained in greater detail in Setting up Self Managed Active Directory (p. 1407):

In your AD domain:

- Create an Organizational Unit (OU).
- Create an AD domain user.
- Delegate control to the AD domain user.

From the AWS Management Console or API:

- Create a AWS KMS key.
- Create a secret using AWS Secrets Manager.
- Create or modify an RDS for SQL Server DB instance and join it to your self-managed AD domain.

Setting up Self Managed Active Directory

To set up Self Managed AD, take the following steps.

Topics
- Step 1: Create an Organizational Unit in your AD (p. 1407)
- Step 2: Create an AD domain user in your AD (p. 1408)
- Step 3: Delegate control to the AD user (p. 1408)
- Step 4: Create an AWS KMS key (p. 1408)
- Step 5: Create an AWS secret (p. 1409)
- Step 6: Create or modify a SQL Server DB instance (p. 1410)
- Step 7: Create Windows Authentication SQL Server logins (p. 1412)

Step 1: Create an Organizational Unit in your AD

Important
We recommend creating a dedicated OU and service credential scoped to that OU for any AWS account that owns an RDS for SQL Server DB instance joined your self-managed AD domain. By dedicating an OU and service credential, you can avoid conflicting permissions and follow the principal of least privilege.

To create an OU in your AD

1. Connect to your AD domain as a domain administrator.
2. Open Active Directory Users and Computers and select the domain where you want to create your OU.
3. Right-click the domain and choose New, then Organizational Unit.
4. Enter a name for the OU.
5. Keep the box selected for Protect container from accidental deletion.
6. Click OK. Your new OU will appear under your domain.
Step 2: Create an AD domain user in your AD

The domain user credentials will be used for the secret in AWS Secrets Manager.

To create an AD domain user in your AD

1. Open Active Directory Users and Computers and select the domain and OU where you want to create your user.
2. Right-click the Users object and choose New, then User.
3. Enter a first name, last name, and logon name for the user. Click Next.
4. Enter a password for the user. Don't select "User must change password at next login". Don't select "Account is disabled". Click Next.
5. Click OK. Your new user will appear under your domain.

Step 3: Delegate control to the AD user

To delegate control to the AD domain user in your domain

1. Open Active Directory Users and Computers MMC snap-in and select the domain where you want to create your user.
2. Right-click the OU that you created earlier and choose Delegate Control.
4. On the Users or Groups section, click Add.
5. On the Select Users, Computers, or Groups section, enter the AD user you created and click Check Names. If your AD user check is successful, click OK.
6. On the Users or Groups section, confirm your AD user was added and click Next.
7. On the Tasks to Delegate section, choose Create a custom task to delegate and click Next.
8. On the Active Directory Object Type section:
   a. Choose Only the following objects in the folder.
   b. Select Computer Objects and click Next.
   c. Select Create selected objects in this folder.
   d. Select Delete selected objects in this folder and click Next.
9. On the Permissions section:
   a. Keep General selected.
   b. Select Validated write to DNS host name.
   c. Select Validated write to service principal name and click Next.
10. For Completing the Delegation of Control Wizard, review and confirm your settings and click Finish.

Step 4: Create an AWS KMS key

The KMS key is used to encrypt your AWS secret.

To create an AWS KMS key

Note
For Encryption Key, don't use the AWS default KMS key. Be sure to create the AWS KMS key in the same AWS account that contains the RDS for SQL Server DB instance that you want to join to your self-managed AD.
1. In the AWS KMS console, choose **Create key**.
2. For **Key Type**, choose **Symmetric**.
3. For **Key Usage**, choose **Encrypt and decrypt**.
4. For **Advanced options**:
   a. For **Key material origin**, choose **KMS**.
   b. For **Regionality**, choose **Single-Region key** and click **Next**.
5. For **Alias**, provide a name for the KMS key.
6. (Optional) For **Description**, provide a description of the KMS key.
7. (Optional) For **Tags**, provide a tag the KMS key and click **Next**.
8. For **Key administrators**, provide the name of an IAM user and select it.
9. For **Key deletion**, keep the box selected for **Allow key administrators to delete this key** and click **Next**.
10. For **Key users**, provide the same IAM user from the previous step and select it. Click **Next**.
11. Review the configuration.
12. For **Key policy**, include the following to the policy **Statement**:

   ```json
   {
       "Sid": "Allow use of the KMS key on behalf of RDS",
       "Effect": "Allow",
       "Principal": {
           "Service": ["rds.amazonaws.com"]
       },
       "Action": "kms:Decrypt",
       "Resource": "*"
   }
   ```
13. Click **Finish**.

**Step 5: Create an AWS secret**

**To create a secret**

**Note**
Be sure to create the secret in the same AWS account that contains the RDS for SQL Server DB instance that you want to join to your self-managed AD.

1. In AWS Secrets Manager, choose **Store a new secret**.
2. For **Secret type**, choose **Other type of secret**.
3. For **Key/value pairs**, add your two keys:
   a. For the first key, enter **CUSTOMER_MANAGED_ACTIVE_DIRECTORY_USERNAME**.
   b. For the value of the first key, enter the name of the AD user that you created on your domain in a previous step.
   c. For the second key, enter **CUSTOMER_MANAGED_ACTIVE_DIRECTORY_PASSWORD**.
   d. For the value of the second key, enter the password that you created for the AD user on your domain.
4. For **Encryption key**, enter the KMS key that you created in a previous step and click **Next**.
5. For **Secret name**, enter a descriptive name that helps you find your secret later.
6. (Optional) For **Description**, enter a description for the secret name.
7. For **Resource permission**, click **Edit**.

8. Add the following policy to the permission policy:

   **Note**
   
   We recommend that you use the `aws:sourceAccount` and `aws:sourceArn` conditions in the policy to avoid the confused deputy problem. Use your AWS account for `aws:sourceAccount` and the RDS for SQL Server DB instance ARN for `aws:sourceArn`. For more information, see Preventing cross-service confused deputy problems (p. 2657).

   ```json
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Effect": "Allow",
   "Principal": {
   "Service": "rds.amazonaws.com"
   },
   "Action": "secretsmanager:GetSecretValue",
   "Resource": "*",
   "Condition": {
   "StringEquals": {
   "aws:sourceAccount": "123456789012"
   },
   "ArnLike": {
   }
   }
   ]
   }
   ```

9. Click **Save** then click **Next**.

10. For **Configure rotation settings**, keep the default values and choose **Next**.

11. Review the settings for the secret and click **Store**.

12. Choose the secret you created and copy the value for the **Secret ARN**. This will be used in the next step to set up self-managed Active Directory.

**Step 6: Create or modify a SQL Server DB instance**

You can use the console, CLI, or RDS API to associate an RDS for SQL Server DB instance with a self-managed AD domain. You can do this in one of the following ways:

- Create a new SQL Server DB instance using the console, the [create-db-instance](#) CLI command, or the [CreateDBInstance](#) RDS API operation.

  For instructions, see Creating an Amazon RDS DB instance (p. 300).

- Modify an existing SQL Server DB instance using the console, the [modify-db-instance](#) CLI command, or the [ModifyDBInstance](#) RDS API operation.

  For instructions, see Modifying an Amazon RDS DB instance (p. 401).

- Restore a SQL Server DB instance from a DB snapshot using the console, the [restore-db-instance-from-db-snapshot](#) CLI command, or the [RestoreDBInstanceFromDBSnapshot](#) RDS API operation.

  For instructions, see Restoring from a DB snapshot (p. 615).
• Restore a SQL Server DB instance to a point-in-time using the console, the `restore-db-instance-to-point-in-time` CLI command, or the `RestoreDBInstanceToPointInTime` RDS API operation.

For instructions, see Restoring a DB instance to a specified time (p. 660).

When you use the AWS CLI, the following parameters are required for the DB instance to be able to use the self-managed Active Directory domain that you created:

• For the `--domain-fqdn` parameter, use the fully qualified domain name (FQDN) of your self-managed Active Directory.
• For the `--domain-ou` parameter, use the OU that you created in your self-managed AD.
• For the `--domain-auth-secret-arn` parameter, use the value of the Secret ARN that you created in a previous step.
• For the `--domain-dns-ips` parameter, use the primary and secondary IPv4 addresses of the DNS servers for your self-managed AD. If you don't have a secondary DNS server IP address, enter the primary IP address twice.

The following example CLI commands show how to create, modify, and remove an RDS for SQL Server DB instance with a self-managed AD domain.

**Important**
If you modify a DB instance to join it to or remove it from a self-managed AD domain, a reboot of the DB instance is required for the modification to take effect. You can choose to apply the changes immediately or wait until the next maintenance window. Choosing the **Apply Immediately** option will cause downtime for a single-AZ DB instance. A multi-AZ DB instance will perform a failover before completing a reboot. For more information, see Using the Apply Immediately setting (p. 402).

The following CLI command creates a new RDS for SQL Server DB instance and joins it to a self-managed AD domain.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
  --db-instance-identifier my-DB-instance \
  --db-instance-class db.m5.xlarge \
  --allocated-storage 50 \
  --engine sqlserver-se \
  --engine-version 15.00.4043.16.v1 \
  --license-model license-included \
  --master-username my-master-username \
  --master-user-password my-master-password \
  --domain-fqdn my_AD_domain.my_AD.my_domain \
  --domain-ou OU=my-AD-test-OU,DC=my-AD-test,DC=my-AD,DC=my-domain \
  --domain-auth-secret-arn arn:aws:secretsmanager:region:account-number:secret:my-AD-test-secret-123456' \
  --domain-dns-ips "10.11.12.13" "10.11.12.14"
```

For Windows:

```
aws rds create-db-instance ^
  --db-instance-identifier my-DB-instance ^
  --db-instance-class db.m5.xlarge ^
  --allocated-storage 50 ^
  --engine sqlserver-se ^
  --engine-version 15.00.4043.16.v1 ^
  --license-model license-included ^
```

1411
The following CLI command modifies an existing RDS for SQL Server DB instance to use a self-managed Active Directory domain.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance
--db-instance-identifier my-DB-instance
--domain-fqdn my_AD_domain.my_AD.my_domain
--domain-ou OU=my-AD-test-OU,DC=my-AD-test,DC=my-AD,DC=my-domain
--domain-dns-ips "10.11.12.13" "10.11.12.14"
```

For Windows:

```bash
aws rds modify-db-instance
--db-instance-identifier my-DBinstance
--domain-fqdn my_AD_domain.my_AD.my_domain
--domain-ou OU=my-AD-test-OU,DC=my-AD-test,DC=my-AD,DC=my-domain
--domain-dns-ips "10.11.12.13" "10.11.12.14"
```

The following CLI command removes an RDS for SQL Server DB instance from a self-managed Active Directory domain.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance
--db-instance-identifier my-DB-instance
--disable-domain
```

For Windows:

```bash
aws rds modify-db-instance
--db-instance-identifier my-DB-instance
--disable-domain
```

**Step 7: Create Windows Authentication SQL Server logins**

Use the Amazon RDS master user credentials to connect to the SQL Server DB instance as you do for any other DB instance. Because the DB instance is joined to the self-managed AD domain, you can provision SQL Server logins and users. You do this from the AD users and groups utility in your self-managed AD domain. Database permissions are managed through standard SQL Server permissions granted and revoked to these Windows logins.

In order for a self-managed AD user to authenticate with SQL Server, a SQL Server Windows login must exist for the self-managed AD user or a self-managed Active Directory group that the user is a member of. Fine-grained access control is handled through granting and revoking permissions on these SQL
Server logins. A self-managed AD user that doesn’t have a SQL Server login or belong to a self-managed AD group with such a login can’t access the SQL Server DB instance.

The ALTER ANY LOGIN permission is required to create a self-managed AD SQL Server login. If you haven’t created any logins with this permission, connect as the DB instance’s master user using SQL Server Authentication and create your self-managed AD SQL Server logins under the context of the master user.

You can run a data definition language (DDL) command such as the following to create a SQL Server login for an self-managed AD user or group.

**Note**
Specify users and groups using the pre-Windows 2000 login name in the format *my_AD_domain\my_AD_domain_user*. You can’t use a user principal name (UPN) in the format *my_AD_domain_user@my_AD_domain*.

```sql
USE [master]
GO
CREATE LOGIN [my_AD_domain\my_AD_domain_user] FROM WINDOWS WITH DEFAULT_DATABASE = [master], DEFAULT_LANGUAGE = [us_english];
GO
```

For more information, see [CREATE LOGIN (Transact-SQL)] in the Microsoft Developer Network documentation.

Users (both humans and applications) from your domain can now connect to the RDS for SQL Server instance from a self-managed AD domain-joined client machine using Windows authentication.

**Managing a DB instance in a self-managed Active Directory Domain**

You can use the console, AWS CLI, or the Amazon RDS API to manage your DB instance and its relationship with your self-managed AD domain. For example, you can move the DB instance into, out of, or between domains.

For example, using the Amazon RDS API, you can do the following:

- To reattempt a self-managed domain join for a failed membership, use the `ModifyDBInstance` API operation and specify the same set of parameters:
  - `--domain-fqdn`
  - `--domain-dns-ips`
  - `--domain-ou`
  - `--domain-auth-secret-arn`

- To remove a DB instance from a self-managed domain, use the `ModifyDBInstance` API operation and specify `--disable-domain` for the domain parameter.

- To move a DB instance from one self-managed domain to another, use the `ModifyDBInstance` API operation and specify the domain parameters for the new domain:
  - `--domain-fqdn`
  - `--domain-dns-ips`
  - `--domain-ou`
  - `--domain-auth-secret-arn`

- To list self-managed AD domain membership for each DB instance, use the `DescribeDBInstances` API operation.
Understanding self-managed Active Directory Domain membership

After you create or modify your DB instance, the instance becomes a member of the self-managed AD domain. The AWS console indicates the status of the self-managed Active Directory domain membership for the DB instance. The status of the DB instance can be one of the following:

- **joined** – The instance is a member of the AD domain.
- **joining** – The instance is in the process of becoming a member of the AD domain.
- **pending-join** – The instance membership is pending.
- **pending-maintenance-join** – AWS will attempt to make the instance a member of the AD domain during the next scheduled maintenance window.
- **pending-removal** – The removal of the instance from the AD domain is pending.
- **pending-maintenance-removal** – AWS will attempt to remove the instance from the AD domain during the next scheduled maintenance window.
- **failed** – A configuration problem has prevented the instance from joining the AD domain. Check and fix your configuration before reissuing the instance modify command.
- **removing** – The instance is being removed from the self-managed AD domain.

A request to become a member of a self-managed AD domain can fail because of a network connectivity issue. For example, you might create a DB instance or modify an existing instance and have the attempt fail for the DB instance to become a member of a self-managed AD domain. In this case, either reissue the command to create or modify the DB instance or modify the newly created instance to join the self-managed AD domain.

Troubleshooting self-managed Active Directory

The following are issues you might encounter when you set up or modify self-managed AD.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
<th>Common causes</th>
<th>Troubleshooting suggestions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error 2 / 0x2</td>
<td>The system cannot find the file specified.</td>
<td>The format or location for the Organizational Unit (OU) specified with the –domain-ou parameter is invalid. The domain service account specified via AWS Secrets Manager lack the permissions required to join the OU.</td>
<td>Review the –domain-ou parameter. Ensure the domain service account has the correct permissions to the OU. For more information, see Configure your AD domain service account (p. 1406).</td>
</tr>
<tr>
<td>Error 5 / 0x5</td>
<td>Access is denied.</td>
<td>Misconfigured permissions for the domain service account, or the computer account already exists in the domain.</td>
<td>Review the domain service account permissions in the domain, and verify that the RDS computer account is not duplicated in the domain. You can verify the name of the RDS computer account by running SELECT @@SERVERNAME on your RDS for SQL Server DB instance. If you are using</td>

</tr>
<tr>
<td>Error 2242 / 0x8c2</td>
<td>The password of this user has expired.</td>
<td>The password for the domain service account specified via AWS Secrets Manager has expired.</td>
<td>Update the password for the domain service account used to join your RDS for SQL Server DB instance to your self-managed AD.</td>
</tr>
</tbody>
</table>

**Restoring a SQL Server DB instance and then adding it to a self-managed Active Directory domain**

You can restore a DB snapshot or do point-in-time recovery (PITR) for a SQL Server DB instance and then add it to a self-managed Active Directory domain. Once the DB instance is restored, modify the instance using the process explained in [Step 6: Create or modify a SQL Server DB instance](p. 1410) to add the DB instance to a self-managed AD domain.
Working with AWS Managed Active Directory with RDS for SQL Server

You can use AWS Managed Microsoft AD to authenticate users with Windows Authentication when they connect to your RDS for SQL Server DB instance. The DB instance works with AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD, to enable Windows Authentication. When users authenticate with a SQL Server DB instance joined to the trusting domain, authentication requests are forwarded to the domain directory that you create with AWS Directory Service.

Region and version availability

Amazon RDS supports using only AWS Managed Microsoft AD for Windows Authentication. RDS doesn't support using AD Connector. For more information, see the following:

- Application compatibility policy for AWS Managed Microsoft AD
- Application compatibility policy for AD Connector

For information on version and Region availability, see Kerberos authentication with RDS for SQL Server.

Overview of setting up Windows authentication

Amazon RDS uses mixed mode for Windows Authentication. This approach means that the master user (the name and password used to create your SQL Server DB instance) uses SQL Authentication. Because the master user account is a privileged credential, you should restrict access to this account.

To get Windows Authentication using an on-premises or self-hosted Microsoft Active Directory, create a forest trust. The trust can be one-way or two-way. For more information on setting up forest trusts using AWS Directory Service, see When to create a trust relationship in the AWS Directory Service Administration Guide.

To set up Windows authentication for a SQL Server DB instance, do the following steps, explained in greater detail in Setting up Windows Authentication for SQL Server DB instances (p. 1418):

1. Use AWS Managed Microsoft AD, either from the AWS Management Console or AWS Directory Service API, to create an AWS Managed Microsoft AD directory.

2. If you use the AWS CLI or Amazon RDS API to create your SQL Server DB instance, create an AWS Identity and Access Management (IAM) role. This role uses the managed IAM policy AmazonRDSDirectoryServiceAccess and allows Amazon RDS to make calls to your directory. If you use the console to create your SQL Server DB instance, AWS creates the IAM role for you.

   For the role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Managing AWS STS in an AWS Region in the IAM User Guide.

3. Create and configure users and groups in the AWS Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users and groups in your Active Directory, see Manage users and groups in AWS Managed Microsoft AD in the AWS Directory Service Administration Guide.

4. If you plan to locate the directory and the DB instance in different VPCs, enable cross-VPC traffic.

5. Use Amazon RDS to create a new SQL Server DB instance either from the console, AWS CLI, or Amazon RDS API. In the create request, you provide the domain identifier ("d-*" identifier) that was generated when you created your directory and the name of the role you created. You can also modify an existing SQL Server DB instance to use Windows Authentication by setting the domain and IAM role parameters for the DB instance.
6. Use the Amazon RDS master user credentials to connect to the SQL Server DB instance as you do any other DB instance. Because the DB instance is joined to the AWS Managed Microsoft AD domain, you can provision SQL Server logins and users from the Active Directory users and groups in their domain. (These are known as SQL Server "Windows" logins.) Database permissions are managed through standard SQL Server permissions granted and revoked to these Windows logins.

Creating the endpoint for Kerberos authentication

Kerberos-based authentication requires that the endpoint be the customer-specified host name, a period, and then the fully qualified domain name (FQDN). For example, the following is an example of an endpoint you might use with Kerberos-based authentication. In this example, the SQL Server DB instance host name is ad-test and the domain name is corp-ad.company.com.

```plaintext
ad-test.corp-ad.company.com
```

If you want to make sure your connection is using Kerberos, run the following query:

```sql
SELECT net_transport, auth_scheme
 FROM sys.dm_exec_connections
 WHERE session_id = @@SPID;
```

Setting up Windows Authentication for SQL Server DB instances

You use AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD, to set up Windows Authentication for a SQL Server DB instance. To set up Windows Authentication, take the following steps.

Step 1: Create a directory using the AWS Directory Service for Microsoft Active Directory

AWS Directory Service creates a fully managed, Microsoft Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and Domain Name Service (DNS) servers on your behalf. The directory servers are created in two subnets in two different Availability Zones within a VPC. This redundancy helps ensure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

- Sets up a Microsoft Active Directory within the VPC.
- Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.
  
  **Note**
  
  Be sure to save this password. AWS Directory Service doesn't store this password, and you can't retrieve or reset it.
- Creates a security group for the directory controllers.

When you launch an AWS Directory Service for Microsoft Active Directory, AWS creates an Organizational Unit (OU) that contains all your directory's objects. This OU, which has the NetBIOS name that you typed when you created your directory, is located in the domain root. The domain root is owned and managed by AWS.

The `admin` account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:
• Create, update, or delete users, groups, and computers.
• Add resources to your domain such as file or print servers, and then assign permissions for those resources to users and groups in your OU.
• Create additional OUs and containers.
• Delegate authority.
• Create and link group policies.
• Restore deleted objects from the Active Directory Recycle Bin.
• Run AD and DNS Windows PowerShell modules on the Active Directory Web Service.

The admin account also has rights to perform the following domain-wide activities:
• Manage DNS configurations (add, remove, or update records, zones, and forwarders).
• View DNS event logs.
• View security event logs.

To create a directory with AWS Managed Microsoft AD

1. In the AWS Directory Service console navigation pane, choose Directories and choose Set up directory.
2. Choose AWS Managed Microsoft AD. This is the only option currently supported for use with Amazon RDS.
3. Choose Next.
4. On the Enter directory information page, provide the following information:
   Edition
   Choose the edition that meets your requirements.
   Directory DNS name
   The fully qualified name for the directory, such as corp.example.com. Names longer than 47 characters aren't supported by SQL Server.
   Directory NetBIOS name
   An optional short name for the directory, such as CORP.
   Directory description
   An optional description for the directory.
   Admin password
   The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.
   The directory administrator password can't include the word admin. The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:
   • Lowercase letters (a-z)
   • Uppercase letters (A-Z)
   • Numbers (0-9)
   • Non-alphanumeric characters (~!#$%^&*-_+"\<>?:/)
   Confirm password
   Retype the administrator password.
5. Choose Next.
6. On the Choose VPC and subnets page, provide the following information:

**VPC**

Choose the VPC for the directory.

**Note**

You can locate the directory and the DB instance in different VPCs, but if you do so, make sure to enable cross-VPC traffic. For more information, see Step 4: Enable cross-VPC traffic between the directory and the DB instance (p. 1423).

**Subnets**

Choose the subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Choose Next.
8. Review the directory information. If changes are needed, choose Previous. When the information is correct, choose Create directory.

It takes several minutes for the directory to be created. When it has been successfully created, the Status value changes to Active.
To see information about your directory, choose the directory ID in the directory listing. Make a note of the **Directory ID**. You need this value when you create or modify your SQL Server DB instance.

![Directory details image](image)

**Step 2: Create the IAM role for use by Amazon RDS**

If you use the console to create your SQL Server DB instance, you can skip this step. If you use the CLI or RDS API to create your SQL Server DB instance, you must create an IAM role that uses the AmazonRDSDirectoryServiceAccess managed IAM policy. This role allows Amazon RDS to make calls to the AWS Directory Service for you.

If you are using a custom policy for joining a domain, rather than using the AWS-managed AmazonRDSDirectoryServiceAccess policy, make sure that you allow the ds:GetAuthorizedApplicationDetails action. This requirement is effective starting July 2019, due to a change in the AWS Directory Service API.

The following IAM policy, AmazonRDSDirectoryServiceAccess, provides access to AWS Directory Service.

**Example IAM policy for providing access to AWS Directory Service**

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "ds:DescribeDirectories",
                "ds:AuthorizeApplication",
                "ds:UnauthorizeApplication"
            ]
        }
    ]
}
```
We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based trust relationships to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role. For Windows Authentication, make sure to include the DB instances, as shown in the following example.

**Example trust relationship with global condition context key for Windows Authentication**

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceArn": [
            "arn:aws:rds:Region:my_account_ID:db:db_instance_identifier"
          ]
        }
      }
    }
  ]
}
```

Create an IAM role using this IAM policy and trust relationship. For more information about creating IAM roles, see Creating customer managed policies in the IAM User Guide.

**Step 3: Create and configure users and groups**

You can create users and groups with the Active Directory Users and Computers tool. This tool is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. Users represent individual people or entities that have access to your directory. Groups are very useful for giving or denying privileges to groups of users, rather than having to apply those privileges to each individual user.

To create users and groups in an AWS Directory Service directory, you must be connected to a Windows EC2 instance that is a member of the AWS Directory Service directory. You must also be logged in as
a user that has privileges to create users and groups. For more information, see Add users and groups (Simple AD and AWS Managed Microsoft AD) in the AWS Directory Service Administration Guide.

Step 4: Enable cross-VPC traffic between the directory and the DB instance

If you plan to locate the directory and the DB instance in the same VPC, skip this step and move on to Step 5: Create or modify a SQL Server DB instance (p. 1423).

If you plan to locate the directory and the DB instance in different VPCs, configure cross-VPC traffic using VPC peering or AWS Transit Gateway.

The following procedure enables traffic between VPCs using VPC peering. Follow the instructions in What is VPC peering? in the Amazon Virtual Private Cloud Peering Guide.

To enable cross-VPC traffic using VPC peering

1. Set up appropriate VPC routing rules to ensure that network traffic can flow both ways.
2. Ensure that the DB instance's security group can receive inbound traffic from the directory's security group.
3. Ensure that there is no network access control list (ACL) rule to block traffic.

If a different AWS account owns the directory, you must share the directory.

To share the directory between AWS accounts

1. Start sharing the directory with the AWS account that the DB instance will be created in by following the instructions in Tutorial: Sharing your AWS Managed Microsoft AD directory for seamless EC2 domain-join in the AWS Directory Service Administration Guide.
2. Sign in to the AWS Directory Service console using the account for the DB instance, and ensure that the domain has the SHARED status before proceeding.
3. While signed into the AWS Directory Service console using the account for the DB instance, note the Directory ID value. You use this directory ID to join the DB instance to the domain.

Step 5: Create or modify a SQL Server DB instance

Create or modify a SQL Server DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new SQL Server DB instance using the console, the `create-db-instance` CLI command, or the `CreateDBInstance` RDS API operation.
  
  For instructions, see Creating an Amazon RDS DB instance (p. 300).

- Modify an existing SQL Server DB instance using the console, the `modify-db-instance` CLI command, or the `ModifyDBInstance` RDS API operation.
  
  For instructions, see Modifying an Amazon RDS DB instance (p. 401).

- Restore a SQL Server DB instance from a DB snapshot using the console, the `restore-db-instance-from-db-snapshot` CLI command, or the `RestoreDBInstanceFromDBSnapshot` RDS API operation.
  
  For instructions, see Restoring from a DB snapshot (p. 615).

- Restore a SQL Server DB instance to a point-in-time using the console, the `restore-db-instance-to-point-in-time` CLI command, or the `RestoreDBInstanceToPointInTime` RDS API operation.
  
  For instructions, see Restoring a DB instance to a specified time (p. 660).
Windows Authentication is only supported for SQL Server DB instances in a VPC.

For the DB instance to be able to use the domain directory that you created, the following is required:

- **Directory**, you must choose the domain identifier (d-ID) generated when you created the directory.
- Make sure that the VPC security group has an outbound rule that lets the DB instance communicate with the directory.

When you use the AWS CLI, the following parameters are required for the DB instance to be able to use the directory that you created:

- For the **--domain** parameter, use the domain identifier (d-ID) generated when you created the directory.
- For the **--domain-iam-role-name** parameter, use the role that you created that uses the managed IAM policy AmazonRDSDirectoryServiceAccess.

For example, the following CLI command modifies a DB instance to use a directory.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --domain d-ID \
  --domain-iam-role-name role-name
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --domain d-ID ^
  --domain-iam-role-name role-name
```

**Important**

If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

**Step 6: Create Windows Authentication SQL Server logins**

Use the Amazon RDS master user credentials to connect to the SQL Server DB instance as you do any other DB instance. Because the DB instance is joined to the AWS Managed Microsoft AD domain, you
can provision SQL Server logins and users. You do this from the Active Directory users and groups in your domain. Database permissions are managed through standard SQL Server permissions granted and revoked to these Windows logins.

For an Active Directory user to authenticate with SQL Server, a SQL Server Windows login must exist for the user or a group that the user is a member of. Fine-grained access control is handled through granting and revoking permissions on these SQL Server logins. A user that doesn't have a SQL Server login or belong to a group with such a login can't access the SQL Server DB instance.

The ALTER ANY LOGIN permission is required to create an Active Directory SQL Server login. If you haven't created any logins with this permission, connect as the DB instance's master user using SQL Server Authentication.

Run a data definition language (DDL) command such as the following example to create a SQL Server login for an Active Directory user or group.

Note
Specify users and groups using the pre-Windows 2000 login name in the format *domainName\login_name*. You can't use a user principal name (UPN) in the format *login_name@DomainName*.

```sql
USE [master]
GO
CREATE LOGIN [mydomain\myuser] FROM WINDOWS WITH DEFAULT_DATABASE = [master],
DEFAULT_LANGUAGE = [us_english];
GO
```

For more information, see [CREATE LOGIN (Transact-SQL)](https://docs.microsoft.com/en-us/sql/t-sql/statements/create-login-transact-sql) in the Microsoft Developer Network documentation.

Users (both humans and applications) from your domain can now connect to the RDS for SQL Server instance from a domain-joined client machine using Windows authentication.

**Managing a DB instance in a Domain**

You can use the console, AWS CLI, or the Amazon RDS API to manage your DB instance and its relationship with your domain. For example, you can move the DB instance into, out of, or between domains.

For example, using the Amazon RDS API, you can do the following:

- To reattempt a domain join for a failed membership, use the [ModifyDBInstance](https://docs.aws.amazon.com/AmazonRDS/latest/APIReference/API_ModifyDBInstance.html) API operation and specify the current membership's directory ID.
- To update the IAM role name for membership, use the `ModifyDBInstance` API operation and specify the current membership's directory ID and the new IAM role.
- To remove a DB instance from a domain, use the `ModifyDBInstance` API operation and specify none as the domain parameter.
- To move a DB instance from one domain to another, use the `ModifyDBInstance` API operation and specify the domain identifier of the new domain as the domain parameter.
- To list membership for each DB instance, use the [DescribeDBInstances](https://docs.aws.amazon.com/AmazonRDS/latest/APIReference/API_DescribeDBInstances.html) API operation.

**Understanding Domain membership**

After you create or modify your DB instance, the instance becomes a member of the domain. The AWS console indicates the status of the domain membership for the DB instance. The status of the DB instance can be one of the following:
• **joined** – The instance is a member of the domain.
• **joining** – The instance is in the process of becoming a member of the domain.
• **pending-join** – The instance membership is pending.
• **pending-maintenance-join** – AWS will attempt to make the instance a member of the domain during the next scheduled maintenance window.
• **pending-removal** – The removal of the instance from the domain is pending.
• **pending-maintenance-removal** – AWS will attempt to remove the instance from the domain during the next scheduled maintenance window.
• **failed** – A configuration problem has prevented the instance from joining the domain. Check and fix your configuration before reissuing the instance modify command.
• **removing** – The instance is being removed from the domain.

A request to become a member of a domain can fail because of a network connectivity issue or an incorrect IAM role. For example, you might create a DB instance or modify an existing instance and have the attempt fail for the DB instance to become a member of a domain. In this case, either reissue the command to create or modify the DB instance or modify the newly created instance to join the domain.

**Connecting to SQL Server with Windows authentication**

To connect to SQL Server with Windows Authentication, you must be logged into a domain-joined computer as a domain user. After launching SQL Server Management Studio, choose **Windows Authentication** as the authentication type, as shown following.

![SQL Server Management Studio](image)

**Restoring a SQL Server DB instance and then adding it to a domain**

You can restore a DB snapshot or do point-in-time recovery (PITR) for a SQL Server DB instance and then add it to a domain. Once the DB instance is restored, modify the instance using the process explained in **Step 5: Create or modify a SQL Server DB instance (p. 1423)** to add the DB instance to a domain.
Updating applications to connect to Microsoft SQL Server DB instances using new SSL/TLS certificates

As of January 13, 2023, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB instances. If they do, you can further check whether those applications require certificate verification to connect.

**Note**
Some applications are configured to connect to SQL Server DB instances only if they can successfully verify the certificate on the server.
For such applications, you must update your client application trust stores to include the new CA certificates.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see [Rotating your SSL/TLS certificate](p. 2613). For more information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB instance](p. 2608). For information about using SSL/TLS with Microsoft SQL Server DB instances, see [Using SSL with a Microsoft SQL Server DB instance](p. 1472).

**Topics**
- Determining whether any applications are connecting to your Microsoft SQL Server DB instance using SSL (p. 1427)
- Determining whether a client requires certificate verification in order to connect (p. 1428)
- Updating your application trust store (p. 1429)

Determining whether any applications are connecting to your Microsoft SQL Server DB instance using SSL

Check the DB instance configuration for the value of the `rds.force_ssl` parameter. By default, the `rds.force_ssl` parameter is set to 0 (off). If the `rds.force_ssl` parameter is set to 1 (on), clients are required to use SSL/TLS for connections. For more information about parameter groups, see [Working with parameter groups](p. 347).

Run the following query to get the current encryption option for all the open connections to a DB instance. The column `ENCRYPT_OPTION` returns TRUE if the connection is encrypted.

```
select SESSION_ID, 
      ENCRYPT_OPTION, 
      NET_TRANSPORT, 
      AUTH_SCHEME 
from SYS.DM_EXEC_CONNECTIONS
```

This query shows only the current connections. It doesn't show whether applications that have connected and disconnected in the past have used SSL.
Determining whether a client requires certificate verification in order to connect

You can check whether different types of clients require certificate verification to connect.

**Note**
If you use connectors other than the ones listed, see the specific connector's documentation for information about how it enforces encrypted connections. For more information, see [Connection modules for Microsoft SQL databases](#) in the Microsoft SQL Server documentation.

**SQL Server Management Studio**

Check whether encryption is enforced for SQL Server Management Studio connections:

1. Launch SQL Server Management Studio.
2. For **Connect to server**, enter the server information, login user name, and password.
3. Choose **Options**.
4. Check if **Encrypt connection** is selected in the connect page.

For more information about SQL Server Management Studio, see [Use SQL Server Management Studio](#).

**Sqlcmd**

The following example with the `sqlcmd` client shows how to check a script's SQL Server connection to determine whether successful connections require a valid certificate. For more information, see [Connecting with sqlcmd](#) in the Microsoft SQL Server documentation.

When using `sqlcmd`, an SSL connection requires verification against the server certificate if you use the `-N` command argument to encrypt connections, as in the following example.

```
$ sqlcmd -N -S dbinstance.rds.amazon.com -d ExampleDB
```

**Note**
If `sqlcmd` is invoked with the `-C` option, it trusts the server certificate, even if that doesn't match the client-side trust store.

**ADO.NET**

In the following example, the application connects using SSL, and the server certificate must be verified.

```
using SQLC = Microsoft.Data.SqlClient;
...

    static public void Main()
    {
        using (var connection = new SQLC.SqlConnection(
            "Server=tcp:dbinstance.rds.amazon.com;" +
            "Database=ExampleDB;User ID=LOGIN_NAME;" +
            "Password=YOUR_PASSWORD;" +
            "Encrypt=True;TrustServerCertificate=False;"
        ))
```
Java

In the following example, the application connects using SSL, and the server certificate must be verified.

```java
String connectionUrl =
    "jdbc:sqlserver://dbinstance.rds.amazon.com;" +
    "databaseName=ExampleDB;integratedSecurity=true;" +
    "encrypt=true;trustServerCertificate=false;"
```

To enable SSL encryption for clients that connect using JDBC, you might need to add the Amazon RDS certificate to the Java CA certificate store. For instructions, see Configuring the client for encryption in the Microsoft SQL Server documentation. You can also provide the trusted CA certificate file name directly by appending `trustStore=path-to-certificate-trust-store-file` to the connection string.

**Note**

If you use `TrustServerCertificate=true` (or its equivalent) in the connection string, the connection process skips the trust chain validation. In this case, the application connects even if the certificate can't be verified. Using `TrustServerCertificate=false` enforces certificate validation and is a best practice.

### Updating your application trust store

You can update the trust store for applications that use Microsoft SQL Server. For instructions, see Encrypting specific connections (p. 1473). Also, see Configuring the client for encryption in the Microsoft SQL Server documentation.

If you are using an operating system other than Microsoft Windows, see the software distribution documentation for SSL/TLS implementation for information about adding a new root CA certificate. For example, OpenSSL and GnuTLS are popular options. Use the implementation method to add trust to the RDS root CA certificate. Microsoft provides instructions for configuring certificates on some systems.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2608).

For sample scripts that import certificates, see Sample script for importing certificates into your trust store (p. 2620).

**Note**

When you update the trust store, you can retain older certificates in addition to adding the new certificates.
Upgrading the Microsoft SQL Server DB engine

When Amazon RDS supports a new version of a database engine, you can upgrade your DB instances to the new version. There are two kinds of upgrades for SQL Server DB instances: major version upgrades and minor version upgrades.

**Major version upgrades** can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your DB instances. You can initiate a major version upgrade by modifying your DB instance. However, before you perform a major version upgrade, we recommend that you test the upgrade by following the steps described in Testing an upgrade (p. 1433).

In contrast, **minor version upgrades** include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your DB instance. Alternatively, you can enable the **Auto minor version upgrade** option when creating or modifying a DB instance. Doing so means that your DB instance is automatically upgraded after Amazon RDS tests and approves the new version. You can confirm whether the minor version upgrade will be automatic by using the describe-db-engine-versions AWS CLI command. For example:

```
aws rds describe-db-engine-versions --engine sqlserver-se --engine-version 14.00.3281.6.v1
```

In the following example, the CLI command returns a response showing **AutoUpgrade** is **true**, indicating that upgrades are automatic.

```
... 
"ValidUpgradeTarget": [ 
    { 
        "Engine": "sqlserver-se",
        "EngineVersion": "14.00.3281.6.v1",
        "Description": "SQL Server 2017 14.00.3281.6.v1",
        "AutoUpgrade": true,
        "IsMajorVersionUpgrade": false
    } 
... 
```

For more information about performing upgrades, see **Upgrading a SQL Server DB instance** (p. 1434). For information about what SQL Server versions are available on Amazon RDS, see **Amazon RDS for Microsoft SQL Server** (p. 1370).

**Topics**

- Overview of upgrading (p. 1431)
- Major version upgrades (p. 1431)
- Multi-AZ and in-memory optimization considerations (p. 1433)
- Read replica considerations (p. 1433)
- Option group considerations (p. 1433)
- Parameter group considerations (p. 1433)
- Testing an upgrade (p. 1433)
- Upgrading a SQL Server DB instance (p. 1434)
- Upgrading deprecated DB instances before support ends (p. 1434)
Overview of upgrading

Amazon RDS takes two DB snapshots during the upgrade process. The first DB snapshot is of the DB instance before any upgrade changes have been made. The second DB snapshot is taken after the upgrade finishes.

**Note**
Amazon RDS only takes DB snapshots if you have set the backup retention period for your DB instance to a number greater than 0. To change your backup retention period, see [Modifying an Amazon RDS DB instance](p. 401).

After an upgrade is completed, you can't revert to the previous version of the database engine. If you want to return to the previous version, restore from the DB snapshot that was taken before the upgrade to create a new DB instance.

During a minor or major version upgrade of SQL Server, the **Free Storage Space** and **Disk Queue Depth** metrics will display -1. After the upgrade is completed, both metrics will return to normal.

Major version upgrades

Amazon RDS currently supports the following major version upgrades to a Microsoft SQL Server DB instance.

You can upgrade your existing DB instance to SQL Server 2017 or 2019 from any version except SQL Server 2008. To upgrade from SQL Server 2008, first upgrade to one of the other versions.

<table>
<thead>
<tr>
<th>Current version</th>
<th>Supported upgrade versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL Server 2017</td>
<td>SQL Server 2019</td>
</tr>
<tr>
<td>SQL Server 2016</td>
<td>SQL Server 2019</td>
</tr>
<tr>
<td></td>
<td>SQL Server 2017</td>
</tr>
<tr>
<td>SQL Server 2014</td>
<td>SQL Server 2019</td>
</tr>
<tr>
<td></td>
<td>SQL Server 2017</td>
</tr>
<tr>
<td></td>
<td>SQL Server 2016</td>
</tr>
<tr>
<td>SQL Server 2012 (end of support)</td>
<td>SQL Server 2019</td>
</tr>
<tr>
<td></td>
<td>SQL Server 2017</td>
</tr>
<tr>
<td></td>
<td>SQL Server 2016</td>
</tr>
<tr>
<td></td>
<td>SQL Server 2014</td>
</tr>
<tr>
<td>SQL Server 2008 R2 (end of support)</td>
<td>SQL Server 2016</td>
</tr>
<tr>
<td></td>
<td>SQL Server 2014</td>
</tr>
<tr>
<td></td>
<td>SQL Server 2012</td>
</tr>
</tbody>
</table>

You can use an AWS CLI query, such as the following example, to find the available upgrades for a particular database engine version.
Example

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions
  --engine sqlserver-se
  --engine-version 14.00.3281.6.v1
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}"
  --output table
```

For Windows:

```
aws rds describe-db-engine-versions
  --engine sqlserver-se
  --engine-version 14.00.3281.6.v1
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}"
  --output table
```

The output shows that you can upgrade version 14.00.3281.6 to the latest available SQL Server 2017 or 2019 versions.

```
| DescribeDBEngineVersions |
+--------------------------+
| EngineVersion            |
+--------------------------+
| 14.00.3294.2.v1          |
| 14.00.3356.20.v1         |
| 14.00.3381.3.v1          |
| 14.00.3401.7.v1          |
| 14.00.3421.10.v1         |
| 14.00.3451.2.v1          |
| 15.00.4043.16.v1         |
| 15.00.4073.23.v1         |
| 15.00.4153.1.v1          |
| 15.00.4198.2.v1          |
| 15.00.4236.7.v1          |
+--------------------------+
```

Database compatibility level

You can use Microsoft SQL Server database compatibility levels to adjust some database behaviors to mimic previous versions of SQL Server. For more information, see [Compatibility level](#) in the Microsoft documentation.

When you upgrade your DB instance, all existing databases remain at their original compatibility level. For example, if you upgrade from SQL Server 2014 to SQL Server 2016, all existing databases have a compatibility level of 120. Any new database created after the upgrade have compatibility level 130.

You can change the compatibility level of a database by using the ALTER DATABASE command. For example, to change a database named customeracct to be compatible with SQL Server 2014, issue the following command:

```
ALTER DATABASE customeracct SET COMPATIBILITY_LEVEL = 120
```
Multi-AZ and in-memory optimization considerations

Amazon RDS supports Multi-AZ deployments for DB instances running Microsoft SQL Server by using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server (p. 1466).

If your DB instance is in a Multi-AZ deployment, both the primary and standby instances are upgraded. Amazon RDS does rolling upgrades. You have an outage only for the duration of a failover.

Read replica considerations

During a database version upgrade, Amazon RDS upgrades all of your read replicas along with the primary DB instance. Amazon RDS does not support database version upgrades on the read replicas separately. For more information on read replicas, see Working with read replicas for Microsoft SQL Server in Amazon RDS (p. 1462).

When you perform a database version upgrade of the primary DB instance, all its read-replicas are also automatically upgraded. Amazon RDS will upgrade all of the read replicas simultaneously before upgrading the primary DB instance. Read replicas may not be available until the database version upgrade on the primary DB instance is complete.

Option group considerations

If your DB instance uses a custom DB option group, in some cases Amazon RDS can't automatically assign your DB instance a new option group. For example, when you upgrade to a new major version, you must specify a new option group. We recommend that you create a new option group, and add the same options to it as your existing custom option group.

For more information, see Creating an option group (p. 332) or Copying an option group (p. 334).

Parameter group considerations

If your DB instance uses a custom DB parameter group:

- Amazon RDS automatically reboots the DB instance after an upgrade.
- In some cases, RDS can't automatically assign a new parameter group to your DB instance.

For example, when you upgrade to a new major version, you must specify a new parameter group. We recommend that you create a new parameter group, and configure the parameters as in your existing custom parameter group.

For more information, see Creating a DB parameter group (p. 350) or Copying a DB parameter group (p. 356).

Testing an upgrade

Before you perform a major version upgrade on your DB instance, you should thoroughly test your database, and all applications that access the database, for compatibility with the new version. We recommend that you use the following procedure.

To test a major version upgrade

1. Review Upgrade SQL Server in the Microsoft documentation for the new version of the database engine to see if there are compatibility issues that might affect your database or applications.
2. If your DB instance uses a custom option group, create a new option group compatible with the new version you are upgrading to. For more information, see Option group considerations (p. 1433).
3. If your DB instance uses a custom parameter group, create a new parameter group compatible with the new version you are upgrading to. For more information, see Parameter group considerations (p. 1433).
4. Create a DB snapshot of the DB instance to be upgraded. For more information, see Creating a DB snapshot (p. 613).
5. Restore the DB snapshot to create a new test DB instance. For more information, see Restoring from a DB snapshot (p. 615).
6. Modify this new test DB instance to upgrade it to the new version, by using one of the following methods:
   • Console (p. 430)
   • AWS CLI (p. 430)
   • RDS API (p. 430)
7. Evaluate the storage used by the upgraded instance to determine if the upgrade requires additional storage.
8. Run as many of your quality assurance tests against the upgraded DB instance as needed to ensure that your database and application work correctly with the new version. Implement any new tests needed to evaluate the impact of any compatibility issues you identified in step 1. Test all stored procedures and functions. Direct test versions of your applications to the upgraded DB instance.
9. If all tests pass, then perform the upgrade on your production DB instance. We recommend that you do not allow write operations to the DB instance until you confirm that everything is working correctly.

**Upgrading a SQL Server DB instance**

For information about manually or automatically upgrading a SQL Server DB instance, see the following:

• Upgrading a DB instance engine version (p. 429)
• Best practices for upgrading SQL Server 2008 R2 to SQL Server 2016 on Amazon RDS for SQL Server

**Important**

If you have any snapshots that are encrypted using AWS KMS, we recommend that you initiate an upgrade before support ends.

**Upgrading deprecated DB instances before support ends**

After a major version is deprecated, you can't install it on new DB instances. RDS will try to automatically upgrade all existing DB instances.

If you need to restore a deprecated DB instance, you can do point-in-time recovery (PITR) or restore a snapshot. Doing this gives you temporary access a DB instance that uses the version that is being deprecated. However, after a major version is fully deprecated, these DB instances will also be automatically upgraded to a supported version.
Importing and exporting SQL Server databases using native backup and restore

Amazon RDS supports native backup and restore for Microsoft SQL Server databases using full backup files (.bak files). When you use RDS, you access files stored in Amazon S3 rather than using the local file system on the database server.

For example, you can create a full backup from your local server, store it on S3, and then restore it onto an existing Amazon RDS DB instance. You can also make backups from RDS, store them on S3, and then restore them wherever you want.

Native backup and restore is available in all AWS Regions for Single-AZ and Multi-AZ DB instances, including Multi-AZ DB instances with read replicas. Native backup and restore is available for all editions of Microsoft SQL Server supported on Amazon RDS.

The following diagram shows the supported scenarios.

Using native .bak files to back up and restore databases is usually the fastest way to back up and restore databases. There are many additional advantages to using native backup and restore. For example, you can do the following:

- Migrate databases to or from Amazon RDS.
- Move databases between RDS for SQL Server DB instances.
- Migrate data, schemas, stored procedures, triggers, and other database code inside .bak files.
- Backup and restore single databases, instead of entire DB instances.
- Create copies of databases for development, testing, training, and demonstrations.
- Store and transfer backup files with Amazon S3, for an added layer of protection for disaster recovery.
- Create native backups of databases that have Transparent Data Encryption (TDE) turned on, and restore those backups to on-premises databases. For more information, see Support for Transparent Data Encryption in SQL Server (p. 1544).
- Restore native backups of on-premises databases that have TDE turned on to RDS for SQL Server DB instances. For more information, see Support for Transparent Data Encryption in SQL Server (p. 1544).

Contents

- Limitations and recommendations (p. 1436)
- Setting up for native backup and restore (p. 1437)
Limitations and recommendations

The following are some limitations to using native backup and restore:

- You can't back up to, or restore from, an Amazon S3 bucket in a different AWS Region from your Amazon RDS DB instance.
- You can't restore a database with the same name as an existing database. Database names are unique.
- We strongly recommend that you don't restore backups from one time zone to a different time zone. If you restore backups from one time zone to a different time zone, you must audit your queries and applications for the effects of the time zone change.
- Amazon S3 has a size limit of 5 TB per file. For native backups of larger databases, you can use multifile backup.
• The maximum database size that can be backed up to S3 depends on the available memory, CPU, I/O, and network resources on the DB instance. The larger the database, the more memory the backup agent consumes. Our testing shows that you can make a compressed backup of a 16-TB database on our newest-generation instance types from 2xlarge instance sizes and larger, given sufficient system resources.

• You can't back up to or restore from more than 10 backup files at the same time.

• A differential backup is based on the last full backup. For differential backups to work, you can't take a snapshot between the last full backup and the differential backup. If you want a differential backup, but a manual or automated snapshot exists, then do another full backup before proceeding with the differential backup.

• Differential and log restores aren't supported for databases with files that have their file_guid (unique identifier) set to NULL.

• You can run up to two backup or restore tasks at the same time.

• You can't perform native log backups from SQL Server on Amazon RDS.

• RDS supports native restores of databases up to 16 TB. Native restores of databases on SQL Server Express Edition are limited to 10 GB.

• You can't do a native backup during the maintenance window, or any time Amazon RDS is in the process of taking a snapshot of the database. If a native backup task overlaps with the RDS daily backup window, the native backup task is canceled.

• On Multi-AZ DB instances, you can only natively restore databases that are backed up in the full recovery model.

• Restoring from differential backups on Multi-AZ instances isn't supported.

• Calling the RDS procedures for native backup and restore within a transaction isn't supported.

• Use a symmetric encryption AWS KMS key to encrypt your backups. Amazon RDS doesn't support asymmetric KMS keys. For more information, see Creating symmetric encryption KMS keys in the AWS Key Management Service Developer Guide.

• Native backup files are encrypted with the specified KMS key using the "Encryption-Only" crypto mode. When you are restoring encrypted backup files, be aware that they were encrypted with the "Encryption-Only" crypto mode.

• You can't restore a database that contains a FILESTREAM file group.

If your database can be offline while the backup file is created, copied, and restored, we recommend that you use native backup and restore to migrate it to RDS. If your on-premises database can't be offline, we recommend that you use the AWS Database Migration Service to migrate your database to Amazon RDS. For more information, see What is AWS Database Migration Service?

Native backup and restore isn't intended to replace the data recovery capabilities of the cross-region snapshot copy feature. We recommend that you use snapshot copy to copy your database snapshot to another AWS Region for cross-region disaster recovery in Amazon RDS. For more information, see Copying a DB snapshot (p. 619).

Setting up for native backup and restore

To set up for native backup and restore, you need three components:

1. An Amazon S3 bucket to store your backup files.

You must have an S3 bucket to use for your backup files and then upload backups you want to migrate to RDS. If you already have an Amazon S3 bucket, you can use that. If you don't, you can create a bucket. Alternatively, you can choose to have a new bucket created for you when you add the SQLSERVER_BACKUP_RESTORE option by using the AWS Management Console.

For information on using S3, see the Amazon Simple Storage Service User Guide.
2. An AWS Identity and Access Management (IAM) role to access the bucket.

   If you already have an IAM role, you can use that. You can choose to have a new IAM role created for you when you add the SQLSERVER_BACKUP_RESTORE option by using the AWS Management Console. Alternatively, you can create a new one manually.

   If you want to create a new IAM role manually, take the approach discussed in the next section. Do the same if you want to attach trust relationships and permissions policies to an existing IAM role.

3. The SQLSERVER_BACKUP_RESTORE option added to an option group on your DB instance.

   To enable native backup and restore on your DB instance, you add the SQLSERVER_BACKUP_RESTORE option to an option group on your DB instance. For more information and instructions, see Support for native backup and restore in SQL Server (p. 1541).

Manually creating an IAM role for native backup and restore

If you want to manually create a new IAM role to use with native backup and restore, you can do so. In this case, you create a role to delegate permissions from the Amazon RDS service to your Amazon S3 bucket. When you create an IAM role, you attach a trust relationship and a permissions policy. The trust relationship allows RDS to assume this role. The permissions policy defines the actions this role can perform. For more information about creating the role, see Creating a role to delegate permissions to an AWS service.

For the native backup and restore feature, use trust relationships and permissions policies similar to the examples in this section. In the following example, we use the service principal name rds.amazonaws.com as an alias for all service accounts. In the other examples, we specify an Amazon Resource Name (ARN) to identify another account, user, or role that we're granting access to in the trust policy.

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based trust relationships to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full ARN of the resources accessing the role. For native backup and restore, make sure to include both the DB option group and the DB instances, as shown in the following example.

Example trust relationship with global condition context key for native backup and restore

```json
{
"Version": "2012-10-17",
"Statement": [
  {
    "Effect": "Allow",
    "Principal": {
      "Service": "rds.amazonaws.com"
    },
    "Action": "sts:AssumeRole",
    "Condition": {
      "aws:SourceArn": "arn:aws:s3:example-bucket:123456789012",
      "aws:SourceAccount": "123456789012"
    }
  }
]}
```
The following example uses an ARN to specify a resource. For more information on using ARNs, see Amazon resource names (ARNs).

Example permissions policy for native backup and restore without encryption support

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:ListBucket",
                "s3:GetBucketLocation"
            ],
            "Resource": "arn:aws:s3:::bucket_name"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObjectAttributes",
                "s3:GetObject",
                "s3:PutObject",
                "s3:ListMultipartUploadParts",
                "s3:AbortMultipartUpload"
            ],
            "Resource": "arn:aws:s3:::bucket_name/*"
        }
    ]
}
```

Example permissions policy for native backup and restore with encryption support

If you want to encrypt your backup files, include an encryption key in your permissions policy. For more information about encryption keys, see Getting started in the AWS Key Management Service Developer Guide.

**Note**

You must use a symmetric encryption KMS key to encrypt your backups. Amazon RDS doesn't support asymmetric KMS keys. For more information, see Creating symmetric encryption KMS keys in the AWS Key Management Service Developer Guide.

The IAM role must also be a key user and key administrator for the KMS key, that is, it must be specified in the key policy. For more information, see Creating symmetric encryption KMS keys in the AWS Key Management Service Developer Guide.
{  
  "Effect": "Allow",
  "Action":
  [  
    "kms:DescribeKey",
    "kms:GenerateDataKey",
    "kms:Encrypt",
    "kms:Decrypt"
  ],
  "Resource": "arn:aws:kms:region:account-id:key/key-id"
},
{  
  "Effect": "Allow",
  "Action":
  [  
    "s3:ListBucket",
    "s3:GetBucketLocation"
  ],
  "Resource": "arn:aws:s3:::bucket_name"
},
{  
  "Effect": "Allow",
  "Action":
  [  
    "s3:GetObjectAttributes",
    "s3:GetObject",
    "s3:PutObject",
    "s3:ListMultipartUploadParts",
    "s3:AbortMultipartUpload"
  ],
  "Resource": "arn:aws:s3:::bucket_name/*"
}  
}
Using native backup and restore

After you have enabled and configured native backup and restore, you can start using it. First, you connect to your Microsoft SQL Server database, and then you call an Amazon RDS stored procedure to do the work. For instructions on connecting to your database, see Connecting to a DB instance running the Microsoft SQL Server database engine (p. 1396).

Some of the stored procedures require that you provide an Amazon Resource Name (ARN) to your Amazon S3 bucket and file. The format for your ARN is arn:aws:s3:::bucket_name/file_name.extension. Amazon S3 doesn't require an account number or AWS Region in ARNs.

If you also provide an optional KMS key, the format for the ARN of the key is arn:aws:kms:region:account-id:key/key-id. For more information, see Amazon resource names (ARNs) and AWS service namespaces. You must use a symmetric encryption KMS key to encrypt your backups. Amazon RDS doesn't support asymmetric KMS keys. For more information, see Creating symmetric encryption KMS keys in the AWS Key Management Service Developer Guide.

**Note**
Whether or not you use a KMS key, the native backup and restore tasks enable server-side Advanced Encryption Standard (AES) 256-bit encryption by default for files uploaded to S3.

For instructions on how to call each stored procedure, see the following topics:

- Backing up a database (p. 1441)
- Restoring a database (p. 1444)
- Restoring a log (p. 1446)
- Finishing a database restore (p. 1447)
- Working with partially restored databases (p. 1448)
- Canceling a task (p. 1448)
- Tracking the status of tasks (p. 1448)

**Backing up a database**

To back up your database, use the rds_backup_database stored procedure.

**Note**
You can't back up a database during the maintenance window, or while Amazon RDS is taking a snapshot.

**Usage**

```
exec msdb.dbo.rds_backup_database
@source_db_name='database_name',
@s3_arn_to_backup_to='arn:aws:s3:::bucket_name/file_name.extension',
[@kms_master_key_arn='arn:aws:kms:region:account-id:key/key-id'],
[@overwrite_s3_backup_file=0|1],
[@type='DIFFERENTIAL|FULL'],
[@number_of_files=n];
```

The following parameters are required:

- `@source_db_name` – The name of the database to back up.
- `@s3_arn_to_backup_to` – The ARN indicating the Amazon S3 bucket to use for the backup, plus the name of the backup file.
The file can have any extension, but .bak is usually used.

The following parameters are optional:

- `@kms_master_key_arn` – The ARN for the symmetric encryption KMS key to use to encrypt the item.
  - You can’t use the default encryption key. If you use the default key, the database won’t be backed up.
  - If you don’t specify a KMS key identifier, the backup file won’t be encrypted. For more information, see [Encrypting Amazon RDS resources](#).
  - When you specify a KMS key, client-side encryption is used.
  - Amazon RDS doesn’t support asymmetric KMS keys. For more information, see [Creating symmetric encryption KMS keys](#) in the [AWS Key Management Service Developer Guide](#).
- `@overwrite_s3_backup_file` – A value that indicates whether to overwrite an existing backup file.
  - `0` – Doesn’t overwrite an existing file. This value is the default.
  - Setting `@overwrite_s3_backup_file` to `0` returns an error if the file already exists.
  - `1` – Overwrites an existing file that has the specified name, even if it isn’t a backup file.
- `@type` – The type of backup.
  - `DIFFERENTIAL` – Makes a differential backup.
  - `FULL` – Makes a full backup. This value is the default.

A differential backup is based on the last full backup. For differential backups to work, you can’t take a snapshot between the last full backup and the differential backup. If you want a differential backup, but a snapshot exists, then do another full backup before proceeding with the differential backup.

You can look for the last full backup or snapshot using the following example SQL query:

```sql
select top 1
database_name , backup_start_date , backup_finish_date
from msdb.dbo.backupset
where database_name='mydatabase'
and type = 'D'
order by backup_start_date desc;
```

- `@number_of_files` – The number of files into which the backup will be divided (chunked). The maximum number is 10.
  - Multifile backup is supported for both full and differential backups.
  - If you enter a value of 1 or omit the parameter, a single backup file is created.

Provide the prefix that the files have in common, then suffix that with an asterisk (*). The asterisk can be anywhere in the `file_name` part of the S3 ARN. The asterisk is replaced by a series of alphanumeric strings in the generated files, starting with `1-of-number_of_files`.

For example, if the file names in the S3 ARN are `backup*.bak` and you set `@number_of_files=4`, the backup files generated are `backup1-of-4.bak`, `backup2-of-4.bak`, `backup3-of-4.bak`, and `backup4-of-4.bak`.

- If any of the file names already exists, and `@overwrite_s3_backup_file` is `0`, an error is returned.
- Multifile backups can only have one asterisk in the `file_name` part of the S3 ARN.
- Single-file backups can have any number of asterisks in the `file_name` part of the S3 ARN. Asterisks aren’t removed from the generated file name.
Examples

Example of differential backup

```
exec msdb.dbo.rds_backup_database
  @source_db_name='mydatabase',
  @s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup1.bak',
  @overwrite_s3_backup_file=1,
  @type='DIFFERENTIAL';
```

Example of full backup with encryption

```
exec msdb.dbo.rds_backup_database
  @source_db_name='mydatabase',
  @s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup1.bak',
  @kms_master_key_arn='arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE',
  @overwrite_s3_backup_file=1,
  @type='FULL';
```

Example of multifile backup

```
exec msdb.dbo.rds_backup_database
  @source_db_name='mydatabase',
  @s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
  @number_of_files=4;
```

Example of multifile differential backup

```
exec msdb.dbo.rds_backup_database
  @source_db_name='mydatabase',
  @s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
  @type='DIFFERENTIAL',
  @number_of_files=4;
```

Example of multifile backup with encryption

```
exec msdb.dbo.rds_backup_database
  @source_db_name='mydatabase',
  @s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
  @kms_master_key_arn='arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE',
  @number_of_files=4;
```

Example of multifile backup with S3 overwrite

```
exec msdb.dbo.rds_backup_database
  @source_db_name='mydatabase',
  @s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
  @overwrite_s3_backup_file=1,
  @number_of_files=4;
```

Example of single-file backup with the @number_of_files parameter

This example generates a backup file named backup*.bak.

```
exec msdb.dbo.rds_backup_database
```
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@number_of_files=1;

Restoring a database

To restore your database, call the rds_restore_database stored procedure. Amazon RDS creates an initial snapshot of the database after the restore task is complete and the database is open.

Usage

dba.rds_restore_database
@restore_db_name='database_name',
@s3_arn_to_restore_from='arn:aws:s3:::bucket_name/file_name.extension',
@with_norecovery=0|1,
[@kms_master_key_arn='arn:aws:kms:region:account-id:key/key-id'],
[@type='DIFFERENTIAL|FULL'];

The following parameters are required:

- **@restore_db_name** – The name of the database to restore. Database names are unique. You can't restore a database with the same name as an existing database.
- **@s3_arn_to_restore_from** – The ARN indicating the Amazon S3 prefix and names of the backup files used to restore the database.
  - For a single-file backup, provide the entire file name.
  - For a multifle backup, provide the prefix that the files have in common, then suffix that with an asterisk (*).
  - If @s3_arn_to_restore_from is empty, the following error message is returned: S3 ARN prefix cannot be empty.

The following parameter is required for differential restores, but optional for full restores:

- **@with_norecovery** – The recovery clause to use for the restore operation.
  - Set it to 0 to restore with RECOVERY. In this case, the database is online after the restore.
  - Set it to 1 to restore with NORECOVERY. In this case, the database remains in the RESTORING state after restore task completion. With this approach, you can do later differential restores.
  - For DIFFERENTIAL restores, specify 0 or 1.
  - For FULL restores, this value defaults to 0.

The following parameters are optional:

- **@kms_master_key_arn** – If you encrypted the backup file, the KMS key to use to decrypt the file.
  - When you specify a KMS key, client-side encryption is used.
- **@type** – The type of restore. Valid types are DIFFERENTIAL and FULL. The default value is FULL.

**Note**

For differential restores, either the database must be in the RESTORING state or a task must already exist that restores with NORECOVERY.
You can't restore later differential backups while the database is online.
You can't submit a restore task for a database that already has a pending restore task with RECOVERY.
Full restores with NORECOVERY and differential restores aren't supported on Multi-AZ instances.
Restoring a database on a Multi-AZ instance with read replicas is similar to restoring a database on a Multi-AZ instance. You don’t have to take any additional actions to restore a database on a replica.

Examples

Example of single-file restore

```sql
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak';
```

Example of multfile restore

To avoid errors when restoring multiple files, make sure that all the backup files have the same prefix, and that no other files use that prefix.

```sql
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup*';
```

Example of full database restore with RECOVERY

The following three examples perform the same task, full restore with RECOVERY.

```sql
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak';
```

```sql
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
[type='DIFFERENTIAL|FULL'];
```

```sql
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@type='FULL',
@with_norecovery=0;
```

Example of full database restore with encryption

```sql
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@kms_master_key_arn='arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE';
```

Example of full database restore with NORECOVERY

```sql
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@type='FULL',
@with_norecovery=1;
```
Example of differential restore with NORECOVERY

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@type='DIFFERENTIAL',
@with_norecovery=1;
```

Example of differential restore with RECOVERY

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@type='DIFFERENTIAL',
@with_norecovery=0;
```

Restoring a log

To restore your log, call the `rds_restore_log` stored procedure.

**Usage**

```
exec msdb.dbo.rds_restore_log
@restore_db_name='database_name',
@s3_arn_to_restore_from='arn:aws:s3:::bucket_name/log_file_name.extension',
[@kms_master_key_arn='arn:aws:kms:region:account-id:key/key-id'],
[@with_norecovery=0|1],
[@stopat='datetime'];
```

The following parameters are required:

- `@restore_db_name` – The name of the database whose log to restore.
- `@s3_arn_to_restore_from` – The ARN indicating the Amazon S3 prefix and name of the log file used to restore the log. The file can have any extension, but `.trn` is usually used.

If `@s3_arn_to_restore_from` is empty, the following error message is returned: S3 ARN prefix cannot be empty.

The following parameters are optional:

- `@kms_master_key_arn` – If you encrypted the log, the KMS key to use to decrypt the log.
- `@with_norecovery` – The recovery clause to use for the restore operation. This value defaults to 1.
  - Set it to 0 to restore with RECOVERY. In this case, the database is online after the restore. You can't restore further log backups while the database is online.
  - Set it to 1 to restore with NORECOVERY. In this case, the database remains in the RESTORING state after restore task completion. With this approach, you can do later log restores.
- `@stopat` – A value that specifies that the database is restored to its state at the date and time specified (in datetime format). Only transaction log records written before the specified date and time are applied to the database.

If this parameter isn't specified (it is NULL), the complete log is restored.

**Note**

For log restores, either the database must be in a state of restoring or a task must already exist that restores with NORECOVERY.
You can't restore log backups while the database is online.
You can't submit a log restore task on a database that already has a pending restore task with
RECOVERY.
Log restores aren't supported on Multi-AZ instances.

Examples

Example of log restore

exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn';

Example of log restore with encryption

exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn',
@kms_master_key_arn='arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE';

Example of log restore with NORECOVERY

The following two examples perform the same task, log restore with NORECOVERY.

exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn',
@with_norecovery=1;

exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn';

Example of log restore with RECOVERY

exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn',
@with_norecovery=0;

Example of log restore with STOPAT clause

exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn',
@with_norecovery=0,
@stopat='2019-12-01 03:57:09';

Finishing a database restore

If the last restore task on the database was performed using @with_norecovery=1, the
database is now in the RESTORING state. Open this database for normal operation by using the
rds_finish_restore stored procedure.
Usage

```sql
exec msdb.dbo.rds_finish_restore @db_name='database_name';
```

**Note**

To use this approach, the database must be in the RESTORING state without any pending restore tasks.
The `rds_finish_restore` procedure isn't supported on Multi-AZ instances.
To finish restoring the database, use the master login. Or use the user login that most recently restored the database or log with NORECOVERY.

**Working with partially restored databases**

**Dropping a partially restored database**

To drop a partially restored database (left in the RESTORING state), use the `rds_drop_database` stored procedure.

```sql
exec msdb.dbo.rds_drop_database @db_name='database_name';
```

**Note**

You can't submit a DROP database request for a database that already has a pending restore or finish restore task.
To drop the database, use the master login. Or use the user login that most recently restored the database or log with NORECOVERY.

**Snapshot restore and point-in-time recovery behavior for partially restored databases**

Partially restored databases in the source instance (left in the RESTORING state) are dropped from the target instance during snapshot restore and point-in-time recovery.

**Canceling a task**

To cancel a backup or restore task, call the `rds_cancel_task` stored procedure.

```sql
exec msdb.dbo.rds_cancel_task @task_id=ID_number;
```

**Note**

You can't cancel a FINISH_RESTORE task.

**Usage**

- `@task_id` – The ID of the task to cancel. You can get the task ID by calling `rds_task_status`.

**Tracking the status of tasks**

To track the status of your backup and restore tasks, call the `rds_task_status` stored procedure. If you don't provide any parameters, the stored procedure returns the status of all tasks. The status for tasks is updated approximately every two minutes. Task history is retained for 36 days.

**Usage**

```sql
exec msdb.dbo.rds_task_status
```
[@db_name='database_name'], [@task_id=ID_number];

The following parameters are optional:

- @db_name – The name of the database to show the task status for.
- @task_id – The ID of the task to show the task status for.

**Examples**

**Example of listing the status for a specific task**

exec msdb.dbo.rds_task_status @task_id=5;

**Example of listing the status for a specific database and task**

exec msdb.dbo.rds_task_status @db_name='my_database', @task_id=5;

**Example of listing all tasks and their statuses on a specific database**

exec msdb.dbo.rds_task_status @db_name='my_database';

**Example of listing all tasks and their statuses on the current instance**

exec msdb.dbo.rds_task_status;

**Response**

The `rds_task_status` stored procedure returns the following columns.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_id</td>
<td>The ID of the task.</td>
</tr>
<tr>
<td>task_type</td>
<td>Task type depending on the input parameters, as follows:</td>
</tr>
<tr>
<td></td>
<td>• For backup tasks:</td>
</tr>
<tr>
<td></td>
<td>• BACKUP_DB – Full database backup</td>
</tr>
<tr>
<td></td>
<td>• BACKUP_DB_DIFFERENTIAL – Differential database backup</td>
</tr>
<tr>
<td></td>
<td>• For restore tasks:</td>
</tr>
<tr>
<td></td>
<td>• RESTORE_DB – Full database restore with RECOVERY</td>
</tr>
<tr>
<td></td>
<td>• RESTORE_DB_NORECOVERY – Full database restore with NORECOVERY</td>
</tr>
<tr>
<td></td>
<td>• RESTORE_DB_DIFFERENTIAL – Differential database restore with RECOVERY</td>
</tr>
<tr>
<td></td>
<td>• RESTORE_DB_DIFFERENTIAL_NORECOVERY – Differential database restore with NORECOVERY</td>

<tr>
<td></td>
<td>Amazon RDS creates an initial snapshot of the database after it is open on completion of the following restore tasks:</td>
</tr>
</tbody>
</table>
|                    | • RESTORE_DB  
|                    | • RESTORE_DB_DIFFERENTIAL  
|                    | • RESTORE_DB_LOG  
|                    | • FINISH_RESTORE                                                                                                                                                                                            |
| database_name      | The name of the database that the task is associated with.                                                                                                                                                   |
| % complete         | The progress of the task as a percent value.                                                                                                                                                                 |
| duration (mins)    | The amount of time spent on the task, in minutes.                                                                                                                                                             |
| lifecycle          | The status of the task. The possible statuses are the following:                                                                                                                                             |
|                    | • CREATED – As soon as you call rds_backup_database or rds_restore_database, a task is created and the status is set to CREATED.                                                                            |
|                    | • IN_PROGRESS – After a backup or restore task starts, the status is set to IN_PROGRESS. It can take up to 5 minutes for the status to change from CREATED to IN_PROGRESS.                                      |
|                    | • SUCCESS – After a backup or restore task completes, the status is set to SUCCESS.                                                                                                                         |
|                    | • ERROR – If a backup or restore task fails, the status is set to ERROR. For more information about the error, see the task_info column.                                                                     |
|                    | • CANCEL_REQUESTED – As soon as you call rds_cancel_task, the status of the task is set to CANCEL_REQUESTED.                                                                                               |
|                    | • CANCELLED – After a task is successfully canceled, the status of the task is set to CANCELLED.                                                                                                           |
| task_info          | Additional information about the task.                                                                                                                                                                     |
|                    | If an error occurs while backing up or restoring a database, this column contains information about the error. For a list of possible errors, and mitigation strategies, see Troubleshooting (p. 1451).           |
| last_updated       | The date and time that the task status was last updated. The status is updated after every 5 percent of progress.                                                                                           |
| created_at         | The date and time that the task was created.                                                                                                                                                                |
| S3_object_arn      | The ARN indicating the Amazon S3 prefix and the name of the file that is being backed up or restored.                                                                                                        |
| overwrite_s3_backup_file | The value of the overwrite_s3_backup_file parameter specified when calling a backup task. For more information, see Backing up a database (p. 1441).              |
| KMS_master_key_arn  | The ARN for the KMS key used for encryption (for backup) and decryption (for restore).                                                                                                                      |
| filepath           | Not applicable to native backup and restore tasks.                                                                                                                                                           |
| overwrite_file     | Not applicable to native backup and restore tasks.                                                                                                                                                           |
Compressing backup files

To save space in your Amazon S3 bucket, you can compress your backup files. For more information about compressing backup files, see Backup compression in the Microsoft documentation.

Compressing your backup files is supported for the following database editions:

- Microsoft SQL Server Enterprise Edition
- Microsoft SQL Server Standard Edition

To turn on compression for your backup files, run the following code:

```
exec rdsadmin..rds_set_configuration 'S3 backup compression', 'true';
```

To turn off compression for your backup files, run the following code:

```
exec rdsadmin..rds_set_configuration 'S3 backup compression', 'false';
```

Troubleshooting

The following are issues you might encounter when you use native backup and restore.

<table>
<thead>
<tr>
<th>Issue</th>
<th>Troubleshooting suggestions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database backup/restore option is not enabled yet or is in the process of being enabled. Please try again later.</td>
<td>Make sure that you have added the SQLSERVER_BACKUP_RESTORE option to the DB option group associated with your DB instance. For more information, see Adding the native backup and restore option (p. 1541).</td>
</tr>
</tbody>
</table>
| Access Denied | The backup or restore process can't access the backup file. This is usually caused by issues like the following:  
  - Referencing the incorrect bucket. Referencing the bucket using an incorrect format. Referencing a file name without using the ARN.  
  - Incorrect permissions on the bucket file. For example, if it is created by a different account that is trying to access it now, add the correct permissions.  
  - An IAM policy that is incorrect or incomplete. Your IAM role must include all the necessary elements, including, for example, the correct version. These are highlighted in Importing and exporting SQL Server databases using native backup and restore (p. 1435). |
| BACKUP DATABASE WITH COMPRESSION isn't supported on <edition_name> Edition | Compressing your backup files is only supported for Microsoft SQL Server Enterprise Edition and Standard Edition.  
For more information, see Compressing backup files (p. 1451). |
| Key <ARN> does not exist | You attempted to restore an encrypted backup, but didn't provide a valid encryption key. Check your encryption key and retry.  
For more information, see Restoring a database (p. 1444). |
<table>
<thead>
<tr>
<th>Issue</th>
<th>Troubleshooting suggestions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Please reissue task with correct type and overwrite property</td>
<td>If you attempt to back up your database and provide the name of a file that already exists, but set the overwrite property to false, the save operation fails. To fix this error, either provide the name of a file that doesn't already exist, or set the overwrite property to true. For more information, see [Backing up a database](p. 1441). It's also possible that you intended to restore your database, but called the <code>rds_backup_database</code> stored procedure accidentally. In that case, call the <code>rds_restore_database</code> stored procedure instead. For more information, see [Restoring a database](p. 1444). If you intended to restore your database and called the <code>rds_restore_database</code> stored procedure, make sure that you provided the name of a valid backup file. For more information, see [Using native backup and restore](p. 1441).</td>
</tr>
<tr>
<td>Please specify a bucket that is in the same region as RDS instance</td>
<td>You can't back up to, or restore from, an Amazon S3 bucket in a different AWS Region from your Amazon RDS DB instance. You can use Amazon S3 replication to copy the backup file to the correct AWS Region. For more information, see [Cross-Region replication](p. 1441) in the Amazon S3 documentation.</td>
</tr>
<tr>
<td>The specified bucket does not exist</td>
<td>Verify that you have provided the correct ARN for your bucket and file, in the correct format. For more information, see [Using native backup and restore](p. 1441).</td>
</tr>
<tr>
<td>User &lt;ARN&gt; is not authorized to perform &lt;kms action&gt; on resource &lt;ARN&gt;</td>
<td>You requested an encrypted operation, but didn't provide correct AWS KMS permissions. Verify that you have the correct permissions, or add them. For more information, see [Setting up for native backup and restore](p. 1437).</td>
</tr>
<tr>
<td>The Restore task is unable to restore from more than 10 backup file(s). Please reduce the number of files matched and try again.</td>
<td>Reduce the number of files that you're trying to restore from. You can make each individual file larger if necessary.</td>
</tr>
<tr>
<td>Database 'database_name' already exists. Two databases that differ only by case or accent are not allowed. Choose a different database name.</td>
<td>You can't restore a database with the same name as an existing database. Database names are unique.</td>
</tr>
</tbody>
</table>
Importing and exporting SQL Server data using other methods

Following, you can find information about using snapshots to import your Microsoft SQL Server data to Amazon RDS. You can also find information about using snapshots to export your data from an RDS DB instance running SQL Server.

If your scenario supports it, it's easier to move data in and out of Amazon RDS by using the native backup and restore functionality. For more information, see Importing and exporting SQL Server databases using native backup and restore (p. 1435).

Note
Amazon RDS for Microsoft SQL Server doesn't support importing data into the msdb database.

Importing data into RDS for SQL Server by using a snapshot

To import data into a SQL Server DB instance by using a snapshot

1. Create a DB instance. For more information, see Creating an Amazon RDS DB instance (p. 300).
2. Stop applications from accessing the destination DB instance.
   - If you prevent access to your DB instance while you are importing data, data transfer is faster. Additionally, you don't need to worry about conflicts while data is being loaded if other applications cannot write to the DB instance at the same time. If something goes wrong and you have to roll back to an earlier database snapshot, the only changes that you lose are the imported data. You can import this data again after you resolve the issue.
   - For information about controlling access to your DB instance, see Controlling access with security groups (p. 2697).
3. Create a snapshot of the target database.
   - If the target database is already populated with data, we recommend that you take a snapshot of the database before you import the data. If something goes wrong with the data import or you want to discard the changes, you can restore the database to its previous state by using the snapshot. For information about database snapshots, see Creating a DB snapshot (p. 613).
   - Note
     When you take a database snapshot, I/O operations to the database are suspended for a moment (milliseconds) while the backup is in progress.
4. Disable automated backups on the target database.
   - Disabling automated backups on the target DB instance improves performance while you are importing your data because Amazon RDS doesn't log transactions when automatic backups are disabled. However, there are some things to consider. Automated backups are required to perform a point-in-time recovery. Thus, you can't restore the database to a specific point in time while you are importing data. Additionally, any automated backups that were created on the DB instance are erased unless you choose to retain them.
   - Choosing to retain the automated backups can help protect you against accidental deletion of data. Amazon RDS also saves the database instance properties along with each automated backup to make it easy to recover. Using this option lets you can restore a deleted database instance to a specified point in time within the backup retention period even after deleting it. Automated backups are automatically deleted at the end of the specified backup window, just as they are for an active database instance.
   - You can also use previous snapshots to recover the database, and any snapshots that you have taken remain available. For information about automated backups, see Working with backups (p. 591).
5. Disable foreign key constraints, if applicable.

If you need to disable foreign key constraints, you can do so with the following script.

```sql
--Disable foreign keys on all tables
DECLARE @table_name SYSNAME;
DECLARE @cmd NVARCHAR(MAX);
DECLARE table_cursor CURSOR FOR SELECT name FROM sys.tables;
OPEN table_cursor;
FETCH NEXT FROM table_cursor INTO @table_name;
WHILE @@FETCH_STATUS = 0 BEGIN
  SELECT @cmd = 'ALTER TABLE ' + QUOTENAME(@table_name) + ' NOCHECK CONSTRAINT ALL';
  EXEC (@cmd);
  FETCH NEXT FROM table_cursor INTO @table_name;
END
CLOSE table_cursor;
DEALLOCATE table_cursor;
GO
```

6. Drop indexes, if applicable.

7. Disable triggers, if applicable.

If you need to disable triggers, you can do so with the following script.

```sql
--Disable triggers on all tables
DECLARE @enable BIT = 0;
DECLARE @trigger SYSNAME;
DECLARE @table SYSNAME;
DECLARE @cmd NVARCHAR(MAX);
DECLARE trigger_cursor CURSOR FOR SELECT trigger_object.name trigger_name,
      table_object.name table_name
  FROM sysobjects trigger_object
  JOIN sysobjects table_object ON trigger_object.parent_obj = table_object.id
  WHERE trigger_object.type = 'TR';
OPEN trigger_cursor;
FETCH NEXT FROM trigger_cursor INTO @trigger, @table;
WHILE @@FETCH_STATUS = 0 BEGIN
  IF @enable = 1
    SET @cmd = 'ENABLE ';
  ELSE
    SET @cmd = 'DISABLE ';
  SET @cmd = @cmd + ' TRIGGER dbo.' + QUOTENAME(@trigger) + ' ON dbo.' + QUOTENAME(@table) + ' ';
  EXEC (@cmd);
  FETCH NEXT FROM trigger_cursor INTO @trigger, @table;
END
CLOSE trigger_cursor;
DEALLOCATE trigger_cursor;
GO
```

8. Query the source SQL Server instance for any logins that you want to import to the destination DB instance.
SQL Server stores logins and passwords in the `master` database. Because Amazon RDS doesn’t grant access to the `master` database, you cannot directly import logins and passwords into your destination DB instance. Instead, you must query the `master` database on the source SQL Server instance to generate a data definition language (DDL) file. This file should include all logins and passwords that you want to add to the destination DB instance. This file also should include role memberships and permissions that you want to transfer.

For information about querying the `master` database, see How to transfer the logins and the passwords between instances of SQL Server 2005 and SQL Server 2008 in the Microsoft Knowledge Base.

The output of the script is another script that you can run on the destination DB instance. The script in the Knowledge Base article has the following code:

```sql
p.type IN
```

Every place `p.type` appears, use the following code instead:

```sql
p.type = 'S'
```

9. Import the data using the method in Import the data (p. 1456).

10. Grant applications access to the target DB instance.

   When your data import is complete, you can grant access to the DB instance to those applications that you blocked during the import. For information about controlling access to your DB instance, see Controlling access with security groups (p. 2697).

11. Enable automated backups on the target DB instance.

   For information about automated backups, see Working with backups (p. 591).

12. Enable foreign key constraints.

    If you disabled foreign key constraints earlier, you can now enable them with the following script.

```
--Enable foreign keys on all tables
DECLARE @table_name SYSNAME;
DECLARE @cmd NVARCHAR(MAX);
DECLARE table_cursor CURSOR FOR SELECT name FROM sys.tables;
OPEN table_cursor;
FETCH NEXT FROM table_cursor INTO @table_name;
WHILE @@FETCH_STATUS = 0 BEGIN
    SELECT @cmd = 'ALTER TABLE '+QUOTENAME(@table_name)+' CHECK CONSTRAINT ALL';
    EXEC (@cmd);
    FETCH NEXT FROM table_cursor INTO @table_name;
END
CLOSE table_cursor;
DEALLOCATE table_cursor;
```

13. Enable indexes, if applicable.

14. Enable triggers, if applicable.

    If you disabled triggers earlier, you can now enable them with the following script.

```
--Enable triggers on all tables
DECLARE @enable BIT = 1;
```
DECLARE @trigger SYSNAME;
DECLARE @table SYSNAME;
DECLARE @cmd NVARCHAR(MAX);
DECLARE trigger_cursor CURSOR FOR SELECT trigger_object.name trigger_name,
table_object.name table_name
FROM sysobjects trigger_object
JOIN sysobjects table_object ON trigger_object.parent_obj = table_object.id
WHERE trigger_object.type = 'TR';

OPEN trigger_cursor;
FETCH NEXT FROM trigger_cursor INTO @trigger, @table;

WHILE @@FETCH_STATUS = 0 BEGIN
  IF @enable = 1
  BEGIN
    SET @cmd = 'ENABLE ';
  ELSE
    SET @cmd = 'DISABLE ';
  END
  SET @cmd = @cmd + ' TRIGGER dbo.'+QUOTENAME(@trigger)+' ON
dbo.'+QUOTENAME(@table)+' '; EXEC (@cmd);
  FETCH NEXT FROM trigger_cursor INTO @trigger, @table;
END

CLOSE trigger_cursor;
DEALLOCATE trigger_cursor;

Import the data

Microsoft SQL Server Management Studio is a graphical SQL Server client that is included in all Microsoft SQL Server editions except the Express Edition. SQL Server Management Studio Express is available from Microsoft as a free download. To find this download, see the Microsoft website.

Note
SQL Server Management Studio is available only as a Windows-based application.

SQL Server Management Studio includes the following tools, which are useful in importing data to a SQL Server DB instance:

- Generate and Publish Scripts Wizard
- Import and Export Wizard
- Bulk copy

Generate and Publish Scripts Wizard

The Generate and Publish Scripts Wizard creates a script that contains the schema of a database, the data itself, or both. You can generate a script for a database in your local SQL Server deployment. You can then run the script to transfer the information that it contains to an Amazon RDS DB instance.

Note
For databases of 1 GiB or larger, it's more efficient to script only the database schema. You then use the Import and Export Wizard or the bulk copy feature of SQL Server to transfer the data.

For detailed information about the Generate and Publish Scripts Wizard, see the Microsoft SQL Server documentation.

In the wizard, pay particular attention to the advanced options on the Set Scripting Options page to ensure that everything you want your script to include is selected. For example, by default, database triggers are not included in the script.
When the script is generated and saved, you can use SQL Server Management Studio to connect to your DB instance and then run the script.

Import and Export Wizard

The Import and Export Wizard creates a special Integration Services package, which you can use to copy data from your local SQL Server database to the destination DB instance. The wizard can filter which tables and even which tuples within a table are copied to the destination DB instance.

Note
The Import and Export Wizard works well for large datasets, but it might not be the fastest way to remotely export data from your local deployment. For an even faster way, consider the SQL Server bulk copy feature.

For detailed information about the Import and Export Wizard, see the Microsoft SQL Server documentation.

In the wizard, on the Choose a Destination page, do the following:

- For Server Name, type the name of the endpoint for your DB instance.
- For the server authentication mode, choose Use SQL Server Authentication.
- For User name and Password, type the credentials for the master user that you created for the DB instance.

Bulk copy

The SQL Server bulk copy feature is an efficient means of copying data from a source database to your DB instance. Bulk copy writes the data that you specify to a data file, such as an ASCII file. You can then run bulk copy again to write the contents of the file to the destination DB instance.

This section uses the `bcp` utility, which is included with all editions of SQL Server. For detailed information about bulk import and export operations, see the Microsoft SQL Server documentation.

Note
Before you use bulk copy, you must first import your database schema to the destination DB instance. The Generate and Publish Scripts Wizard, described earlier in this topic, is an excellent tool for this purpose.

The following command connects to the local SQL Server instance. It generates a tab-delimited file of a specified table in the C: root directory of your existing SQL Server deployment. The table is specified by its fully qualified name, and the text file has the same name as the table that is being copied.

```
bcp dbname.schema_name.table_name out C:\table_name.txt -n -S localhost -U username -P password -b 10000
```

The preceding code includes the following options:

- `-n` specifies that the bulk copy uses the native data types of the data to be copied.
- `-S` specifies the SQL Server instance that the `bcp` utility connects to.
- `-U` specifies the user name of the account to log in to the SQL Server instance.
- `-P` specifies the password for the user specified by `-U`.
- `-b` specifies the number of rows per batch of imported data.

Note
There might be other parameters that are important to your import situation. For example, you might need the `-E` parameter that pertains to identity values. For more information; see
the full description of the command line syntax for the bcp utility in the Microsoft SQL Server documentation.

For example, suppose that a database named store that uses the default schema, dbo, contains a table named customers. The user account admin, with the password insecure, copies 10,000 rows of the customers table to a file named customers.txt.

```
bcp store.dbo.customers out C:\customers.txt -n -S localhost -U admin -P insecure -b 10000
```

After you generate the data file, you can upload the data to your DB instance by using a similar command. Beforehand, create the database and schema on the target DB instance. Then use the in argument to specify an input file instead of out to specify an output file. Instead of using localhost to specify the local SQL Server instance, specify the endpoint of your DB instance. If you use a port other than 1433, specify that too. The user name and password are the master user and password for your DB instance. The syntax is as follows.

```
bcp dbname.schema_name.table_name in C:\table_name.txt -n -S endpoint,port -U master_user_name -P master_user_password -b 10000
```

To continue the previous example, suppose that the master user name is admin, and the password is insecure. The endpoint for the DB instance is rds.ckz2kqd4qsn1.us-east-1.rds.amazonaws.com, and you use port 4080. The command is as follows.

```
bcp store.dbo.customers in C:\customers.txt -n -S rds.ckz2kqd4qsn1.us-east-1.rds.amazonaws.com,4080 -U admin -P insecure -b 10000
```

Note
Specify a password other than the prompt shown here as a security best practice.

### Exporting data from RDS for SQL Server

You can choose one of the following options to export data from an RDS for SQL Server DB instance:

- **Native database backup using a full backup file (.bak)** – Using .bak files to backup databases is heavily optimized, and is usually the fastest way to export data. For more information, see Importing and exporting SQL Server databases using native backup and restore (p. 1435).

- **SQL Server Import and Export Wizard** – For more information, see SQL Server Import and Export Wizard (p. 1458).

- **SQL Server Generate and Publish Scripts Wizard and bcp utility** – For more information, see SQL Server Generate and Publish Scripts Wizard and bcp utility (p. 1460).

### SQL Server Import and Export Wizard

You can use the SQL Server Import and Export Wizard to copy one or more tables, views, or queries from your RDS for SQL Server DB instance to another data store. This choice is best if the target data store is not SQL Server. For more information, see SQL Server Import and Export Wizard in the SQL Server documentation.

The SQL Server Import and Export Wizard is available as part of Microsoft SQL Server Management Studio. This graphical SQL Server client is included in all Microsoft SQL Server editions except the Express Edition. SQL Server Management Studio is available only as a Windows-based application. SQL Server Management Studio Express is available from Microsoft as a free download. To find this download, see the Microsoft website.
To use the SQL Server Import and Export Wizard to export data

1. In SQL Server Management Studio, connect to your RDS for SQL Server DB instance. For details on how to do this, see Connecting to a DB instance running the Microsoft SQL Server database engine (p. 1396).

2. In Object Explorer, expand Databases, open the context (right-click) menu for the source database, choose Tasks, and then choose Export Data. The wizard appears.

3. On the Choose a Data Source page, do the following:

   a. For Data source, choose SQL Server Native Client 11.0.
   b. Verify that the Server name box shows the endpoint of your RDS for SQL Server DB instance.
   c. Select Use SQL Server Authentication. For User name and Password, type the master user name and password of your DB instance.
   d. Verify that the Database box shows the database from which you want to export data.
   e. Choose Next.

4. On the Choose a Destination page, do the following:

   a. For Destination, choose SQL Server Native Client 11.0.
      
      Note
      Other target data sources are available. These include .NET Framework data providers, OLE DB providers, SQL Server Native Client providers, ADO.NET providers, Microsoft Office Excel, Microsoft Office Access, and the Flat File source. If you choose to target one of these data sources, skip the remainder of step 4. For details on the connection information to provide next, see Choose a destination in the SQL Server documentation.

   b. For Server name, type the server name of the target SQL Server DB instance.
   c. Choose the appropriate authentication type. Type a user name and password if necessary.
   d. For Database, choose the name of the target database, or choose New to create a new database to contain the exported data.

      If you choose New, see Create database in the SQL Server documentation for details on the database information to provide.

   e. Choose Next.

5. On the Table Copy or Query page, choose Copy data from one or more tables or views or Write a query to specify the data to transfer. Choose Next.

6. If you choose Write a query to specify the data to transfer, you see the Provide a Source Query page. Type or paste in a SQL query, and then choose Parse to verify it. Once the query validates, choose Next.

7. On the Select Source Tables and Views page, do the following:

   a. Select the tables and views that you want to export, or verify that the query you provided is selected.
   b. Choose Edit Mappings and specify database and column mapping information. For more information, see Column mappings in the SQL Server documentation.
   c. (Optional) To see a preview of data to be exported, select the table, view, or query, and then choose Preview.

   d. Choose Next.

8. On the Run Package page, verify that Run immediately is selected. Choose Next.

9. On the Complete the Wizard page, verify that the data export details are as you expect. Choose Finish.

10. On the The execution was successful page, choose Close.
SQL Server Generate and Publish Scripts Wizard and bcp utility

You can use the SQL Server Generate and Publish Scripts Wizard to create scripts for an entire database or just selected objects. You can run these scripts on a target SQL Server DB instance to recreate the scripted objects. You can then use the bcp utility to bulk export the data for the selected objects to the target DB instance. This choice is best if you want to move a whole database (including objects other than tables) or large quantities of data between two SQL Server DB instances. For a full description of the bcp command-line syntax, see bcp utility in the Microsoft SQL Server documentation.

The SQL Server Generate and Publish Scripts Wizard is available as part of Microsoft SQL Server Management Studio. This graphical SQL Server client is included in all Microsoft SQL Server editions except the Express Edition. SQL Server Management Studio is available only as a Windows-based application. SQL Server Management Studio Express is available from Microsoft as a free download.

To use the SQL Server Generate and Publish Scripts Wizard and the bcp utility to export data

1. In SQL Server Management Studio, connect to your RDS for SQL Server DB instance. For details on how to do this, see Connecting to a DB instance running the Microsoft SQL Server database engine (p. 1396).
2. In Object Explorer, expand the Databases node and select the database you want to script.
3. Follow the instructions in Generate and publish scripts Wizard in the SQL Server documentation to create a script file.
4. In SQL Server Management Studio, connect to your target SQL Server DB instance.
5. With the target SQL Server DB instance selected in Object Explorer, choose Open on the File menu, choose File, and then open the script file.
6. If you have scripted the entire database, review the CREATE DATABASE statement in the script. Make sure that the database is being created in the location and with the parameters that you want. For more information, see CREATE DATABASE in the SQL Server documentation.
7. If you are creating database users in the script, check to see if server logins exist on the target DB instance for those users. If not, create logins for those users; the scripted commands to create the database users fail otherwise. For more information, see Create a login in the SQL Server documentation.
8. Choose Execute on the SQL Editor menu to run the script file and create the database objects. When the script finishes, verify that all database objects exist as expected.
9. Use the bcp utility to export data from the RDS for SQL Server DB instance into files. Open a command prompt and type the following command.

```
bcp database_name.schema_name.table_name out data_file -n -S aws_rds_sql_endpoint -U username -P password
```

The preceding code includes the following options:

- `table_name` is the name of one of the tables that you've recreated in the target database and now want to populate with data.
- `data_file` is the full path and name of the data file to be created.
- `-n` specifies that the bulk copy uses the native data types of the data to be copied.
- `-S` specifies the SQL Server DB instance to export from.
- `-U` specifies the user name to use when connecting to the SQL Server DB instance.
- `-P` specifies the password for the user specified by `-U`.

The following shows an example command.
Repeat this step until you have data files for all of the tables you want to export.

10. Prepare your target DB instance for bulk import of data by following the instructions at Basic guidelines for bulk importing data in the SQL Server documentation.

11. Decide on a bulk import method to use after considering performance and other concerns discussed in About bulk import and bulk export operations in the SQL Server documentation.

12. Bulk import the data from the data files that you created using the bcp utility. To do so, follow the instructions at either Import and export bulk data by using the bcp utility or Import bulk data by using BULK INSERT or OPENROWSET(BULK...) in the SQL Server documentation, depending on what you decided in step 11.
Working with read replicas for Microsoft SQL Server in Amazon RDS

You usually use read replicas to configure replication between Amazon RDS DB instances. For general information about read replicas, see Working with DB instance read replicas (p. 438).

In this section, you can find specific information about working with read replicas on Amazon RDS for SQL Server.

Topics
- Configuring read replicas for SQL Server (p. 1462)
- Read replica limitations with SQL Server (p. 1462)
- Option considerations for RDS for SQL Server replicas (p. 1463)
- Synchronizing database users and objects with a SQL Server read replica (p. 1464)
- Troubleshooting a SQL Server read replica problem (p. 1465)

Configuring read replicas for SQL Server

Before a DB instance can serve as a source instance for replication, you must enable automatic backups on the source DB instance. To do so, you set the backup retention period to a value other than 0. The source DB instance must be a Multi-AZ deployment with Always On Availability Groups (AGs). Setting this type of deployment also enforces that automatic backups are enabled.

Creating a SQL Server read replica doesn't require an outage for the primary DB instance. Amazon RDS sets the necessary parameters and permissions for the source DB instance and the read replica without any service interruption. A snapshot is taken of the source DB instance, and this snapshot becomes the read replica. No outage occurs when you delete a read replica.

You can create up to 15 read replicas from one source DB instance. For replication to operate effectively, we recommend that you configure each read replica with the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, also scale the read replicas.

The SQL Server DB engine version of the source DB instance and all of its read replicas must be the same. Amazon RDS upgrades the primary immediately after upgrading the read replicas, regardless of the maintenance window. For more information about upgrading the DB engine version, see Upgrading the Microsoft SQL Server DB engine (p. 1430).

For a read replica to receive and apply changes from the source, it should have sufficient compute and storage resources. If a read replica reaches compute, network, or storage resource capacity, the read replica stops receiving or applying changes from its source. You can modify the storage and CPU resources of a read replica independently from its source and other read replicas.

Read replica limitations with SQL Server

The following limitations apply to SQL Server read replicas on Amazon RDS:

- Read replicas are only available on the SQL Server Enterprise Edition (EE) engine.
- Read replicas are available for SQL Server versions 2016–2019.
- The source DB instance to be replicated must be a Multi-AZ deployment with Always On AGs.
- You can create up to 15 read replicas from one source DB instance.
- Read replicas are only available for DB instances running on DB instance classes with four or more vCPUs.
Option considerations

The following aren't supported on Amazon RDS for SQL Server:

- Backup retention of read replicas
- Point-in-time recovery from read replicas
- Manual snapshots of read replicas
- Multi-AZ read replicas
- Creating read replicas of read replicas
- Synchronization of user logins to read replicas

Amazon RDS for SQL Server doesn't intervene to mitigate high replica lag between a source DB instance and its read replicas. Make sure that the source DB instance and its read replicas are sized properly, in terms of computing power and storage, to suit their operational load.

Option considerations for RDS for SQL Server replicas

Before you create an RDS for SQL Server replica, consider the following requirements, restrictions, and recommendations:

- If your SQL Server replica is in the same Region as its source DB instance, make sure that it belongs to the same option group as the source DB instance. Modifications to the source option group or source option group membership propagate to replicas. These changes are applied to the replicas immediately after they are applied to the source DB instance, regardless of the replica's maintenance window.

For more information about option groups, see Working with option groups (p. 331).

- When you create a SQL Server cross-Region replica, Amazon RDS creates a dedicated option group for it.

You can't remove an SQL Server cross-Region replica from its dedicated option group. No other DB instances can use the dedicated option group for a SQL Server cross-Region replica.

The following options are replicated options. To add replicated options to a SQL Server cross-Region replica, add it to the source DB instance's option group. The option is also installed on all of the source DB instance's replicas.

- TDE

The following options are non-replicated options. You can add or remove non-replicated options from a dedicated option group.

- MSDTC
- SQLSERVER_AUDIT

To enable the SQLSERVER_AUDIT option on cross-Region read replica, add the SQLSERVER_AUDIT option on the dedicated option group on the cross-Region read replica and the source instance's option group. By adding the SQLSERVER_AUDIT option on the source instance of SQL Server cross-Region read replica, you can create Server Level Audit Object and Server Level Audit Specifications on each of the cross-Region read replicas of the source instance. To allow the cross-Region read replicas access to upload the completed audit logs to an Amazon S3 bucket, add the SQLSERVER_AUDIT option to the dedicated option group and configure the option settings. The Amazon S3 bucket that you use as a target for audit files must be in the same Region as the cross-Region read replica. You can modify the option setting of the SQLSERVER_AUDIT option for each cross region read replica independently so each can access an Amazon S3 bucket in their respective Region.

The following options are not supported for cross-Region read replicas.

- SSRS
- SSAS
The following options are partially supported for cross-Region read replicas.

- SSIS

The source DB instance of a SQL Server cross-Region replica can have the SQLSERVER_BACKUP_RESTORE option, but you can not perform native restores on the source DB instance until you delete all its cross-Region replicas. Any existing native restore tasks will be cancelled during the creation of a cross-Region replica. You can't add the SQLSERVER_BACKUP_RESTORE option to a dedicated option group.

For more information on native backup and restore, see Importing and exporting SQL Server databases using native backup and restore (p. 1435).

When you promote a SQL Server cross-Region read replica, the promoted replica behaves the same as other SQL Server DB instances, including the management of its options. For more information about option groups, see Working with option groups (p. 331).

**Synchronizing database users and objects with a SQL Server read replica**

Any logins, custom server roles, SQL agent jobs, or other server-level objects that exist in the primary DB instance at the time of creating a read replica are expected to be present in the newly created read replica. However, any server-level objects that are created in the primary DB instance after the creation of the read replica will not be automatically replicated, and you must create them manually in the read replica.

The database users are automatically replicated from the primary DB instance to the read replica. As the read replica database is in read-only mode, the security identifier (SID) of the database user cannot be updated in the database. Therefore, when creating SQL logins in the read replica, it's essential to ensure that the SID of the login matches the SID of the corresponding SQL login in the primary DB instance. If you don't synchronize the SIDs of the SQL logins, they won't be able to access the database in the read replica. Windows Active Directory (AD) Authenticated Logins do not experience this issue because the SQL Server obtains the SID from the Active Directory.

To synchronize a SQL login from the primary DB instance to the read replica

1. Connect to the primary DB instance.
2. Create a new SQL login in the primary DB instance.

   ```sql
   USE [master]
   GO
   CREATE LOGIN TestLogin1
   WITH PASSWORD = 'REPLACE WITH PASSWORD';
   ```

   **Note**
   Specify a password other than the prompt shown here as a security best practice.

3. Create a new database user for the SQL login in the database.

   ```sql
   USE [REPLACE WITH YOUR DB NAME]
   GO
   CREATE USER TestLogin1 FOR LOGIN TestLogin1;
   GO
   ```

4. Check the SID of the newly created SQL login in primary DB instance.
SELECT name, sid FROM sys.server_principals WHERE name = 'TestLogin1;

5. Connect to the read replica. Create the new SQL login.

CREATE LOGIN TestLogin1 WITH PASSWORD = 'REPLACE WITH PASSWORD', SID=[REPLACE WITH sid FROM STEP #4];

Alternately, if you have access to the read replica database, you can fix the orphaned user as follows:

1. Connect to the read replica.
2. Identify the orphaned users in the database.

USE [REPLACE WITH YOUR DB NAME]
GO
EXEC sp_change_users_login 'Report';
GO

3. Create a new SQL login for the orphaned database user.

CREATE LOGIN TestLogin1 WITH PASSWORD = 'REPLACE WITH PASSWORD', SID=[REPLACE WITH sid FROM STEP #2];

Example:

CREATE LOGIN TestLogin1 WITH PASSWORD = 'TestPa$$word#1',
SID=[0x1A2B3C4D5E6F7G8H9I0J1K2L3M4N5O6P];

Note
Specify a password other than the prompt shown here as a security best practice.

Troubleshooting a SQL Server read replica problem

You can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS ReplicaLag metric. For information about replication lag time, see Monitoring read replication (p. 449).

If replication lag is too long, you can use the following query to get information about the lag.

SELECT AR.replica_server_name,
       DB_NAME (ARS.database_id) 'database_name'
    , AR.availability_mode_desc
    , AR.synchronization_health_desc
    , ARS.last_hardened_lsn
    , ARS.last_redone_lsn
    , ARS.secondary_lag_seconds
FROM sys.dm_hadr_database_replica_states ARS
INNER JOIN sys.availability_replicas AR ON ARS.replica_id = AR.replica_id
--WHERE DB_NAME(ARS.database_id) = 'database_name'
ORDER BY AR.replica_server_name;
Multi-AZ deployments for Amazon RDS for Microsoft SQL Server

Multi-AZ deployments provide increased availability, data durability, and fault tolerance for DB instances. In the event of planned database maintenance or unplanned service disruption, Amazon RDS automatically fails over to the up-to-date secondary DB instance. This functionality lets database operations resume quickly without manual intervention. The primary and standby instances use the same endpoint, whose physical network address transitions to the secondary replica as part of the failover process. You don’t have to reconfigure your application when a failover occurs.

Amazon RDS supports Multi-AZ deployments for Microsoft SQL Server by using either SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). Amazon RDS monitors and maintains the health of your Multi-AZ deployment. If problems occur, RDS automatically repairs unhealthy DB instances, reestablishes synchronization, and initiates failovers. Failover only occurs if the standby and primary are fully in sync. You don’t have to manage anything.

When you set up SQL Server Multi-AZ, RDS automatically configures all databases on the instance to use DBM or AGs. Amazon RDS handles the primary, the witness, and the secondary DB instance for you. Because configuration is automatic, RDS selects DBM or Always On AGs based on the version of SQL Server that you deploy.

Amazon RDS supports Multi-AZ with Always On AGs for the following SQL Server versions and editions:

- SQL Server 2019:
  - Standard Edition 15.00.4073.23 and higher
  - Enterprise Edition
- SQL Server 2017:
  - Standard Edition 14.00.3401.7 and higher
  - Enterprise Edition 14.00.3049.1 and higher
- SQL Server 2016: Enterprise Edition 13.00.5216.0 and higher

Amazon RDS supports Multi-AZ with DBM for the following SQL Server versions and editions, except for the versions noted previously:

- SQL Server 2019: Standard Edition 15.00.4043.16
- SQL Server 2017: Standard and Enterprise Editions
- SQL Server 2016: Standard and Enterprise Editions
- SQL Server 2014: Standard and Enterprise Editions

You can use the following SQL query to determine whether your SQL Server DB instance is Single-AZ, Multi-AZ with DBM, or Multi-AZ with Always On AGs.

```
SELECT CASE WHEN dm.mirroring_state_desc IS NOT NULL THEN 'Multi-AZ (Mirroring)'
             WHEN dhdrs.group_database_id IS NOT NULL THEN 'Multi-AZ (AlwaysOn)'
             ELSE 'Single-AZ'
       END 'high_availability'
FROM sys.databases sd
LEFT JOIN sys.database_mirroring dm ON sd.database_id = dm.database_id
LEFT JOIN sys.dm_hadr_database_replica_states dhdrs ON sd.database_id = dhdrs.database_id
       AND dhdrs.is_local = 1
WHERE DB_NAME(sd.database_id) = 'rdsadmin';
```
Adding Multi-AZ to a Microsoft SQL Server DB instance

When you create a new SQL Server DB instance using the AWS Management Console, you can add Multi-AZ with Database Mirroring (DBM) or Always On AGs. You do so by choosing Yes (Mirroring / Always On) from Multi-AZ deployment. For more information, see Creating an Amazon RDS DB instance (p. 300).

When you modify an existing SQL Server DB instance using the console, you can add Multi-AZ with DBM or AGs by choosing Yes (Mirroring / Always On) from Multi-AZ deployment on the Modify DB instance page. For more information, see Modifying an Amazon RDS DB instance (p. 401).

Note
If your DB instance is running Database Mirroring (DBM)—not Always On Availability Groups (AGs)—you might need to disable in-memory optimization before you add Multi-AZ. Disable in-memory optimization with DBM before you add Multi-AZ if your DB instance runs SQL Server 2014, 2016, or 2017 Enterprise Edition and has in-memory optimization enabled. If your DB instance is running AGs, it doesn't require this step.

Removing Multi-AZ from a Microsoft SQL Server DB instance

When you modify an existing SQL Server DB instance using the AWS Management Console, you can remove Multi-AZ with DBM or AGs. You can do this by choosing No (Mirroring / Always On) from Multi-AZ deployment on the Modify DB instance page. For more information, see Modifying an Amazon RDS DB instance (p. 401).

Microsoft SQL Server Multi-AZ deployment limitations, notes, and recommendations

The following are some limitations when working with Multi-AZ deployments on RDS for SQL Server DB instances:

- Cross-Region Multi-AZ isn't supported.
- You can't configure the secondary DB instance to accept database read activity.
- Multi-AZ with Always On Availability Groups (AGs) supports in-memory optimization.
- Multi-AZ with Always On Availability Groups (AGs) doesn't support Kerberos authentication for the availability group listener. This is because the listener has no Service Principal Name (SPN).
- You can't rename a database on a SQL Server DB instance that is in a SQL Server Multi-AZ deployment. If you need to rename a database on such an instance, first turn off Multi-AZ for the DB instance, then rename the database. Finally, turn Multi-AZ back on for the DB instance.
- You can only restore Multi-AZ DB instances that are backed up using the full recovery model.
- Multi-AZ deployments have a limit of 100 SQL Server Agent jobs.

If you need a higher limit, request an increase by contacting AWS Support. Open the AWS Support Center page, sign in if necessary, and choose Create case. Choose Service limit increase. Complete and submit the form.
The following are some notes about working with Multi-AZ deployments on RDS for SQL Server DB instances:

- Amazon RDS exposes the Always On AGs availability group listener endpoint. The endpoint is visible in the console, and is returned by the DescribeDBInstances API operation as an entry in the endpoints field.
- Amazon RDS supports availability group mult subnet failovers.
- To use SQL Server Multi-AZ with a SQL Server DB instance in a virtual private cloud (VPC), first create a DB subnet group that has subnets in at least two distinct Availability Zones. Then assign the DB subnet group to the primary replica of the SQL Server DB instance.
- When a DB instance is modified to be a Multi-AZ deployment, during the modification it has a status of modifying. Amazon RDS creates the standby, and makes a backup of the primary DB instance. After the process is complete, the status of the primary DB instance becomes available.
- Multi-AZ deployments maintain all databases on the same node. If a database on the primary host fails over, all your SQL Server databases fail over as one atomic unit to your standby host. Amazon RDS provisions a new healthy host, and replaces the unhealthy host.
- Multi-AZ with DBM or AGs supports a single standby replica.
- Users, logins, and permissions are automatically replicated for you on the secondary. You don't need to recreate them. User-defined server roles are only replicated in DB instances that use Always On AGs for Multi-AZ deployments.
- In Multi-AZ deployments, SQL Server Agent jobs are replicated from the primary host to the secondary host when the job replication feature is turned on. For more information, see Turning on SQL Server Agent job replication (p. 1633).
- You might observe elevated latencies compared to a standard DB instance deployment (in a single Availability Zone) because of the synchronous data replication.
- Failover times are affected by the time it takes to complete the recovery process. Large transactions increase the failover time.
- In SQL Server Multi-AZ deployments, reboot with failover reboots only the primary DB instance. After the failover, the primary DB instance becomes the new secondary DB instance. Parameters might not be updated for Multi-AZ instances. For reboot without failover, both the primary and secondary DB instances reboot, and parameters are updated after the reboot. If the DB instance is unresponsive, we recommend reboot without failover.

The following are some recommendations for working with Multi-AZ deployments on RDS for Microsoft SQL Server DB instances:

- For databases used in production or preproduction, we recommend the following options:
  - Multi-AZ deployments for high availability
  - "Provisioned IOPS" for fast, consistent performance
  - "Memory optimized" rather than "General purpose"
- You can't select the Availability Zone (AZ) for the secondary instance, so when you deploy application hosts, take this into account. Your database might fail over to another AZ, and the application hosts might not be in the same AZ as the database. For this reason, we recommend that you balance your application hosts across all AZs in the given AWS Region.
- For best performance, don't enable Database Mirroring or Always On AGs during a large data load operation. If you want your data load to be as fast as possible, finish loading data before you convert your DB instance to a Multi-AZ deployment.
- Applications that access the SQL Server databases should have exception handling that catches connection errors. The following code sample shows a try/catch block that catches a communication error. In this example, the break statement exits the while loop if the connection is successful, but retries up to 10 times if an exception is thrown.
Determining the location of the secondary

You can determine the location of the secondary replica by using the AWS Management Console. You need to know the location of the secondary if you are setting up your primary DB instance in a VPC.
You can also view the Availability Zone of the secondary using the AWS CLI command `describe-db-instances` or RDS API operation `DescribeDBInstances`. The output shows the secondary AZ where the standby mirror is located.

**Migrating from Database Mirroring to Always On Availability Groups**

In version 14.00.3049.1 of Microsoft SQL Server Enterprise Edition, Always On Availability Groups (AGs) are enabled by default.

To migrate from Database Mirroring (DBM) to AGs, first check your version. If you are using a DB instance with a version prior to Enterprise Edition 13.00.5216.0, modify the instance to patch it to 13.00.5216.0 or later. If you are using a DB instance with a version prior to Enterprise Edition 14.00.3049.1, modify the instance to patch it to 14.00.3049.1 or later.

If you want to upgrade a mirrored DB instance to use AGs, run the upgrade first, modify the instance to remove Multi-AZ, and then modify it again to add Multi-AZ. This converts your instance to use Always On AGs.
Additional features for Microsoft SQL Server on Amazon RDS

In the following sections, you can find information about augmenting Amazon RDS instances running the Microsoft SQL Server DB engine.

Topics

- Using SSL with a Microsoft SQL Server DB instance (p. 1472)
- Configuring security protocols and ciphers (p. 1475)
- Integrating an Amazon RDS for SQL Server DB instance with Amazon S3 (p. 1480)
- Using Database Mail on Amazon RDS for SQL Server (p. 1494)
- Instance store support for the tempdb database on Amazon RDS for SQL Server (p. 1505)
- Using extended events with Amazon RDS for Microsoft SQL Server (p. 1507)
- Access to transaction log backups with RDS for SQL Server (p. 1510)
Using SSL with a Microsoft SQL Server DB instance

You can use Secure Sockets Layer (SSL) to encrypt connections between your client applications and your Amazon RDS DB instances running Microsoft SQL Server. SSL support is available in all AWS regions for all supported SQL Server editions.

When you create a SQL Server DB instance, Amazon RDS creates an SSL certificate for it. The SSL certificate includes the DB instance endpoint as the Common Name (CN) for the SSL certificate to guard against spoofing attacks.

There are 2 ways to use SSL to connect to your SQL Server DB instance:

- Force SSL for all connections — this happens transparently to the client, and the client doesn't have to do any work to use SSL.
- Encrypt specific connections — this sets up an SSL connection from a specific client computer, and you must do work on the client to encrypt connections.

For information about Transport Layer Security (TLS) support for SQL Server, see TLS 1.2 support for Microsoft SQL Server.

Forcing connections to your DB instance to use SSL

You can force all connections to your DB instance to use SSL. If you force connections to use SSL, it happens transparently to the client, and the client doesn't have to do any work to use SSL.

If you want to force SSL, use the rds.force_ssl parameter. By default, the rds.force_ssl parameter is set to 0 (off). Set the rds.force_ssl parameter to 1 (on) to force connections to use SSL. The rds.force_ssl parameter is static, so after you change the value, you must reboot your DB instance for the change to take effect.

To force all connections to your DB instance to use SSL

1. Determine the parameter group that is attached to your DB instance:
   a. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   b. In the top right corner of the Amazon RDS console, choose the AWS Region of your DB instance.
   c. In the navigation pane, choose Databases, and then choose the name of your DB instance to show its details.
   d. Choose the Configuration tab. Find the Parameter group in the section.
2. If necessary, create a new parameter group. If your DB instance uses the default parameter group, you must create a new parameter group. If your DB instance uses a nondefault parameter group, you can choose to edit the existing parameter group or to create a new parameter group. If you edit an existing parameter group, the change affects all DB instances that use that parameter group.

   To create a new parameter group, follow the instructions in Creating a DB parameter group (p. 350).
3. Edit your new or existing parameter group to set the rds.force_ssl parameter to true. To edit the parameter group, follow the instructions in Modifying parameters in a DB parameter group (p. 352).
4. If you created a new parameter group, modify your DB instance to attach the new parameter group. Modify the DB Parameter Group setting of the DB instance. For more information, see Modifying an Amazon RDS DB instance (p. 401).
5. Reboot your DB instance. For more information, see Rebooting a DB instance (p. 436).
Encrypting specific connections

You can force all connections to your DB instance to use SSL, or you can encrypting connections from specific client computers only. To use SSL from a specific client, you must obtain certificates for the client computer, import certificates on the client computer, and then encrypt the connections from the client computer.

**Note**

All SQL Server instances created after August 5, 2014, use the DB instance endpoint in the Common Name (CN) field of the SSL certificate. Prior to August 5, 2014, SSL certificate verification was not available for VPC-based SQL Server instances. If you have a VPC-based SQL Server DB instance that was created before August 5, 2014, and you want to use SSL certificate verification and ensure that the instance endpoint is included as the CN for the SSL certificate for that DB instance, then rename the instance. When you rename a DB instance, a new certificate is deployed and the instance is rebooted to enable the new certificate.

Obtaining certificates for client computers

To encrypt connections from a client computer to an Amazon RDS DB instance running Microsoft SQL Server, you need a certificate on your client computer.

To obtain that certificate, download the certificate to your client computer. You can download a root certificate that works for all regions. You can also download a certificate bundle that contains both the old and new root certificate. In addition, you can download region-specific intermediate certificates. For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2608).

After you have downloaded the appropriate certificate, import the certificate into your Microsoft Windows operating system by following the procedure in the section following.

Importing certificates on client computers

You can use the following procedure to import your certificate into the Microsoft Windows operating system on your client computer.

**To import the certificate into your Windows operating system:**

1. On the Start menu, type Run in the search box and press Enter.
2. In the Open box, type MMC and then choose OK.
3. In the MMC console, on the File menu, choose Add/Remove Snap-in.
4. In the Add or Remove Snap-ins dialog box, for Available snap-ins, select Certificates, and then choose Add.
5. In the Certificates snap-in dialog box, choose Computer account, and then choose Next.
6. In the Select computer dialog box, choose Finish.
7. In the Add or Remove Snap-ins dialog box, choose OK.
8. In the MMC console, expand Certificates, open the context (right-click) menu for Trusted Root Certification Authorities, choose All Tasks, and then choose Import.
10. On the second page of the Certificate Import Wizard, choose Browse. In the browse window, change the file type to All files (*.*) because .pem is not a standard certificate extension. Locate the .pem file that you downloaded previously.
11. Choose Open to select the certificate file, and then choose Next.
13. On the fourth page of the Certificate Import Wizard, choose Finish. A dialog box appears indicating that the import was successful.
14. In the MMC console, expand Certificates, expand Trusted Root Certification Authorities, and then choose Certificates. Locate the certificate to confirm it exists, as shown here.

![Certificate View](image)

Encrypting connections to an Amazon RDS DB instance running Microsoft SQL Server

After you have imported a certificate into your client computer, you can encrypt connections from the client computer to an Amazon RDS DB instance running Microsoft SQL Server.

For SQL Server Management Studio, use the following procedure. For more information about SQL Server Management Studio, see Use SQL Server management studio.

To encrypt connections from SQL Server Management Studio

1. Launch SQL Server Management Studio.
2. For Connect to server, type the server information, login user name, and password.
3. Choose Options.
4. Select Encrypt connection.
5. Choose Connect.
6. Confirm that your connection is encrypted by running the following query. Verify that the query returns true for encrypt_option.

```
select ENCRYPT_OPTION from SYS.DM_EXEC_CONNECTIONS where SESSION_ID = @@SPID
```

For any other SQL client, use the following procedure.

To encrypt connections from other SQL clients

1. Append encrypt=true to your connection string. This string might be available as an option, or as a property on the connection page in GUI tools.

   **Note**
   To enable SSL encryption for clients that connect using JDBC, you might need to add the Amazon RDS SQL certificate to the Java CA certificate (cacerts) store. You can do this by using the keytool utility.

2. Confirm that your connection is encrypted by running the following query. Verify that the query returns true for encrypt_option.

```
select ENCRYPT_OPTION from SYS.DM_EXEC_CONNECTIONS where SESSION_ID = @@SPID
```
# Configuring security protocols and ciphers

You can turn certain security protocols and ciphers on and off using DB parameters. The security parameters that you can configure (except for TLS version 1.2) are shown in the following table.

For parameters other than `rds.fips`, the value of `default` means that the operating system default value is used, whether it is enabled or disabled.

**Note**

You can't disable TLS 1.2, because Amazon RDS uses it internally.

<table>
<thead>
<tr>
<th>DB parameter</th>
<th>Allowed values (default in bold)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>rds.tls10</code></td>
<td><code>default, enabled, disabled</code></td>
<td>TLS 1.0.</td>
</tr>
<tr>
<td><code>rds.tls11</code></td>
<td><code>default, enabled, disabled</code></td>
<td>TLS 1.1.</td>
</tr>
<tr>
<td><code>rds.tls12</code></td>
<td><code>default</code></td>
<td>TLS 1.2. You can't modify this value.</td>
</tr>
<tr>
<td><code>rds.fips</code></td>
<td><code>0, 1</code></td>
<td>When you set the parameter to 1, RDS forces the use of modules that are compliant with the Federal Information Processing Standard (FIPS) 140-2 standard. For more information, see <a href="https://docs.microsoft.com/en-us/sql-server/2016">Use SQL Server 2016 in FIPS 140-2-compliant mode</a> in the Microsoft documentation. <strong>Note</strong> You must reboot the DB instance after the modification to make it effective.</td>
</tr>
<tr>
<td><code>rds.rc4</code></td>
<td><code>default, enabled, disabled</code></td>
<td>RC4 stream cipher.</td>
</tr>
<tr>
<td><code>rds.diffie-hellman</code></td>
<td><code>default, enabled, disabled</code></td>
<td>Diffie-Hellman key-exchange encryption.</td>
</tr>
<tr>
<td><code>rds.diffie-hellman-min-key-bit-length</code></td>
<td><code>default, 1024, 2048, 4096</code></td>
<td>Minimum bit length for Diffie-Hellman keys.</td>
</tr>
<tr>
<td><code>rds.curve25519</code></td>
<td><code>default, enabled, disabled</code></td>
<td>Curve25519 elliptic-curve encryption cipher. This parameter isn't supported for all engine versions.</td>
</tr>
<tr>
<td><code>rds.3des168</code></td>
<td><code>default, enabled, disabled</code></td>
<td>Triple Data Encryption Standard (DES) encryption cipher with a 168-bit key length.</td>
</tr>
</tbody>
</table>
Note
For more information on the default values for SQL Server security protocols and ciphers, see Protocols in TLS/SSL (Schannel SSP) and Cipher Suites in TLS/SSL (Schannel SSP) in the Microsoft documentation.
For more information on viewing and setting these values in the Windows Registry, see Transport Layer Security (TLS) best practices with the .NET Framework in the Microsoft documentation.

Use the following process to configure the security protocols and ciphers:

1. Create a custom DB parameter group.
2. Modify the parameters in the parameter group.
3. Associate the DB parameter group with your DB instance.

For more information on DB parameter groups, see Working with parameter groups (p. 347).

Creating the security-related parameter group

Create a parameter group for your security-related parameters that corresponds to the SQL Server edition and version of your DB instance.

Console

The following procedure creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose Create parameter group.
4. In the Create parameter group pane, do the following:
   a. For Parameter group family, choose sqlserver-se-13.0.
   b. For Group name, enter an identifier for the parameter group, such as sqlserver-ciphers-se-13.
   c. For Description, enter Parameter group for security protocols and ciphers.
5. Choose Create.

CLI

The following procedure creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

- Run one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group
  --db-parameter-group-name sqlserver-ciphers-se-13
  --db-parameter-group-family "sqlserver-se-13.0"
```
Modifying security-related parameters

Modify the security-related parameters in the parameter group that corresponds to the SQL Server edition and version of your DB instance.

Console

The following procedure modifies the parameter group that you created for SQL Server Standard Edition 2016. This example turns off TLS version 1.0.

To modify the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose the parameter group, such as sqlserver-ciphers-se-13.
4. Under Parameters, filter the parameter list for rds.
5. Choose Edit parameters.
7. For Values, choose disabled.
8. Choose Save changes.

CLI

The following procedure modifies the parameter group that you created for SQL Server Standard Edition 2016. This example turns off TLS version 1.0.

To modify the parameter group

- Run one of the following commands.

Example

For Linux, macOS, or Unix:

```sh/aws rds modify-db-parameter-group \   --db-parameter-group-name sqlserver-ciphers-se-13 \   --parameters "ParameterName='rds.tls10',ParameterValue='disabled',ApplyMethod=pending-reboot"
```

For Windows:

```sh
/aws rds modify-db-parameter-group ^
```
Associating the security-related parameter group with your DB instance

To associate the parameter group with your DB instance, use the AWS Management Console or the AWS CLI.

Console

You can associate the parameter group with a new or existing DB instance:

- For a new DB instance, associate it when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 300).
- For an existing DB instance, associate it by modifying the instance. For more information, see Modifying an Amazon RDS DB instance (p. 401).

CLI

You can associate the parameter group with a new or existing DB instance.

To create a DB instance with the parameter group

- Specify the same DB engine type and major version as you used when creating the parameter group.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
  --db-instance-identifier mydbinstance \
  --db-instance-class db.m5.2xlarge \
  --engine sqlserver-se \
  --engine-version 13.00.5426.0.v1 \
  --allocated-storage 100 \
  --master-user-password secret123 \
  --master-username admin \
  --storage-type gp2 \
  --license-model li \
  --db-parameter-group-name sqlserver-ciphers-se-13
```

For Windows:

```
aws rds create-db-instance ^
  --db-instance-identifier mydbinstance ^
  --db-instance-class db.m5.2xlarge ^
  --engine sqlserver-se ^
  --engine-version 13.00.5426.0.v1 ^
  --allocated-storage 100 ^
  --master-user-password secret123 ^
  --master-username admin ^
  --storage-type gp2 ^
  --license-model li ^
  --db-parameter-group-name sqlserver-ciphers-se-13
```
**Note**
Specify a password other than the prompt shown here as a security best practice.

**To modify a DB instance and associate the parameter group**

- Run one of the following commands.

**Example**

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --db-parameter-group-name sqlserver-ciphers-se-13 \
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --db-parameter-group-name sqlserver-ciphers-se-13 ^
  --apply-immediately
```
Integrating an Amazon RDS for SQL Server DB instance with Amazon S3

You can transfer files between a DB instance running Amazon RDS for SQL Server and an Amazon S3 bucket. By doing this, you can use Amazon S3 with SQL Server features such as BULK INSERT. For example, you can download .csv, .xml, .txt, and other files from Amazon S3 to the DB instance host and import the data from D:\S3\ into the database. All files are stored in D:\S3\ on the DB instance.

The following limitations apply:

- Files in the D:\S3 folder are deleted on the standby replica after a failover on Multi-AZ instances. For more information, see Multi-AZ limitations for S3 integration (p. 1492).
- The DB instance and the S3 bucket must be in the same AWS Region.
- If you run more than one S3 integration task at a time, the tasks run sequentially, not in parallel. **Note**
  S3 integration tasks share the same queue as native backup and restore tasks. At maximum, you can have only two tasks in progress at any time in this queue. Therefore, two running native backup and restore tasks will block any S3 integration tasks.
- You must re-enable the S3 integration feature on restored instances. S3 integration isn't propagated from the source instance to the restored instance. Files in D:\S3 are deleted on a restored instance.
- Downloading to the DB instance is limited to 100 files. In other words, there can't be more than 100 files in D:\S3\.
- Only files without file extensions or with the following file extensions are supported for download: .abf, .asdatabase, .bcp, .configsettings, .csv, .dat, .deploymentoptions, .deploymenttargets, .fmt, .info, .ispac, .lst, .tbl, .txt, .xml, and .xmla.
- The S3 bucket must have the same owner as the related AWS Identity and Access Management (IAM) role. Therefore, cross-account S3 integration isn't supported.
- The S3 bucket can't be open to the public.
- The file size for uploads from RDS to S3 is limited to 50 GB per file.
- The file size for downloads from S3 to RDS is limited to the maximum supported by S3.

- Disabling RDS for SQL Server integration with S3 (p. 1492)

For more information on working with files in Amazon S3, see Getting started with Amazon Simple Storage Service.
Prerequisites for integrating RDS for SQL Server with S3

Before you begin, find or create the S3 bucket that you want to use. Also, add permissions so that the RDS DB instance can access the S3 bucket. To configure this access, you create both an IAM policy and an IAM role.

Console

To create an IAM policy for access to Amazon S3

1. In the IAM Management Console, choose Policies in the navigation pane.
2. Create a new policy, and use the Visual editor tab for the following steps.
3. For Service, enter S3 and then choose the S3 service.
4. For Actions, choose the following to grant the access that your DB instance requires:
   - ListAllMyBuckets – required
   - ListBucket – required
   - GetBucketACL – required
   - GetBucketLocation – required
   - GetObject – required for downloading files from S3 to D:\S3\
   - PutObject – required for uploading files from D:\S3\ to S3
   - ListMultipartUploadParts – required for uploading files from D:\S3\ to S3
   - AbortMultipartUpload – required for uploading files from D:\S3\ to S3
5. For Resources, the options that display depend on which actions you choose in the previous step. You might see options for bucket, object, or both. For each of these, add the appropriate Amazon Resource Name (ARN).

   For bucket, add the ARN for the bucket that you want to use. For example, if your bucket is named example-bucket, set the ARN to arn:aws:s3:::example-bucket.

   For object, enter the ARN for the bucket and then choose one of the following:

     - To grant access to all files in the specified bucket, choose Any for both Bucket name and Object name.
     - To grant access to specific files or folders in the bucket, provide ARNs for the specific buckets and objects that you want SQL Server to access.
6. Follow the instructions in the console until you finish creating the policy.

   The preceding is an abbreviated guide to setting up a policy. For more detailed instructions on creating IAM policies, see Creating IAM policies in the IAM User Guide.

To create an IAM role that uses the IAM policy from the previous procedure

1. In the IAM Management Console, choose Roles in the navigation pane.
2. Create a new IAM role, and choose the following options as they appear in the console:

   - AWS service
   - RDS
   - RDS – Add Role to Database

   Then choose Next:Permissions at the bottom.
3. For Attach permissions policies, enter the name of the IAM policy that you previously created. Then choose the policy from the list.
4. Follow the instructions in the console until you finish creating the role.

The preceding is an abbreviated guide to setting up a role. If you want more detailed instructions on creating roles, see IAM roles in the IAM User Guide.

AWS CLI

To grant Amazon RDS access to an Amazon S3 bucket, use the following process:

1. Create an IAM policy that grants Amazon RDS access to an S3 bucket.
2. Create an IAM role that Amazon RDS can assume on your behalf to access your S3 buckets.
   
   For more information, see Creating a role to delegate permissions to an IAM user in the IAM User Guide.
3. Attach the IAM policy that you created to the IAM role that you created.

To create the IAM policy

Include the appropriate actions to grant the access your DB instance requires:

- ListAllMyBuckets – required
- ListBucket – required
- GetBucketACL – required
- GetBucketLocation – required
- GetObject – required for downloading files from S3 to D:\S3\n- PutObject – required for uploading files from D:\S3\ to S3
- ListMultipartUploadParts – required for uploading files from D:\S3\ to S3
- AbortMultipartUpload – required for uploading files from D:\S3\ to S3

1. The following AWS CLI command creates an IAM policy named rds-s3-integration-policy with these options. It grants access to a bucket named bucket_name.

   Example

   For Linux, macOS, or Unix:

   ```bash
   aws iam create-policy
   --policy-name rds-s3-integration-policy
   --policy-document '{
       "Version": "2012-10-17",
       "Statement": [
         {
           "Effect": "Allow",
           "Action": "s3:ListAllMyBuckets",
           "Resource": "*"
         },
         {
           "Effect": "Allow",
           "Action": [
             "s3:ListBucket",
             "s3:GetBucketACL",
             "s3:GetBucketLocation"
           ],
           "Resource": "arn:aws:s3:::bucket_name"
         },
         {
           "Effect": "Allow",
           "Action": [
             "s3:AbortMultipartUpload",
             "s3:GetObject",
             "s3:GetObject_acl",
             "s3:GetObjectLocation",
             "s3:ListBucket",
             "s3:PutObject",
             "s3:PutObject acl",
             "s3:PutObjectLocation"
           ],
           "Resource": "arn:aws:s3:::bucket_name/*"
         }
       ]
     }
   '}
   ```
"Effect": "Allow",
"Action": [
    "s3:GetObject",
    "s3:PutObject",
    "s3:ListMultipartUploadParts",
    "s3:AbortMultipartUpload"
],
"Resource": "arn:aws:s3:::bucket_name/key_prefix/*"
}
]

For Windows:

Make sure to change the line endings to the ones supported by your interface (^ instead of \\). Also, in Windows, you must escape all double quotes with a \. To avoid the need to escape the quotes in the JSON, you can save it to a file instead and pass that in as a parameter.

First, create the policy.json file with the following permission policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "s3:ListAllMyBuckets",
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListBucket",
        "s3:GetBucketACL",
        "s3:GetBucketLocation"
      ],
      "Resource": "arn:aws:s3:::bucket_name"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:PutObject",
        "s3:ListMultipartUploadParts",
        "s3:AbortMultipartUpload"
      ],
      "Resource": "arn:aws:s3:::bucket_name/key_prefix/*"
    }
  ]
}
```

Then use the following command to create the policy:

```
aws iam create-policy
  --policy-name rds-s3-integration-policy
  --policy-document file://file_path/assume_role_policy.json
```

2. After the policy is created, note the Amazon Resource Name (ARN) of the policy. You need the ARN for a later step.
To create the IAM role

- The following AWS CLI command creates the `rds-s3-integration-role` IAM role for this purpose.

**Example**

For Linux, macOS, or Unix:

```bash
aws iam create-role \
  --role-name rds-s3-integration-role \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole"
      }
    ]
  }'
```

For Windows:

Make sure to change the line endings to the ones supported by your interface (^ instead of \
). Also, in Windows, you must escape all double quotes with a \. To avoid the need to escape the quotes in
the JSON, you can save it to a file instead and pass that in as a parameter.

First, create the `assume_role_policy.json` file with the following policy:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": ["rds.amazonaws.com"]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

Then use the following command to create the IAM role:

```bash
aws iam create-role ^
  --role-name rds-s3-integration-role ^
  --assume-role-policy-document file:///path/assume_role_policy.json
```

**Example of using the global condition context key to create the IAM role**

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys
in resource-based policies to limit the service's permissions to a specific resource. This is the most
effective way to protect against the confused deputy problem.
You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the policy, make sure to use the `aws:SourceArn` global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role. For S3 integration, make sure to include the DB instance ARNs, as shown in the following example.

For Linux, macOS, or Unix:

```bash
aws iam create-role \
  --role-name rds-s3-integration-role \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
          "StringEquals": {
            "aws:SourceArn":"arn:aws:rds:Region:my_account_ID:db:db_instance_identifier"
          }
        }
      }
    ]
  }'
```

For Windows:

Add the global condition context key to `assume_role_policy.json`.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": ["rds.amazonaws.com"
      ],
      "Action": "sts: AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:db_instance_identifier"
        }
      }
    }
  ]
}
```
To attach the IAM policy to the IAM role

- The following AWS CLI command attaches the policy to the role named rds-s3-integration-role. Replace your-policy-arn with the policy ARN that you noted in a previous step.

Example

For Linux, macOS, or Unix:

```bash
aws iam attach-role-policy --policy-arn your-policy-arn --role-name rds-s3-integration-role
```

For Windows:

```bash
aws iam attach-role-policy --policy-arn your-policy-arn --role-name rds-s3-integration-role
```

Enabling RDS for SQL Server integration with S3

In the following section, you can find how to enable Amazon S3 integration with Amazon RDS for SQL Server. To work with S3 integration, your DB instance must be associated with the IAM role that you previously created before you use the S3_INTEGRATION feature-name parameter.

**Note**

To add an IAM role to a DB instance, the status of the DB instance must be available.

**Console**

**To associate your IAM role with your DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the RDS for SQL Server DB instance name to display its details.
3. On the Connectivity & security tab, in the Manage IAM roles section, choose the IAM role to add for Add IAM roles to this instance.
4. For Feature, choose S3_INTEGRATION.
5. Choose Add role.
AWS CLI

To add the IAM role to the RDS for SQL Server DB instance

- The following AWS CLI command adds your IAM role to an RDS for SQL Server DB instance named `mydbinstance`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds add-role-to-db-instance --db-instance-identifier mydbinstance --feature-name S3_INTEGRATION --role-arn your-role-arn
```

For Windows:

```bash
aws rds add-role-to-db-instance --db-instance-identifier mydbinstance --feature-name S3_INTEGRATION --role-arn your-role-arn
```

Replace `your-role-arn` with the role ARN that you noted in a previous step. `S3_INTEGRATION` must be specified for the `--feature-name` option.

Transferring files between RDS for SQL Server and Amazon S3

You can use Amazon RDS stored procedures to download and upload files between Amazon S3 and your RDS DB instance. You can also use Amazon RDS stored procedures to list and delete files on the RDS instance.

The files that you download from and upload to S3 are stored in the `D:\S3` folder. This is the only folder that you can use to access your files. You can organize your files into subfolders, which are created for you when you include the destination folder during download.

Some of the stored procedures require that you provide an Amazon Resource Name (ARN) to your S3 bucket and file. The format for your ARN is `arn:aws:s3:::bucket_name/file_name`. Amazon S3 doesn't require an account number or AWS Region in ARNs.

S3 integration tasks run sequentially and share the same queue as native backup and restore tasks. At maximum, you can have only two tasks in progress at any time in this queue. It can take up to five minutes for the task to begin processing.

**Downloading files from an Amazon S3 bucket to a SQL Server DB instance**

To download files from an S3 bucket to an RDS for SQL Server DB instance, use the Amazon RDS stored procedure `msdb.dbo.rds_download_from_s3` with the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@s3_arn_of_file</td>
<td>NVARCHAR</td>
<td>–</td>
<td>Required</td>
<td>The S3 ARN of the file to download, for example: <code>arn:aws:s3:::bucket_name/mydata.csv</code></td>
</tr>
</tbody>
</table>
Parameter name | Data type | Default | Required | Description
--- | --- | --- | --- | ---
@rds_file_path | NVARCHAR | – | Optional | The file path for the RDS instance. If not specified, the file path is D:\S3\<filename in s3>. RDS supports absolute paths and relative paths. If you want to create a subfolder, include it in the file path.

@overwrite_file | INT | 0 | Optional | Overwrite the existing file:
0 = Don't overwrite
1 = Overwrite

You can download files without a file extension and files with the following file extensions: .bcp, .csv, .dat, .fmt, .info, .lst, .tbl, .txt, and .xml.

**Note**
Files with the .ispac file extension are supported for download when SQL Server Integration Services is enabled. For more information on enabling SSIS, see [SQL Server Integration Services](p. 1578).
Files with the following file extensions are supported for download when SQL Server Analysis Services is enabled: .abf, .asdatabase, .configsettings, .deploymentoptions, .deploymenttargets, and .xmla. For more information on enabling SSAS, see [SQL Server Analysis Services](p. 1559).

The following example shows the stored procedure to download files from S3.

```sql
exec msdb.dbo.rds_download_from_s3
    @s3_arn_of_file='arn:aws:s3:::bucket_name/bulk_data.csv',
    @rds_file_path='D:\S3\seed_data\data.csv',
    @overwrite_file=1;
```

The example `rds_download_from_s3` operation creates a folder named `seed_data` in `D:\S3\`, if the folder doesn't exist yet. Then the example downloads the source file `bulk_data.csv` from S3 to a new file named `data.csv` on the DB instance. If the file previously existed, it's overwritten because the `@overwrite_file` parameter is set to 1.

**Uploading files from a SQL Server DB instance to an Amazon S3 bucket**

To upload files from an RDS for SQL Server DB instance to an S3 bucket, use the Amazon RDS stored procedure `msdb.dbo.rds_upload_to_s3` with the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@s3_arn_of_file</td>
<td>NVARCHAR</td>
<td>–</td>
<td>Required</td>
<td>The S3 ARN of the file to be created in S3, for example: <code>arn:aws:s3:::bucket_name/mydata.csv</code></td>
</tr>
<tr>
<td>@rds_file_path</td>
<td>NVARCHAR</td>
<td>–</td>
<td>Required</td>
<td>The file path of the file to upload to S3. Absolute and relative paths are supported.</td>
</tr>
</tbody>
</table>
Amazon Relational Database Service User Guide
Amazon S3 integration

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@overwrite_file</td>
<td>INT</td>
<td>–</td>
<td>Optional</td>
<td>Overwrite the existing file:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>0 = Don't overwrite</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>1 = Overwrite</td>
</tr>
</tbody>
</table>

The following example uploads the file named `data.csv` from the specified location in D:\S3\seed_data\ to a file `new_data.csv` in the S3 bucket specified by the ARN.

```sql
exec msdb.dbo.rds_upload_to_s3
@rds_file_path='D:\S3\seed_data\data.csv',
@s3_arn_of_file='arn:aws:s3:::bucket_name/new_data.csv',
@overwrite_file=1;
```

If the file previously existed in S3, it's overwritten because the `@overwrite_file` parameter is set to 1.

**Listing files on the RDS DB instance**

To list the files available on the DB instance, use both a stored procedure and a function. First, run the following stored procedure to gather file details from the files in D:\S3\.  

```sql
exec msdb.dbo.rds_gather_file_details;
```

The stored procedure returns the ID of the task. Like other tasks, this stored procedure runs asynchronously. As soon as the status of the task is SUCCESS, you can use the task ID in the `rds_fn_list_file_details` function to list the existing files and directories in D:\S3\, as shown following.

```sql
SELECT * FROM msdb.dbo.rds_fn_list_file_details(TASK_ID);
```

The `rds_fn_list_file_details` function returns a table with the following columns.

<table>
<thead>
<tr>
<th>Output parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>filepath</td>
<td>Absolute path of the file (for example, D:\S3\mydata.csv)</td>
</tr>
<tr>
<td>size_in_bytes</td>
<td>File size (in bytes)</td>
</tr>
<tr>
<td>last_modified_utc</td>
<td>Last modification date and time in UTC format</td>
</tr>
<tr>
<td>is_directory</td>
<td>Option that indicates whether the item is a directory (true/false)</td>
</tr>
</tbody>
</table>

**Deleting files on the RDS DB instance**

To delete the files available on the DB instance, use the Amazon RDS stored procedure `msdb.dbo.rds_delete_from_filesystem` with the following parameters.
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@rds_file_path</td>
<td>NVARCHAR</td>
<td>–</td>
<td>Required</td>
<td>The file path of the file to delete. Absolute and relative paths are</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>supported.</td>
</tr>
<tr>
<td>@force_delete</td>
<td>INT</td>
<td>0</td>
<td>Optional</td>
<td>To delete a directory, this flag must be included and set to 1.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>1 = delete a directory</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>This parameter is ignored if you are deleting a file.</td>
</tr>
</tbody>
</table>

To delete a directory, the @rds_file_path must end with a backslash (\) and @force_delete must be set to 1.

The following example deletes the file D:\S3\delete_me.txt.

```sql
exec msdb.dbo.rds_delete_from_filesystem
  @rds_file_path='D:\S3\delete_me.txt';
```

The following example deletes the directory D:\S3\example_folder\.

```sql
exec msdb.dbo.rds_delete_from_filesystem
  @rds_file_path='D:\S3\example_folder',
  @force_delete=1;
```

**Monitoring the status of a file transfer task**

To track the status of your S3 integration task, call the `rds_fn_task_status` function. It takes two parameters. The first parameter should always be NULL because it doesn't apply to S3 integration. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to NULL and the second parameter to 0, as shown in the following example.

```sql
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL, 0);
```

To get a specific task, set the first parameter to NULL and the second parameter to the task ID, as shown in the following example.

```sql
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL, 42);
```

The `rds_fn_task_status` function returns the following information.

<table>
<thead>
<tr>
<th>Output parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_id</td>
<td>The ID of the task.</td>
</tr>
<tr>
<td>task_type</td>
<td>For S3 integration, tasks can have the following task types:</td>
</tr>
<tr>
<td>Output parameter</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-----------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>• DOWNLOAD_FROM_S3</td>
<td></td>
</tr>
<tr>
<td>• UPLOAD_TO_S3</td>
<td></td>
</tr>
<tr>
<td>• LIST_FILES_ON_DISK</td>
<td></td>
</tr>
<tr>
<td>• DELETE_FILES_ON_DISK</td>
<td></td>
</tr>
<tr>
<td>database_name</td>
<td>Not applicable to S3 integration tasks.</td>
</tr>
<tr>
<td>% complete</td>
<td>The progress of the task as a percentage.</td>
</tr>
<tr>
<td>duration(mins)</td>
<td>The amount of time spent on the task, in minutes.</td>
</tr>
<tr>
<td>lifecycle</td>
<td>The status of the task. Possible statuses are the following:</td>
</tr>
<tr>
<td>• CREATED – After you call one of the S3 integration stored procedures, a task is created and the status is set to CREATED.</td>
<td></td>
</tr>
<tr>
<td>• IN_PROGRESS – After a task starts, the status is set to IN_PROGRESS. It can take up to five minutes for the status to change from CREATED to IN_PROGRESS.</td>
<td></td>
</tr>
<tr>
<td>• SUCCESS – After a task completes, the status is set to SUCCESS.</td>
<td></td>
</tr>
<tr>
<td>• ERROR – If a task fails, the status is set to ERROR. For more information about the error, see the task_info column.</td>
<td></td>
</tr>
<tr>
<td>• CANCEL_REQUESTED – After you call rds_cancel_task, the status of the task is set to CANCEL_REQUESTED.</td>
<td></td>
</tr>
<tr>
<td>• CANCELLED – After a task is successfully canceled, the status of the task is set to CANCELLED.</td>
<td></td>
</tr>
<tr>
<td>task_info</td>
<td>Additional information about the task. If an error occurs during processing, this column contains information about the error.</td>
</tr>
<tr>
<td>last_updated</td>
<td>The date and time that the task status was last updated.</td>
</tr>
<tr>
<td>created_at</td>
<td>The date and time that the task was created.</td>
</tr>
<tr>
<td>S3_object_arn</td>
<td>The ARN of the S3 object downloaded from or uploaded to.</td>
</tr>
<tr>
<td>overwrite_S3_backup_file</td>
<td>Not applicable to S3 integration tasks.</td>
</tr>
<tr>
<td>KMS_master_key_arn</td>
<td>Not applicable to S3 integration tasks.</td>
</tr>
<tr>
<td>filepath</td>
<td>The file path on the RDS DB instance.</td>
</tr>
<tr>
<td>overwrite_file</td>
<td>An option that indicates if an existing file is overwritten.</td>
</tr>
<tr>
<td>task_metadata</td>
<td>Not applicable to S3 integration tasks.</td>
</tr>
</tbody>
</table>
Canceling a task

To cancel S3 integration tasks, use the msdb.dbo.rds_cancel_task stored procedure with the task_id parameter. Delete and list tasks that are in progress can't be cancelled. The following example shows a request to cancel a task.

```
exec msdb.dbo.rds_cancel_task @task_id = 1234;
```

To get an overview of all tasks and their task IDs, use the rds_fn_task_status function as described in Monitoring the status of a file transfer task (p. 1490).

Multi-AZ limitations for S3 integration

On Multi-AZ instances, files in the D:\S3 folder are deleted on the standby replica after a failover. A failover can be planned, for example, during DB instance modifications such as changing the instance class or upgrading the engine version. Or a failover can be unplanned, during an outage of the primary.

**Note**

We don't recommend using the D:\S3 folder for file storage. The best practice is to upload created files to Amazon S3 to make them durable, and download files when you need to import data.

To determine the last failover time, you can use the msdb.dbo.rds_failover_time stored procedure. For more information, see Determining the last failover time (p. 1628).

**Example of no recent failover**

This example shows the output when there is no recent failover in the error logs. No failover has happened since 2020-04-29 23:59:00.01.

Therefore, all files downloaded after that time that haven't been deleted using the rds_delete_from_filesystem stored procedure are still accessible on the current host. Files downloaded before that time might also be available.

<table>
<thead>
<tr>
<th>errorlog_available_from</th>
<th>recent_failover_time</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-04-29 23:59:00.0100000</td>
<td>null</td>
</tr>
</tbody>
</table>

**Example of recent failover**

This example shows the output when there is a failover in the error logs. The most recent failover was at 2020-05-05 18:57:51.89.

All files downloaded after that time that haven't been deleted using the rds_delete_from_filesystem stored procedure are still accessible on the current host.

<table>
<thead>
<tr>
<th>errorlog_available_from</th>
<th>recent_failover_time</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-04-29 23:59:00.0100000</td>
<td>2020-05-05 18:57:51.8900000</td>
</tr>
</tbody>
</table>

Disabling RDS for SQL Server integration with S3

Following, you can find how to disable Amazon S3 integration with Amazon RDS for SQL Server. Files in D:\S3\ aren't deleted when disabling S3 integration.
Note
To remove an IAM role from a DB instance, the status of the DB instance must be available.

Console

To disassociate your IAM role from your DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://
   console.aws.amazon.com/rds/.
2. Choose the RDS for SQL Server DB instance name to display its details.
3. On the Connectivity & security tab, in the Manage IAM roles section, choose the IAM role to
   remove.
4. Choose Delete.

AWS CLI

To remove the IAM role from the RDS for SQL Server DB instance

- The following AWS CLI command removes the IAM role from a RDS for SQL Server DB instance
  named mydbinstance.

Example

For Linux, macOS, or Unix:

```bash
aws rds remove-role-from-db-instance \
   --db-instance-identifier mydbinstance \
   --feature-name S3_INTEGRATION \
   --role-arn your-role-arn
```

For Windows:

```bash
aws rds remove-role-from-db-instance ^
   --db-instance-identifier mydbinstance ^
   --feature-name S3_INTEGRATION ^
   --role-arn your-role-arn
```

Replace your-role-arn with the appropriate IAM role ARN for the --feature-name option.
Using Database Mail on Amazon RDS for SQL Server

You can use Database Mail to send email messages to users from your Amazon RDS on SQL Server database instance. The messages can contain files and query results. Database Mail includes the following components:

- **Configuration and security objects** – These objects create profiles and accounts, and are stored in the msdb database.
- **Messaging objects** – These objects include the `sp_send_dbmail` stored procedure used to send messages, and data structures that hold information about messages. They're stored in the msdb database.
- **Logging and auditing objects** – Database Mail writes logging information to the msdb database and the Microsoft Windows application event log.
- **Database Mail executable** – `DatabaseMail.exe` reads from a queue in the msdb database and sends email messages.

RDS supports Database Mail for all SQL Server versions on the Web, Standard, and Enterprise Editions.

Limitations

The following limitations apply to using Database Mail on your SQL Server DB instance:

- Database Mail isn't supported for SQL Server Express Edition.
- Modifying Database Mail configuration parameters isn't supported. To see the preset (default) values, use the `sysmail_help_configure_sp` stored procedure.
- File attachments aren't fully supported. For more information, see [Working with file attachments](p. 1503).
- The maximum file attachment size is 1 MB.
- Database Mail requires additional configuration on Multi-AZ DB instances. For more information, see [Considerations for Multi-AZ deployments](p. 1504).
- Configuring SQL Server Agent to send email messages to predefined operators isn't supported.

Enabling Database Mail

Use the following process to enable Database Mail for your DB instance:

1. Create a new parameter group.
2. Modify the parameter group to set the `database mail xps` parameter to 1.
3. Associate the parameter group with the DB instance.

Creating the parameter group for Database Mail

Create a parameter group for the `database mail xps` parameter that corresponds to the SQL Server edition and version of your DB instance.

**Note**

You can also modify an existing parameter group. Follow the procedure in [Modifying the parameter that enables Database Mail](p. 1495).

Console

The following example creates a parameter group for SQL Server Standard Edition 2016.
To create the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose Create parameter group.
4. In the Create parameter group pane, do the following:
   a. For Parameter group family, choose sqlserver-se-13.0.
   b. For Group name, enter an identifier for the parameter group, such as dbmail-sqlserver-se-13.
   c. For Description, enter Database Mail XPs.
5. Choose Create.

CLI

The following example creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

- Use one of the following commands.

Example

For Linux, macOS, or Unix:

```bash
aws rds create-db-parameter-group
   --db-parameter-group-name dbmail-sqlserver-se-13
   --db-parameter-group-family "sqlserver-se-13.0"
   --description "Database Mail XPs"
```

For Windows:

```bash
aws rds create-db-parameter-group
   --db-parameter-group-name dbmail-sqlserver-se-13
   --db-parameter-group-family "sqlserver-se-13.0"
   --description "Database Mail XPs"
```

Modifying the parameter that enables Database Mail

Modify the database mail xps parameter in the parameter group that corresponds to the SQL Server edition and version of your DB instance.

To enable Database Mail, set the database mail xps parameter to 1.

Console

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

To modify the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose the parameter group, such as `dbmail-sqlserver-se-13`.
4. Under **Parameters**, filter the parameter list for `mail`.
5. Choose `database mail xps`.
6. Choose **Edit parameters**.
7. Enter 1.
8. Choose **Save changes**.

**CLI**

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

**To modify the parameter group**

- Use one of the following commands.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group \
   --db-parameter-group-name dbmail-sqlserver-se-13 \
   --parameters "ParameterName='database mail xps',ParameterValue=1,ApplyMethod=immediate"
```

For Windows:

```bash
aws rds modify-db-parameter-group ^
   --db-parameter-group-name dbmail-sqlserver-se-13 ^
   --parameters "ParameterName='database mail xps',ParameterValue=1,ApplyMethod=immediate"
```

**Associating the parameter group with the DB instance**

You can use the AWS Management Console or the AWS CLI to associate the Database Mail parameter group with the DB instance.

**Console**

You can associate the Database Mail parameter group with a new or existing DB instance.

- For a new DB instance, associate it when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#) (p. 300).
- For an existing DB instance, associate it by modifying the instance. For more information, see [Modifying an Amazon RDS DB instance](#) (p. 401).

**CLI**

You can associate the Database Mail parameter group with a new or existing DB instance.

**To create a DB instance with the Database Mail parameter group**

- Specify the same DB engine type and major version as you used when creating the parameter group.
Using Database Mail

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
   --db-instance-identifier mydbinstance \
   --db-instance-class db.m5.2xlarge \
   --engine sqlserver-se \
   --engine-version 13.00.5426.0.v1 \
   --allocated-storage 100 \
   --manage-master-user-password \
   --master-username admin \
   --storage-type gp2 \
   --license-model li \
   --db-parameter-group-name dbmail-sqlserver-se-13
```

For Windows:

```
aws rds create-db-instance ^
   --db-instance-identifier mydbinstance ^
   --db-instance-class db.m5.2xlarge ^
   --engine sqlserver-se ^
   --engine-version 13.00.5426.0.v1 ^
   --allocated-storage 100 ^
   --manage-master-user-password ^
   --master-username admin ^
   --storage-type gp2 ^
   --license-model li ^
   --db-parameter-group-name dbmail-sqlserver-se-13
```

To modify a DB instance and associate the Database Mail parameter group

- Use one of the following commands.

**Example**

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
   --db-instance-identifier mydbinstance \
   --db-parameter-group-name dbmail-sqlserver-se-13 \
   --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
   --db-instance-identifier mydbinstance ^
   --db-parameter-group-name dbmail-sqlserver-se-13 ^
   --apply-immediately
```

Configuring Database Mail

You perform the following tasks to configure Database Mail:

1. Create the Database Mail profile.
2. Create the Database Mail account.
3. Add the Database Mail account to the Database Mail profile.
4. Add users to the Database Mail profile.

**Note**
To configure Database Mail, make sure that you have execute permission on the stored procedures in the msdb database.

**Creating the Database Mail profile**

To create the Database Mail profile, you use the `sysmail_add_profile_sp` stored procedure. The following example creates a profile named `Notifications`.

**To create the profile**

- Use the following SQL statement.

```sql
USE msdb
GO
EXECUTE msdb.dbo.sysmail_add_profile_sp
    @profile_name = 'Notifications',
    @description = 'Profile used for sending outgoing notifications using Amazon SES.';
GO
```

**Creating the Database Mail account**

To create the Database Mail account, you use the `sysmail_add_account_sp` stored procedure. The following example creates an account named `SES` on an RDS for SQL Server DB instance in a private VPC, using Amazon Simple Email Service.

Using Amazon SES requires the following parameters:

- `@email_address` – An Amazon SES verified identity. For more information, see [Verified identities in Amazon SES](#).
- `@mailserver_name` – An Amazon SES SMTP endpoint. For more information, see [Connecting to an Amazon SES SMTP endpoint](#).
- `@username` – An Amazon SES SMTP user name. For more information, see [Obtaining Amazon SES SMTP credentials](#).

Don't use an AWS Identity and Access Management user name.

- `@password` – An Amazon SES SMTP password. For more information, see [Obtaining Amazon SES SMTP credentials](#).

**To create the account**

- Use the following SQL statement.

```sql
USE msdb
GO
EXECUTE msdb.dbo.sysmail_add_account_sp
    @account_name = 'SES',
```

1498
@description         = 'Mail account for sending outgoing notifications.',
@email_address       = 'nobody@example.com',
&display_name        = 'Automated Mailer',
@mailserver_name     = 'vpce-0a1b2c3d4e5f-01234567.email-smtp.us-west-2.vpce.amazonaws.com',
@port                = 587,
@Enable_ssl          = 1,
$username            = 'Smtp_Username',
$password            = 'Smtp_Password';
GO

Note
Specify credentials other than the prompts shown here as a security best practice.

Adding the Database Mail account to the Database Mail profile

To add the Database Mail account to the Database Mail profile, you use the
sysmail_add_profileaccount_sp stored procedure. The following example adds the SES account to the
Notifications profile.

To add the account to the profile

- Use the following SQL statement.

USE msdb
GO
EXECUTE msdb.dbo.sysmail_add_profileaccount_sp
    @profile_name        = 'Notifications',
    @account_name        = 'SES',
    @sequence_number     = 1;
GO

Adding users to the Database Mail profile

To grant permission for an msdb database principal to use a Database Mail profile, you use the
sysmail_add_principalprofile_sp stored procedure. A principal is an entity that can request SQL
Server resources. The database principal must map to a SQL Server authentication user, a Windows
Authentication user, or a Windows Authentication group.

The following example grants public access to the Notifications profile.

To add a user to the profile

- Use the following SQL statement.

USE msdb
GO
EXECUTE msdb.dbo.sysmail_add_principalprofile_sp
    @profile_name       = 'Notifications',
    @principal_name     = 'public',
    @is_default         = 1;
GO

1499
Amazon RDS stored procedures and functions for Database Mail

Microsoft provides stored procedures for using Database Mail, such as creating, listing, updating, and deleting accounts and profiles. In addition, RDS provides the stored procedures and functions for Database Mail shown in the following table.

<table>
<thead>
<tr>
<th>Procedure/Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rds_fn_sysmail_allitems</td>
<td>Shows sent messages, including those submitted by other users.</td>
</tr>
<tr>
<td>rds_fn_sysmail_event_log</td>
<td>Shows events, including those for messages submitted by other users.</td>
</tr>
<tr>
<td>rds_fn_sysmail_mailattachments</td>
<td>Shows attachments, including those to messages submitted by other users.</td>
</tr>
<tr>
<td>rds_sysmail_control</td>
<td>Starts and stops the mail queue (DatabaseMail.exe process).</td>
</tr>
<tr>
<td>rds_sysmail_delete_mailitems_sp</td>
<td>Deletes email messages sent by all users from the Database Mail internal tables.</td>
</tr>
</tbody>
</table>

Sending email messages using Database Mail

You use the sp_send_dbmail stored procedure to send email messages using Database Mail.

Usage

```
EXEC msdb.dbo.sp_send_dbmail
@profile_name = 'profile_name',
@recipients = 'recipient1@example.com; recipient2; ... recipientn',
@subject = 'subject',
@body = 'message_body',
[body_format = 'HTML'],
[file_attachments = 'file_path1; file_path2; ... file_pathn'],
[query = 'SQL_query'],
[attach_query_result_as_file = 0|1]'
```

The following parameters are required:

- `@profile_name` – The name of the Database Mail profile from which to send the message.
- `@recipients` – The semicolon-delimited list of email addresses to which to send the message.
- `@subject` – The subject of the message.
- `@body` – The body of the message. You can also use a declared variable as the body.

The following parameters are optional:

- `@body_format` – This parameter is used with a declared variable to send email in HTML format.
- `@file_attachments` – The semicolon-delimited list of message attachments. File paths must be absolute paths.
- `@query` – A SQL query to run. The query results can be attached as a file or included in the body of the message.
- `@attach_query_result_as_file` – Whether to attach the query result as a file. Set to 0 for no, 1 for yes. The default is 0.
Examples

The following examples demonstrate how to send email messages.

Example of sending a message to a single recipient

```
USE msdb
GO
EXEC msdb.dbo.sp_send_dbmail
    @profile_name       = 'Notifications',
    @recipients         = 'nobody@example.com',
    @subject            = 'Automated DBMail message - 1',
    @body               = 'Database Mail configuration was successful.
GO
```

Example of sending a message to multiple recipients

```
USE msdb
GO
EXEC msdb.dbo.sp_send_dbmail
    @profile_name       = 'Notifications',
    @recipients         = 'recipient1@example.com;recipient2@example.com',
    @subject            = 'Automated DBMail message - 2',
    @body               = 'This is a message.
GO
```

Example of sending a SQL query result as a file attachment

```
USE msdb
GO
EXEC msdb.dbo.sp_send_dbmail
    @profile_name       = 'Notifications',
    @recipients         = 'nobody@example.com',
    @subject            = 'Test SQL query',
    @body               = 'This is a SQL query test.',
    @query              = 'SELECT * FROM abc.dbo.test',
    @attach_query_result_as_file = 1;
GO
```

Example of sending a message in HTML format

```
USE msdb
GO
DECLARE @HTML_Body as NVARCHAR(500) = 'Hi, <h4> Heading </h4> </br> See the report. <b> Regards </b>'';
EXEC msdb.dbo.sp_send_dbmail
    @profile_name       = 'Notifications',
    @recipients         = 'nobody@example.com',
    @subject            = 'Test HTML message',
    @body               = @HTML_Body,
    @body_format        = 'HTML';
GO
```
Example of sending a message using a trigger when a specific event occurs in the database

```sql
USE AdventureWorks2017
GO
IF OBJECT_ID ('Production.iProductNotification', 'TR') IS NOT NULL
    DROP TRIGGER Purchasing.iProductNotification
GO
CREATE TRIGGER iProductNotification ON Production.Product
    FOR INSERT
    AS
    DECLARE @ProductInformation nvarchar(255);
    SELECT
        @ProductInformation = 'A new product, ' + Name + ', is now available for $' +
        CAST(StandardCost AS nvarchar(20)) + '!
    FROM INSERTED i;
EXEC msdb.dbo.sp_send_dbmail
    @profile_name       = 'Notifications',
    @recipients         = 'nobody@example.com',
    @subject            = 'New product information',
    @body               = @ProductInformation;
GO
```

Viewing messages, logs, and attachments

You use RDS stored procedures to view messages, event logs, and attachments.

**To view all email messages**

- Use the following SQL query.

```sql
SELECT * FROM msdb.dbo.rds_fn_sysmail_allitems(); --WHERE sent_status='sent' or 'failed' or 'unsent'
```

**To view all email event logs**

- Use the following SQL query.

```sql
SELECT * FROM msdb.dbo.rds_fn_sysmail_event_log();
```

**To view all email attachments**

- Use the following SQL query.

```sql
SELECT * FROM msdb.dbo.rds_fn_sysmail_mailattachments();
```

Deleting messages

You use the `rds_sysmail_delete_mailitems_sp` stored procedure to delete messages.

**Note**

RDS automatically deletes mail table items when DBMail history data reaches 1 GB in size, with a retention period of at least 24 hours.
If you want to keep mail items for a longer period, you can archive them. For more information, see Create a SQL Server Agent job to archive Database Mail messages and event logs in the Microsoft documentation.

To delete all email messages

- Use the following SQL statement.

```sql
DECLARE @GETDATE datetime
SET @GETDATE = GETDATE();
EXECUTE msdb.dbo.rds_sysmail_delete_mailitems_sp @sent_before = @GETDATE;
GO
```

To delete all email messages with a particular status

- Use the following SQL statement to delete all failed messages.

```sql
DECLARE @GETDATE datetime
SET @GETDATE = GETDATE();
EXECUTE msdb.dbo.rds_sysmail_delete_mailitems_sp @sent_status = 'failed';
GO
```

Starting the mail queue

You use the `rds_sysmail_control` stored procedure to start the Database Mail process.

**Note**

Enabling Database Mail automatically starts the mail queue.

To start the mail queue

- Use the following SQL statement.

```sql
EXECUTE msdb.dbo.rds_sysmail_control start;
GO
```

Stopping the mail queue

You use the `rds_sysmail_control` stored procedure to stop the Database Mail process.

To stop the mail queue

- Use the following SQL statement.

```sql
EXECUTE msdb.dbo.rds_sysmail_control stop;
GO
```

Working with file attachments

The following file attachment extensions aren't supported in Database Mail messages from RDS on SQL Server: .ade, .adp, .apk, .appx, .appxbundle, .bat, .bak, .cab, .chm, .cmd, .com, .cpl, .dll, .dmg, .exe, .hta, .inf, .ins, .isp, .is1, .is2, .jar, .js, .jsx, .mcr, .msg, .ps1, .psc1, .reg, .rgs, .scr, .sct, .shb, .shs, .svg, .sys, .u3p, .vb, .vbe, .vbs, .vbscript, .vxd, .ws, .wsc, .wsf, and .wsh.
Database Mail uses the Microsoft Windows security context of the current user to control access to files. Users who log in with SQL Server Authentication can't attach files using the @file_attachments parameter with the sp_send_dbmail stored procedure. Windows doesn't allow SQL Server to provide credentials from a remote computer to another remote computer. Therefore, Database Mail can't attach files from a network share when the command is run from a computer other than the computer running SQL Server.

However, you can use SQL Server Agent jobs to attach files. For more information on SQL Server Agent, see Using SQL Server Agent (p. 1633) and SQL Server Agent in the Microsoft documentation.

**Considerations for Multi-AZ deployments**

When you configure Database Mail on a Multi-AZ DB instance, the configuration isn't automatically propagated to the secondary. We recommend converting the Multi-AZ instance to a Single-AZ instance, configuring Database Mail, and then converting the DB instance back to Multi-AZ. Then both the primary and secondary nodes have the Database Mail configuration.

If you create a read replica from your Multi-AZ instance that has Database Mail configured, the replica inherits the configuration, but without the password to the SMTP server. Update the Database Mail account with the password.
Instance store support for the tempdb database on Amazon RDS for SQL Server

An instance store provides temporary block-level storage for your DB instance. This storage is located on disks that are physically attached to the host computer. These disks have Non-Volatile Memory Express (NVMe) instance storage that is based on solid-state drives (SSDs). This storage is optimized for low latency, very high random I/O performance, and high sequential read throughput.

By placing tempdb data files and tempdb log files on the instance store, you can achieve lower read and write latencies compared to standard storage based on Amazon EBS.

**Note**
SQL Server database files and database log files aren't placed on the instance store.

Enabling the instance store

When RDS provisions DB instances with one of the following instance classes, the tempdb database is automatically placed onto the instance store:

- db.m5d
- db.r5d
- db.x2i.1edn

To enable the instance store, do one of the following:

- Create a SQL Server DB instance using one of these instance types. For more information, see Creating an Amazon RDS DB instance (p. 300).
- Modify an existing SQL Server DB instance to use one of them. For more information, see Modifying an Amazon RDS DB instance (p. 401).

The instance store is available in all AWS Regions where one or more of these instance types are supported. For more information on the db.m5d and db.r5d instance classes, see DB instance classes (p. 11). For more information on the instance classes supported by Amazon RDS for SQL Server, see DB instance class support for Microsoft SQL Server (p. 1374).

File location and size considerations

On instances without an instance store, RDS stores the tempdb data and log files in the D:\rdsdbdata\DATA directory. Both files start at 8 MB by default.

On instances with an instance store, RDS stores the tempdb data and log files in the T:\rdsdbdata\DATA directory.

When tempdb has only one data file (tempdb.mdf) and one log file (templog.ldf), templog.ldf starts at 8 MB by default and tempdb.mdf starts at 80% or more of the instance's storage capacity. Twenty percent of the storage capacity or 200 GB, whichever is less, is kept free to start. Multiple tempdb data files split the 80% disk space evenly, while log files always have an 8-MB initial size.

For example, if you modify your DB instance class from db.m5.2xlarge to db.m5d.2xlarge, the size of tempdb data files increases from 8 MB each to 234 GB in total.

**Note**
Besides the tempdb data and log files on the instance store (T:\rdsdbdata\DATA), you can still create extra tempdb data and log files on the data volume (D:\rdsdbdata\DATA). Those files always have an 8 MB initial size.
Backup considerations

You might need to retain backups for long periods, incurring costs over time. The tempdb data and log blocks can change very often depending on the workload. This can greatly increase the DB snapshot size.

When tempdb is on the instance store, snapshots don't include temporary files. This means that snapshot sizes are smaller and consume less of the free backup allocation compared to EBS-only storage.

Disk full errors

If you use all of the available space in the instance store, you might receive errors such as the following:

- The transaction log for database 'tempdb' is full due to 'ACTIVE_TRANSACTION'.
- Could not allocate space for object 'dbo.SORT temporary run storage: 14073941419520' in database 'tempdb' because the 'PRIMARY' filegroup is full. Create disk space by deleting unneeded files, dropping objects in the filegroup, adding additional files to the filegroup, or setting autogrowth on for existing files in the filegroup.

You can do one or more of the following when the instance store is full:

- Adjust your workload or the way you use tempdb.
- Scale up to use a DB instance class with more NVMe storage.
- Stop using the instance store, and use an instance class with only EBS storage.
- Use a mixed mode by adding secondary data or log files for tempdb on the EBS volume.

Removing the instance store

To remove the instance store, modify your SQL Server DB instance to use an instance type that doesn't support instance store, such as db.m5, db.r5, or db.x1e.

**Note**

When you remove the instance store, the temporary files are moved to the D:\rdsdbdata\DATA directory and reduced in size to 8 MB.
Using extended events with Amazon RDS for Microsoft SQL Server

You can use extended events in Microsoft SQL Server to capture debugging and troubleshooting information for Amazon RDS for SQL Server. Extended events replace SQL Trace and Server Profiler, which have been deprecated by Microsoft. Extended events are similar to profiler traces but with more granular control on the events being traced. Extended events are supported for SQL Server versions 2014 and later on Amazon RDS. For more information, see Extended events overview in the Microsoft documentation.

Extended events are turned on automatically for users with master user privileges in Amazon RDS for SQL Server.

Topics
• Limitations and recommendations (p. 1507)
• Configuring extended events on RDS for SQL Server (p. 1507)
• Considerations for Multi-AZ deployments (p. 1508)
• Querying extended event files (p. 1509)

Limitations and recommendations

When using extended events on RDS for SQL Server, the following limitations apply:

• Extended events are supported only for the Enterprise and Standard Editions.
• You can't alter default extended event sessions.
• Make sure to set the session memory partition mode to NONE.
• Session event retention mode can be either ALLOW_SINGLE_EVENT_LOSS or ALLOW_MULTIPLE_EVENT_LOSS.
• Event Tracing for Windows (ETW) targets aren't supported.
• Make sure that file targets are in the D:\rdsdbdata\log directory.
• For pair matching targets, set the respond_to_memory_pressure property to 1.
• Ring buffer target memory can't be greater than 4 MB.
• The following actions aren't supported:
  • debug_break
  • create_dump_all_threads
  • create_dump_single_threads
• The rpc_completed event is supported on the following versions and later: 15.0.4083.2, 14.0.3370.1, 13.0.5865.1, 12.0.6433.1, 11.0.7507.2.

Configuring extended events on RDS for SQL Server

On RDS for SQL Server, you can configure the values of certain parameters of extended event sessions. The following table describes the configurable parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xe_session_max_memory</td>
<td>Specifies the maximum amount of memory.</td>
</tr>
<tr>
<td>xe_session_max_event_size</td>
<td>Specifies the maximum memory size for events.</td>
</tr>
</tbody>
</table>
### Using extended events

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xe_session_max_dispatch_latency</td>
<td>Specifies the amount of time that events are</td>
</tr>
<tr>
<td></td>
<td>buffered in memory before being dispatched to</td>
</tr>
<tr>
<td></td>
<td>extended event session.</td>
</tr>
<tr>
<td>xe_file_target_size</td>
<td>Specifies the maximum size of the file target.</td>
</tr>
<tr>
<td>xe_file_retention</td>
<td>Specifies the retention time in days.</td>
</tr>
</tbody>
</table>

**Note**

Setting `xe_file_retention` to zero causes `.xel` files to be removed automatically after the lock on these files is released by SQL Server. The lock is released whenever an `.xel` file reaches the size limit set in `xe_file_target_size`.

You can use the `rdsadmin.dbo.rds_show_configuration` stored procedure to show the current values of these parameters. For example, use the following SQL statement to view the current setting of `xe_session_max_memory`.

```
exec rdsadmin..rds_show_configuration 'xe_session_max_memory'
```

You can use the `rdsadmin.dbo.rds_set_configuration` stored procedure to modify them. For example, use the following SQL statement to set `xe_session_max_memory` to 4 MB.

```
exec rdsadmin..rds_set_configuration 'xe_session_max_memory', 4
```

### Considerations for Multi-AZ deployments

When you create an extended event session on a primary DB instance, it doesn't propagate to the standby replica. You can fail over and create the extended event session on the new primary DB instance. Or you can remove and then re-add the Multi-AZ configuration to propagate the extended event session to the standby replica. RDS stops all nondefault extended event sessions on the standby replica, so that these sessions don't consume resources on the standby. Because of this, after a standby replica becomes the primary DB instance, make sure to manually start the extended event sessions on the new primary.

**Note**

This approach applies to both Always On Availability Groups and Database Mirroring.

You can also use a SQL Server Agent job to track the standby replica and start the sessions if the standby becomes the primary. For example, use the following query in your SQL Server Agent job step to restart event sessions on a primary DB instance.

```
BEGIN
  IF (DATABASEPROPERTYEX('rdsadmin','Updateability')='READ_WRITE'
  AND DATABASEPROPERTYEX('rdsadmin','status')='ONLINE'
  AND (DATABASEPROPERTYEX('rdsadmin','Collation') IS NOT NULL OR
  DATABASEPROPERTYEX('rdsadmin','IsAutoClose')=1)
  BEGIN
    IF NOT EXISTS (SELECT 1 FROM sys.dm_xe_sessions WHERE name='xe1')
      ALTER EVENT SESSION xe1 ON SERVER STATE=START
    IF NOT EXISTS (SELECT 1 FROM sys.dm_xe_sessions WHERE name='xe2')
      ALTER EVENT SESSION xe2 ON SERVER STATE=START
  END
END
```

This query restarts the event sessions `xe1` and `xe2` on a primary DB instance if these sessions are in a stopped state. You can also add a schedule with a convenient interval to this query.
Querying extended event files

You can either use SQL Server Management Studio or the sys.fn_xe_file_target_read_file function to view data from extended events that use file targets. For more information on this function, see sys.fn_xe_file_target_read_file (Transact-SQL) in the Microsoft documentation.

Extended event file targets can only write files to the D:\rdsdbdata\log directory on RDS for SQL Server.

As an example, use the following SQL query to list the contents of all files of extended event sessions whose names start with xe.

```
SELECT * FROM sys.fn_xe_file_target_read_file('d:\rdsdbdata\log\xe*', null,null,null);
```
Access to transaction log backups with RDS for SQL Server

With access to transaction log backups for RDS for SQL Server, you can list the transaction log backup files for a database and copy them to a target Amazon S3 bucket. By copying transaction log backups in an Amazon S3 bucket, you can use them in combination with full and differential database backups to perform point in time database restores. You use RDS stored procedures to set up access to transaction log backups, list available transaction log backups, and copy them to your Amazon S3 bucket.

Access to transaction log backups provides the following capabilities and benefits:

- List and view the metadata of available transaction log backups for a database on an RDS for SQL Server DB instance.
- Copy available transaction log backups from RDS for SQL Server to a target Amazon S3 bucket.
- Perform point-in-time restores of databases without the need to restore an entire DB instance. For more information on restoring a DB instance to a point in time, see Restoring a DB instance to a specified time (p. 660).

Availability and support

Access to transaction log backups is supported in all AWS Regions. Access to transaction log backups is available for all editions and versions of Microsoft SQL Server supported on Amazon RDS.

Requirements

The following requirements must be met before enabling access to transaction log backups:

- Automated backups must be enabled on the DB instance and the backup retention must be set to a value of one or more days. For more information on enabling automated backups and configuring a retention policy, see Enabling automated backups (p. 593).
- An Amazon S3 bucket must exist in the same account and Region as the source DB instance. Before enabling access to transaction log backups, choose an existing Amazon S3 bucket or create a new bucket to use for your transaction log backup files.
- An Amazon S3 bucket permissions policy must be configured as follows to allow Amazon RDS to copy transaction log files into it:
  1. Set the object account ownership property on the bucket to Bucket Owner Preferred.
  2. Add the following policy. There will be no policy by default, so use the bucket Access Control Lists (ACL) to edit the bucket policy and add it.

The following example uses an ARN to specify a resource. We recommend using the SourceArn and SourceAccount global condition context keys in resource-based trust relationships to limit the service's permissions to a specific resource. For more information on working with ARNs, see Amazon resource names (ARNs) and Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 471).

Example of an Amazon S3 permissions policy for access to transaction log backups

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Only allow writes to my bucket with bucket owner full control",
```
An AWS Identity and Access Management (IAM) role to access the Amazon S3 bucket. If you already have an IAM role, you can use that. You can choose to have a new IAM role created for you when you add the SQLSERVER_BACKUP_RESTORE option by using the AWS Management Console. Alternatively, you can create a new one manually. For more information on creating and configuring an IAM role with SQLSERVER_BACKUP_RESTORE, see Manually creating an IAM role for native backup and restore (p. 1438).

The SQLSERVER_BACKUP_RESTORE option must be added to an option group on your DB instance. For more information on adding the SQLSERVER_BACKUP_RESTORE option, see Support for native backup and restore in SQL Server (p. 1541).

Note
If your DB instance has storage encryption enabled, the AWS KMS (KMS) actions and key must be provided in the IAM role provided in the native backup and restore option group.

Optionally, if you intend to use the rds_restore_log stored procedure to perform point in time database restores, we recommend using the same Amazon S3 path for the native backup and restore option group and access to transaction log backups. This method ensures that when Amazon RDS assumes the role from the option group to perform the restore log functions, it has access to retrieve transaction log backups from the same Amazon S3 path.

If the DB instance is encrypted, regardless of encryption type (AWS managed key or Customer managed key), you must provide a Customer managed KMS key in the IAM role and in the rds_tlog_backup_copy_to_S3 stored procedure.

Limitations and recommendations
Access to transaction log backups has the following limitations and recommendations:

- You can list and copy up to the last seven days of transaction log backups for any DB instance that has backup retention configured between one to 35 days.
- The Amazon S3 bucket used for access to transaction log backups must exist in the same account and Region as the source DB instance. Cross-account and cross-region copy is not supported.
- Only one Amazon S3 bucket can be configured as a target to copy transaction log backups into. You can choose a new target Amazon S3 bucket with the rds_tlog_copy_setup stored procedure. For more information on choosing a new target Amazon S3 bucket, see Setting up access to transaction log backups (p. 1512).
- You cannot specify the KMS key when using the rds_tlog_backup_copy_to_S3 stored procedure if your RDS instance is not enabled for storage encryption.
- Multi-account copying is not supported. The IAM role used for copying will only permit write access to Amazon S3 buckets within the owner account of the DB instance.
- Only two concurrent tasks of any type may be run on an RDS for SQL Server DB instance.
• Only one copy task can run for a single database at a given time. If you want to copy transaction log backups for multiple databases on the DB instance, use a separate copy task for each database.

• If you copy a transaction log backup that already exists with the same name in the Amazon S3 bucket, the existing transaction log backup will be overwritten.

• You can only run the stored procedures that are provided with access to transaction log backups on the primary DB instance. You can't run these stored procedures on an RDS for SQL Server read replica or on a secondary instance of a Multi-AZ DB cluster.

• If the RDS for SQL Server DB instance is rebooted while the `rds_tlog_backup_copy_to_S3` stored procedure is running, the task will automatically restart from the beginning when the DB instance is back online. Any transaction log backups that had been copied to the Amazon S3 bucket while the task was running before the reboot will be overwritten.

• The Microsoft SQL Server system databases and the `RDSAdmin` database cannot be configured for access to transaction log backups.

• Copying to buckets encrypted by SSE-KMS isn't supported.

### Setting up access to transaction log backups

To set up access to transaction log backups, complete the list of requirements in the Requirements (p. 1510) section, and then run the `rds_tlog_copy_setup` stored procedure. The procedure will enable the access to transaction log backups feature at the DB instance level. You don't need to run it for each individual database on the DB instance.

**Important**
The database user must be granted the `db_owner` role within SQL Server on each database to configure and use the access to transaction log backups feature.

**Example usage:**

```sql
exec msdb.dbo.rds_tlog_copy_setup @target_s3_arn='arn:aws:s3:::mybucket/myfolder';
```

The following parameter is required:

• @target_s3_arn – The ARN of the target Amazon S3 bucket to copy transaction log backups files to.

**Example of setting an Amazon S3 target bucket:**

```sql
exec msdb.dbo.rds_tlog_copy_setup @target_s3_arn='arn:aws:s3:::accessstlogs-testbucket/mytestdb1';
```

To validate the configuration, call the `rds_show_configuration` stored procedure.

**Example of validating the configuration:**

```sql
exec rdsadmin.dbo.rds_show_configuration @name='target_s3_arn_for_tlog_copy';
```

To modify access to transaction log backups to point to a different Amazon S3 bucket, you can view the current Amazon S3 bucket value and re-run the `rds_tlog_copy_setup` stored procedure using a new value for the `@target_s3_arn` parameter.
Example of viewing the existing Amazon S3 bucket configured for access to transaction log backups

```sql
exec rdsadmin.dbo.rds_show_configuration @name='target_s3_arn_for_tlog_copy';
```

Example of updating to a new target Amazon S3 bucket

```sql
exec msdb.dbo.rds_tlog_copy_setup @target_s3_arn='arn:aws:s3:::mynewbucket/mynewfolder';
```

Listing available transaction log backups

With RDS for SQL Server, databases configured to use the full recovery model and a DB instance backup retention set to one or more days have transaction log backups automatically enabled. By enabling access to transaction log backups, up to seven days of those transaction log backups are made available for you to copy into your Amazon S3 bucket.

After you have enabled access to transaction log backups, you can start using it to list and copy available transaction log backup files.

Listing transaction log backups

To list all transaction log backups available for an individual database, call the `rds_fn_list_tlog_backup_metadata` function. You can use an ORDER BY or a WHERE clause when calling the function.

Example of listing and filtering available transaction log backup files

```sql
SELECT * from msdb.dbo.rds_fn_list_tlog_backup_metadata('mydatabasename');
SELECT * from msdb.dbo.rds_fn_list_tlog_backup_metadata('mydatabasename') WHERE rds_backup_seq_id = 3507;
SELECT * from msdb.dbo.rds_fn_list_tlog_backup_metadata('mydatabasename') WHERE backup_file_time_utc > '2022-09-15 20:44:01' ORDER BY backup_file_time_utc DESC;
```
The `rds_fn_list_tlog_backup_metadata` function returns the following output:

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>db_name</td>
<td>sysname</td>
<td>The database name provided to list the transaction log backups for.</td>
</tr>
<tr>
<td>db_id</td>
<td>int</td>
<td>The internal database identifier for the input parameter <code>db_name</code>.</td>
</tr>
<tr>
<td>family_guid</td>
<td>uniqueidentifier</td>
<td>The unique ID of the original database at creation. This value remains the same when the database is restored, even to a different database name.</td>
</tr>
<tr>
<td>rds_backup_seq_id</td>
<td>int</td>
<td>The ID that RDS uses internally to maintain a sequence number for each transaction log backup file.</td>
</tr>
<tr>
<td>backup_file_epoch</td>
<td>bigint</td>
<td>The epoch time that a transaction backup file was generated.</td>
</tr>
<tr>
<td>backup_file_time_utc</td>
<td>datetime</td>
<td>The UTC time-converted value for the <code>backup_file_epoch</code> value.</td>
</tr>
<tr>
<td>starting_lsn</td>
<td>numeric(25,0)</td>
<td>The log sequence number of the first or oldest log record of a transaction log backup file.</td>
</tr>
<tr>
<td>ending_lsn</td>
<td>numeric(25,0)</td>
<td>The log sequence number of the last or next log record of a transaction log backup file.</td>
</tr>
<tr>
<td>is_log_chain_broken</td>
<td>bit</td>
<td>A boolean value indicating if the log chain is broken between the current transaction log backup file and the previous transaction log backup file.</td>
</tr>
</tbody>
</table>
### Access to transaction log backups

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_size_bytes</td>
<td>bigint</td>
<td>The size of the transactional backup set in bytes.</td>
</tr>
<tr>
<td>Error</td>
<td>varchar(4000)</td>
<td>Error message if the <code>rds_fn_list_tlog_backup_metadata</code> function throws an exception. NULL if no exceptions.</td>
</tr>
</tbody>
</table>

### Copying transaction log backups

To copy a set of available transaction log backups for an individual database to your Amazon S3 bucket, call the `rds_tlog_backup_copy_to_S3` stored procedure. The `rds_tlog_backup_copy_to_S3` stored procedure will initiate a new task to copy transaction log backups.

**Note**
The `rds_tlog_backup_copy_to_S3` stored procedure will copy the transaction log backups without validating against `is_log_chain_broken` attribute. For this reason, you should manually confirm an unbroken log chain before running the `rds_tlog_backup_copy_to_S3` stored procedure. For further explanation, see [Validating the transaction log backup log chain](p. 1519).

**Example usage of the `rds_tlog_backup_copy_to_S3` stored procedure**

```sql
exec msdb.dbo.rds_tlog_backup_copy_to_S3
@db_name='mydatabasename',
[@kms_key_arn='arn:aws:kms:region:account-id:key/key-id'],
[@backup_file_start_time='2022-09-01 01:00:15'],
[@backup_file_end_time='2022-09-01 21:30:45'],
[@starting_lsn=149000000112100001],
[@ending_lsn=149000000120400001],
[@rds_backup_starting_seq_id=5],
[@rds_backup_ending_seq_id=10];
```

The following input parameters are available:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@db_name</td>
<td>The name of the database to copy transaction log backups for</td>
</tr>
<tr>
<td>@kms_key_arn</td>
<td>The ARN of the KMS key used to encrypt a storage-encrypted DB instance.</td>
</tr>
<tr>
<td>@backup_file_start_time</td>
<td>The UTC timestamp as provided from the <code>[backup_file_time_utc]</code> column of the <code>rds_fn_list_tlog_backup_metadata</code> function.</td>
</tr>
<tr>
<td>@backup_file_end_time</td>
<td>The UTC timestamp as provided from the <code>[backup_file_time_utc]</code> column of the <code>rds_fn_list_tlog_backup_metadata</code> function.</td>
</tr>
<tr>
<td>@starting_lsn</td>
<td>The log sequence number (LSN) as provided from the <code>[starting_lsn]</code> column of the <code>rds_fn_list_tlog_backup_metadata</code> function.</td>
</tr>
<tr>
<td>@ending_lsn</td>
<td>The log sequence number (LSN) as provided from the <code>[ending_lsn]</code> column of the <code>rds_fn_list_tlog_backup_metadata</code> function.</td>
</tr>
<tr>
<td>@rds_backup_starting_seq_id</td>
<td>The sequence ID as provided from the <code>[rds_backup_seq_id]</code> column of the <code>rds_fn_list_tlog_backup_metadata</code> function.</td>
</tr>
</tbody>
</table>
Access to transaction log backups

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@rds_backup_ending_seq_id</td>
<td>The sequence ID as provided from the [rds_backup_seq_id] column of the rds_fn_list_tlog_backup_metadata function.</td>
</tr>
</tbody>
</table>

You can specify a set of either the time, LSN, or sequence ID parameters. Only one set of parameters are required.

You can also specify just a single parameter in any of the sets. For example, by providing a value for only the backup_file_end_time parameter, all available transaction log backup files prior to that time within the seven-day limit will be copied to your Amazon S3 bucket.

Following are the valid input parameter combinations for the rds_tlog_backup_copy_to_S3 stored procedure.

<table>
<thead>
<tr>
<th>Parameters provided</th>
<th>Expected result</th>
</tr>
</thead>
</table>
|exec
msdb.dbo.rds_tlog_backup_copy_to_S3
@db_name = 'testdb1',
@backup_file_start_time = '2022-08-23 00:00:00',
@backup_file_end_time = '2022-08-30 00:00:00'; | Copies transaction log backups from the last seven days and exist between the provided range of backup_file_start_time and backup_file_end_time. In this example, the stored procedure will copy transaction log backups that were generated between '2022-08-23 00:00:00' and '2022-08-30 00:00:00'. |
|exec
msdb.dbo.rds_tlog_backup_copy_to_S3
@db_name = 'testdb1',
@backup_file_start_time = '2022-08-23 00:00:00'; | Copies transaction log backups from the last seven days and starting from the provided backup_file_start_time. In this example, the stored procedure will copy transaction log backups from '2022-08-23 00:00:00' up to the latest transaction log backup. |
|exec
msdb.dbo.rds_tlog_backup_copy_to_S3
@db_name = 'testdb1',
@backup_file_end_time = '2022-08-30 00:00:00'; | Copies transaction log backups from the last seven days up to the provided backup_file_end_time. In this example, the |
<table>
<thead>
<tr>
<th>Parameters provided</th>
<th>Expected result</th>
</tr>
</thead>
<tbody>
<tr>
<td>@backup_file_end_time='2022-08-30 00:00:00';</td>
<td>stored procedure will copy transaction log backups from '2022-08-23 00:00:00' up to '2022-08-30 00:00:00'.</td>
</tr>
<tr>
<td>exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name='testdb1', @starting_lsn =1490000000040007, @ending_lsn = 1490000000050009;</td>
<td>Copies transaction log backups that are available from the last seven days and are between the provided range of the starting_lsn and ending_lsn. In this example, the stored procedure will copy transaction log backups from the last seven days with an LSN range between 1490000000040007 and 1490000000050009.</td>
</tr>
<tr>
<td>exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name='testdb1', @starting_lsn =1490000000040007;</td>
<td>Copies transaction log backups that are available from the last seven days, beginning from the provided starting_lsn. In this example, the stored procedure will copy transaction log backups from LSN 1490000000040007 up to the latest transaction log backup.</td>
</tr>
<tr>
<td>exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name='testdb1', @ending_lsn =1490000000050009;</td>
<td>Copies transaction log backups that are available from the last seven days, up to the provided ending_lsn. In this example, the stored procedure will copy transaction log backups beginning from the last seven days up to lsn 1490000000050009.</td>
</tr>

<tr>
<td>--------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name='testdb1', @rds_backup_starting_seq_id=2000; @rds_backup_ending_seq_id=2000;</td>
<td>Copies a single transaction log backup with the provided rds_backup_starting_seq_id, if available within the last seven days. In this example, the stored procedure will copy a single transaction log backup that has a seq_id of 2000, if it exists within the last seven days.</td>
</tr>
</tbody>
</table>

**Validating the transaction log backup log chain**

Databases configured for access to transaction log backups must have automated backup retention enabled. Automated backup retention sets the databases on the DB instance to the FULL recovery model. To support point in time restore for a database, avoid changing the database recovery model, which can result in a broken log chain. We recommend keeping the database set to the FULL recovery model.

To manually validate the log chain before copying transaction log backups, call the rds_fn_list_tlog_backup_metadata function and review the values in the is_log_chain_broken column. A value of “1” indicates the log chain was broken between the current log backup and the previous log backup.

The following example shows a broken log chain in the output from the rds_fn_list_tlog_backup_metadata stored procedure.

<table>
<thead>
<tr>
<th>rds_sequence_id</th>
<th>first_lsn</th>
<th>last_lsn</th>
<th>is_log_chain_broken</th>
</tr>
</thead>
<tbody>
<tr>
<td>43</td>
<td>90023</td>
<td>90457</td>
<td>0</td>
</tr>
<tr>
<td>44</td>
<td>90457</td>
<td>90985</td>
<td>0</td>
</tr>
<tr>
<td>45</td>
<td>90987</td>
<td>92034</td>
<td>1</td>
</tr>
</tbody>
</table>

In a normal log chain, the log sequence number (LSN) value for first_lsn for given rds_sequence_id should match the value of last_lsn in the preceding rds_sequence_id. In the image, the rds_sequence_id of 45 has a first_lsn value 90987, which does not match the last_lsn value of 90985 for preceding rds_sequence_id 44.

For more information about SQL Server transaction log architecture and log sequence numbers, see [Transaction Log Logical Architecture](#) in the Microsoft SQL Server documentation.

**Amazon S3 bucket folder and file structure**

Transaction log backups have the following standard structure and naming convention within an Amazon S3 bucket:

- A new folder is created under the target_s3_arn path for each database with the naming structure as `{db_id}.{family_guid}`.
- Within the folder, transaction log backups have a filename structure as `{db_id}.{family_guid}.{rds_backup_seq_id}.{backup_file_epoch}`.
• You can view the details of family_guid, db_id, rds_backup_seq_id and backup_file_epoch with the rds_fn_list_tlog_backup_metadata function.

The following example shows the folder and file structure of a set of transaction log backups within an Amazon S3 bucket.

### Tracking the status of tasks

To track the status of your copy tasks, call the rds_task_status stored procedure. If you don't provide any parameters, the stored procedure returns the status of all tasks.

**Example usage:**

```sql
exec msdb.dbo.rds_task_status
@db_name='database_name',
```
Access to transaction log backups

@task_id=ID_number;

The following parameters are optional:

- @db_name – The name of the database to show the task status for.
- @task_id – The ID of the task to show the task status for.

Example of listing the status for a specific task ID:

```
exec msdb.dbo.rds_task_status @task_id=5;
```

Example of listing the status for a specific database and task:

```
exec msdb.dbo.rds_task_status @db_name='my_database', @task_id=5;
```

Example of listing all tasks and their status for a specific database:

```
exec msdb.dbo.rds_task_status @db_name='my_database';
```

Example of listing all tasks and their status on the current DB instance:

```
exec msdb.dbo.rds_task_status;
```

**Canceling a task**

To cancel a running task, call the `rds_cancel_task` stored procedure.

**Example usage:**

```
exec msdb.dbo.rds_cancel_task @task_id=ID_number;
```

The following parameter is required:

- @task_id – The ID of the task to cancel. You can view the task ID by calling the `rds_task_status` stored procedure.

For more information on viewing and canceling running tasks, see Importing and exporting SQL Server databases using native backup and restore (p. 1435).

**Troubleshooting access to transaction log backups**

The following are issues you might encounter when you use the stored procedures for access to transaction log backups.

<table>
<thead>
<tr>
<th>Stored Procedure</th>

<th>Issue</th>
<th>Troubleshooting suggestions</th>
</tr>
</thead>
<tbody>
<tr>
<td>rds_tlog_backup_copy_to_S3</td>
<td>You must run the rds_tlog_copy_setup stored procedure and set the @target_s3_arn, before running the rds_tlog_backup_copy_to_S3 stored procedure.</td>
<td>The access to transaction log backups setup procedure was not completed before attempting to run the rds_tlog_backup_copy_to_S3 stored procedure.</td>
<td>Run the rds_tlog_copy_setup stored procedure before running the rds_tlog_backup_copy_to_S3 stored procedure. For more information on running the setup procedure for access to transaction log backups, see Setting up access to transaction log backups (p. 1512).</td>
</tr>
</tbody>
</table>
Options for the Microsoft SQL Server database engine

In this section, you can find descriptions for options that are available for Amazon RDS instances running the Microsoft SQL Server DB engine. To enable these options, you add them to an option group, and then associate the option group with your DB instance. For more information, see Working with option groups (p. 331).

If you're looking for optional features that aren't added through RDS option groups (such as SSL, Microsoft Windows Authentication, and Amazon S3 integration), see Additional features for Microsoft SQL Server on Amazon RDS (p. 1471).

Amazon RDS supports the following options for Microsoft SQL Server DB instances.

<table>
<thead>
<tr>
<th>Option</th>
<th>Option ID</th>
<th>Engine editions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linked Servers with Oracle OLEDB</td>
<td>OLEDB_ORACLE</td>
<td>SQL Server Enterprise Edition</td>
</tr>
<tr>

<td>SQLSERVER_AUDIT</td>
<td>In RDS, starting with SQL Server 2014, all editions of SQL Server support server-level audits, and Enterprise Edition also supports database-level audits. Starting with SQL Server SQL Server 2016 (13.x) SP1, all editions support both server-level and database-level audits. For more information, see SQL Server Audit (database engine)</td>
</tr>
</tbody>
</table>
Listing the available options for SQL Server versions and editions

You can use the `describe-option-group-options` AWS CLI command to list the available options for SQL Server versions and editions, and the settings for those options.

The following example shows the options and option settings for SQL Server 2019 Enterprise Edition. The `--engine-name` option is required.

```
aws rds describe-option-group-options --engine-name sqlserver-ee --major-engine-version 15.00
```

The output resembles the following:

```
{
  "OptionGroupOptions": [
    {
      "Name": "MSDTC",
      "Description": "Microsoft Distributed Transaction Coordinator",
      "EngineName": "sqlserver-ee",
      "MajorEngineVersion": "15.00",

]
Support for Linked Servers with Oracle OLEDB in Amazon RDS for SQL Server

Linked servers with the Oracle Provider for OLEDB on RDS for SQL Server lets you access external data sources on an Oracle database. You can read data from remote Oracle data sources and run commands against remote Oracle database servers outside of your RDS for SQL Server DB instance. Using linked servers with Oracle OLEDB, you can:

- Directly access data sources other than SQL Server
- Query against diverse Oracle data sources with the same query without moving the data
- Issue distributed queries, updates, commands, and transactions on data sources across an enterprise ecosystem
- Integrate connections to an Oracle database from within the Microsoft Business Intelligence suite (SSIS, SSRS, SSAS)
- Migrate from an Oracle database to RDS for SQL Server

You can activate one or more linked servers for Oracle on either an existing or new RDS for SQL Server DB instance. Then you can integrate external Oracle data sources with your DB instance.

Contents

- Supported versions and Regions (p. 1533)
- Limitations and recommendations (p. 1533)
- Activating linked servers with Oracle (p. 1534)
  - Creating the option group for OLEDB_ORACLE (p. 1534)
  - Adding the OLEDB_ORACLE option to the option group (p. 1535)
  - Associating the option group with your DB instance (p. 1536)
- Modifying OLEDB provider properties (p. 1537)
- Modifying OLEDB driver properties (p. 1538)
- Deactivating linked servers with Oracle (p. 1539)

Supported versions and Regions

RDS for SQL Server supports linked servers with Oracle OLEDB in all Regions for SQL Server Standard and Enterprise Editions on the following versions:

- SQL Server 2019, all versions
- SQL Server 2017, all versions

Linked servers with Oracle OLEDB is supported for the following Oracle Database versions:

- Oracle Database 21c, all versions
- Oracle Database 19c, all versions
- Oracle Database 18c, all versions

Limitations and recommendations

Keep in mind the following limitations and recommendations that apply to linked servers with Oracle OLEDB:
• Allow network traffic by adding the applicable TCP port in the security group for each RDS for SQL Server DB instance. For example, if you’re configuring a linked server between an EC2 Oracle DB instance and an RDS for SQL Server DB instance, then you must allow traffic from the IP address of the EC2 Oracle DB instance. You also must allow traffic on the port that SQL Server is using to listen for database communication. For more information on security groups, see Controlling access with security groups (p. 2697).

• Perform a reboot of the RDS for SQL Server DB instance after turning on, turning off, or modifying the OLEDB_ORACLE option in your option group. The option group status displays pending_reboot for these events and is required.

• Only simple authentication is supported with a user name and password for the Oracle data source.

• Open Database Connectivity (ODBC) drivers are not supported. Only the latest version of the OLEDB driver is supported.

• Distributed transactions (XA) are supported. To activate distributed transactions, turn on the MSDTC option in the Option Group for your DB instance and make sure XA transactions are turned on. For more information, see Support for Microsoft Distributed Transaction Coordinator in RDS for SQL Server (p. 1606).

• Creating data source names (DSNs) to use as a shortcut for a connection string is not supported.

• OLEDB driver tracing is not supported. You can use SQL Server Extended Events to trace OLEDB events. For more information, see Set up Extended Events in RDS for SQL Server.

• Access to the catalogs folder for an Oracle linked server is not supported using SQL Server Management Studio (SSMS).

Activating linked servers with Oracle

Activate linked servers with Oracle by adding the OLEDB_ORACLE option to your RDS for SQL Server DB instance. Use the following process:

1. Create a new option group, or choose an existing option group.
2. Add the OLEDB_ORACLE option to the option group.
3. Choose a version of the OLEDB driver to use.
4. Associate the option group with the DB instance.
5. Reboot the DB instance.

Creating the option group for OLEDB_ORACLE

To work with linked servers with Oracle, create an option group or modify an option group that corresponds to the SQL Server edition and version of the DB instance that you plan to use. To complete this procedure, use the AWS Management Console or the AWS CLI.

Console

The following procedure creates an option group for SQL Server Standard Edition 2019.

To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose Create group.
4. In the Create option group window, do the following:
a. For Name, enter a name for the option group that is unique within your AWS account, such as `oracle-oledb-se-2019`. The name can contain only letters, digits, and hyphens.

b. For Description, enter a brief description of the option group, such as `OLEDB_ORACLE option group for SQL Server SE 2019`. The description is used for display purposes.

c. For Engine, choose `sqlserver-se`.

d. For Major engine version, choose `15.00`.

5. Choose Create.

**CLI**

The following procedure creates an option group for SQL Server Standard Edition 2019.

**To create the option group**

- Run one of the following commands.

**Example**

For Linux, macOS, or Unix:

```
aws rds create-option-group
  --option-group-name oracle-oledb-se-2019
  --engine-name sqlserver-se
  --major-engine-version 15.00
  --option-group-description "OLEDB_ORACLE option group for SQL Server SE 2019"
```

For Windows:

```
aws rds create-option-group ^
  --option-group-name oracle-oledb-se-2019 ^
  --engine-name sqlserver-se ^
  --major-engine-version 15.00 ^
  --option-group-description "OLEDB_ORACLE option group for SQL Server SE 2019"
```

**Adding the OLEDB_ORACLE option to the option group**

Next, use the AWS Management Console or the AWS CLI to add the OLEDB_ORACLE option to your option group.

**Console**

**To add the OLEDB_ORACLE option**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created, which is `oracle-oledb-se-2019` in this example.
4. Choose **Add option**.
5. Under **Option details**, choose **OLEDB_ORACLE** for **Option name**.
6. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
7. Choose **Add option**.
CLI

To add the OLEDB_ORACLE option

- Add the OLEDB_ORACLE option to the option group.

**Example**

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group
   --option-group-name oracle-oledb-se-2019
   --options OptionName=OLEDB_ORACLE
   --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group
   --option-group-name oracle-oledb-se-2019
   --options OptionName=OLEDB_ORACLE
   --apply-immediately
```

Associating the option group with your DB instance

To associate the OLEDB_ORACLE option group and parameter group with your DB instance, use the AWS Management Console or the AWS CLI.

**Console**

To finish activating linked servers for Oracle, associate your OLEDB_ORACLE option group with a new or existing DB instance:

- For a new DB instance, associate them when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 300).
- For an existing DB instance, associate them by modifying the instance. For more information, see Modifying an Amazon RDS DB instance (p. 401).

**CLI**

You can associate the OLEDB_ORACLE option group and parameter group with a new or existing DB instance.

**To create an instance with the OLEDB_ORACLE option group and parameter group**

- Specify the same DB engine type and major version that you used when creating the option group.

**Example**

For Linux, macOS, or Unix:

```
aws rds create-db-instance
   --db-instance-identifier mytestsqlsveroracleoledbinstance
   --db-instance-class db.m5.2xlarge
   --engine sqlserver-se
   --engine-version 15.0.4236.7.v1
   --allocated-storage 100
   --manage-master-user-password
```
For Windows:

```bash
aws rds create-db-instance ^
   --db-instance-identifier mytestsqlserveroracleoledbinstance ^
   --db-instance-class db.m5.2xlarge ^
   --engine sqlserver-se ^
   --engine-version 15.0.4236.7.v1 ^
   --allocated-storage 100 ^
   --manage-master-user-password ^
   --master-username admin ^
   --storage-type gp2 ^
   --license-model li ^
   --domain-iam-role-name my-directory-iam-role ^
   --domain my-domain-id ^
   --option-group-name oracle-oledb-se-2019 ^
   --db-parameter-group-name my-parameter-group-name
```

To modify an instance and associate the OLEDB_ORACLE option group

- Run one of the following commands.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
   --db-instance-identifier mytestsqlserveroracleoledbinstance \
   --option-group-name oracle-oledb-se-2019 \
   --db-parameter-group-name my-parameter-group-name \
   --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
   --db-instance-identifier mytestsqlserveroracleoledbinstance ^
   --option-group-name oracle-oledb-se-2019 ^
   --db-parameter-group-name my-parameter-group-name ^
   --apply-immediately
```

**Modifying OLEDB provider properties**

You can view and change the properties of the OLEDB provider. Only the master user can perform this task. All linked servers for Oracle that are created on the DB instance use the same properties of that OLEDB provider. Call the `sp_MSset_oledb_prop` stored procedure to change the properties of the OLEDB provider.

To change the OLEDB provider properties
USE [master]
GO
EXEC sp_MSset_oledb_prop N'OraOLEDB.Oracle', N'AllowInProcess', 1
EXEC sp_MSset_oledb_prop N'OraOLEDB.Oracle', N'DynamicParameters', 0
GO
The following properties can be modified:

<table>
<thead>
<tr>
<th>Property name</th>
<th>Recommended Value (1 = On, 0 = Off)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic parameter</td>
<td>1</td>
<td>Allows SQL placeholders (represented by '?') in parameterized queries.</td>
</tr>
<tr>
<td>Nested queries</td>
<td>1</td>
<td>Allows nested SELECT statements in the FROM clause, such as sub-queries.</td>
</tr>
<tr>
<td>Level zero only</td>
<td>0</td>
<td>Only base-level OLEDB interfaces are called against the provider.</td>
</tr>
<tr>
<td>Allow inprocess</td>
<td>1</td>
<td>If turned on, Microsoft SQL Server allows the provider to be instantiated as an in-process server.</td>
</tr>
<tr>
<td>Non transacted updates</td>
<td>0</td>
<td>If non-zero, SQL Server allows updates.</td>
</tr>
<tr>
<td>Index as access path</td>
<td>False</td>
<td>If non-zero, SQL Server attempts to use indexes of the provider to fetch data.</td>
</tr>
<tr>
<td>Disallow adhoc access</td>
<td>False</td>
<td>If set, SQL Server does not allow running pass-through queries against the OLEDB provider.</td>
</tr>
<tr>
<td>Supports LIKE operator</td>
<td>1</td>
<td>Indicates that the provider supports queries using the LIKE keyword.</td>
</tr>
</tbody>
</table>

Modifying OLEDB driver properties

You can view and change the properties of the OLEDB driver when creating a linked server for Oracle. Only the master user can perform this task. Driver properties define how the OLEDB driver handles data when working with a remote Oracle data source. Driver properties are specific to each Oracle linked server created on the DB instance. Call the master.dbo.sp_addlinkedserver stored procedure to change the properties of the OLEDB driver.

Example: To create a linked server and change the OLEDB driver FetchSize property

```
EXEC master.dbo.sp_addlinkedserver
@server = N'Oracle_link2',
@srvproduct=N'Oracle',
@provider=N'OraOLEDB.Oracle',
@datasrc=N'my-oracle-test.cnetsipka.us-west-2.rds.amazonaws.com:1521/ORCL',
@provstr='FetchSize=200'
GO
```
EXEC master.dbo.sp_addlinkedsrvlogin
    @rmtsrvname=N'Oracle_link2',
    @useself=N'False',
    @locallogin=NULL,
    @rmtuser=N'master',
    @rmtpassword='Test#1234'
GO

Note
Specify a password other than the prompt shown here as a security best practice.

Deactivating linked servers with Oracle

To deactivate linked servers with Oracle, remove the OLEDB_ORACLE option from its option group.

Important
Removing the option doesn't delete the existing linked server configurations on the DB instance. You must manually drop them to remove them from the DB instance. You can reactivate the OLEDB_ORACLE option after removal to reuse the linked server configurations that were previously configured on the DB instance.

Console

The following procedure removes the OLEDB_ORACLE option.

To remove the OLEDB_ORACLE option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose the option group with the OLEDB_ORACLE option (oracle-oledb-se-2019 in the previous examples).
4. Choose Delete option.
5. Under Deletion options, choose OLEDB_ORACLE for Options to delete.
6. Under Apply immediately, choose Yes to delete the option immediately, or No to delete it during the next maintenance window.
7. Choose Delete.

CLI

The following procedure removes the OLEDB_ORACLE option.

To remove the OLEDB_ORACLE option from its option group

• Run one of the following commands.

Example

For Linux, macOS, or Unix:

```bash
aws rds remove-option-from-option-group --option-group-name oracle-oledb-se-2019
    --options OLEDB_ORACLE
    --apply-immediately
```

For Windows:
aws rds remove-option-from-option-group
  --option-group-name oracle-oledb-se-2019
  --options OLEDB_ORACLE
  --apply-immediately
Support for native backup and restore in SQL Server

By using native backup and restore for SQL Server databases, you can create a differential or full backup of your on-premises database and store the backup files on Amazon S3. You can then restore to an existing Amazon RDS DB instance running SQL Server. You can also back up an RDS for SQL Server database, store it on Amazon S3, and restore it in other locations. In addition, you can restore the backup to an on-premises server, or a different Amazon RDS DB instance running SQL Server. For more information, see Importing and exporting SQL Server databases using native backup and restore (p. 1435).

Amazon RDS supports native backup and restore for Microsoft SQL Server databases by using differential and full backup files (.bak files).

Adding the native backup and restore option

The general process for adding the native backup and restore option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the SQLSERVER_BACKUP_RESTORE option to the option group.
3. Associate an AWS Identity and Access Management (IAM) role with the option. The IAM role must have access to an S3 bucket to store the database backups.

   That is, the option must have as its option setting a valid Amazon Resource Name (ARN) in the format arn:aws:iam::account-id:role/role-name. For more information, see Amazon Resource Names (ARNs) in the AWS General Reference.

   The IAM role must also have a trust relationship and a permissions policy attached. The trust relationship allows RDS to assume the role, and the permissions policy defines the actions that the role can perform. For more information, see Manually creating an IAM role for native backup and restore (p. 1438).

4. Associate the option group with the DB instance.

After you add the native backup and restore option, you don't need to restart your DB instance. As soon as the option group is active, you can begin backing up and restoring immediately.

Console

To add the native backup and restore option

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Create a new option group or use an existing option group. For information on how to create a custom DB option group, see Creating an option group (p. 332).

   To use an existing option group, skip to the next step.

4. Add the SQLSERVER_BACKUP_RESTORE option to the option group. For more information about adding options, see Adding an option to an option group (p. 335).

5. Do one of the following:

   • To use an existing IAM role and Amazon S3 settings, choose an existing IAM role for IAM Role. If you use an existing IAM role, RDS uses the Amazon S3 settings configured for this role.

   • To create a new role and configure Amazon S3 settings, do the following:

     1. For IAM role, choose Create a new role.
2. For **S3 bucket**, choose an S3 bucket from the list.

3. For **S3 prefix (optional)**, specify a prefix to use for the files stored in your Amazon S3 bucket.

   This prefix can include a file path but doesn't have to. If you provide a prefix, RDS attaches that prefix to all backup files. RDS then uses the prefix during a restore to identify related files and ignore irrelevant files. For example, you might use the S3 bucket for purposes besides holding backup files. In this case, you can use the prefix to have RDS perform native backup and restore only on a particular folder and its subfolders.

   If you leave the prefix blank, then RDS doesn't use a prefix to identify backup files or files to restore. As a result, during a multiple-file restore, RDS attempts to restore every file in every folder of the S3 bucket.

4. Choose the **Enable encryption** check box to encrypt the backup file. Leave the check box cleared (the default) to have the backup file unencrypted.

   If you chose **Enable encryption**, choose an encryption key for **AWS KMS key**. For more information about encryption keys, see [Getting started](#) in the [AWS Key Management Service Developer Guide](#).

6. **Choose Add option.**

7. **Apply the option group to a new or existing DB instance:**

   - For a new DB instance, apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).
   - For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. For more information, see [Modifying an Amazon RDS DB instance](#).

**CLI**

This procedure makes the following assumptions:

- You're adding the SQLSERVER_BACKUP_RESTORE option to an option group that already exists. For more information about adding options, see [Adding an option to an option group](#).
- You're associating the option with an IAM role that already exists and has access to an S3 bucket to store the backups.
- You're applying the option group to a DB instance that already exists. For more information, see [Modifying an Amazon RDS DB instance](#).

**To add the native backup and restore option**

1. Add the SQLSERVER_BACKUP_RESTORE option to the option group.

   **Example**

   For Linux, macOS, or Unix:

   ```bash
   aws rds add-option-to-option-group \
   --apply-immediately \
   --option-group-name mybackupgroup \
   --options "OptionName=SQLSERVER_BACKUP_RESTORE,\n   OptionSettings=[{Name=IAM_ROLE_ARN,Value=arn:aws:iam::account-id:role/role-name}]"
   ```

   For Windows:

   ```bash
   aws rds add-option-to-option-group ^
   --option-group-name mybackupgroup ^
   ```
Native Interface backup and restore

```bash
--options "[
    {
      "OptionName": "SQLSERVER_BACKUP_RESTORE",
      "OptionSettings": [
        {
          "Name": "IAM_ROLE_ARN",
          "Value": "arn:aws:iam::account-id:role/role-name"
        }
      ]
    }
  ]",
--apply-immediately
```

**Note**

When using the Windows command prompt, you must escape double quotes (") in JSON code by prefixing them with a backslash (\).

2. Apply the option group to the DB instance.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance
--db-instance-identifier mydbinstance
--option-group-name mybackupgroup
--apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance
--db-instance-identifier mydbinstance
--option-group-name mybackupgroup
--apply-immediately
```

### Modifying native backup and restore option settings

After you enable the native backup and restore option, you can modify the settings for the option. For more information about how to modify option settings, see [Modifying an option setting](p. 340).

### Removing the native backup and restore option

You can turn off native backup and restore by removing the option from your DB instance. After you remove the native backup and restore option, you don't need to restart your DB instance.

To remove the native backup and restore option from a DB instance, do one of the following:

- Remove the option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see [Removing an option from an option group](p. 343).
- Modify the DB instance and specify a different option group that doesn't include the native backup and restore option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see [Modifying an Amazon RDS DB instance](p. 401).
Support for Transparent Data Encryption in SQL Server

Amazon RDS supports using Transparent Data Encryption (TDE) to encrypt stored data on your DB instances running Microsoft SQL Server. TDE automatically encrypts data before it is written to storage, and automatically decrypts data when the data is read from storage.

Amazon RDS supports TDE for the following SQL Server versions and editions:

- SQL Server 2019 Standard and Enterprise Editions
- SQL Server 2017 Enterprise Edition
- SQL Server 2016 Enterprise Edition
- SQL Server 2014 Enterprise Edition

Transparent Data Encryption for SQL Server provides encryption key management by using a two-tier key architecture. A certificate, which is generated from the database master key, is used to protect the data encryption keys. The database encryption key performs the actual encryption and decryption of data on the user database. Amazon RDS backs up and manages the database master key and the TDE certificate.

Transparent Data Encryption is used in scenarios where you need to encrypt sensitive data. For example, you might want to provide data files and backups to a third party, or address security-related regulatory compliance issues. You can't encrypt the system databases for SQL Server, such as the model or master databases.

A detailed discussion of Transparent Data Encryption is beyond the scope of this guide, but make sure that you understand the security strengths and weaknesses of each encryption algorithm and key. For information about Transparent Data Encryption for SQL Server, see Transparent Data Encryption (TDE) in the Microsoft documentation.

Topics

- Turning on TDE for RDS for SQL Server (p. 1544)
- Encrypting data on RDS for SQL Server (p. 1545)
- Backing up and restoring TDE certificates on RDS for SQL Server (p. 1546)
- Backing up and restoring TDE certificates for on-premises databases (p. 1549)
- Turning off TDE for RDS for SQL Server (p. 1551)

Turning on TDE for RDS for SQL Server

To turn on Transparent Data Encryption for an RDS for SQL Server DB instance, specify the TDE option in an RDS option group that's associated with that DB instance:

1. Determine whether your DB instance is already associated with an option group that has the TDE option. To view the option group that a DB instance is associated with, use the RDS console, the describe-db-instance AWS CLI command, or the API operation DescribeDBInstances.

2. If the DB instance isn't associated with an option group that has TDE turned on, you have two choices. You can create an option group and add the TDE option, or you can modify the associated option group to add it.

   Note
   In the RDS console, the option is named TRANSPARENT_DATA_ENCRYPTION. In the AWS CLI and RDS API, it's named TDE.
For information about creating or modifying an option group, see Working with option groups (p. 331). For information about adding an option to an option group, see Adding an option to an option group (p. 335).

3. Associate the DB instance with the option group that has the TDE option. For information about associating a DB instance with an option group, see Modifying an Amazon RDS DB instance (p. 401).

Option group considerations

The TDE option is a persistent option. You can't remove it from an option group unless all DB instances and backups are no longer associated with the option group. After you add the TDE option to an option group, the option group can be associated only with DB instances that use TDE. For more information about persistent options in an option group, see Option groups overview (p. 331).

Because the TDE option is a persistent option, you can have a conflict between the option group and an associated DB instance. You can have a conflict in the following situations:

- The current option group has the TDE option, and you replace it with an option group that doesn't have the TDE option.
- You restore from a DB snapshot to a new DB instance that doesn't have an option group that contains the TDE option. For more information about this scenario, see Option group considerations (p. 624).

SQL Server performance considerations

Using Transparent Data Encryption can affect the performance of a SQL Server DB instance.

Performance for unencrypted databases can also be degraded if the databases are on a DB instance that has at least one encrypted database. As a result, we recommend that you keep encrypted and unencrypted databases on separate DB instances.

Encrypting data on RDS for SQL Server

When the TDE option is added to an option group, Amazon RDS generates a certificate that's used in the encryption process. You can then use the certificate to run SQL statements that encrypt data in a database on the DB instance.

The following example uses the RDS-created certificate called RDSTDECertificateName to encrypt a database called myDatabase.

```
-------- Turning on TDE ---------

-- Find an RDS TDE certificate to use
USE [master]
GO
SELECT name FROM sys.certificates WHERE name LIKE 'RDSTDECertificate%'
GO

USE [myDatabase]
GO

-- Create a database encryption key (DEK) using one of the certificates from the previous step
CREATE DATABASE ENCRYPTION KEY WITH ALGORITHM = AES_256
ENCRYPTION BY SERVER CERTIFICATE [RDSTDECertificateName]
GO

-- Turn on encryption for the database
ALTER DATABASE [myDatabase] SET ENCRYPTION ON
GO
```
-- Verify that the database is encrypted
USE [master]
GO
SELECT name FROM sys.databases WHERE is_encrypted = 1
GO
SELECT db_name(database_id) as DatabaseName, * FROM sys.dm_database_encryption_keys
GO

The time that it takes to encrypt a SQL Server database using TDE depends on several factors. These include the size of the DB instance, whether the instance uses Provisioned IOPS storage, the amount of data, and other factors.

**Backing up and restoring TDE certificates on RDS for SQL Server**

RDS for SQL Server provides stored procedures for backing up, restoring, and dropping TDE certificates. RDS for SQL Server also provides a function for viewing restored user TDE certificates.

User TDE certificates are used to restore databases to RDS for SQL Server that are on-premises and have TDE turned on. These certificates have the prefix `UserTDECertificate_`. After restoring databases, and before making them available to use, RDS modifies the databases that have TDE turned on to use RDS-generated TDE certificates. These certificates have the prefix `RDSTDECertificate`.

User TDE certificates remain on the RDS for SQL Server DB instance, unless you drop them using the `rds_drop_tde_certificate` stored procedure. For more information, see [Dropping restored TDE certificates](p. 1549).

You can use a user TDE certificate to restore other databases from the source DB instance. The databases to restore must use the same TDE certificate and have TDE turned on. You don't have to import (restore) the same certificate again.

**Topics**

- Prerequisites (p. 1546)
- Limitations (p. 1547)
- Backing up a TDE certificate (p. 1547)
- Restoring a TDE certificate (p. 1548)
- Viewing restored TDE certificates (p. 1549)
- Dropping restored TDE certificates (p. 1549)

**Prerequisites**

Before you can back up or restore TDE certificates on RDS for SQL Server, make sure to perform the following tasks. The first three are described in [Setting up for native backup and restore](p. 1437).

1. Create Amazon S3 buckets for storing files to back up and restore.
   
   We recommend that you use separate buckets for database backups and for TDE certificate backups.
2. Create an IAM role for backing up and restoring files.
   
   The IAM role must be both a user and an administrator for the AWS KMS key.

   In addition to the permissions required for SQL Server native backup and restore, the IAM role also requires the following permissions:
   - `s3:GetBucketACL`, `s3:GetBucketLocation`, and `s3:ListBucket` on the S3 bucket resource
   - `s3:ListAllMyBuckets` on the * resource
3. Add the SQLSERVER_BACKUP_RESTORE option to an option group on your DB instance.

   This is in addition to the TRANSPARENT_DATA_ENCRYPTION (TDE) option.

4. Make sure that you have a symmetric encryption KMS key. You have the following options:
   - If you have an existing KMS key in your account, you can use it. No further action is necessary.
   - If you don’t have an existing symmetric encryption KMS key in your account, create a KMS key by
     following the instructions in Creating keys in the AWS Key Management Service Developer Guide.

5. Enable Amazon S3 integration to transfer files between the DB instance and Amazon S3.

   For more information on enabling Amazon S3 integration, see Integrating an Amazon RDS for SQL
   Server DB instance with Amazon S3 (p. 1480).

Limitations

Using stored procedures to back up and restore TDE certificates has the following limitations:

- Both the SQLSERVER_BACKUP_RESTORE and TRANSPARENT_DATA_ENCRYPTION (TDE) options must
  be added to the option group that you associated with your DB instance.
- TDE certificate backup and restore aren’t supported on Multi-AZ DB instances.
- Canceling TDE certificate backup and restore tasks isn’t supported.
- You can’t use a user TDE certificate for TDE encryption of any other database on your RDS for SQL
  Server DB instance. You can use it to restore only other databases from the source DB instance that
  have TDE turned on and that use the same TDE certificate.
- You can drop only user TDE certificates.
- The maximum number of user TDE certificates supported on RDS is 10. If the number exceeds 10, drop
  unused TDE certificates and try again.
- The certificate name can’t be empty or null.
- When restoring a certificate, the certificate name can’t include the keyword RDSTDECERTIFICATE,
  and must start with the UserTDECertificate_prefix.
- The @certificate_name parameter can include only the following characters: a-z, 0-9, @, $, #, and
  underscore (_).
- The file extension for @certificate_file_s3_arn must be .cer (case-insensitive).
- The file extension for @private_key_file_s3_arn must be .pvk (case-insensitive).
- The S3 metadata for the private key file must include the x-amz-meta-rds-tde-pwd tag. For more
  information, see Backing up and restoring TDE certificates for on-premises databases (p. 1549).

Backing up a TDE certificate

To back up TDE certificates, use the rds_backup_tde_certificate stored procedure. It has the
following syntax.

```sql
EXECUTE msdb.dbo.rds_backup_tde_certificate
    @certificate_name='UserTDECertificate_certificate_name | RDSTDECertificateTimestamp',
    @certificate_file_s3_arn='arn:aws:s3:::bucket_name/certificate_file_name.cer',
    @private_key_file_s3_arn='arn:aws:s3:::bucket_name/key_file_name.pvk',
    @kms_password_key_arn='arn:aws:kms:region:account-id:key/key-id',
    [@overwrite_s3_files=0|1];
```

The following parameters are required:

- @certificate_name – The name of the TDE certificate to back up.
• @certificate_file_s3_arn – The destination Amazon Resource Name (ARN) for the certificate backup file in Amazon S3.
• @private_key_file_s3_arn – The destination S3 ARN of the private key file that secures the TDE certificate.
• @kms_password_key_arn – The ARN of the symmetric KMS key used to encrypt the private key password.

The following parameter is optional:

• @overwrite_s3_files – Indicates whether to overwrite the existing certificate and private key files in S3:
  • 0 – Doesn't overwrite the existing files. This value is the default.
  • 1 – Overwrites an existing file to 0 returns an error if a file already exists.

Example of backing up a TDE certificate

```sql
EXECUTE msdb.dbo.rds_backup_tde_certificate
    @certificate_name='RDSTDECertificate20211115T185333',
    @certificate_file_s3_arn='arn:aws:s3:::TDE_certs/mycertfile.cer',
    @private_key_file_s3_arn='arn:aws:s3:::TDE_certs/mykeyfile.pvk',
    @kms_password_key_arn='arn:aws:kms:us-west-2:123456789012:key/AKIAIOSFODNN7EXAMPLE',
    @overwrite_s3_files=1;
```

Restoring a TDE certificate

You use the `rds_restore_tde_certificate` stored procedure to restore (import) user TDE certificates. It has the following syntax.

```sql
EXECUTE msdb.dbo.rds_restore_tde_certificate
    @certificate_name='UserTDECertificate_certificate_name',
    @certificate_file_s3_arn='arn:aws:s3:::bucket_name/certificate_file_name.cer',
    @private_key_file_s3_arn='arn:aws:s3:::bucket_name/key_file_name.pvk',
    @kms_password_key_arn='arn:aws:kms:region:account-id:key/key-id';
```

The following parameters are required:

• @certificate_name – The name of the TDE certificate to restore. The name must start with the UserTDECertificate prefix.
• @certificate_file_s3_arn – The S3 ARN of the backup file used to restore the TDE certificate.
• @private_key_file_s3_arn – The S3 ARN of the private key backup file of the TDE certificate to be restored.
• @kms_password_key_arn – The ARN of the symmetric KMS key used to encrypt the private key password.

Example of restoring a TDE certificate

```sql
EXECUTE msdb.dbo.rds_restore_tde_certificate
    @certificate_name='UserTDECertificate_myTDEcertificate',
    @certificate_file_s3_arn='arn:aws:s3:::TDE_certs/mycertfile.cer',
    @private_key_file_s3_arn='arn:aws:s3:::TDE_certs/mykeyfile.pvk',
    @kms_password_key_arn='arn:aws:kms:us-west-2:123456789012:key/AKIAIOSFODNN7EXAMPLE';
```
Viewing restored TDE certificates

You use the `rds_fn_list_user_tde_certificates` function to view restored (imported) user TDE certificates. It has the following syntax.

```
SELECT * FROM msdb.dbo.rds_fn_list_user_tde_certificates();
```

The output resembles the following. Not all columns are shown here.

<table>
<thead>
<tr>
<th>name</th>
<th>certificate_id</th>
<th>principal_id</th>
<th>pvt_key_encryption_type_desc</th>
<th>issuer_name</th>
<th>cert_serial_number</th>
<th>thumbprint</th>
<th>subject</th>
<th>start_date</th>
<th>expiry_date</th>
<th>pvt_key_last_backup_date</th>
</tr>
</thead>

Dropping restored TDE certificates

To drop restored (imported) user TDE certificates that you aren't using, use the `rds_drop_tde_certificate` stored procedure. It has the following syntax.

```
EXECUTE msdb.dbo.rds_drop_tde_certificate
@certificate_name='UserTDECertificate_certificate_name';
```

The following parameter is required:

- `@certificate_name` – The name of the TDE certificate to drop.

You can drop only restored (imported) TDE certificates. You can't drop RDS-created certificates.

Example of dropping a TDE certificate

```
EXECUTE msdb.dbo.rds_drop_tde_certificate
@certificate_name='UserTDECertificate_myTDEcertificate';
```

Backing up and restoring TDE certificates for on-premises databases

You can back up TDE certificates for on-premises databases, then later restore them to RDS for SQL Server. You can also restore an RDS for SQL Server TDE certificate to an on-premises DB instance.

The following procedure backs up a TDE certificate and private key. The private key is encrypted using a data key generated from your symmetric encryption KMS key.

To back up an on-premises TDE certificate

1. Generate the data key using the AWS CLI `generate-data-key` command.

   ```
   aws kms generate-data-key \
   ```
Amazon Relational Database Service User Guide
Transparent Data Encryption

```bash
--key-id my_KMS_key_ID \
--key-spec AES_256
```

The output resembles the following.

```json
{
    "CiphertextBlob": "AQIDAHimL2NEoAI0Y68n7Ljfnxi/OZe9kTQo/QXxdug1merrwGL7g5ux4av9GFZLxYTDATAAAAFjBBQgkqhk1G9w0B
    BwagzBtAgEAMGgCqSgS1b3DQEHATAcg7lgkbg2QMEAS4sEQQMyCxLMI7GRZgKqD6s5AgEQgDtjvZLJo2cQ31Vetngzm2ybHDo
    2RezQy3sAS6ZHcCjfnfn0c65bFdhxXjSMnudY7AKw==",
    "Plaintext": "U/fpGtmzGCYBi8A2+0/9qcRQRK2zmG/a0n939ZnK1/0=",
    "KeyId": "arn:aws:kms:us-west-2:123456789012:key/1234abcd-00ee-99ff-88dd-aa11bb22cc33"
}
```

You use the plain text output in the next step as the private key password.

2. Back up your TDE certificate as shown in the following example.

```sql
BACKUP CERTIFICATE myOnPremTDECertificate TO FILE = 'D:\tde-cert-backup.cer'
WITH PRIVATE KEY (FILE = 'C:\Program Files\Microsoft SQL Server\MSSQL14.MSSQLSERVER\MSSQL\DATA\cert-backup-key.pvk',
    ENCRYPTION BY PASSWORD = 'U/fpGtmzGCYBi8A2+0/9qcRQRK2zmG/a0n939ZnK1/0');
```

3. Save the certificate backup file to your Amazon S3 certificate bucket.

4. Save the private key backup file to your S3 certificate bucket, with the following tag in the file's metadata:

   - **Key** – x-amz-meta-rds-tde-pwd
   - **Value** – The CiphertextBlob value from generating the data key, as in the following example.

   ```text
   AQIDAHimL2NEoAI0Y68n7Ljfnxi/OZe9kTQo/QXxdug1merrwGL7g5ux4av9GFZLxYTDATAAAAFjBBQgkqhk1G9w0B
   BwagzBtAgEAMGgCqSgS1b3DQEHATAcg7lgkbg2QMEAS4sEQQMyCxLMI7GRZgKqD6s5AgEQgDtjvZLJo2cQ31Vetngzm2ybHDo
   2RezQy3sAS6ZHcCjfnfn0c65bFdhxXjSMnudY7AKw==
   ```

The following procedure restores an RDS for SQL Server TDE certificate to an on-premises DB instance. You copy and restore the TDE certificate on your destination DB instance using the certificate backup, corresponding private key file, and data key. The restored certificate is encrypted by the database master key of the new server.

### To restore a TDE certificate

1. Copy the TDE certificate backup file and private key file from Amazon S3 to the destination instance. For more information on copying files from Amazon S3, see Transferring files between RDS for SQL Server and Amazon S3 (p. 1487).

2. Use your KMS key to decrypt the output cipher text to retrieve the plain text of the data key. The cipher text is located in the S3 metadata of the private key backup file.

   ```bash
   aws kms decrypt \
   --key-id my_KMS_key_ID \
   --ciphertext-blob fileb://exampleCiphertextFile | base64 -d \
   --output text \
   --query Plaintext
   ```

   You use the plain text output in the next step as the private key password.

3. Use the following SQL command to restore your TDE certificate.
CREATE CERTIFICATE myOnPremTDEcertificate FROM FILE='D:\tde-cert-backup.cer'
WITH PRIVATE KEY (FILE = N'D:\tde-cert-key.pvk',
DECRYPTION BY PASSWORD = 'plain_text_output');

For more information on KMS decryption, see decrypt in the KMS section of the AWS CLI Command Reference.

After the TDE certificate is restored on the destination DB instance, you can restore encrypted databases with that certificate.

Note
You can use the same TDE certificate to encrypt multiple SQL Server databases on the source DB instance. To migrate multiple databases to a destination instance, copy the TDE certificate associated with them to the destination instance only once.

Turning off TDE for RDS for SQL Server

To turn off TDE for an RDS for SQL Server DB instance, first make sure that there are no encrypted objects left on the DB instance. To do so, either decrypt the objects or drop them. If any encrypted objects exist on the DB instance, you can't turn off TDE for the DB instance. When you use the console to remove the TDE option from an option group, the console indicates that it's processing. In addition, an error event is created if the option group is associated with an encrypted DB instance or DB snapshot.

The following example removes the TDE encryption from a database called customerDatabase.

------------- Removing TDE ----------------
USE [customerDatabase]
GO
-- Turn off encryption of the database
ALTER DATABASE [customerDatabase]
SET ENCRYPTION OFF
GO

-- Wait until the encryption state of the database becomes 1. The state is 5 (Decryption in progress) for a while
SELECT db_name(database_id) as DatabaseName, * FROM sys.dm_database_encryption_keys
GO

-- Drop the DEK used for encryption
DROP DATABASE ENCRYPTION KEY
GO

-- Alter to SIMPLE Recovery mode so that your encrypted log gets truncated
USE [master]
GO
ALTER DATABASE [customerDatabase] SET RECOVERY SIMPLE
GO

When all objects are decrypted, you have two options:

1. You can modify the DB instance to be associated with an option group without the TDE option.
2. You can remove the TDE option from the option group.
SQL Server Audit

In Amazon RDS, you can audit Microsoft SQL Server databases by using the built-in SQL Server auditing mechanism. You can create audits and audit specifications in the same way that you create them for on-premises database servers.

RDS uploads the completed audit logs to your S3 bucket, using the IAM role that you provide. If you enable retention, RDS keeps your audit logs on your DB instance for the configured period of time.

For more information, see SQL Server Audit (database engine) in the Microsoft SQL Server documentation.

SQL Server Audit with Database Activity Streams

You can use Database Activity Streams for RDS to integrate SQL Server Audit events with database activity monitoring tools from Imperva, McAfee, and IBM. For more information about auditing with Database Activity Streams for RDS SQL Server, see Auditing in Microsoft SQL Server (p. 945)

Topics
- Support for SQL Server Audit (p. 1552)
- Adding SQL Server Audit to the DB instance options (p. 1553)
- Using SQL Server Audit (p. 1554)
- Viewing audit logs (p. 1554)
- Using SQL Server Audit with Multi-AZ instances (p. 1555)
- Configuring an S3 bucket (p. 1555)
- Manually creating an IAM role for SQL Server Audit (p. 1556)

Support for SQL Server Audit

In Amazon RDS, starting with SQL Server 2014, all editions of SQL Server support server-level audits, and the Enterprise edition also supports database-level audits. Starting with SQL Server 2016 (13.x) SP1, all editions support both server-level and database-level audits. For more information, see SQL Server Audit (database engine) in the SQL Server documentation.

RDS supports configuring the following option settings for SQL Server Audit.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IAM_ROLE_ARN</td>
<td>A valid Amazon Resource Name (ARN) in the format arn:aws:iam::account-id:role/role-name.</td>
<td>The ARN of the IAM role that grants access to the S3 bucket where you want to store your audit logs. For more information, see Amazon Resource Names (ARNs) in the AWS General Reference.</td>
</tr>
<tr>
<td>S3_BUCKET_ARN</td>
<td>A valid ARN in the format arn:aws:s3:::bucket-name or arn:aws:s3:::bucket-name/key-prefix</td>
<td>The ARN for the S3 bucket where you want to store your audit logs.</td>
</tr>
<tr>
<td>ENABLE_COMPRESSION</td>
<td>true or false</td>
<td>Controls audit log compression. By default, compression is enabled (set to true).</td>
</tr>
<tr>
<td>Option setting</td>
<td>Valid values</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>--------------</td>
<td>-------------</td>
</tr>
<tr>
<td>RETENTION_TIME</td>
<td>0 to 840</td>
<td>The retention time (in hours) that SQL Server audit records are kept on your RDS instance. By default, retention is disabled.</td>
</tr>
</tbody>
</table>

RDS supports SQL Server Audit in all AWS Regions except Middle East (Bahrain).

**Adding SQL Server Audit to the DB instance options**

Enabling SQL Server Audit requires two steps: enabling the option on the DB instance, and enabling the feature inside SQL Server. The process for adding the SQL Server Audit option to a DB instance is as follows:

1. Create a new option group, or copy or modify an existing option group.
2. Add and configure all required options.
3. Associate the option group with the DB instance.

After you add the SQL Server Audit option, you don't need to restart your DB instance. As soon as the option group is active, you can create audits and store audit logs in your S3 bucket.

**To add and configure SQL Server Audit on a DB instance's option group**

1. Choose one of the following:
   - Use an existing option group.
   - Create a custom DB option group and use that option group. For more information, see [Creating an option group](p. 332).
2. Add the SQLSERVER_AUDIT option to the option group, and configure the option settings. For more information about adding options, see [Adding an option to an option group](p. 335).
   - For IAM role, if you already have an IAM role with the required policies, you can choose that role. To create a new IAM role, choose [Create a New Role](p. 1556).
   - For **Select S3 destination**, if you already have an S3 bucket that you want to use, choose it. To create an S3 bucket, choose [Create a New S3 Bucket](p. 367).
   - For **Enable Compression**, leave this option chosen to compress audit files. Compression is enabled by default. To disable compression, clear **Enable Compression**.
   - For **Audit log retention**, to keep audit records on the DB instance, choose this option. Specify a retention time in hours. The maximum retention time is 35 days.
3. Apply the option group to a new or existing DB instance. Choose one of the following:
   - If you are creating a new DB instance, apply the option group when you launch the instance.
   - On an existing DB instance, apply the option group by modifying the instance and then attaching the new option group. For more information, see [Modifying an Amazon RDS DB instance](p. 401).

**Modifying the SQL Server Audit option**

After you enable the SQL Server Audit option, you can modify the settings. For information about how to modify option settings, see [Modifying an option setting](p. 340).
Removing SQL Server Audit from the DB instance options

You can turn off the SQL Server Audit feature by disabling audits and then deleting the option.

To remove auditing

1. Disable all of the audit settings inside SQL Server. To learn where audits are running, query the SQL Server security catalog views. For more information, see Security catalog views in the Microsoft SQL Server documentation.
2. Delete the SQL Server Audit option from the DB instance. Choose one of the following:
   - Delete the SQL Server Audit option from the option group that the DB instance uses. This change affects all DB instances that use the same option group. For more information, see Removing an option from an option group (p. 343).
   - Modify the DB instance, and then choose an option group without the SQL Server Audit option. This change affects only the DB instance that you modify. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 401).
3. After you delete the SQL Server Audit option from the DB instance, you don't need to restart the instance. Remove unneeded audit files from your S3 bucket.

Using SQL Server Audit

You can control server audits, server audit specifications, and database audit specifications the same way that you control them for on-premises database servers.

Creating audits

You create server audits in the same way that you create them for on-premises database servers. For information about how to create server audits, see CREATE SERVER AUDIT in the Microsoft SQL Server documentation.

To avoid errors, adhere to the following limitations:

- Don't exceed the maximum number of supported server audits per instance of 50.
- Instruct SQL Server to write data to a binary file.
- Don't use RDS_ as a prefix in the server audit name.
- For FILEPATH, specify D:\rdsdbdata\SQLAudit.
- For MAXSIZE, specify a size between 2 MB and 50 MB.
- Don't configure MAX_ROLLOVER_FILES or MAX_FILES.
- Don't configure SQL Server to shut down the DB instance if it fails to write the audit record.

Creating audit specifications

You create server audit specifications and database audit specifications the same way that you create them for on-premises database servers. For information about creating audit specifications, see CREATE SERVER AUDIT SPECIFICATION and CREATE DATABASE AUDIT SPECIFICATION in the Microsoft SQL Server documentation.

To avoid errors, don't use RDS_ as a prefix in the name of the database audit specification or server audit specification.

Viewing audit logs

Your audit logs are stored in D:\rdsdbdata\SQLAudit.
After SQL Server finishes writing to an audit log file—when the file reaches its size limit—Amazon RDS uploads the file to your S3 bucket. If retention is enabled, Amazon RDS moves the file into the retention folder: D:\rdsdbdata\SQLAudit\transmitted.

For information about configuring retention, see Adding SQL Server Audit to the DB instance options (p. 1553).

Audit records are kept on the DB instance until the audit log file is uploaded. You can view the audit records by running the following command.

```sql
SELECT   *
FROM msdb.dbo.rds_fn_get_audit_file
('D:\rdsdbdata\SQLAudit\*.sqlaudit', default, default )
```

You can use the same command to view audit records in your retention folder by changing the filter to D:\rdsdbdata\SQLAudit\transmitted\*.sqlaudit.

```sql
SELECT   *
FROM msdb.dbo.rds_fn_get_audit_file
('D:\rdsdbdata\SQLAudit\transmitted\*.sqlaudit', default, default )
```

**Using SQL Server Audit with Multi-AZ instances**

For Multi-AZ instances, the process for sending audit log files to Amazon S3 is similar to the process for Single-AZ instances. However, there are some important differences:

- Database audit specification objects are replicated to all nodes.
- Server audits and server audit specifications aren't replicated to secondary nodes. Instead, you have to create or modify them manually.

To capture server audits or a server audit specification from both nodes:

1. Create a server audit or a server audit specification on the primary node.
2. Fail over to the secondary node and create a server audit or a server audit specification with the same name and GUID on the secondary node. Use the `AUDIT_GUID` parameter to specify the GUID.

**Configuring an S3 bucket**

The audit log files are automatically uploaded from the DB instance to your S3 bucket. The following restrictions apply to the S3 bucket that you use as a target for audit files:

- It must be in the same AWS Region as the DB instance.
- It must not be open to the public.
- It can't use S3 Object Lock.
- The bucket owner must also be the IAM role owner.

The target key that is used to store the data follows this naming schema: bucket-name/key-prefix/instance-name/audit-name/node_file-name.ext
Note
You set both the bucket name and the key prefix values with the (S3_BUCKET_ARN) option setting.

The schema is composed of the following elements:

- **bucket-name** – The name of your S3 bucket.
- **key-prefix** – The custom key prefix you want to use for audit logs.
- **instance-name** – The name of your Amazon RDS instance.
- **audit-name** – The name of the audit.
- **node** – The identifier of the node that is the source of the audit logs (node1 or node2). There is one node for a Single-AZ instance and two replication nodes for a Multi-AZ instance. These are not primary and secondary nodes, because the roles of primary and secondary change over time. Instead, the node identifier is a simple label.
  - **node1** – The first replication node (Single-AZ has one node only).
  - **node2** – The second replication node (Multi-AZ has two nodes).
- **file-name** – The target file name. The file name is taken as-is from SQL Server.
- **ext** – The extension of the file (zip or sqlaudit):
  - **zip** – If compression is enabled (default).
  - **sqlaudit** – If compression is disabled.

Manually creating an IAM role for SQL Server Audit

Typically, when you create a new option, the AWS Management Console creates the IAM role and the IAM trust policy for you. However, you can manually create a new IAM role to use with SQL Server Audits, so that you can customize it with any additional requirements you might have. To do this, you create an IAM role and delegate permissions so that the Amazon RDS service can use your Amazon S3 bucket. When you create this IAM role, you attach trust and permissions policies. The trust policy allows Amazon RDS to assume this role. The permission policy defines the actions that this role can do. For more information, see [Creating a role to delegate permissions to an AWS service](https://docs.aws.amazon.com/IAM/latest/userguide/iam-product-overview.html) in the *AWS Identity and Access Management User Guide*.

You can use the examples in this section to create the trust relationships and permissions policies you need.

The following example shows a trust relationship for SQL Server Audit. It uses the *service principal* `rds.amazonaws.com` to allow RDS to write to the S3 bucket. A *service principal* is an identifier that is used to grant permissions to a service. Anytime you allow access to `rds.amazonaws.com` in this way, you are allowing RDS to perform an action on your behalf. For more information about service principals, see [AWS JSON policy elements: Principal](https://docs.aws.amazon.com/IAM/latest/userguide/reference-policies-conditions-syntax.html).

**Example trust relationship for SQL Server Audit**

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```
We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based trust relationships to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role. For SQL Server Audit, make sure to include both the DB option group and the DB instances, as shown in the following example.

**Example trust relationship with global condition context key for SQL Server Audit**

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceArn": [
            "arn:aws:rds:Region:my_account_ID:og:option_group_name"
          ]
        }
      }
    }
  ]
}
```

In the following example of a permissions policy for SQL Server Audit, we specify an ARN for the Amazon S3 bucket. You can use ARNs to identify a specific account, user, or role that you want grant access to. For more information about using ARNs, see [Amazon resource names (ARNS)](https://docs.aws.amazon.com/general/latest/gr/aws-arns-and-namespaces.html).

**Example permissions policy for SQL Server Audit**

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "s3:ListAllMyBuckets",
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListBucket",
        "s3:GetBucketACL",
        "s3:GetBucketLocation"
      ]
    }
  ]
}
```
"Resource": "arn:aws:s3:::bucket_name"
},
{
"Effect": "Allow",
"Action": [
"s3:PutObject",
"s3:ListMultipartUploadParts",
"s3:AbortMultipartUpload"
],
"Resource": "arn:aws:s3:::bucket_name/key_prefix/*"
}
]
}

Note
The s3:ListAllMyBuckets action is required for verifying that the same AWS account owns both the S3 bucket and the SQL Server DB instance. The action lists the names of the buckets in the account.
S3 bucket namespaces are global. If you accidentally delete your bucket, another user can create a bucket with the same name in a different account. Then the SQL Server Audit data is written to the new bucket.
Support for SQL Server Analysis Services in Amazon RDS for SQL Server

Microsoft SQL Server Analysis Services (SSAS) is part of the Microsoft Business Intelligence (MSBI) suite. SSAS is an online analytical processing (OLAP) and data mining tool that is installed within SQL Server. You use SSAS to analyze data to help make business decisions. SSAS differs from the SQL Server relational database because SSAS is optimized for queries and calculations common in a business intelligence environment.

You can turn on SSAS for existing or new DB instances. It's installed on the same DB instance as your database engine. For more information on SSAS, see the Microsoft Analysis services documentation.

Amazon RDS supports SSAS for SQL Server Standard and Enterprise Editions on the following versions:

- **Tabular mode:**
  - SQL Server 2019, version 15.00.4043.16.v1 and higher
  - SQL Server 2017, version 14.00.3223.3.v1 and higher
  - SQL Server 2016, version 13.00.5426.0.v1 and higher

- **Multidimensional mode:**
  - SQL Server 2017, version 14.00.3381.3.v1 and higher
  - SQL Server 2016, version 13.00.5882.1.v1 and higher

Limitations

The following limitations apply to using SSAS on RDS for SQL Server:
• RDS for SQL Server supports running SSAS in Tabular or Multidimensional mode. For more information, see Comparing tabular and multidimensional solutions in the Microsoft documentation.

• You can only use one SSAS mode at a time. Before changing modes, make sure to delete all of the SSAS databases.

  For more information, see Changing the SSAS mode (p. 1573).

• Multidimensional mode isn't supported on SQL Server 2019.

• Multi-AZ instances aren't supported.

• Instances must use self-managed Active Directory or AWS Directory Service for Microsoft Active Directory for SSAS authentication. For more information, see Working with Active Directory with RDS for SQL Server (p. 1403).

• Users aren't given SSAS server administrator access, but they can be granted database-level administrator access.

• The only supported port for accessing SSAS is 2383.

• You can't deploy projects directly. We provide an RDS stored procedure to do this. For more information, see Deploying SSAS projects on Amazon RDS (p. 1565).

• Processing during deployment isn't supported.

• Using .xmla files for deployment isn't supported.

• SSAS project input files and database backup output files can only be in the D:\S3 folder on the DB instance.

### Turning on SSAS

Use the following process to turn on SSAS for your DB instance:

1. Create a new option group, or choose an existing option group.
2. Add the SSAS option to the option group.
3. Associate the option group with the DB instance.
4. Allow inbound access to the virtual private cloud (VPC) security group for the SSAS listener port.
5. Turn on Amazon S3 integration.

### Creating an option group for SSAS

Use the AWS Management Console or the AWS CLI to create an option group that corresponds to the SQL Server engine and version of the DB instance that you plan to use.

**Note**

You can also use an existing option group if it's for the correct SQL Server engine and version.

**Console**

The following console procedure creates an option group for SQL Server Standard Edition 2017.

**To create the option group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** pane, do the following:
   a. For **Name**, enter a name for the option group that is unique within your AWS account, such as `ssas-se-2017`. The name can contain only letters, digits, and hyphens.
   b. For **Description**, enter a brief description of the option group, such as **SSAS option group for SQL Server SE 2017**. The description is used for display purposes.
   c. For **Engine**, choose `sqlserver-se`.
   d. For **Major engine version**, choose `14.00`.
5. Choose **Create**.

**CLI**

The following CLI example creates an option group for SQL Server Standard Edition 2017.

**To create the option group**

- Use one of the following commands.

**Example**

For Linux, macOS, or Unix:

```
aws rds create-option-group \
    --option-group-name ssas-se-2017 \
    --engine-name sqlserver-se \
    --major-engine-version 14.00 \
    --option-group-description "SSAS option group for SQL Server SE 2017"
```

For Windows:

```
aws rds create-option-group ^
    --option-group-name ssas-se-2017 ^
    --engine-name sqlserver-se ^
    --major-engine-version 14.00 ^
    --option-group-description "SSAS option group for SQL Server SE 2017"
```

**Adding the SSAS option to the option group**

Next, use the AWS Management Console or the AWS CLI to add the SSAS option to the option group.

**Console**

**To add the SSAS option**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created.
4. Choose **Add option**.
5. Under **Option details**, choose **SSAS** for **Option name**.
6. Under **Option settings**, do the following:
   a. For **Max memory**, enter a value in the range 10–80.
**Max memory** specifies the upper threshold above which SSAS begins releasing memory more aggressively to make room for requests that are running, and also new high-priority requests. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80, and the default is 45.

b. For **Mode**, choose the SSAS server mode, **Tabular** or **Multidimensional**.

If you don't see the **Mode** option setting, it means that Multidimensional mode isn't supported in your AWS Region. For more information, see **Limitations** (p. 1559).

**Tabular** is the default.

c. For **Security groups**, choose the VPC security group to associate with the option.

**Note**
The port for accessing SSAS, 2383, is prepopulated.

7. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.

8. Choose **Add option**.

**CLI**

**To add the SSAS option**

1. Create a JSON file, for example ssas-option.json, with the following parameters:

   • **OptionGroupName** – The name of option group that you created or chose previously (ssas-se-2017 in the following example).
   • **Port** – The port that you use to access SSAS. The only supported port is 2383.
   • **VpcSecurityGroupMemberships** – Memberships for VPC security groups for your RDS DB instance.
   • **MAX_MEMORY** – The upper threshold above which SSAS should begin releasing memory more aggressively to make room for requests that are running, and also new high-priority requests. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80, and the default is 45.
   • **MODE** – The SSAS server mode, either **Tabular** or **Multidimensional**. **Tabular** is the default.

   If you receive an error that the **MODE** option setting isn't valid, it means that Multidimensional mode isn't supported in your AWS Region. For more information, see Limitations (p. 1559).

   The following is an example of a JSON file with SSAS option settings.

   ```json
   {
     "OptionGroupName": "ssas-se-2017",
     "OptionsToInclude": [
       {
         "OptionName": "SSAS",
         "Port": 2383,
         "VpcSecurityGroupMemberships": ["sg-0abcdef123"],
         "OptionSettings": [
           {"Name": "MAX_MEMORY", "Value": "60"},
           {"Name": "MODE", "Value": "Multidimensional"}
         ]
       },
       "ApplyImmediately": true
     }
   }
   ```

2. Add the SSAS option to the option group.
Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
  --cli-input-json file://ssas-option.json \
  --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
  --cli-input-json file://ssas-option.json ^
  --apply-immediately
```

Associating the option group with your DB instance

You can use the console or the CLI to associate the option group with your DB instance.

Console

Associate your option group with a new or existing DB instance:

- For a new DB instance, associate the option group with the DB instance when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 300).
- For an existing DB instance, modify the instance and associate the new option group with it. For more information, see Modifying an Amazon RDS DB instance (p. 401).

**Note**

If you use an existing instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new instance, specify an existing Active Directory domain and IAM role. For more information, see Working with Active Directory with RDS for SQL Server (p. 1403).

CLI

You can associate your option group with a new or existing DB instance.

**Note**

If you use an existing instance, it must already have an Active Directory domain and IAM role associated with it. If you create a new instance, specify an existing Active Directory domain and IAM role. For more information, see Working with Active Directory with RDS for SQL Server (p. 1403).

To create a DB instance that uses the option group

- Specify the same DB engine type and major version that you used when creating the option group.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
  --db-instance-identifier myssasinstance \
  --db-instance-class db.m5.2xlarge \
  --engine sqlserver-se
```
- --engine-version \texttt{14.00.3223.3.v1} \ 
- --allocated-storage \texttt{100} \ 
- --manage-master-user-password \ 
- --master-username \texttt{admin} \ 
- --storage-type \texttt{gp2} \ 
- --license-model \texttt{li} \ 
- --domain-iam-role-name \texttt{my-directory-iam-role} \ 
- --domain \texttt{my-domain-id} \ 
- --option-group-name \texttt{ssas-se-2017} 

For Windows:

\begin{verbatim}
aws rds create-db-instance ^
  --db-instance-identifier \texttt{myssasinstance} ^
  --db-instance-class \texttt{db.m5.2xlarge} ^
  --engine \texttt{sqlserver-se} ^
  --engine-version \texttt{14.00.3223.3.v1} ^
  --allocated-storage \texttt{100} ^
  --manage-master-user-password ^
  --master-username \texttt{admin} ^
  --storage-type \texttt{gp2} ^
  --license-model \texttt{li} ^
  --domain-iam-role-name \texttt{my-directory-iam-role} ^
  --domain \texttt{my-domain-id} ^
  --option-group-name \texttt{ssas-se-2017}
\end{verbatim}

**To modify a DB instance to associate the option group**

- Use one of the following commands.

**Example**

For Linux, macOS, or Unix:

\begin{verbatim}
aws rds modify-db-instance \
  --db-instance-identifier \texttt{myssasinstance} \
  --option-group-name \texttt{ssas-se-2017} \
  --apply-immediately
\end{verbatim}

For Windows:

\begin{verbatim}
aws rds modify-db-instance ^
  --db-instance-identifier \texttt{myssasinstance} ^
  --option-group-name \texttt{ssas-se-2017} ^
  --apply-immediately
\end{verbatim}

**Allowing inbound access to your VPC security group**

Create an inbound rule for the specified SSAS listener port in the VPC security group associated with your DB instance. For more information about setting up security groups, see [Provide access to your DB instance in your VPC by creating a security group (p. 177)](Integrating an Amazon RDS for SQL Server DB instance with Amazon S3 (p. 1480)).

**Enabling Amazon S3 integration**

To download model configuration files to your host for deployment, use Amazon S3 integration. For more information, see [Integrating an Amazon RDS for SQL Server DB instance with Amazon S3 (p. 1480)].
Deploying SSAS projects on Amazon RDS

On RDS, you can't deploy SSAS projects directly by using SQL Server Management Studio (SSMS). To deploy projects, use an RDS stored procedure.

**Note**
Using .xmla files for deployment isn't supported.

Before you deploy projects, make sure of the following:

- Amazon S3 integration is turned on. For more information, see [Integrating an Amazon RDS for SQL Server DB instance with Amazon S3](p. 1480).
- The Processing Option configuration setting is set to Do Not Process. This setting means that no processing happens after deployment.
- You have both the `myssasproject.asdatabase` and `myssasproject.deploymentoptions` files. They're automatically generated when you build the SSAS project.

**To deploy an SSAS project on RDS**

1. Download the `asdatabase` (SSAS model) file from your S3 bucket to your DB instance, as shown in the following example. For more information on the download parameters, see [Downloading files from an Amazon S3 bucket to a SQL Server DB instance](p. 1487).

   ```sql
   exec msdb.dbo.rds_download_from_s3
   @s3_arn_of_file='arn:aws:s3:::bucket_name/myssasproject.asdatabase',
   [@rds_file_path='D:\S3\myssasproject.asdatabase'],
   [@overwrite_file=1];
   ```

2. Download the `deploymentoptions` file from your S3 bucket to your DB instance.

   ```sql
   exec msdb.dbo.rds_download_from_s3
   @s3_arn_of_file='arn:aws:s3:::bucket_name/myssasproject.deploymentoptions',
   [@rds_file_path='D:\S3\myssasproject.deploymentoptions'],
   [@overwrite_file=1];
   ```

3. Deploy the project.

   ```sql
   exec msdb.dbo.rds_msbi_task
   @task_type='SSAS_DEPLOY_PROJECT',
   @file_path='D:\S3\myssasproject.asdatabase';
   ```

**Monitoring the status of a deployment task**

To track the status of your deployment (or download) task, call the `rds_fn_task_status` function. It takes two parameters. The first parameter should always be NULL because it doesn't apply to SSAS. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to NULL and the second parameter to 0, as shown in the following example.

```sql
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL, 0);
```
The `rds_fn_task_status` function returns the following information.

<table>
<thead>
<tr>
<th>Output parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_id</td>
<td>The ID of the task.</td>
</tr>
<tr>
<td>task_type</td>
<td>For SSAS, tasks can have the following task types:</td>
</tr>
<tr>
<td></td>
<td>• SSAS_DEPLOY_PROJECT</td>
</tr>
<tr>
<td></td>
<td>• SSAS_ADD_DB_ADMIN_MEMBER</td>
</tr>
<tr>
<td></td>
<td>• SSAS_BACKUP_DB</td>
</tr>
<tr>
<td></td>
<td>• SSAS_RESTORE_DB</td>
</tr>
<tr>
<td>database_name</td>
<td>Not applicable to SSAS tasks.</td>
</tr>
<tr>
<td>% complete</td>
<td>The progress of the task as a percentage.</td>
</tr>
<tr>
<td>duration (mins)</td>
<td>The amount of time spent on the task, in minutes.</td>
</tr>
<tr>
<td>lifecycle</td>
<td>The status of the task. Possible statuses are the following:</td>
</tr>
<tr>
<td></td>
<td>• CREATED – After you call one of the SSAS stored procedures, a task is created and the status is set to CREATED.</td>
</tr>
<tr>
<td></td>
<td>• IN_PROGRESS – After a task starts, the status is set to IN_PROGRESS. It can take up to five minutes for the status to change from CREATED to IN_PROGRESS.</td>
</tr>
<tr>
<td></td>
<td>• SUCCESS – After a task completes, the status is set to SUCCESS.</td>
</tr>
<tr>
<td></td>
<td>• ERROR – If a task fails, the status is set to ERROR. For more information about the error, see the <code>task_info</code> column.</td>
</tr>
<tr>
<td></td>
<td>• CANCEL_REQUESTED – After you call <code>rds_cancel_task</code>, the status of the task is set to CANCEL_REQUESTED.</td>
</tr>
<tr>
<td></td>
<td>• CANCELLED – After a task is successfully canceled, the status of the task is set to CANCELLED.</td>
</tr>
<tr>
<td>task_info</td>
<td>Additional information about the task. If an error occurs during processing, this column contains information about the error.</td>
</tr>
<tr>
<td></td>
<td>For more information, see Troubleshooting SSAS issues (p. 1575).</td>
</tr>
<tr>
<td>last_updated</td>
<td>The date and time that the task status was last updated.</td>
</tr>
<tr>
<td>created_at</td>
<td>The date and time that the task was created.</td>
</tr>
<tr>
<td>S3_object_arn</td>
<td>Not applicable to SSAS tasks.</td>
</tr>
</tbody>
</table>
Output parameter | Description
---|---
overwrite_S3_backup_file | Not applicable to SSAS tasks.
KMS_master_key_arn | Not applicable to SSAS tasks.
filepath | Not applicable to SSAS tasks.
overwrite_file | Not applicable to SSAS tasks.
task_metadata | Metadata associated with the SSAS task.

Using SSAS on Amazon RDS

After deploying the SSAS project, you can directly process the OLAP database on SSMS.

To use SSAS on RDS

1. In SSMS, connect to SSAS using the user name and password for the Active Directory domain.
2. Expand Databases. The newly deployed SSAS database appears.
3. Locate the connection string, and update the user name and password to give access to the source SQL database. Doing this is required for processing SSAS objects.
   a. For Tabular mode, do the following:
      1. Expand the Connections tab.
      2. Open the context (right-click) menu for the connection object, and then choose Properties.
      3. Update the user name and password in the connection string.
   b. For Multidimensional mode, do the following:
      1. Expand the Data Sources tab.
      2. Open the context (right-click) menu for the data source object, and then choose Properties.
      3. Update the user name and password in the connection string.
4. Open the context (right-click) menu for the SSAS database that you created and choose Process Database.

Depending on the size of the input data, the processing operation might take several minutes to complete.

Topics

- Setting up a Windows-authenticated user for SSAS (p. 1567)
- Adding a domain user as a database administrator (p. 1568)
- Creating an SSAS proxy (p. 1569)
- Scheduling SSAS database processing using SQL Server Agent (p. 1570)
- Revoking SSAS access from the proxy (p. 1571)

Setting up a Windows-authenticated user for SSAS

The main administrator user (sometimes called the master user) can use the following code example to set up a Windows-authenticated login and grant the required procedure permissions. Doing this grants permissions to the domain user to run SSAS customer tasks, use S3 file transfer procedures, create
You can grant some or all of the following permissions as needed to Windows-authenticated users.

**Example**

```
-- Create a server-level domain user login, if it doesn't already exist
USE [master]
GO
CREATE LOGIN [mydomain\user_name] FROM WINDOWS
GO

-- Create domain user, if it doesn't already exist
USE [msdb]
GO
CREATE USER [mydomain\user_name] FOR LOGIN [mydomain\user_name]
GO

-- Grant necessary privileges to the domain user
USE [master]
GO
GRANT ALTER ANY CREDENTIAL TO [mydomain\user_name]
GO
USE [msdb]
GO
GRANT EXEC ON msdb.dbo.rds_msbi_task TO [mydomain\user_name] with grant option
GRANT SELECT ON msdb.dbo.rds_fn_task_status TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_task_status TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_cancel_task TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_download_from_s3 TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_upload_to_s3 TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_delete_from_filesystem TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_gather_file_details TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_add_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_update_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_grant_login_to_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_revoke_login_from_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_delete_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_enum_login_for_proxy to [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_enum_proxy_for_subsystem TO [mydomain\user_name] with grant option
ALTER ROLE [SQLAgentUserRole] ADD MEMBER [mydomain\user_name]
GO
```

**Adding a domain user as a database administrator**

You can add a domain user as an SSAS database administrator in the following ways:

- A database administrator can use SSMS to create a role with `admin` privileges, then add users to that role.
- You can use the following stored procedure.

```
exec msdb.dbo.rds_msbi_task
    @task_type='SSAS_ADD_DB_ADMIN_MEMBER',
    @database_name='myssasdb',
    @ssas_role_name='exampleRole',
    @ssas_role_member='domain_name\domain_user_name';
```

The following parameters are required:
• @task_type – The type of the MSBI task, in this case SSAS_ADD_DB_ADMIN_MEMBER.
• @database_name – The name of the SSAS database to which you're granting administrator privileges.
• @ssas_role_name – The SSAS database administrator role name. If the role doesn't already exist, it's created.
• @ssas_role_member – The SSAS database user that you're adding to the administrator role.

Creating an SSAS proxy

To be able to schedule SSAS database processing using SQL Server Agent, create an SSAS credential and an SSAS proxy. Run these procedures as a Windows-authenticated user.

To create the SSAS credential

• Create the credential for the proxy. To do this, you can use SSMS or the following SQL statement.

```sql
USE [master]
GO
CREATE CREDENTIAL [SSAS_Credential] WITH IDENTITY = N'mydomain\user_name', SECRET = N'mysecret'
GO
```

Note

IDENTITY must be a domain-authenticated login. Replace mysecret with the password for the domain-authenticated login.

To create the SSAS proxy

1. Use the following SQL statement to create the proxy.

```sql
USE [msdb]
GO
EXEC msdb.dbo.sp_add_proxy
    @proxy_name=N'SSAS_Proxy',@credential_name=N'SSAS_Credential',@description=N''
GO
```

2. Use the following SQL statement to grant access to the proxy to other users.

```sql
USE [msdb]
GO
EXEC msdb.dbo.sp_grant_login_to_proxy
    @proxy_name=N'SSAS_Proxy',@login_name=N'mydomain\user_name'
GO
```

3. Use the following SQL statement to give the SSAS subsystem access to the proxy.

```sql
USE [msdb]
GO
EXEC msdb.dbo.rds_sqlagent_proxy
    @task_type='GRANT_SUBSYSTEM_ACCESS',@proxy_name='SSAS_Proxy',@proxy_subsystem='SSAS'
GO
```

To view the proxy and grants on the proxy

1. Use the following SQL statement to view the grantees of the proxy.
USE [msdb]
GO
EXEC sp_help_proxy
GO

2. Use the following SQL statement to view the subsystem grants.

USE [msdb]
GO
EXEC msdb.dbo.sp_enum_proxy_for_subsystem
GO

Scheduling SSAS database processing using SQL Server Agent

After you create the credential and proxy and grant SSAS access to the proxy, you can create a SQL Server Agent job to schedule SSAS database processing.

To schedule SSAS database processing

- Use SSMS or T-SQL for creating the SQL Server Agent job. The following example uses T-SQL. You can further configure its job schedule through SSMS or T-SQL.
  - The @command parameter outlines the XML for Analysis (XMLA) command to be run by the SQL Server Agent job. This example configures SSAS Multidimensional database processing.
  - The @server parameter outlines the target SSAS server name of the SQL Server Agent job.

To call the SSAS service within the same RDS DB instance where the SQL Server Agent job resides, use localhost:2383.

To call the SSAS service from outside the RDS DB instance, use the RDS endpoint. You can also use the Kerberos Active Directory (AD) endpoint (your-DB-instance-name, your-AD-domain-name) if the RDS DB instances are joined by the same domain. For external DB instances, make sure to properly configure the VPC security group associated with the RDS DB instance for a secure connection.

You can further edit the query to support various XMLA operations. Make edits either by directly modifying the T-SQL query or by using the SSMS UI following SQL Server Agent job creation.

USE [msdb]
GO
DECLARE @jobId BINARY(16)
EXEC msdb.dbo.sp_add_job @job_name=N'SSAS_Job',
   @enabled=1,
   @notify_level_eventlog=0,
   @notify_level_email=0,
   @notify_level_netsend=0,
   @notify_level_page=0,
   @delete_level=0,
   @category_name=N'[Uncategorized (Local)]',
   @job_id = @jobId OUTPUT
GO
EXEC msdb.dbo.sp_add_jobserver
   @job_name=N'SSAS_Job',
   @server_name = N'(local)'
GO
EXEC msdb.dbo.sp_add_jobstep @job_name=N'SSAS_Job', @step_name=N'Process_SSAS_Object',
   @step_id=1,
Revoking SSAS access from the proxy

You can revoke access to the SSAS subsystem and delete the SSAS proxy using the following stored procedures.

To revoke access and delete the proxy

1. Revoke subsystem access.

```sql
USE [msdb]
GO
EXEC msdb.dbo.rds_sqlagent_proxy
    @task_type='REVOKE_SUBSYSTEM_ACCESS',@proxy_name='SSAS_Proxy',@proxy_subsystem='SSAS'
GO
```

2. Revoke the grants on the proxy.

```sql
USE [msdb]
GO
```
EXEC msdb.dbo.sp_revoke_login_from_proxy
    @proxy_name=N' SSAS_Proxy',@name=N' mydomain\user_name'
GO

3. Delete the proxy.

USE [msdb]
GO
EXEC dbo.sp_delete_proxy @proxy_name = N' SSAS_Proxy'
GO

Back up an SSAS database

You can create SSAS database backup files only in the D:\S3 folder on the DB instance. To move the backup files to your S3 bucket, use Amazon S3.

You can back up an SSAS database as follows:

- A domain user with the admin role for a particular database can use SSMS to back up the database to the D:\S3 folder.

For more information, see Adding a domain user as a database administrator (p. 1568).

- You can use the following stored procedure. This stored procedure doesn't support encryption.

```sql
exec msdb.dbo.rds_msbi_task
@task_type='SSAS_BACKUP_DB',
@database_name='myssasdb',
@file_path='D:\S3\ssas_db_backup.abf',
[ssas_apply_compression=1],
[ssas_overwrite_file=1];
```

The following parameters are required:

- `@task_type` – The type of the MSBI task, in this case SSAS_BACKUP_DB.
- `@database_name` – The name of the SSAS database that you're backing up.
- `@file_path` – The path for the SSAS backup file. The .abf extension is required.

The following parameters are optional:

- `@ssas_apply_compression` – Whether to apply SSAS backup compression. Valid values are 1 (Yes) and 0 (No).
- `@ssas_overwrite_file` – Whether to overwrite the SSAS backup file. Valid values are 1 (Yes) and 0 (No).

Restoring an SSAS database

Use the following stored procedure to restore an SSAS database from a backup.

You can't restore a database if there is an existing SSAS database with the same name. The stored procedure for restoring doesn't support encrypted backup files.

```sql
exec msdb.dbo.rds_msbi_task
@task_type='SSAS_RESTORE_DB',
@database_name='mynewssasdb',
@file_path='D:\S3\ssas_db_backup.abf';
```

The following parameters are required:
• `@task_type` – The type of the MSBI task, in this case `SSAS_RESTORE_DB`.
• `@database_name` – The name of the new SSAS database that you're restoring to.
• `@file_path` – The path to the SSAS backup file.

**Restoring a DB instance to a specified time**

Point-in-time recovery (PITR) doesn't apply to SSAS databases. If you do PITR, only the SSAS data in the last snapshot before the requested time is available on the restored instance.

**To have up-to-date SSAS databases on a restored DB instance**

1. Back up your SSAS databases to the D:\S3 folder on the source instance.
2. Transfer the backup files to the S3 bucket.
3. Transfer the backup files from the S3 bucket to the D:\S3 folder on the restored instance.
4. Run the stored procedure to restore the SSAS databases onto the restored instance.

You can also reprocess the SSAS project to restore the databases.

**Changing the SSAS mode**

You can change the mode in which SSAS runs, either Tabular or Multidimensional. To change the mode, use the AWS Management Console or the AWS CLI to modify the options settings in the SSAS option.

**Important**

You can only use one SSAS mode at a time. Make sure to delete all of the SSAS databases before changing the mode, or you receive an error.

**Console**

The following Amazon RDS console procedure changes the SSAS mode to Tabular and sets the `MAX_MEMORY` parameter to 70 percent.

**To modify the SSAS option**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the SSAS option that you want to modify (ssas-se-2017 in the previous examples).
4. Choose **Modify option**.
5. Change the option settings:
   a. For **Max memory**, enter 70.
   b. For **Mode**, choose **Tabular**.
6. Choose **Modify option**.

**AWS CLI**

The following AWS CLI example changes the SSAS mode to Tabular and sets the `MAX_MEMORY` parameter to 70 percent.

For the CLI command to work, make sure to include all of the required parameters, even if you're not modifying them.
To modify the SSAS option

- Use one of the following commands.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds add-option-to-option-group \
   --option-group-name ssas-se-2017 \
   --options "OptionName=SSAS, VpcSecurityGroupMemberships=sg-12345e67, OptionSettings=[[Name=MAX_MEMORY, Value=70], [Name=MODE, Value=Tabular]]" \
   --apply-immediately
```

For Windows:

```bash
aws rds add-option-to-option-group ^
   --option-group-name ssas-se-2017 ^
   --options OptionName=SSAS, VpcSecurityGroupMemberships=sg-12345e67, OptionSettings=[[Name=MAX_MEMORY, Value=70], [Name=MODE, Value=Tabular]] ^
   --apply-immediately
```

Turning off SSAS

To turn off SSAS, remove the SSAS option from its option group.

**Important**

Before you remove the SSAS option, delete your SSAS databases. We highly recommend that you back up your SSAS databases before deleting them and removing the SSAS option.

**Console**

To remove the SSAS option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the SSAS option that you want to remove (ssas-se-2017 in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose SSAS for **Options to delete**.
6. Under **Apply immediately**, choose Yes to delete the option immediately, or No to delete it at the next maintenance window.
7. Choose **Delete**.

**AWS CLI**

To remove the SSAS option from its option group

- Use one of the following commands.
Example

For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \\
    --option-group-name ssas-se-2017 \\
    --options SSAS \\
    --apply-immediately
```

For Windows:

```
aws rds remove-option-from-option-group \\
    --option-group-name ssas-se-2017 \\
    --options SSAS \\
    --apply-immediately

```

Troubleshooting SSAS issues

You might encounter the following issues when using SSAS.

<table>
<thead>
<tr>
<th>Issue</th>
<th>Type</th>
<th>Troubleshooting suggestions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unable to configure the SSAS option. The requested SSAS mode is new_mode, but the current DB instance has number current_mode databases. Delete the existing databases before switching to new_mode mode. To regain access to current_mode mode for database deletion, either update the current DB option group, or attach a new option group with %s as the MODE option setting value for the SSAS option.</td>
<td>RDS event</td>
<td>You can't change the SSAS mode if you still have SSAS databases that use the current mode. Delete the SSAS databases, then try again.</td>
</tr>
<tr>
<td>Unable to remove the SSAS option because there are number existing mode databases. The SSAS option can't be removed until all SSAS databases are deleted. Add the SSAS option again, delete all SSAS databases, and try again.</td>
<td>RDS event</td>
<td>You can't turn off SSAS if you still have SSAS databases. Delete the SSAS databases, then try again.</td>
</tr>
<tr>
<td>The SSAS option isn't enabled or is in the process of being enabled. Try again later.</td>
<td>RDS stored procedure</td>
<td>You can't run SSAS stored procedures when the option is turned off, or when it's being turned on.</td>
</tr>
<tr>

Support for SQL Server Integration Services in Amazon RDS for SQL Server

Microsoft SQL Server Integration Services (SSIS) is a component that you can use to perform a broad range of data migration tasks. SSIS is a platform for data integration and workflow applications. It features a data warehousing tool used for data extraction, transformation, and loading (ETL). You can also use this tool to automate maintenance of SQL Server databases and updates to multidimensional cube data.

SSIS projects are organized into packages saved as XML-based .dtsx files. Packages can contain control flows and data flows. You use data flows to represent ETL operations. After deployment, packages are stored in SQL Server in the SSISDB database. SSISDB is an online transaction processing (OLTP) database in the full recovery mode.

Amazon RDS for SQL Server supports running SSIS directly on an RDS DB instance. You can enable SSIS on an existing or new DB instance. SSIS is installed on the same DB instance as your database engine.

RDS supports SSIS for SQL Server Standard and Enterprise Editions on the following versions:

- SQL Server 2019, version 15.00.4043.16.v1 and higher
- SQL Server 2017, version 14.00.3223.3.v1 and higher
- SQL Server 2016, version 13.00.5426.0.v1 and higher

Limitations and recommendations

The following limitations and recommendations apply to running SSIS on RDS for SQL Server:
• The DB instance must have an associated parameter group with the `clr enabled` parameter set to 1. For more information, see Modifying the parameter for SSIS (p. 1583).

  **Note**
  If you enable the `clr enabled` parameter on SQL Server 2017 or 2019, you can't use the common language runtime (CLR) on your DB instance. For more information, see Features not supported and features with limited support (p. 1383).

• The following control flow tasks are supported:
  • Analysis Services Execute DDL Task
  • Analysis Services Processing Task
  • Bulk Insert Task
  • Check Database Integrity Task
  • Data Flow Task
  • Data Mining Query Task
  • Data Profiling Task
  • Execute Package Task
  • Execute SQL Server Agent Job Task
  • Execute SQL Task
  • Execute T-SQL Statement Task
  • Notify Operator Task
  • Rebuild Index Task
  • Reorganize Index Task
  • Shrink Database Task
  • Transfer Database Task
  • Transfer Jobs Task
  • Transfer Logins Task
  • Transfer SQL Server Objects Task
  • Update Statistics Task

• Only project deployment is supported.
• Running SSIS packages by using SQL Server Agent is supported.
• SSIS log records can be inserted only into user-created databases.
• Use only the `D:\S3` folder for working with files. Files placed in any other directory are deleted. Be aware of a few other file location details:
  • Place SSIS project input and output files in the `D:\S3` folder.
  • For the Data Flow Task, change the location for `BLOBTempStoragePath` and `BufferTempStoragePath` to a file inside the `D:\S3` folder. The file path must start with `D:\S3\`.
  • Ensure that all parameters, variables, and expressions used for file connections point to the `D:\S3` folder.
  • On Multi-AZ instances, files created by SSIS in the `D:\S3` folder are deleted after a failover. For more information, see Multi-AZ limitations for S3 integration (p. 1492).
  • Upload the files created by SSIS in the `D:\S3` folder to your Amazon S3 bucket to make them durable.
• Import Column and Export Column transformations and the Script component on the Data Flow Task aren't supported.
• You can't enable dump on running SSIS packages, and you can't add data taps on SSIS packages.
• The SSIS Scale Out feature isn't supported.
• Build SSIS project (.ispac) files with the DoNotSavePasswords protection mode for deploying on RDS.
• SSIS isn't supported on Always On instances with read replicas.
• You can't back up the SSISDB database that is associated with the SSIS option.
• Importing and restoring the SSISDB database from other instances of SSIS isn't supported.
• You can connect to other SQL Server DB instances or to an Oracle data source. Connecting to other database engines, such as MySQL or PostgreSQL, isn't supported for SSIS on RDS for SQL Server. For more information on connecting to an Oracle data source, see Linked Servers with Oracle OLEDB (p. 1533).

Enabling SSIS

You enable SSIS by adding the SSIS option to your DB instance. Use the following process:

1. Create a new option group, or choose an existing option group.
2. Add the SSIS option to the option group.
3. Create a new parameter group, or choose an existing parameter group.
4. Modify the parameter group to set the clr enabled parameter to 1.
5. Associate the option group and parameter group with the DB instance.
6. Enable Amazon S3 integration.

Note
If a database with the name SSISDB or a reserved SSIS login already exists on the DB instance, you can't enable SSIS on the instance.

Creating the option group for SSIS

To work with SSIS, create an option group or modify an option group that corresponds to the SQL Server edition and version of the DB instance that you plan to use. To do this, use the AWS Management Console or the AWS CLI.

Console

The following procedure creates an option group for SQL Server Standard Edition 2016.

To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose Create group.
4. In the Create option group window, do the following:
   a. For Name, enter a name for the option group that is unique within your AWS account, such as ssis-se-2016. The name can contain only letters, digits, and hyphens.
   b. For Description, enter a brief description of the option group, such as SSIS option group for SQL Server SE 2016. The description is used for display purposes.
   c. For Engine, choose sqlserver-se.
   d. For Major engine version, choose 13.00.
5. Choose Create.
CLI

The following procedure creates an option group for SQL Server Standard Edition 2016.

**To create the option group**

- Run one of the following commands.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-option-group
   --option-group-name ssis-se-2016
   --engine-name sqlserver-se
   --major-engine-version 13.00
   --option-group-description "SSIS option group for SQL Server SE 2016"
```

For Windows:

```bash
aws rds create-option-group
   --option-group-name ssis-se-2016
   --engine-name sqlserver-se
   --major-engine-version 13.00
   --option-group-description "SSIS option group for SQL Server SE 2016"
```

Adding the SSIS option to the option group

Next, use the AWS Management Console or the AWS CLI to add the SSIS option to your option group.

**Console**

**To add the SSIS option**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created, **ssis-se-2016** in this example.
4. Choose **Add option**.
5. Under **Option details**, choose **SSIS** for **Option name**.
6. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
7. Choose **Add option**.

**CLI**

**To add the SSIS option**

- Add the SSIS option to the option group.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds add-option-to-option-group
   --option-group-name ssis-se-2016
   --option-name sqlserver-se
   --major-engine-version 13.00
   --option-group-description "SSIS option group for SQL Server SE 2016"
```
---option-group-name ssis-se-2016 \
--options OptionName=SSIS \
--apply-immediately

For Windows:

aws rds add-option-to-option-group ^
--option-group-name ssis-se-2016 ^
--options OptionName=SSIS ^
--apply-immediately

Creating the parameter group for SSIS

Create or modify a parameter group for the clr enabled parameter that corresponds to the SQL Server edition and version of the DB instance that you plan to use for SSIS.

Console

The following procedure creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose Create parameter group.
4. In the Create parameter group pane, do the following:
   a. For Parameter group family, choose sqlserver-se-13.0.
   b. For Group name, enter an identifier for the parameter group, such as ssis-ssqlserver-se-13.
   c. For Description, enter clr enabled parameter group.
5. Choose Create.

CLI

The following procedure creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

- Run one of the following commands.

Example

For Linux, macOS, or Unix:

aws rds create-db-parameter-group \ 
--db-parameter-group-name ssis-ssqlserver-se-13 \ 
--db-parameter-group-family "sqlserver-se-13.0" \ 
--description "clr enabled parameter group"

For Windows:

aws rds create-db-parameter-group ^
Modifying the parameter for SSIS

Modify the clr enabled parameter in the parameter group that corresponds to the SQL Server edition and version of your DB instance. For SSIS, set the clr enabled parameter to 1.

### Console

The following procedure modifies the parameter group that you created for SQL Server Standard Edition 2016.

#### To modify the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose the parameter group, such as ssis-sqlserver-se-13.
4. Under Parameters, filter the parameter list for clr.
5. Choose clr enabled.
6. Choose Edit parameters.
7. From Values, choose 1.
8. Choose Save changes.

#### CLI

The following procedure modifies the parameter group that you created for SQL Server Standard Edition 2016.

#### To modify the parameter group

- Run one of the following commands.

**Example**

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name ssis-sqlserver-se-13 \
  --parameters ParameterName='clr enabled',ParameterValue=1,ApplyMethod=immediate
```

For Windows:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name ssis-sqlserver-se-13 \
  --parameters ParameterName='clr enabled',ParameterValue=1,ApplyMethod=immediate
```

### Associating the option group and parameter group with your DB instance

To associate the SSIS option group and parameter group with your DB instance, use the AWS Management Console or the AWS CLI.
Note
If you use an existing instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new instance, specify an existing Active Directory domain and IAM role. For more information, see Working with Active Directory with RDS for SQL Server (p. 1403).

Console
To finish enabling SSIS, associate your SSIS option group and parameter group with a new or existing DB instance:

- For a new DB instance, associate them when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 300).
- For an existing DB instance, associate them by modifying the instance. For more information, see Modifying an Amazon RDS DB instance (p. 401).

CLI
You can associate the SSIS option group and parameter group with a new or existing DB instance.

To create an instance with the SSIS option group and parameter group
- Specify the same DB engine type and major version as you used when creating the option group.

Example
For Linux, macOS, or Unix:

```
aws rds create-db-instance \
  --db-instance-identifier myssisinstance \
  --db-instance-class db.m5.2xlarge \
  --engine sqlserver-se \
  --engine-version 13.00.5426.0.v1 \
  --allocated-storage 100 \
  --master-username admin \
  --storage-type gp2 \
  --license-model li \
  --domain-iam-role-name my-directory-iam-role \
  --domain my-domain-id \
  --option-group-name ssis-se-2016 \
  --db-parameter-group-name ssis-sqlserver-se-13
```

For Windows:

```
aws rds create-db-instance ^
  --db-instance-identifier myssisinstance ^
  --db-instance-class db.m5.2xlarge ^
  --engine sqlserver-se ^
  --engine-version 13.00.5426.0.v1 ^
  --allocated-storage 100 ^
  --master-username admin ^
  --storage-type gp2 ^
  --license-model li ^
  --domain-iam-role-name my-directory-iam-role ^
  --domain my-domain-id ^
  --option-group-name ssis-se-2016 ^
  --db-parameter-group-name ssis-sqlserver-se-13
```
To modify an instance and associate the SSIS option group and parameter group

- Run one of the following commands.

**Example**

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier myssisinstance \
  --option-group-name ssis-se-2016 \
  --db-parameter-group-name ssis-sqlserver-se-13 \
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier myssisinstance ^
  --option-group-name ssis-se-2016 ^
  --db-parameter-group-name ssis-sqlserver-se-13 ^
  --apply-immediately
```

**Enabling S3 integration**

To download SSIS project (.ispac) files to your host for deployment, use S3 file integration. For more information, see Integrating an Amazon RDS for SQL Server DB instance with Amazon S3 (p. 1480).

**Administrative permissions on SSISDB**

When the instance is created or modified with the SSIS option, the result is an SSISDB database with the ssis_admin and ssis_logreader roles granted to the master user. The master user has the following privileges in SSISDB:

- alter on ssis_admin role
- alter on ssis_logreader role
- alter any user

Because the master user is a SQL-authenticated user, you can't use the master user for executing SSIS packages. The master user can use these privileges to create new SSISDB users and add them to the ssis_admin and ssis_logreader roles. Doing this is useful for giving access to your domain users for using SSIS.

**Setting up a Windows-authenticated user for SSIS**

The master user can use the following code example to set up a Windows-authenticated login in SSISDB and grant the required procedure permissions. Doing this grants permissions to the domain user to deploy and run SSIS packages, use S3 file transfer procedures, create credentials, and work with the SQL Server Agent proxy. For more information, see Credentials (database engine) and Create a SQL Server Agent proxy in the Microsoft documentation.

**Note**

You can grant some or all of the following permissions as needed to Windows-authenticated users.
Example

```sql
-- Create a server-level SQL login for the domain user, if it doesn't already exist
USE [master]
GO
CREATE LOGIN [mydomain\user_name] FROM WINDOWS
GO

-- Create a database-level account for the domain user, if it doesn't already exist
USE [SSISDB]
GO
CREATE USER [mydomain\user_name] FOR LOGIN [mydomain\user_name]

-- Add SSIS role membership to the domain user
ALTER ROLE [ssis_admin] ADD MEMBER [mydomain\user_name]
ALTER ROLE [ssis_logreader] ADD MEMBER [mydomain\user_name]
GO

-- Add MSDB role membership to the domain user
USE [msdb]
GO
CREATE USER [mydomain\user_name] FOR LOGIN [mydomain\user_name]

-- Grant MSDB stored procedure privileges to the domain user
GRANT EXEC ON msdb.dbo.rds_msbi_task TO [mydomain\user_name] with grant option
GRANT SELECT ON msdb.dbo.rds_fn_task_status TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_task_status TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_cancel_task TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_download_from_s3 TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_upload_to_s3 TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_delete_from_filesystem TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_gather_file_details TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_add_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_update_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_grant_login_to_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_revoke_login_from_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_delete_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_enum_login_for_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_enum_proxy_for_subsystem TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_sqlagent_proxy TO [mydomain\user_name] WITH GRANT OPTION

-- Add the SQLAgentUserRole privilege to the domain user
USE [msdb]
GO
ALTER ROLE [SQLAgentUserRole] ADD MEMBER [mydomain\user_name]
GO

-- Grant the ALTER ANY CREDENTIAL privilege to the domain user
USE [master]
GO
GRANT ALTER ANY CREDENTIAL TO [mydomain\user_name]
GO
```

Deploying an SSIS project

On RDS, you can't deploy SSIS projects directly by using SQL Server Management Studio (SSMS) or SSIS procedures. To download project files from Amazon S3 and then deploy them, use RDS stored procedures.

To run the stored procedures, log in as any user that you granted permissions for running the stored procedures. For more information, see Setting up a Windows-authenticated user for SSIS (p. 1585).
To deploy the SSIS project

1. Download the project (.ispac) file.

   ```sql
   exec msdb.dbo.rds_download_from_s3
   @s3_arn_of_file='arn:aws:s3:::bucket_name/ssisproject.ispac',
   [@rds_file_path='D:\S3\ssisproject.ispac'],
   [@overwrite_file=1];
   ```

2. Submit the deployment task, making sure of the following:
   - The folder is present in the SSIS catalog.
   - The project name matches the project name that you used while developing the SSIS project.

   ```sql
   exec msdb.dbo.rds_msbi_task
   @task_type='SSIS_DEPLOY_PROJECT',
   @folder_name='DEMO',
   @project_name='ssisproject',
   @file_path='D:\S3\ssisproject.ispac';
   ```

Monitoring the status of a deployment task

To track the status of your deployment task, call the `rds_fn_task_status` function. It takes two parameters. The first parameter should always be NULL because it doesn't apply to SSIS. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to NULL and the second parameter to 0, as shown in the following example.

```sql
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL, 0);
```

To get a specific task, set the first parameter to NULL and the second parameter to the task ID, as shown in the following example.

```sql
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL, 42);
```

The `rds_fn_task_status` function returns the following information.

<table>
<thead>
<tr>
<th>Output parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_id</td>
<td>The ID of the task.</td>
</tr>
<tr>
<td>task_type</td>
<td>SSIS_DEPLOY_PROJECT</td>
</tr>
<tr>
<td>database_name</td>
<td>Not applicable to SSIS tasks.</td>
</tr>
<tr>
<td>% complete</td>
<td>The progress of the task as a percentage.</td>
</tr>
<tr>
<td>duration (mins)</td>
<td>The amount of time spent on the task, in minutes.</td>
</tr>
<tr>
<td>lifecycle</td>
<td>The status of the task. Possible statuses are the following:</td>
</tr>
<tr>
<td></td>
<td>• CREATED – After you call the <code>msdb.dbo.rds_msbi_task</code> stored procedure,</td>
</tr>
</tbody>
</table>
a task is created and the status is set to CREATED.

- IN_PROGRESS – After a task starts, the status is set to IN_PROGRESS. It can take up to five minutes for the status to change from CREATED to IN_PROGRESS.

- SUCCESS – After a task completes, the status is set to SUCCESS.

- ERROR – If a task fails, the status is set to ERROR. For more information about the error, see the task_info column.

- CANCEL_REQUESTED – After you call rds_cancel_task, the status of the task is set to CANCEL_REQUESTED.

- CANCELLED – After a task is successfully canceled, the status of the task is set to CANCELLED.

task_info

Additional information about the task. If an error occurs during processing, this column contains information about the error.

last_updated

The date and time that the task status was last updated.

created_at

The date and time that the task was created.

S3_object_arn

Not applicable to SSIS tasks.

overwrite_S3_backup_file

Not applicable to SSIS tasks.

KMS_master_key_arn

Not applicable to SSIS tasks.

filepath

Not applicable to SSIS tasks.

overwrite_file

Not applicable to SSIS tasks.

task_metadata

Metadata associated with the SSIS task.

### Using SSIS

After deploying the SSIS project into the SSIS catalog, you can run packages directly from SSMS or schedule them by using SQL Server Agent. You must use a Windows-authenticated login for executing SSIS packages. For more information, see Setting up a Windows-authenticated user for SSIS (p. 1585).

### Topics

- Setting database connection managers for SSIS projects (p. 1589)
- Creating an SSIS proxy (p. 1589)
- Scheduling an SSIS package using SQL Server Agent (p. 1590)
- Revoking SSIS access from the proxy (p. 1591)
Setting database connection managers for SSIS projects

When you use a connection manager, you can use these types of authentication:

- For local database connections using AWS Managed Active Directory, you can use SQL authentication or Windows authentication. For Windows authentication, use `DB_instance_name.fully_qualified_domain_name` as the server name of the connection string.

  An example is `myssisinstance.corp-ad.example.com`, where `myssisinstance` is the DB instance name and `corp-ad.example.com` is the fully qualified domain name.

- For remote connections, always use SQL authentication.

- For local database connections using self-managed Active Directory, you can use SQL authentication or Windows authentication. For Windows authentication, use `.\LocalHost` or `\LocalHost` as the server name of the connection string.

Creating an SSIS proxy

To be able to schedule SSIS packages using SQL Server Agent, create an SSIS credential and an SSIS proxy. Run these procedures as a Windows-authenticated user.

To create the SSIS credential

- Create the credential for the proxy. To do this, you can use SSMS or the following SQL statement.

  ```sql
  USE [master]
  GO
  CREATE CREDENTIAL [SSIS_Credential] WITH IDENTITY = N'mydomain\user_name', SECRET = N'mysecret'
  GO
  ```

  **Note**
  IDENTITY must be a domain-authenticated login. Replace `mysecret` with the password for the domain-authenticated login. Whenever the SSISDB primary host is changed, alter the SSIS proxy credentials to allow the new host to access them.

To create the SSIS proxy

1. Use the following SQL statement to create the proxy.

   ```sql
   USE [msdb]
   GO
   EXEC msdb.dbo.sp_add_proxy
   @proxy_name=N'SSIS_Proxy',@credential_name=N'SSIS_Credential',@description=N''
   GO
   ```

2. Use the following SQL statement to grant access to the proxy to other users.

   ```sql
   USE [msdb]
   GO
   EXEC msdb.dbo.sp_grant_login_to_proxy
   @proxy_name=N'SSIS_Proxy',@login_name=N'mydomain\user_name'
   GO
   ```

3. Use the following SQL statement to give the SSIS subsystem access to the proxy.

   ```sql
   USE [msdb]
   ```
To view the proxy and grants on the proxy

1. Use the following SQL statement to view the grantees of the proxy.

```
USE [msdb]
GO
EXEC sp_help_proxy
GO
```

2. Use the following SQL statement to view the subsystem grants.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_enum_proxy_for_subsystem
GO
```

Scheduling an SSIS package using SQL Server Agent

After you create the credential and proxy and grant SSIS access to the proxy, you can create a SQL Server Agent job to schedule the SSIS package.

To schedule the SSIS package

- You can use SSMS or T-SQL for creating the SQL Server Agent job. The following example uses T-SQL.

```
USE [msdb]
GO
DECLARE @jobId BINARY(16)
EXEC msdb.dbo.sp_add_job @job_name=N'MYSSISJob',
    @enabled=1,
    @notify_level_eventlog=0,
    @notify_level_email=2,
    @notify_level_page=2,
    @delete_level=0,
    @category_name=N'[Uncategorized (Local)]',
    @job_id = @jobId OUTPUT
GO
EXEC msdb.dbo.sp_add_jobserver @job_name=N'MYSSISJob',@server_name=N'(local)' 
GO
EXEC msdb.dbo.sp_add_jobstep @job_name=N'MYSSISJob',@step_name=N'ExecuteSSISPackage',
    @step_id=1,
    @cmdexec_success_code=0,
    @on_success_action=1,
    @on_fail_action=2,
    @retry_attempts=0,
    @retry_interval=0,
    @os_run_priority=0,
    @subsystem=N'SSIS',
    @command=N'/ISSERVER "\\SSISDB\MySSISFolder\MySSISProject\MySSISPackage.dtsx"' / 
    SERVER "\\my-rds-ssis-instance.corp-ad.company.com/"" 
    /Par """$ServerOption::LOGGING_LEVEL(Int16)"";1 /Par 
    """$ServerOption::SYNCHRONIZED(Boolean)"";True /CALLERINFO SQLAGENT /REPORTING E',
    @database_name=N'master',
```
Revoking SSIS access from the proxy

You can revoke access to the SSIS subsystem and delete the SSIS proxy using the following stored procedures.

**To revoke access and delete the proxy**

1. Revoke subsystem access.

```
USE [msdb]
GO
EXEC msdb.dbo.rds_sqlagent_proxy
  @task_type='REVOKE_SUBSYSTEM_ACCESS',@proxy_name='SSIS_Proxy',@proxy_subsystem='SSIS'
GO
```

2. Revoke the grants on the proxy.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_revoke_login_from_proxy
  @proxy_name=N'SSIS_Proxy',@name=N'\mydomain\user_name'
GO
```

3. Delete the proxy.

```
USE [msdb]
GO
EXEC dbo.sp_delete_proxy @proxy_name = N'SSIS_Proxy'
GO
```

**Disabling SSIS**

To disable SSIS, remove the SSIS option from its option group.

**Important**

Removing the option doesn't delete the SSISDB database, so you can safely remove the option without losing the SSIS projects.

You can re-enable the SSIS option after removal to reuse the SSIS projects that were previously deployed to the SSIS catalog.

**Console**

The following procedure removes the SSIS option.

**To remove the SSIS option from its option group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the SSIS option (ssis-se-2016 in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose **SSIS** for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it at the next maintenance window.

7. Choose **Delete**.

### CLI

The following procedure removes the SSIS option.

**To remove the SSIS option from its option group**

- Run one of the following commands.

  **Example**

  For Linux, macOS, or Unix:

  ```
  aws rds remove-option-from-option-group \\n  --option-group-name ssis-se-2016 \\n  --options SSIS \\n  --apply-immediately
  ```

  For Windows:

  ```
  aws rds remove-option-from-option-group ^
  --option-group-name ssis-se-2016 ^
  --options SSIS ^
  --apply-immediately
  ```

### Dropping the SSISDB database

After removing the SSIS option, the SSISDB database isn't deleted. To drop the SSISDB database, use the `rds_drop_ssis_database` stored procedure after removing the SSIS option.

**To drop the SSIS database**

- Use the following stored procedure.

  ```
  USE [msdb]
  GO
  EXEC dbo.rds_drop_ssis_database
  GO
  ```

After dropping the SSISDB database, if you re-enable the SSIS option you get a fresh SSISDB catalog.
Support for SQL Server Reporting Services in Amazon RDS for SQL Server

Microsoft SQL Server Reporting Services (SSRS) is a server-based application used for report generation and distribution. It's part of a suite of SQL Server services that also includes SQL Server Analysis Services (SSAS) and SQL Server Integration Services (SSIS). SSRS is a service built on top of SQL Server. You can use it to collect data from various data sources and present it in a way that's easily understandable and ready for analysis.

Amazon RDS for SQL Server supports running SSRS directly on RDS DB instances. You can use SSRS with existing or new DB instances.

RDS supports SSRS for SQL Server Standard and Enterprise Editions on the following versions:

- SQL Server 2019, version 15.00.4043.16.v1 and higher
- SQL Server 2017, version 14.00.3223.3.v1 and higher
- SQL Server 2016, version 13.00.5820.21.v1 and higher

Limitations and recommendations

The following limitations and recommendations apply to running SSRS on RDS for SQL Server:

- You can't use SSRS on DB instances that have read replicas.
- Instances must use self-managed Active Directory or AWS Directory Service for Microsoft Active Directory for SSRS web portal and web server authentication. For more information, see Working with Active Directory with RDS for SQL Server (p. 1403).
- You can't back up the reporting server databases that are created with the SSRS option.
- Importing and restoring report server databases from other instances of SSRS isn't supported.
Make sure to use the databases that are created when the SSRS option is added to the RDS DB instance. For more information, see Report server databases (p. 1599).

- You can't configure SSRS to listen on the default SSL port (443). The allowed values are 1150–49511, except 1234, 1434, 3260, 3343, 3389, and 47001.
- Subscriptions through a Microsoft Windows file share aren't supported.
- Using Reporting Services Configuration Manager isn't supported.
- Creating and modifying roles isn't supported.
- Modifying report server properties isn't supported.
- System administrator and system user roles aren't granted.
- You can't edit system-level role assignments through the web portal.

### Turning on SSRS

Use the following process to turn on SSRS for your DB instance:

1. Create a new option group, or choose an existing option group.
2. Add the SSRS option to the option group.
3. Associate the option group with the DB instance.
4. Allow inbound access to the virtual private cloud (VPC) security group for the SSRS listener port.

### Creating an option group for SSRS

To work with SSRS, create an option group that corresponds to the SQL Server engine and version of the DB instance that you plan to use. To do this, use the AWS Management Console or the AWS CLI.

**Note**

You can also use an existing option group if it's for the correct SQL Server engine and version.

#### Console

The following procedure creates an option group for SQL Server Standard Edition 2017.

**To create the option group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose Create group.
4. In the Create option group pane, do the following:
   a. For **Name**, enter a name for the option group that is unique within your AWS account, such as ssrs-se-2017. The name can contain only letters, digits, and hyphens.
   b. For **Description**, enter a brief description of the option group, such as SSRS option group for SQL Server SE 2017. The description is used for display purposes.
   c. For **Engine**, choose sqlserver-se.
   d. For **Major engine version**, choose 14.00.
5. Choose Create.

#### CLI

The following procedure creates an option group for SQL Server Standard Edition 2017.
To create the option group

- Run one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds create-option-group \
  --option-group-name ssrs-se-2017 \
  --engine-name sqlserver-se \
  --major-engine-version 14.00 \
  --option-group-description "SSRS option group for SQL Server SE 2017"
```

For Windows:

```
aws rds create-option-group ^
  --option-group-name ssrs-se-2017 ^
  --engine-name sqlserver-se ^
  --major-engine-version 14.00 ^
  --option-group-description "SSRS option group for SQL Server SE 2017"
```

Adding the SSRS option to your option group

Next, use the AWS Management Console or the AWS CLI to add the SSRS option to your option group.

Console

To add the SSRS option

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose the option group that you just created, then choose Add option.
4. Under Option details, choose SSRS for Option name.
5. Under Option settings, do the following:
   a. Enter the port for the SSRS service to listen on. The default is 8443. For a list of allowed values, see Limitations and recommendations (p. 1593).
   b. Enter a value for Max memory.

   Max memory specifies the upper threshold above which no new memory allocation requests are granted to report server applications. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80.
   c. For Security groups, choose the VPC security group to associate with the option. Use the same security group that is associated with your DB instance.
6. To use SSRS Email to send reports, choose the Configure email delivery options check box under Email delivery in reporting services, and then do the following:
   a. For Sender email address, enter the email address to use in the From field of messages sent by SSRS Email.
      Specify a user account that has permission to send mail from the SMTP server.
   b. For SMTP server, specify the SMTP server or gateway to use.
It can be an IP address, the NetBIOS name of a computer on your corporate intranet, or a fully qualified domain name.

c. For **SMTP port**, enter the port to use to connect to the mail server. The default is 25.

d. To use authentication:
   
i. Select the **Use authentication** check box.
   
   ii. For **Secret Amazon Resource Name (ARN)** enter the AWS Secrets Manager ARN for the user credentials.

   Use the following format:

   \[
   \text{arn:aws:secretsmanager:Region:AccountId:secret:SecretName-6RandomCharacters}
   \]

   For example:

   \[
   \text{arn:aws:secretsmanager:us-west-2:123456789012:secret:MySecret-a1b2c3}
   \]

   For more information on creating the secret, see Using SSRS Email to send reports (p. 1601).

e. Select the **Use Secure Sockets Layer (SSL)** check box to encrypt email messages using SSL.

7. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.

8. Choose **Add option**.

**CLI**

**To add the SSRS option**

1. Create a JSON file, for example **ssis-option.json**.

   a. Set the following required parameters:

      • **OptionGroupName** – The name of option group that you created or chose previously (**ssrs-se-2017** in the following example).
      
      • **Port** – The port for the SSRS service to listen on. The default is 8443. For a list of allowed values, see Limitations and recommendations (p. 1593).
      
      • **VpcSecurityGroupMemberships** – VPC security group memberships for your RDS DB instance.
      
      • **MAX_MEMORY** – The upper threshold above which no new memory allocation requests are granted to report server applications. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80.

   b. (Optional) Set the following parameters to use SSRS Email:

      • **SMTP_ENABLE_EMAIL** – Set to true to use SSRS Email. The default is false.
      
      • **SMTP_SENDER_EMAIL_ADDRESS** – The email address to use in the From field of messages sent by SSRS Email. Specify a user account that has permission to send mail from the SMTP server.
      
      • **SMTP_SERVER** – The SMTP server or gateway to use. It can be an IP address, the NetBIOS name of a computer on your corporate intranet, or a fully qualified domain name.
      
      • **SMTP_PORT** – The port to use to connect to the mail server. The default is 25.
      
      • **SMTP_USE_SSL** – Set to true to encrypt email messages using SSL. The default is true.
      
      • **SMTP_EMAIL_CREDENTIALS_SECRET_ARN** – The Secrets Manager ARN that holds the user credentials. Use the following format:
arn:aws:secretsmanager:Region:AccountId:secret:SecretName-6RandomCharacters

For more information on creating the secret, see Using SSRS Email to send reports (p. 1601).

- SMTP_USE_ANONYMOUS_AUTHENTICATION – Set to true and don't include SMTP_EMAIL_CREDENTIALS_SECRET_ARN if you don't want to use authentication.

  The default is false when SMTP_ENABLE_EMAIL is true.

The following example includes the SSRS Email parameters, using the secret ARN.

```json
{
  "OptionGroupName": "ssrs-se-2017",
  "OptionsToInclude": [
    {
      "OptionName": "SSRS",
      "Port": 8443,
      "VpcSecurityGroupMemberships": ["sg-0abcdef123"],
      "OptionSettings": [
        {"Name": "MAX_MEMORY","Value": "60"},
        {"Name": "SMTP_ENABLE_EMAIL","Value": "true"},
        {"Name": "SMTP_SENDER_EMAIL_ADDRESS","Value": "nobody@example.com"},
        {"Name": "SMTP_SERVER","Value": "email-smtp.us-west-2.amazonaws.com"},
        {"Name": "SMTP_PORT","Value": "25"},
        {"Name": "SMTP_USE_SSL","Value": "true"},
        {"Name": "SMTP_EMAIL_CREDENTIALS_SECRET_ARN","Value": 
          "arn:aws:secretsmanager:us-west-2:123456789012:secret:MySecret-a1b2c3"
        }
      ]
    },
    {"ApplyImmediately": true}
  ]
}
```

2. Add the SSRS option to the option group.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds add-option-to-option-group \
  --cli-input-json file://ssrs-option.json \
  --apply-immediately
```

For Windows:

```bash
aws rds add-option-to-option-group ^
  --cli-input-json file://ssrs-option.json ^
  --apply-immediately
```

**Associating your option group with your DB instance**

Use the AWS Management Console or the AWS CLI to associate your option group with your DB instance.

If you use an existing DB instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new instance, specify an existing Active Directory domain and IAM role. For more information, see Working with Active Directory with RDS for SQL Server (p. 1409).
You can associate your option group with a new or existing DB instance:

- For a new DB instance, associate the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 300).
- For an existing DB instance, modify the instance and associate the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 401).

CLI

You can associate your option group with a new or existing DB instance.

**To create a DB instance that uses your option group**

- Specify the same DB engine type and major version as you used when creating the option group.

**Example**

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
 --db-instance-identifier myssrsinstance \
 --db-instance-class db.m5.2xlarge \
 --engine sqlserver-se \
 --engine-version 14.00.3223.3.v1 \
 --allocated-storage 100 \
 --manage-master-user-password \
 --master-username admin \
 --storage-type gp2 \
 --license-model li \
 --domain-iam-role-name my-directory-iam-role \
 --domain my-domain-id \
 --option-group-name ssrs-se-2017
```

For Windows:

```
aws rds create-db-instance ^
 --db-instance-identifier myssrsinstance ^
 --db-instance-class db.m5.2xlarge ^
 --engine sqlserver-se ^
 --engine-version 14.00.3223.3.v1 ^
 --allocated-storage 100 ^
 --manage-master-user-password ^
 --master-username admin ^
 --storage-type gp2 ^
 --license-model li ^
 --domain-iam-role-name my-directory-iam-role ^
 --domain my-domain-id ^
 --option-group-name ssrs-se-2017
```

**To modify a DB instance to use your option group**

- Run one of the following commands.

**Example**

For Linux, macOS, or Unix:

```
Allowing inbound access to your VPC security group

To allow inbound access to the VPC security group associated with your DB instance, create an inbound rule for the specified SSRS listener port. For more information about setting up security groups, see Provide access to your DB instance in your VPC by creating a security group (p. 177).

Report server databases

When your DB instance is associated with the SSRS option, two new databases are created on your DB instance: rdsadmin_ReportServer and rdsadmin_ReportServerTempDB. These databases act as the ReportServer and ReportServerTempDB databases. SSRS stores its data in the ReportServer database and caches its data in the ReportServerTempDB database.

RDS owns and manages these databases, so database operations on them such as ALTER and DROP aren't permitted. However, you can perform read operations on the rdsadmin_ReportServer database.

SSRS log files

You can access ReportServerService_\_timestamp.log files. These report server logs can be found in the D:\rdsdbdata\Log\SSRS directory. (The D:\rdsdbdata\Log directory is also the parent directory for error logs and SQL Server Agent logs.)

For existing SSRS instances, restarting the SSRS service might be necessary to access report server logs. You can restart the service by updating the SSRS option.

For more information, see Working with Microsoft SQL Server logs (p. 1635).

Accessing the SSRS web portal

Use the following process to access the SSRS web portal:

1. Turn on Secure Sockets Layer (SSL).
2. Grant access to domain users.
3. Access the web portal using a browser and the domain user credentials.

Using SSL on RDS

SSRS uses the HTTPS SSL protocol for its connections. To work with this protocol, import an SSL certificate into the Microsoft Windows operating system on your client computer.

For more information on SSL certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2608). For more information about using SSL with SQL Server, see Using SSL with a Microsoft SQL Server DB instance (p. 1472).
Granting access to domain users

In a new SSRS activation, there are no role assignments in SSRS. To give a domain user or user group access to the web portal, RDS provides a stored procedure.

To grant access to a domain user on the web portal

- Use the following stored procedure.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSRS_GRANT_PORTAL_PERMISSION',
@ssrs_group_or_username=N'AD_domain\user';
```

The domain user or user group is granted the RDS_SSRS_ROLE system role. This role has the following system-level tasks granted to it:

- Run reports
- Manage jobs
- Manage shared schedules
- View shared schedules

The item-level role of Content Manager on the root folder is also granted.

Accessing the web portal

After the SSRS_GRANT_PORTAL_PERMISSION task finishes successfully, you have access to the portal using a web browser. The web portal URL has the following format.

```
https://rds_endpoint:port/Reports
```

In this format, the following applies:

- **rds_endpoint** – The endpoint for the RDS DB instance that you're using with SSRS.
  
  You can find the endpoint on the Connectivity & security tab for your DB instance. For more information, see Connecting to a DB instance running the Microsoft SQL Server database engine (p. 1396).
- **port** – The listener port for SSRS that you set in the SSRS option.

To access the web portal

1. Enter the web portal URL in your browser.

   ```
   https://myssrsinstance.cg034itsfake.us-east-1.rds.amazonaws.com:8443/Reports
   ```

2. Log in with the credentials for a domain user that you granted access with the SSRS_GRANT_PORTAL_PERMISSION task.

Deploying reports to SSRS

After you have access to the web portal, you can deploy reports to it. You can use the Upload tool in the web portal to upload reports, or deploy directly from SQL Server data tools (SSDT). When deploying from SSDT, ensure the following:
• The user who launched SSDT has access to the SSRS web portal.
• The TargetServerURL value in the SSRS project properties is set to the HTTPS endpoint of the RDS DB instance suffixed with ReportServer, for example:

### Configuring the report data source

After you deploy a report to SSRS, you should configure the report data source. When configuring the report data source, ensure the following:

- For RDS for SQL Server DB instances joined to AWS Directory Service for Microsoft Active Directory, use the fully qualified domain name (FQDN) as the data source name of the connection string. An example is `myssrsinstance.corp-ad.example.com`, where `myssrsinstance` is the DB instance name and `corp-ad.example.com` is the fully qualified domain name.
- For RDS for SQL Server DB instances joined to self-managed Active Directory, use `.\`, or `LocalHost` as the data source name of the connection string.

### Using SSRS Email to send reports

SSRS includes the SSRS Email extension, which you can use to send reports to users.

To configure SSRS Email, use the SSRS option settings. For more information, see [Adding the SSRS option to your option group](p. 1595).

After configuring SSRS Email, you can subscribe to reports on the report server. For more information, see [Email delivery in Reporting Services](in the Microsoft documentation).

Integration with AWS Secrets Manager is required for SSRS Email to function on RDS. To integrate with Secrets Manager, you create a secret.

**Note**

If you change the secret later, you also have to update the SSRS option in the option group.

**To create a secret for SSRS Email**

1. Follow the steps in [Create a secret](in the AWS Secrets Manager User Guide).
   - For **Select secret type**, choose **Other type of secrets**.
   - For **Key/value pairs**, enter the following:
     - **SMTP_USERNAME** – Enter a user with permission to send mail from the SMTP server.
     - **SMTP_PASSWORD** – Enter a password for the SMTP user.
   - For **Encryption key**, don't use the default AWS KMS key. Use your own existing key, or create a new one.

   The KMS key policy must allow the `kms:Decrypt` action, for example:

   ```json
   {  
     "Sid": "Allow use of the key",  
     "Effect": "Allow",  
     "Principal": {  
       "Service": [  
         "rds.amazonaws.com"  
       ]  
     }  
   }
   ```
2. Follow the steps in Attach a permissions policy to a secret in the AWS Secrets Manager User Guide. The permissions policy gives the secretsmanager:GetSecretValue action to the rds.amazonaws.com service principal.

We recommend that you use the aws:sourceAccount and aws:sourceArn conditions in the policy to avoid the confused deputy problem. Use your AWS account for aws:sourceAccount and the option group ARN for aws:sourceArn. For more information, see Preventing cross-service confused deputy problems (p. 2657).

The following example shows a permissions policy.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Principal": {
      "Service": "rds.amazonaws.com"
    },
    "Action": "secretsmanager:GetSecretValue",
    "Resource": "*",
    "Condition": {
      "StringEquals": {
        "aws:sourceAccount": "123456789012"
      },
      "ArnLike": {
      }
    }
  }]
}
```

For more examples, see Permissions policy examples for AWS Secrets Manager in the AWS Secrets Manager User Guide.

## Revoking system-level permissions

The RDS_SSRS_ROLE system role doesn't have sufficient permissions to delete system-level role assignments. To remove a user or user group from RDS_SSRS_ROLE, use the same stored procedure that you used to grant the role but use the SSRS_REVOKE_PORTAL_PERMISSION task type.

**To revoke access from a domain user for the web portal**

- Use the following stored procedure.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSRS_REVOKE_PORTAL_PERMISSION',
@ssrs_group_or_username=N'AD_domain\user';
```

Doing this deletes the user from the RDS_SSRS_ROLE system role. It also deletes the user from the Content Manager item-level role if the user has it.
Monitoring the status of a task

To track the status of your granting or revoking task, call the `rds_fn_task_status` function. It takes two parameters. The first parameter should always be NULL because it doesn't apply to SSRS. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to NULL and the second parameter to 0, as shown in the following example.

```sql
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL, 0);
```

To get a specific task, set the first parameter to NULL and the second parameter to the task ID, as shown in the following example.

```sql
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL, 42);
```

The `rds_fn_task_status` function returns the following information.

<table>
<thead>
<tr>
<th>Output parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_id</td>
<td>The ID of the task.</td>
</tr>
<tr>
<td>task_type</td>
<td>For SSRS, tasks can have the following task types:</td>
</tr>
<tr>
<td></td>
<td>• SSRS_GRANT_PORTAL_PERMISSION</td>
</tr>
<tr>
<td></td>
<td>• SSRS_REVOKE_PORTAL_PERMISSION</td>
</tr>
<tr>
<td>database_name</td>
<td>Not applicable to SSRS tasks.</td>
</tr>
<tr>
<td>% complete</td>
<td>The progress of the task as a percentage.</td>
</tr>
<tr>
<td>duration (mins)</td>
<td>The amount of time spent on the task, in minutes.</td>
</tr>
<tr>
<td>lifecycle</td>
<td>The status of the task. Possible statuses are the following:</td>
</tr>
<tr>
<td></td>
<td>• CREATED – After you call one of the SSRS stored procedures, a task is created and the status is set to CREATED.</td>
</tr>
<tr>
<td></td>
<td>• IN_PROGRESS – After a task starts, the status is set to IN_PROGRESS. It can take up to five minutes for the status to change from CREATED to IN_PROGRESS.</td>
</tr>
<tr>
<td></td>
<td>• SUCCESS – After a task completes, the status is set to SUCCESS.</td>
</tr>
<tr>
<td></td>
<td>• ERROR – If a task fails, the status is set to ERROR. For more information about the error, see the task_info column.</td>
</tr>
<tr>
<td></td>
<td>• CANCEL_REQUESTED – After you call the <code>rds_cancel_task</code> stored procedure, the status of the task is set to CANCEL_REQUESTED.</td>
</tr>
<tr>
<td></td>
<td>• CANCELLED – After a task is successfully canceled, the status of the task is set to CANCELLED.</td>
</tr>
</tbody>
</table>
Output parameter | Description
--- | ---
task_info | Additional information about the task. If an error occurs during processing, this column contains information about the error.
last_updated | The date and time that the task status was last updated.
created_at | The date and time that the task was created.
S3_object_arn | Not applicable to SSRS tasks.
overwrite_S3_backup_file | Not applicable to SSRS tasks.
KMS_master_key_arn | Not applicable to SSRS tasks.
filepath | Not applicable to SSRS tasks.
overwrite_file | Not applicable to SSRS tasks.
task_metadata | Metadata associated with the SSRS task.

### Turning off SSRS

To turn off SSRS, remove the SSRS option from its option group. Removing the option doesn't delete the SSRS databases. For more information, see [Deleting the SSRS databases](p. 1605).

You can turn SSRS on again by adding back the SSRS option. If you have also deleted the SSRS databases, readding the option on the same DB instance creates new report server databases.

**Console**

**To remove the SSRS option from its option group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose the option group with the SSRS option (ssrs-se-2017 in the previous examples).
4. Choose Delete option.
5. Under Deletion options, choose SSRS for Options to delete.
6. Under Apply immediately, choose Yes to delete the option immediately, or No to delete it at the next maintenance window.
7. Choose Delete.

**CLI**

**To remove the SSRS option from its option group**

- Run one of the following commands.

  **Example**

  For Linux, macOS, or Unix:

  ```bash
  aws rds remove-option-from-option-group
  ```
Deleting the SSRS databases

Removing the SSRS option doesn’t delete the report server databases. To delete them, use the following stored procedure.

To delete the report server databases, be sure to remove the SSRS option first.

**To delete the SSRS databases**

- Use the following stored procedure.

```sql
exec msdb.dbo.rds_drop_ssrs_databases
```
Support for Microsoft Distributed Transaction Coordinator in RDS for SQL Server

A distributed transaction is a database transaction in which two or more network hosts are involved. RDS for SQL Server supports distributed transactions among hosts, where a single host can be one of the following:

- RDS for SQL Server DB instance
- On-premises SQL Server host
- Amazon EC2 host with SQL Server installed
- Any other EC2 host or RDS DB instance with a database engine that supports distributed transactions

In RDS, starting with SQL Server 2012 (version 11.00.5058.0.v1 and later), all editions of RDS for SQL Server support distributed transactions. The support is provided using Microsoft Distributed Transaction Coordinator (MSDTC). For in-depth information about MSDTC, see Distributed Transaction Coordinator in the Microsoft documentation.

Contents

- Limitations (p. 1606)
- Enabling MSDTC (p. 1607)
  - Creating the option group for MSDTC (p. 1607)
  - Adding the MSDTC option to the option group (p. 1608)
  - Creating the parameter group for MSDTC (p. 1610)
  - Modifying the parameter for MSDTC (p. 1610)
  - Associating the option group and parameter group with the DB instance (p. 1611)
- Using distributed transactions (p. 1613)
- Using XA transactions (p. 1613)
- Using transaction tracing (p. 1614)
- Modifying the MSDTC option (p. 1615)
- Disabling MSDTC (p. 1615)
- Troubleshooting MSDTC for RDS for SQL Server (p. 1616)

Limitations

The following limitations apply to using MSDTC on RDS for SQL Server:

- MSDTC isn't supported on instances using SQL Server Database Mirroring. For more information, see Transactions - availability groups and database mirroring.
- The in-doubt xact resolution parameter must be set to 1 or 2. For more information, see Modifying the parameter for MSDTC (p. 1610).
- MSDTC requires all hosts participating in distributed transactions to be resolvable using their host names. RDS automatically maintains this functionality for domain-joined instances. However, for standalone instances make sure to configure the DNS server manually.
- Java Database Connectivity (JDBC) XA transactions are supported for SQL Server 2017 version 14.00.3223.3 and higher, and SQL Server 2019.
- Distributed transactions that depend on client dynamic link libraries (DLLs) on RDS instances aren't supported.
- Using custom XA dynamic link libraries isn't supported.
Enabling MSDTC

Use the following process to enable MSDTC for your DB instance:

1. Create a new option group, or choose an existing option group.
2. Add the MSDTC option to the option group.
3. Create a new parameter group, or choose an existing parameter group.
4. Modify the parameter group to set the in-doubt xact resolution parameter to 1 or 2.
5. Associate the option group and parameter group with the DB instance.

Creating the option group for MSDTC

Use the AWS Management Console or the AWS CLI to create an option group that corresponds to the SQL Server engine and version of your DB instance.

**Note**
You can also use an existing option group if it's for the correct SQL Server engine and version.

**Console**

The following procedure creates an option group for SQL Server Standard Edition 2016.

**To create the option group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** pane, do the following:
   a. For **Name**, enter a name for the option group that is unique within your AWS account, such as **msdtc-se-2016**. The name can contain only letters, digits, and hyphens.
   b. For **Description**, enter a brief description of the option group, such as **MSDTC option group for SQL Server SE 2016**. The description is used for display purposes.
   c. For **Engine**, choose **sqlserver-se**.
   d. For **Major engine version**, choose **13.00**.
5. Choose **Create**.

**CLI**

The following example creates an option group for SQL Server Standard Edition 2016.

**To create the option group**

- Use one of the following commands.

**Example**

For Linux, macOS, or Unix:

```
aws rds create-option-group \
   --option-group-name msdtc-se-2016 \
   --engine-name sqlserver-se \
   --major-engine-version 13.00 \
```
Adding the MSDTC option to the option group

Next, use the AWS Management Console or the AWS CLI to add the MSDTC option to the option group.

The following option settings are required:

- **Port** – The port that you use to access MSDTC. Allowed values are 1150–49151 except for 1234, 1434, 3260, 3343, 3389, and 47001. The default value is 5000.

  Make sure that the port you want to use is enabled in your firewall rules. Also, make sure as needed that this port is enabled in the inbound and outbound rules for the security group associated with your DB instance. For more information, see Can't connect to Amazon RDS DB instance (p. 2744).

- **Security groups** – The VPC security group memberships for your RDS DB instance.

- **Authentication type** – The authentication mode between hosts. The following authentication types are supported:
  - **Mutual** – The RDS instances are mutually authenticated to each other using integrated authentication. If this option is selected, all instances associated with this option group must be domain-joined.
  - **None** – No authentication is performed between hosts. We don't recommend using this mode in production environments.

- **Transaction log size** – The size of the MSDTC transaction log. Allowed values are 4–1024 MB. The default size is 4 MB.

The following option settings are optional:

- **Enable inbound connections** – Whether to allow inbound MSDTC connections to instances associated with this option group.

- **Enable outbound connections** – Whether to allow outbound MSDTC connections from instances associated with this option group.

- **Enable XA** – Whether to allow XA transactions. For more information on the XA protocol, see XA specification.

- **Enable SNA LU** – Whether to allow the SNA LU protocol to be used for distributed transactions. For more information on SNA LU protocol support, see Managing IBM CICS LU 6.2 transactions in the Microsoft documentation.

**Console**

**To add the MSDTC option**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com>rds/
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created.
4. Choose **Add option**.
5. Under **Option details**, choose **MSDTC** for **Option name**.
6. Under **Option settings**:
   a. For **Port**, enter the port number for accessing MSDTC. The default is **5000**.
   b. For **Security groups**, choose the VPC security group to associate with the option.
   c. For **Authentication type**, choose **Mutual** or **None**.
   d. For **Transaction log size**, enter a value from 4–1024. The default is **4**.
7. Under **Additional configuration**, do the following:
   a. For **Connections**, as needed choose **Enable inbound connections** and **Enable outbound connections**.
   b. For **Allowed protocols**, as needed choose **Enable XA** and **Enable SNA LU**.
8. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
9. Choose **Add option**.
   To add this option, no reboot is required.

**CLI**

**To add the MSDTC option**

1. Create a JSON file, for example **msdtc-option.json**, with the following required parameters.

```json
{
    "OptionGroupName": "msdtc-se-2016",
    "OptionsToInclude": [
    {
        "OptionName": "MSDTC",
        "Port": 5000,
        "VpcSecurityGroupMemberships": ["sg-0abcdef123"],
        "OptionSettings": [
            {"Name": "AUTHENTICATION", "Value": "MUTUAL"},
            {"Name": "TRANSACTION_LOG_SIZE", "Value": "4"}
        ]
    }],
    "ApplyImmediately": true
}
```

2. Add the MSDTC option to the option group.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds add-option-to-option-group \
    --cli-input-json file://msdtc-option.json \
    --apply-immediately
```

For Windows:

```bash
aws rds add-option-to-option-group ^
    --cli-input-json file://msdtc-option.json ^
    --apply-immediately
```

No reboot is required.
Creating the parameter group for MSDTC

Create or modify a parameter group for the in-doubt xact resolution parameter that corresponds to the SQL Server edition and version of your DB instance.

**Console**

The following example creates a parameter group for SQL Server Standard Edition 2016.

**To create the parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose Create parameter group.
4. In the Create parameter group pane, do the following:
   a. For Parameter group family, choose sqlserver-se-13.0.
   b. For Group name, enter an identifier for the parameter group, such as msdtc-sqlserver-se-13.
   c. For Description, enter in-doubt xact resolution.
5. Choose Create.

**CLI**

The following example creates a parameter group for SQL Server Standard Edition 2016.

**To create the parameter group**

- Use one of the following commands.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-parameter-group \
--db-parameter-group-name msdtc-sqlserver-se-13 \
--db-parameter-group-family "sqlserver-se-13.0" \
--description "in-doubt xact resolution"
```

For Windows:

```bash
aws rds create-db-parameter-group ^
--db-parameter-group-name msdtc-sqlserver-se-13 ^
--db-parameter-group-family "sqlserver-se-13.0" ^
--description "in-doubt xact resolution"
```

Modifying the parameter for MSDTC

Modify the in-doubt xact resolution parameter in the parameter group that corresponds to the SQL Server edition and version of your DB instance.

For MSDTC, set the in-doubt xact resolution parameter to one of the following:

- 1 – Presume commit. Any MSDTC in-doubt transactions are presumed to have committed.
• 2 – Presume abort. Any MSDTC in-doubt transactions are presumed to have stopped.

For more information, see in-doubt xact resolution server configuration option in the Microsoft documentation.

Console

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

To modify the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose the parameter group, such as msdtc-sqlserver-se-13.
4. Under Parameters, filter the parameter list for xact.
5. Choose in-doubt xact resolution.
6. Choose Edit parameters.
7. Enter 1 or 2.
8. Choose Save changes.

CLI

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

To modify the parameter group

• Use one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
   --db-parameter-group-name msdtc-sqlserver-se-13 \
   --parameters "ParameterName='in-doubt xact resolution',ParameterValue=1,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
   --db-parameter-group-name msdtc-sqlserver-se-13 ^
   --parameters "ParameterName='in-doubt xact resolution',ParameterValue=1,ApplyMethod=immediate"
```

Associating the option group and parameter group with the DB instance

You can use the AWS Management Console or the AWS CLI to associate the MSDTC option group and parameter group with the DB instance.

Console

You can associate the MSDTC option group and parameter group with a new or existing DB instance.
• For a new DB instance, associate them when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 300).

• For an existing DB instance, associate them by modifying the instance. For more information, see Modifying an Amazon RDS DB instance (p. 401).

Note
If you use an domain-joined existing DB instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new domain-joined instance, specify an existing Active Directory domain and IAM role. For more information, see Working with AWS Managed Active Directory with RDS for SQL Server (p. 1417).

CLI
You can associate the MSDTC option group and parameter group with a new or existing DB instance.

Note
If you use an existing domain-joined DB instance, it must already have an Active Directory domain and IAM role associated with it. If you create a new domain-joined instance, specify an existing Active Directory domain and IAM role. For more information, see Working with AWS Managed Active Directory with RDS for SQL Server (p. 1417).

To create a DB instance with the MSDTC option group and parameter group

• Specify the same DB engine type and major version as you used when creating the option group.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
  --db-instance-identifier mydbinstance \
  --db-instance-class db.m5.2xlarge \
  --engine sqlserver-se \
  --engine-version 13.00.5426.0.v1 \
  --allocated-storage 100 \
  --manage-master-user-password \
  --master-username admin \
  --storage-type gp2 \
  --license-model li \
  --domain-iam-role-name my-directory-iam-role \
  --domain my-domain-id \
  --option-group-name msdtc-se-2016 \
  --db-parameter-group-name msdtc-sqlserver-se-13
```

For Windows:

```
aws rds create-db-instance ^
  --db-instance-identifier mydbinstance ^
  --db-instance-class db.m5.2xlarge ^
  --engine sqlserver-se ^
  --engine-version 13.00.5426.0.v1 ^
  --allocated-storage 100 ^
  --manage-master-user-password ^
  --master-username admin ^
  --storage-type gp2 ^
  --license-model li ^
  --domain-iam-role-name my-directory-iam-role ^
  --domain my-domain-id ^
  --option-group-name msdtc-se-2016 ^
```

1612
To modify a DB instance and associate the MSDTC option group and parameter group

- Use one of the following commands.

**Example**

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --option-group-name msdtc-se-2016 \
  --db-parameter-group-name msdtc-sqlserver-se-13 \
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier ^mydbinstance ^
  --option-group-name msdtc-se-2016 ^
  --db-parameter-group-name msdtc-sqlserver-se-13 ^
  --apply-immediately
```

**Using distributed transactions**

In Amazon RDS for SQL Server, you run distributed transactions in the same way as distributed transactions running on-premises:

- Using .NET framework System.Transactions promotable transactions, which optimizes distributed transactions by deferring their creation until they're needed.

  In this case, promotion is automatic and doesn't require you to make any intervention. If there's only one resource manager within the transaction, no promotion is performed. For more information about implicit transaction scopes, see [Implementing an implicit transaction using transaction scope](https://docs.microsoft.com/en-us/sql/relational-databases/transactions/implicit-transaction-scopes) in the Microsoft documentation.

  Promotable transactions are supported with these .NET implementations:

  - ODP.NET supports System.Transactions. A local transaction is created for the first connection opened in the TransactionsScope scope to Oracle Database 11g release 1 (version 11.1) and later. When a second connection is opened, this transaction is automatically promoted to a distributed transaction. For more information about distributed transaction support in ODP.NET, see [Microsoft Distributed Transaction Coordinator integration](https://docs.oracle.com/cd/E11882_01/appdev.112/e25509/index.htm) in the Microsoft documentation.

  - Using the `BEGIN DISTRIBUTED TRANSACTION` statement. For more information, see [BEGIN DISTRIBUTED TRANSACTION (Transact-SQL)](https://docs.microsoft.com/en-us/sql/relational-databases/transactions/begin-distributed-transaction-transact-sql) in the Microsoft documentation.

**Using XA transactions**

Starting from RDS for SQL Server 2017 version 14.00.3223.3, you can control distributed transactions using JDBC. When you set the `Enable XA` option setting to true in the MSDTC option, RDS
automatically enables JDBC transactions and grants the $SqlJDBCXAUser role to the guest user. This allows executing distributed transactions through JDBC. For more information, including a code example, see Understanding XA transactions in the Microsoft documentation.

**Using transaction tracing**

RDS supports controlling MSDTC transaction traces and downloading them from the RDS DB instance for troubleshooting. You can control transaction tracing sessions by running the following RDS stored procedure.

```sql
exec msdb.dbo.rds_msdtc_transaction_tracing 'trace_action',
    [@traceall='0/1'],
    [@traceaborted='0/1'],
    [@tracelong='0/1'];
```

The following parameter is required:

- `trace_action` – The tracing action. It can be START, STOP, or STATUS.

The following parameters are optional:

- `@traceall` – Set to 1 to trace all distributed transactions. The default is 0.
- `@traceaborted` – Set to 1 to trace canceled distributed transactions. The default is 0.
- `@tracelong` – Set to 1 to trace long-running distributed transactions. The default is 0.

**Example of START tracing action**

To start a new transaction tracing session, run the following example statement.

```sql
exec msdb.dbo.rds_msdtc_transaction_tracing 'START',
    @traceall='0',
    @traceaborted='1',
    @tracelong='1';
```

**Note**

Only one transaction tracing session can be active at one time. If a new tracing session START command is issued while a tracing session is active, an error is returned and the active tracing session remains unchanged.

**Example of STOP tracing action**

To stop a transaction tracing session, run the following statement.

```sql
exec msdb.dbo.rds_msdtc_transaction_tracing 'STOP'
```

This statement stops the active transaction tracing session and saves the transaction trace data into the log directory on the RDS DB instance. The first row of the output contains the overall result, and the following lines indicate details of the operation.

The following is an example of a successful tracing session stop.

**OK: Trace session has been successfully stopped.**

Setting log file to: D:\rdsdbdata\MSDTC\Trace\dtctrace.log
Examining D:\rdsdbdata\MSDTC\Trace\msdtctr.mof for message formats, 8 found.
Searching for TMF files on path: (null)
Logfile D:\rdsdddata\MSDTC\Trace\dtctrace.log:
  OS version    10.0.14393  (Currently running on 6.2.9200)
  Start Time    <timestamp>
  End Time      <timestamp>
  Timezone is   @tzres.dll,-932 (Bias is 0mins)
  BufferSize    16384 B
  Maximum File Size     10 MB
  Buffers Written   Not set (Logger may not have been stopped).
  Logger Mode Settings (11000002) ( circular paged
  ProcessorCount         1
  Processing completed   Buffers: 1, Events: 3, EventsLost: 0 :: Format Errors: 0, Unknowns: 3
  Event traces dumped to d:\rdsdddata\Log\msdtc_<timestamp>.log

You can use the detailed information to query the name of the generated log file. For more information about downloading log files from the RDS DB instance, see Monitoring Amazon RDS log files (p. 895).

The trace session logs remain on the instance for 35 days. Any older trace session logs are automatically deleted.

**Example of STATUS tracing action**

To trace the status of a transaction tracing session, run the following statement.

```sql
exec msdb.dbo.rds_msdtc_transaction_tracing 'STATUS'
```

This statement outputs the following as separate rows of the result set.

| OK          | SessionStatus: <Started|Stopped> |
|-------------|------------------------|
| TraceAll:   | <True|False>               |
| TraceAborted: | <True|False>             |
| TraceLongLived: | <True|False>       |

The first line indicates the overall result of the operation: OK or ERROR with details, if applicable. The subsequent lines indicate details about the tracing session status:

- **SessionStatus** can be one of the following:
  - Started if a tracing session is running.
  - Stopped if no tracing session is running.
  - The tracing session flags can be True or False depending on how they were set in the START command.

**Modifying the MSDTC option**

After you enable the MSDTC option, you can modify its settings. For information about how to modify option settings, see Modifying an option setting (p. 340).

**Note**

Some changes to MSDTC option settings require the MSDTC service to be restarted. This requirement can affect running distributed transactions.

**Disabling MSDTC**

To disable MSDTC, remove the MSDTC option from its option group.
Console

To remove the MSDTC option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose the option group with the MSDTC option (msdtc-se-2016 in the previous examples).
4. Choose Delete option.
5. Under Deletion options, choose MSDTC for Options to delete.
6. Under Apply immediately, choose Yes to delete the option immediately, or No to delete it at the next maintenance window.
7. Choose Delete.

CLI

To remove the MSDTC option from its option group

- Use one of the following commands.

   **Example**

   For Linux, macOS, or Unix:

```bash
aws rds remove-option-from-option-group \
   --option-group-name msdtc-se-2016 \
   --options MSDTC \
   --apply-immediately
```

For Windows:

```bash
aws rds remove-option-from-option-group ^
   --option-group-name msdtc-se-2016 ^
   --options MSDTC ^
   --apply-immediately
```

Troubleshooting MSDTC for RDS for SQL Server

In some cases, you might have trouble establishing a connection between MSDTC running on a client computer and the MSDTC service running on an RDS for SQL Server DB instance. If so, make sure of the following:

- The inbound rules for the security group associated with the DB instance are configured correctly. For more information, see Can't connect to Amazon RDS DB instance (p. 2744).
- Your client computer is configured correctly.
- The MSDTC firewall rules on your client computer are enabled.

To configure the client computer

1. Open Component Services.

   Or, in Server Manager, choose Tools, and then choose Component Services.
2. Expand Component Services, expand Computers, expand My Computer, and then expand Distributed Transaction Coordinator.
3. Open the context (right-click) menu for Local DTC and choose Properties.
5. Choose all of the following:
   - Network DTC Access
   - Allow Inbound
   - Allow Outbound
6. Make sure that the correct authentication mode is chosen:
   - Mutual Authentication Required – The client machine is joined to the same domain as other nodes participating in distributed transaction, or there is a trust relationship configured between domains.
   - No Authentication Required – All other cases.
7. Choose OK to save your changes.
8. If prompted to restart the service, choose Yes.

To enable MSDTC firewall rules

1. Open Windows Firewall, then choose Advanced settings.

   Or, in Server Manager, choose Tools, and then choose Windows Firewall with Advanced Security.

   Note
   Depending on your operating system, Windows Firewall might be called Windows Defender Firewall.

2. Choose Inbound Rules in the left pane.
3. Enable the following firewall rules, if they are not already enabled:
   - Distributed Transaction Coordinator (RPC)
   - Distributed Transaction Coordinator (RPC)-EPMAP
   - Distributed Transaction Coordinator (TCP-In)
Common DBA tasks for Microsoft SQL Server

This section describes the Amazon RDS-specific implementations of some common DBA tasks for DB instances that are running the Microsoft SQL Server database engine. In order to deliver a managed service experience, Amazon RDS does not provide shell access to DB instances, and it restricts access to certain system procedures and tables that require advanced privileges.

**Note**
When working with a SQL Server DB instance, you can run scripts to modify a newly created database, but you cannot modify the [model] database, the database used as the model for new databases.

**Topics**
- Accessing the tempdb database on Microsoft SQL Server DB instances on Amazon RDS (p. 1619)
- Analyzing your database workload on an Amazon RDS for SQL Server DB instance with Database Engine Tuning Advisor (p. 1621)
- Collations and character sets for Microsoft SQL Server (p. 1623)
- Creating a database user (p. 1627)
- Determining a recovery model for your Microsoft SQL Server database (p. 1627)
- Determining the last failover time (p. 1628)
- Disabling fast inserts during bulk loading (p. 1628)
- Dropping a Microsoft SQL Server database (p. 1629)
- Renaming a Microsoft SQL Server database in a Multi-AZ deployment (p. 1629)
- Resetting the db_owner role password (p. 1629)
- Restoring license-terminated DB instances (p. 1630)
- Transitioning a Microsoft SQL Server database from OFFLINE to ONLINE (p. 1630)
- Using change data capture (p. 1630)
- Using SQL Server Agent (p. 1633)
- Working with Microsoft SQL Server logs (p. 1635)
- Working with trace and dump files (p. 1636)
Accessing the tempdb database on Microsoft SQL Server DB instances on Amazon RDS

You can access the tempdb database on your Microsoft SQL Server DB instances on Amazon RDS. You can run code on tempdb by using Transact-SQL through Microsoft SQL Server Management Studio (SSMS), or any other standard SQL client application. For more information about connecting to your DB instance, see Connecting to a DB instance running the Microsoft SQL Server database engine (p. 1396).

The master user for your DB instance is granted CONTROL access to tempdb so that this user can modify the tempdb database options. The master user isn't the database owner of the tempdb database. If necessary, the master user can grant CONTROL access to other users so that they can also modify the tempdb database options.

**Note**
You can't run Database Console Commands (DBCC) on the tempdb database.

Modifying tempdb database options

You can modify the database options on the tempdb database on your Amazon RDS DB instances. For more information about which options can be modified, see tempdb database in the Microsoft documentation.

Database options such as the maximum file size options are persistent after you restart your DB instance. You can modify the database options to optimize performance when importing data, and to prevent running out of storage.

**Optimizing performance when importing data**

To optimize performance when importing large amounts of data into your DB instance, set the SIZE and FILEGROWTH properties of the tempdb database to large numbers. For more information about how to optimize tempdb, see Optimizing tempdb performance in the Microsoft documentation.

The following example demonstrates setting the size to 100 GB and file growth to 10 percent.

```sql
alter database[tempdb] modify file (NAME = N'templog', SIZE=100GB, FILEGROWTH = 10%)
```

**Preventing storage problems**

To prevent the tempdb database from using all available disk space, set the MAXSIZE property. The following example demonstrates setting the property to 2048 MB.

```sql
alter database [tempdb] modify file (NAME = N'templog', MAXSIZE = 2048MB)
```

**Shrinking the tempdb database**

There are two ways to shrink the tempdb database on your Amazon RDS DB instance. You can use the rds_shrink_tempdbfile procedure, or you can set the SIZE property.

**Using the rds_shrink_tempdbfile procedure**

You can use the Amazon RDS procedure msdb.dbo.rds_shrink_tempdbfile to shrink the tempdb database. You can only call rds_shrink_tempdbfile if you have CONTROL access to tempdb. When you call rds_shrink_tempdbfile, there is no downtime for your DB instance.
The `rds_shrink_tempdbfile` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@temp_filename</td>
<td>SYSNAME</td>
<td>—</td>
<td>required</td>
<td>The logical name of the file to shrink.</td>
</tr>
<tr>
<td>@target_size</td>
<td>int</td>
<td>null</td>
<td>optional</td>
<td>The new size for the file, in megabytes.</td>
</tr>
</tbody>
</table>

The following example gets the names of the files for the tempdb database.

```
use tempdb;
GO
select name, * from sys.sysfiles;
GO
```

The following example shrinks a tempdb database file named `test_file`, and requests a new size of 10 megabytes:

```
exec msdb.dbo.rds_shrink_tempdbfile @temp_filename = N'test_file', @target_size = 10;
```

**Setting the SIZE property**

You can also shrink the tempdb database by setting the SIZE property and then restarting your DB instance. For more information about restarting your DB instance, see Rebooting a DB instance (p. 436).

The following example demonstrates setting the SIZE property to 1024 MB.

```
alter database [tempdb] modify file (NAME = N'templog', SIZE = 1024MB)
```

**Considerations for Multi-AZ deployments**

If your Amazon RDS DB instance is in a Multi-AZ Deployment for Microsoft SQL Server with Database Mirroring (DBM) or Always On Availability Groups (AGs), there are some things to consider.

The tempdb database can’t be replicated. No data that you store on your primary instance is replicated to your secondary instance.

If you modify any database options on the tempdb database, you can capture those changes on the secondary by using one of the following methods:

- First modify your DB instance and turn Multi-AZ off, then modify tempdb, and finally turn Multi-AZ back on. This method doesn't involve any downtime.

  For more information, see Modifying an Amazon RDS DB instance (p. 401).

- First modify tempdb in the original primary instance, then fail over manually, and finally modify tempdb in the new primary instance. This method involves downtime.

  For more information, see Rebooting a DB instance (p. 436).
Analyzing your database workload on an Amazon RDS for SQL Server DB instance with Database Engine Tuning Advisor

Database Engine Tuning Advisor is a client application provided by Microsoft that analyzes database workload and recommends an optimal set of indexes for your Microsoft SQL Server databases based on the kinds of queries you run. Like SQL Server Management Studio, you run Tuning Advisor from a client computer that connects to your Amazon RDS DB instance that is running SQL Server. The client computer can be a local computer that you run on premises within your own network or it can be an Amazon EC2 Windows instance that is running in the same region as your Amazon RDS DB instance.

This section shows how to capture a workload for Tuning Advisor to analyze. This is the preferred process for capturing a workload because Amazon RDS restricts host access to the SQL Server instance. For more information, see Database Engine Tuning Advisor in the Microsoft documentation.

To use Tuning Advisor, you must provide what is called a workload to the advisor. A workload is a set of Transact-SQL statements that run against a database or databases that you want to tune. Database Engine Tuning Advisor uses trace files, trace tables, Transact-SQL scripts, or XML files as workload input when tuning databases. When working with Amazon RDS, a workload can be a file on a client computer or a database table on an Amazon RDS for SQL Server DB accessible to your client computer. The file or the table must contain queries against the databases you want to tune in a format suitable for replay.

For Tuning Advisor to be most effective, a workload should be as realistic as possible. You can generate a workload file or table by performing a trace against your DB instance. While a trace is running, you can either simulate a load on your DB instance or run your applications with a normal load.

There are two types of traces: client-side and server-side. A client-side trace is easier to set up and you can watch trace events being captured in real-time in SQL Server Profiler. A server-side trace is more complex to set up and requires some Transact-SQL scripting. In addition, because the trace is written to a file on the Amazon RDS DB instance, storage space is consumed by the trace. It is important to track of how much storage space a running server-side trace uses because the DB instance could enter a storage-full state and would no longer be available if it runs out of storage space.

For a client-side trace, when a sufficient amount of trace data has been captured in the SQL Server Profiler, you can then generate the workload file by saving the trace to either a file on your local computer or in a database table on a DB instance that is available to your client computer. The main disadvantage of using a client-side trace is that the trace may not capture all queries when under heavy loads. This could weaken the effectiveness of the analysis performed by the Database Engine Tuning Advisor. If you need to run a trace under heavy loads and you want to ensure that it captures every query during a trace session, you should use a server-side trace.

For a server-side trace, you must get the trace files on the DB instance into a suitable workload file or you can save the trace to a table on the DB instance after the trace completes. You can use the SQL Server Profiler to save the trace to a file on your local computer or have the Tuning Advisor read from the trace table on the DB instance.

Running a client-side trace on a SQL Server DB instance

To run a client-side trace on a SQL Server DB instance

1. Start SQL Server Profiler. It is installed in the Performance Tools folder of your SQL Server instance folder. You must load or define a trace definition template to start a client-side trace.
2. In the SQL Server Profiler File menu, choose New Trace. In the Connect to Server dialog box, enter the DB instance endpoint, port, master user name, and password of the database you would like to run a trace on.
3. In the **Trace Properties** dialog box, enter a trace name and choose a trace definition template. A default template, TSQL_Replay, ships with the application. You can edit this template to define your trace. Edit events and event information under the **Events Selection** tab of the **Trace Properties** dialog box.

For more information about trace definition templates and using the SQL Server Profiler to specify a client-side trace, see [Database Engine Tuning Advisor](https://docs.microsoft.com/en-us/sql/database-engine/tuning-advisor/tune-your-sql-server-system?view=sql-server-ver15) in the Microsoft documentation.

4. Start the client-side trace and watch SQL queries in real-time as they run against your DB instance.

5. Select **Stop Trace** from the **File** menu when you have completed the trace. Save the results as a file or as a trace table on your DB instance.

### Running a server-side trace on a SQL Server DB instance

Writing scripts to create a server-side trace can be complex and is beyond the scope of this document. This section contains sample scripts that you can use as examples. As with a client-side trace, the goal is to create a workload file or trace table that you can open using the Database Engine Tuning Advisor.

The following is an abridged example script that starts a server-side trace and captures details to a workload file. The trace initially saves to the file RDSTrace.trc in the D:\RDSDBDATA\Log directory and rolls-over every 100 MB so subsequent trace files are named RDSTrace_1.trc, RDSTrace_2.trc, etc.

```sql
DECLARE @file_name NVARCHAR(245) = 'D:\RDSDBDATA\Log\RDSTrace';
DECLARE @max_file_size BIGINT = 100;
DECLARE @on BIT = 1
DECLARE @rc INT
DECLARE @traceid INT
EXEC @rc = sp_trace_create @traceid OUTPUT, 2, @file_name, @max_file_size
IF (@rc = 0) BEGIN
  EXEC sp_trace_setevent @traceid, 10, 1, @on
  EXEC sp_trace_setevent @traceid, 10, 2, @on
  EXEC sp_trace_setevent @traceid, 10, 3, @on
  EXEC sp_trace_setfilter @traceid, 10, 0, 7, N'SQL Profiler'
  EXEC sp_trace_setstatus @traceid, 1
END
```

The following example is a script that stops a trace. Note that a trace created by the previous script continues to run until you explicitly stop the trace or the process runs out of disk space.

```sql
DECLARE @traceid INT
SELECT @traceid = traceid FROM ::fn_trace_getinfo(default)
WHERE property = 5 AND value = 1 AND traceid <> 1
IF @traceid IS NOT NULL BEGIN
  EXEC sp_trace_setstatus @traceid, 0
  EXEC sp_trace_setstatus @traceid, 2
END
```

You can save server-side trace results to a database table and use the database table as the workload for the Tuning Advisor by using the fn_trace_gettable function. The following commands load the results of all files named RDSTrace.trc in the D:\rdsdbdata\Log directory, including all rollover files like RDSTrace_1.trc, into a table named RDSTrace in the current database.

```sql
SELECT * INTO RDSTrace
FROM fn_trace_gettable('D:\rdsdbdata\Log\RDSTrace.trc', default);
```
To save a specific rollover file to a table, for example the RDSTrace_1.trc file, specify the name of the rollover file and substitute 1 instead of default as the last parameter to fn_trace_gettable.

```sql
SELECT * INTO RDSTrace_1
FROM fn_trace_gettable('D:\rdsdbdata\Log\RDSTrace_1.trc', 1);
```

**Running Tuning Advisor with a trace**

Once you create a trace, either as a local file or as a database table, you can then run Tuning Advisor against your DB instance. Using Tuning Advisor with Amazon RDS is the same process as when working with a standalone, remote SQL Server instance. You can either use the Tuning Advisor UI on your client machine or use the dta.exe utility from the command line. In both cases, you must connect to the Amazon RDS DB instance using the endpoint for the DB instance and provide your master user name and master user password when using Tuning Advisor.

The following code example demonstrates using the dta.exe command line utility against an Amazon RDS DB instance with an endpoint of `dta.cnazcmklsdei.us-east-1.rds.amazonaws.com`. The example includes the master user name `admin` and the master user password `test`, the example database to tune is named machine named `C:\RDSTrace.trc`. The example command line code also specifies a trace session named `RDSTrace1` and specifies output files to the local machine named `RDSTrace.sql` for the SQL output script, `RDSTrace.txt` for a result file, and `RDSTrace.xml` for an XML file of the analysis. There is also an error table specified on the RDSDTA database named `RDSTraceErrors`.

```text
dta -S dta.cnazcmklsdei.us-east-1.rds.amazonaws.com -U admin -P test -D RDSDTA -if C:\RDSTrace.trc -s RDSTrace1 -of C:\ RDSTrace.sql -or C:\ RDSTrace.txt -ox C:\ RDSTrace.xml -e RDSDTA.dbo.RDSTraceErrors
```

Here is the same example command line code except the input workload is a table on the remote Amazon RDS instance named `RDSTrace` which is on the `RDSDTA` database.

```text
dta -S dta.cnazcmklsdei.us-east-1.rds.amazonaws.com -U admin -P test -D RDSDTA -it RDSDTA.dbo.RDSTrace -s RDSTrace1 -of C:\ RDSTrace.sql -or C:\ RDSTrace.txt -ox C:\ RDSTrace.xml -e RDSDTA.dbo.RDSTraceErrors
```

For a full list of dta utility command-line parameters, see [dta Utility](#) in the Microsoft documentation.

**Collations and character sets for Microsoft SQL Server**

SQL Server supports collations at multiple levels. You set the default server collation when you create the DB instance. You can override the collation in the database, table, or column level.

**Topics**

- [Server-level collation for Microsoft SQL Server (p. 1623)](#)
- [Database-level collation for Microsoft SQL Server (p. 1626)](#)

**Server-level collation for Microsoft SQL Server**

When you create a Microsoft SQL Server DB instance, you can set the server collation that you want to use. If you don't choose a different collation, the server-level collation defaults to
SQL_Latin1_General_CP1_CI_AS. The server collation is applied by default to all databases and database objects.

**Note**
You can't change the collation when you restore from a DB snapshot.

Currently, Amazon RDS supports the following server collations:

<table>
<thead>
<tr>
<th>Collation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chinese_PRC_BIN2</td>
<td>Chinese-PRC, binary code point sort order</td>
</tr>
<tr>
<td>Chinese_PRC_CI_AS</td>
<td>Chinese-PRC, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>Chinese_Taiwan_Stroke_CI_AS</td>
<td>Chinese-Taiwan-Stroke, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>Danish_Norwegian_CI_AS</td>
<td>Danish-Norwegian, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>Finnish_Swedish_CI_AS</td>
<td>Finnish, Swedish, and Swedish (Finland), case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>French_CI_AS</td>
<td>French, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>Hebrew_BIN</td>
<td>Hebrew, binary sort</td>
</tr>
<tr>
<td>Hebrew_CI_AS</td>
<td>Hebrew, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>Japanese_BIN</td>
<td>Japanese, binary sort</td>
</tr>
<tr>
<td>Japanese_CI_AS</td>
<td>Japanese, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>Japanese_CS_AS</td>
<td>Japanese, case-sensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>Japanese_XJIS_140_CI_AS</td>
<td>Japanese-XJIS-140, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive, supplementary characters, variation selector insensitive</td>
</tr>
<tr>
<td>Japanese_XJIS_140_CI_AS_KS_VSS</td>
<td>Japanese-XJIS-140, case-insensitive, accent-sensitive, kanatype-sensitive, width-insensitive, supplementary characters, variation selector sensitive</td>
</tr>
<tr>
<td>Japanese_XJIS_140_CI_AS_VSS</td>
<td>Japanese-XJIS-140, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive, supplementary characters, variation selector sensitive</td>
</tr>
<tr>
<td>Korean_Wansung_CI_AS</td>
<td>Korean-Wansung, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>Latin1_General_100_BIN</td>
<td>Latin1-General-100, binary sort</td>
</tr>
<tr>
<td>Collation</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Latin1_General_100_BIN2</td>
<td>Latin1-General-100, binary code point sort order</td>
</tr>
<tr>
<td>Latin1_General_100_BIN2_UTF8</td>
<td>Latin1-General-100, binary code point sort order, UTF-8 encoded</td>
</tr>
<tr>
<td>Latin1_General_100_CI_AS</td>
<td>Latin1-General-100, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>Latin1_General_100_CI_AS_SC_UTF8</td>
<td>Latin1-General-100, case-insensitive, accent-sensitive, supplementary characters, UTF-8 encoded</td>
</tr>
<tr>
<td>Latin1_General_BIN</td>
<td>Latin1-General, binary sort</td>
</tr>
<tr>
<td>Latin1_General_BIN2</td>
<td>Latin1-General, binary code point sort order</td>
</tr>
<tr>
<td>Latin1_General_CI_AI</td>
<td>Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>Latin1_General_CI_AS</td>
<td>Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>Latin1_General_CI_AS_KS</td>
<td>Latin1-General, case-insensitive, accent-sensitive, kanatype-sensitive, width-insensitive</td>
</tr>
<tr>
<td>Latin1_General_CS_AS</td>
<td>Latin1-General, case-sensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>Modern_Spanish_CI_AS</td>
<td>Modern-Spanish, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>SQL_1xCompat_CP850_CI_AS</td>
<td>Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 49 on Code Page 850 for non-Unicode Data</td>
</tr>
<tr>
<td>SQL_Latin1_General_CP1_CI_AI</td>
<td>Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 54 on Code Page 1252 for non-Unicode Data</td>
</tr>
<tr>
<td><strong>SQL_Latin1_General_CP1_CI_AS (default)</strong></td>
<td>Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 52 on Code Page 1252 for non-Unicode Data</td>
</tr>
<tr>
<td>SQL_Latin1_General_CP1_CS_AS</td>
<td>Latin1-General, case-sensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 51 on Code Page 1252 for non-Unicode Data</td>
</tr>
<tr>
<td>SQL_Latin1_General_CP437_CI_AI</td>
<td>Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 34 on Code Page 437 for non-Unicode Data</td>
</tr>
</tbody>
</table>
Collations and character sets

<table>
<thead>
<tr>
<th>Collation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL_Latin1_General_CP850_BIN2</td>
<td>Latin1-General, binary code point sort order for Unicode Data, SQL Server Sort Order 40 on Code Page 850 for non-Unicode Data</td>
</tr>
<tr>
<td>SQL_Latin1_General_CP850_CI_AS</td>
<td>Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 42 on Code Page 850 for non-Unicode Data</td>
</tr>
<tr>
<td>SQL_Latin1_General_CP1256_CI_AS</td>
<td>Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 146 on Code Page 1256 for non-Unicode Data</td>
</tr>
<tr>
<td>Thai_CI_AS</td>
<td>Thai, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
</tbody>
</table>

To choose the collation:

- If you're using the Amazon RDS console, when creating a new DB instance choose Additional configuration, then enter the collation in the Collation field. For more information, see Creating an Amazon RDS DB instance (p. 300).
- If you're using the AWS CLI, use the --character-set-name option with the create-db-instance command. For more information, see create-db-instance.
- If you're using the Amazon RDS API, use the CharacterSetName parameter with the CreateDBInstance operation. For more information, see CreateDBInstance.

Database-level collation for Microsoft SQL Server

You can change the default collation at the database, table, or column level by overriding the collation when creating a new database or database object. For example, if your default server collation is SQL_Latin1_General_CP1_CI_AS, you can change it to Mohawk_100_CI_AS for Mohawk collation support. Even arguments in a query can be type-cast to use a different collation if necessary.

For example, the following query would change the default collation for the AccountName column to Mohawk_100_CI_AS

```sql
CREATE TABLE [dbo].[Account]
(
    [AccountID] [nvarchar](10) NOT NULL,
    [AccountName] [nvarchar](100) COLLATE Mohawk_100_CI_AS NOT NULL
) ON [PRIMARY];
```

The Microsoft SQL Server DB engine supports Unicode by the built-in NCHAR, NVARCHAR, and NTEXT data types. For example, if you need CJK support, use these Unicode data types for character storage and override the default server collation when creating your databases and tables. Here are several links from Microsoft covering collation and Unicode support for SQL Server:

- Working with collations
- Collation and international terminology
- Using SQL Server collations
- International considerations for databases and database engine applications
Creating a database user

You can create a database user for your Amazon RDS for Microsoft SQL Server DB instance by running a T-SQL script like the following example. Use an application such as SQL Server Management Suite (SSMS). You log into the DB instance as the master user that was created when you created the DB instance.

```sql
--Initially set context to master database
USE [master];
GO
--Create a server-level login named theirname with password theirpassword
CREATE LOGIN [theirname] WITH PASSWORD = 'theirpassword';
GO
--Set context to msdb database
USE [msdb];
GO
--Create a database user named theirname and link it to server-level login theirname
CREATE USER [theirname] FOR LOGIN [theirname];
GO
```

For an example of adding a database user to a role, see [Adding a user to the SQLAgentUser role](p. 1634).

**Note**

If you get permission errors when adding a user, you can restore privileges by modifying the DB instance master user password. For more information, see [Resetting the db_owner role password](p. 1629).

Determining a recovery model for your Microsoft SQL Server database

In Amazon RDS, the recovery model, retention period, and database status are linked. It's important to understand the consequences before making a change to one of these settings. Each setting can affect the others. For example:

- If you change a database's recovery model to SIMPLE or BULK_LOGGED while backup retention is enabled, Amazon RDS resets the recovery model to FULL within five minutes. This also results in RDS taking a snapshot of the DB instance.
- If you set backup retention to 0 days, RDS sets the recovery mode to SIMPLE.
- If you change a database's recovery model from SIMPLE to any other option while backup retention is set to 0 days, RDS resets the recovery model to SIMPLE.

**Important**

Never change the recovery model on Multi-AZ instances, even if it seems you can do so—for example, by using ALTER DATABASE. Backup retention, and therefore FULL recovery mode, is required for Multi-AZ. If you alter the recovery model, RDS immediately changes it back to FULL. This automatic reset forces RDS to completely rebuild the mirror. During this rebuild, the availability of the database is degraded for about 30-90 minutes until the mirror is ready for failover. The DB instance also experiences performance degradation in the same way it does during a conversion from Single-AZ to Multi-AZ. How long performance is degraded depends on the database storage size—the bigger the stored database, the longer the degradation.

For more information on SQL Server recovery models, see [Recovery models (SQL Server)] in the Microsoft documentation.
Determining the last failover time

To determine the last failover time, use the following stored procedure:

```sql
execute msdb.dbo.rds_failover_time;
```

This procedure returns the following information.

<table>
<thead>
<tr>
<th>Output parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>errorlog_available_from</td>
<td>Shows the time from when error logs are available in the log directory.</td>
</tr>
<tr>
<td>recent_failover_time</td>
<td>Shows the last failover time if it's available from the error logs. Otherwise it shows null.</td>
</tr>
</tbody>
</table>

**Note**

The stored procedure searches all of the available SQL Server error logs in the log directory to retrieve the most recent failover time. If the failover messages have been overwritten by SQL Server, then the procedure doesn't retrieve the failover time.

**Example of no recent failover**

This example shows the output when there is no recent failover in the error logs. No failover has happened since 2020-04-29 23:59:00.01.

<table>
<thead>
<tr>
<th>errorlog_available_from</th>
<th>recent_failover_time</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-04-29 23:59:00.0100000</td>
<td>null</td>
</tr>
</tbody>
</table>

**Example of recent failover**

This example shows the output when there is a failover in the error logs. The most recent failover was at 2020-05-05 18:57:51.89.

<table>
<thead>
<tr>
<th>errorlog_available_from</th>
<th>recent_failover_time</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-04-29 23:59:00.0100000</td>
<td>2020-05-05 18:57:51.8900000</td>
</tr>
</tbody>
</table>

Disabling fast inserts during bulk loading

Starting with SQL Server 2016, fast inserts are enabled by default. Fast inserts leverage the minimal logging that occurs while the database is in the simple or bulk logged recovery model to optimize insert performance. With fast inserts, each bulk load batch acquires new extents, bypassing the allocation lookup for existing extents with available free space to optimize insert performance.

However, with fast inserts bulk loads with small batch sizes can lead to increased unused space consumed by objects. If increasing batch size isn't feasible, enabling trace flag 692 can help reduce unused reserved space, but at the expense of performance. Enabling this trace flag disables fast inserts while bulk loading data into heap or clustered indexes.
You enable trace flag 692 as a startup parameter using DB parameter groups. For more information, see Working with parameter groups (p. 347).

Trace flag 692 is supported for Amazon RDS on SQL Server 2016 and later. For more information on trace flags, see DBCC TRACEON - trace flags in the Microsoft documentation.

Dropping a Microsoft SQL Server database

You can drop a database on an Amazon RDS DB instance running Microsoft SQL Server in a Single-AZ or Multi-AZ deployment. To drop the database, use the following command:

```sql
--replace your-database-name with the name of the database you want to drop
EXECUTE msdb.dbo.rds_drop_database N'your-database-name'
```

**Note**
Use straight single quotes in the command. Smart quotes will cause an error.

After you use this procedure to drop the database, Amazon RDS drops all existing connections to the database and removes the database's backup history.

Renaming a Microsoft SQL Server database in a Multi-AZ deployment

To rename a Microsoft SQL Server database instance that uses Multi-AZ, use the following procedure:

1. First, turn off Multi-AZ for the DB instance.
2. Rename the database by running rdsadmin.dbo.rds_modify_db_name.
3. Then, turn on Multi-AZ Mirroring or Always On Availability Groups for the DB instance, to return it to its original state.

For more information, see Adding Multi-AZ to a Microsoft SQL Server DB instance (p. 1467).

**Note**
If your instance doesn't use Multi-AZ, you don't need to change any settings before or after running rdsadmin.dbo.rds_modify_db_name.

**Example:** In the following example, the rdsadmin.dbo.rds_modify_db_name stored procedure renames a database from M00 to ZAR. This is similar to running the statement DDL ALTER DATABASE [M00] MODIFY NAME = [ZAR].

```sql
EXEC rdsadmin.dbo.rds_modify_db_name N'M00', N'ZAR'
GO
```

Resetting the db_owner role password

If you lock yourself out of the db_owner role on your Microsoft SQL Server database, you can reset the db_owner role password by modifying the DB instance master password. By changing the DB instance master password, you can regain access to the DB instance, access databases using the modified password for the db_owner, and restore privileges for the db_owner role that may have been accidentally revoked. You can change the DB instance password by using the Amazon RDS console, the AWS CLI command modify-db-instance, or by using the ModifyDBInstance operation. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 401).
Restoring license-terminated DB instances

Microsoft has requested that some Amazon RDS customers who did not report their Microsoft License Mobility information terminate their DB instance. Amazon RDS takes snapshots of these DB instances, and you can restore from the snapshot to a new DB instance that has the License Included model.

To restore from a SQL Server snapshot after Amazon RDS has created a final snapshot of your instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Choose the snapshot of your SQL Server DB instance. Amazon RDS creates a final snapshot of your DB instance. The name of the terminated instance snapshot is in the format instance_name-final-snapshot. For example, if your DB instance name is mytest.cdxyghslksma.us-east-1.rds.com, the final snapshot is called mytest-final-snapshot and is located in the same AWS Region as the original DB instance.
4. For Actions, choose Restore Snapshot.
   The Restore DB Instance window appears.
5. For License Model, choose license-included.
6. Choose the SQL Server DB engine that you want to use.
7. For DB Instance Identifier, enter the name for the restored DB instance.
8. Choose Restore DB Instance.

For more information about restoring from a snapshot, see Restoring from a DB snapshot (p. 615).

Transitioning a Microsoft SQL Server database from OFFLINE to ONLINE

You can transition your Microsoft SQL Server database on an Amazon RDS DB instance from OFFLINE to ONLINE.

<table>
<thead>
<tr>
<th>SQL Server method</th>
<th>Amazon RDS method</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTER DATABASE db_name SET ONLINE;</td>
<td>EXEC rdsadmin.dbo.rds_set_database_online db_name</td>
</tr>
</tbody>
</table>

Using change data capture

Amazon RDS supports change data capture (CDC) for your DB instances running Microsoft SQL Server. CDC captures changes that are made to the data in your tables. It stores metadata about each change, which you can access later. For more information about how CDC works, see Change data capture in the Microsoft documentation.

Before you use CDC with your Amazon RDS DB instances, enable it in the database by running msdb.dbo.rds_cdc_enable_db. You must have master user privileges to enable CDC in the Amazon
RDS DB instance. After CDC is enabled, any user who is db_owner of that database can enable or disable CDC on tables in that database.

**Important**
During restores, CDC will be disabled. All of the related metadata is automatically removed from the database. This applies to snapshot restores, point-in-time restores, and SQL Server Native restores from S3. After performing one of these types of restores, you can re-enable CDC and re-specify tables to track.

To enable CDC for a DB instance, run the `msdb.dbo.rds_cdc_enable_db` stored procedure.

```
exec msdb.dbo.rds_cdc_enable_db 'database_name'
```

To disable CDC for a DB instance, run the `msdb.dbo.rds_cdc_disable_db` stored procedure.

```
exec msdb.dbo.rds_cdc_disable_db 'database_name'
```

**Topics**

- [Tracking tables with change data capture (p. 1631)]
- [Change data capture jobs (p. 1632)]
- [Change data capture for Multi-AZ instances (p. 1632)]

**Tracking tables with change data capture**

After CDC is enabled on the database, you can start tracking specific tables. You can choose the tables to track by running `sys.sp_cdc_enable_table`.

```
--Begin tracking a table
exec sys.sp_cdc_enable_table
    @source_schema           = N'source_schema'
    , @source_name             = N'source_name'
    , @role_name               = N'role_name'

--The following parameters are optional:
    --, @capture_instance       = 'capture_instance'
    --, @supports_net_changes   = supports_net_changes
    --, @index_name             = 'index_name'
    --, @captured_column_list   = 'captured_column_list'
    --, @filegroup_name         = 'filegroup_name'
    --, @allow_partition_switch = 'allow_partition_switch'
;                       
```

To view the CDC configuration for your tables, run `sys.sp_cdc_help_change_data_capture`.

```
--View CDC configuration
exec sys.sp_cdc_help_change_data_capture

--The following parameters are optional and must be used together.
--  'schema_name', 'table_name'
;                          
```

For more information on CDC tables, functions, and stored procedures in SQL Server documentation, see the following:

- [Change data capture stored procedures (Transact-SQL)]
• **Change data capture functions (Transact-SQL)**
• **Change data capture tables (Transact-SQL)**

### Change data capture jobs

When you enable CDC, SQL Server creates the CDC jobs. Database owners (db_owner) can view, create, modify, and delete the CDC jobs. However, the RDS system account owns them. Therefore, the jobs aren't visible from native views, procedures, or in SQL Server Management Studio.

To control behavior of CDC in a database, use native SQL Server procedures such as `sp_cdc_enable_table` and `sp_cdc_start_job`. To change CDC job parameters, like `maxtrans` and `maxscans`, you can use `sp_cdc_change_job`.

To get more information regarding the CDC jobs, you can query the following dynamic management views:

- `sys.dm_cdc_errors`
- `sys.dm_cdc_log_scan_sessions`
- `sysjobs`
- `sysjobhistory`

### Change data capture for Multi-AZ instances

If you use CDC on a Multi-AZ instance, make sure the mirror's CDC job configuration matches the one on the principal. CDC jobs are mapped to the `database_id`. If the database IDs on the secondary are different from the principal, then the jobs won't be associated with the correct database. To try to prevent errors after failover, RDS drops and recreates the jobs on the new principal. The recreated jobs use the parameters that the principal recorded before failover.

Although this process runs quickly, it's still possible that the CDC jobs might run before RDS can correct them. Here are three ways to force parameters to be consistent between primary and secondary replicas:

- Use the same job parameters for all the databases that have CDC enabled.
- Before you change the CDC job configuration, convert the Multi-AZ instance to Single-AZ.
- Manually transfer the parameters whenever you change them on the principal.

To view and define the CDC parameters that are used to recreate the CDC jobs after a failover, use `rds_show_configuration` and `rds_set_configuration`.

The following example returns the value set for `cdc_capture_maxtrans`. For any parameter that is set to `RDS_DEFAULT`, RDS automatically configures the value.

```sql
-- Show configuration for each parameter on either primary and secondary replicas.
exec rdsadmin.dbo.rds_show_configuration 'cdc_capture_maxtrans';
```

To set the configuration on the secondary, run `rdsadmin.dbo.rds_set_configuration`. This procedure sets the parameter values for all of the databases on the secondary server. These settings are used only after a failover. The following example sets the `maxtrans` for all CDC capture jobs to 1000:

```sql
-- To set values on secondary. These are used after failover.
exec rdsadmin.dbo.rds_set_configuration 'cdc_capture_maxtrans', 1000;
```
To set the CDC job parameters on the principal, use `sys.sp_cdc_change_job` instead.

**Using SQL Server Agent**

With Amazon RDS, you can use SQL Server Agent on a DB instance running Microsoft SQL Server Enterprise Edition, Standard Edition, or Web Edition. SQL Server Agent is a Microsoft Windows service that runs scheduled administrative tasks that are called jobs. You can use SQL Server Agent to run T-SQL jobs to rebuild indexes, run corruption checks, and aggregate data in a SQL Server DB instance.

When you create a SQL Server DB instance, the master user is enrolled in the `SQLAgentUserRole` role.

SQL Server Agent can run a job on a schedule, in response to a specific event, or on demand. For more information, see [SQL Server Agent](#) in the Microsoft documentation.

**Note**

Avoid scheduling jobs to run during the maintenance and backup windows for your DB instance. The maintenance and backup processes that are launched by AWS could interrupt a job or cause it to be canceled.

In Multi-AZ deployments, SQL Server Agent jobs are replicated from the primary host to the secondary host when the job replication feature is turned on. For more information, see [Turning on SQL Server Agent job replication](#).

Multi-AZ deployments have a limit of 100 SQL Server Agent jobs. If you need a higher limit, request an increase by contacting AWS Support. Open the [AWS Support Center](#) page, sign in if necessary, and choose [Create case](#). Choose [Service limit increase](#). Complete and submit the form.

To view the history of an individual SQL Server Agent job in SQL Server Management Studio (SSMS), open Object Explorer, right-click the job, and then choose [View History](#).

Because SQL Server Agent is running on a managed host in a DB instance, some actions aren't supported:

- Running replication jobs and running command-line scripts by using ActiveX, Windows command shell, or Windows PowerShell aren't supported.
- You can't manually start, stop, or restart SQL Server Agent.
- Email notifications through SQL Server Agent aren't available from a DB instance.
- SQL Server Agent alerts and operators aren't supported.
- Using SQL Server Agent to create backups isn't supported. Use Amazon RDS to back up your DB instance.

**Turning on SQL Server Agent job replication**

You can turn on SQL Server Agent job replication by using the following stored procedure:

```
EXECUTE msdb.dbo.rds_set_system_database_sync_objects @object_types = 'SQLAgentJob';
```

You can run the stored procedure on all SQL Server versions supported by Amazon RDS for SQL Server. Jobs in the following categories are replicated:

- [Uncategorized (Local)]
- [Uncategorized (Multi-Server)]
- [Uncategorized]
- Data Collector
- Database Engine Tuning Advisor

1633
Only jobs that use T-SQL job steps are replicated. Jobs with step types such as SQL Server Integration Services (SSIS), SQL Server Reporting Services (SSRS), Replication, and PowerShell aren’t replicated. Jobs that use Database Mail and server-level objects aren’t replicated.

**Important**
The primary host is the source of truth for replication. Before turning on job replication, make sure that your SQL Server Agent jobs are on the primary. If you don’t do this, it could lead to the deletion of your SQL Server Agent jobs if you turn on the feature when newer jobs are on the secondary host.

You can use the following function to confirm whether replication is turned on.

```sql
SELECT * from msdb.dbo.rds_fn_get_system_database_sync_objects();
```

The T-SQL query returns the following if SQL Server Agent jobs are replicating. If they’re not replicating, it returns nothing for `object_class`.

You can use the following function to find the last time objects were synchronized in UTC time.

```sql
SELECT * from msdb.dbo.rds_fn_server_object_last_sync_time();
```

For example, suppose that you modify a SQL Server Agent job at 01:00. You expect the most recent synchronization time to be after 01:00, indicating that synchronization has taken place.

After synchronization, the values returned for `date_created` and `date_modified` on the secondary node are expected to match.

---

**Adding a user to the SQLAgentUser role**

To allow an additional login or user to use SQL Server Agent, log in as the master user and do the following:

1. Create another server-level login by using the `CREATE LOGIN` command.
2. Create a user in `msdb` using `CREATE USER` command, and then link this user to the login that you created in the previous step.
3. Add the user to the SQLAgentUserRole using the `sp_addrolemember` system stored procedure.

For example, suppose that your master user name is `admin` and you want to give access to SQL Server Agent to a user named `theirname` with a password `theirpassword`. In that case, you can use the following procedure.
To add a user to the SQLAgentUserRole

1. Log in as the master user.
2. Run the following commands:

```sql
--Initially set context to master database
USE [master];
GO
--Create a server-level login named theirname with password theirpassword
CREATE LOGIN [theirname] WITH PASSWORD = 'theirpassword';
GO
--Set context to msdb database
USE [msdb];
GO
--Create a database user named theirname and link it to server-level login theirname
CREATE USER [theirname] FOR LOGIN [theirname];
GO
--Added database user theirname in msdb to SQLAgentUserRole in msdb
EXEC sp_addrolemember [SQLAgentUserRole], [theirname];
```

Deleting a SQL Server Agent job

You use the `sp_delete_job` stored procedure to delete SQL Server Agent jobs on Amazon RDS for Microsoft SQL Server.

You can't use SSMS to delete SQL Server Agent jobs. If you try to do so, you get an error message similar to the following:

```
The EXECUTE permission was denied on the object 'xp_regread', database 'mssqlsystemresource', schema 'sys'.
```

As a managed service, RDS is restricted from running procedures that access the Windows registry. When you use SSMS, it tries to run a process (`xp_regread`) for which RDS isn't authorized.

**Note**

On RDS for SQL Server, only members of the sysadmin role are allowed to update or delete jobs owned by a different login.

To delete a SQL Server Agent job

- Run the following T-SQL statement:

```sql
EXEC msdb..sp_delete_job @job_name = 'job_name';
```

Working with Microsoft SQL Server logs

You can use the Amazon RDS console to view, watch, and download SQL Server Agent logs, Microsoft SQL Server error logs, and SQL Server Reporting Services (SSRS) logs.

Watching log files

If you view a log in the Amazon RDS console, you can see its contents as they exist at that moment. Watching a log in the console opens it in a dynamic state so that you can see updates to it in near-real time.
Only the latest log is active for watching. For example, suppose you have the following logs shown:

<table>
<thead>
<tr>
<th>Name</th>
<th>Last written</th>
</tr>
</thead>
<tbody>
<tr>
<td>log/ERROR</td>
<td>April 19, 2023, 10:06 (UTC-05:00)</td>
</tr>
<tr>
<td>log/ERROR.1</td>
<td>April 18, 2023, 18:59 (UTC-05:00)</td>
</tr>
<tr>
<td>log/ERROR.10</td>
<td>April 18, 2023, 18:59 (UTC-05:00)</td>
</tr>
<tr>
<td>log/ERROR.11</td>
<td>April 18, 2023, 18:59 (UTC-05:00)</td>
</tr>
<tr>
<td>log/ERROR.12</td>
<td>April 18, 2023, 18:59 (UTC-05:00)</td>
</tr>
</tbody>
</table>

Only log/ERROR, as the most recent log, is being actively updated. You can choose to watch others, but they are static and will not update.

### Archiving log files

The Amazon RDS console shows logs for the past week through the current day. You can download and archive logs to keep them for reference past that time. One way to archive logs is to load them into an Amazon S3 bucket. For instructions on how to set up an Amazon S3 bucket and upload a file, see [Amazon S3 basics](http://aws.amazon.com) in the [Amazon Simple Storage Service Getting Started Guide](http://aws.amazon.com) and click *Get Started*.

### Viewing error and agent logs

To view Microsoft SQL Server error and agent logs, use the Amazon RDS stored procedure `rds_read_error_log` with the following parameters:

- `@index` – the version of the log to retrieve. The default value is 0, which retrieves the current error log. Specify 1 to retrieve the previous log, specify 2 to retrieve the one before that, and so on.
- `@type` – the type of log to retrieve. Specify 1 to retrieve an error log. Specify 2 to retrieve an agent log.

**Example**

The following example requests the current error log.

```sql
EXEC rdsadmin.dbo.rds_read_error_log @index = 0, @type = 1;
```

For more information on SQL Server errors, see [Database engine errors](http://msdn.microsoft.com) in the Microsoft documentation.

### Working with trace and dump files

This section describes working with trace files and dump files for your Amazon RDS DB instances running Microsoft SQL Server.
Generating a trace SQL query

```sql
declare @rc int
declare @TraceID int
declare @maxfilesize bigint
set @maxfilesize = 5
exec @rc = sp_trace_create @TraceID output, 0, N'D:\rdsdbdata\log\rdstest', @maxfilesize, NULL
```

Viewing an open trace

```sql
select * from ::fn_trace_getinfo(default)
```

Viewing trace contents

```sql
select * from ::fn_trace_gettable('D:\rdsdbdata\log\rdstest.trc', default)
```

Setting the retention period for trace and dump files

Trace and dump files can accumulate and consume disk space. By default, Amazon RDS purges trace and dump files that are older than seven days.

To view the current trace and dump file retention period, use the `rds_show_configuration` procedure, as shown in the following example.

```sql
exec rdsadmin..rds_show_configuration;
```

To modify the retention period for trace files, use the `rds_set_configuration` procedure and set the `tracefile retention` in minutes. The following example sets the trace file retention period to 24 hours.

```sql
exec rdsadmin..rds_set_configuration 'tracefile retention', 1440;
```

To modify the retention period for dump files, use the `rds_set_configuration` procedure and set the `dumpfile retention` in minutes. The following example sets the dump file retention period to 3 days.

```sql
exec rdsadmin..rds_set_configuration 'dumpfile retention', 4320;
```

For security reasons, you cannot delete a specific trace or dump file on a SQL Server DB instance. To delete all unused trace or dump files, set the retention period for the files to 0.
Amazon RDS for MySQL

Amazon RDS supports DB instances that run the following versions of MySQL:

- MySQL 8.0
- MySQL 5.7

For more information about minor version support, see MySQL on Amazon RDS versions (p. 1643).

To create an Amazon RDS for MySQL DB instance, use the Amazon RDS management tools or interfaces. You can then do the following:

- Resize your DB instance
- Authorize connections to your DB instance
- Create and restore from backups or snapshots
- Create Multi-AZ secondaries
- Create read replicas
- Monitor the performance of your DB instance

To store and access the data in your DB instance, you use standard MySQL utilities and applications.

Amazon RDS for MySQL is compliant with many industry standards. For example, you can use RDS for MySQL databases to build HIPAA-compliant applications. You can use RDS for MySQL databases to store healthcare related information, including protected health information (PHI) under a Business Associate Agreement (BAA) with AWS. Amazon RDS for MySQL also meets Federal Risk and Authorization Management Program (FedRAMP) security requirements. In addition, Amazon RDS for MySQL has received a FedRAMP Joint Authorization Board (JAB) Provisional Authority to Operate (P-ATO) at the FedRAMP HIGH Baseline within the AWS GovCloud (US) Regions. For more information on supported compliance standards, see AWS cloud compliance.

For information about the features in each version of MySQL, see The main features of MySQL in the MySQL documentation.

Before creating a DB instance, complete the steps in Setting up for Amazon RDS (p. 174). When you create a DB instance, the RDS master user gets DBA privileges, with some limitations. Use this account for administrative tasks such as creating additional database accounts.

You can create the following:

- DB instances
- DB snapshots
- Point-in-time restores
- Automated backups
- Manual backups

You can use DB instances running MySQL inside a virtual private cloud (VPC) based on Amazon VPC. You can also add features to your MySQL DB instance by turning on various options. Amazon RDS supports Multi-AZ deployments for MySQL as a high-availability, failover solution.

Important
To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that need advanced
privileges. You can access your database using standard SQL clients such as the mysql client. However, you can't access the host directly by using Telnet or Secure Shell (SSH).

MySQL feature support on Amazon RDS

RDS for MySQL supports most of the features and capabilities of MySQL. Some features might have limited support or restricted privileges.

You can filter new Amazon RDS features on the What's New with Database? page. For Products, choose Amazon RDS. Then search using keywords such as MySQL 2022.

Note
The following lists are not exhaustive.

Topics
- Supported storage engines for RDS for MySQL (p. 1640)
- Using memcached and other options with MySQL on Amazon RDS (p. 1640)
- InnoDB cache warming for MySQL on Amazon RDS (p. 1641)
- MySQL features not supported by Amazon RDS (p. 1641)

Supported storage engines for RDS for MySQL

While MySQL supports multiple storage engines with varying capabilities, not all of them are optimized for recovery and data durability. Amazon RDS fully supports the InnoDB storage engine for MySQL DB instances. Amazon RDS features such as Point-In-Time restore and snapshot restore require a recoverable storage engine and are supported for the InnoDB storage engine only. For more information, see MySQL memcached support (p. 1754).

The Federated Storage Engine is currently not supported by Amazon RDS for MySQL.

For user-created schemas, the MyISAM storage engine does not support reliable recovery and can result in lost or corrupt data when MySQL is restarted after a recovery, preventing Point-In-Time restore or snapshot restore from working as intended. However, if you still choose to use MyISAM with Amazon RDS, snapshots can be helpful under some conditions.

Note
System tables in the mysql schema can be in MyISAM storage.

If you want to convert existing MyISAM tables to InnoDB tables, you can use the ALTER TABLE command (for example, alter table TABLE_NAME engine=innodb;). Bear in mind that MyISAM and InnoDB have different strengths and weaknesses, so you should fully evaluate the impact of making this switch on your applications before doing so.

MySQL 5.1, 5.5, and 5.6 are no longer supported in Amazon RDS. However, you can restore existing MySQL 5.1, 5.5, and 5.6 snapshots. When you restore a MySQL 5.1, 5.5, or 5.6 snapshot, the DB instance is automatically upgraded to MySQL 5.7.

Using memcached and other options with MySQL on Amazon RDS

Most Amazon RDS DB engines support option groups that allow you to select additional features for your DB instance. RDS for MySQL DB instances support the memcached option, a simple, key-based cache. For more information about memcached and other options, see Options for MySQL DB instances (p. 1748). For more information about working with option groups, see Working with option groups (p. 331).
InnoDB cache warming for MySQL on Amazon RDS

InnoDB cache warming can provide performance gains for your MySQL DB instance by saving the current state of the buffer pool when the DB instance is shut down, and then reloading the buffer pool from the saved information when the DB instance starts up. This bypasses the need for the buffer pool to "warm up" from normal database use and instead preloads the buffer pool with the pages for known common queries. The file that stores the saved buffer pool information only stores metadata for the pages that are in the buffer pool, and not the pages themselves. As a result, the file does not require much storage space. The file size is about 0.2 percent of the cache size. For example, for a 64 GiB cache, the cache warming file size is 128 MiB. For more information on InnoDB cache warming, see Saving and restoring the buffer pool state in the MySQL documentation.

RDS for MySQL DB instances support InnoDB cache warming. To enable InnoDB cache warming, set the `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup` parameters to 1 in the parameter group for your DB instance. Changing these parameter values in a parameter group will affect all MySQL DB instances that use that parameter group. To enable InnoDB cache warming for specific MySQL DB instances, you might need to create a new parameter group for those instances. For information on parameter groups, see Working with parameter groups (p. 347).

InnoDB cache warming primarily provides a performance benefit for DB instances that use standard storage. If you use PIOPS storage, you do not commonly see a significant performance benefit.

**Important**

If your MySQL DB instance does not shut down normally, such as during a failover, then the buffer pool state will not be saved to disk. In this case, MySQL loads whatever buffer pool file is available when the DB instance is restarted. No harm is done, but the restored buffer pool might not reflect the most recent state of the buffer pool prior to the restart. To ensure that you have a recent state of the buffer pool available to warm the InnoDB cache on startup, we recommend that you periodically dump the buffer pool "on demand."

You can create an event to dump the buffer pool automatically and on a regular interval. For example, the following statement creates an event named `periodic_buffer_pool_dump` that dumps the buffer pool every hour.

```sql
CREATE EVENT periodic_buffer_pool_dump
ON SCHEDULE EVERY 1 HOUR
DO CALL mysql.rds_innodb_buffer_pool_dump_now();
```

For more information on MySQL events, see Event syntax in the MySQL documentation.

### Dumping and loading the buffer pool on demand

You can save and load the InnoDB cache "on demand."

- To dump the current state of the buffer pool to disk, call the `mysql.rds_innodb_buffer_pool_dump_now` stored procedure.
- To load the saved state of the buffer pool from disk, call the `mysql.rds_innodb_buffer_pool_load_now` stored procedure.
- To cancel a load operation in progress, call the `mysql.rds_innodb_buffer_pool_load_abort` stored procedure.

### MySQL features not supported by Amazon RDS

Amazon RDS doesn't currently support the following MySQL features:

- Authentication Plugin
• Error Logging to the System Log
• Group Replication Plugin
• InnoDB Tablespace Encryption
• Password Strength Plugin
• Persisted system variables
• Rewriter Query Rewrite Plugin
• Semisynchronous replication
• Transportable tablespace
• X Plugin

**Note**
Global transaction IDs are supported for all RDS for MySQL 5.7 versions, and for RDS for MySQL 8.0.26 and higher 8.0 versions.

To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application. Amazon RDS doesn't allow direct host access to a DB instance by using Telnet, Secure Shell (SSH), or Windows Remote Desktop Connection. When you create a DB instance, you are assigned to the `db_owner` role for all databases on that instance, and you have all database-level permissions except for those used for backups. Amazon RDS manages backups for you.
MySQL on Amazon RDS versions

For MySQL, version numbers are organized as version = X.Y.Z. In Amazon RDS terminology, X.Y denotes the major version, and Z is the minor version number. For Amazon RDS implementations, a version change is considered major if the major version number changes—for example, going from version 5.7 to 8.0. A version change is considered minor if only the minor version number changes—for example, going from version 8.0.28 to 8.0.32.

Topics
- Supported MySQL minor versions on Amazon RDS (p. 1643)
- Supported MySQL major versions on Amazon RDS (p. 1645)
- Deprecated versions for Amazon RDS for MySQL (p. 1645)

Supported MySQL minor versions on Amazon RDS

Amazon RDS currently supports the following minor versions of MySQL.

**Note**
Dates with only a month and a year are approximate and are updated with an exact date when it’s known.

</table>
* Amazon RDS Extended Support eligible minor engine version. For more information, see Using Amazon RDS Extended Support (p. 565).

You can specify any currently supported MySQL version when creating a new DB instance. You can specify the major version (such as MySQL 5.7), and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified. To see a list of supported versions, as well as defaults for newly created DB instances, use the describe-db-engine-versions AWS CLI command.

For example, to list the supported engine versions for RDS for MySQL, run the following CLI command:

```bash
```

The default MySQL version might vary by AWS Region. To create a DB instance with a specific minor version, specify the minor version during DB instance creation. You can determine the default minor version for an AWS Region using the following AWS CLI command:

```bash
```

Replace `major-engine-version` with the major engine version, and replace `region` with the AWS Region. For example, the following AWS CLI command returns the default MySQL minor engine version for the 5.7 major version and the US West (Oregon) AWS Region (us-west-2):

```bash
```

With Amazon RDS, you control when to upgrade your MySQL instance to a new major version supported by Amazon RDS. You can maintain compatibility with specific MySQL versions, test new versions with your application before deploying in production, and perform major version upgrades at times that best fit your schedule.

When automatic minor version upgrade is enabled, your DB instance will be upgraded automatically to new MySQL minor versions as they are supported by Amazon RDS. This patching occurs during your scheduled maintenance window. You can modify a DB instance to enable or disable automatic minor version upgrades.

If you opt out of automatically scheduled upgrades, you can manually upgrade to a supported minor version release by following the same procedure as you would for a major version update. For information, see Upgrading a DB instance engine version (p. 429).

Amazon RDS currently supports the major version upgrades from MySQL version 5.6 to version 5.7, and from MySQL version 5.7 to version 8.0. Because major version upgrades involve some compatibility risk, they do not occur automatically; you must make a request to modify the DB instance. You should thoroughly test any upgrade before upgrading your production instances. For information about upgrading a MySQL DB instance, see Upgrading the MySQL DB engine (p. 1680).

You can test a DB instance against a new version before upgrading by creating a DB snapshot of your existing DB instance, restoring from the DB snapshot to create a new DB instance, and then initiating a version upgrade for the new DB instance. You can then experiment safely on the upgraded clone of your DB instance before deciding whether or not to upgrade your original DB instance.
Supported MySQL major versions on Amazon RDS

RDS for MySQL major versions are available under standard support at least until community end of life for the corresponding community version. You can continue running a major version past its RDS end of standard support date for a fee. For more information, see Using Amazon RDS Extended Support (p. 565) and Amazon RDS for MySQL pricing.

You can use the following dates to plan your testing and upgrade cycles.

Note
Dates with only a month and a year are approximate and are updated with an exact date when it's known.

<table>
<thead>
<tr>
<th>MySQL major version</th>
<th>Community release date</th>
<th>RDS release date</th>
<th>Community end of life date</th>
<th>RDS end of standard support date</th>
<th>RDS start of Extended Support year 1 pricing date</th>
<th>RDS start of Extended Support year 3 pricing date</th>
<th>RDS end of Extended Support date</th>
</tr>

Deprecated versions for Amazon RDS for MySQL

Amazon RDS for MySQL version 5.1, 5.5, and 5.6 are deprecated.

For information about the Amazon RDS deprecation policy for MySQL, see Amazon RDS FAQs.
Connecting to a DB instance running the MySQL database engine

Before you can connect to a DB instance running the MySQL database engine, you must create a DB instance. For information, see Creating an Amazon RDS DB instance (p. 300). After Amazon RDS provisions your DB instance, you can use any standard MySQL client application or utility to connect to the instance. In the connection string, you specify the DNS address from the DB instance endpoint as the host parameter, and specify the port number from the DB instance endpoint as the port parameter.

To authenticate to your RDS DB instance, you can use one of the authentication methods for MySQL and AWS Identity and Access Management (IAM) database authentication:

- To learn how to authenticate to MySQL using one of the authentication methods for MySQL, see Authentication method in the MySQL documentation.
- To learn how to authenticate to MySQL using IAM database authentication, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 2659).

You can connect to a MySQL DB instance by using tools like the MySQL command-line client. For more information on using the MySQL command-line client, see mysql - the MySQL command-line client in the MySQL documentation. One GUI-based application you can use to connect is MySQL Workbench. For more information, see the Download MySQL Workbench page. For information about installing MySQL (including the MySQL command-line client), see Installing and upgrading MySQL.

Most Linux distributions include the MariaDB client instead of the Oracle MySQL client. To install the MySQL command-line client on Amazon Linux 2023, run the following command:

```
sudo dnf install mariadb105
```

To install the MySQL command-line client on Amazon Linux 2, run the following command:

```
sudo yum install mariadb
```

To install the MySQL command-line client on most DEB-based Linux distributions, run the following command:

```
apt-get install mariadb-client
```

To check the version of your MySQL command-line client, run the following command:

```
mysql --version
```

To read the MySQL documentation for your current client version, run the following command:

```
man mysql
```

To connect to a DB instance from outside of its Amazon VPC, the DB instance must be publicly accessible, access must be granted using the inbound rules of the DB instance’s security group, and other requirements must be met. For more information, see Can’t connect to Amazon RDS DB instance (p. 2744).

You can use Secure Sockets Layer (SSL) or Transport Layer Security (TLS) encryption on connections to a MySQL DB instance. For information, see Using SSL/TLS with a MySQL DB instance (p. 1655).
you are using AWS Identity and Access Management (IAM) database authentication, make sure to use an SSL/TLS connection. For information, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 2659).

You can also connect to a DB instance from a web server. For more information, see Tutorial: Create a web server and an Amazon RDS DB instance (p. 249).

Note
For information on connecting to a MariaDB DB instance, see Connecting to a DB instance running the MariaDB database engine (p. 1285).

Topics
• Finding the connection information for a MySQL DB instance (p. 1647)
• Connecting from the MySQL command-line client (unencrypted) (p. 1649)
• Connecting from MySQL Workbench (p. 1650)
• Connecting with the Amazon Web Services JDBC Driver for MySQL (p. 1651)
• Troubleshooting connections to your MySQL DB instance (p. 1652)

Finding the connection information for a MySQL DB instance

The connection information for a DB instance includes its endpoint, port, and a valid database user, such as the master user. For example, suppose that an endpoint value is mydb.123456789012.us-east-1.rds.amazonaws.com. In this case, the port value is 3306, and the database user is admin. Given this information, you specify the following values in a connection string:

• For host or host name or DNS name, specify mydb.123456789012.us-east-1.rds.amazonaws.com.
• For port, specify 3306.
• For user, specify admin.

To connect to a DB instance, use any client for the MySQL DB engine. For example, you might use the MySQL command-line client or MySQL Workbench.

To find the connection information for a DB instance, you can use the AWS Management Console, the AWS CLI describe-db-instances command, or the Amazon RDS API DescribeDBInstances operation to list its details.

Console

To find the connection information for a DB instance in the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases to display a list of your DB instances.
3. Choose the name of the MySQL DB instance to display its details.
4. On the Connectivity & security tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.
5. If you need to find the master user name, choose the Configuration tab and view the Master username value.

**AWS CLI**

To find the connection information for a MySQL DB instance by using the AWS CLI, call the `describe-db-instances` command. In the call, query for the DB instance ID, endpoint, port, and master user name.
For Linux, macOS, or Unix:

```bash
aws rds describe-db-instances \
  --filters "Name=engine,Values=mysql" \
  --query "*[].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

For Windows:

```bash
aws rds describe-db-instances ^
  --filters "Name=engine,Values=mysql" ^
  --query "*[].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

Your output should be similar to the following.

```
[
  [
    "mydb1",
    "mydb1.123456789012.us-east-1.rds.amazonaws.com",
    3306,
    "admin"
  ],
  [
    "mydb2",
    "mydb2.123456789012.us-east-1.rds.amazonaws.com",
    3306,
    "admin"
  ]
]
```

**RDS API**

To find the connection information for a DB instance by using the Amazon RDS API, call the `DescribeDBInstances` operation. In the output, find the values for the endpoint address, endpoint port, and master user name.

**Connecting from the MySQL command-line client (unencrypted)**

*Important*

Only use an unencrypted MySQL connection when the client and server are in the same VPC and the network is trusted. For information about using encrypted connections, see [Connecting from the MySQL command-line client with SSL/TLS (encrypted)](p. 1656).

To connect to a DB instance using the MySQL command-line client, enter the following command at the command prompt. For the `-h` parameter, substitute the DNS name (endpoint) for your DB instance. For the `-P` parameter, substitute the port for your DB instance. For the `-u` parameter, substitute the user name of a valid database user, such as the master user. Enter the master user password when prompted.

```bash
mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com -P 3306 -u mymasteruser -p
```

After you enter the password for the user, you should see output similar to the following.

```
Welcome to the MySQL monitor. Commands end with ; or \g.
```
Connecting from MySQL Workbench

To connect from MySQL Workbench

1. Download and install MySQL Workbench at [Download MySQL Workbench].
2. Open MySQL Workbench.
3. From Database, choose Manage Connections.
4. In the Manage Server Connections window, choose New.
5. In the Connect to Database window, enter the following information:
   - Stored Connection – Enter a name for the connection, such as MyDB.
   - Hostname – Enter the DB instance endpoint.
   - Port – Enter the port used by the DB instance.
   - Username – Enter the user name of a valid database user, such as the master user.
   - Password – Optionally, choose Store in Vault and then enter and save the password for the user.

The window looks similar to the following:
You can use the features of MySQL Workbench to customize connections. For example, you can use the SSL tab to configure SSL/TLS connections. For information about using MySQL Workbench, see the MySQL Workbench documentation. Encrypting client connections to MySQL DB instances with SSL/TLS, see Encrypting client connections to MySQL DB instances with SSL/TLS (p. 1655).

6. Optionally, choose Test Connection to confirm that the connection to the DB instance is successful.
7. Choose Close.
8. From Database, choose Connect to Database.
9. From Stored Connection, choose your connection.
10. Choose OK.

Connecting with the Amazon Web Services JDBC Driver for MySQL

The AWS JDBC Driver for MySQL is a client driver designed for RDS for MySQL. By default, the driver has settings that are optimized for use with RDS for MySQL. For more information about the driver and complete instructions for using it, see the AWS JDBC Driver for MySQL GitHub repository.

The driver is drop-in compatible with the MySQL Connector/J driver. To install or upgrade your connector, replace the MySQL connector .jar file (located in the application CLASSPATH) with the AWS JDBC Driver for MySQL .jar file, and update the connection URL prefix from jdbc:mysql:// to jdbc:mysql:aws://.

The AWS JDBC Driver for MySQL supports IAM database authentication. For more information, see AWS IAM Database Authentication in the AWS JDBC Driver for MySQL GitHub repository. For more information about IAM database authentication, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 2659).
Troubleshooting connections to your MySQL DB instance

Two common causes of connection failures to a new DB instance are:

- The DB instance was created using a security group that doesn't authorize connections from the device or Amazon EC2 instance where the MySQL application or utility is running. The DB instance must have a VPC security group that authorizes the connections. For more information, see Amazon VPC VPCs and Amazon RDS (p. 2705).

  You can add or edit an inbound rule in the security group. For Source, choose My IP. This allows access to the DB instance from the IP address detected in your browser.

- The DB instance was created using the default port of 3306, and your company has firewall rules blocking connections to that port from devices in your company network. To fix this failure, recreate the instance with a different port.

For more information on connection issues, see Can't connect to Amazon RDS DB instance (p. 2744).
Securing MySQL DB instance connections

You can manage the security of your MySQL DB instances.

Topics

- MySQL security on Amazon RDS (p. 1653)
- Using the Password Validation Plugin for RDS for MySQL (p. 1654)
- Encrypting client connections to MySQL DB instances with SSL/TLS (p. 1655)
- Updating applications to connect to MySQL DB instances using new SSL/TLS certificates (p. 1658)
- Using Kerberos authentication for MySQL (p. 1661)

MySQL security on Amazon RDS

Security for MySQL DB instances is managed at three levels:

- AWS Identity and Access Management controls who can perform Amazon RDS management actions on DB instances. When you connect to AWS using IAM credentials, your IAM account must have IAM policies that grant the permissions required to perform Amazon RDS management operations. For more information, see Identity and access management for Amazon RDS (p. 2623).
- When you create a DB instance, you use a VPC security group to control which devices and Amazon EC2 instances can open connections to the endpoint and port of the DB instance. These connections can be made using Secure Sockets Layer (SSL) and Transport Layer Security (TLS). In addition, firewall rules at your company can control whether devices running at your company can open connections to the DB instance.
- To authenticate login and permissions for a MySQL DB instance, you can take either of the following approaches, or a combination of them.

      
You can take the same approach as with a stand-alone instance of MySQL. Commands such as CREATE USER, RENAME USER, GRANT, REVOKE, and SET PASSWORD work just as they do in on-premises databases, as does directly modifying database schema tables. For information, see Access control and account management in the MySQL documentation.

You can also use IAM database authentication. With IAM database authentication, you authenticate to your DB instance by using an IAM user or IAM role and an authentication token. An authentication token is a unique value that is generated using the Signature Version 4 signing process. By using IAM database authentication, you can use the same credentials to control access to your AWS resources and your databases. For more information, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 2659).

Another option is Kerberos authentication for RDS for MySQL. The DB instance works with AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to enable Kerberos authentication. When users authenticate with a MySQL DB instance joined to the trusting domain, authentication requests are forwarded. Forwarded requests go to the domain directory that you create with AWS Directory Service. For more information, see Using Kerberos authentication for MySQL (p. 1661).

When you create an Amazon RDS DB instance, the master user has the following default privileges:

- alter
- alter routine
- create
- create routine
• create temporary tables
• create user
• create view
• delete
• drop
• event
• execute
• grant option
• index
• insert
• lock tables
• process
• references
• replication client
• replication slave
• select
• show databases
• show view
• trigger
• update

**Note**
Although it is possible to delete the master user on the DB instance, it is not recommended. To recreate the master user, use the ModifyDBInstance RDS API operation or the `modify-db-instance` AWS CLI command and specify a new master user password with the appropriate parameter. If the master user does not exist in the instance, the master user is created with the specified password.

To provide management services for each DB instance, the rdsadmin user is created when the DB instance is created. Attempting to drop, rename, change the password, or change privileges for the rdsadmin account will result in an error.

To allow management of the DB instance, the standard `kill` and `kill_query` commands have been restricted. The Amazon RDS commands `rds_kill` and `rds_kill_query` are provided to allow you to end user sessions or queries on DB instances.

**Using the Password Validation Plugin for RDS for MySQL**

MySQL provides the validate_password plugin for improved security. The plugin enforces password policies using parameters in the DB parameter group for your MySQL DB instance. The plugin is supported for DB instances running MySQL version 5.7 and 8.0. For more information about the validate_password plugin, see [The Password Validation Plugin](#) in the MySQL documentation.

**To enable the validate_password plugin for a MySQL DB instance**

1. Connect to your MySQL DB instance and run the following command.
INSTALL PLUGIN validate_password SONAME 'validate_password.so';

2. Configure the parameters for the plugin in the DB parameter group used by the DB instance.

   For more information about the parameters, see Password Validation Plugin options and variables in the MySQL documentation.

   For more information about modifying DB instance parameters, see Modifying parameters in a DB parameter group (p. 352).

After installing and enabling the password_validate plugin, reset existing passwords to comply with your new validation policies.

Amazon RDS doesn't validate passwords. The MySQL DB instance performs password validation. If you set a user password with the AWS Management Console, the modify-db-instance AWS CLI command, or the ModifyDBInstance RDS API operation, the change can succeed even if the new password doesn't satisfy your password policies. However, a new password is set in the MySQL DB instance only if it satisfies the password policies. In this case, Amazon RDS records the following event.

"RDS-EVENT-0067" - An attempt to reset the master password for the DB instance has failed.

For more information about Amazon RDS events, see Working with Amazon RDS event notification (p. 855).

Encrypting client connections to MySQL DB instances with SSL/TLS

Secure Sockets Layer (SSL) is an industry-standard protocol for securing network connections between client and server. After SSL version 3.0, the name was changed to Transport Layer Security (TLS). Amazon RDS supports SSL/TLS encryption for MySQL DB instances. Using SSL/TLS, you can encrypt a connection between your application client and your MySQL DB instance. SSL/TLS support is available in all AWS Regions for MySQL.

Topics

- Using SSL/TLS with a MySQL DB instance (p. 1655)
- Requiring SSL/TLS for all connections to a MySQL DB instance (p. 1656)
- Connecting from the MySQL command-line client with SSL/TLS (encrypted) (p. 1656)

Using SSL/TLS with a MySQL DB instance

Amazon RDS creates an SSL/TLS certificate and installs the certificate on the DB instance when Amazon RDS provisions the instance. These certificates are signed by a certificate authority. The SSL/TLS certificate includes the DB instance endpoint as the Common Name (CN) for the SSL/TLS certificate to guard against spoofing attacks.

An SSL/TLS certificate created by Amazon RDS is the trusted root entity and should work in most cases but might fail if your application does not accept certificate chains. If your application does not accept certificate chains, you might need to use an intermediate certificate to connect to your AWS Region. For example, you must use an intermediate certificate to connect to the AWS GovCloud (US) Regions using SSL/TLS.
Encrypting with SSL/TLS

For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2608). For more information about using SSL/TLS with MySQL, see Updating applications to connect to MySQL DB instances using new SSL/TLS certificates (p. 1658).

MySQL uses OpenSSL for secure connections. Amazon RDS for MySQL supports Transport Layer Security (TLS) versions 1.0, 1.1, 1.2, and 1.3. TLS support depends on the MySQL version. The following table shows the TLS support for MySQL versions.

<table>
<thead>
<tr>
<th>MySQL version</th>
<th>TLS 1.0</th>
<th>TLS 1.1</th>
<th>TLS 1.2</th>
<th>TLS 1.3</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 8.0</td>
<td>Not supported</td>
<td>Not supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>MySQL 5.7</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
<td>Not supported</td>
</tr>
</tbody>
</table>

You can require SSL/TLS connections for specific users accounts. For example, you can use one of the following statements, depending on your MySQL version, to require SSL/TLS connections on the user account encrypted_user.

To do so, use the following statement.

```
ALTER USER 'encrypted_user'@'%' REQUIRE SSL;
```

For more information on SSL/TLS connections with MySQL, see the Using encrypted connections in the MySQL documentation.

Requiring SSL/TLS for all connections to a MySQL DB instance

Use the require_secure_transport parameter to require that all user connections to your MySQL DB instance use SSL/TLS. By default, the require_secure_transport parameter is set to OFF. You can set the require_secure_transport parameter to ON to require SSL/TLS for connections to your DB instance.

You can set the require_secure_transport parameter value by updating the DB parameter group for your DB instance. You don't need to reboot your DB instance for the change to take effect.

When the require_secure_transport parameter is set to ON for a DB instance, a database client can connect to it if it can establish an encrypted connection. Otherwise, an error message similar to the following is returned to the client:

```
MySQL Error 3159 (HY000): Connections using insecure transport are prohibited while --
require_secure_transport=ON.
```

For information about setting parameters, see Modifying parameters in a DB parameter group (p. 352).

For more information about the require_secure_transport parameter, see the MySQL documentation.

Connecting from the MySQL command-line client with SSL/TLS (encrypted)

The mysql client program parameters are slightly different if you are using the MySQL 5.7 version, the MySQL 8.0 version, or the MariaDB version.
To find out which version you have, run the `mysql` command with the `--version` option. In the following example, the output shows that the client program is from MariaDB.

```
$ mysql --version
mysql Ver 15.1 Distrib 10.5.15-MariaDB, for osx10.15 (x86_64) using readline 5.1
```

Most Linux distributions, such as Amazon Linux, CentOS, SUSE, and Debian have replaced MySQL with MariaDB, and the `mysql` version in them is from MariaDB.

To connect to your DB instance using SSL/TLS, follow these steps:

### To connect to a DB instance with SSL/TLS using the MySQL command-line client

1. Download a root certificate that works for all AWS Regions.

   For information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB instance](p. 2608).

2. Use a MySQL command-line client to connect to a DB instance with SSL/TLS encryption. For the `--h` parameter, substitute the DNS name (endpoint) for your DB instance. For the `--ssl-ca` parameter, substitute the SSL/TLS certificate file name. For the `--ssl-mode` parameter, substitute the port for your DB instance. For the `--u` parameter, substitute the user name of a valid database user, such as the master user. Enter the master user password when prompted.

   The following example shows how to launch the client using the `--ssl-ca` parameter using the MySQL 5.7 client or later:

   ```
   mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl-mode=REQUIRED -P 3306 -u myadmin -p
   ```

   To require that the SSL/TLS connection verifies the DB instance endpoint against the endpoint in the SSL/TLS certificate, enter the following command:

   ```
   mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl-mode=VERIFY_IDENTITY -P 3306 -u myadmin -p
   ```

   The following example shows how to launch the client using the `--ssl-ca` parameter using the MariaDB client:

   ```
   mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl -P 3306 -u myadmin -p
   ```

3. Enter the master user password when prompted.

   You will see output similar to the following.

   ```
   Welcome to the MySQL monitor. Commands end with ; or \g.
   Your MySQL connection id is 9738
   Server version: 8.0.28 Source distribution
   Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
   mysql>
   ```
Updating applications to connect to MySQL DB instances using new SSL/TLS certificates

As of January 13, 2023, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB instances. If they do, you can further check whether those applications require certificate verification to connect.

**Note**

Some applications are configured to connect to MySQL DB instances only if they can successfully verify the certificate on the server. For such applications, you must update your client application trust stores to include the new CA certificates.

You can specify the following SSL modes: disabled, preferred, and required. When you use the preferred SSL mode and the CA certificate doesn't exist or isn't up to date, the connection falls back to not using SSL and connects without encryption.

Because these later versions use the OpenSSL protocol, an expired server certificate doesn't prevent successful connections unless the required SSL mode is specified.

We recommend avoiding preferred mode. In preferred mode, if the connection encounters an invalid certificate, it stops using encryption and proceeds unencrypted.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate (p. 2613). For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2608). For information about using SSL/TLS with MySQL DB instances, see Using SSL/TLS with a MySQL DB instance (p. 1655).

**Topics**

- Determining whether any applications are connecting to your MySQL DB instance using SSL (p. 1658)
- Determining whether a client requires certificate verification to connect (p. 1659)
- Updating your application trust store (p. 1660)
- Example Java code for establishing SSL connections (p. 1660)

Determining whether any applications are connecting to your MySQL DB instance using SSL

If you are using Amazon RDS for MySQL version 5.7 or 8.0 and the Performance Schema is enabled, run the following query to check if connections are using SSL/TLS. For information about enabling the Performance Schema, see Performance Schema quick start in the MySQL documentation.

```
mysql> SELECT id, user, host, connection_type
    FROM performance_schema.threads pst
    INNER JOIN information_schema.processlist isp
    ON pst.processlist_id = isp.id;
```

In this sample output, you can see both your own session (admin) and an application logged in as webapp1 are using SSL.
Determining whether a client requires certificate verification to connect

You can check whether JDBC clients and MySQL clients require certificate verification to connect.

**JDBC**

The following example with MySQL Connector/J 8.0 shows one way to check an application's JDBC connection properties to determine whether successful connections require a valid certificate. For more information on all of the JDBC connection options for MySQL, see Configuration properties in the MySQL documentation.

When using the MySQL Connector/J 8.0, an SSL connection requires verification against the server CA certificate if your connection properties have `sslMode` set to `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```java
Properties properties = new Properties();
properties.setProperty("sslMode", "VERIFY_IDENTITY");
properties.put("user", DB_USER);
properties.put("password", DB_PASSWORD);
```

**Note**

If you use either the MySQL Java Connector v5.1.38 or later, or the MySQL Java Connector v8.0.9 or later to connect to your databases, even if you haven't explicitly configured your applications to use SSL/TLS when connecting to your databases, these client drivers default to using SSL/TLS. In addition, when using SSL/TLS, they perform partial certificate verification and fail to connect if the database server certificate is expired.

**MySQL**

The following examples with the MySQL Client show two ways to check a script's MySQL connection to determine whether successful connections require a valid certificate. For more information on all of the connection options with the MySQL Client, see Client-side configuration for encrypted connections in the MySQL documentation.

When using the MySQL 5.7 or MySQL 8.0 Client, an SSL connection requires verification against the server CA certificate if for the `--ssl-mode` option you specify `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem --ssl-mode=VERIFY_CA
```
When using the MySQL 5.6 Client, an SSL connection requires verification against the server CA certificate if you specify the --ssl-verify-server-cert option, as in the following example.

```bash
code
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem --ssl-verify-server-cert
```

### Updating your application trust store

For information about updating the trust store for MySQL applications, see [Installing SSL certificates](#) in the MySQL documentation.

For information about downloading the root certificate, see [Using SSL/TLS to encrypt a connection to a DB instance](#) (p. 2608).

For sample scripts that import certificates, see [Sample script for importing certificates into your trust store](#) (p. 2620).

**Note**

When you update the trust store, you can retain older certificates in addition to adding the new certificates.

If you are using the mysql JDBC driver in an application, set the following properties in the application.

```java
System.setProperty("javax.net.ssl.trustStore", "certs");
System.setProperty("javax.net.ssl.trustStorePassword", "password");
```

When you start the application, set the following properties.

```java
code
java -Djavax.net.ssl.trustStore=/path_to_truststore/MyTruststore.jks -Djavax.net.ssl.trustStorePassword=my_truststore_password com.companyName.MyApplication
```

**Note**

Specify a password other than the prompt shown here as a security best practice.

### Example Java code for establishing SSL connections

The following code example shows how to set up the SSL connection that validates the server certificate using JDBC.

```java
public class MySQLSSLSSTest {
    private static final String DB_USER = "username";
    private static final String DB_PASSWORD = "password";
    // This key store has only the prod root ca.
    private static final String KEY_STORE_FILE_PATH = "file-path-to-keystore";
    private static final String KEY_STORE_PASS = "keystore-password";

    public static void test(String[] args) throws Exception {
        Class.forName("com.mysql.jdbc.Driver");
    }
}
```
Using Kerberos authentication for MySQL

You can use Kerberos authentication to authenticate users when they connect to your MySQL DB instance. The DB instance works with AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to enable Kerberos authentication. When users authenticate with a MySQL DB instance joined to the trusting domain, authentication requests are forwarded. Forwarded requests go to the domain directory that you create with AWS Directory Service.

Keeping all of your credentials in the same directory can save you time and effort. With this approach, you have a centralized place for storing and managing credentials for multiple DB instances. Using a directory can also improve your overall security profile.
Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of Amazon RDS with Kerberos authentication, see Kerberos authentication (p. 141).

Overview of Setting up Kerberos authentication for MySQL DB instances

To set up Kerberos authentication for a MySQL DB instance, complete the following general steps, described in more detail later:

1. Use AWS Managed Microsoft AD to create an AWS Managed Microsoft AD directory. You can use the AWS Management Console, the AWS CLI, or the AWS Directory Service to create the directory. For details about doing so, see Create your AWS Managed Microsoft AD directory in the AWS Directory Service Administration Guide.

2. Create an AWS Identity and Access Management (IAM) role that uses the managed IAM policy AmazonRDSDirectoryServiceAccess. The role allows Amazon RDS to make calls to your directory. For the role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Activating and deactivating AWS STS in an AWS Region in the IAM User Guide.

3. Create and configure users in the AWS Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users in your Active Directory, see Manage users and groups in AWS managed Microsoft AD in the AWS Directory Service Administration Guide.

4. Create or modify a MySQL DB instance. If you use either the CLI or RDS API in the create request, specify a domain identifier with the Domain parameter. Use the d-* identifier that was generated when you created your directory and the name of the role that you created. If you modify an existing MySQL DB instance to use Kerberos authentication, set the domain and IAM role parameters for the DB instance. Locate the DB instance in the same VPC as the domain directory.

5. Use the Amazon RDS master user credentials to connect to the MySQL DB instance. Create the user in MySQL using the CREATE USER clause IDENTIFIED WITH `auth_pam`. Users that you create this way can log in to the MySQL DB instance using Kerberos authentication.

Setting up Kerberos authentication for MySQL DB instances

You use AWS Managed Microsoft AD to set up Kerberos authentication for a MySQL DB instance. To set up Kerberos authentication, you take the following steps.

Step 1: Create a directory using AWS Managed Microsoft AD

AWS Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and Domain Name System (DNS) servers on your behalf. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

- Sets up an Active Directory within the VPC.
- Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.
Note
Be sure to save this password. AWS Directory Service doesn't store it. You can reset it, but you can't retrieve it.

• Creates a security group for the directory controllers.

When you launch an AWS Managed Microsoft AD, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU has the NetBIOS name that you typed when you created your directory and is located in the domain root. The domain root is owned and managed by AWS.

The Admin account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

• Create, update, or delete users
• Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
• Create additional OUs and containers
• Delegate authority
• Restore deleted objects from the Active Directory Recycle Bin
• Run AD and DNS Windows PowerShell modules on the Active Directory Web Service

The Admin account also has rights to perform the following domain-wide activities:

• Manage DNS configurations (add, remove, or update records, zones, and forwarders)
• View DNS event logs
• View security event logs

To create a directory with AWS Managed Microsoft AD

2. In the navigation pane, choose Directories and choose Set up Directory.
3. Choose AWS Managed Microsoft AD. AWS Managed Microsoft AD is the only option that you can currently use with Amazon RDS.
4. Enter the following information:

Directory DNS name
The fully qualified name for the directory, such as corp.example.com.

Directory NetBIOS name
The short name for the directory, such as CORP.

Directory description
(Optional) A description for the directory.

Admin password
The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.

The directory administrator password and can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:
• Lowercase letters (a–z)
• Uppercase letters (A–Z)
• Numbers (0–9)
• Non-alphanumeric characters (~!@#$%^&*_-+=`|(){}[]:;"'<>,.?/)

Confirm password

The administrator password retyped.

5. Choose Next.

6. Enter the following information in the Networking section and then choose Next:

VPC

The VPC for the directory. Create the MySQL DB instance in this same VPC.

Subnets

Subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Review the directory information and make any necessary changes. When the information is correct, choose Create directory.
It takes several minutes for the directory to be created. When it has been successfully created, the Status value changes to Active.

To see information about your directory, choose the directory name in the directory listing. Note the Directory ID value because you need this value when you create or modify your MySQL DB instance.
Step 2: Create the IAM role for use by Amazon RDS

For Amazon RDS to call AWS Directory Service for you, an IAM role that uses the managed IAM policy AmazonRDSDirectoryServiceAccess is required. This role allows Amazon RDS to make calls to the AWS Directory Service.

When a DB instance is created using the AWS Management Console and the console user has the iam:CreateRole permission, the console creates this role automatically. In this case, the role name is rds-directoryservice-kerberos-access-role. Otherwise, you must create the IAM role manually. When you create this IAM role, choose Directory Service, and attach the AWS managed policy AmazonRDSDirectoryServiceAccess to it.

For more information about creating IAM roles for a service, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

Note
The IAM role used for Windows Authentication for RDS for SQL Server can't be used for RDS for MySQL.

Optionally, you can create policies with the required permissions instead of using the managed IAM policy AmazonRDSDirectoryServiceAccess. In this case, the IAM role must have the following IAM trust policy.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "sts:AssumeRole"
            ],
            "Principal": {
                "Service": "rds.amazonaws.com"
            }
        }
    ]
}
```
"Statement": [ 
  
  "Sid": "",
  "Effect": "Allow",
  "Principal": { 
    "Service": [ 
      "directoryservice.rds.amazonaws.com",
      "rds.amazonaws.com"
    ], 
    "Action": "sts:AssumeRole"
  } 
]

The role must also have the following IAM role policy.

{
  "Version": "2012-10-17",
  "Statement": [ 
    
    "Action": [ 
      "ds:DescribeDirectories",
      "ds:AuthorizeApplication",
      "ds:UnauthorizeApplication",
      "ds:GetAuthorizedApplicationDetails"
    ],
    "Effect": "Allow",
    "Resource": "*"
  ]
]

Step 3: Create and configure users

You can create users with the Active Directory Users and Computers tool. This tool is part of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. Users represent individual people or entities that have access to your directory.

To create users in an AWS Directory Service directory, you must be connected to an Amazon EC2 instance based on Microsoft Windows. This instance must be a member of the AWS Directory Service directory and be logged in as a user that has privileges to create users. For more information, see Manage users and groups in AWS Managed Microsoft AD in the AWS Directory Service Administration Guide.

Step 4: Create or modify a MySQL DB instance

Create or modify a MySQL DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new MySQL DB instance using the console, the `create-db-instance` CLI command, or the `CreateDBInstance` RDS API operation.
  For instructions, see Creating an Amazon RDS DB instance (p. 300).
- Modify an existing MySQL DB instance using the console, the `modify-db-instance` CLI command, or the `ModifyDBInstance` RDS API operation.
  For instructions, see Modifying an Amazon RDS DB instance (p. 401).
- Restore a MySQL DB instance from a DB snapshot using the console, the `restore-db-instance-from-db-snapshot` CLI command, or the `RestoreDBInstanceFromDBSnapshot` RDS API operation.
  For instructions, see Restoring from a DB snapshot (p. 615).
• Restore a MySQL DB instance to a point-in-time using the console, the `restore-db-instance-to-point-in-time` CLI command, or the `RestoreDBInstanceToPointInTime` RDS API operation. For instructions, see [Restoring a DB instance to a specified time (p. 660)](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/UsingRDS.RestoreDbInstance.html).

Kerberos authentication is only supported for MySQL DB instances in a VPC. The DB instance can be in the same VPC as the directory, or in a different VPC. The DB instance must use a security group that allows egress within the directory's VPC so the DB instance can communicate with the directory.

When you use the console to create, modify, or restore a DB instance, choose **Password and Kerberos authentication** in the **Database authentication** section. Choose **Browse Directory** and then select the directory, or choose **Create a new directory**.

When you use the AWS CLI or RDS API, associate a DB instance with a directory. The following parameters are required for the DB instance to use the domain directory you created:

- For the **--domain** parameter, use the domain identifier ("d-*" identifier) generated when you created the directory.
- For the **--domain-iam-role-name** parameter, use the role you created that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

For example, the following CLI command modifies a DB instance to use a directory.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --domain d-ID \
  --domain-iam-role-name role-name
```

For Windows:

```
aws rds modify-db-instance ^
```
Using Kerberos authentication for MySQL

```
--db-instance-identifier mydbinstance ^
--domain d-ID ^
--domain-iam-role-name role-name
```

Important
If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

Step 5: Create Kerberos authentication MySQL logins

Use the Amazon RDS master user credentials to connect to the MySQL DB instance as you do any other DB instance. The DB instance is joined to the AWS Managed Microsoft AD domain. Thus, you can provision MySQL logins and users from the Active Directory users in your domain. Database permissions are managed through standard MySQL permissions that are granted to and revoked from these logins.

You can allow an Active Directory user to authenticate with MySQL. To do this, first use the Amazon RDS master user credentials to connect to the MySQL DB instance as with any other DB instance. After you’re logged in, create an externally authenticated user with PAM (Pluggable Authentication Modules) in MySQL as shown following.

```
CREATE USER 'testuser'@'%' IDENTIFIED WITH 'auth_pam';
```

Replace `testuser` with the user name. Users (both humans and applications) from your domain can now connect to the DB instance from a domain joined client machine using Kerberos authentication.

Important
We strongly recommended that clients use SSL/TLS connections when using PAM authentication. If they don’t use SSL/TLS connections, the password might be sent as clear text in some cases. To require an SSL/TLS encrypted connection for your AD user, run the following command:

```
UPDATE mysql.user SET ssl_type = 'any' WHERE ssl_type = '' AND PLUGIN = 'auth_pam' and USER = 'testuser';
FLUSH PRIVILEGES;
```

For more information, see Using SSL/TLS with a MySQL DB instance (p. 1655).

Managing a DB instance in a domain

You can use the CLI or the RDS API to manage your DB instance and its relationship with your managed Active Directory. For example, you can associate an Active Directory for Kerberos authentication and disassociate an Active Directory to disable Kerberos authentication. You can also move a DB instance to be externally authenticated by one Active Directory to another.

For example, using the Amazon RDS API, you can do the following:

- To reattempt enabling Kerberos authentication for a failed membership, use the ModifyDBInstance API operation and specify the current membership's directory ID.
- To update the IAM role name for membership, use the ModifyDBInstance API operation and specify the current membership's directory ID and the new IAM role.
- To disable Kerberos authentication on a DB instance, use the ModifyDBInstance API operation and specify none as the domain parameter.
- To move a DB instance from one domain to another, use the ModifyDBInstance API operation and specify the domain identifier of the new domain as the domain parameter.
- To list membership for each DB instance, use the DescribeDBInstances API operation.
Understanding domain membership

After you create or modify your DB instance, it becomes a member of the domain. You can view the status of the domain membership for the DB instance by running the `describe-db-instances` CLI command. The status of the DB instance can be one of the following:

- **kerberos-enabled** – The DB instance has Kerberos authentication enabled.
- **enabling-kerberos** – AWS is in the process of enabling Kerberos authentication on this DB instance.
- **pending-enable-kerberos** – The enabling of Kerberos authentication is pending on this DB instance.
- **pending-maintenance-enable-kerberos** – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- **pending-disable-kerberos** – The disabling of Kerberos authentication is pending on this DB instance.
- **pending-maintenance-disable-kerberos** – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- **enable-kerberos-failed** – A configuration problem has prevented AWS from enabling Kerberos authentication on the DB instance. Check and fix your configuration before reissuing the DB instance modify command.
- **disabling-kerberos** – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. For example, suppose that you create a DB instance or modify an existing DB instance and the attempt to enable Kerberos authentication fails. If this happens, re-issue the modify command or modify the newly created DB instance to join the domain.

Connecting to MySQL with Kerberos authentication

To connect to MySQL with Kerberos authentication, you must log in using the Kerberos authentication type.

To create a database user that you can connect to using Kerberos authentication, use an `IDENTIFIED WITH` clause on the `CREATE USER` statement. For instructions, see Step 5: Create Kerberos authentication MySQL logins (p. 1669).

To avoid errors, use the MariaDB `mysql` client. You can download MariaDB software at [https://downloads.mariadb.org/](https://downloads.mariadb.org/).

At a command prompt, connect to one of the endpoints associated with your MySQL DB instance. Follow the general procedures in Connecting to a DB instance running the MySQL database engine (p. 1646). When you're prompted for the password, enter the Kerberos password associated with that user name.

Restoring a MySQL DB instance and adding it to a domain

You can restore a DB snapshot or complete a point-in-time restore for a MySQL DB instance and then add it to a domain. After the DB instance is restored, modify the DB instance using the process explained in Step 4: Create or modify a MySQL DB instance (p. 1667) to add the DB instance to a domain.

Kerberos authentication MySQL limitations

The following limitations apply to Kerberos authentication for MySQL:

- Only an AWS Managed Microsoft AD is supported. However, you can join RDS for MySQL DB instances to shared Managed Microsoft AD domains owned by different accounts in the same AWS Region.
• You must reboot the DB instance after enabling the feature.
• The domain name length can't be longer than 61 characters.
• You can't enable Kerberos authentication and IAM authentication at the same time. Choose one authentication method or the other for your MySQL DB instance.
• Don't modify the DB instance port after enabling the feature.
• Don't use Kerberos authentication with read replicas.
• If you have auto minor version upgrade turned on for a MySQL DB instance that is using Kerberos authentication, you must turn off Kerberos authentication and then turn it back on after an automatic upgrade. For more information about auto minor version upgrades, see Automatic minor version upgrades for MySQL (p. 1685).
• To delete a DB instance with this feature enabled, first disable the feature. To do so, use the modify-db-instance CLI command for the DB instance and specify none for the --domain parameter.

If you use the CLI or RDS API to delete a DB instance with this feature enabled, expect a delay.
• You can't set up a forest trust relationship between your on-premises or self-hosted Microsoft Active Directory and the AWS Managed Microsoft AD.
You can achieve faster query processing for RDS for MySQL with Amazon RDS Optimized Reads. An RDS for MySQL DB instance or Multi-AZ DB cluster that uses RDS Optimized Reads can achieve up to 2x faster query processing compared to a DB instance or cluster that doesn't use it.

**Overview of RDS Optimized Reads**

When you use an RDS for MySQL DB instance or Multi-AZ DB cluster that has RDS Optimized Reads turned on, it achieves faster query performance through the use of an instance store. An instance store provides temporary block-level storage for your DB instance or Multi-AZ DB cluster. The storage is located on Non-Volatile Memory Express (NVMe) solid state drives (SSDs) that are physically attached to the host server. This storage is optimized for low latency, high random I/O performance, and high sequential read throughput.

RDS Optimized Reads is turned on by default when a DB instance or Multi-AZ DB cluster uses a DB instance class with an instance store, such as db.m5d or db.m6gd. With RDS Optimized Reads, some temporary objects are stored on the instance store. These temporary objects include internal temporary files, internal on-disk temp tables, memory map files, and binary log (binlog) cache files. For more information about the instance store, see [Amazon EC2 instance store](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/instance-store.html) in the [Amazon Elastic Compute Cloud User Guide for Linux Instances](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/instance-store.html).

The workloads that generate temporary objects in MySQL for query processing can take advantage of the instance store for faster query processing. This type of workload includes queries involving sorts, hash aggregations, high-load joins, Common Table Expressions (CTEs), and queries on unindexed columns. These instance store volumes provide higher IOPS and performance, regardless of the storage configurations used for persistent Amazon EBS storage. Because RDS Optimized Reads offloads operations on temporary objects to the instance store, the input/output operations per second (IOPS) or throughput of the persistent storage (Amazon EBS) can now be used for operations on persistent objects. These operations include regular data file reads and writes, and background engine operations, such as flushing and insert buffer merges.

**Note**

Both manual and automated RDS snapshots only contain engine files for persistent objects. The temporary objects created in the instance store aren't included in RDS snapshots.

**Use cases for RDS Optimized Reads**

If you have workloads that rely heavily on temporary objects, such as internal tables or files, for their query execution, then you can benefit from turning on RDS Optimized Reads. The following use cases are candidates for RDS Optimized Reads:

- Applications that run analytical queries with complex common table expressions (CTEs), derived tables, and grouping operations
• Read replicas that serve heavy read traffic with unoptimized queries
• Applications that run on-demand or dynamic reporting queries that involve complex operations, such as queries with GROUP BY and ORDER BY clauses
• Workloads that use internal temporary tables for query processing

You can monitor the engine status variable created_tmp_disk_tables to determine the number of disk-based temporary tables created on your DB instance.

• Applications that create large temporary tables, either directly or in procedures, to store intermediate results
• Database queries that perform grouping or ordering on non-indexed columns

Best practices for RDS Optimized Reads

Use the following best practices for RDS Optimized Reads:

• Add retry logic for read-only queries in case they fail because the instance store is full during the execution.
• Monitor the storage space available on the instance store with the CloudWatch metric FreeLocalStorage. If the instance store is reaching its limit because of workload on the DB instance, modify the DB instance to use a larger DB instance class.
• When your DB instance or Multi-AZ DB cluster has sufficient memory but is still reaching the storage limit on the instance store, increase the binlog_cache_size value to maintain the session-specific binlog entries in memory. This configuration prevents writing the binlog entries to temporary binlog cache files on disk.

The binlog_cache_size parameter is session-specific. You can change the value for each new session. The setting for this parameter can increase the memory utilization on the DB instance during peak workload. Therefore, consider increasing the parameter value based on the workload pattern of your application and available memory on the DB instance.

• Use the default value of MIXED for the binlog_format. Depending on the size of the transactions, setting binlog_format to ROW can result in large binlog cache files on the instance store.
• Set the internal_tmp_mem_storage_engine parameter to TempTable, and set the temptable_max_mmap parameter to match the size of the available storage on the instance store.
• Avoid performing bulk changes in a single transaction. These types of transactions can generate large binlog cache files on the instance store and can cause issues when the instance store is full. Consider splitting writes into multiple small transactions to minimize storage use for binlog cache files.
• Use the default value of ABORT_SERVER for the binlog_error_action parameter. Doing so avoids issues with the binary logging on DB instances with backups enabled.

Using RDS Optimized Reads

When you provision an RDS for MySQL DB instance with one of the following DB instance classes in a Single-AZ DB instance deployment, Multi-AZ DB instance deployment, or Multi-AZ DB cluster deployment, the DB instance automatically uses RDS Optimized Reads.

To turn on RDS Optimized Reads, do one of the following:

• Create an RDS for MySQL DB instance or Multi-AZ DB cluster using one of these DB instance classes. For more information, see Creating an Amazon RDS DB instance (p. 300).
• Modify an existing RDS for MySQL DB instance or Multi-AZ DB cluster to use one of these DB instance classes. For more information, see Modifying an Amazon RDS DB instance (p. 401).
RDS Optimized Reads is available in all AWS Regions where one or more of the DB instance classes with local NVMe SSD storage are supported. For information about DB instance classes, see the section called "DB instance classes" (p. 11).

DB instance class availability differs for AWS Regions. To determine whether a DB instance class is supported in a specific AWS Region, see the section called "Determining DB instance class support in AWS Regions" (p. 68).

If you don’t want to use RDS Optimized Reads, modify your DB instance or Multi-AZ DB cluster so that it doesn’t use a DB instance class that supports the feature.

**Monitoring DB instances that use RDS Optimized Reads**

You can monitor DB instances that use RDS Optimized Reads with the following CloudWatch metrics:

- FreeLocalStorage
- ReadIOPSLocalStorage
- ReadLatencyLocalStorage
- ReadThroughputLocalStorage
- WriteIOPSLocalStorage
- WriteLatencyLocalStorage
- WriteThroughputLocalStorage

These metrics provide data about available instance store storage, IOPS, and throughput. For more information about these metrics, see Amazon CloudWatch instance-level metrics for Amazon RDS (p. 806).

**Limitations for RDS Optimized Reads**

The following limitations apply to RDS Optimized Reads:

- RDS Optimized Reads is supported for RDS for MySQL version 8.0.28 and higher. For information about RDS for MySQL versions, see MySQL on Amazon RDS versions (p. 1643).
- You can’t change the location of temporary objects to persistent storage (Amazon EBS) on the DB instance classes that support RDS Optimized Reads.
- When binary logging is enabled on a DB instance, the maximum transaction size is limited by the size of the instance store. In MySQL, any session that requires more storage than the value of binlog_cache_size writes transaction changes to temporary binlog cache files, which are created on the instance store.
- Transactions can fail when the instance store is full.
Improving write performance with Amazon RDS Optimized Writes for MySQL

You can improve the performance of write transactions with Amazon RDS Optimized Writes for MySQL. When your RDS for MySQL database uses RDS OptimizedWrites, it can achieve up to two times higher write transaction throughput.

Topics

- Overview of RDS Optimized Writes (p. 1300)
- Using RDS Optimized Writes (p. 1676)
- Limitations for RDS Optimized Writes (p. 1679)

Overview of RDS Optimized Writes

When you turn on Amazon RDS Optimized Writes, your RDS for MySQL databases write only once when flushing data to durable storage without the need for the doublewrite buffer. The databases continue to provide ACID property protections for reliable database transactions, along with improved performance.

Relational databases, like MySQL, provide the ACID properties of atomicity, consistency, isolation, and durability for reliable database transactions. To help provide these properties, MySQL uses a data storage area called the doublewrite buffer that prevents partial page write errors. These errors occur when there is a hardware failure while the database is updating a page, such as in the case of a power outage. A MySQL database can detect partial page writes and recover with a copy of the page in the doublewrite buffer. While this technique provides protection, it also results in extra write operations. For more information about the MySQL doublewrite buffer, see Doublewrite Buffer in the MySQL documentation.

With RDS Optimized Writes turned on, RDS for MySQL databases write only once when flushing data to durable storage without using the doublewrite buffer. RDS Optimized Writes is useful if you run write-heavy workloads on your RDS for MySQL databases. Examples of databases with write-heavy workloads include ones that support digital payments, financial trading, and gaming applications.

These databases run on DB instance classes that use the AWS Nitro System. Because of the hardware configuration in these systems, the database can write 16-KiB pages directly to data files reliably and durably in one step. The AWS Nitro System makes RDS Optimized Writes possible.

You can set the new database parameter rds.optimized_writes to control the RDS Optimized Writes feature for RDS for MySQL databases. Access this parameter in the DB parameter groups of RDS for MySQL version 8.0. Set the parameter using the following values:

- AUTO – Turn on RDS Optimized Writes if the database supports it. Turn off RDS Optimized Writes if the database doesn't support it. This setting is the default.
- OFF – Turn off RDS Optimized Writes even if the database supports it.

If you migrate an RDS for MySQL database that is configured to use RDS Optimized Writes to a DB instance class that doesn't support the feature, RDS automatically turns off RDS Optimized Writes for the database.

When RDS Optimized Writes is turned off, the database uses the MySQL doublewrite buffer.

To determine whether an RDS for MySQL database is using RDS Optimized Writes, view the current value of the innodb_doublewrite parameter for the database. If the database is using RDS Optimized Writes, this parameter is set to FALSE (0).
Using RDS Optimized Writes

You can turn on RDS Optimized Writes when you create an RDS for MySQL database with the RDS console, the AWS CLI, or the RDS API. RDS Optimized Writes is turned on automatically when both of the following conditions apply during database creation:

- You specify a DB engine version and DB instance class that support RDS Optimized Writes.
  - RDS Optimized Writes is supported for RDS for MySQL version 8.0.30 and higher. For information about RDS for MySQL versions, see MySQL on Amazon RDS versions (p. 1643).
  - RDS Optimized Writes is supported for RDS for MySQL databases that use the following DB instance classes:
    - db.m7g
    - db.m6g
    - db.m6gd
    - db.m6i
    - db.m5d
    - db.r7g
    - db.r6g
    - db.r6gd
    - db.r6i
    - db.r5
    - db.r5b
    - db.r5d
    - db.x2iedn
  - For information about DB instance classes, see the section called “DB instance classes” (p. 11).
  - DB instance class availability differs for AWS Regions. To determine whether a DB instance class is supported in a specific AWS Region, see the section called “Determining DB instance class support in AWS Regions” (p. 68).
  - In the parameter group associated with the database, the rds.optimized_writes parameter is set to AUTO. In default parameter groups, this parameter is always set to AUTO.

If you want to use a DB engine version and DB instance class that support RDS Optimized Writes, but you don't want to use this feature, then specify a custom parameter group when you create the database. In this parameter group, set the rds.optimized_writes parameter to OFF. If you want the database to use RDS Optimized Writes later, you can set the parameter to AUTO to turn it on. For information about creating custom parameter groups and setting parameters, see Working with parameter groups (p. 347).

For information about creating a DB instance, see Creating an Amazon RDS DB instance (p. 300).

Console

When you use the RDS console to create an RDS for MySQL database, you can filter for the DB engine versions and DB instance classes that support RDS Optimized Writes. After you turn on the filters, you can choose from the available DB engine versions and DB instance classes.

To choose a DB engine version that supports RDS Optimized Writes, filter for the RDS for MySQL DB engine versions that support it in Engine version, and then choose a version.
Engine options

- Aurora (MySQL Compatible)
- Aurora (PostgreSQL Compatible)
- MySQL
- MariaDB
- PostgreSQL
- Oracle
- Microsoft SQL Server

Edition
- MySQL Community

Known issues/limitations
Review the Known issues/limitations [link] to learn about potential compatibility issues with specific database versions.

Show versions that support the Multi-AZ DB cluster
Create a Multi-AZ DB cluster with one primary DB instance and two readable standby DB instances. Multi-AZ DB clusters provide up to 2x faster transaction commit latency and automatic failover in typically under 35 seconds.

Show versions that support the Amazon RDS Optimized Writes
Amazon RDS Optimized Writes improves write throughput by up to 2x at no additional cost.

Engine Version
MySQL 8.0.32
In the **Instance configuration** section, filter for the DB instance classes that support RDS Optimized Writes, and then choose a DB instance class.

After you make these selections, you can choose other settings that meet your requirements and finish creating the RDS for MySQL database with the console.

**AWS CLI**

To create a DB instance by using the AWS CLI, use the `create-db-instance` command. Make sure the `--engine-version` and `--db-instance-class` values support RDS Optimized Writes. In addition, make sure the parameter group associated with the DB instance has the `rds.optimized_writes` parameter set to `AUTO`. This example associates the default parameter group with the DB instance.

**Example Creating a DB instance that uses RDS Optimized Writes**

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance
    --db-instance-identifier mydbinstance
    --engine mysql
    --engine-version 8.0.30
    --db-instance-class db.r5b.large
    --manage-master-user-password
    --master-username admin
    --allocated-storage 200
```

For Windows:

```bash
aws rds create-db-instance
    --db-instance-identifier mydbinstance
    --engine mysql
    --engine-version 8.0.30
    --db-instance-class db.r5b.large
    --manage-master-user-password
    --master-username admin
    --allocated-storage 200
```

**RDS API**

You can create a DB instance using the `CreateDBInstance` operation. When you use this operation, make sure the `EngineVersion` and `DBInstanceClass` values support RDS Optimized Writes. In addition, make sure the parameter group associated with the DB instance has the `rds.optimized_writes` parameter set to `AUTO`. 

---

1678
Limitations for RDS Optimized Writes

The following limitations apply to RDS Optimized Writes:

- You can only modify a database to turn on RDS Optimized Writes if the database was created with a DB engine version and DB instance class that support the feature. In this case, if RDS Optimized Writes is turned off for the database, you can turn it on by setting the \texttt{rds.optimizedWrites} parameter to \texttt{AUTO}. For more information, see \textit{Using RDS Optimized Writes} (p. 1676).

- You can only modify a database to turn on RDS Optimized Writes if the database was created \textit{after} the feature was released. The underlying file system format and organization that RDS Optimized Writes needs is incompatible with the file system format of databases created before the feature was released. By extension, you can't use any snapshots of previously created instances with this feature because the snapshots use the older, incompatible file system.

  \textbf{Important}

  To convert the old format to the new format, you need to perform a full database migration. If you want to use this feature on DB instances that were created \textit{before} the feature was released, create a new empty DB instance and manually migrate your older DB instance to the newer DB instance. You can migrate your older DB instance using the native \texttt{mysqldump} tool, replication, or AWS Database Migration Service. For more information, see \texttt{mysqldump} — A Database Backup Program in the MySQL 8.0 Reference Manual, Working with MySQL replication in Amazon RDS (p. 1724), and the AWS Database Migration Service User Guide. For help with migrating using AWS tools, contact support.

- When you are restoring an RDS for MySQL database from a snapshot, you can only turn on RDS Optimized Writes for the database if all of the following conditions apply:
  - The snapshot was created from a database that supports RDS Optimized Writes.
  - The snapshot was created from a database that was created \textit{after} RDS Optimized Writes was released.
  - The snapshot is restored to a database that supports RDS Optimized Writes.
  - The restored database is associated with a parameter group that has the \texttt{rds.optimizedWrites} parameter set to \texttt{AUTO}.
Upgrading the MySQL DB engine

When Amazon RDS supports a new version of a database engine, you can upgrade your DB instances to the new version. There are two kinds of upgrades for MySQL DB instances: major version upgrades and minor version upgrades.

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your DB instances. You can initiate a major version upgrade by modifying your DB instance. However, before you perform a major version upgrade, we recommend that you follow the instructions in Major version upgrades for MySQL (p. 1681).

In contrast, minor version upgrades include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your DB instance. Or you can enable the Auto minor version upgrade option when creating or modifying a DB instance. Doing so means that your DB instance is automatically upgraded after Amazon RDS tests and approves the new version. For information about performing an upgrade, see Upgrading a DB instance engine version (p. 429).

If your MySQL DB instance is using read replicas, you must upgrade all of the read replicas before upgrading the source instance. If your DB instance is in a Multi-AZ deployment, both the primary and standby replicas are upgraded. Your DB instance will not be available until the upgrade is complete.

Database engine upgrades require downtime. The duration of the downtime varies based on the size of your DB instance.

Tip
You can minimize the downtime required for DB instance upgrade by using a blue/green deployment. For more information, see Using Amazon RDS Blue/Green Deployments for database updates (p. 566).

Topics
- Overview of upgrading (p. 1680)
- Major version upgrades for MySQL (p. 1681)
- Testing an upgrade (p. 1685)
- Upgrading a MySQL DB instance (p. 1685)
- Automatic minor version upgrades for MySQL (p. 1685)
- Using a read replica to reduce downtime when upgrading a MySQL database (p. 1687)

Overview of upgrading

When you use the AWS Management Console to upgrade a DB instance, it shows the valid upgrade targets for the DB instance. You can also use the following AWS CLI command to identify the valid upgrade targets for a DB instance:

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions --engine mysql --engine-version version-number --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

For Windows:
For example, to identify the valid upgrade targets for a MySQL version 8.0.28 DB instance, run the following AWS CLI command:

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions \
  --engine mysql \
  --engine-version 8.0.28 \
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

For Windows:

```bash
aws rds describe-db-engine-versions ^
  --engine mysql ^
  --engine-version 8.0.28 ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

Amazon RDS takes two or more DB snapshots during the upgrade process. Amazon RDS takes up to two snapshots of the DB instance before making any upgrade changes. If the upgrade doesn't work for your databases, you can restore one of these snapshots to create a DB instance running the old version. Amazon RDS takes another snapshot of the DB instance when the upgrade completes. Amazon RDS takes these snapshots regardless of whether AWS Backup manages the backups for the DB instance.

**Note**

Amazon RDS only takes DB snapshots if you have set the backup retention period for your DB instance to a number greater than 0. To change your backup retention period, see [Modifying an Amazon RDS DB instance](p. 401).

After the upgrade is complete, you can't revert to the previous version of the database engine. If you want to return to the previous version, restore the first DB snapshot taken to create a new DB instance.

You control when to upgrade your DB instance to a new version supported by Amazon RDS. This level of control helps you maintain compatibility with specific database versions and test new versions with your application before deploying in production. When you are ready, you can perform version upgrades at the times that best fit your schedule.

If your DB instance is using read replication, you must upgrade all of the Read Replicas before upgrading the source instance.

If your DB instance is in a Multi-AZ deployment, both the primary and standby DB instances are upgraded. The primary and standby DB instances are upgraded at the same time and you will experience an outage until the upgrade is complete. The time for the outage varies based on your database engine, engine version, and the size of your DB instance.

### Major version upgrades for MySQL

Amazon RDS supports the following in-place upgrades for major versions of the MySQL database engine:

- MySQL 5.6 to MySQL 5.7
- MySQL 5.7 to MySQL 8.0
Note
You can only create MySQL version 5.7 and 8.0 DB instances with latest-generation and current-generation DB instance classes, in addition to the db.m3 previous-generation DB instance class. In some cases, you want to upgrade a MySQL version 5.6 DB instance running on a previous-generation DB instance class (other than db.m3) to a MySQL version 5.7 DB instance. In these cases, first modify the DB instance to use a latest-generation or current-generation DB instance class. After you do this, you can then modify the DB instance to use the MySQL version 5.7 database engine. For information on Amazon RDS DB instance classes, see DB instance classes (p. 11).

Topics
• Overview of MySQL major version upgrades (p. 1682)
• Upgrades to MySQL version 5.7 might be slow (p. 1682)
• Prechecks for upgrades from MySQL 5.7 to 8.0 (p. 1683)
• Rollback after failure to upgrade from MySQL 5.7 to 8.0 (p. 1684)

Overview of MySQL major version upgrades

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, Amazon RDS doesn't apply major version upgrades automatically; you must manually modify your DB instance. We recommend that you thoroughly test any upgrade before applying it to your production instances.

To perform a major version upgrade for a MySQL version 5.6 DB instance on Amazon RDS to MySQL version 5.7 or later, first perform any available OS updates. After OS updates are complete, upgrade to each major version: 5.6 to 5.7 and then 5.7 to 8.0. MySQL DB instances created before April 24, 2014, show an available OS update until the update has been applied. For more information on OS updates, see Applying updates for a DB instance (p. 421).

During a major version upgrade of MySQL, Amazon RDS runs the MySQL binary mysql_upgrade to upgrade tables, if necessary. Also, Amazon RDS empties the slow_log and general_log tables during a major version upgrade. To preserve log information, save the log contents before the major version upgrade.

MySQL major version upgrades typically complete in about 10 minutes. Some upgrades might take longer because of the DB instance class size or because the instance doesn't follow certain operational guidelines in Best practices for Amazon RDS (p. 286). If you upgrade a DB instance from the Amazon RDS console, the status of the DB instance indicates when the upgrade is complete. If you upgrade using the AWS Command Line Interface (AWS CLI), use the describe-db-instances command and check the Status value.

Upgrades to MySQL version 5.7 might be slow

MySQL version 5.6.4 introduced a new date and time format for the datetime, time, and timestamp columns that allows fractional components in date and time values. When upgrading a DB instance to MySQL version 5.7, MySQL forces the conversion of all date and time column types to the new format.

Because this conversion rebuilds your tables, it might take a considerable amount of time to complete the DB instance upgrade. The forced conversion occurs for any DB instances that are running a version before MySQL version 5.6.4. It also occurs for any DB instances that were upgraded from a version before MySQL version 5.6.4 to a version other than 5.7.

If your DB instance runs a version before MySQL version 5.6.4, or was upgraded from a version before 5.6.4, we recommend an extra step. In these cases, we recommend that you convert the datetime, time, and timestamp columns in your database before upgrading your DB instance to MySQL version 5.7. This conversion can significantly reduce the amount of time required to upgrade the DB instance to MySQL version 5.7. To upgrade your date and time columns to the new format, issue the ALTER TABLE
<table_name> FORCE; command for each table that contains date or time columns. Because altering a table locks the table as read-only, we recommend that you perform this update during a maintenance window.

To find all tables in your database that have datetime, time, or timestamp columns and create an ALTER TABLE <table_name> FORCE; command for each table, use the following query.

```
SET show_old_temporals = ON;
SELECT table_schema, table_name, column_name, column_type
FROM information_schema.columns
WHERE column_type LIKE '%/* 5.5 binary format */';
SET show_old_temporals = OFF;
```

Prechecks for upgrades from MySQL 5.7 to 8.0

MySQL 8.0 includes a number of incompatibilities with MySQL 5.7. These incompatibilities can cause problems during an upgrade from MySQL 5.7 to MySQL 8.0. So, some preparation might be required on your database for the upgrade to be successful. The following is a general list of these incompatibilities:

- **There must be no tables that use obsolete data types or functions.**
- **There must be no orphan *.frm files.**
- **Triggers must not have a missing or empty definer or an invalid creation context.**
- **There must be no partitioned table that uses a storage engine that does not have native partitioning support.**
- **There must be no keyword or reserved word violations. Some keywords might be reserved in MySQL 8.0 that were not reserved previously.**
  
  For more information, see [Keywords and reserved words](https://dev.mysql.com/doc/refman/8.0/en/keywords.html) in the MySQL documentation.

- **There must be no tables in the MySQL 5.7 mysql system database that have the same name as a table used by the MySQL 8.0 data dictionary.**
  
- **There must be no obsolete SQL modes defined in your sql_mode system variable setting.**
- **There must be no tables or stored procedures with individual ENUM or SET column elements that exceed 255 characters or 1020 bytes in length.**
- **Before upgrading to MySQL 8.0.13 or higher, there must be no table partitions that reside in shared InnoDB tablespaces.**
- **There must be no queries and stored program definitions from MySQL 8.0.12 or lower that use ASC or DESC qualifiers for GROUP BY clauses.**
- **Your MySQL 5.7 installation must not use features that are not supported in MySQL 8.0.**
  
  For more information, see [Features removed in MySQL 8.0](https://dev.mysql.com/doc/refman/8.0/en/removed-features.html) in the MySQL documentation.

- **There must be no foreign key constraint names longer than 64 characters.**
- **For improved Unicode support, consider converting objects that use the utf8mb3 charset to use the utf8mb4 charset. The utf8mb3 character set is deprecated. Also, consider using utf8mb4 for character set references instead of utf8, because currently utf8 is an alias for the utf8mb3 charset.**
  

When you start an upgrade from MySQL 5.7 to 8.0, Amazon RDS runs prechecks automatically to detect these incompatibilities. For information about upgrading to MySQL 8.0, see [Upgrading MySQL](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/Concepts.MysqlUpgrade.html) in the MySQL documentation.

These prechecks are mandatory. You can't choose to skip them. The prechecks provide the following benefits:
• They enable you to avoid unplanned downtime during the upgrade.
• If there are incompatibilities, Amazon RDS prevents the upgrade and provides a log for you to learn about them. You can then use the log to prepare your database for the upgrade to MySQL 8.0 by reducing the incompatibilities. For detailed information about removing incompatibilities, see Preparing your installation for upgrade in the MySQL documentation and Upgrading to MySQL 8.0? Here is what you need to know... on the MySQL Server Blog.

The prechecks include some that are included with MySQL and some that were created specifically by the Amazon RDS team. For information about the prechecks provided by MySQL, see Upgrade checker utility.

The prechecks run before the DB instance is stopped for the upgrade, meaning that they don't cause any downtime when they run. If the prechecks find an incompatibility, Amazon RDS automatically cancels the upgrade before the DB instance is stopped. Amazon RDS also generates an event for the incompatibility. For more information about Amazon RDS events, see Working with Amazon RDS event notification (p. 855).

Amazon RDS records detailed information about each incompatibility in the log file PrePatchCompatibility.log. In most cases, the log entry includes a link to the MySQL documentation for correcting the incompatibility. For more information about viewing log files, see Viewing and listing database log files (p. 895).

Due to the nature of the prechecks, they analyze the objects in your database. This analysis results in resource consumption and increases the time for the upgrade to complete.

Note
Amazon RDS runs all of these prechecks only for an upgrade from MySQL 5.7 to MySQL 8.0. For an upgrade from MySQL 5.6 to MySQL 5.7, prechecks are limited to confirming that there are no orphan tables and that there is enough storage space to rebuild tables. Prechecks aren't run for upgrades to releases lower than MySQL 5.7.

Rollback after failure to upgrade from MySQL 5.7 to 8.0

When you upgrade a DB instance from MySQL version 5.7 to MySQL version 8.0, the upgrade can fail. In particular, it can fail if the data dictionary contains incompatibilities that weren't captured by the prechecks. In this case, the database fails to start up successfully in the new MySQL 8.0 version. At this point, Amazon RDS rolls back the changes performed for the upgrade. After the rollback, the MySQL DB instance is running MySQL version 5.7. When an upgrade fails and is rolled back, Amazon RDS generates an event with the event ID RDS-EVENT-0188.

Typically, an upgrade fails because there are incompatibilities in the metadata between the databases in your DB instance and the target MySQL version. When an upgrade fails, you can view the details about these incompatibilities in the upgradeFailure.log file. Resolve the incompatibilities before attempting to upgrade again.

During an unsuccessful upgrade attempt and rollback, your DB instance is restarted. Any pending parameter changes are applied during the restart and persist after the rollback.

For more information about upgrading to MySQL 8.0, see the following topics in the MySQL documentation:

• Preparing Your Installation for Upgrade
• Upgrading to MySQL 8.0? Here is what you need to know...

Note
Currently, automatic rollback after upgrade failure is supported only for MySQL 5.7 to 8.0 major version upgrades.
Testing an upgrade

Before you perform a major version upgrade on your DB instance, thoroughly test your database for compatibility with the new version. In addition, thoroughly test all applications that access the database for compatibility with the new version. We recommend that you use the following procedure.

To test a major version upgrade

1. Review the upgrade documentation for the new version of the database engine to see if there are compatibility issues that might affect your database or applications:
   - Changes in MySQL 5.6
   - Changes in MySQL 5.7
   - Changes in MySQL 8.0
2. If your DB instance is a member of a custom DB parameter group, create a new DB parameter group with your existing settings that is compatible with the new major version. Specify the new DB parameter group when you upgrade your test instance, so your upgrade testing ensures that it works correctly. For more information about creating a DB parameter group, see Working with parameter groups (p. 347).
3. Create a DB snapshot of the DB instance to be upgraded. For more information, see Creating a DB snapshot (p. 613).
4. Restore the DB snapshot to create a new test DB instance. For more information, see Restoring from a DB snapshot (p. 615).
5. Modify this new test DB instance to upgrade it to the new version, using one of the methods detailed following. If you created a new parameter group in step 2, specify that parameter group.
6. Evaluate the storage used by the upgraded instance to determine if the upgrade requires additional storage.
7. Run as many of your quality assurance tests against the upgraded DB instance as needed to ensure that your database and application work correctly with the new version. Implement any new tests needed to evaluate the impact of any compatibility issues that you identified in step 1. Test all stored procedures and functions. Direct test versions of your applications to the upgraded DB instance.
8. If all tests pass, then perform the upgrade on your production DB instance. We recommend that you don't allow write operations to the DB instance until you confirm that everything is working correctly.

Upgrading a MySQL DB instance

For information about manually or automatically upgrading a MySQL DB instance, see Upgrading a DB instance engine version (p. 429).

Automatic minor version upgrades for MySQL

If you specify the following settings when creating or modifying a DB instance, you can have your DB instance automatically upgraded.

- The Auto minor version upgrade setting is enabled.
- The Backup retention period setting is greater than 0.

In the AWS Management Console, these settings are under Additional configuration. The following image shows the Auto minor version upgrade setting.
For more information about these settings, see Settings for DB instances (p. 402).

For some RDS for MySQL major versions in some AWS Regions, one minor version is designated by RDS as the automatic upgrade version. After a minor version has been tested and approved by Amazon RDS, the minor version upgrade occurs automatically during your maintenance window. RDS doesn't automatically set newer released minor versions as the automatic upgrade version. Before RDS designates a newer automatic upgrade version, several criteria are considered, such as the following:

- Known security issues
- Bugs in the MySQL community version
- Overall fleet stability since the minor version was released

You can use the following AWS CLI command to determine the current automatic minor upgrade target version for a specified MySQL minor version in a specific AWS Region.

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions
--engine mysql
--engine-version minor-version
--region region
--query "DBEngineVersions[*].ValidUpgradeTarget[*].{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" 
--output text
```

For Windows:

```bash
aws rds describe-db-engine-versions ^
--engine mysql ^
--engine-version minor-version ^
--region region ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output text
```

For example, the following AWS CLI command determines the automatic minor upgrade target for MySQL minor version 8.0.11 in the US East (Ohio) AWS Region (us-east-2).
For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions
  --engine mysql
  --engine-version 8.0.11
  --region us-east-2
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].
    {AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}"
  --output table
```

For Windows:

```bash
aws rds describe-db-engine-versions
  --engine mysql
  --engine-version 8.0.11
  --region us-east-2
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].
    {AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}"
  --output table
```

Your output is similar to the following.

```
<table>
<thead>
<tr>
<th>DescribeDBEngineVersions</th>
</tr>
</thead>
<tbody>
<tr>
<td>AutoUpgrade</td>
</tr>
<tr>
<td>--------------+----------------</td>
</tr>
<tr>
<td>False</td>
</tr>
<tr>
<td>False</td>
</tr>
<tr>
<td>False</td>
</tr>
<tr>
<td>False</td>
</tr>
<tr>
<td>False</td>
</tr>
<tr>
<td>False</td>
</tr>
<tr>
<td>True</td>
</tr>
<tr>
<td>False</td>
</tr>
</tbody>
</table>
```

In this example, the AutoUpgrade value is True for MySQL version 8.0.23. So, the automatic minor upgrade target is MySQL version 8.0.23, which is highlighted in the output.

A MySQL DB instance is automatically upgraded during your maintenance window if the following criteria are met:

- The **Auto minor version upgrade** setting is enabled.
- The **Backup retention period** setting is greater than 0.
- The DB instance is running a minor DB engine version that is less than the current automatic upgrade minor version.

For more information, see [Automatically upgrading the minor engine version](p. 431).

### Using a read replica to reduce downtime when upgrading a MySQL database

In most cases, a blue/green deployment is the best option to reduce downtime when upgrading a MySQL DB instance. For more information, see [Using Amazon RDS Blue/Green Deployments for database updates](p. 566).
If you can't use a blue/green deployment and your MySQL DB instance is currently in use with a production application, you can use the following procedure to upgrade the database version for your DB instance. This procedure can reduce the amount of downtime for your application.

By using a read replica, you can perform most of the maintenance steps ahead of time and minimize the necessary changes during the actual outage. With this technique, you can test and prepare the new DB instance without making any changes to your existing DB instance.

The following procedure shows an example of upgrading from MySQL version 5.7 to MySQL version 8.0. You can use the same general steps for upgrades to other major versions.

**Note**

When you are upgrading from MySQL version 5.7 to MySQL version 8.0, complete the prechecks before performing the upgrade. For more information, see [Prechecks for upgrades from MySQL 5.7 to 8.0](p. 1683).

To upgrade a MySQL database while a DB instance is in use

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Create a read replica of your MySQL 5.7 DB instance. This process creates an upgradable copy of your database. Other read replicas of the DB instance might also exist.
   a. In the console, choose **Databases**, and then choose the DB instance that you want to upgrade.
   b. For **Actions**, choose **Create read replica**.
   c. Provide a value for **DB instance identifier** for your read replica and ensure that the **DB instance class** and other settings match your MySQL 5.7 DB instance.
   d. Choose **Create read replica**.
3. (Optional) When the read replica has been created and **Status** shows **Available**, convert the read replica into a Multi-AZ deployment and enable backups.
   By default, a read replica is created as a Single-AZ deployment with backups disabled. Because the read replica ultimately becomes the production DB instance, it is a best practice to configure a Multi-AZ deployment and enable backups now.
   a. In the console, choose **Databases**, and then choose the read replica that you just created.
   b. Choose **Modify**.
   c. For **Multi-AZ deployment**, choose **Create a standby instance**.
   d. For **Backup Retention Period**, choose a positive nonzero value, such as 3 days, and then choose **Continue**.
   e. For **Scheduling of modifications**, choose **Apply immediately**.
   f. Choose **Modify DB instance**.
4. When the read replica **Status** shows **Available**, upgrade the read replica to MySQL 8.0:
   a. In the console, choose **Databases**, and then choose the read replica that you just created.
   b. Choose **Modify**.
   c. For **DB engine version**, choose the MySQL 8.0 version to upgrade to, and then choose **Continue**.
   d. For **Scheduling of modifications**, choose **Apply immediately**.
   e. Choose **Modify DB instance** to start the upgrade.
5. When the upgrade is complete and **Status** shows **Available**, verify that the upgraded read replica is up-to-date with the source MySQL 5.7 DB instance. To verify, connect to the read replica and run the **SHOW REPLICA STATUS** command. If the **Seconds_Behind_Master** field is 0, then replication is up-to-date.
Note
Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

6. **(Optional) Create a read replica of your read replica.**

   If you want the DB instance to have a read replica after it is promoted to a standalone DB instance, you can create the read replica now.
   
   a. In the console, choose **Databases**, and then choose the read replica that you just upgraded.
   
   b. For **Actions**, choose **Create read replica**.
   
   c. Provide a value for **DB instance identifier** for your read replica and ensure that the **DB instance class** and other settings match your MySQL 5.7 DB instance.
   
   d. Choose **Create read replica**.

7. **(Optional) Configure a custom DB parameter group for the read replica.**

   If you want the DB instance to use a custom parameter group after it is promoted to a standalone DB instance, you can create the DB parameter group now and associate it with the read replica.
   
   a. Create a custom DB parameter group for MySQL 8.0. For instructions, see [Creating a DB parameter group](p. 350).
   
   b. Modify the parameters that you want to change in the DB parameter group you just created. For instructions, see [Modifying parameters in a DB parameter group](p. 352).
   
   c. In the console, choose **Databases**, and then choose the read replica.
   
   d. Choose **Modify**.
   
   e. For **DB parameter group**, choose the MySQL 8.0 DB parameter group you just created, and then choose **Continue**.
   
   f. For **Scheduling of modifications**, choose **Apply immediately**.
   
   g. Choose **Modify DB instance** to start the upgrade.

8. **Make your MySQL 8.0 read replica a standalone DB instance.**

   **Important**
   When you promote your MySQL 8.0 read replica to a standalone DB instance, it is no longer a replica of your MySQL 5.7 DB instance. We recommend that you promote your MySQL 8.0 read replica during a maintenance window when your source MySQL 5.7 DB instance is in read-only mode and all write operations are suspended. When the promotion is completed, you can direct your write operations to the upgraded MySQL 8.0 DB instance to ensure that no write operations are lost.
   
   In addition, we recommend that, before promoting your MySQL 8.0 read replica, you perform all necessary data definition language (DDL) operations on your MySQL 8.0 read replica. An example is creating indexes. This approach avoids negative effects on the performance of the MySQL 8.0 read replica after it has been promoted. To promote a read replica, use the following procedure.
   
   a. In the console, choose **Databases**, and then choose the read replica that you just upgraded.
   
   b. For **Actions**, choose **Promote**.
   
   c. Choose **Yes** to enable automated backups for the read replica instance. For more information, see [Working with backups](p. 591).
   
   d. Choose **Continue**.
   
   e. Choose **Promote Read Replica**.

9. **You now have an upgraded version of your MySQL database. At this point, you can direct your applications to the new MySQL 8.0 DB instance.**
### Importing data into a MySQL DB instance

You can use several different techniques to import data into an RDS for MySQL DB instance. The best approach depends on the source of the data, the amount of data, and whether the import is done one time or is ongoing. If you are migrating an application along with the data, also consider the amount of downtime that you are willing to experience.

#### Overview

Find techniques to import data into an RDS for MySQL DB instance in the following table.

<table>
<thead>
<tr>
<th>Source</th>
<th>Amount of data</th>
<th>One time or ongoing</th>
<th>Application downtime</th>
<th>Technique</th>
<th>More information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Existing MySQL database on premises or on Amazon EC2</td>
<td>Any</td>
<td>One time</td>
<td>Some</td>
<td>Create a backup of your on-premises database, store it on Amazon S3, and then restore the backup file to a new Amazon RDS DB instance running MySQL.</td>
<td>[Restoring a backup into a MySQL DB instance (p. 1696)]</td>
</tr>
<tr>
<td>Any existing database</td>
<td>Any</td>
<td>One time or ongoing</td>
<td>Minimal</td>
<td>Use AWS Database Migration Service to migrate the database with minimal downtime and, for many database DB engines, continue ongoing replication.</td>
<td><a href="#">What is AWS Database Migration Service and Using a MySQL-compatible database as a target for AWS DMS in the AWS Database Migration Service User Guide</a></td>
</tr>
<tr>
<td>Existing MySQL DB instance</td>

</table>

### Note

The 'mysql' system database contains authentication and authorization information required to log in to your DB instance and access your data. Dropping, altering, renaming, or truncating tables, data, or other contents of the 'mysql' database in your DB instance can result in error and might render the DB instance and your data inaccessible. If this occurs, you can restore the DB instance from a snapshot using the AWS CLI `restore-db-instance-from-db-snapshot` command. You can recover the DB instance using the AWS CLI `restore-db-instance-to-point-in-time` command.
Importing data considerations

Following, you can find additional technical information related to loading data into MySQL. This information is intended for advanced users who are familiar with the MySQL server architecture. All comments related to LOAD DATA LOCAL INFILE also apply to mysqlimport.

Binary log

Data loads incur a performance penalty and require additional free disk space (up to four times more) when binary logging is enabled versus loading the same data with binary logging turned off. The severity of the performance penalty and the amount of free disk space required is directly proportional to the size of the transactions used to load the data.

Transaction size

Transaction size plays an important role in MySQL data loads. It has a major influence on resource consumption, disk space utilization, resume process, time to recover, and input format (flat files or SQL). This section describes how transaction size affects binary logging and makes the case for disabling binary logging during large data loads. As noted earlier, binary logging is enabled and disabled by setting the Amazon RDS automated backup retention period. Non-zero values enable binary logging, and zero disables it. We also describe the impact of large transactions on InnoDB and why it's important to keep transaction sizes small.

Small transactions

For small transactions, binary logging doubles the number of disk writes required to load the data. This effect can severely degrade performance for other database sessions and increase the time required to load the data. The degradation experienced depends in part upon the upload rate, other database activity taking place during the load, and the capacity of your Amazon RDS DB instance.

The binary logs also consume disk space roughly equal to the amount of data loaded until they are backed up and removed. Fortunately, Amazon RDS minimizes this by backing up and removing binary logs on a frequent basis.

Large transactions

Large transactions incur a 3X penalty for IOPS and disk consumption with binary logging enabled. This is due to the binary log cache spilling to disk, consuming disk space and incurring additional IO for each write. The cache cannot be written to the binlog until the transaction commits or rolls back, so it consumes disk space in proportion to the amount of data loaded. When the transaction commits, the cache must be copied to the binlog, creating a third copy of the data on disk.

Because of this, there must be at least three times as much free disk space available to load the data compared to loading with binary logging disabled. For example, 10 GiB of data loaded as a single transaction consumes at least 30 GiB disk space during the load. It consumes 10 GiB for the table + 10 GiB for the binary log cache + 10 GiB for the binary log itself. The cache file remains on disk until the session that created it terminates or the session fills its binary log cache again during another transaction. The binary log must remain on disk until backed up, so it might be some time before the extra 20 GiB is freed.

If the data was loaded using LOAD DATA LOCAL INFILE, yet another copy of the data is created if the database has to be recovered from a backup made before the load. During recovery, MySQL extracts the data from the binary log into a flat file. MySQL then runs LOAD DATA LOCAL INFILE, just as in the original transaction. However, this time the input file is local to the database server. Continuing with the example preceding, recovery fails unless there is at least 40 GiB free disk space available.
Disable binary logging

Whenever possible, disable binary logging during large data loads to avoid the resource overhead and addition disk space requirements. In Amazon RDS, disabling binary logging is as simple as setting the backup retention period to zero. If you do this, we recommend that you take a DB snapshot of the database instance immediately before the load. By doing this, you can quickly and easily undo changes made during loading if you need to.

After the load, set the backup retention period back to an appropriate (no zero) value.

You can't set the backup retention period to zero if the DB instance is a source DB instance for read replicas.

InnoDB

The information in this section provides a strong argument for keeping transaction sizes small when using InnoDB.

Undo

InnoDB generates undo to support features such as transaction rollback and MVCC. Undo is stored in the InnoDB system tablespace (usually ibdata1) and is retained until removed by the purge thread. The purge thread cannot advance beyond the undo of the oldest active transaction, so it is effectively blocked until the transaction commits or completes a rollback. If the database is processing other transactions during the load, their undo also accumulates in the system tablespace and cannot be removed even if they commit and no other transaction needs the undo for MVCC. In this situation, all transactions (including read-only transactions) that access any of the rows changed by any transaction (not just the load transaction) slow down. The slowdown occurs because transactions scan through undo that could have been purged if not for the long-running load transaction.

Undo is stored in the system tablespace, and the system tablespace never shrinks in size. Thus, large data load transactions can cause the system tablespace to become quite large, consuming disk space that you can't reclaim without recreating the database from scratch.

Rollback

InnoDB is optimized for commits. Rolling back a large transaction can take a very, very long time. In some cases, it might be faster to perform a point-in-time recovery or restore a DB snapshot.

Input data format

MySQL can accept incoming data in one of two forms: flat files and SQL. This section points out some key advantages and disadvantages of each.

Flat files

Loading flat files with LOAD DATA LOCAL INFILE can be the fastest and least costly method of loading data as long as transactions are kept relatively small. Compared to loading the same data with SQL, flat files usually require less network traffic, lowering transmission costs and load much faster due to the reduced overhead in the database.

One big transaction

LOAD DATA LOCAL INFILE loads the entire flat file as one transaction. This isn't necessarily a bad thing. If the size of the individual files can be kept small, this has a number of advantages:

- Resume capability – Keeping track of which files have been loaded is easy. If a problem arises during the load, you can pick up where you left off with little effort. Some data might have to be retransmitted to Amazon RDS, but with small files, the amount retransmitted is minimal.
Importing data considerations

- Load data in parallel – If you’ve got IOPS and network bandwidth to spare with a single file load, loading in parallel might save time.
- Throttle the load rate – Data load having a negative impact on other processes? Throttle the load by increasing the interval between files.

Be careful

The advantages of LOAD DATA LOCAL INFILE diminish rapidly as transaction size increases. If breaking up a large set of data into smaller ones isn’t an option, SQL might be the better choice.

SQL

SQL has one main advantage over flat files: it’s easy to keep transaction sizes small. However, SQL can take significantly longer to load than flat files and it can be difficult to determine where to resume the load after a failure. For example, mysqldump files are not restartable. If a failure occurs while loading a mysqldump file, the file requires modification or replacement before the load can resume. The alternative is to restore to the point in time before the load and replay the file after the cause of the failure has been corrected.

Take checkpoints using Amazon RDS snapshots

If you have a load that’s going to take several hours or even days, loading without binary logging isn’t a very attractive prospect unless you can take periodic checkpoints. This is where the Amazon RDS DB snapshot feature comes in very handy. A DB snapshot creates a point-in-time consistent copy of your database instance which can be used restore the database to that point in time after a crash or other mishap.

To create a checkpoint, simply take a DB snapshot. Any previous DB snapshots taken for checkpoints can be removed without affecting durability or restore time.

Snapshots are fast too, so frequent checkpointing doesn't add significantly to load time.

Decreasing load time

Here are some additional tips to reduce load times:

- Create all secondary indexes before loading. This is counter-intuitive for those familiar with other databases. Adding or modifying a secondary index causes MySQL to create a new table with the index changes, copy the data from the existing table to the new table, and drop the original table.
- Load data in PK order. This is particularly helpful for InnoDB tables, where load times can be reduced by 75–80 percent and data file size cut in half.
- Disable foreign key constraints foreign_key_checks=0. For flat files loaded with LOAD DATA LOCAL INFILE, this is required in many cases. For any load, disabling FK checks provides significant performance gains. Just be sure to enable the constraints and verify the data after the load.
- Load in parallel unless already near a resource limit. Use partitioned tables when appropriate.
- Use multi-value inserts when loading with SQL to minimize overhead when running statements. When using mysqldump, this is done automatically.
- Reduce InnoDB log IO innodb_flush_log_at_trx_commit=0
- If you are loading data into a DB instance that does not have read replicas, set the sync_binlog parameter to 0 while loading data. When data loading is complete, set the sync_binlog parameter to back to 1.
- Load data before converting the DB instance to a Multi-AZ deployment. However, if the DB instance already uses a Multi-AZ deployment, switching to a Single-AZ deployment for data loading is not recommended, because doing so only provides marginal improvements.
Note
Using innodb_flush_log_at_trx_commit=0 causes InnoDB to flush its logs every second instead of at each commit. This provides a significant speed advantage, but can lead to data loss during a crash. Use with caution.

Topics
- Restoring a backup into a MySQL DB instance (p. 1696)
- Importing data from a MariaDB or MySQL database to a MariaDB or MySQL DB instance (p. 1704)
- Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime (p. 1706)
- Importing data from any source to a MariaDB or MySQL DB instance (p. 1719)
Restoring a backup into a MySQL DB instance

Amazon RDS supports importing MySQL databases by using backup files. You can create a backup of your database, store it on Amazon S3, and then restore the backup file onto a new Amazon RDS DB instance running MySQL.

The scenario described in this section restores a backup of an on-premises database. You can use this technique for databases in other locations, such as Amazon EC2 or non-AWS cloud services, as long as the database is accessible.

You can find the supported scenario in the following diagram.

Importing backup files from Amazon S3 is supported for MySQL in all AWS Regions.

We recommend that you import your database to Amazon RDS by using backup files if your on-premises database can be offline while the backup file is created, copied, and restored. If your database can't be offline, you can use binary log (binlog) replication to update your database after you have migrated to Amazon RDS through Amazon S3 as explained in this topic. For more information, see Configuring binary log file position replication with an external source instance (p. 1740). You can also use the AWS Database Migration Service to migrate your database to Amazon RDS. For more information, see What is AWS Database Migration Service?

Limitations and recommendations for importing backup files from Amazon S3 to Amazon RDS

The following are some limitations and recommendations for importing backup files from Amazon S3:

- You can only import your data to a new DB instance, not an existing DB instance.
- You must use Percona XtraBackup to create the backup of your on-premises database.
- You can't import data from a DB snapshot export to Amazon S3.
- You can't migrate from a source database that has tables defined outside of the default MySQL data directory.
- You must import your data to the default minor version of your MySQL major version in your AWS Region. For example, if your major version is MySQL 8.0, and the default minor version for your AWS Region is 8.0.28, then you must import your data into a MySQL version 8.0.28 DB instance. You can upgrade your DB instance after importing. For information about determining the default minor version, see MySQL on Amazon RDS versions (p. 1643).
- Backward migration is not supported for both major versions and minor versions. For example, you can't migrate from version 8.0 to version 5.7, and you can't migrate from version 8.0.32 to version 8.0.31.
• You can't import a MySQL 5.5 or 5.6 database.
• You can't import an on-premises MySQL database from one major version to another. For example, you can't import a MySQL 5.7 database to an RDS for MySQL 8.0 database. You can upgrade your DB instance after you complete the import.
• You can't restore from an encrypted source database, but you can restore to an encrypted Amazon RDS DB instance.
• You can't restore from an encrypted backup in the Amazon S3 bucket.
• You can't restore from an Amazon S3 bucket in a different AWS Region than your Amazon RDS DB instance.
• Importing from Amazon S3 is not supported on the db.t2.micro DB instance class. However, you can restore to a different DB instance class and change the DB instance class later. For more information about instance classes, see Hardware specifications for DB instance classes (p. 87).
• Amazon S3 limits the size of a file uploaded to an Amazon S3 bucket to 5 TB. If a backup file exceeds 5 TB, then you must split the backup file into smaller files.
• When you restore the database, the backup is copied and then extracted on your DB instance. Therefore, provision storage space for your DB instance that is equal to or greater than the sum of the backup size, plus the original database's size on disk.
• Amazon RDS limits the number of files uploaded to an Amazon S3 bucket to 1 million. If the backup data for your database, including all full and incremental backups, exceeds 1 million files, use a Gzip (`.gz`), tar (`.tar.gz`), or Percona xbstream (`.xbstream`) file to store full and incremental backup files in the Amazon S3 bucket. Percona XtraBackup 8.0 only supports Percona xbstream for compression.
• User accounts are not imported automatically. Save your user accounts from your source database and add them to your new DB instance later.
• Functions are not imported automatically. Save your functions from your source database and add them to your new DB instance later.
• Stored procedures are not imported automatically. Save your stored procedures from your source database and add them to your new DB instance later.
• Time zone information is not imported automatically. Record the time zone information for your source database, and set the time zone of your new DB instance later. For more information, see Local time zone for MySQL DB instances (p. 1765).

The following examples show file names that are not allowed:
"innodb_data_file_path=ibdata1:12M:autoextend" and "innodb_data_file_path=ibdata01:12M:autoextend".

• The maximum size of the restored database is the maximum database size supported minus the size of the backup. So, if the maximum database size supported is 64 TiB and the size of the backup is 30 TiB, then the maximum size of the restored database is 34 TiB, as in the following example:

64 TiB - 30 TiB = 34 TiB

For information about the maximum database size supported by Amazon RDS for MySQL, see General Purpose SSD storage (p. 102) and Provisioned IOPS SSD storage (p. 104).

Overview of setting up to import backup files from Amazon S3 to Amazon RDS

These are the components you need to set up to import backup files from Amazon S3 to Amazon RDS:

• An Amazon S3 bucket to store your backup files.
• A backup of your on-premises database created by Percona XtraBackup.
• An AWS Identity and Access Management (IAM) role to allow Amazon RDS to access the bucket.

If you already have an Amazon S3 bucket, you can use that. If you don't have an Amazon S3 bucket, you can create a new one. If you want to create a new bucket, see Creating a bucket.

Use the Percona XtraBackup tool to create your backup. For more information, see Creating your database backup (p. 1698).

If you already have an IAM role, you can use that. If you don't have an IAM role, you can create a new one manually. Alternatively, you can choose to have a new IAM role created for you in your account by the wizard when you restore the database by using the AWS Management Console. If you want to create a new IAM role manually, or attach trust and permissions policies to an existing IAM role, see Creating an IAM role manually (p. 1700). If you want to have a new IAM role created for you, follow the procedure in Console (p. 1701).

Creating your database backup

Use the Percona XtraBackup software to create your backup. We recommend that you use the latest version of Percona XtraBackup. You can install Percona XtraBackup from Download Percona XtraBackup.

Warning
When creating a database backup, XtraBackup might save credentials in the xtrabackup_info file. Make sure you examine that file so that the tool_command setting in it doesn't contain any sensitive information.

Note
For MySQL 8.0 migration, you must use Percona XtraBackup 8.0. Percona XtraBackup 8.0.12 and higher versions support migration of all versions of MySQL. If you are migrating to RDS for MySQL 8.0.20 or higher, you must use Percona XtraBackup 8.0.12 or higher. For MySQL 5.7 migrations, you can also use Percona XtraBackup 2.4. For migrations of earlier MySQL versions, you can also use Percona XtraBackup 2.3 or 2.4.

You can create a full backup of your MySQL database files using Percona XtraBackup. Alternatively, if you already use Percona XtraBackup to back up your MySQL database files, you can upload your existing full and incremental backup directories and files.

For more information about backing up your database with Percona XtraBackup, see Percona XtraBackup documentation and The xtrabackup binary on the Percona website.

Creating a full backup with Percona XtraBackup

To create a full backup of your MySQL database files that can be restored from Amazon S3, use the Percona XtraBackup utility (xtrabackup) to back up your database.

For example, the following command creates a backup of a MySQL database and stores the files in the folder /on-premises/s3-restore/backup folder.

```
xtrabackup --backup --user=<myuser> --password=<password> --target-dir=/on-premises/s3-restore/backup
```

If you want to compress your backup into a single file (which can be split later, if needed), you can save your backup in one of the following formats:

• Gzip (.gz)
• tar (.tar)
• Percona xbstream (.xbstream)

**Note**

Percona XtraBackup 8.0 only supports Percona xbstream for compression.

The following command creates a backup of your MySQL database split into multiple Gzip files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=tar --target-dir=/on-premises/s3-restore/backup | gzip -d --bytes=500MB - | split -d --bytes=500MB - /on-premises/s3-restore/backup/backup/.tar.gz
```

The following command creates a backup of your MySQL database split into multiple tar files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=tar --target-dir=/on-premises/s3-restore/backup | split -d --bytes=500MB - /on-premises/s3-restore/backup/backup.tar
```

The following command creates a backup of your MySQL database split into multiple xbstream files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=xbstream --target-dir=/on-premises/s3-restore/backup | split -d --bytes=500MB - /on-premises/s3-restore/backup/backup.xbstream
```

**Note**

If you see the following error, it might be caused by mixing file formats in your command:

```
ERROR:/bin/tar: This does not look like a tar archive
```

**Using incremental backups with Percona XtraBackup**

If you already use Percona XtraBackup to perform full and incremental backups of your MySQL database files, you don't need to create a full backup and upload the backup files to Amazon S3. Instead, you can save a significant amount of time by copying your existing backup directories and files to your Amazon S3 bucket. For more information about creating incremental backups using Percona XtraBackup, see [Incremental backup](#).

When copying your existing full and incremental backup files to an Amazon S3 bucket, you must recursively copy the contents of the base directory. Those contents include the full backup and also all incremental backup directories and files. This copy must preserve the directory structure in the Amazon S3 bucket. Amazon RDS iterates through all files and directories. Amazon RDS uses the `xtrabackup-checkpoints` file that is included with each incremental backup to identify the base directory, and to order incremental backups by log sequence number (LSN) range.

**Backup considerations for Percona XtraBackup**

Amazon RDS consumes your backup files based on the file name. Name your backup files with the appropriate file extension based on the file format—for example, `.xbstream` for files stored using the Percona xbstream format.

Amazon RDS consumes your backup files in alphabetical order and also in natural number order. Use the `split` option when you issue the `xtrabackup` command to ensure that your backup files are written and named in the proper order.

Amazon RDS doesn't support partial backups created using Percona XtraBackup. You can't use the following options to create a partial backup when you back up the source files for your database: --
tables, --tables-exclude, --tables-file, --databases, --databases-exclude, or --databases-file.

Amazon RDS supports incremental backups created using Percona XtraBackup. For more information about creating incremental backups using Percona XtraBackup, see Incremental backup.

Creating an IAM role manually

If you don’t have an IAM role, you can create a new one manually. Alternatively, you can choose to have a new IAM role created for you by the wizard when you restore the database by using the AWS Management Console. If you want to have a new IAM role created for you, follow the procedure in Console (p. 1701).

To manually create a new IAM role for importing your database from Amazon S3, create a role to delegate permissions from Amazon RDS to your Amazon S3 bucket. When you create an IAM role, you attach trust and permissions policies. To import your backup files from Amazon S3, use trust and permissions policies similar to the examples following. For more information about creating the role, see Creating a role to delegate permissions to an AWS service.

Alternatively, you can choose to have a new IAM role created for you by the wizard when you restore the database by using the AWS Management Console. If you want to have a new IAM role created for you, follow the procedure in Console (p. 1701).

The trust and permissions policies require that you provide an Amazon Resource Name (ARN). For more information about ARN formatting, see Amazon Resource Names (ARNs) and AWS service namespaces.

Example Trust policy for importing from Amazon S3

```json
{
    "Version": "2012-10-17",
    "Statement":
    [
        {
            "Effect": "Allow",
            "Principal": {"Service": "rds.amazonaws.com"},
            "Action": "sts:AssumeRole"
        }
    ]
}
```

Example Permissions policy for importing from Amazon S3 — IAM user permissions

```json
{
    "Version": "2012-10-17",
    "Statement":
    [
        {
            "Sid": "AllowS3AccessRole",
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": "arn:aws:iam::IAM User ID:role/S3Access"
        }
    ]
}
```

Example Permissions policy for importing from Amazon S3 — role permissions

```json
{
    "Version": "2012-10-17",
}
```
"Statement":
[
  {
    "Effect": "Allow",
    "Action":
      [
        "s3:ListBucket",
        "s3:GetBucketLocation"
      ],
    "Resource": "arn:aws:s3:::bucket_name"
  },
  {
    "Effect": "Allow",
    "Action":
      [
        "s3:GetObject"
      ],
    "Resource": "arn:aws:s3:::bucket_name/prefix*"
  }
]

**Note**
If you include a file name prefix, include the asterisk (*) after the prefix. If you don't want to specify a prefix, specify only an asterisk.

---

**Importing data from Amazon S3 to a new MySQL DB instance**

You can import data from Amazon S3 to a new MySQL DB instance using the AWS Management Console, AWS CLI, or RDS API.

**Console**

**To import data from Amazon S3 to a new MySQL DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the top right corner of the Amazon RDS console, choose the AWS Region in which to create your DB instance. Choose the same AWS Region as the Amazon S3 bucket that contains your database backup.
3. In the navigation pane, choose **Databases**.
4. Choose **Restore from S3**.

The **Create database by restoring from S3** page appears.
5. **Under S3 destination:**

   a. Choose the S3 bucket that contains the backup.

   b. *(Optional) For S3 folder path prefix,* enter a file path prefix for the files stored in your Amazon S3 bucket.

If you don't specify a prefix, then RDS creates your DB instance using all of the files and folders in the root folder of the S3 bucket. If you do specify a prefix, then RDS creates your DB instance using the files and folders in the S3 bucket where the path for the file begins with the specified prefix.

For example, suppose that you store your backup files on S3 in a subfolder named backups, and you have multiple sets of backup files, each in its own directory (gzip_backup1, gzip_backup2, and so on). In this case, you specify a prefix of backups/gzip_backup1 to restore from the files in the gzip_backup1 folder.
6. Under **Engine options**:
   a. For **Engine type**, choose **MySQL**.
   b. For **Source engine version**, choose the MySQL major version of your source database.
   c. For **Version**, choose the default minor version of your MySQL major version in your AWS Region.

   In the AWS Management Console, only the default minor version is available. You can upgrade your DB instance after importing.

7. For **IAM role**, you can choose an existing IAM role.

8. (Optional) You can also have a new IAM role created for you by choosing **Create a new role** and entering the **IAM role name**.

9. Specify your DB instance information. For information about each setting, see **Settings for DB instances** (p. 308).

   **Note**
   Be sure to allocate enough memory for your new DB instance so that the restore operation can succeed.
   You can also choose **Enable storage autoscaling** to allow for future growth automatically.

10. Choose additional settings as needed.

11. Choose **Create database**.

### AWS CLI

To import data from Amazon S3 to a new MySQL DB instance by using the AWS CLI, call the `restore-db-instance-from-s3` command with the following parameters. For information about each setting, see **Settings for DB instances** (p. 308).

   **Note**
   Be sure to allocate enough memory for your new DB instance so that the restore operation can succeed.
   You can also use the `--max-allocated-storage` parameter to enable storage autoscaling and allow for future growth automatically.

   - `--allocated-storage`
   - `--db-instance-identifier`
   - `--db-instance-class`
   - `--engine`
   - `--master-username`
   - `--manage-master-user-password`
   - `--s3-bucket-name`
   - `--s3-ingestion-role-arn`
   - `--s3-prefix`
   - `--source-engine`
   - `--source-engine-version`

**Example**

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-s3 \
   --allocated-storage 250 \
```
Importing data from a MariaDB or MySQL database to a MariaDB or MySQL DB instance

You can also import data from an existing MariaDB or MySQL database to a MySQL or MariaDB DB instance. You do so by copying the database with `mysqldump` and piping it directly into the MariaDB or MySQL DB instance. The `mysqldump` command line utility is commonly used to make backups and transfer data from one MariaDB or MySQL server to another. It's included with MySQL and MariaDB client software.

**Note**
If you are using a MySQL DB instance and your scenario supports it, it's easier to move data in and out of Amazon RDS by using backup files and Amazon S3. For more information, see [Restoring a backup into a MySQL DB instance](p. 1696).

A typical `mysqldump` command to move data from an external database to an Amazon RDS DB instance looks similar to the following.

```
mysqldump -u local_user \
--databases database_name \
--single-transaction \
--compress \
--order-by-primary \
-p local_password | mysql -u RDS_user \
    --port=port_number \
    --host=host_name \
```
Important
---
Make sure not to leave a space between the -p option and the entered password.
Specify credentials other than the prompts shown here as a security best practice.

Make sure that you're aware of the following recommendations and considerations:

- Exclude the following schemas from the dump file: `sys`, `performance_schema`, and `information_schema`. The `mysqldump` utility excludes these schemas by default.
- If you need to migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the `pt-show-grants` utility.
- To perform the import, make sure the user doing so has access to the DB instance. For more information, see [Controlling access with security groups](p. 2697).

The parameters used are as follows:

- `-u local_user` – Use to specify a user name. In the first usage of this parameter, you specify the name of a user account on the local MariaDB or MySQL database identified by the `--databases` parameter.
- `--databases database_name` – Use to specify the name of the database on the local MariaDB or MySQL instance that you want to import into Amazon RDS.
- `--single-transaction` – Use to ensure that all of the data loaded from the local database is consistent with a single point in time. If there are other processes changing the data while `mysqldump` is reading it, using this parameter helps maintain data integrity.
- `--compress` – Use to reduce network bandwidth consumption by compressing the data from the local database before sending it to Amazon RDS.
- `--order-by-primary` – Use to reduce load time by sorting each table's data by its primary key.
- `-p local_password` – Use to specify a password. In the first usage of this parameter, you specify the password for the user account identified by the first `-u` parameter.
- `-u RDS_user` – Use to specify a user name. In the second usage of this parameter, you specify the name of a user account on the default database for the MariaDB or MySQL DB instance identified by the `--host` parameter.
- `--port port_number` – Use to specify the port for your MariaDB or MySQL DB instance. By default, this is 3306 unless you changed the value when creating the instance.
- `--host host_name` – Use to specify the Domain Name System (DNS) name from the Amazon RDS DB instance endpoint, for example, `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the Amazon RDS Management Console.
- `-p RDS_password` – Use to specify a password. In the second usage of this parameter, you specify the password for the user account identified by the second `-u` parameter.

Make sure to create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, then exclude them when you run `mysqldump`. To do so, include the following parameters with your `mysqldump` command: `--routines=0 --triggers=0 --events=0`.

The following example copies the `world` sample database on the local host to a MySQL DB instance.

For Linux, macOS, or Unix:

```bash
sudo mysqldump -u localuser
```

---

1705
For Windows, run the following command in a command prompt that has been opened by right-clicking Command Prompt on the Windows programs menu and choosing Run as administrator:

```
mysqldump -u localuser ^
   --databases world ^
   --single-transaction ^
   --compress ^
   --order-by-primary ^
   --routines=0 ^
   --triggers=0 ^
   --events=0 ^
   -p localpassword | mysql -u rdsuser ^
       --port=3306 ^
       --host=myinstance.123456789012.us-east-1.rds.amazonaws.com ^
   -p rdspassword
```

**Note**
Specify credentials other than the prompts shown here as a security best practice.

### Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime

In some cases, you might need to import data from an external MariaDB or MySQL database that supports a live application to a MariaDB DB instance, a MySQL DB instance, or a MySQL Multi-AZ DB cluster. Use the following procedure to minimize the impact on availability of applications. This procedure can also help if you are working with a very large database. Using this procedure, you can reduce the cost of the import by reducing the amount of data that is passed across the network to AWS.

In this procedure, you transfer a copy of your database data to an Amazon EC2 instance and import the data into a new Amazon RDS database. You then use replication to bring the Amazon RDS database up-to-date with your live external instance, before redirecting your application to the Amazon RDS database. Configure MariaDB replication based on global transaction identifiers (GTIDs) if the external instance is MariaDB 10.0.24 or higher and the target instance is RDS for MariaDB. Otherwise, configure replication based on binary log coordinates. We recommend GTID-based replication if your external database supports it because GTID-based replication is a more reliable method. For more information, see [Global transaction ID in the MariaDB documentation](https://mariadb.com/kb/en/gtid/).

**Note**
If you want to import data into a MySQL DB instance and your scenario supports it, we recommend moving data in and out of Amazon RDS by using backup files and Amazon S3. For more information, see [Restoring a backup into a MySQL DB instance](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/USER_MariaDB.html).
Note
We don't recommend that you use this procedure with source MySQL databases from MySQL versions earlier than version 5.5 because of potential replication issues. For more information, see Replication compatibility between MySQL versions in the MySQL documentation.

Create a copy of your existing database

The first step in the process of migrating a large amount of data to an RDS for MariaDB or RDS for MySQL database with minimal downtime is to create a copy of the source data.
You can use the mysqldump utility to create a database backup in either SQL or delimited-text format. We recommend that you do a test run with each format in a non-production environment to see which method minimizes the amount of time that mysqldump runs.

We also recommend that you weigh mysqldump performance against the benefit offered by using the delimited-text format for loading. A backup using delimited-text format creates a tab-separated text file for each table being dumped. To reduce the amount of time required to import your database, you can load these files in parallel using the `LOAD DATA LOCAL INFILE` command. For more information about choosing a mysqldump format and then loading the data, see [Using mysqldump for backups](#) in the MySQL documentation.

Before you start the backup operation, make sure to set the replication options on the MariaDB or MySQL database that you are copying to Amazon RDS. The replication options include turning on binary logging and setting a unique server ID. Setting these options causes your server to start logging database transactions and prepares it to be a source replication instance later in this process.

**Note**

Use the `--single-transaction` option with mysqldump because it dumps a consistent state of the database. To ensure a valid dump file, don't run data definition language (DDL) statements while mysqldump is running. You can schedule a maintenance window for these operations.

Exclude the following schemas from the dump file: `sys`, `performance_schema`, and `information_schema`. The mysqldump utility excludes these schemas by default.

To migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the [pt-show-grants](#) utility.

**To set replication options**

1. Edit the `my.cnf` file (this file is usually under `/etc`).

   ```
   sudo vi /etc/my.cnf
   ```

   Add the `log_bin` and `server_id` options to the `[mysqld]` section. The `log_bin` option provides a file name identifier for binary log files. The `server_id` option provides a unique identifier for the server in source-replica relationships.

   The following example shows the updated `[mysqld]` section of a `my.cnf` file.

   ```
   [mysqld]
   log-bin=mysql-bin
   server-id=1
   ```

   For more information, see [the MySQL documentation](#).

2. For replication with a Multi-AZ DB cluster, set the `ENFORCE_GTID_CONSISTENCY` and the `GTID_MODE` parameter to `ON`.

   ```
   mysql> SET @GLOBAL.ENFORCE_GTID_CONSISTENCY = ON;
   ```

   ```
   mysql> SET @GLOBAL.GTID_MODE = ON;
   ```

   These settings aren't required for replication with a DB instance.

3. Restart the `mysql` service.

   ```
   sudo service mysqld restart
   ```
To create a backup copy of your existing database

1. Create a backup of your data using the mysqldump utility, specifying either SQL or delimited-text format.

Specify --master-data=2 to create a backup file that can be used to start replication between servers. For more information, see the `mysqldump` documentation.

To improve performance and ensure data integrity, use the --order-by-primary and --single-transaction options of mysqldump.

To avoid including the MySQL system database in the backup, do not use the --all-databases option with mysqldump. For more information, see `Creating a data snapshot using mysqldump` in the MySQL documentation.

Use chmod if necessary to make sure that the directory where the backup file is being created is writeable.

**Important**

On Windows, run the command window as an administrator.

- To produce SQL output, use the following command.

For Linux, macOS, or Unix:

```
sudo mysqldump
   --databases database_name
   --master-data=2
   --single-transaction
   --order-by-primary
   -r backup.sql
   -u local_user
   -p password
```

**Note**

Specify credentials other than the prompts shown here as a security best practice.

For Windows:

```
mysqldump ^
   --databases database_name ^
   --master-data=2 ^
   --single-transaction ^
   --order-by-primary ^
   -r backup.sql ^
   -u local_user ^
   -p password ^
```

**Note**

Specify credentials other than the prompts shown here as a security best practice.

- To produce delimited-text output, use the following command.

For Linux, macOS, or Unix:

```
sudo mysqldump
   --tab=target_directory
   --fields-terminated-by ','
   --fields-enclosed-by '"'
   --lines-terminated-by 0x0d0a
   database_name
```

1709
Importing data with reduced downtime

```bash
--master-data=2 \
--single-transaction \
--order-by-primary \
-p password
```

For Windows:

```bash
mysqldump ^
--tab=target_directory ^
--fields-terminated-by "," ^
--fields-enclosed-by "" ^
--lines-terminated-by 0x0d0a ^
-database_name ^
--master-data=2 ^
--single-transaction ^
--order-by-primary ^
-p password
```

**Note**

Specify credentials other than the prompts shown here as a security best practice. Make sure to create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, exclude them when you run mysqldump. To do so, include the following arguments with your mysqldump command: --routines=0 --triggers=0 --events=0.

When using the delimited-text format, a CHANGE MASTER TO comment is returned when you run mysqldump. This comment contains the master log file name and position. If the external instance is other than MariaDB version 10.0.24 or higher, note the values for MASTER_LOG_FILE and MASTER_LOG_POS. You need these values when setting up replication.

```
-- Position to start replication or point-in-time recovery from
--
-- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031', MASTER_LOG_POS=107;
```

If you are using SQL format, you can get the master log file name and position in the CHANGE MASTER TO comment in the backup file. If the external instance is MariaDB version 10.0.24 or higher, you can get the GTID in the next step.

2. If the external instance you are using is MariaDB version 10.0.24 or higher, you use GTID-based replication. Run `SHOW MASTER STATUS` on the external MariaDB instance to get the binary log file name and position, then convert them to a GTID by running `BINLOG_GTID_POS` on the external MariaDB instance.

```sql
SELECT BINLOG_GTID_POS('binary log file name', binary log file position);
```

Note the GTID returned; you need it to configure replication.

3. Compress the copied data to reduce the amount of network resources needed to copy your data to the Amazon RDS database. Note the size of the backup file. You need this information when determining how large an Amazon EC2 instance to create. When you are done, compress the backup file using GZIP or your preferred compression utility.

- To compress SQL output, use the following command.

```
gzip backup.sql
```

- To compress delimited-text output, use the following command.
Create an Amazon EC2 instance and copy the compressed database

Copying your compressed database backup file to an Amazon EC2 instance takes fewer network resources than doing a direct copy of uncompressed data between database instances. After your data is in Amazon EC2, you can copy it from there directly to your MariaDB or MySQL database. For you to save on the cost of network resources, your Amazon EC2 instance must be in the same AWS Region as your Amazon RDS DB instance. Having the Amazon EC2 instance in the same AWS Region as your Amazon RDS database also reduces network latency during the import.

To create an Amazon EC2 instance and copy your data

1. In the AWS Region where you plan to create the RDS database, create a virtual private cloud (VPC), a VPC security group, and a VPC subnet. Ensure that the inbound rules for your VPC security group allow the IP addresses required for your application to connect to AWS. You can specify a range of IP addresses (for example, 203.0.113.0/24), or another VPC security group. You can use the Amazon VPC Management Console to create and manage VPCs, subnets, and security groups. For more information, see Getting started with Amazon VPC in the Amazon Virtual Private Cloud Getting Started Guide.

2. Open the Amazon EC2 Management Console and choose the AWS Region to contain both your Amazon EC2 instance and your Amazon RDS database. Launch an Amazon EC2 instance using the VPC, subnet, and security group that you created in Step 1. Ensure that you select an instance type with enough storage for your database backup file when it is uncompressed. For details on Amazon EC2 instances, see Getting started with Amazon EC2 Linux instances in the Amazon Elastic Compute Cloud User Guide for Linux.

3. To connect to your Amazon RDS database from your Amazon EC2 instance, edit your VPC security group. Add an inbound rule specifying the private IP address of your EC2 instance. You can find the private IP address on the Details tab of the Instance pane in the EC2 console window. To edit the VPC
security group and add an inbound rule, choose **Security Groups** in the EC2 console navigation pane, choose your security group, and then add an inbound rule for MySQL or Aurora specifying the private IP address of your EC2 instance. To learn how to add an inbound rule to a VPC security group, see *Adding and removing rules* in the *Amazon VPC User Guide*.

4. Copy your compressed database backup file from your local system to your Amazon EC2 instance. Use `chmod` if necessary to make sure that you have write permission for the target directory of the Amazon EC2 instance. You can use `scp` or a Secure Shell (SSH) client to copy the file. The following is an example.

```bash
$ scp -r -i key pair.pem backup.sql.gz ec2-user@EC2 DNS:/target_directory/backup.sql.gz
```

**Important**

Be sure to copy sensitive data using a secure network transfer protocol.

5. Connect to your Amazon EC2 instance and install the latest updates and the MySQL client tools using the following commands.

```bash
sudo yum update -y
sudo yum install mysql -y
```

For more information, see [*Connect to your instance*](https://docs.aws.amazon.com/AmazonElastic Compute Cloud User Guide for Linux) in the *Amazon Elastic Compute Cloud User Guide for Linux*.

**Important**

This example installs the MySQL client on an Amazon Machine Image (AMI) for an Amazon Linux distribution. To install the MySQL client on a different distribution, such as Ubuntu or Red Hat Enterprise Linux, this example doesn’t work. For information about installing MySQL, see *Installing and Upgrading MySQL* in the MySQL documentation.

6. While connected to your Amazon EC2 instance, decompress your database backup file. The following are examples.

- To decompress SQL output, use the following command.

  ```bash
gzip backup.sql.gz -d
  ```

- To decompress delimited-text output, use the following command.

  ```bash
tar xzvf backup.tar.gz
  ```

### Create a MySQL or MariaDB database and import data from your Amazon EC2 instance

By creating a MariaDB DB instance, a MySQL DB instance, or a MySQL Multi-AZ DB cluster in the same AWS Region as your Amazon EC2 instance, you can import the database backup file from EC2 faster than over the internet.
To create a MariaDB or MySQL database and import your data

1. Determine which DB instance class and what amount of storage space is required to support the expected workload for this Amazon RDS database. As part of this process, decide what is sufficient space and processing capacity for your data load procedures. Also decide what is required to handle the production workload. You can estimate this based on the size and resources of the source MariaDB or MySQL database. For more information, see DB instance classes (p. 11).

2. Create a DB instance or Multi-AZ DB cluster in the AWS Region that contains your Amazon EC2 instance.

   To create a MySQL Multi-AZ DB cluster, follow the instructions in Creating a Multi-AZ DB cluster (p. 508).

   To create a MariaDB or MySQL DB instance, follow the instructions in Creating an Amazon RDS DB instance (p. 300) and use the following guidelines:

   • Specify a DB engine version that is compatible with your source DB instance, as follows:
     • If your source instance is MySQL 5.5.x, the Amazon RDS DB instance must be MySQL.
     • If your source instance is MySQL 5.6.x or 5.7.x, the Amazon RDS DB instance must be MySQL or MariaDB.
     • If your source instance is MySQL 8.0.x, the Amazon RDS DB instance must be MySQL 8.0.x.
     • If your source instance is MariaDB 5.5 or higher, the Amazon RDS DB instance must be MariaDB.
   • Specify the same virtual private cloud (VPC) and VPC security group as for your Amazon EC2 instance. This approach ensures that your Amazon EC2 instance and your Amazon RDS instance are visible to each other over the network. Make sure your DB instance is publicly accessible. To set up replication with your source database as described later, your DB instance must be publicly accessible.
   • Don't configure multiple Availability Zones, backup retention, or read replicas until after you have imported the database backup. When that import is completed, you can configure Multi-AZ and backup retention for the production instance.

3. Review the default configuration options for the Amazon RDS database. If the default parameter group for the database doesn't have the configuration options that you want, find a different one.
that does or create a new parameter group. For more information on creating a parameter group, see Working with parameter groups (p. 347).

4. Connect to the new Amazon RDS database as the master user. Create the users required to support the administrators, applications, and services that need to access the instance. The hostname for the Amazon RDS database is the **Endpoint** value for this instance without including the port number. An example is `mysampledb.123456789012.us-west-2.rds.amazonaws.com`. You can find the endpoint value in the database details in the Amazon RDS Management Console.

5. Connect to your Amazon EC2 instance. For more information, see Connect to your instance in the Amazon Elastic Compute Cloud User Guide for Linux.

6. Connect to your Amazon RDS database as a remote host from your Amazon EC2 instance using the `mysql` command. The following is an example.

```
mysql -h host_name -P 3306 -u db_master_user -p
```

The hostname is the Amazon RDS database endpoint.

7. At the `mysql` prompt, run the `source` command and pass it the name of your database dump file to load the data into the Amazon RDS DB instance:

- For SQL format, use the following command.

```
mysql> source backup.sql;
```

- For delimited-text format, first create the database, if it isn't the default database you created when setting up the Amazon RDS database.

```
mysql> create database database_name;
$ mysql> use database_name;
```

Then create the tables.

```
mysql> source table1.sql
$ mysql> source table2.sql
etc...
```

Then import the data.

```
mysql> LOAD DATA LOCAL INFILE 'table1.txt' INTO TABLE table1 FIELDS TERMINATED BY ','
  ENCLOSED BY '"' LINES TERMINATED BY '0x0d0a';
$ mysql> LOAD DATA LOCAL INFILE 'table2.txt' INTO TABLE table2 FIELDS TERMINATED BY ','
  ENCLOSED BY '"' LINES TERMINATED BY '0x0d0a';
etc...
```

To improve performance, you can perform these operations in parallel from multiple connections so that all of your tables are created and then loaded at the same time.

**Note**

If you used any data-formating options with mysqldump when you initially dumped the table, make sure to use the same options with `mysqlimport` or `LOAD DATA LOCAL INFILE` to ensure proper interpretation of the data file contents.

8. Run a simple SELECT query against one or two of the tables in the imported database to verify that the import was successful.
If you no longer need the Amazon EC2 instance used in this procedure, terminate the EC2 instance to reduce your AWS resource usage. To terminate an EC2 instance, see Terminating an instance in the Amazon EC2 User Guide.

Replicate between your external database and new Amazon RDS database

Your source database was likely updated during the time that it took to copy and transfer the data to the MariaDB or MySQL database. Thus, you can use replication to bring the copied database up-to-date with the source database.

![Diagram showing replication between a corporate data center and AWS Cloud](image)

The permissions required to start replication on an Amazon RDS database are restricted and not available to your Amazon RDS master user. Because of this, make sure to use either the Amazon RDS `mysql.rds_set_external_master` command or the `mysql.rds_set_external_master_gtid` command to configure replication, and the `mysql.rds_start_replication` command to start replication between your live database and your Amazon RDS database.

To start replication

Earlier, you turned on binary logging and set a unique server ID for your source database. Now you can set up your Amazon RDS database as a replica with your live database as the source replication instance.

1. In the Amazon RDS Management Console, add the IP address of the server that hosts the source database to the VPC security group for the Amazon RDS database. For more information on modifying a VPC security group, see Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

You might also need to configure your local network to permit connections from the IP address of your Amazon RDS database, so that it can communicate with your source instance. To find the IP address of the Amazon RDS database, use the `host` command.

```
host rds_db_endpoint
```
The hostname is the DNS name from the Amazon RDS database endpoint, for example myinstance.123456789012.us-east-1.rds.amazonaws.com. You can find the endpoint value in the instance details in the Amazon RDS Management Console.

2. Using the client of your choice, connect to the source instance and create a user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following is an example.

**MySQL 5.5, 5.6, and 5.7**

```sql
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

**MySQL 8.0**

```sql
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY 'password';
```

**Note**
Specify credentials other than the prompts shown here as a security best practice.

3. For the source instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. For example, to grant the `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the `repl_user` user for your domain, issue the following command.

**MySQL 5.5, 5.6, and 5.7**

```sql
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

**MySQL 8.0**

```sql
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

**Note**
Specify credentials other than the prompts shown here as a security best practice.

4. If you used SQL format to create your backup file and the external instance is not MariaDB 10.0.24 or higher, look at the contents of that file.

```bash
cat backup.sql
```

The file includes a `CHANGE MASTER TO` comment that contains the master log file name and position. This comment is included in the backup file when you use the `--master-data` option with `mysqldump`. Note the values for `MASTER_LOG_FILE` and `MASTER_LOG_POS`.

```bash
--
-- Position to start replication or point-in-time recovery from
--
-- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031', MASTER_LOG_POS=107;
```

If you used delimited text format to create your backup file and the external instance isn't MariaDB 10.0.24 or higher, you should already have binary log coordinates from step 1 of the procedure at "To create a backup copy of your existing database" in this topic.
If the external instance is MariaDB 10.0.24 or higher, you should already have the GTID from which to start replication from step 2 of the procedure at “To create a backup copy of your existing database” in this topic.

5. Make the Amazon RDS database the replica. If the external instance isn't MariaDB 10.0.24 or higher, connect to the Amazon RDS database as the master user and identify the source database as the source replication instance by using the `mysql.rds_set_external_master` (p. 1785) command. Use the master log file name and master log position that you determined in the previous step if you have a SQL format backup file. Or use the name and position that you determined when creating the backup files if you used delimited-text format. The following is an example.

```
CALL mysql.rds_set_external_master ("myserver.mydomain.com", 3306,
    "repl_user", "password", "mysql-bin-changelog.000031", 107, 0);
```

**Note**
Specify credentials other than the prompts shown here as a security best practice.

If the external instance is MariaDB 10.0.24 or higher, connect to the Amazon RDS database as the master user and identify the source database as the source replication instance by using the `mysql.rds_set_external_master_gtid` (p. 1361) command. Use the GTID that you determined in step 2 of the procedure at “To create a backup copy of your existing database” in this topic. The following is an example.

```
CALL mysql.rds_set_external_master_gtid ("source_server_ip_address", 3306,
    'ReplicationUser', "password", "GTID", 0);
```

The `source_server_ip_address` is the IP address of source replication instance. An EC2 private DNS address is currently not supported.

**Note**
Specify credentials other than the prompts shown here as a security best practice.

6. On the Amazon RDS database, issue the `mysql.rds_start_replication` (p. 1796) command to start replication.

```
CALL mysql.rds_start_replication;
```

7. On the Amazon RDS database, run the `SHOW REPLICA STATUS` command to determine when the replica is up-to-date with the source replication instance. The results of the `SHOW REPLICA STATUS` command include the `Seconds_Behind_Master` field. When the `Seconds_Behind_Master` field returns 0, then the replica is up-to-date with the source replication instance.

**Note**
Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

For a MariaDB 10.5, 10.6, or 10.11 DB instance, run the `mysql.rds_replica_status` (p. 1360) procedure instead of the MySQL command.

8. After the Amazon RDS database is up-to-date, turn on automated backups so you can restore that database if needed. You can turn on or modify automated backups for your Amazon RDS database using the Amazon RDS Management Console. For more information, see Working with backups (p. 591).
Redirect your live application to your Amazon RDS instance

After the MariaDB or MySQL database is up-to-date with the source replication instance, you can now update your live application to use the Amazon RDS instance.

To redirect your live application to your MariaDB or MySQL database and stop replication

1. To add the VPC security group for the Amazon RDS database, add the IP address of the server that hosts the application. For more information on modifying a VPC security group, see Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

2. Verify that the Seconds_Behind_Master field in the SHOW REPLICA STATUS command results is 0, which indicates that the replica is up-to-date with the source replication instance.

   ```
   SHOW REPLICA STATUS;
   ```

   **Note**
   Previous versions of MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

   For a MariaDB 10.5, 10.6, or 10.11 DB instance, run the mysql.rds_replica_status (p. 1360) procedure instead of the MySQL command.

3. Close all connections to the source when their transactions complete.

4. Update your application to use the Amazon RDS database. This update typically involves changing the connection settings to identify the hostname and port of the Amazon RDS database, the user account and password to connect with, and the database to use.

5. Connect to the DB instance.

   For a Multi-AZ DB cluster, connect to the writer DB instance.

6. Stop replication for the Amazon RDS instance using the mysql.rds_stop_replication (p. 1798) command.
7. Run the `mysql.rds_stop_replication` command on your Amazon RDS database to reset the replication configuration so this instance is no longer identified as a replica.

8. Turn on additional Amazon RDS features such as Multi-AZ support and read replicas. For more information, see Configuring and managing a Multi-AZ deployment (p. 492) and Working with DB instance read replicas (p. 438).

### Importing data from any source to a MariaDB or MySQL DB instance

If you have more than 1 GiB of data to load, or if your data is coming from somewhere other than a MariaDB or MySQL database, we recommend creating flat files and loading them with mysqlimport. The mysqlimport utility is another command line utility bundled with the MySQL and MariaDB client software. Its purpose is to load flat files into MySQL or MariaDB. For information about mysqlimport, see mysqlimport - a data import program in the MySQL documentation.

We also recommend creating DB snapshots of the target Amazon RDS DB instance before and after the data load. Amazon RDS DB snapshots are complete backups of your DB instance that can be used to restore your DB instance to a known state. When you initiate a DB snapshot, I/O operations to your DB instance are momentarily suspended while your database is backed up.

Creating a DB snapshot immediately before the load makes it possible for you to restore the database to its state before the load, if you need to. A DB snapshot taken immediately after the load protects you from having to load the data again in case of a mishap and can also be used to seed new database instances.

The following list shows the steps to take. Each step is discussed in more detail following.

1. Create flat files containing the data to be loaded.
2. Stop any applications accessing the target DB instance.
3. Create a DB snapshot.
4. Consider turning off Amazon RDS automated backups.
5. Load the data using mysqlimport.
6. Enable automated backups again.

### Step 1: Create flat files containing the data to be loaded

Use a common format, such as comma-separated values (CSV), to store the data to be loaded. Each table must have its own file; you can't combine data for multiple tables in the same file. Give each file the same name as the table it corresponds to. The file extension can be anything you like. For example, if the table name is `sales`, the file name might be `sales.csv` or `sales.txt`, but not `sales_01.csv`.

Whenever possible, order the data by the primary key of the table being loaded. Doing this drastically improves load times and minimizes disk storage requirements.

The speed and efficiency of this procedure depends on keeping the size of the files small. If the uncompressed size of any individual file is larger than 1 GiB, split it into multiple files and load each one separately.
On Unix-like systems (including Linux), use the `split` command. For example, the following command
splits the `sales.csv` file into multiple files of less than 1 GiB, splitting only at line breaks `-C 1024m). The new files are named `sales.part_00`, `sales.part_01`, and so on.

```
split -C 1024m -d sales.csv sales.part_
```

Similar utilities are available for other operating systems.

**Step 2: Stop any applications accessing the target DB instance**

Before starting a large load, stop all application activity accessing the target DB instance that you plan
to load to. We recommend this particularly if other sessions will be modifying the tables being loaded
or tables that they reference. Doing this reduces the risk of constraint violations occurring during the
load and improves load performance. It also makes it possible to restore the DB instance to the point just
before the load without losing changes made by processes not involved in the load.

Of course, this might not be possible or practical. If you can't stop applications from accessing the DB
instance before the load, take steps to ensure the availability and integrity of your data. The specific
steps required vary greatly depending upon specific use cases and site requirements.

**Step 3: Create a DB snapshot**

If you plan to load data into a new DB instance that contains no data, you can skip this step. Otherwise,
creating a DB snapshot of your DB instance makes it possible for you to restore the DB instance to the
point just before the load, if it becomes necessary. As previously mentioned, when you initiate a DB
snapshot, I/O operations to your DB instance are suspended for a few minutes while the database is
backed up.

The example following uses the AWS CLI `create-db-snapshot` command to create a DB snapshot of
the AcmeRDS instance and give the DB snapshot the identifier "preload".

For Linux, macOS, or Unix:

```
aws rds create-db-snapshot
    --db-instance-identifier AcmeRDS
    --db-snapshot-identifier preload
```

For Windows:

```
aws rds create-db-snapshot
    --db-instance-identifier AcmeRDS
    --db-snapshot-identifier preload
```

You can also use the restore from DB snapshot functionality to create test DB instances for dry runs or to
undo changes made during the load.

Keep in mind that restoring a database from a DB snapshot creates a new DB instance that, like all
DB instances, has a unique identifier and endpoint. To restore the DB instance without changing the
endpoint, first delete the DB instance so that you can reuse the endpoint.

For example, to create a DB instance for dry runs or other testing, you give the DB instance its own
identifier. In the example, `AcmeRDS-2` is the identifier. The example connects to the DB instance using
the endpoint associated with `AcmeRDS-2`.

For Linux, macOS, or Unix:
aws rds restore-db-instance-from-db-snapshot \
    --db-instance-identifier AcmeRDS-2 \
    --db-snapshot-identifier preload

For Windows:

aws rds restore-db-instance-from-db-snapshot ^
    --db-instance-identifier AcmeRDS-2 ^
    --db-snapshot-identifier preload

To reuse the existing endpoint, first delete the DB instance and then give the restored database the same identifier.

For Linux, macOS, or Unix:

aws rds delete-db-instance \
    --db-instance-identifier AcmeRDS \
    --final-db-snapshot-identifier AcmeRDS-Final

aws rds restore-db-instance-from-db-snapshot \
    --db-instance-identifier AcmeRDS \
    --db-snapshot-identifier preload

For Windows:

aws rds delete-db-instance ^
    --db-instance-identifier AcmeRDS ^
    --final-db-snapshot-identifier AcmeRDS-Final

aws rds restore-db-instance-from-db-snapshot ^
    --db-instance-identifier AcmeRDS ^
    --db-snapshot-identifier preload

The preceding example takes a final DB snapshot of the DB instance before deleting it. This is optional but recommended.

**Step 4: Consider turning off Amazon RDS automated backups**

**Warning**

Do not turn off automated backups if you need to perform point-in-time recovery.

Turning off automated backups erases all existing backups, so point-in-time recovery isn't possible after automated backups have been turned off. Disabling automated backups is a performance optimization and isn't required for data loads. Manual DB snapshots aren't affected by turning off automated backups. All existing manual DB snapshots are still available for restore.

Turning off automated backups reduces load time by about 25 percent and reduces the amount of storage space required during the load. If you plan to load data into a new DB instance that contains no data, turning off backups is an easy way to speed up the load and avoid using the additional storage needed for backups. However, in some cases you might plan to load into a DB instance that already contains data. If so, weigh the benefits of turning off backups against the impact of losing the ability to perform point-in-time-recovery.

DB instances have automated backups turned on by default (with a one day retention period). To turn off automated backups, set the backup retention period to zero. After the load, you can turn backups back on by setting the backup retention period to a nonzero value. To turn on or turn off backups, Amazon RDS shuts the DB instance down and restarts it to turn MariaDB or MySQL logging on or off.
Use the AWS CLI `modify-db-instance` command to set the backup retention to zero and apply the change immediately. Setting the retention period to zero requires a DB instance restart, so wait until the restart has completed before proceeding.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance
   --db-instance-identifier AcmeRDS
   --apply-immediately
   --backup-retention-period 0
```

For Windows:

```
aws rds modify-db-instance ^
   --db-instance-identifier AcmeRDS ^
   --apply-immediately ^
   --backup-retention-period 0
```

You can check the status of your DB instance with the AWS CLI `describe-db-instances` command. The following example displays the DB instance status of the AcmeRDS DB instance.

```
aws rds describe-db-instances --db-instance-identifier AcmeRDS --query "[*].{DBInstanceStatus:DBInstanceStatus}"
```

When the DB instance status is available, you're ready to proceed.

**Step 5: Load the data**

Use the `mysqlimport` utility to load the flat files into Amazon RDS. The following example tells `mysqlimport` to load all of the files named "sales" with an extension starting with "part_". This is a convenient way to load all of the files created in the "split" example.

Use the `--compress` option to minimize network traffic. The `--fields-terminated-by=','` option is used for CSV files, and the `--local` option specifies that the incoming data is located on the client. Without the `--local` option, the Amazon RDS DB instance looks for the data on the database host, so always specify the `--local` option. For the `--host` option, specify the DB instance endpoint of the RDS for MySQL DB instance.

In the following examples, replace `master_user` with the master username for your DB instance.

Replace `hostname` with the endpoint for your DB instance. An example of a DB instance endpoint is `my-db-instance.123456789012.us-west-2.rds.amazonaws.com`.

For RDS for MySQL version 8.0.15 and higher, run the following statement before using the `mysqlimport` utility.

```
GRANT SESSION_VARIABLES_ADMIN ON *.* TO master_user;
```

For Linux, macOS, or Unix:

```
mysqlimport --local
   --compress
   --user=master_user
   --password
   --host=hostname
   --fields-terminated-by=',
   Acme sales.part_*
```

For Windows:
For very large data loads, take additional DB snapshots periodically between loading files and note which files have been loaded. If a problem occurs, you can easily resume from the point of the last DB snapshot, avoiding lengthy reloads.

**Step 6: Turn Amazon RDS automated backups back on**

After the load is finished, turn Amazon RDS automated backups on by setting the backup retention period back to its preload value. As noted earlier, Amazon RDS restarts the DB instance, so be prepared for a brief outage.

The following example uses the AWS CLI `modify-db-instance` command to turn on automated backups for the AcmeRDS DB instance and set the retention period to one day.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance
    --db-instance-identifier AcmeRDS
    --backup-retention-period 1
    --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance
    --db-instance-identifier AcmeRDS
    --backup-retention-period 1
    --apply-immediately
```
Working with MySQL replication in Amazon RDS

You usually use read replicas to configure replication between Amazon RDS DB instances. For general information about read replicas, see Working with DB instance read replicas (p. 438). For specific information about working with read replicas on Amazon RDS for MySQL, see Working with MySQL read replicas (p. 1724).

You can use global transaction identifiers (GTIDs) for replication with RDS for MySQL. For more information, see Using GTID-based replication for Amazon RDS for MySQL (p. 1735).

You can also set up replication between an RDS for MySQL DB instance and a MariaDB or MySQL instance that is external to Amazon RDS. For information about configuring replication with an external source, see Configuring binary log file position replication with an external source instance (p. 1740).

For any of these replication options, you can use either row-based replication, statement-based, or mixed replication. Row-based replication only replicates the changed rows that result from a SQL statement. Statement-based replication replicates the entire SQL statement. Mixed replication uses statement-based replication when possible, but switches to row-based replication when SQL statements that are unsafe for statement-based replication are run. In most cases, mixed replication is recommended. The binary log format of the DB instance determines whether replication is row-based, statement-based, or mixed. For information about setting the binary log format, see Configuring MySQL binary logging (p. 921).

Note
You can configure replication to import databases from a MariaDB or MySQL instance that is external to Amazon RDS, or to export databases to such instances. For more information, see Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime (p. 1706) and Exporting data from a MySQL DB instance by using replication (p. 1744).

• Configuring binary log file position replication with an external source instance (p. 1740)

Working with MySQL read replicas

Following, you can find specific information about working with read replicas on RDS for MySQL. For general information about read replicas and instructions for using them, see Working with DB instance read replicas (p. 438).

Topics
• Configuring read replicas with MySQL (p. 1725)
• Configuring replication filters with MySQL (p. 1725)
• Configuring delayed replication with MySQL (p. 1730)
• Updating read replicas with MySQL (p. 1732)
• Working with Multi-AZ read replica deployments with MySQL (p. 1732)
• Using cascading read replicas with RDS for MySQL (p. 1732)
• Monitoring MySQL read replicas (p. 1733)
• Starting and stopping replication with MySQL read replicas (p. 1734)
• Troubleshooting a MySQL read replica problem (p. 1734)
Configuring read replicas with MySQL

Before a MySQL DB instance can serve as a replication source, make sure to enable automatic backups on the source DB instance. To do this, set the backup retention period to a value other than 0. This requirement also applies to a read replica that is the source DB instance for another read replica. Automatic backups are supported for read replicas running any version of MySQL. You can configure replication based on binary log coordinates for a MySQL DB instance.

On RDS for MySQL version 5.7.37 and higher MySQL 5.7 versions and RDS for MySQL 8.0.28 and higher 8.0 versions, you can configure replication using global transaction identifiers (GTIDs). For more information, see Using GTID-based replication for Amazon RDS for MySQL (p. 1735).

You can create up to 15 read replicas from one DB instance within the same Region. For replication to operate effectively, each read replica should have the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, also scale the read replicas.

RDS for MySQL supports cascading read replicas. To learn how to configure cascading read replicas, see Using cascading read replicas with RDS for MySQL (p. 1732).

You can run multiple read replica create and delete actions at the same time that reference the same source DB instance. When you perform these actions, stay within the limit of 15 read replicas for each source instance.

A read replica of a MySQL DB instance can't use a lower DB engine version than its source DB instance.

Preparing MySQL DB instances that use MyISAM

If your MySQL DB instance uses a nontransactional engine such as MyISAM, you need to perform the following steps to successfully set up your read replica. These steps are required to make sure that the read replica has a consistent copy of your data. These steps are not required if all of your tables use a transactional engine such as InnoDB.

1. Stop all data manipulation language (DML) and data definition language (DDL) operations on non-transactional tables in the source DB instance and wait for them to complete. SELECT statements can continue running.
2. Flush and lock the tables in the source DB instance.
3. Create the read replica using one of the methods in the following sections.
4. Check the progress of the read replica creation using, for example, the DescribeDBInstances API operation. Once the read replica is available, unlock the tables of the source DB instance and resume normal database operations.

Configuring replication filters with MySQL

You can use replication filters to specify which databases and tables are replicated with a read replica. Replication filters can include databases and tables in replication or exclude them from replication.

The following are some use cases for replication filters:

- To reduce the size of a read replica. With replication filtering, you can exclude the databases and tables that aren't needed on the read replica.
- To exclude databases and tables from read replicas for security reasons.
- To replicate different databases and tables for specific use cases at different read replicas. For example, you might use specific read replicas for analytics or sharding.
- For a DB instance that has read replicas in different AWS Regions, to replicate different databases or tables in different AWS Regions.
Note
You can also use replication filters to specify which databases and tables are replicated with a primary MySQL DB instance that is configured as a replica in an inbound replication topology. For more information about this configuration, see Configuring binary log file position replication with an external source instance (p. 1740).

Topics
- Setting replication filtering parameters for RDS for MySQL (p. 1726)
- Replication filtering limitations for RDS for MySQL (p. 1727)
- Replication filtering examples for RDS for MySQL (p. 1727)
- Viewing the replication filters for a read replica (p. 1729)

Setting replication filtering parameters for RDS for MySQL

To configure replication filters, set the following replication filtering parameters on the read replica:

- `replicate-do-db` – Replicate changes to the specified databases. When you set this parameter for a read replica, only the databases specified in the parameter are replicated.
- `replicate-ignore-db` – Don't replicate changes to the specified databases. When the `replicate-do-db` parameter is set for a read replica, this parameter isn't evaluated.
- `replicate-do-table` – Replicate changes to the specified tables. When you set this parameter for a read replica, only the tables specified in the parameter are replicated. Also, when the `replicate-do-db` or `replicate-ignore-db` parameter is set, make sure to include the database that includes the specified tables in replication with the read replica.
- `replicate-ignore-table` – Don't replicate changes to the specified tables. When the `replicate-do-table` parameter is set for a read replica, this parameter isn't evaluated.
- `replicate-wild-do-table` – Replicate tables based on the specified database and table name patterns. The `%` and `_` wildcard characters are supported. When the `replicate-do-db` or `replicate-ignore-db` parameter is set, make sure to include the database that includes the specified tables in replication with the read replica.
- `replicate-wild-ignore-table` – Don't replicate tables based on the specified database and table name patterns. The `%` and `_` wildcard characters are supported. When the `replicate-do-table` or `replicate-wild-do-table` parameter is set for a read replica, this parameter isn't evaluated.

The parameters are evaluated in the order that they are listed. For more information about how these parameters work, see the MySQL documentation:

- For general information, see Replica Server Options and Variables.
- For information about how database replication filtering parameters are evaluated, see Evaluation of Database-Level Replication and Binary Logging Options.
- For information about how table replication filtering parameters are evaluated, see Evaluation of Table-Level Replication Options.

By default, each of these parameters has an empty value. On each read replica, you can use these parameters to set, change, and delete replication filters. When you set one of these parameters, separate each filter from others with a comma.

You can use the `%` and `_` wildcard characters in the `replicate-wild-do-table` and `replicate-wild-ignore-table` parameters. The `%` wildcard matches any number of characters, and the `_` wildcard matches only one character.

The binary logging format of the source DB instance is important for replication because it determines the record of data changes. The setting of the `binlog_format` parameter determines whether the
replication is row-based or statement-based. For more information, see Configuring MySQL binary logging (p. 921).

**Note**
All data definition language (DDL) statements are replicated as statements, regardless of the binlog_format setting on the source DB instance.

### Replication filtering limitations for RDS for MySQL

The following limitations apply to replication filtering for RDS for MySQL:

- Each replication filtering parameter has a 2,000-character limit.
- Commas aren't supported in replication filters.
- The MySQL --binlog-do-db and --binlog-ignore-db options for binary log filtering aren't supported.
- Replication filtering doesn't support XA transactions.

For more information, see Restrictions on XA Transactions in the MySQL documentation.

### Replication filtering examples for RDS for MySQL

To configure replication filtering for a read replica, modify the replication filtering parameters in the parameter group associated with the read replica.

**Note**
You can't modify a default parameter group. If the read replica is using a default parameter group, create a new parameter group and associate it with the read replica. For more information on DB parameter groups, see Working with parameter groups (p. 347).

You can set parameters in a parameter group using the AWS Management Console, AWS CLI, or RDS API. For information about setting parameters, see Modifying parameters in a DB parameter group (p. 352). When you set parameters in a parameter group, all of the DB instances associated with the parameter group use the parameter settings. If you set the replication filtering parameters in a parameter group, make sure that the parameter group is associated only with read replicas. Leave the replication filtering parameters empty for source DB instances.

The following examples set the parameters using the AWS CLI. These examples set ApplyMethod to immediate so that the parameter changes occur immediately after the CLI command completes. If you want a pending change to be applied after the read replica is rebooted, set ApplyMethod to pending-reboot.

The following examples set replication filters:

- **Including databases in replication**
- **Including tables in replication**
- **Including tables in replication with wildcard characters**
- **Excluding databases from replication**
- **Excluding tables from replication**
- **Excluding tables from replication using wildcard characters**

**Example Including databases in replication**

The following example includes the mydb1 and mydb2 databases in replication.

For Linux, macOS, or Unix:
aws rds modify-db-parameter-group  
  --db-parameter-group-name myparametergroup  
  --parameters "ParameterName=replicate-do-db,ParameterValue='mydb1,mydb2',ApplyMethod=immediate"

For Windows:
aws rds modify-db-parameter-group  
  --db-parameter-group-name myparametergroup  
  --parameters "ParameterName=replicate-do-db,ParameterValue='mydb1,mydb2',ApplyMethod=immediate"

Example Including tables in replication
The following example includes the `table1` and `table2` tables in database `mydb1` in replication.

For Linux, macOS, or Unix:
aws rds modify-db-parameter-group  
  --db-parameter-group-name myparametergroup  
  --parameters "ParameterName=replicate-do-table,ParameterValue='mydb1.table1,mydb1.table2',ApplyMethod=immediate"

For Windows:
aws rds modify-db-parameter-group  
  --db-parameter-group-name myparametergroup  
  --parameters "ParameterName=replicate-do-table,ParameterValue='mydb1.table1,mydb1.table2',ApplyMethod=immediate"

Example Including tables in replication using wildcard characters
The following example includes tables with names that begin with `order` and `return` in database `mydb` in replication.

For Linux, macOS, or Unix:
aws rds modify-db-parameter-group  
  --db-parameter-group-name myparametergroup  
  --parameters "ParameterName=replicate-wild-do-table,ParameterValue='mydb.order %,mydb.return%',ApplyMethod=immediate"

For Windows:
aws rds modify-db-parameter-group  
  --db-parameter-group-name myparametergroup  
  --parameters "ParameterName=replicate-wild-do-table,ParameterValue='mydb.order %,mydb.return%',ApplyMethod=immediate"

Example Excluding databases from replication
The following example excludes the `mydb5` and `mydb6` databases from replication.

For Linux, macOS, or Unix:
Example Excluding tables from replication

The following example excludes tables table1 in database mydb5 and table2 in database mydb6 from replication.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "ParameterName=replicate-ignore-table,ParameterValue='mydb5.table1,mydb6.table2',ApplyMethod=immediate"
```

For Windows:

```bash
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "ParameterName=replicate-ignore-table,ParameterValue='mydb5.table1,mydb6.table2',ApplyMethod=immediate"
```

Example Excluding tables from replication using wildcard characters

The following example excludes tables with names that begin with order and return in database mydb7 from replication.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "ParameterName=replicate-wild-ignore-table,ParameterValue='mydb7.order %,mydb7.return %',ApplyMethod=immediate"
```

For Windows:

```bash
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "ParameterName=replicate-wild-ignore-table,ParameterValue='mydb7.order %,mydb7.return %',ApplyMethod=immediate"
```

Viewing the replication filters for a read replica

You can view the replication filters for a read replica in the following ways:
• Check the settings of the replication filtering parameters in the parameter group associated with the read replica.

For instructions, see Viewing parameter values for a DB parameter group (p. 359).

• In a MySQL client, connect to the read replica and run the SHOW REPLICA STATUS statement.

In the output, the following fields show the replication filters for the read replica:
  • Replicate_Do_DB
  • Replicate_Ignore_DB
  • Replicate_Do_Table
  • Replicate_Ignore_Table
  • Replicate_Wild_Do_Table
  • Replicate_Wild_Ignore_Table

For more information about these fields, see Checking Replication Status in the MySQL documentation.

**Note**

Previous versions of MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

### Configuring delayed replication with MySQL

You can use delayed replication as a strategy for disaster recovery. With delayed replication, you specify the minimum amount of time, in seconds, to delay replication from the source to the read replica. In the event of a disaster, such as a table deleted unintentionally, you complete the following steps to recover from the disaster quickly:

• Stop replication to the read replica before the change that caused the disaster is sent to it.

  Use the `mysql.rds_stop_replication` (p. 1798) stored procedure to stop replication.

• Start replication and specify that replication stops automatically at a log file location.

  You specify a location just before the disaster using the `mysql.rds_start_replication_until` (p. 1796) stored procedure.

• Promote the read replica to be the new source DB instance by using the instructions in Promoting a read replica to be a standalone DB instance (p. 447).

**Note**

• On RDS for MySQL 8.0, delayed replication is supported for MySQL 8.0.28 and higher. On RDS for MySQL 5.7, delayed replication is supported for MySQL 5.7.37 and higher.

• Use stored procedures to configure delayed replication. You can't configure delayed replication with the AWS Management Console, the AWS CLI, or the Amazon RDS API.

• On RDS for MySQL 5.7.37 and higher MySQL 5.7 versions and RDS for MySQL 8.0.28 and higher 8.0 versions, you can use replication based on global transaction identifiers (GTIDs) in a delayed replication configuration. If you use GTID-based replication, use the `mysql.rds_start_replication_until_gtid` (p. 1797) stored procedure instead of the `mysql.rds_start_replication_until` (p. 1796) stored procedure. For more information about GTID-based replication, see Using GTID-based replication for Amazon RDS for MySQL (p. 1735).
Configuring delayed replication during read replica creation

To configure delayed replication for any future read replica created from a DB instance, run the `mysql.rds_set_configuration` stored procedure with the `target delay` parameter.

To configure delayed replication during read replica creation

1. Using a MySQL client, connect to the MySQL DB instance to be the source for read replicas as the master user.
2. Run the `mysql.rds_set_configuration` stored procedure with the `target delay` parameter.

   For example, run the following stored procedure to specify that replication is delayed by at least one hour (3,600 seconds) for any read replica created from the current DB instance.

   ```sql
   call mysql.rds_set_configuration('target delay', 3600);
   ```

   **Note**
   After running this stored procedure, any read replica you create using the AWS CLI or Amazon RDS API is configured with replication delayed by the specified number of seconds.

Modifying delayed replication for an existing read replica

To modify delayed replication for an existing read replica, run the `mysql.rds_set_source_delay` stored procedure.

To modify delayed replication for an existing read replica

1. Using a MySQL client, connect to the read replica as the master user.
2. Use the `mysql.rds_stop_replication` stored procedure to stop replication.
3. Run the `mysql.rds_set_source_delay` stored procedure.

   For example, run the following stored procedure to specify that replication to the read replica is delayed by at least one hour (3600 seconds).

   ```sql
   call mysql.rds_set_source_delay(3600);
   ```

4. Use the `mysql.rds_start_replication` stored procedure to start replication.

Setting a location to stop replication to a read replica

After stopping replication to the read replica, you can start replication and then stop it at a specified binary log file location using the `mysql.rds_start_replication_until` stored procedure.

To start replication to a read replica and stop replication at a specific location

1. Using a MySQL client, connect to the source MySQL DB instance as the master user.
2. Run the `mysql.rds_start_replication_until` stored procedure.
The following example initiates replication and replicates changes until it reaches location 120 in the `mysql-bin-changelog.000777` binary log file. In a disaster recovery scenario, assume that location 120 is just before the disaster.

```sql
call mysql.rds_start_replication_until('mysql-bin-changelog.000777', 120);
```

Replication stops automatically when the stop point is reached. The following RDS event is generated:

Replication has been stopped since the replica reached the stop point specified by the `rds_start_replication_until` stored procedure.

## Promoting a read replica

After replication is stopped, in a disaster recovery scenario, you can promote a read replica to be the new source DB instance. For information about promoting a read replica, see [Promoting a read replica to be a standalone DB instance](p. 447).

## Updating read replicas with MySQL

Read replicas are designed to support read queries, but you might need occasional updates. For example, you might need to add an index to optimize the specific types of queries accessing the replica.

Although you can enable updates by setting the `read_only` parameter to 0 in the DB parameter group for the read replica, we recommend that you don't do so because it can cause problems if the read replica becomes incompatible with the source DB instance. For maintenance operations, we recommend that you use blue/green deployments. For more information, see [Using Blue/Green Deployments for database updates](p. 566).

If you disable read-only on a read replica, change the value of the `read_only` parameter back to 1 as soon as possible.

## Working with Multi-AZ read replica deployments with MySQL

You can create a read replica from either single-AZ or Multi-AZ DB instance deployments. You use Multi-AZ deployments to improve the durability and availability of critical data, but you can't use the Multi-AZ secondary to serve read-only queries. Instead, you can create read replicas from high-traffic Multi-AZ DB instances to offload read-only queries. If the source instance of a Multi-AZ deployment fails over to the secondary, any associated read replicas automatically switch to use the secondary (now primary) as their replication source. For more information, see [Configuring and managing a Multi-AZ deployment](p. 492).

You can create a read replica as a Multi-AZ DB instance. Amazon RDS creates a standby of your replica in another Availability Zone for failover support for the replica. Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.

## Using cascading read replicas with RDS for MySQL

RDS for MySQL supports cascading read replicas. With cascading read replicas, you can scale reads without adding overhead to your source RDS for MySQL DB instance.

With cascading read replicas, your RDS for MySQL DB instance sends data to the first read replica in the chain. That read replica then sends data to the second replica in the chain, and so on. The end result is that all read replicas in the chain have the changes from the RDS for MySQL DB instance, but without the overhead solely on the source DB instance.
You can create a series of up to three read replicas in a chain from a source RDS for MySQL DB instance. For example, suppose that you have an RDS for MySQL DB instance, `mysql-main`. You can do the following:

- Starting with `mysql-main`, create the first read replica in the chain, `read-replica-1`.
- Next, from `read-replica-1`, create the next read replica in the chain, `read-replica-2`.
- Finally, from `read-replica-2`, create the third read replica in the chain, `read-replica-3`.

You can't create another read replica beyond this third cascading read replica in the series for `mysql-main`. A complete series of instances from an RDS for MySQL source DB instance through to the end of a series of cascading read replicas can consist of at most four DB instances.

For cascading read replicas to work, each source RDS for MySQL DB instance must have automated backups turned on. To turn on automatic backups on a read replica, first create the read replica, and then modify the read replica to turn on automatic backups. For more information, see Creating a read replica (p. 445).

As with any read replica, you can promote a read replica that's part of a cascade. Promoting a read replica from within a chain of read replicas removes that replica from the chain. For example, suppose that you want to move some of the workload from your `mysql-main` DB instance to a new instance for use by the accounting department only. Assuming the chain of three read replicas from the example, you decide to promote `read-replica-2`. The chain is affected as follows:

- Promoting `read-replica-2` removes it from the replication chain.
  - It is now a full read/write DB instance.
  - It continues replicating to `read-replica-3`, just as it was doing before promotion.
  - Your `mysql-main` continues replicating to `read-replica-1`.

For more information about promoting read replicas, see Promoting a read replica to be a standalone DB instance (p. 447).

**Monitoring MySQL read replicas**

For MySQL read replicas, you can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS ReplicaLag metric. The ReplicaLag metric reports the value of the Seconds_Behind_Master field of the SHOW REPLICA STATUS command.

**Note**

Previous versions of MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

Common causes for replication lag for MySQL are the following:

- A network outage.
- Writing to tables that have different indexes on a read replica. If the `read_only` parameter is set to 0 on the read replica, replication can break if the read replica becomes incompatible with the source DB instance. After you've performed maintenance tasks on the read replica, we recommend that you set the `read_only` parameter back to 1.
- Using a nontransactional storage engine such as MyISAM. Replication is only supported for the InnoDB storage engine on MySQL.

When the ReplicaLag metric reaches 0, the replica has caught up to the source DB instance. If the ReplicaLag metric returns -1, then replication is currently not active. ReplicaLag = -1 is equivalent to Seconds_Behind_Master = NULL.
Starting and stopping replication with MySQL read replicas

You can stop and restart the replication process on an Amazon RDS DB instance by calling the system stored procedures `mysql.rds_stop_replication` (p. 1798) and `mysql.rds_start_replication` (p. 1796). You can do this when replicating between two Amazon RDS instances for long-running operations such as creating large indexes. You also need to stop and start replication when importing or exporting databases. For more information, see Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime (p. 1706) and Exporting data from a MySQL DB instance by using replication (p. 1744).

If replication is stopped for more than 30 consecutive days, either manually or due to a replication error, Amazon RDS terminates replication between the source DB instance and all read replicas. It does so to prevent increased storage requirements on the source DB instance and long failover times. The read replica DB instance is still available. However, replication can’t be resumed because the binary logs required by the read replica are deleted from the source DB instance after replication is terminated. You can create a new read replica for the source DB instance to reestablish replication.

Troubleshooting a MySQL read replica problem

For MySQL DB instances, in some cases read replicas present replication errors or data inconsistencies (or both) between the read replica and its source DB instance. This problem occurs when some binary log (binlog) events or InnoDB redo logs aren’t flushed during a failure of the read replica or the source DB instance. In these cases, manually delete and recreate the read replicas. You can reduce the chance of this happening by setting the following parameter values: `sync_binlog=1` and `innodb_flush_log_at_trx_commit=1`. These settings might reduce performance, so test their impact before implementing the changes in a production environment.

**Warning**

In the parameter group associated with the source DB instance, we recommend keeping these parameter values: `sync_binlog=1` and `innodb_flush_log_at_trx_commit=1`. These parameters are dynamic. If you don’t want to use these settings, we recommend temporarily setting those values before executing any operation on the source DB instance that might cause it to restart. These operations include, but are not limited to, rebooting, rebooting with failover, upgrading the database version, and changing the DB instance class or its storage. The same recommendation applies to creating new read replicas for the source DB instance. Failure to follow this guidance increases the risk of read replicas presenting replication errors or data inconsistencies (or both) between the read replica and its source DB instance.

The replication technologies for MySQL are asynchronous. Because they are asynchronous, occasional `BinLogDiskUsage` increases on the source DB instance and `ReplicaLag` on the read replica are to be expected. For example, a high volume of write operations to the source DB instance can occur in parallel. In contrast, write operations to the read replica are serialized using a single I/O thread, which can lead to a lag between the source instance and read replica. For more information about read-only replicas in the MySQL documentation, see Replication implementation details.

You can do several things to reduce the lag between updates to a source DB instance and the subsequent updates to the read replica, such as the following:

- Sizing a read replica to have a storage size and DB instance class comparable to the source DB instance.
- Ensuring that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the `max_allowed_packet` parameter later in this section.

Amazon RDS monitors the replication status of your read replicas and updates the Replication State field of the read replica instance to Error if replication stops for any reason. An example might be if DML queries run on your read replica conflict with the updates made on the source DB instance.
You can review the details of the associated error thrown by the MySQL engine by viewing the Replication Error field. Events that indicate the status of the read replica are also generated, including RDS-EVENT-0045 (p. 887), RDS-EVENT-0046 (p. 888), and RDS-EVENT-0047 (p. 883). For more information about events and subscribing to events, see Working with Amazon RDS event notification (p. 855). If a MySQL error message is returned, review the error number in the MySQL error message documentation.

One common issue that can cause replication errors is when the value for the max_allowed_packet parameter for a read replica is less than the max_allowed_packet parameter for the source DB instance. The max_allowed_packet parameter is a custom parameter that you can set in a DB parameter group. You use max_allowed_packet to specify the maximum size of DML code that can be run on the database. In some cases, the max_allowed_packet value in the DB parameter group associated with a read replica is smaller than the max_allowed_packet value in the DB parameter group associated with the source DB instance. In these cases, the replication process can throw the error Packet bigger than 'max_allowed_packet' bytes and stop replication. To fix the error, have the source DB instance and read replica use DB parameter groups with the same max_allowed_packet parameter values.

Other common situations that can cause replication errors include the following:

- Writing to tables on a read replica. In some cases, you might create indexes on a read replica that are different from the indexes on the source DB instance. If you do, set the read_only parameter to 0 to create the indexes. If you write to tables on the read replica, it might break replication if the read replica becomes incompatible with the source DB instance. After you perform maintenance tasks on the read replica, we recommend that you set the read_only parameter back to 1.

- Using a non-transactional storage engine such as MyISAM. Read replicas require a transactional storage engine. Replication is only supported for the InnoDB storage engine on MySQL.

- Using unsafe nondeterministic queries such as SYSDATE(). For more information, see Determination of safe and unsafe statements in binary logging.

If you decide that you can safely skip an error, you can follow the steps described in the section Skipping the current replication error (p. 1760). Otherwise, you can first delete the read replica. Then you create an instance using the same DB instance identifier so that the endpoint remains the same as that of your old read replica. If a replication error is fixed, the Replication State changes to replicating.

### Using GTID-based replication for Amazon RDS for MySQL

Following, you can learn how to use global transaction identifiers (GTIDs) with binary log (binlog) replication among Amazon RDS for MySQL DB instances.

If you use binlog replication and aren't familiar with GTID-based replication with MySQL, see Replication with global transaction identifiers in the MySQL documentation for background.

GTID-based replication is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL version 8.0.26 and higher MySQL 8.0 versions. All MySQL DB instances in a replication configuration must meet this requirement.

**Topics**

- Overview of global transaction identifiers (GTIDs) (p. 1736)
- Parameters for GTID-based replication (p. 1736)
- Configuring GTID-based replication for new read replicas (p. 1737)
- Configuring GTID-based replication for existing read replicas (p. 1737)
Overview of global transaction identifiers (GTIDs)

*Global transaction identifiers (GTIDs)* are unique identifiers generated for committed MySQL transactions. You can use GTIDs to make binlog replication simpler and easier to troubleshoot.

MySQL uses two different types of transactions for binlog replication:

- **GTID transactions** – Transactions that are identified by a GTID.
- **Anonymous transactions** – Transactions that don’t have a GTID assigned.

In a replication configuration, GTIDs are unique across all DB instances. GTIDs simplify replication configuration because when you use them, you don’t have to refer to log file positions. GTIDs also make it easier to track replicated transactions and determine whether the source instance and replicas are consistent.

You can use GTID-based replication to replicate data with RDS for MySQL read replicas. You can configure GTID-based replication when you are creating new read replicas, or you can convert existing read replicas to use GTID-based replication.

You can also use GTID-based replication in a delayed replication configuration with RDS for MySQL. For more information, see [Configuring delayed replication with MySQL](#). For more information, see [Configuring delayed replication with MySQL](#).

**Parameters for GTID-based replication**

Use the following parameters to configure GTID-based replication.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>gtid_mode</code></td>
<td>OFF, OFF_PERMISSIVE, ON_PERMISSIVE, ON</td>
<td>OFF specifies that new transactions are anonymous transactions (that is, don't have GTIDs), and a transaction must be anonymous to be replicated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>OFF_PERMISSIVE specifies that new transactions are anonymous transactions, but all transactions can be replicated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ON_PERMISSIVE specifies that new transactions are GTID transactions, but all transactions can be replicated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ON specifies that new transactions are GTID transactions, and a transaction must be a GTID transaction to be replicated.</td>
</tr>
<tr>
<td><code>enforce_gtid</code></td>
<td>OFF, ON, WARN</td>
<td>OFF allows transactions to violate GTID consistency.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ON prevents transactions from violating GTID consistency.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>WARN allows transactions to violate GTID consistency but generates a warning when a violation occurs.</td>
</tr>
</tbody>
</table>
Note
In the AWS Management Console, the gtid_mode parameter appears as gtid-mode.

For GTID-based replication, use these settings for the parameter group for your DB instance or read replica:

- **ON** and **ON_PERMISSIVE** apply only to outgoing replication from an RDS DB instance. Both of these values cause your RDS DB instance to use GTIDs for transactions that are replicated. **ON** requires that the target database also use GTID-based replication. **ON_PERMISSIVE** makes GTID-based replication optional on the target database.
- **OFF_PERMISSIVE**, if set, means that your RDS DB instances can accept incoming replication from a source database. They can do this regardless of whether the source database uses GTID-based replication.
- **OFF**, if set, means that your RDS DB instance only accepts incoming replication from source databases that don't use GTID-based replication.

For more information about parameter groups, see Working with parameter groups (p. 347).

Configuring GTID-based replication for new read replicas

When GTID-based replication is enabled for an RDS for MySQL DB instance, GTID-based replication is configured automatically for read replicas of the DB instance.

To enable GTID-based replication for new read replicas

1. Make sure that the parameter group associated with the DB instance has the following parameter settings:
   - **gtid_mode** – **ON** or **ON_PERMISSIVE**
   - **enforce_gtid_consistency** – **ON**

   For more information about setting configuration parameters using parameter groups, see Working with parameter groups (p. 347).

2. If you changed the parameter group of the DB instance, reboot the DB instance. For more information on how to do so, see Rebooting a DB instance (p. 436).

3. Create one or more read replicas of the DB instance. For more information on how to do so, see Creating a read replica (p. 445).

Amazon RDS attempts to establish GTID-based replication between the MySQL DB instance and the read replicas using the **MASTER_AUTO_POSITION**. If the attempt fails, Amazon RDS uses log file positions for replication with the read replicas. For more information about the **MASTER_AUTO_POSITION**, see GTID auto-positioning in the MySQL documentation.

Configuring GTID-based replication for existing read replicas

For an existing MySQL DB instance with read replicas that doesn't use GTID-based replication, you can configure GTID-based replication between the DB instance and the read replicas.

To enable GTID-based replication for existing read replicas

1. If the DB instance or any read replica is using an 8.0 version of RDS for MySQL version lower than 8.0.26, upgrade the DB instance or read replica to 8.0.26 or a higher MySQL 8.0 version. All RDS for MySQL 5.7 versions support GTID-based replication.

   For more information, see Upgrading the MySQL DB engine (p. 1680).
Using GTID-based replication

2. (Optional) Reset the GTID parameters and test the behavior of the DB instance and read replicas:
   a. Make sure that the parameter group associated with the DB instance and each read replica has the `enforce_gtid_consistency` parameter set to `WARN`.
      
      For more information about setting configuration parameters using parameter groups, see Working with parameter groups (p. 347).
   b. If you changed the parameter group of the DB instance, reboot the DB instance. If you changed the parameter group for a read replica, reboot the read replica.
      
      For more information, see Rebooting a DB instance (p. 436).
   c. Run your DB instance and read replicas with your normal workload and monitor the log files.
      
      If you see warnings about GTID-incompatible transactions, adjust your application so that it only uses GTID-compatible features. Make sure that the DB instance is not generating any warnings about GTID-incompatible transactions before proceeding to the next step.

3. Reset the GTID parameters for GTID-based replication that allows anonymous transactions until the read replicas have processed all of them.
   a. Make sure that the parameter group associated with the DB instance and each read replica has the following parameter settings:
      
      • `gtid_mode` – `ON_PERMISSIVE`
      • `enforce_gtid_consistency` – `ON`
   
   b. If you changed the parameter group of the DB instance, reboot the DB instance. If you changed the parameter group for a read replica, reboot the read replica.

4. Wait for all of your anonymous transactions to be replicated. To check that these are replicated, do the following:
   a. Run the following statement on your source DB instance.

      ```sql
      SHOW MASTER STATUS;
      ```

      Note the values in the `File` and `Position` columns.

   b. On each read replica, use the file and position information from its source instance in the previous step to run the following query.

      ```sql
      SELECT MASTER_POS_WAIT('file', position);
      ```

      For example, if the file name is `mysql-bin-changelog.000031` and the position is 107, run the following statement.

      ```sql
      SELECT MASTER_POS_WAIT('mysql-bin-changelog.000031', 107);
      ```

      If the read replica is past the specified position, the query returns immediately. Otherwise, the function waits. Proceed to the next step when the query returns for all read replicas.

5. Reset the GTID parameters for GTID-based replication only.
   a. Make sure that the parameter group associated with the DB instance and each read replica has the following parameter settings:

      • `gtid_mode` – `ON`
      • `enforce_gtid_consistency` – `ON`

   b. Reboot the DB instance and each read replica.
To disable GTID-based replication for a MySQL DB instance with read replicas

1. **On each read replica**, run the following procedure.

   ```sql
   CALL mysql.rds_set_master_auto_position(0);  (Aurora MySQL version 2)
   CALL mysql.rds_set_source_auto_position(0);  (Aurora MySQL version 3)
   ```

2. **Reset the `gtid_mode` to `ON_PERMISSIVE`**:
   
   a. Make sure that the parameter group associated with the MySQL DB instance and each read replica has `gtid_mode` set to `ON_PERMISSIVE`.

      For more information about setting configuration parameters using parameter groups, see Working with parameter groups (p. 347).

   b. Reboot the MySQL DB instance and each read replica. For more information about rebooting, see Rebooting a DB instance (p. 436).

3. **Reset the `gtid_mode` to `OFF_PERMISSIVE`**:
   
   a. Make sure that the parameter group associated with the MySQL DB instance and each read replica has `gtid_mode` set to `OFF_PERMISSIVE`.

   b. Reboot the MySQL DB instance and each read replica.

4. **Wait for all of the GTID transactions to be applied on all of the read replicas**. To check that these are applied, do the following:

   Wait for all of the GTID transactions to be applied on the Aurora primary instance. To check that these are applied, do the following:

   a. **On the MySQL DB instance**, run the `SHOW MASTER STATUS` command.

      Your output should be similar to the following.

      ```
      File                        Position
      ------------------------------------
      mysql-bin-changelog.000031      107
      ------------------------------------
      ```

      Note the file and position in your output.

   b. **On each read replica**, use the file and position information from its source instance in the previous step to run the following query.

      ```sql
      SELECT MASTER_POS_WAIT('file', position);
      ```

      For example, if the file name is `mysql-bin-changelog.000031` and the position is 107, run the following statement.
SELECT MASTER_POS_WAIT('mysql-bin-changelog.000031', 107);

If the read replica is past the specified position, the query returns immediately. Otherwise, the function waits. When the query returns for all read replicas, go to the next step.

5. Reset the GTID parameters to disable GTID-based replication:
   a. Make sure that the parameter group associated with the MySQL DB instance and each read replica has the following parameter settings:
      - gtid_mode – OFF
      - enforce_gtid_consistency – OFF
   b. Reboot the MySQL DB instance and each read replica.

### Configuring binary log file position replication with an external source instance

You can set up replication between an RDS for MySQL or MariaDB DB instance and a MySQL or MariaDB instance that is external to Amazon RDS using binary log file replication.

**Topics**

- Before you begin (p. 1347)
- Configuring binary log file position replication with an external source instance (p. 1347)

### Before you begin

You can configure replication using the binary log file position of replicated transactions.

The permissions required to start replication on an Amazon RDS DB instance are restricted and not available to your Amazon RDS master user. Because of this, make sure that you use the Amazon RDS mysql.rds_set_external_master (p. 1785) and mysql.rds_start_replication (p. 1796) commands to set up replication between your live database and your Amazon RDS database.

To set the binary logging format for a MySQL or MariaDB database, update the `binlog_format` parameter. If your DB instance uses the default DB instance parameter group, create a new DB parameter group to modify `binlog_format` settings. We recommend that you use the default setting for `binlog_format`, which is MIXED. However, you can also set `binlog_format` to ROW or STATEMENT if you need a specific binary log (binlog) format. Reboot your DB instance for the change to take effect.

For information about setting the `binlog_format` parameter, see Configuring MySQL binary logging (p. 921). For information about the implications of different MySQL replication types, see Advantages and disadvantages of statement-based and row-based replication in the MySQL documentation.

### Configuring binary log file position replication with an external source instance

Follow these guidelines when you set up an external source instance and a replica on Amazon RDS:

- Monitor failover events for the Amazon RDS DB instance that is your replica. If a failover occurs, then the DB instance that is your replica might be recreated on a new host with a different network address. For information on how to monitor failover events, see Working with Amazon RDS event notification (p. 855).
• Maintain the binlogs on your source instance until you have verified that they have been applied to
the replica. This maintenance makes sure that you can restore your source instance in the event of a
failure.

• Turn on automated backups on your Amazon RDS DB instance. Turning on automated backups makes
sure that you can restore your replica to a particular point in time if you need to re-synchronize your
source instance and replica. For information on backups and point-in-time restore, see Backing up and
restoring (p. 590).

To configure binary log file replication with an external source instance

1. Make the source MySQL or MariaDB instance read-only.

```sql
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

2. Run the `SHOW MASTER STATUS` command on the source MySQL or MariaDB instance to determine
the binlog location.

You receive output similar to the following example.

<table>
<thead>
<tr>
<th>File</th>
<th>Position</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql-bin-changelog.000031</td>
<td>107</td>
</tr>
<tr>
<td>------------------------------</td>
<td>----------</td>
</tr>
</tbody>
</table>

3. Copy the database from the external instance to the Amazon RDS DB instance using `mysqldump`.
For very large databases, you might want to use the procedure in Importing data to an Amazon RDS
MariaDB or MySQL database with reduced downtime (p. 1706).

For Linux, macOS, or Unix:

```bash
mysqldump --databases database_name \
    --single-transaction \ 
    --compress \ 
    --order-by-primary \ 
    -u local_user \ 
    -plocal_password | mysql \
    --host=hostname \ 
    --port=3306 \ 
    -u RDS_user_name \ 
    -pRDS_password
```

For Windows:

```bash
mysqldump --databases database_name ^
    --single-transaction ^
    --compress ^
    --order-by-primary ^
    -u local_user ^
    -plocal_password | mysql ^
    --host=hostname ^
    --port=3306 ^
    -u RDS_user_name ^
    -pRDS_password
```

**Note**

Make sure that there isn’t a space between the `-p` option and the entered password.
To specify the host name, user name, port, and password to connect to your Amazon RDS DB instance, use the `--host`, `--user (-u)`, `--port` and `-p` options in the `mysql` command. The host name is the Domain Name Service (DNS) name from the Amazon RDS DB instance endpoint, for example `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the AWS Management Console.

4. Make the source MySQL or MariaDB instance writeable again.

   ```
   mysql> SET GLOBAL read_only = OFF;
   mysql> UNLOCK TABLES;
   ```

   For more information on making backups for use with replication, see the MySQL documentation.

5. In the AWS Management Console, add the IP address of the server that hosts the external database to the virtual private cloud (VPC) security group for the Amazon RDS DB instance. For more information on modifying a VPC security group, see Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

   The IP address can change when the following conditions are met:

   - You are using a public IP address for communication between the external source instance and the DB instance.
   - The external source instance was stopped and restarted.

   If these conditions are met, verify the IP address before adding it.

   You might also need to configure your local network to permit connections from the IP address of your Amazon RDS DB instance. You do this so that your local network can communicate with your external MySQL or MariaDB instance. To find the IP address of the Amazon RDS DB instance, use the `host` command.

   ```
   host db_instance_endpoint
   ```

   The host name is the DNS name from the Amazon RDS DB instance endpoint.

6. Using the client of your choice, connect to the external instance and create a user to use for replication. Use this account solely for replication and restrict it to your domain to improve security. The following is an example.

   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
   ```

   **Note**

   Specify a password other than the prompt shown here as a security best practice.

7. For the external instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. For example, to grant the REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the `repl_user` user for your domain, issue the following command.

   ```
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
   ```

8. Make the Amazon RDS DB instance the replica. To do so, first connect to the Amazon RDS DB instance as the master user. Then identify the external MySQL or MariaDB database as the source instance by using the `mysql.rds_set_external_master` (p. 1785) command. Use the master log file name and master log position that you determined in step 2. The following is an example.
CALL mysql.rds_set_external_master ('mymasterserver.mydomain.com', 3306, 'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0);

**Note**

On RDS for MySQL, you can choose to use delayed replication by running the `mysql.rds_set_external_master_with_delay` stored procedure instead.

On RDS for MySQL, one reason to use delayed replication is to turn on disaster recovery with the `mysql.rds_start_replication_until` stored procedure.

Currently, RDS for MariaDB supports delayed replication but doesn't support the `mysql.rds_start_replication_until` procedure.

9. On the Amazon RDS DB instance, issue the `mysql.rds_start_replication` command to start replication.

CALL mysql.rds_start_replication;
Exporting data from a MySQL DB instance by using replication

To export data from an RDS for MySQL DB instance to a MySQL instance running external to Amazon RDS, you can use replication. In this scenario, the MySQL DB instance is the source MySQL DB instance, and the MySQL instance running external to Amazon RDS is the external MySQL database.

The external MySQL database can run either on-premises in your data center, or on an Amazon EC2 instance. The external MySQL database must run the same version as the source MySQL DB instance, or a later version.

Replication to an external MySQL database is only supported during the time it takes to export a database from the source MySQL DB instance. The replication should be terminated when the data has been exported and applications can start accessing the external MySQL instance.

The following list shows the steps to take. Each step is discussed in more detail in later sections.

1. Prepare an external MySQL DB instance.
2. Prepare the source MySQL DB instance for replication.
3. Use the mysqldump utility to transfer the database from the source MySQL DB instance to the external MySQL database.
4. Start replication to the external MySQL database.
5. After the export completes, stop replication.

Prepare an external MySQL database

Perform the following steps to prepare the external MySQL database.

To prepare the external MySQL database

1. Install the external MySQL database.
2. Connect to the external MySQL database as the master user. Then create the users required to support the administrators, applications, and services that access the database.
3. Follow the directions in the MySQL documentation to prepare the external MySQL database as a replica. For more information, see the MySQL documentation.
4. Configure an egress rule for the external MySQL database to operate as a read replica during the export. The egress rule allows the external MySQL database to connect to the source MySQL DB instance during replication. Specify an egress rule that allows Transmission Control Protocol (TCP) connections to the port and IP address of the source MySQL DB instance.

Specify the appropriate egress rules for your environment:

- If the external MySQL database is running in an Amazon EC2 instance in a virtual private cloud (VPC) based on the Amazon VPC service, specify the egress rules in a VPC security group. For more information, see Controlling access with security groups (p. 2697).
- If the external MySQL database is installed on-premises, specify the egress rules in a firewall.

5. If the external MySQL database is running in a VPC, configure rules for the VPC access control list (ACL) rules in addition to the security group egress rule:

- Configure an ACL ingress rule allowing TCP traffic to ports 1024–65535 from the IP address of the source MySQL DB instance.
- Configure an ACL egress rule allowing outbound TCP traffic to the port and IP address of the source MySQL DB instance.
Prepare the source MySQL DB instance

Perform the following steps to prepare the source MySQL DB instance as the replication source.

To prepare the source MySQL DB instance

1. Ensure that your client computer has enough disk space available to save the binary logs while setting up replication.
2. Connect to the source MySQL DB instance, and create a replication account by following the directions in Creating a user for replication in the MySQL documentation.
3. Configure ingress rules on the system running the source MySQL DB instance to allow the external MySQL database to connect during replication. Specify an ingress rule that allows TCP connections to the port used by the source MySQL DB instance from the IP address of the external MySQL database.
4. Specify the egress rules:
   - If the source MySQL DB instance is running in a VPC, specify the ingress rules in a VPC security group. For more information, see Controlling access with security groups (p. 2697).
5. If source MySQL DB instance is running in a VPC, configure VPC ACL rules in addition to the security group ingress rule:
   - Configure an ACL ingress rule to allow TCP connections to the port used by the Amazon RDS instance from the IP address of the external MySQL database.
   - Configure an ACL egress rule to allow TCP connections from ports 1024–65535 to the IP address of the external MySQL database.

For more information about Amazon VPC network ACLs, see Network ACLs in the Amazon VPC User Guide.

6. Ensure that the backup retention period is set long enough that no binary logs are purged during the export. If any of the logs are purged before the export has completed, you must restart replication from the beginning. For more information about setting the backup retention period, see Working with backups (p. 591).
7. Use the mysql.rds_set_configuration stored procedure to set the binary log retention period long enough that the binary logs aren't purged during the export. For more information, see Accessing MySQL binary logs (p. 922).
8. Create an Amazon RDS read replica from the source MySQL DB instance to further ensure that the binary logs of the source MySQL DB instance are not purged. For more information, see Creating a read replica (p. 445).
9. After the Amazon RDS read replica has been created, call the mysql.rds_stop_replication stored procedure to stop the replication process. The source MySQL DB instance no longer purges its binary log files, so they are available for the replication process.
10. (Optional) Set both the max_allowed_packet parameter and the slave_max_allowed_packet parameter to the maximum size to avoid replication errors. The maximum size for both parameters is 1 GB. We recommend this setting for both parameters. For information about setting parameters, see Modifying parameters in a DB parameter group (p. 352).
Copy the database

Perform the following steps to copy the database.

To copy the database

1. Connect to the RDS read replica of the source MySQL DB instance, and run the MySQL SHOW REPLICA STATUS\G statement. Note the values for the following:
   - Master_Host
   - Master_Port
   - Master_Log_File
   - Exec_Master_Log_Pos

   **Note**
   Previous versions of MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

2. Use the mysqldump utility to create a snapshot, which copies the data from Amazon RDS to your local client computer. Ensure that your client computer has enough space to hold the mysqldump files from the databases to be replicated. This process can take several hours for very large databases. Follow the directions in Creating a data snapshot using mysqldump in the MySQL documentation.

   The following example runs mysqldump on a client and writes the dump to a file.

   For Linux, macOS, or Unix:
   ```
   mysqldump -h source_MySQL_DB_instance_endpoint
   -u user
   -p
   --port=3306
   --single-transaction
   --routines
   --triggers
   --databases database database2
   > path/rds-dump.sql
   ```

   For Windows:
   ```
   mysqldump -h source_MySQL_DB_instance_endpoint
   -u user
   -p
   --port=3306
   --single-transaction
   --routines
   --triggers
   --databases database database2
   > path\rds-dump.sql
   ```

   You can load the backup file into the external MySQL database. For more information, see Reloading SQL-Format Backups in the MySQL documentation. You can run another utility to load the data into the external MySQL database.

Complete the export

Perform the following steps to complete the export.
Amazon Relational Database Service User Guide
Complete the export

To complete the export

1. Use the MySQL CHANGE MASTER statement to configure the external MySQL database. Specify the ID and password of the user granted REPLICATION SLAVE permissions. Specify the Master_Host, Master_Port, Relay_Master_Log_File, and Exec_Master_Log_Pos values that you got from the MySQL SHOW REPLICA STATUS\G statement that you ran on the RDS read replica. For more information, see the MySQL documentation.

   Note
   Previous versions of MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

2. Use the MySQL START REPLICA command to initiate replication from the source MySQL DB instance to the external MySQL database.

   Doing this starts replication from the source MySQL DB instance and exports all source changes that have occurred after you stopped replication from the Amazon RDS read replica.

   Note
   Previous versions of MySQL used START SLAVE instead of START REPLICA. If you are using a MySQL version before 8.0.23, then use START SLAVE.

3. Run the MySQL SHOW REPLICA STATUS\G command on the external MySQL database to verify that it is operating as a read replica. For more information about interpreting the results, see the MySQL documentation.

4. After replication on the external MySQL database has caught up with the source MySQL DB instance, use the MySQL STOP REPLICA command to stop replication from the source MySQL DB instance.

   Note
   Previous versions of MySQL used STOP SLAVE instead of STOP REPLICA. If you are using a MySQL version before 8.0.23, then use STOP SLAVE.

5. On the Amazon RDS read replica, call the mysql.rds_start_replication stored procedure. Doing this allows Amazon RDS to start purging the binary log files from the source MySQL DB instance.
Options for MySQL DB instances

Following, you can find a description of options, or additional features, that are available for Amazon RDS instances running the MySQL DB engine. To enable these options, you can add them to a custom option group, and then associate the option group with your DB instance. For more information about working with option groups, see Working with option groups (p. 331).

Amazon RDS supports the following options for MySQL:

<table>
<thead>
<tr>
<th>Option</th>
<th>Option ID</th>
<th>Engine versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>MariaDB Audit Plugin support for MySQL (p. 1749)</td>
<td>MARIADB_AUDIT_PLUGIN</td>
<td>MySQL 8.0.28 and higher 8.0 versions All MySQL 5.7 versions</td>
</tr>
<tr>
<td>MySQL memcached support (p. 1754)</td>
<td>MEMCACHED</td>
<td>All MySQL 5.7 and 8.0 versions</td>
</tr>
</tbody>
</table>
MariaDB Audit Plugin support for MySQL

Amazon RDS offers an audit plugin for MySQL database instances based on the open source MariaDB Audit Plugin. For more information, see the Audit Plugin for MySQL Server GitHub repository.

Note
The audit plugin for MySQL is based on the MariaDB Audit Plugin. Throughout this article, we refer to it as MariaDB Audit Plugin.

The MariaDB Audit Plugin records database activity, including users logging on to the database and queries run against the database. The record of database activity is stored in a log file.

Note
Currently, the MariaDB Audit Plugin is only supported for the following RDS for MySQL versions:

- MySQL 8.0.28 and higher 8.0 versions
- All MySQL 5.7 versions

Audit Plugin option settings

Amazon RDS supports the following settings for the MariaDB Audit Plugin option.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SERVER_AUDIT_FILE_PATH</td>
<td>/rdsdbdata/log/audit/</td>
<td>/rdsdbdata/log/audit/</td>
<td>The location of the log file. The log file contains the record of the activity specified in SERVER_AUDIT_EVENTS. For more information, see Viewing and listing database log files (p. 895) and MySQL database log files (p. 915).</td>
</tr>
<tr>
<td>SERVER_AUDIT_FILE_ROTATE_SIZE</td>
<td>1–100000000</td>
<td>1000000</td>
<td>The size in bytes that when reached, causes the file to rotate. For more information, see Overview of RDS for MySQL database logs (p. 915).</td>
</tr>
<tr>
<td>SERVER_AUDIT_FILE_ROTATIONS</td>
<td>0–100</td>
<td>9</td>
<td>The number of log rotations to save when server_audit_output_type=file. If set to 0, then the log file never rotates. For more information, see Overview of RDS for MySQL database logs (p. 915) and Downloading a database log file (p. 896).</td>
</tr>
<tr>
<td>SERVER_AUDIT_EVENTS</td>
<td>CONNECT, QUERY, QUERY_DDL, QUERY_DML, QUERY_DML_NO_SELECT, QUERY_DCL</td>
<td>CONNECT, QUERY</td>
<td>The types of activity to record in the log. Installing the MariaDB Audit Plugin is itself logged.</td>
</tr>
</tbody>
</table>

- CONNECT: Log successful and unsuccessful connections to the database, and disconnections from the database.
- QUERY: Log the text of all queries run against the database.
- QUERY_DDL: Similar to the QUERY event, but returns only data definition language (DDL) queries (CREATE, ALTER, and so on).
- QUERY_DML: Similar to the QUERY event, but returns only data manipulation language (DML) queries (INSERT, UPDATE, and so on, and also SELECT).
<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td>• QUERY_DML_NO_SELECT: Similar to the QUERY_DML event, but doesn't log SELECT queries.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>The QUERY_DML_NO_SELECT setting is supported only for RDS for MySQL 5.7.34 and higher 5.7 versions, and 8.0.25 and higher 8.0 versions.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• QUERY_DCL: Similar to the QUERY event, but returns only data control language (DCL) queries (GRANT, REVOKE, and so on).</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>For MySQL, TABLE is not supported.</td>
</tr>
<tr>
<td>SERVER_AUDIT_INCL_USERS</td>
<td>Multiple</td>
<td>None</td>
<td>Include only activity from the specified users. By default, activity is recorded for all users. SERVER_AUDIT_INCL_USERS and SERVER_AUDIT_EXCL_USERS are mutually exclusive. If you add values to SERVER_AUDIT_INCL_USERS, make sure no values are added to SERVER_AUDIT_EXCL_USERS.</td>
</tr>
<tr>
<td>SERVER_AUDIT_EXCL_USERS</td>
<td>Multiple</td>
<td>None</td>
<td>Exclude activity from the specified users. By default, activity is recorded for all users. SERVER_AUDIT_INCL_USERS and SERVER_AUDIT_EXCL_USERS are mutually exclusive. If you add values to SERVER_AUDIT_EXCL_USERS, make sure no values are added to SERVER_AUDIT_INCL_USERS.</td>
</tr>
<tr>
<td></td>
<td>comma-separated values</td>
<td></td>
<td>The rdsadmin user queries the database every second to check the health of the database. Depending on your other settings, this activity can possibly cause the size of your log file to grow very large, very quickly. If you don't need to record this activity, add the rdsadmin user to the SERVER_AUDIT_EXCL_USERS list.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td><strong>Note</strong> CONNECT activity is always recorded for all users, even if the user is specified for this option setting.</td>
</tr>
<tr>
<td>SERVER_AUDIT_LOGGING</td>
<td>ON</td>
<td>ON</td>
<td>Logging is active. The only valid value is ON. Amazon RDS does not support deactivating logging. If you want to deactivate logging, remove the MariaDB Audit Plugin. For more information, see Removing the MariaDB Audit Plugin (p. 1752).</td>
</tr>
<tr>
<td>SERVER_AUDIT_QUERY_LOG_LIMIT</td>
<td>0–2147483647</td>
<td>1024</td>
<td>The limit on the length of the query string in a record.</td>
</tr>
</tbody>
</table>
**Adding the MariaDB Audit Plugin**

The general process for adding the MariaDB Audit Plugin to a DB instance is the following:

- Create a new option group, or copy or modify an existing option group
- Add the option to the option group
- Associate the option group with the DB instance

After you add the MariaDB Audit Plugin, you don't need to restart your DB instance. As soon as the option group is active, auditing begins immediately.

**Important**
Adding the MariaDB Audit Plugin to a DB instance might cause an outage. We recommend adding the MariaDB Audit Plugin during a maintenance window or during a time of low database workload.

**To add the MariaDB Audit Plugin**

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group. Choose `mysql` for **Engine**, and choose `5.7` or `8.0` for **Major engine version**. For more information, see [Creating an option group](p. 332).

2. Add the `MARIADB_AUDIT_PLUGIN` option to the option group, and configure the option settings. For more information about adding options, see [Adding an option to an option group (p. 335)](Adding an option to an option group). For more information about each setting, see [Audit Plugin option settings (p. 1749)](Audit Plugin option settings).

3. Apply the option group to a new or existing DB instance.
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance (p. 300)](Creating an Amazon RDS DB instance).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see [Modifying an Amazon RDS DB instance (p. 401)](Modifying an Amazon RDS DB instance).

**Audit log format**

Log files are represented as comma-separated variable (CSV) files in UTF-8 format.

**Tip**

Log file entries are not in sequential order. To order the entries, use the timestamp value. To see the latest events, you might have to review all log files. For more flexibility in sorting and searching the log data, turn on the setting to upload the audit logs to CloudWatch and view them using the CloudWatch interface.

To view audit data with more types of fields and with output in JSON format, you can also use the Database Activity Streams feature. For more information, see [Monitoring Amazon RDS with Database Activity Streams (p. 944)](Monitoring Amazon RDS with Database Activity Streams).

The audit log files include the following comma-delimited information in rows, in the specified order:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timestamp</td>
<td>The <code>YYYYMMDD</code> followed by the <code>HH:MI:SS</code> (24-hour clock) for the logged event.</td>
</tr>
<tr>
<td>serverhost</td>
<td>The name of the instance that the event is logged for.</td>
</tr>
<tr>
<td>username</td>
<td>The connected user name of the user.</td>
</tr>
</tbody>
</table>
### Field | Description
--- | ---
host | The host that the user connected from.
connectionid | The connection ID number for the logged operation.
queryid | The query ID number, which can be used for finding the relational table events and related queries. For TABLE events, multiple lines are added.
operation | The recorded action type. Possible values are: CONNECT, QUERY, READ, WRITE, CREATE, ALTER, RENAME, and DROP.
database | The active database, as set by the USE command.
object | For QUERY events, this value indicates the query that the database performed. For TABLE events, it indicates the table name.
retcode | The return code of the logged operation.
connection_type | The security state of the connection to the server. Possible values are:
  - 0 – Undefined
  - 1 – TCP/IP
  - 2 – Socket
  - 3 – Named pipe
  - 4 – SSL/TLS
  - 5 – Shared memory
This field is included only for RDS for MySQL version 5.7.34 and higher 5.7 versions, and all 8.0 versions.

### Viewing and downloading the MariaDB Audit Plugin log

After you enable the MariaDB Audit Plugin, you access the results in the log files the same way you access any other text-based log files. The audit log files are located at /rdsdbdata/log/audit/. For information about viewing the log file in the console, see Viewing and listing database log files (p. 895). For information about downloading the log file, see Downloading a database log file (p. 896).

### Modifying MariaDB Audit Plugin settings

After you enable the MariaDB Audit Plugin, you can modify the settings. For more information about how to modify option settings, see Modifying an option setting (p. 340). For more information about each setting, see Audit Plugin option settings (p. 1749).

### Removing the MariaDB Audit Plugin

Amazon RDS doesn't support turning off logging in the MariaDB Audit Plugin. However, you can remove the plugin from a DB instance. When you remove the MariaDB Audit Plugin, the DB instance is restarted automatically to stop auditing.

To remove the MariaDB Audit Plugin from a DB instance, do one of the following:

- Remove the MariaDB Audit Plugin option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 343).
• Modify the DB instance and specify a different option group that doesn't include the plugin. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 401).
MySQL memcached support

Amazon RDS supports using the memcached interface to InnoDB tables that was introduced in MySQL 5.6. The memcached API enables applications to use InnoDB tables in a manner similar to NoSQL key-value data stores.

The memcached interface is a simple, key-based cache. Applications use memcached to insert, manipulate, and retrieve key-value data pairs from the cache. MySQL 5.6 introduced a plugin that implements a daemon service that exposes data from InnoDB tables through the memcached protocol. For more information about the MySQL memcached plugin, see InnoDB integration with memcached.

To enable memcached support for an RDS for MySQL DB instance

1. Determine the security group to use for controlling access to the memcached interface. If the set of applications already using the SQL interface are the same set that will access the memcached interface, you can use the existing VPC security group used by the SQL interface. If a different set of applications will access the memcached interface, define a new VPC or DB security group. For more information about managing security groups, see Controlling access with security groups.

2. Create a custom DB option group, selecting MySQL as the engine type and version. For more information about creating an option group, see Creating an option group.

3. Add the MEMCACHED option to the option group. Specify the port that the memcached interface will use, and the security group to use in controlling access to the interface. For more information about adding options, see Adding an option to an option group.

4. Modify the option settings to configure the memcached parameters, if necessary. For more information about how to modify option settings, see Modifying an option setting.

5. Apply the option group to an instance. Amazon RDS enables memcached support for that instance when the option group is applied:
   - You enable memcached support for a new instance by specifying the custom option group when you launch the instance. For more information about launching a MySQL instance, see Creating an Amazon RDS DB instance.
   - You enable memcached support for an existing instance by specifying the custom option group when you modify the instance. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

6. Specify which columns in your MySQL tables can be accessed through the memcached interface. The memcached plug-in creates a catalog table named containers in a dedicated database named innodb_memcache. You insert a row into the containers table to map an InnoDB table for access through memcached. You specify a column in the InnoDB table that is used to store the memcached key values, and one or more columns that are used to store the data values associated with the key. You also specify a name that a memcached application uses to refer to that set of columns. For details on inserting rows in the containers table, see InnoDB memcached plugin internals. For an example of mapping an InnoDB table and accessing it through memcached, see Writing applications for the InnoDB memcached plugin.

7. If the applications accessing the memcached interface are on different computers or EC2 instances than the applications using the SQL interface, add the connection information for those computers to the VPC security group associated with the MySQL instance. For more information about managing security groups, see Controlling access with security groups.

You turn off the memcached support for an instance by modifying the instance and specifying the default option group for your MySQL version. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.
MySQL memcached security considerations

The memcached protocol does not support user authentication. For more information about MySQL memcached security considerations, see Security Considerations for the InnoDB memcached Plugin in the MySQL documentation.

You can take the following actions to help increase the security of the memcached interface:

- Specify a different port than the default of 11211 when adding the MEMCACHED option to the option group.
- Ensure that you associate the memcached interface with a VPC security group that limits access to known, trusted client addresses and EC2 instances. For more information about managing security groups, see Controlling access with security groups (p. 2697).

MySQL memcached connection information

To access the memcached interface, an application must specify both the DNS name of the Amazon RDS instance and the memcached port number. For example, if an instance has a DNS name of my-cache-instance.cg034hkpmjtt.region.rds.amazonaws.com and the memcached interface is using port 11212, the connection information specified in PHP would be:

```php
<?php
    $cache = new Memcache;
    $cache->connect('my-cache-instance.cg034hkpmjtt.region.rds.amazonaws.com',11212);
?>
```

To find the DNS name and memcached port of a MySQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the top right corner of the AWS Management Console, select the region that contains the DB instance.
3. In the navigation pane, choose Databases.
4. Choose the MySQL DB instance name to display its details.
5. In the Connect section, note the value of the Endpoint field. The DNS name is the same as the endpoint. Also, note that the port in the Connect section is not used to access the memcached interface.
6. In the Details section, note the name listed in the Option Group field.
7. In the navigation pane, choose Option groups.
8. Choose the name of the option group used by the MySQL DB instance to show the option group details. In the Options section, note the value of the Port setting for the MEMCACHED option.

MySQL memcached option settings

Amazon RDS exposes the MySQL memcached parameters as option settings in the Amazon RDS MEMCACHED option.

MySQL memcached parameters

- DAEMON_MEMCACHED_R_BATCH_SIZE – an integer that specifies how many memcached read operations (get) to perform before doing a COMMIT to start a new transaction. The allowed values are 1 to 4294967295; the default is 1. The option does not take effect until the instance is restarted.
• **DAEMON_MEMCACHED_W_BATCH_SIZE** – an integer that specifies how many memcached write operations, such as add, set, or incr, to perform before doing a COMMIT to start a new transaction. The allowed values are 1 to 4294967295; the default is 1. The option does not take effect until the instance is restarted.

• **INNODB_API_BK_COMMIT_INTERVAL** – an integer that specifies how often to auto-commit idle connections that use the InnoDB memcached interface. The allowed values are 1 to 1073741824; the default is 5. The option takes effect immediately, without requiring that you restart the instance.

• **INNODB_API_DISABLE_ROWLOCK** – a Boolean that disables (1 (true)) or enables (0 (false)) the use of row locks when using the InnoDB memcached interface. The default is 0 (false). The option does not take effect until the instance is restarted.

• **INNODB_API_ENABLE_MDL** – a Boolean that when set to 0 (false) locks the table used by the InnoDB memcached plugin, so that it cannot be dropped or altered by DDL through the SQL interface. The default is 0 (false). The option does not take effect until the instance is restarted.

• **INNODB_API_TRX_LEVEL** – an integer that specifies the transaction isolation level for queries processed by the memcached interface. The allowed values are 0 to 3. The default is 0. The option does not take effect until the instance is restarted.

Amazon RDS configures these MySQL memcached parameters, and they cannot be modified: **DAEMON_MEMCACHED_LIB_NAME**, **DAEMON_MEMCACHED_LIB_PATH**, and **INNODB_API_ENABLE_BINLOG**. The parameters that MySQL administrators set by using *daemon_memcached_options* are available as individual MEMCACHED option settings in Amazon RDS.

### MySQL daemon_memcached_options parameters

• **BINDING_PROTOCOL** – a string that specifies the binding protocol to use. The allowed values are auto, ascii, or binary. The default is auto, which means the server automatically negotiates the protocol with the client. The option does not take effect until the instance is restarted.

• **BACKLOG_QUEUE_LIMIT** – an integer that specifies how many network connections can be waiting to be processed by memcached. Increasing this limit may reduce errors received by a client that is not able to connect to the memcached instance, but does not improve the performance of the server. The allowed values are 1 to 2048; the default is 1024. The option does not take effect until the instance is restarted.

• **CAS_DISABLED** – a Boolean that enables (1 (true)) or disables (0 (false)) the use of compare and swap (CAS), which reduces the per-item size by 8 bytes. The default is 0 (false). The option does not take effect until the instance is restarted.

• **CHUNK_SIZE** – an integer that specifies the minimum chunk size, in bytes, to allocate for the smallest item's key, value, and flags. The allowed values are 1 to 48. The default is 48 and you can significantly improve memory efficiency with a lower value. The option does not take effect until the instance is restarted.

• **CHUNK_SIZE_GROWTH_FACTOR** – a float that controls the size of new chunks. The size of a new chunk is the size of the previous chunk times **CHUNK_SIZE_GROWTH_FACTOR**. The allowed values are 1 to 2; the default is 1.25. The option does not take effect until the instance is restarted.

• **ERROR_ON_MEMORY_EXHAUSTED** – a Boolean that when set to 1 (true) specifies that memcached will return an error rather than evicting items when there is no more memory to store items. If set to 0 (false), memcached will evict items if there is no more memory. The default is 0 (false). The option does not take effect until the instance is restarted.

• **MAX_SIMULTANEOUS_CONNECTIONS** – an integer that specifies the maximum number of concurrent connections. Setting this value to anything under 10 prevents MySQL from starting. The allowed values are 10 to 1024; the default is 1024. The option does not take effect until the instance is restarted.

• **VERBOSITY** – a string that specifies the level of information logged in the MySQL error log by the memcached service. The default is v. The option does not take effect until the instance is restarted. The allowed values are:
• v – Logs errors and warnings while running the main event loop.
• vv – In addition to the information logged by v, also logs each client command and the response.
• vvv – In addition to the information logged by vv, also logs internal state transitions.

Amazon RDS configures these MySQL DAEMON_MEMCACHED_OPTIONS parameters, they cannot be modified: DAEMON_PROCESS, LARGE_MEMORY_PAGES, MAXIMUM_CORE_FILE_LIMIT, MAX_ITEM_SIZE, LOCK_DOWN_PAGE_MEMORY, MASK, IDFILE, REQUESTS_PER_EVENT, SOCKET, and USER.
Parameters for MySQL

By default, a MySQL DB instance uses a DB parameter group that is specific to a MySQL database. This parameter group contains parameters for the MySQL database engine. For information about working with parameter groups and setting parameters, see Working with parameter groups (p. 347).

RDS for MySQL parameters are set to the default values of the storage engine that you have selected. For more information about MySQL parameters, see the MySQL documentation. For more information about MySQL storage engines, see Supported storage engines for RDS for MySQL (p. 1640).

You can view the parameters available for a specific RDS for MySQL version using the RDS console or the AWS CLI. For information about viewing the parameters in a MySQL parameter group in the RDS console, see Viewing parameter values for a DB parameter group (p. 359).

Using the AWS CLI, you can view the parameters for an RDS for MySQL version by running the describe-engine-default-parameters command. Specify one of the following values for the --db-parameter-group-family option:

- mysql8.0
- mysql5.7

For example, to view the parameters for RDS for MySQL version 8.0, run the following command.

```
aws rds describe-engine-default-parameters --db-parameter-group-family mysql8.0
```

Your output looks similar to the following.

```json
{
    "EngineDefaults": {
        "Parameters": [
            {
                "ParameterName": "activate_all_roles_on_login",
                "ParameterValue": "0",
                "Description": "Automatically set all granted roles as active after the user has authenticated successfully.",
                "Source": "engine-default",
                "ApplyType": "dynamic",
                "DataType": "boolean",
                "AllowedValues": "0,1",
                "IsModifiable": true
            },
            {
                "ParameterName": "allow-suspicious-udfs",
                "Description": "Controls whether user-defined functions that have only an xxx symbol for the main function can be loaded",
                "Source": "engine-default",
                "ApplyType": "static",
                "DataType": "boolean",
                "AllowedValues": "0,1",
                "IsModifiable": false
            },
            {
                "ParameterName": "auto_generate_certs",
                "Description": "Controls whether the server autogenerates SSL key and certificate files in the data directory, if they do not already exist.",
                "Source": "engine-default",
                "ApplyType": "static",
                "DataType": "boolean",
                "AllowedValues": "0,1",
                "IsModifiable": true
            }
        ]
    }
}
```
To list only the modifiable parameters for RDS for MySQL version 8.0, run the following command.

For Linux, macOS, or Unix:

```bash
aws rds describe-engine-default-parameters --db-parameter-group-family mysql8.0 \
   --query 'EngineDefaults.Parameters[?IsModifiable==`true`]'
```

For Windows:

```bash
aws rds describe-engine-default-parameters --db-parameter-group-family mysql8.0 ^
   --query "EngineDefaults.Parameters[?IsModifiable==`true`]"
```
Common DBA tasks for MySQL DB instances

Following, you can find descriptions of the Amazon RDS–specific implementations of some common DBA tasks for DB instances running the MySQL database engine. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. Also, it restricts access to certain system procedures and tables that require advanced privileges.

For information about working with MySQL log files on Amazon RDS, see MySQL database log files (p. 915).

Topics
- Ending a session or query (p. 1760)
- Skipping the current replication error (p. 1760)
- Working with InnoDB tablespaces to improve crash recovery times (p. 1761)
- Managing the Global Status History (p. 1763)

Ending a session or query

You can end user sessions or queries on DB instances by using the rds_kill and rds_kill_query commands. First connect to your MySQL DB instance, then issue the appropriate command as shown following. For more information, see Connecting to a DB instance running the MySQL database engine (p. 1646).

```
CALL mysql.rds_kill(thread-ID)
CALL mysql.rds_kill_query(thread-ID)
```

For example, to end the session that is running on thread 99, you would type the following:

```
CALL mysql.rds_kill(99);
```

To end the query that is running on thread 99, you would type the following:

```
CALL mysql.rds_kill_query(99);
```

Skipping the current replication error

You can skip an error on your read replica if the error is causing your read replica to stop responding and the error doesn't affect the integrity of your data.

**Note**
First verify that the error in question can be safely skipped. In a MySQL utility, connect to the read replica and run the following MySQL command.

```
SHOW REPLICA STATUS\G
```

For information about the values returned, see the MySQL documentation. Previous versions of MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

You can skip an error on your read replica in the following ways.

Topics
Calling the mysql.rds_skip_repl_error procedure

Amazon RDS provides a stored procedure that you can call to skip an error on your read replicas. First connect to your read replica, then issue the appropriate commands as shown following. For more information, see [Connecting to a DB instance running the MySQL database engine](#).

To skip the error, issue the following command.

```
CALL mysql.rds_skip_repl_error;
```

This command has no effect if you run it on the source DB instance, or on a read replica that hasn't encountered a replication error.

For more information, such as the versions of MySQL that support `mysql.rds_skip_repl_error`, see [mysql.rds_skip_repl_error](#).

**Important**

If you attempt to call `mysql.rds_skip_repl_error` and encounter the following error:

```
ERROR 1305 (42000): PROCEDURE mysql.rds_skip_repl_error does not exist.
```

then upgrade your MySQL DB instance to the latest minor version or one of the minimum minor versions listed in [mysql.rds_skip_repl_error](#).

Setting the slave_skip_errors parameter

To skip one or more errors, you can set the `slave_skip_errors` static parameter on the read replica. You can set this parameter to skip one or more specific replication error codes. Currently, you can set this parameter only for RDS for MySQL 5.7 DB instances. After you change the setting for this parameter, make sure to reboot your DB instance for the new setting to take effect. For information about setting this parameter, see the MySQL documentation.

We recommend setting this parameter in a separate DB parameter group. You can associate this DB parameter group only with the read replicas that need to skip errors. Following this best practice reduces the potential impact on other DB instances and read replicas.

**Important**

Setting a nondefault value for this parameter can lead to replication inconsistency. Only set this parameter to a nondefault value if you have exhausted other options to resolve the problem and you are sure of the potential impact on your read replica's data.

Working with InnoDB tablespaces to improve crash recovery times

Every table in MySQL consists of a table definition, data, and indexes. The MySQL storage engine InnoDB stores table data and indexes in a **tablespace**. InnoDB creates a global shared tablespace that contains a data dictionary and other relevant metadata, and it can contain table data and indexes. InnoDB can also create separate tablespaces for each table and partition. These separate tablespaces are stored in files with a `.ibd` extension and the header of each tablespace contains a number that uniquely identifies it.

Amazon RDS provides a parameter in a MySQL parameter group called `innodb_file_per_table`. This parameter controls whether InnoDB adds new table data and indexes to the shared tablespace (by setting the parameter value to 0) or to individual tablespaces (by setting the parameter value to 1).
Amazon RDS sets the default value for `innodb_file_per_table` parameter to 1, which allows you to drop individual InnoDB tables and reclaim storage used by those tables for the DB instance. In most use cases, setting the `innodb_file_per_table` parameter to 1 is the recommended setting.

You should set the `innodb_file_per_table` parameter to 0 when you have a large number of tables, such as over 1000 tables when you use standard (magnetic) or general purpose SSD storage or over 10,000 tables when you use Provisioned IOPS storage. When you set this parameter to 0, individual tablespaces are not created and this can improve the time it takes for database crash recovery.

MySQL processes each metadata file, which includes tablespaces, during the crash recovery cycle. The time it takes MySQL to process the metadata information in the shared tablespace is negligible compared to the time it takes to process thousands of tablespace files when there are multiple tablespaces. Because the tablespace number is stored within the header of each file, the aggregate time to read all the tablespace files can take up to several hours. For example, a million InnoDB tablespaces on standard storage can take from five to eight hours to process during a crash recovery cycle. In some cases, InnoDB can determine that it needs additional cleanup after a crash recovery cycle so it will begin another crash recovery cycle, which will extend the recovery time. Keep in mind that a crash recovery cycle also entails rolling-back transactions, fixing broken pages, and other operations in addition to the processing of tablespace information.

Since the `innodb_file_per_table` parameter resides in a parameter group, you can change the parameter value by editing the parameter group used by your DB instance without having to reboot the DB instance. After the setting is changed, for example, from 1 (create individual tables) to 0 (use shared tablespace), new InnoDB tables will be added to the shared tablespace while existing tables continue to have individual tablespaces. To move an InnoDB table to the shared tablespace, you must use the `ALTER TABLE` command.

### Migrating multiple tablespaces to the shared tablespace

You can move an InnoDB table's metadata from its own tablespace to the shared tablespace, which will rebuild the table metadata according to the `innodb_file_per_table` parameter setting. First connect to your MySQL DB instance, then issue the appropriate commands as shown following. For more information, see [Connecting to a DB instance running the MySQL database engine (p. 1646)](Connecting%20to%20a%20DB%20instance%20running%20the%20MySQL%20database%20engine%20(p.%201646)).

```sql
ALTER TABLE `table_name` ENGINE = InnoDB, ALGORITHM=COPY;
```

For example, the following query returns an `ALTER TABLE` statement for every InnoDB table that is not in the shared tablespace.

#### For MySQL 5.7 DB instances:

```sql
SELECT CONCAT('ALTER TABLE `',
REPLACE(LEFT(NAME , INSTR((NAME), '/') - 1), '`', '``'), '`.`',
REPLACE(SUBSTR(NAME FROM INSTR(NAME, '/') + 1), '`', '``'), `ENGINE=InnoDB,
ALGORITHM=COPY;') AS Query
FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES
WHERE SPACE <> 0 AND LEFT(NAME, INSTR((NAME), '/') - 1) NOT IN ('mysql','');
```

#### For MySQL 8.0 DB instances:

```sql
SELECT CONCAT('ALTER TABLE `',
REPLACE(LEFT(NAME , INSTR((NAME), '/') - 1), '`', '``'), '`.`',
REPLACE(SUBSTR(NAME FROM INSTR(NAME, '/') + 1), '`', '``'), `ENGINE=InnoDB,
ALGORITHM=COPY;') AS Query
FROM INFORMATION_SCHEMA.INNODB_TABLES
WHERE SPACE <> 0 AND LEFT(NAME, INSTR((NAME), '/') - 1) NOT IN ('mysql','');
```
Rebuilding a MySQL table to move the table's metadata to the shared tablespace requires additional storage space temporarily to rebuild the table, so the DB instance must have storage space available. During rebuilding, the table is locked and inaccessible to queries. For small tables or tables not frequently accessed, this might not be an issue. For large tables or tables frequently accessed in a heavily concurrent environment, you can rebuild tables on a read replica.

You can create a read replica and migrate table metadata to the shared tablespace on the read replica. While the ALTER TABLE statement blocks access on the read replica, the source DB instance is not affected. The source DB instance will continue to generate its binary logs while the read replica lags during the table rebuilding process. Because the rebuilding requires additional storage space and the replay log file can become large, you should create a read replica with storage allocated that is larger than the source DB instance.

To create a read replica and rebuild InnoDB tables to use the shared tablespace, take the following steps:

1. Make sure that backup retention is enabled on the source DB instance so that binary logging is enabled.
2. Use the AWS Management Console or AWS CLI to create a read replica for the source DB instance. Because the creation of a read replica involves many of the same processes as crash recovery, the creation process can take some time if there is a large number of InnoDB tablespaces. Allocate more storage space on the read replica than is currently used on the source DB instance.
3. When the read replica has been created, create a parameter group with the parameter settings `read_only = 0` and `innodb_file_per_table = 0`. Then associate the parameter group with the read replica.
4. Issue the following SQL statement for all tables that you want migrated on the replica:

   ```sql
   ALTER TABLE name ENGINE = InnoDB
   ```

5. When all of your ALTER TABLE statements have completed on the read replica, verify that the read replica is connected to the source DB instance and that the two instances are in sync.
6. Use the console or CLI to promote the read replica to be the instance. Make sure that the parameter group used for the new standalone DB instance has the `innodb_file_per_table` parameter set to 0. Change the name of the new standalone DB instance, and point any applications to the new standalone DB instance.

## Managing the Global Status History

**Tip**
To analyze database performance, you can also use Performance Insights on Amazon RDS. For more information, see [Monitoring DB load with Performance Insights on Amazon RDS](p. 720).

MySQL maintains many status variables that provide information about its operation. Their value can help you detect locking or memory issues on a DB instance. The values of these status variables are cumulative since last time the DB instance was started. You can reset most status variables to 0 by using the `FLUSH STATUS` command.

To allow for monitoring of these values over time, Amazon RDS provides a set of procedures that will snapshot the values of these status variables over time and write them to a table, along with any changes since the last snapshot. This infrastructure, called Global Status History (GoSH), is installed on all MySQL DB instances starting with versions 5.5.23. GoSH is disabled by default.

To enable GoSH, you first enable the event scheduler from a DB parameter group by setting the parameter `event_scheduler` to `ON`. For MySQL DB instances running MySQL 5.7, also set the parameter `show_compatibility_56` to 1. For information about creating and modifying a DB parameter group, see [Working with parameter groups](p. 347). For information about the side effects of enabling this parameter, see `show_compatibility_56` in the [MySQL 5.7 Reference Manual](#).
You can then use the procedures in the following table to enable and configure GoSH. First connect to your MySQL DB instance, then issue the appropriate commands as shown following. For more information, see Connecting to a DB instance running the MySQL database engine (p. 1646). For each procedure, type the following:

```
CALL procedure-name;
```

Where `procedure-name` is one of the procedures in the table.

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mysql.rds_enable_gsh_collector</code></td>
<td>Enables GoSH to take default snapshots at intervals specified by <code>rds_set_gsh_collector</code>.</td>
</tr>
<tr>
<td><code>mysql.rds_set_gsh_collector</code></td>
<td>Specifies the interval, in minutes, between snapshots. Default value is 5.</td>
</tr>
<tr>
<td><code>mysql.rds_disable_gsh_collector</code></td>
<td>Disables snapshots.</td>
</tr>
<tr>
<td><code>mysql.rds_collect_global_status_history</code></td>
<td>Takes a snapshot on demand.</td>
</tr>
<tr>
<td><code>mysql.rds_enable_gsh_rotation</code></td>
<td>Enables rotation of the contents of the <code>mysql.rds_global_status_history</code> table to <code>mysql.rds_global_status_history_old</code> at intervals specified by <code>rds_set_gsh_rotation</code>.</td>
</tr>
<tr>
<td><code>mysql.rds_set_gsh_rotation</code></td>
<td>Specifies the interval, in days, between table rotations. Default value is 7.</td>
</tr>
<tr>
<td><code>mysql.rds_disable_gsh_rotation</code></td>
<td>Disables table rotation.</td>
</tr>
<tr>
<td><code>mysql.rds_rotate_global_status_history</code></td>
<td>Rotates the contents of the <code>mysql.rds_global_status_history</code> table to <code>mysql.rds_global_status_history_old</code> on demand.</td>
</tr>
</tbody>
</table>

When GoSH is running, you can query the tables that it writes to. For example, to query the hit ratio of the InnoDB buffer pool, you would issue the following query:

```sql
select a.collection_end, a.collection_start, ((a.variable_Delta - b.variable_delta)/a.variable_delta)*100 as "HitRatio"
from mysql.rds_global_status_history as a join mysql.rds_global_status_history as b
on a.collection_end = b.collection_end
where a.variable_name = 'Innodb_buffer_pool_read_requests' and b.variable_name = 'Innodb_buffer_pool_reads'
```
Local time zone for MySQL DB instances

By default, the time zone for a MySQL DB instance is Universal Time Coordinated (UTC). You can set the time zone for your DB instance to the local time zone for your application instead.

To set the local time zone for a DB instance, set the `time_zone` parameter in the parameter group for your DB instance to one of the supported values listed later in this section. When you set the `time_zone` parameter for a parameter group, all DB instances and read replicas that are using that parameter group change to use the new local time zone. For information on setting parameters in a parameter group, see Working with parameter groups (p. 347).

After you set the local time zone, all new connections to the database reflect the change. If you have any open connections to your database when you change the local time zone, you won't see the local time zone update until after you close the connection and open a new connection.

You can set a different local time zone for a DB instance and one or more of its read replicas. To do this, use a different parameter group for the DB instance and the replica or replicas and set the `time_zone` parameter in each parameter group to a different local time zone.

If you are replicating across AWS Regions, then the source DB instance and the read replica use different parameter groups (parameter groups are unique to an AWS Region). To use the same local time zone for each instance, you must set the `time_zone` parameter in the instance's and read replica's parameter groups.

When you restore a DB instance from a DB snapshot, the local time zone is set to UTC. You can update the time zone to your local time zone after the restore is complete. If you restore a DB instance to a point in time, then the local time zone for the restored DB instance is the time zone setting from the parameter group of the restored DB instance.

The Internet Assigned Numbers Authority (IANA) publishes new time zones at https://www.iana.org/time-zones several times a year. Every time RDS releases a new minor maintenance release of MySQL, it ships with the latest time zone data at the time of the release. When you use the latest RDS for MySQL versions, you have recent time zone data from RDS. To ensure that your DB instance has recent time zone data, we recommend upgrading to a higher DB engine version. Alternatively, you can modify the time zone tables in MariaDB DB instances manually. To do so, you can use SQL commands or run the `mysql_tzinfo_to_sql` tool in a SQL client. After updating the time zone data manually, reboot your DB instance so that the changes take effect. RDS doesn't modify or reset the time zone data of running DB instances. New time zone data is installed only when you perform a database engine version upgrade.

You can set your local time zone to one of the following values.

<table>
<thead>
<tr>
<th>Africa/Cairo</th>
<th>Asia/Riyadh</th>

Known issues and limitations for Amazon RDS for MySQL

Known issues and limitations for working with Amazon RDS for MySQL are as follows.

Topics

- InnoDB reserved word (p. 1768)
- Storage-full behavior for Amazon RDS for MySQL (p. 1768)
- Inconsistent InnoDB buffer pool size (p. 1769)
- Index merge optimization returns incorrect results (p. 1769)
- Log file size (p. 1770)
- MySQL parameter exceptions for Amazon RDS DB instances (p. 1770)
- MySQL file size limits in Amazon RDS (p. 1770)
- MySQL Keyring Plugin not supported (p. 1772)
- Custom ports (p. 1772)
- MySQL stored procedure limitations (p. 1772)
- GTID-based replication with an external source instance (p. 1772)

InnoDB reserved word

InnoDB is a reserved word for RDS for MySQL. You can't use this name for a MySQL database.

Storage-full behavior for Amazon RDS for MySQL

When storage becomes full for a MySQL DB instance, there can be metadata inconsistencies, dictionary mismatches, and orphan tables. To prevent these issues, Amazon RDS automatically stops a DB instance that reaches the storage-full state.

A MySQL DB instance reaches the storage-full state in the following cases:

- The DB instance has less than 20,000 MiB of storage, and available storage reaches 200 MiB or less.
- The DB instance has more than 102,400 MiB of storage, and available storage reaches 1024 MiB or less.
- The DB instance has between 20,000 MiB and 102,400 MiB of storage, and has less than 1% of storage available.

After Amazon RDS stops a DB instance automatically because it reached the storage-full state, you can still modify it. To restart the DB instance, complete at least one of the following:

- Modify the DB instance to enable storage autoscaling.
  
  For more information about storage autoscaling, see Managing capacity automatically with Amazon RDS storage autoscaling (p. 480).

- Modify the DB instance to increase its storage capacity.
  
  For more information about increasing storage capacity, see Increasing DB instance storage capacity (p. 478).
After you make one of these changes, the DB instance is restarted automatically. For information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 401).

**Inconsistent InnoDB buffer pool size**

For MySQL 5.7, there is currently a bug in the way that the InnoDB buffer pool size is managed. MySQL 5.7 might adjust the value of the `innodb_buffer_pool_size` parameter to a large value that can result in the InnoDB buffer pool growing too large and using up too much memory. This effect can cause the MySQL database engine to stop running or can prevent it from starting. This issue is more common for DB instance classes that have less memory available.

To resolve this issue, set the value of the `innodb_buffer_pool_size` parameter to a multiple of the product of the `innodb_buffer_pool_instances` parameter value and the `innodb_buffer_pool_chunk_size` parameter value. For example, you might set the `innodb_buffer_pool_size` parameter value to a multiple of eight times the product of the `innodb_buffer_pool_instances` and `innodb_buffer_pool_chunk_size` parameter values, as shown in the following example.

```
innodb_buffer_pool_chunk_size = 536870912
innodb_buffer_pool_instances = 4
innodb_buffer_pool_size = (536870912 * 4) * 8 = 17179869184
```

For details on this MySQL 5.7 bug, see https://bugs.mysql.com/bug.php?id=79379 in the MySQL documentation.

**Index merge optimization returns incorrect results**

Queries that use index merge optimization might return incorrect results due to a bug in the MySQL query optimizer that was introduced in MySQL 5.5.37. When you issue a query against a table with multiple indexes, the optimizer scans ranges of rows based on the multiple indexes, but does not merge the results together correctly. For more information on the query optimizer bug, see http://bugs.mysql.com/bug.php?id=72745 and http://bugs.mysql.com/bug.php?id=68194 in the MySQL bug database.

For example, consider a query on a table with two indexes where the search arguments reference the indexed columns.

```
SELECT * FROM table1
WHERE indexed_col1 = 'value1' AND indexed_col2 = 'value2';
```

In this case, the search engine will search both indexes. However, due to the bug, the merged results are incorrect.

To resolve this issue, you can do one of the following:

- Set the `optimizer_switch` parameter to `index_merge=off` in the DB parameter group for your MySQL DB instance. For information on setting DB parameter group parameters, see Working with parameter groups (p. 347).
- Upgrade your MySQL DB instance to MySQL version 5.7 or 8.0. For more information, see Upgrading the MySQL DB engine (p. 1680).
- If you cannot upgrade your instance or change the `optimizer_switch` parameter, you can work around the bug by explicitly identifying an index for the query, for example:

```
SELECT * FROM table1
USE INDEX covering_index
```
WHERE indexed_col1 = 'value1' AND indexed_col2 = 'value2';

For more information, see Index merge optimization in the MySQL documentation.

## Log file size

For MySQL, there is a size limit on BLOBs written to the redo log. To account for this limit, ensure that the `innodb_log_file_size` parameter for your MySQL DB instance is 10 times larger than the largest BLOB data size found in your tables, plus the length of other variable length fields (VARCHAR, VARBINARY, TEXT) in the same tables. For information on how to set parameter values, see Working with parameter groups (p. 347). For information on the `innodb_log_file_size` parameter, see the MySQL documentation.

## MySQL parameter exceptions for Amazon RDS DB instances

Some MySQL parameters require special considerations when used with an Amazon RDS DB instance.

### lower_case_table_names

Because Amazon RDS uses a case-sensitive file system, setting the value of the `lower_case_table_names` server parameter to 2 (names stored as given but compared in lowercase) is not supported. The following are the supported values for Amazon RDS for MySQL DB instances:

- 0 (names stored as given and comparisons are case-sensitive) is supported for all RDS for MySQL versions.
- 1 (names stored in lowercase and comparisons are not case-sensitive) is supported for RDS for MySQL version 5.7 and version 8.0.28 and higher 8.0 versions.

Set the `lower_case_table_names` parameter in a custom DB parameter group before creating a DB instance. Then, specify the custom DB parameter group when you create the DB instance.

When a parameter group is associated with a MySQL DB instance with a version lower than 8.0, we recommend that you avoid changing the `lower_case_table_names` parameter in the parameter group. Changing it could cause inconsistencies with point-in-time recovery backups and read replica DB instances.

When a parameter group is associated with a version 8.0 MySQL DB instance, you can't modify the `lower_case_table_names` parameter in the parameter group.

Read replicas should always use the same `lower_case_table_names` parameter value as the source DB instance.

### long_query_time

You can set the `long_query_time` parameter to a floating point value so that you can log slow queries to the MySQL slow query log with microsecond resolution. You can set a value such as 0.1 seconds, which would be 100 milliseconds, to help when debugging slow transactions that take less than one second.

## MySQL file size limits in Amazon RDS

For MySQL DB instances, the maximum provisioned storage limit constrains the size of a table to a maximum size of 16 TB when using InnoDB file-per-table tablespaces. This limit also constrains the
system tablespace to a maximum size of 16 TB. InnoDB file-per-table tablespaces (with tables each in their own tablespace) is set by default for MySQL DB instances.

**Note**
Some existing DB instances have a lower limit. For example, MySQL DB instances created before April 2014 have a file and table size limit of 2 TB. This 2 TB file size limit also applies to DB instances or read replicas created from DB snapshots taken before April 2014, regardless of when the DB instance was created.

There are advantages and disadvantages to using InnoDB file-per-table tablespaces, depending on your application. To determine the best approach for your application, see [File-per-table tablespaces](#) in the MySQL documentation.

We don't recommend allowing tables to grow to the maximum file size. In general, a better practice is to partition data into smaller tables, which can improve performance and recovery times.

One option that you can use for breaking up a large table into smaller tables is partitioning. Partitioning distributes portions of your large table into separate files based on rules that you specify. For example, if you store transactions by date, you can create partitioning rules that distribute older transactions into separate files using partitioning. Then periodically, you can archive the historical transaction data that doesn't need to be readily available to your application. For more information, see [Partitioning](#) in the MySQL documentation.

Because there is no single system table or view that provides the size of all the tables and the InnoDB system tablespace, you must query multiple tables to determine the size of the tablespaces.

**To determine the size of the InnoDB system tablespace and the data dictionary tablespace**

- Use the following SQL command to determine if any of your tablespaces are too large and are candidates for partitioning.

  ```sql
  select FILE_NAME, TABLESPACE_NAME, ROUND((((TOTAL_EXTENTS*EXTENT_SIZE) /1024/1024/1024), 2) as "File Size (GB)" from information_schema.FILES
  where tablespace_name in ('mysql','innodb_system');
  ```

  **Note**
The data dictionary tablespace is specific to MySQL 8.0.

**To determine the size of InnoDB user tables outside of the InnoDB system tablespace (for MySQL 5.7 versions)**

- Use the following SQL command to determine if any of your tables are too large and are candidates for partitioning.

  ```sql
  SELECT SPACE, NAME, ROUND((ALLOCATED_SIZE/1024/1024/1024), 2) as "Tablespace Size (GB)"
  FROM information_schema.INNODB_SYS_TABLESPACES ORDER BY 3 DESC;
  ```

**To determine the size of InnoDB user tables outside of the InnoDB system tablespace (for MySQL 8.0 versions)**

- Use the following SQL command to determine if any of your tables are too large and are candidates for partitioning.

  ```sql
  SELECT SPACE, NAME, ROUND((ALLOCATED_SIZE/1024/1024/1024), 2) as "Tablespace Size (GB)"
  FROM information_schema.INNODB_TABLESPACES ORDER BY 3 DESC;
  ```
To determine the size of non-InnoDB user tables

- Use the following SQL command to determine if any of your non-InnoDB user tables are too large.

```
SELECT TABLE_SCHEMA, TABLE_NAME, round(((DATA_LENGTH + INDEX_LENGTH+DATA_FREE) / 1024 / 1024/ 1024), 2) As "Approximate size (GB)" FROM information_schema.TABLES WHERE TABLE_SCHEMA NOT IN ('mysql', 'information_schema', 'performance_schema') and ENGINE<>"InnoDB";
```

To enable InnoDB file-per-table tablespaces

- Set the `innodb_file_per_table` parameter to 1 in the parameter group for the DB instance.

To disable InnoDB file-per-table tablespaces

- Set the `innodb_file_per_table` parameter to 0 in the parameter group for the DB instance.

For information on updating a parameter group, see [Working with parameter groups](p. 347).

When you have enabled or disabled InnoDB file-per-table tablespaces, you can issue an `ALTER TABLE` command to move a table from the global tablespace to its own tablespace, or from its own tablespace to the global tablespace as shown in the following example:

```
ALTER TABLE table_name ENGINE=InnoDB;
```

MySQL Keyring Plugin not supported

Currently, Amazon RDS for MySQL doesn't support the MySQL `keyring_aws` Amazon Web Services Keyring Plugin.

Custom ports

Amazon RDS blocks connections to custom port 33060 for the MySQL engine. Choose a different port for your MySQL engine.

MySQL stored procedure limitations

The `mysql.rds_kill` and `mysql.rds_kill_query` stored procedures can't terminate sessions or queries owned by MySQL users with usernames longer than 16 characters on the following RDS for MySQL versions:

- 8.0.32 and lower 8 versions
- 5.7.41 and lower 5.7 versions

GTID-based replication with an external source instance

Amazon RDS doesn't support replication based on global transaction identifiers (GTIDs) from an external MySQL instance into an Amazon RDS for MySQL DB instance that requires setting `GTID_PURGED` during configuration.
RDS for MySQL stored procedure reference

These topics describe system stored procedures that are available for Amazon RDS instances running the MySQL DB engine. The master user must run these procedures.

Topics

- Configuring (p. 1774)
- Ending a session or query (p. 1777)
- Logging (p. 1779)
- Managing the Global Status History (p. 1780)
- Replicating (p. 1783)
- Warming the InnoDB cache (p. 1800)
Configuring

The following stored procedures set and show configuration parameters, such as for binary log file retention.

Topics
- mysql.rds_set_configuration (p. 1774)
- mysql.rds_show_configuration (p. 1776)

mysql.rds_set_configuration

Specifies the number of hours to retain binary logs or the number of seconds to delay replication.

Syntax

CALL mysql.rds_set_configuration(name, value);

Parameters

name

The name of the configuration parameter to set.

value

The value of the configuration parameter.

Usage notes

The mysql.rds_set_configuration procedure supports the following configuration parameters:

- binlog retention hours (p. 1774)
- source delay (p. 1775)
- target delay (p. 1775)

The configuration parameters are stored permanently and survive any DB instance reboot or failover.

binlog retention hours

The binlog retention hours parameter is used to specify the number of hours to retain binary log files. Amazon RDS normally purges a binary log as soon as possible, but the binary log might still be required for replication with a MySQL database external to RDS.

The default value of binlog retention hours is NULL. For RDS for MySQL, NULL means binary logs aren't retained (0 hours).

To specify the number of hours to retain binary logs on a DB instance, use the mysql.rds_set_configuration stored procedure and specify a period with enough time for replication to occur, as shown in the following example.

call mysql.rds_set_configuration('binlog retention hours', 24);

Note

You can't use the value 0 for binlog retention hours.
For MySQL DB instances, the maximum binlog retention hours value is 168 (7 days).

After you set the retention period, monitor storage usage for the DB instance to make sure that the retained binary logs don't take up too much storage.

**source delay**

Use the `source delay` parameter in a read replica to specify the number of seconds to delay replication from the read replica to its source DB instance. Amazon RDS normally replicates changes as soon as possible, but you might want some environments to delay replication. For example, when replication is delayed, you can roll forward a delayed read replica to the time just before a disaster. If a table is dropped accidentally, you can use delayed replication to quickly recover it. The default value of `target delay` is 0 (don't delay replication).

When you use this parameter, it runs `mysql.rds_set_source_delay` and applies `CHANGE primary TO MASTER_DELAY = input value`. If successful, the procedure saves the `source delay` parameter to the `mysql.rds_configuration` table.

To specify the number of seconds for Amazon RDS to delay replication to a source DB instance, use the `mysql.rds_set_configuration` stored procedure and specify the number of seconds to delay replication. In the following example, the replication is delayed by at least one hour (3,600 seconds).

```
call mysql.rds_set_configuration('source delay', 3600);
```

The procedure then runs `mysql.rds_set_source_delay(3600)`.

The limit for the `source delay` parameter is one day (86400 seconds).

**Note**

The `source delay` parameter isn't supported for RDS for MySQL version 8.0 or MariaDB versions below 10.2.

**target delay**

Use the `target delay` parameter to specify the number of seconds to delay replication between a DB instance and any future RDS-managed read replicas created from this instance. This parameter is ignored for non-RDS-managed read replicas. Amazon RDS normally replicates changes as soon as possible, but you might want some environments to delay replication. For example, when replication is delayed, you can roll forward a delayed read replica to the time just before a disaster. If a table is dropped accidentally, you can use delayed replication to recover it quickly. The default value of `target delay` is 0 (don't delay replication).

For disaster recovery, you can use this configuration parameter with the `mysql.rds_start_replication_until` stored procedure or the `mysql.rds_start_replication_until_gtid` stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the `mysql.rds_set_configuration` procedure with this parameter set. After the `mysql.rds_start_replication_until` or `mysql.rds_start_replication_until_gtid` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in *Promoting a read replica to be a standalone DB instance*.

To roll forward changes to a delayed read replica to the time just before a disaster, you can roll forward replication by running the `mysql.rds_set_configuration` procedure with the `target delay` parameter set. After the `mysql.rds_start_replication_until` or `mysql.rds_start_replication_until_gtid` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in *Promoting a read replica to be a standalone DB instance*.

To use the `mysql.rds_rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the `mysql.rds_skip_transaction_with_gtid` stored procedure. For more information about working with GTID-based replication, see *Using GTID-based replication for Amazon RDS for MySQL*.

To specify the number of seconds for Amazon RDS to delay replication to a read replica, use the `mysql.rds_set_configuration` stored procedure and specify the number of seconds to delay replication.
replication. The following example specifies that replication is delayed by at least one hour (3,600 seconds).

call mysql.rds_set_configuration('target delay', 3600);

The limit for the target delay parameter is one day (86400 seconds).

**Note**
The target delay parameter isn't supported for RDS for MySQL version 8.0 or MariaDB versions earlier than 10.2.

**mysql.rds_show_configuration**

The number of hours that binary logs are retained.

**Syntax**

```
CALL mysql.rds_show_configuration;
```

**Usage notes**

To verify the number of hours that Amazon RDS retains binary logs, use the mysql.rds_show_configuration stored procedure.

**Examples**

The following example displays the retention period:

```
call mysql.rds_show_configuration;
```

<table>
<thead>
<tr>
<th>name</th>
<th>value</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>binlog retention hours</td>
<td>24</td>
<td>binlog retention hours specifies the duration in hours before binary logs are automatically deleted.</td>
</tr>
</tbody>
</table>
Ending a session or query

The following stored procedures end a session or query.

**Topics**
- [mysql.rds_kill](#) (p. 1777)
- [mysql.rds_kill_query](#) (p. 1777)

### mysql.rds_kill

Ends a connection to the MySQL server.

**Syntax**

```
CALL mysql.rds_kill(processID);
```

**Parameters**

- **processID**
  
  The identity of the connection thread to be ended.

**Usage notes**

Each connection to the MySQL server runs in a separate thread. To end a connection, use the `mysql.rds_kill` procedure and pass in the thread ID of that connection. To obtain the thread ID, use the MySQL `SHOW PROCESSLIST` command.

For information about limitations, see [MySQL stored procedure limitations](#) (p. 1772).

**Examples**

The following example ends a connection with a thread ID of 4243:

```
CALL mysql.rds_kill(4243);
```

### mysql.rds_kill_query

Ends a query running against the MySQL server.

**Syntax**

```
CALL mysql.rds_kill_query(processID);
```

**Parameters**

- **processID**
  
  The identity of the process or thread that is running the query to be ended.
Usage notes

To stop a query running against the MySQL server, use the `mysql_rds_kill_query` procedure and pass in the connection ID of the thread that is running the query. The procedure then terminates the connection.

To obtain the ID, query the MySQL `INFORMATION_SCHEMA.PROCESSLIST` table or use the MySQL `SHOW PROCESSLIST` command. The value in the ID column from `SHOW PROCESSLIST` or `SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST` is the `processID`.

For information about limitations, see MySQL stored procedure limitations (p. 1772).

Examples

The following example stops a query with a query thread ID of 230040:

```sql
CALL mysql.rds_kill_query(230040);
```
Logging

The following stored procedures rotate MySQL logs to backup tables. For more information, see MySQL database log files (p. 915).

Topics

• `mysql.rds_rotate_general_log (p. 1779)`
• `mysql.rds_rotate_slow_log (p. 1779)`

**mysql.rds_rotate_general_log**

Rotates the `mysql.general_log` table to a backup table.

**Syntax**

```sql
CALL mysql.rds_rotate_general_log;
```

**Usage notes**

You can rotate the `mysql.general_log` table to a backup table by calling the `mysql.rds_rotate_general_log` procedure. When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If a backup log table already exists, then it is deleted before the current log table is copied to the backup. You can query the backup log table if needed. The backup log table for the `mysql.general_log` table is named `mysql.general_log_backup`.

You can run this procedure only when the `log_output` parameter is set to `TABLE`.

**mysql.rds_rotate_slow_log**

Rotates the `mysql.slow_log` table to a backup table.

**Syntax**

```sql
CALL mysql.rds_rotate_slow_log;
```

**Usage notes**

You can rotate the `mysql.slow_log` table to a backup table by calling the `mysql.rds_rotate_slow_log` procedure. When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If a backup log table already exists, then it is deleted before the current log table is copied to the backup.

You can query the backup log table if needed. The backup log table for the `mysql.slow_log` table is named `mysql.slow_log_backup`.
Managing the Global Status History

Amazon RDS provides a set of procedures that take snapshots of the values of status variables over time and write them to a table, along with any changes since the last snapshot. This infrastructure is called Global Status History. For more information, see Managing the Global Status History (p. 1763).

The following stored procedures manage how the Global Status History is collected and maintained.

Topics
- `mysql.rds_collect_global_status_history` (p. 1780)
- `mysql.rds_disable_gsh_collector` (p. 1780)
- `mysql.rds_disable_gsh_rotation` (p. 1780)
- `mysql.rds_enable_gsh_collector` (p. 1780)
- `mysql.rds_enable_gsh_rotation` (p. 1781)
- `mysql.rds_rotate_global_status_history` (p. 1781)
- `mysql.rds_set_gsh_collector` (p. 1781)
- `mysql.rds_set_gsh_rotation` (p. 1781)

`mysql.rds_collect_global_status_history`

Takes a snapshot on demand for the Global Status History.

Syntax

```
CALL mysql.rds_collect_global_status_history;
```

`mysql.rds_disable_gsh_collector`

Turns off snapshots taken by the Global Status History.

Syntax

```
CALL mysql.rds_disable_gsh_collector;
```

`mysql.rds_disable_gsh_rotation`

Turns off rotation of the `mysql.global_status_history` table.

Syntax

```
CALL mysql.rds_disable_gsh_rotation;
```

`mysql.rds_enable_gsh_collector`

Turns on the Global Status History to take default snapshots at intervals specified by `rds_set_gsh_collector`.

Syntax

```
```
CALL mysql.rds_enable_gsh_collector;

**mysql.rds_enable_gsh_rotation**

Turns on rotation of the contents of the `mysql.global_status_history` table to `mysql.global_status_history_old` at intervals specified by `rds_set_gsh_rotation`.

**Syntax**

```
CALL mysql.rds_enable_gsh_rotation;
```

**mysql.rds_rotate_global_status_history**

Rotates the contents of the `mysql.global_status_history` table to `mysql.global_status_history_old` on demand.

**Syntax**

```
CALL mysql.rds_rotate_global_status_history;
```

**mysql.rds_set_gsh_collector**

Specifies the interval, in minutes, between snapshots taken by the Global Status History.

**Syntax**

```
CALL mysql.rds_set_gsh_collector(intervalPeriod);
```

**Parameters**

`intervalPeriod`

The interval, in minutes, between snapshots. Default value is 5.

**mysql.rds_set_gsh_rotation**

Specifies the interval, in days, between rotations of the `mysql.global_status_history` table.

**Syntax**

```
CALL mysql.rds_set_gsh_rotation(intervalPeriod);
```

**Parameters**

`intervalPeriod`

The interval, in days, between table rotations. Default value is 7.
Replicating

The following stored procedures control how transactions are replicated from an external database into RDS for MySQL, or from RDS for MySQL to an external database. To learn how to use replication based on global transaction identifiers (GTIDs) with RDS for MySQL, see Using GTID-based replication for Amazon RDS for MySQL (p. 1735).

Topics

- mysql.rds_next_master_log (p. 1783)
- mysql.rds_reset_external_master (p. 1785)
- mysql.rds_set_external_master (p. 1785)
- mysql.rds_set_external_master_with_auto_position (p. 1788)
- mysql.rds_set_external_master_with_delay (p. 1790)
- mysql.rds_set_master_auto_position (p. 1793)
- mysql.rds_set_source_delay (p. 1793)
- mysql.rds_skip_transaction_with_gtid (p. 1794)
- mysql.rds_skip_repl_error (p. 1795)
- mysql.rds_start_replication (p. 1796)
- mysql.rds_start_replication_until (p. 1796)
- mysql.rds_start_replication_until_gtid (p. 1797)
- mysql.rds_stop_replication (p. 1798)

mysql.rds_next_master_log

Changes the source database instance log position to the start of the next binary log on the source database instance. Use this procedure only if you are receiving replication I/O error 1236 on a read replica.

Syntax

```sql
CALL mysql.rds_next_master_log(
    curr_master_log
);
```

Parameters

- `curr_master_log`
  
  The index of the current master log file. For example, if the current file is named `mysql-bin-changelog.012345`, then the index is 12345. To determine the current master log file name, run the `SHOW REPLICA STATUS` command and view the `Master_Log_File` field.

  **Note**
  Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

Usage notes

The master user must run the `mysql.rds_next_master_log` procedure.
Warning
Call `mysql.rds_next_master_log` only if replication fails after a failover of a Multi-AZ DB instance that is the replication source, and the `Last_IO_Errno` field of `SHOW REPLICA STATUS` reports I/O error 1236.
Calling `mysql.rds_next_master_log` can result in data loss in the read replica if transactions in the source instance were not written to the binary log on disk before the failover event occurred.
You can reduce the chance of this happening by setting the source instance parameters `sync_binlog` and `innodb_support_xa` to 1, although this might reduce performance. For more information, see Troubleshooting a MySQL read replica problem (p. 1734).

Examples
Assume replication fails on an RDS for MySQL read replica. Running `SHOW REPLICA STATUS\G` on the read replica returns the following result:

```
 ********************** 1. row ***************************
 Replica_IO_State: 
   Source_Host: myhost.XXXXXXXXXXXXXX.rr-rrrr-1.rds.amazonaws.com 
   Source_User: MasterUser 
   Source_Port: 3306 
   Connect_Retry: 10 
   Source_Log_File: mysql-bin-changelog.012345 
   Read_Source_Log_Pos: 1219393 
   Relay_Log_File: relaylog.012340 
   Relay_Log_Pos: 30223388 
   Relay_Source_Log_File: mysql-bin-changelog.012345 
   Replica_IO_Running: No 
   Replica_SQL_Running: Yes 
   Replicate_Do_DB: 
   Replicate_Ignore_DB: 
   Replicate_Do_Table: 
   Replicate_Ignore_Table: 
   Replicate_Wild_Do_Table: 
   Replicate_Wild_Ignore_Table: 
   Last_Errno: 0 
   Last_Error: 
   Skip_Counter: 0 
   Exec_Source_Log_Pos: 30223232 
   Relay_Log_Space: 5248928866 
   Until_Condition: None 
   Until_Log_File: 
   Until_Log_Pos: 0 
   Source_SSL_Allowed: No 
   Source_SSL_CA_File: 
   Source_SSL_CA_Path: 
   Source_SSL_Cert: 
   Source_SSL_CIPHER: 
   Source_SSL_KEY: 
   Seconds_Behind_Master: NULL 
   Source_SSL_VERIFY_SERVER_CERT: No 
   Last_IO_Errno: 1236 
   Last_IO_Error: Got fatal error 1236 from master when reading data from binary log: 'Client requested master to start replication from impossible position; the first event 'mysql-bin-changelog.013406' at 1219393, the last event read from '/rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4, the last byte read from '/rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4.' 
   Last_SQL_Errno: 0 
   Last_SQL_Error: 
   Replicate_Ignore_Server_Ids: 
   Source_Server_Id: 67285976
```
The Last_IO_Errno field shows that the instance is receiving I/O error 1236. The Master_Log_File field shows that the file name is mysql-bin-changelog.012345, which means that the log file index is 12345. To resolve the error, you can call `mysql.rds_next_master_log` with the following parameter:

```sql
CALL mysql.rds_next_master_log(12345);
```

**Note**

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

### `mysql.rds_reset_external_master`

Reconfigures an RDS for MySQL DB instance to no longer be a read replica of an instance of MySQL running external to Amazon RDS.

**Important**

To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see [Modifying parameters in a DB parameter group](#).

**Syntax**

```sql
CALL mysql.rds_reset_external_master;
```

**Usage notes**

The master user must run the `mysql.rds_reset_external_master` procedure. This procedure must be run on the MySQL DB instance to be removed as a read replica of a MySQL instance running external to Amazon RDS.

**Note**

We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see [Working with DB instance read replicas](#).

For more information about using replication to import data from an instance of MySQL running external to Amazon RDS, see [Configuring binary log file position replication with an external source instance](#).

### `mysql.rds_set_external_master`

Configures an RDS for MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

**Important**

To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see [Modifying parameters in a DB parameter group](#).

**Note**

You can use the `mysql.rds_set_external_master_with_delay` stored procedure to configure an external source database instance and delayed replication.
Syntax

```sql
CALL mysql.rds_set_external_master ( 
    host_name,
    host_port,
    replication_user_name,
    replication_user_password,
    mysql_binary_log_file_name,
    mysql_binary_log_file_location,
    ssl_encryption
);
```

Parameters

**host_name**

The host name or IP address of the MySQL instance running external to Amazon RDS to become the source database instance.

**host_port**

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

**replication_user_name**

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

**replication_user_password**

The password of the user ID specified in replication_user_name.

**mysql_binary_log_file_name**

The name of the binary log on the source database instance that contains the replication information.

**mysql_binary_log_file_location**

The location in the mysql_binary_log_file_name binary log at which replication starts reading the replication information.

You can determine the binlog file name and location by running `SHOW MASTER STATUS` on the source database instance.

**ssl_encryption**

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

**Note**

The MASTER_SSL_VERIFY_SERVER_CERT option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

Usage notes

The master user must run the `mysql.rds_set_external_master` procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.
Before you run `mysql.rds_set_external_master`, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify `replication_user_name` and `replication_user_password` values that indicate a replication user that has REPLICATION CLIENT and REPLICATION SLAVE permissions on the external instance of MySQL.

**To configure an external instance of MySQL as a source database instance**

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

   **MySQL 5.7**
   
   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
   ```

   **MySQL 8.0**
   
   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY 'password';
   ```

   **Note**
   Specify a password other than the prompt shown here as a security best practice.

2. On the external instance of MySQL, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain.

   **MySQL 5.7**
   
   ```
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
   ```

   **MySQL 8.0**
   
   ```
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
   ```

To use encrypted replication, configure source database instance to use SSL connections.

**Note**
We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see [Working with DB instance read replicas](p. 438).

After calling `mysql.rds_set_external_master` to configure an Amazon RDS DB instance as a read replica, you can call `mysql.rds_start_replication` on the read replica to start the replication process. You can call `mysql.rds_reset_external_master` to remove the read replica configuration.

When `mysql.rds_set_external_master` is called, Amazon RDS records the time, user, and an action of set master in the `mysql.rds_history` and `mysql.rds_replication_status` tables.
Examples

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

```sql
call mysql.rds_set_external_master('Externaldb.some.com', 3306, 'repl_user', 'password', 'mysql-bin-changelog.0777', 120, 0);
```

mysql.rds_set_external_master_with_auto_position

Configures an RDS for MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. This procedure also configures delayed replication and replication based on global transaction identifiers (GTIDs).

Important

To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group (p. 352).

Syntax

```sql
CALL mysql.rds_set_external_master_with_auto_position (host_name, host_port, replication_user_name, replication_user_password, ssl_encryption, delay);
```

Parameters

`host_name`

The host name or IP address of the MySQL instance running external to Amazon RDS to become the source database instance.

`host_port`

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

`replication_user_name`

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

`replication_user_password`

The password of the user ID specified in replication_user_name.
ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

Note
The MASTER_SSL_VERIFY_SERVER_CERT option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

delay

The minimum number of seconds to delay replication from source database instance.

The limit for this parameter is one day (86,400 seconds).

Usage notes

The master user must run the mysql.rds_set_external_master_with_auto_position procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

This procedure is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions.

Before you run mysql.rds_set_external_master_with_auto_position, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify values for replication_user_name and replication_user_password. These values must indicate a replication user that has REPLICATION CLIENT and REPLICATION SLAVE permissions on the external instance of MySQL.

To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'

2. On the external instance of MySQL, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain.

   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'

For more information, see Configuring binary log file position replication with an external source instance (p. 1740).

Note

We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see Working with DB instance read replicas (p. 438).

After calling mysql.rds_set_external_master_with_auto_position to configure an Amazon RDS DB instance as a read replica, you can call mysql.rds_start_replication (p. 1796) on the read replica...
to start the replication process. You can call `mysql.rds_reset_external_master` to remove the read replica configuration.

When you call `mysql.rds_set_external_master_with_auto_position`, Amazon RDS records the time, the user, and an action of `set_master` in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

For disaster recovery, you can use this procedure with the `mysql.rds_start_replication_until` or `mysql.rds_start_replication_until_gtid` stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the `mysql.rds_set_external_master_with_auto_position` procedure. After the `mysql.rds_start_replication_until_gtid` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance.

To use the `mysql.rds_rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the `mysql.rds_skip_transaction_with_gtid` stored procedure. For more information about working with GTID-based replication, see Using GTID-based replication for Amazon RDS for MySQL.

Examples

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. It sets the minimum replication delay to one hour (3,600 seconds) on the MySQL DB instance. A change from the MySQL source database instance running external to Amazon RDS isn't applied on the MySQL DB instance read replica for at least one hour.

```sql
CALL mysql.rds_set_external_master_with_auto_position(
    'Externaldb.some.com',
    3306,
    'repl_user',
    'SomePassW0rd',
    0,
    3600);
```

`mysql.rds_set_external_master_with_delay` Configures an RDS for MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS and configures delayed replication.

**Important**

To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group.

**Syntax**

```sql
CALL mysql.rds_set_external_master_with_delay (host_name, host_port, replication_user_name, replication_user_password, mysql_binary_log_file_name, mysql_binary_log_file_location, ssl_encryption)
```
Parameters

host_name

The host name or IP address of the MySQL instance running external to Amazon RDS that will become the source database instance.

host_port

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes SSH port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

The ID of a user with REPLICATION_CLIENT and REPLICATION_SLAVE permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

replication_user_password

The password of the user ID specified in replication_user_name.

mysql_binary_log_file_name

The name of the binary log on the source database instance contains the replication information.

mysql_binary_log_file_location

The location in the mysql_binary_log_file_name binary log at which replication will start reading the replication information.

You can determine the binlog file name and location by running SHOW MASTER STATUS on the source database instance.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

Note

The MASTER_SSL_VERIFY_SERVER_CERT option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

delay

The minimum number of seconds to delay replication from source database instance.

The limit for this parameter is one day (86400 seconds).

Usage notes

The master user must run the mysql.rds_set_external_master_with_delay procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

Before you run mysql.rds_set_external_master_with_delay, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify values for replication_user_name and
replication_user_password. These values must indicate a replication user that has REPLICATION CLIENT and REPLICATION SLAVE permissions on the external instance of MySQL.

To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'

2. On the external instance of MySQL, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain.

   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'

For more information, see Configuring binary log file position replication with an external source instance (p. 1740).

**Note**

We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see Working with DB instance read replicas (p. 438).

After calling mysql.rds_set_external_master_with_delay to configure an Amazon RDS DB instance as a read replica, you can call mysql.rds_start_replication (p. 1796) on the read replica to start the replication process. You can call mysql.rds_reset_external_master (p. 1785) to remove the read replica configuration.

When you call mysql.rds_set_external_master_with_delay, Amazon RDS records the time, the user, and an action of set master in the mysql.rds_history and mysql.rds_replication_status tables.

For disaster recovery, you can use this procedure with the mysql.rds_start_replication_until (p. 1796) or mysql.rds_start_replication_until_gtid (p. 1797) stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the mysql.rds_set_external_master_with_delay procedure. After the mysql.rds_start_replication_until_gtid procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance (p. 447).

To use the mysql.rds_rds_start_replication_until_gtid procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the mysql.rds_skip_transaction_with_gtid (p. 1794) stored procedure. For more information about working with GTID-based replication, see Using GTID-based replication for Amazon RDS for MySQL (p. 1735).

The mysql.rds_set_external_master_with_delay procedure is available in these versions of RDS for MySQL:

- MySQL 8.0.26 and higher 8.0 versions
- All 5.7 versions
Examples

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. It sets the minimum replication delay to one hour (3,600 seconds) on the MySQL DB instance. A change from the MySQL source database instance running external to Amazon RDS isn't applied on the MySQL DB instance read replica for at least one hour.

```sql
CALL mysql.rds_set_external_master_with_delay('Externaldb.some.com',
3306,
'repl_user',
'SomePassW0rd',
'mysql-bin-changelog.000777',
120,
0,
3600);
```

**mysql.rds_set_master_auto_position**

Sets the replication mode to be based on either binary log file positions or on global transaction identifiers (GTIDs).

**Syntax**

```sql
CALL mysql.rds_set_master_auto_position (auto_position_mode);
```

**Parameters**

- `auto_position_mode`
  
  A value that indicates whether to use log file position replication or GTID-based replication:
  - 0 – Use the replication method based on binary log file position. The default is 0.
  - 1 – Use the GTID-based replication method.

**Usage notes**

The master user must run the `mysql.rds_set_master_auto_position` procedure.

This procedure is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions.

**mysql.rds_set_source_delay**

Sets the minimum number of seconds to delay replication from source database instance to the current read replica. Use this procedure when you are connected to a read replica to delay replication from its source database instance.

**Syntax**

```sql
CALL mysql.rds_set_source_delay(delay)
```
Parameters

`delay`

The minimum number of seconds to delay replication from the source database instance.

The limit for this parameter is one day (86400 seconds).

Usage notes

The master user must run the `mysql.rds_set_source_delay` procedure.

For disaster recovery, you can use this procedure with the `mysql.rds_start_replication_until` stored procedure or the `mysql.rds_start_replication_until_gtid` stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the `mysql.rds_set_source_delay` procedure. After the `mysql.rds_start_replication_until` or `mysql.rds_start_replication_until_gtid` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance (p. 447).

To use the `mysql.rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the `mysql.rds_skip_transaction_with_gtid` stored procedure. For more information on GTID-based replication, see Using GTID-based replication for Amazon RDS for MySQL (p. 1735).

The `mysql.rds_set_source_delay` procedure is available in these versions of RDS for MySQL:

- MySQL 8.0.26 and higher 8.0 versions
- All 5.7 versions

Examples

To delay replication from source database instance to the current read replica for at least one hour (3,600 seconds), you can call `mysql.rds_set_source_delay` with the following parameter:

```
CALL mysql.rds_set_source_delay(3600);
```

`mysql.rds_skip_transaction_with_gtid`

Skips replication of a transaction with the specified global transaction identifier (GTID) on a MySQL DB instance.

You can use this procedure for disaster recovery when a specific GTID transaction is known to cause a problem. Use this stored procedure to skip the problematic transaction. Examples of problematic transactions include transactions that disable replication, delete important data, or cause the DB instance to become unavailable.

Syntax

```
CALL mysql.rds_skip_transaction_with_gtid (gtid_to_skip);
```
Parameter

\texttt{gtid\_to\_skip}

The GTID of the replication transaction to skip.

Usage notes

The master user must run the \texttt{mysql.rds\_skip\_transaction\_with\_gtid} procedure.

This procedure is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions.

Examples

The following example skips replication of the transaction with the GTID 3E11FA47-71CA-11E1-9E33-C80AA9429562:23.

\begin{verbatim}
call mysql.rds\_skip\_transaction\_with\_gtid('3E11FA47-71CA-11E1-9E33-C80AA9429562:23');
\end{verbatim}

\textbf{mysql.rds\_skip\_repl\_error}

Skips and deletes a replication error on a MySQL DB read replica.

Syntax

\begin{verbatim}
CALL mysql.rds\_skip\_repl\_error;
\end{verbatim}

Usage notes

The master user must run the \texttt{mysql.rds\_skip\_repl\_error} procedure on a read replica. For more information about this procedure, see \texttt{Calling the mysql.rds\_skip\_repl\_error procedure} (p. 1761).

To determine if there are errors, run the MySQL \texttt{SHOW REPLICA STATUS\G} command. If a replication error isn't critical, you can run \texttt{mysql.rds\_skip\_repl\_error} to skip the error. If there are multiple errors, \texttt{mysql.rds\_skip\_repl\_error} deletes the first error, then warns that others are present.

You can then use \texttt{SHOW REPLICA STATUS\G} to determine the correct course of action for the next error. For information about the values returned, see \texttt{SHOW REPLICA STATUS statement} in the MySQL documentation.

\textbf{Note}

Previous versions of MySQL used \texttt{SHOW SLAVE STATUS} instead of \texttt{SHOW REPLICA STATUS}. If you are using a MySQL version before 8.0.23, then use \texttt{SHOW SLAVE STATUS}.

For more information about addressing replication errors with Amazon RDS, see \texttt{Troubleshooting a MySQL read replica problem} (p. 1734).

Replication stopped error

When you call the \texttt{mysql.rds\_skip\_repl\_error} procedure, you might receive an error message stating that the replica is down or disabled.

This error message appears if you run the procedure on the primary instance instead of the read replica. You must run this procedure on the read replica for the procedure to work.

This error message might also appear if you run the procedure on the read replica, but replication can't be restarted successfully.
If you need to skip a large number of errors, the replication lag can increase beyond the default retention period for binary log (binlog) files. In this case, you might encounter a fatal error due to binlog files being purged before they have been replayed on the read replica. This purge causes replication to stop, and you can no longer call the `mysql.rds_skip_repl_error` command to skip replication errors.

You can mitigate this issue by increasing the number of hours that binlog files are retained on your source database instance. After you have increased the binlog retention time, you can restart replication and call the `mysql.rds_skip_repl_error` command as needed.

To set the binlog retention time, use the `mysql.rds_set_configuration` procedure and specify a configuration parameter of 'binlog retention hours' along with the number of hours to retain binlog files on the DB cluster. The following example sets the retention period for binlog files to 48 hours.

```sql
CALL mysql.rds_set_configuration('binlog retention hours', 48);
```

**mysql.rds_start_replication**

Initiates replication from an RDS for MySQL DB instance.

**Note**
You can use the `mysql.rds_start_replication_until` or `mysql.rds_start_replication_until_gtid` stored procedure to initiate replication from an RDS for MySQL DB instance and stop replication at the specified binary log file location.

**Syntax**

```sql
CALL mysql.rds_start_replication;
```

**Usage notes**

The master user must run the `mysql.rds_start_replication` procedure.

To import data from an instance of MySQL external to Amazon RDS, call `mysql.rds_start_replication` on the read replica to start the replication process after you call `mysql.rds_set_external_master` to build the replication configuration. For more information, see *Restoring a backup into a MySQL DB instance*.

To export data to an instance of MySQL external to Amazon RDS, call `mysql.rds_start_replication` and `mysql.rds_stop_replication` on the read replica to control some replication actions, such as purging binary logs. For more information, see *Exporting data from a MySQL DB instance by using replication*.

You can also call `mysql.rds_start_replication` on the read replica to restart any replication process that you previously stopped by calling `mysql.rds_stop_replication`. For more information, see *Working with DB instance read replicas*.

**mysql.rds_start_replication_until**

Initiates replication from an RDS for MySQL DB instance and stops replication at the specified binary log file location.

**Syntax**

```sql
CALL mysql.rds_start_replication_until ( 
```
Amazon Relational Database Service User Guide
Replicating

```
replication_log_file, replication_stop_point);
```

Parameters

**replication_log_file**

The name of the binary log on the source database instance contains the replication information.

**replication_stop_point**

The location in the replication_log_file binary log at which replication will stop.

Usage notes

The master user must run the `mysql.rds_start_replication_until` procedure.

The `mysql.rds_start_replication_until` procedure is available in these versions of RDS for MySQL:

- MySQL 8.0.26 and higher 8.0 versions
- All 5.7 versions

You can use this procedure with delayed replication for disaster recovery. If you have delayed replication configured, you can use this procedure to roll forward changes to a delayed read replica to the time just before a disaster. After this procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in [Promoting a read replica to be a standalone DB instance](p. 447).

You can configure delayed replication using the following stored procedures:

- `mysql.rds_set_configuration` (p. 1774)
- `mysql.rds_set_external_master_with_delay` (p. 1790)
- `mysql.rds_set_source_delay` (p. 1793)

The file name specified for the `replication_log_file` parameter must match the source database instance binlog file name.

When the `replication_stop_point` parameter specifies a stop location that is in the past, replication is stopped immediately.

Examples

The following example initiates replication and replicates changes until it reaches location 120 in the `mysql-bin-changelog.000777` binary log file.

```
call mysql.rds_start_replication_until(
    'mysql-bin-changelog.000777',
    120);
```

**mysql.rds_start_replication_until_gtid**

Initiates replication from an RDS for MySQL DB instance and stops replication immediately after the specified global transaction identifier (GTID).
Syntax

```sql
CALL mysql.rds_start_replication_until_gtid(gtid);
```

**Parameters**

`gtid`

The GTID after which replication is to stop.

**Usage notes**

The master user must run the `mysql.rds_start_replication_until_gtid` procedure. This procedure is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher.

You can use this procedure with delayed replication for disaster recovery. If you have delayed replication configured, you can use this procedure to roll forward changes to a delayed read replica to the time just before a disaster. After this procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in [Promoting a read replica to be a standalone DB instance](#).

You can configure delayed replication using the following stored procedures:

- `mysql.rds_set_configuration (p. 1774)`
- `mysql.rds_set_external_master_with_delay (p. 1790)`
- `mysql.rds_set_source_delay (p. 1793)`

When the `gtid` parameter specifies a transaction that has already been run by the replica, replication is stopped immediately.

**Examples**

The following example initiates replication and replicates changes until it reaches GTID 3E11FA47-71CA-11E1-9E33-C80AA9429562:23.

```sql
call mysql.rds_start_replication_until_gtid('3E11FA47-71CA-11E1-9E33-C80AA9429562:23');
```

**mysql.rds_stop_replication**

Stops replication from a MySQL DB instance.

**Syntax**

```sql
CALL mysql.rds_stop_replication;
```

**Usage notes**

The master user must run the `mysql.rds_stop_replication` procedure. If you are configuring replication to import data from an instance of MySQL running external to Amazon RDS, you call `mysql.rds_stop_replication` on the read replica to stop the replication process.
after the import has completed. For more information, see Restoring a backup into a MySQL DB instance (p. 1696).

If you are configuring replication to export data to an instance of MySQL external to Amazon RDS, you call mysql.rds_start_replication and mysql.rds_stop_replication on the read replica to control some replication actions, such as purging binary logs. For more information, see Exporting data from a MySQL DB instance by using replication (p. 1744).

You can also use mysql.rds_stop_replication to stop replication between two Amazon RDS DB instances. You typically stop replication to perform a long running operation on the read replica, such as creating a large index on the read replica. You can restart any replication process that you stopped by calling mysql.rds_start_replication (p. 1796) on the read replica. For more information, see Working with DB instance read replicas (p. 438).
Warming the InnoDB cache

The following stored procedures save, load, or cancel loading the InnoDB buffer pool on RDS for MySQL DB instances. For more information, see InnoDB cache warming for MySQL on Amazon RDS (p. 1641).

Topics

- `mysql.rds_innodb_buffer_pool_dump_now` (p. 1800)
- `mysql.rds_innodb_buffer_pool_load_abort` (p. 1800)
- `mysql.rds_innodb_buffer_pool_load_now` (p. 1800)

### mysql.rds_innodb_buffer_pool_dump_now

Dumps the current state of the buffer pool to disk.

**Syntax**

```sql
CALL mysql.rds_innodb_buffer_pool_dump_now();
```

**Usage notes**

The master user must run the `mysql.rds_innodb_buffer_pool_dump_now` procedure.

### mysql.rds_innodb_buffer_pool_load_abort

Cancels a load of the saved buffer pool state while in progress.

**Syntax**

```sql
CALL mysql.rds_innodb_buffer_pool_load_abort();
```

**Usage notes**

The master user must run the `mysql.rds_innodb_buffer_pool_load_abort` procedure.

### mysql.rds_innodb_buffer_pool_load_now

Loads the saved state of the buffer pool from disk.

**Syntax**

```sql
CALL mysql.rds_innodb_buffer_pool_load_now();
```

**Usage notes**

The master user must run the `mysql.rds_innodb_buffer_pool_load_now` procedure.
Amazon RDS supports DB instances that run the following versions and editions of Oracle Database:

- Oracle Database 21c (21.0.0.0)
- Oracle Database 19c (19.0.0.0)

**Note**
Oracle Database 11g, Oracle Database 12c, and Oracle Database 18c are legacy versions that are no longer supported in Amazon RDS.

Before creating a DB instance, complete the steps in the Setting up for Amazon RDS (p. 174) section of this guide. When you create a DB instance using your master account, the account gets DBA privileges, with some limitations. Use this account for administrative tasks such as creating additional database accounts. You can't use SYS, SYSTEM, or other Oracle-supplied administrative accounts.

You can create the following:

- DB instances
- DB snapshots
- Point-in-time restores
- Automated backups
- Manual backups

You can use DB instances running Oracle inside a VPC. You can also add features to your Oracle DB instance by enabling various options. Amazon RDS supports Multi-AZ deployments for Oracle as a high-availability, failover solution.

**Important**
To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that need advanced privileges. You can access your database using standard SQL clients such as Oracle SQL*Plus. However, you can't access the host directly by using Telnet or Secure Shell (SSH).

**Topics**

- Working with read replicas for Amazon RDS for Oracle (p. 1989)
- Adding options to Oracle DB instances (p. 2006)
- Upgrading the RDS for Oracle DB engine (p. 2119)
- Using third-party software with your RDS for Oracle DB instance (p. 2131)
Overview of Oracle on Amazon RDS

You can read the following sections to get an overview of RDS for Oracle.

Topics
- RDS for Oracle features (p. 1802)
- RDS for Oracle releases (p. 1805)
- RDS for Oracle licensing options (p. 1809)
- RDS for Oracle users and privileges (p. 1812)
- RDS for Oracle instance classes (p. 1812)
- RDS for Oracle database architecture (p. 1816)
- RDS for Oracle parameters (p. 1817)
- RDS for Oracle character sets (p. 1817)
- RDS for Oracle limitations (p. 1820)

RDS for Oracle features

Amazon RDS for Oracle supports most of the features and capabilities of Oracle Database. Some features might have limited support or restricted privileges. Some features are only available in Enterprise Edition, and some require additional licenses. For more information about Oracle Database features for specific Oracle Database versions, see the Oracle Database Licensing Information User Manual for the version you're using.

You can filter new Amazon RDS features on the What's New with Database? page. For Products, choose Amazon RDS. Then search using keywords such as Oracle 2022.

Note
The following lists are not exhaustive.

Topics
- New features in RDS for Oracle (p. 1802)
- Supported features in RDS for Oracle (p. 1802)
- Unsupported features in RDS for Oracle (p. 1804)

New features in RDS for Oracle

To see new RDS for Oracle features, use the following techniques:

- Search Document history (p. 2761) for the keyword Oracle.
- You can filter new Amazon RDS features on the What's New with Database? page. For Products, choose Amazon RDS. Then search for Oracle YYYY, where YYYY is a year such as 2022.

Supported features in RDS for Oracle

Amazon RDS for Oracle supports the following Oracle Database features:

- Advanced Compression
• Application Express (APEX)
  For more information, see Oracle Application Express (APEX) (p. 2025).
• Automatic Memory Management
• Automatic Undo Management
• Automatic Workload Repository (AWR)
  For more information, see Generating performance reports with Automatic Workload Repository (AWR) (p. 1891).
• Active Data Guard with Maximum Performance in the same AWS Region or across AWS Regions
  For more information, see Working with read replicas for Amazon RDS for Oracle (p. 1989).
• Blockchain tables (Oracle Database 21c and higher)
  For more information, see Managing Blockchain Tables, in the Oracle Database documentation.
• Continuous Query Notification (version 12.1.0.2.v7 and higher)
  For more information, see Using Continuous Query Notification (CQN) in the Oracle documentation.
• Data Redaction
• Database Change Notification
  For more information, see Database Change Notification in the Oracle documentation.

  Note
  This feature changes to Continuous Query Notification in Oracle Database 12c Release 1 (12.1) and higher.
• Database In-Memory (Oracle Database 12c and higher)
• Distributed Queries and Transactions
• Edition-Based Redefinition
  For more information, see Setting the default edition for a DB instance (p. 1895).
• EM Express (12c and higher)
  For more information, see Oracle Enterprise Manager (p. 2050).
• Fine-Grained Auditing
• Flashback Table, Flashback Query, Flashback Transaction Query
• Gradual password rollover for applications (Oracle Database 21c and higher)
  For more information, see Managing Gradual Database Password Rollover for Applications, in the Oracle Database documentation.
• HugePages
  For more information, see Turning on HugePages for an RDS for Oracle instance (p. 1958).
• Import/export (legacy and Data Pump) and SQL*Loader
  For more information, see Importing data into Oracle on Amazon RDS (p. 1963).
• Java Virtual Machine (JVM)
  For more information, see Oracle Java virtual machine (p. 2047).
• JavaScript (Oracle Database 21c and higher)
  For more information, see DBMS_MLE in the Oracle Database documentation.
• Label Security (Oracle Database 12c and higher)
  For more information, see Oracle Label Security (p. 2065).
• Locator
  For more information, see Oracle Locator (p. 2068).
• Materialized Views
• Multimedia
  For more information, see Oracle Multimedia (p. 2071).
• Multitenant (single-tenant configuration only)
  The multitenant architecture is supported for all Oracle Database 19c and higher releases. For more information, see Overview of RDS for Oracle CDBs (p. 1856) and Limitations of a single-tenant CDB (p. 1821).
• Network encryption
  For more information, see Oracle native network encryption (p. 2073) and Oracle Secure Sockets Layer (p. 2084).
• Partitioning
• Application-level sharding (but not the Oracle Sharding feature)
• Spatial and Graph
  For more information, see Oracle Spatial (p. 2091).
• Star Query Optimization
• Streams and Advanced Queuing
• Summary Management – Materialized View Query Rewrite
• Text (File and URL data store types are not supported)
• Total Recall
• Transparent Data Encryption (TDE)
  For more information, see Oracle Transparent Data Encryption (p. 2113).
• Unified Auditing, Mixed Mode
  For more information, see Mixed mode auditing in the Oracle documentation.
• XML DB (without the XML DB Protocol Server)
  For more information, see Oracle XML DB (p. 2118).
• Virtual Private Database

Unsupported features in RDS for Oracle

Amazon RDS for Oracle doesn't support the following Oracle Database features:

• Automatic Storage Management (ASM)
• Database Vault
• Flashback Database

  Note
  For alternative solutions, see the AWS Database Blog entry Alternatives to the Oracle flashback database feature in Amazon RDS for Oracle.
• FTP and SFTP
• Hybrid partitioned tables
• Messaging Gateway
• Oracle Enterprise Manager Cloud Control Management Repository
• Real Application Clusters (Oracle RAC)
• Real Application Security (RAS)
• Real Application Testing
• Unified Auditing, Pure Mode
• Workspace Manager (WMSYS) schema

Note
The preceding list is not exhaustive.

Warning
In general, Amazon RDS doesn't prevent you from creating schemas for unsupported features. However, if you create schemas for Oracle features and components that require SYSDBA privileges, you can damage the data dictionary and affect the availability of your DB instance. Use only supported features and schemas that are available in Adding options to Oracle DB instances (p. 2006).

RDS for Oracle releases

Amazon RDS for Oracle supports multiple Oracle Database releases.

Note
For information about upgrading your releases, see Upgrading the RDS for Oracle DB engine (p. 2119).

Topics
• Oracle Database 21c with Amazon RDS (p. 1805)
• Oracle Database 19c with Amazon RDS (p. 1807)
• Oracle Database 12c with Amazon RDS (p. 1808)

Oracle Database 21c with Amazon RDS

Amazon RDS supports Oracle Database 21c, which includes Oracle Enterprise Edition and Oracle Standard Edition Two. Oracle Database 21c (21.0.0.0) includes many new features and updates from the previous version. A key change is that Oracle Database 21c supports only the multitenant architecture: you can no longer create a database as a traditional non-CDB. To learn more about the differences between CDBs and non-CDBs, see Limitations of a single-tenant CDB (p. 1821).

In this section, you can find the features and changes important to using Oracle Database 21c (21.0.0.0) on Amazon RDS. For a complete list of the changes, see the Oracle database 21c documentation. For a complete list of features supported by each Oracle Database 21c edition, see Permitted features, options, and management packs by Oracle database offering in the Oracle documentation.

Amazon RDS parameter changes for Oracle Database 21c (21.0.0.0)

Oracle Database 21c (21.0.0.0) includes several new parameters and parameters with new ranges and new default values.

Topics
• New parameters (p. 1806)
• Changes for the compatible parameter (p. 1807)
• Removed parameters (p. 1807)
### New parameters

The following table shows the new Amazon RDS parameters for Oracle Database 21c (21.0.0.0).

<table>
<thead>
<tr>
<th>Name</th>
<th>Range of values</th>
<th>Default value</th>
<th>Modifiable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>blockchain_table_max_no_drop</td>
<td>NONE</td>
<td>0</td>
<td>NONE</td>
<td>Y</td>
</tr>
<tr>
<td>dbnest_enable</td>
<td>NONE</td>
<td>CDB_RESOURCE_PDB_ALL</td>
<td>NONE</td>
<td>N</td>
</tr>
<tr>
<td>dbnest_pdb_fs_conf</td>
<td>NONE</td>
<td>pathname</td>
<td>NONE</td>
<td>N</td>
</tr>
<tr>
<td>diagnostics_control</td>
<td>ERROR</td>
<td>WARNING</td>
<td>IGNORE</td>
<td>Y</td>
</tr>
<tr>
<td>drcp_dedicated_opt</td>
<td>YES</td>
<td>NO</td>
<td>YES</td>
<td>Y</td>
</tr>
<tr>
<td>enable_per_pdb_drcp</td>
<td>true</td>
<td>false</td>
<td>true</td>
<td>N</td>
</tr>
<tr>
<td>inmemory_deep_vectorization</td>
<td>true</td>
<td>false</td>
<td>true</td>
<td>Y</td>
</tr>
<tr>
<td>mandatory_user_profile</td>
<td>profile_name</td>
<td>N/A</td>
<td>N</td>
<td>N</td>
</tr>
<tr>
<td>optimizer_capture_sql_quarantine</td>
<td>false</td>
<td>false</td>
<td>Y</td>
<td>Enables or disables the deep vectorization framework.</td>
</tr>
<tr>
<td>optimizer_use_sql_quarantine</td>
<td>false</td>
<td>false</td>
<td>Y</td>
<td>Enables or disables the automatic creation of SQL Quarantine configurations.</td>
</tr>
<tr>
<td>result_cache_execution_threshold</td>
<td>0 to 68719476736</td>
<td>2</td>
<td>Y</td>
<td>Specifies the maximum number of times a PL/SQL function can be executed before its result is stored in the result cache.</td>
</tr>
<tr>
<td>result_cache_max_temp_result</td>
<td>0 to 100</td>
<td>5</td>
<td>Y</td>
<td>Specifies the percentage of RESULT_CACHE_MAX_TEMP_SIZE that any single cached query result can consume.</td>
</tr>
</tbody>
</table>
### Oracle versions

<table>
<thead>
<tr>
<th>Name</th>
<th>Range of values</th>
<th>Default value</th>
<th>Modifiable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>result_cache_max_temp_size</code></td>
<td>0 to 2199023255552</td>
<td>RESULT_CACHE_SIZE * 10</td>
<td>Y</td>
<td>Specifies the maximum amount of temporary tablespace (in bytes) that can be consumed by the result cache.</td>
</tr>
<tr>
<td><code>sga_min_size</code></td>
<td>0 to 2199023255552 (maximum value is 50% of sga_target)</td>
<td>0</td>
<td>Y</td>
<td>Indicates a possible minimum value for SGA usage of a pluggable database (PDB).</td>
</tr>
<tr>
<td><code>tablespace_encryption_default_algorithm</code></td>
<td>GOST256</td>
<td>AES128</td>
<td>Y</td>
<td>Specifies the default algorithm the database uses when encrypting a tablespace.</td>
</tr>
</tbody>
</table>

**Changes for the compatible parameter**

The `compatible` parameter has a new maximum value for Oracle Database 21c (21.0.0.0) on Amazon RDS. The following table shows the new default value.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Oracle Database 21c (21.0.0.0) maximum value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compatible</code></td>
<td>21.0.0</td>
</tr>
</tbody>
</table>

**Removed parameters**

The following parameters were removed in Oracle Database 21c (21.0.0.0):

- `remote_os_authent`
- `sec_case_sensitive_logon`
- `unified_audit_sga_queue_size`

### Oracle Database 19c with Amazon RDS

Amazon RDS supports Oracle Database 19c, which includes Oracle Enterprise Edition and Oracle Standard Edition Two.

Oracle Database 19c (19.0.0.0) includes many new features and updates from the previous version. In this section, you can find the features and changes important to using Oracle Database 19c (19.0.0.0) on Amazon RDS. For a complete list of the changes, see the [Oracle database 19c documentation](https://docs.oracle.com/en/database/oracle/oracle-database/19/index.html). For a complete list of features supported by each Oracle Database 19c edition, see [Permitted features, options, and management packs by Oracle database offering](https://docs.oracle.com/en/database/oracle/oracle-database/19/index.html) in the Oracle documentation.

**Amazon RDS parameter changes for Oracle Database 19c (19.0.0.0)**

Oracle Database 19c (19.0.0.0) includes several new parameters and parameters with new ranges and new default values.
New parameters

The following table shows the new Amazon RDS parameters for Oracle Database 19c (19.0.0.0).

<table>
<thead>
<tr>
<th>Name</th>
<th>Values</th>
<th>Modifiable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_signature_enable</td>
<td>TRUE, FALSE (default)</td>
<td>Y</td>
<td>Enables or disables the LOB locator signature feature.</td>
</tr>
<tr>
<td>max_datapump_parallel_per_job</td>
<td>1 to 1024, or AUTO</td>
<td>Y</td>
<td>Specifies the maximum number of parallel processes allowed for each Oracle Data Pump job.</td>
</tr>
</tbody>
</table>

Changes to the compatible parameter

The compatible parameter has a new maximum value for Oracle Database 19c (19.0.0.0) on Amazon RDS. The following table shows the new default value.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Oracle Database 19c (19.0.0.0) maximum value</th>
</tr>
</thead>
<tbody>
<tr>
<td>compatible</td>
<td>19.0.0</td>
</tr>
</tbody>
</table>

Removed parameters

The following parameters were removed in Oracle Database 19c (19.0.0.0):

- exafusion_enabled
- max_connections
- o7_dictionary_access

Oracle Database 12c with Amazon RDS

Amazon RDS has deprecated support for Oracle Database 12c on both Oracle Enterprise Edition and Oracle Standard Edition 2.

Topics

- Oracle Database 12c Release 2 (12.2.0.1) with Amazon RDS (p. 1808)
- Oracle Database 12c Release 1 (12.1.0.2) with Amazon RDS (p. 1809)

Oracle Database 12c Release 2 (12.2.0.1) with Amazon RDS

On March 31, 2022, Oracle Corporation deprecated support for Oracle Database 12c Release 2 (12.2.0.1) for BYOL and Li. On this date, the release moved from Oracle Extended Support to Oracle Sustaining Support.
Support, indicating the end of support for this release. For more information, see the end of support timeline on AWS re:Post.

<table>
<thead>
<tr>
<th>Date</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>April 1, 2022</td>
<td>Amazon RDS began automatic upgrades of your Oracle Database 12c Release 2 (12.2.0.1) instances to Oracle Database 19c.</td>
</tr>
<tr>
<td>April 1, 2022</td>
<td>Amazon RDS began automatic upgrades to Oracle Database 19c for any Oracle Database 12c Release 2 (12.2.0.1) DB instances restored from snapshots. The automatic upgrade occurs during maintenance windows. If maintenance windows aren’t available when the upgrade needs to occur, Amazon RDS upgrades the engine immediately.</td>
</tr>
</tbody>
</table>

**Oracle Database 12c Release 1 (12.1.0.2) with Amazon RDS**

On July 31, 2022, Amazon RDS deprecated support for Oracle Database 12c Release 1 (12.1.0.2) for BYOL and LI. The release moved from Oracle Extended Support to Oracle Sustaining Support, indicating that Oracle Support will no longer release critical patch updates for this release. For more information, see the end of support timeline on AWS re:Post.

<table>
<thead>
<tr>
<th>Date</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>August 1, 2022</td>
<td>Amazon RDS began automatic upgrades of your Oracle Database 12c Release 1 (12.1.0.2) instances to the latest Release Update (RU) for Oracle Database 19c. The automatic upgrade occurs during maintenance windows. If maintenance windows aren’t available when the upgrade needs to occur, Amazon RDS upgrades the engine immediately.</td>
</tr>
<tr>
<td>August 1, 2022</td>
<td>Amazon RDS began automatic upgrades to Oracle Database 19c for any Oracle Database 12c Release 1 (12.1.0.2) DB instances restored from snapshots.</td>
</tr>
</tbody>
</table>

**RDS for Oracle licensing options**

Amazon RDS for Oracle has two licensing options: License Included (LI) and Bring Your Own License (BYOL). After you create an Oracle DB instance on Amazon RDS, you can change the licensing model by modifying the DB instance. For more information, see Modifying an Amazon RDS DB instance (p. 401).

**License Included**

In the License Included model, you don’t need to purchase Oracle Database licenses separately. AWS holds the license for the Oracle database software. In this model, if you have an AWS Support account with case support, contact AWS Support for both Amazon RDS and Oracle Database service requests. The License Included model is only supported on Amazon RDS for Oracle Database Standard Edition Two (SE2).

**Bring Your Own License (BYOL)**

In the BYOL model, you can use your existing Oracle Database licenses to deploy databases on Amazon RDS. Make sure that you have the appropriate Oracle Database license (with Software Update License and Support) for the DB instance class and Oracle Database edition you wish to run. You must also follow Oracle’s policies for licensing Oracle Database software in the cloud computing environment. For more information on Oracle’s licensing policy for Amazon EC2, see Licensing Oracle software in the cloud computing environment.
In this model, you continue to use your active Oracle support account, and you contact Oracle directly for Oracle Database service requests. If you have an AWS Support account with case support, you can contact AWS Support for Amazon RDS issues. Amazon Web Services and Oracle have a multi-vendor support process for cases that require assistance from both organizations.

Amazon RDS supports the BYOL model only for Oracle Database Enterprise Edition (EE) and Oracle Database Standard Edition Two (SE2).

**Integrating with AWS License Manager**

To make it easier to monitor Oracle license usage in the BYOL model, [AWS License Manager](https://aws.amazon.com/license-manager/) integrates with Amazon RDS for Oracle. License Manager supports tracking of RDS for Oracle engine editions and licensing packs based on virtual cores (vCPUs). You can also use License Manager with AWS Organizations to manage all of your organizational accounts centrally.

The following table shows the product information filters for RDS for Oracle.

<table>
<thead>
<tr>
<th>Filter</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Engine Edition</td>
<td>oracle-ee</td>
<td>Oracle Database Enterprise Edition (EE)</td>
</tr>
<tr>
<td></td>
<td>oracle-se2</td>
<td>Oracle Database Standard Edition Two (SE2)</td>
</tr>
<tr>
<td></td>
<td>olap</td>
<td>See <a href="https://docs.aws.amazon.com/OracleOLAPGuide/latest/OracleOLAPGuide.html">Oracle OLAP (p. 2081)</a></td>
</tr>
<tr>
<td></td>
<td>diagnostic pack</td>
<td>See <a href="https://docs.oracle.com/database/121/SQLTPD/index.html">Oracle SQLT (p. 2094)</a></td>
</tr>
<tr>
<td></td>
<td>sqlt</td>
<td>See <a href="https://docs.oracle.com/database/121/SQLTPD/index.html">Oracle SQLT (p. 2094)</a></td>
</tr>
<tr>
<td></td>
<td>tuning pack sqlt</td>
<td>See <a href="https://docs.oracle.com/database/121/SQLTPD/index.html">Oracle SQLT (p. 2094)</a></td>
</tr>
</tbody>
</table>

To track license usage of your Oracle DB instances, you can create a license configuration. In this case, RDS for Oracle resources that match the product information filter are automatically associated with the license configuration. Discovery of Oracle DB instances can take up to 24 hours.

**Console**

**To create a license configuration to track the license usage of your Oracle DB instances**

2. Create a license configuration.

   For instructions, see [Create a license configuration](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/license-manager.html) in the *AWS License Manager User Guide*.

   Add a rule for an **RDS Product Information Filter** in the **Product Information** panel.

   For more information, see [ProductInformation](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/license-manager.html) in the *AWS License Manager API Reference*.

**AWS CLI**

To create a license configuration by using the AWS CLI, call the `create-license-configuration` command. Use the `--cli-input-json` or `--cli-input-yaml` parameters to pass the parameters to the command.
Example

The following code creates a license configuration for Oracle Enterprise Edition.

```bash
aws license-manager create-license-configuration --cli-input-json file://rds-oracle-ee.json
```

The following is the sample `rds-oracle-ee.json` file used in the example.

```json
{
    "Name": "rds-oracle-ee",
    "Description": "RDS Oracle Enterprise Edition",
    "LicenseCountingType": "vCPU",
    "LicenseCountHardLimit": false,
    "ProductInformationList": [
        {
            "ResourceType": "RDS",
            "ProductInformationFilterList": [
                {
                    "ProductInformationFilterName": "Engine Edition",
                    "ProductInformationFilterValue": ["oracle-ee"],
                    "ProductInformationFilterComparator": "EQUALS"
                }
            ]
        }
    ]
}
```

For more information about product information, see Automated discovery of resource inventory in the AWS License Manager User Guide.

For more information about the `--cli-input` parameter, see Generating AWS CLI skeleton and input parameters from a JSON or YAML input file in the AWS CLI User Guide.

Migrating between Oracle editions

If you have an unused BYOL Oracle license appropriate for the edition and class of DB instance that you plan to run, you can migrate from Standard Edition 2 (SE2) to Enterprise Edition (EE). You can’t migrate from Enterprise Edition to other editions.

To change the edition and retain your data

1. Create a snapshot of the DB instance.
   
   For more information, see Creating a DB snapshot (p. 613).

2. Restore the snapshot to a new DB instance, and select the Oracle database edition you want to use.
   
   For more information, see Restoring from a DB snapshot (p. 615).

3. (Optional) Delete the old DB instance, unless you want to keep it running and have the appropriate Oracle Database licenses for it.
   
   For more information, see Deleting a DB instance (p. 489).

Licensing Oracle Multi-AZ deployments

Amazon RDS supports Multi-AZ deployments for Oracle as a high-availability, failover solution. We recommend Multi-AZ for production workloads. For more information, see Configuring and managing a Multi-AZ deployment (p. 492).
If you use the Bring Your Own License model, you must have a license for both the primary DB instance and the standby DB instance in a Multi-AZ deployment.

**RDS for Oracle users and privileges**

When you create an Amazon RDS for Oracle DB instance, the default master user has most of the maximum user permissions on the DB instance. Use the master user account for any administrative tasks, such as creating additional user accounts in your database. Because RDS is a managed service, you aren't allowed to log in as SYS and SYSTEM, and thus don't have SYSDBA privileges.

**Topics**
- [Limitations for Oracle DBA privileges](p. 1812)
- [How to manage privileges on SYS objects](p. 1812)

**Limitations for Oracle DBA privileges**

In the database, a *role* is a collection of privileges that you can grant to or revoke from a user. An Oracle database uses roles to provide security. For more information, see [Configuring Privilege and Role Authorization](p. 2046) in the Oracle Database documentation.

The predefined role DBA normally allows all administrative privileges on an Oracle database. When you create a DB instance, your master user account gets DBA privileges (with some limitations). To deliver a managed experience, an RDS for Oracle database doesn't provide the following privileges for the DBA role:

- ALTER DATABASE
- ALTER SYSTEM
- CREATE ANY DIRECTORY
- DROP ANY DIRECTORY
- GRANT ANY PRIVILEGE
- GRANT ANY ROLE

For more RDS for Oracle system privilege and role information, see [Master user account privileges](p. 2699).

**How to manage privileges on SYS objects**

You can manage privileges on SYS objects by using the `rdsadmin.rdsadmin_util` package. For example, if you create the database user `myuser`, you could use the `rdsadmin.rdsadmin_util.grant_sys_object` procedure to grant `SELECT` privileges on `V_$SQLAREA` to `myuser`. For more information, see the following topics:

- [Granting SELECT or EXECUTE privileges to SYS objects](p. 1875)
- [Revoking SELECT or EXECUTE privileges on SYS objects](p. 1877)
- [Granting privileges to non-master users](p. 1877)

**RDS for Oracle instance classes**

The computation and memory capacity of a DB instance is determined by its instance class. The DB instance class you need depends on your processing power and memory requirements.
Supported RDS for Oracle instance classes

The supported RDS for Oracle instance classes are a subset of the RDS DB instance classes. For the complete list of RDS instance classes, see DB instance classes (p. 11).

RDS for Oracle also offers instance classes that are optimized for workloads that require additional memory, storage, and I/O per vCPU. These instance classes use the following naming convention:

```
db.r5b. instance_size .tpc threads_per_core .mem ratio
db.r5. instance_size .tpc threads_per_core .mem ratio
```

The following is an example of a supported instance class:

```
db.r5b.4xlarge.tpc2.mem2x
```

The components of the preceding instance class name are as follows:

- `db.r5b.4xlarge` – The name of the instance class.
- `tpc2` – The threads per core. A value of 2 means that multithreading is turned on. If the value is 1, multithreading is turned off.
- `mem2x` – The ratio of additional memory to the standard memory for the instance class. In this example, the optimization provides twice as much memory as a standard db.r5.4xlarge instance.

The following table lists all instance classes supported for Oracle Database. Oracle Database 12c Release 1 (12.1.0.2) and Oracle Database 12c Release 2 (12.2.0.2) are listed in the table, but support for these releases is deprecated. For information about the memory attributes of each type, see RDS for Oracle instance types.

<table>
<thead>
<tr>
<th>Oracle edition</th>
<th>Oracle Database 19c and higher, Oracle Database 12c Release 2 (12.2.0.1) (deprecated)</th>
<th>Oracle Database 12c Release 1 (12.1.0.2) (deprecated)</th>

</table>
Note
We encourage all BYOL customers to consult their licensing agreement to assess the impact of Amazon RDS for Oracle deprecations. For more information on the compute capacity of DB instance classes supported by RDS for Oracle, see DB instance classes (p. 11) and Configuring the processor for a DB instance class in RDS for Oracle (p. 71).

Note
If you have DB snapshots of DB instances that were using deprecated DB instance classes, you can choose a DB instance class that is not deprecated when you restore the DB snapshots. For more information, see Restoring from a DB snapshot (p. 615).

Deprecated Oracle DB instance classes

The following DB instance classes are deprecated for RDS for Oracle:

- db.m1, db.m2, db.m3, db.m4
- db.t3.micro (supported only on 12.1.0.2, which is deprecated)
- db.t1, db.t2
- db.r1, db.r2, db.r3, db.r4

The preceding DB instance classes have been replaced by better performing DB instance classes that are generally available at a lower cost. If you have DB instances that use deprecated DB instance classes, you have the following options:

- Allow Amazon RDS to modify each DB instance automatically to use a comparable non-deprecated DB instance class. For deprecation timelines, see DB instance class types (p. 11).
- Change the DB instance class yourself by modifying the DB instance. For more information, see Modifying an Amazon RDS DB instance (p. 401).

If you have DB snapshots of DB instances that were using deprecated DB instance classes, you can choose a DB instance class that is not deprecated when you restore the DB snapshots. For more information, see Restoring from a DB snapshot (p. 615).

RDS for Oracle database architecture

The multitenant architecture enables an Oracle database to function as a multitenant container database (CDB). A CDB can include customer-created pluggable databases (PDBs). A non-CDB is an Oracle database that uses the traditional architecture, which can’t contain PDBs. For more information about the multitenant architecture, see Oracle Multitenant Administrator’s Guide.

For Oracle Database 19c and higher, RDS for Oracle supports the single-tenant configuration of the multitenant architecture. In this case, your CDB contains only one PDB. The single-tenant configuration of the multitenant architecture uses the same RDS APIs as the non-CDB architecture. Thus, your experience with a PDB is mostly identical to your experience with a non-CDB.

Note
You can’t access the CDB itself.

In Oracle Database 21c and higher, all databases are CDBs. In contrast, you can create an Oracle Database 19c DB instance as either a CDB or non-CDB. You can’t upgrade a non-CDB to a CDB, but you convert an Oracle Database 19c non-CDB to a CDB, and then upgrade it. You can’t convert a CDB to a non-CDB.

For more information, see the following resources:

- Working with CDBs in RDS for Oracle (p. 1856)
RDS for Oracle parameters

In Amazon RDS, you manage parameters using parameter groups. For more information, see Working with parameter groups (p. 347). To view the supported parameters for a specific Oracle Database edition and version, run the AWS CLI command describe-engine-default-parameters.

For example, to view the supported parameters for the Enterprise Edition of Oracle Database 19c, run the following command.

```
aws rds describe-engine-default-parameters
   --db-parameter-group-family oracle-ee-19
```

RDS for Oracle character sets

RDS for Oracle supports two types of character sets: the DB character set and national character set.

**DB character set**

The Oracle database character set is used in the CHAR, VARCHAR2, and CLOB data types. The database also uses this character set for metadata such as table names, column names, and SQL statements. The Oracle database character set is typically referred to as the **DB character set**.

You set the character set when you create a DB instance. You can't change the DB character set after you create the database.

**Supported DB character sets**

The following table lists the Oracle DB character sets that are supported in Amazon RDS. You can use a value from this table with the --character-set-name parameter of the AWS CLI create-db-instance command or with the CharacterSetName parameter of the Amazon RDS API CreateDBInstance operation.

```
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AL32UTF8</td>
<td>Unicode 5.0 UTF-8 Universal character set (default)</td>
</tr>
<tr>
<td>AR8ISO8859P6</td>
<td>ISO 8859-6 Latin/Arabic</td>
</tr>
<tr>
<td>AR8MSWIN1256</td>
<td>Microsoft Windows Code Page 1256 8-bit Latin/Arabic</td>
</tr>
<tr>
<td>BLT8ISO8859P13</td>
<td>ISO 8859-13 Baltic</td>
</tr>
<tr>
<td>BLT8MSWIN1257</td>
<td>Microsoft Windows Code Page 1257 8-bit Baltic</td>
</tr>
<tr>

<td>ISO 8859-5 Latin/Cyrillic</td>
</tr>
<tr>
<td>CL8MSWIN1251</td>
<td>Microsoft Windows Code Page 1251 8-bit Latin/Cyrillic</td>
</tr>
</tbody>
</table>
```

Note

The character set for a CDB is always AL32UTF8. You can set a different character set for the PDB only.

**NLS_LANG environment variable**

A *locale* is a set of information addressing linguistic and cultural requirements that corresponds to a given language and country. Setting the NLS_LANG environment variable in your client's environment is the simplest way to specify locale behavior for Oracle. This variable sets the language and territory used by the client application and the database server. It also indicates the client's character set, which corresponds to the character set for data entered or displayed by a client application. For more information on NLS_LANG and character sets, see [What is a character set or code page?](#) in the Oracle documentation.

**NLS initialization parameters**

You can also set the following National Language Support (NLS) initialization parameters at the instance level for an Oracle DB instance in Amazon RDS:

- NLS_DATE_FORMAT
- NLS_LENGTH_SEMANTICS
- NLS_NCHAR_CONV_EXCP
- NLS_TIME_FORMAT
- NLS_TIME_TZ_FORMAT
- NLS_TIMESTAMP_FORMAT
- NLS_TIMESTAMP_TZ_FORMAT

For information about modifying instance parameters, see [Working with parameter groups](#).

You can set other NLS initialization parameters in your SQL client. For example, the following statement sets the NLS_LANGUAGE initialization parameter to GERMAN in a SQL client that is connected to an Oracle DB instance:

```sql
ALTER SESSION SET NLS_LANGUAGE=GERMAN;
```

For information about connecting to an Oracle DB instance with a SQL client, see [Connecting to your RDS for Oracle DB instance](#).

**National character set**

The national character set is used in the NCHAR, NVARCHAR2, and NCL0B data types. The national character set is typically referred to as the *NCHAR character set*. Unlike the DB character set, the NCHAR character set doesn't affect database metadata.

The NCHAR character set supports the following character sets:

- AL16UTF16 (default)
- UTF8

You can specify either value with the `--nchar-character-set-name` parameter of the `create-db-instance` command (AWS CLI version 2 only). If you use the Amazon RDS API, specify the `NcharCharacterSetName` parameter of `CreateDBInstance` operation. You can't change the national character set after you create the database.
For more information about Unicode in Oracle databases, see [Supporting multilingual databases with unicode](#) in the Oracle documentation.

## RDS for Oracle limitations

In the following sections, you can find important limitations of using RDS for Oracle.

**Note**

This list is not exhaustive.

### Topics

- [Oracle file size limits in Amazon RDS (p. 1820)](#)
- [Public synonyms for Oracle-supplied schemas (p. 1820)](#)
- [Schemas for unsupported features (p. 1820)](#)
- [Limitations for Oracle DBA privileges (p. 1812)](#)
- [Limitations of a single-tenant CDB (p. 1821)](#)
- [Deprecation of TLS 1.0 and 1.1 Transport Layer Security (p. 1821)](#)

### Oracle file size limits in Amazon RDS

The maximum size of a single file on RDS for Oracle DB instances is 16 TiB (tebibytes). This limit is imposed by the ext4 filesystem used by the instance. Thus, Oracle bigfile data files are limited to 16 TiB. If you try to resize a data file in a bigfile tablespace to a value over the limit, you receive an error such as the following.

```
ORA-01237: cannot extend datafile 6
ORA-01110: data file 6: '/rdsdbdata/db/mydir/datafile/myfile.dbf'
ORA-27059: could not reduce file size
Linux-x86_64 Error: 27: File too large
Additional information: 2
```

### Public synonyms for Oracle-supplied schemas

Don't create or modify public synonyms for Oracle-supplied schemas, including SYS, SYSTEM, and RDSADMIN. Such actions might result in invalidation of core database components and affect the availability of your DB instance.

You can create public synonyms referencing objects in your own schemas.

### Schemas for unsupported features

In general, Amazon RDS doesn't prevent you from creating schemas for unsupported features. However, if you create schemas for Oracle features and components that require SYS privileges, you can damage the data dictionary and affect your instance availability. Use only supported features and schemas that are available in [Adding options to Oracle DB instances (p. 2006)](#).

### Limitations for Oracle DBA privileges

In the database, a role is a collection of privileges that you can grant to or revoke from a user. An Oracle database uses roles to provide security.

The predefined role DBA normally allows all administrative privileges on an Oracle database. When you create a DB instance, your master user account gets DBA privileges (with some limitations). To deliver a
managed experience, an RDS for Oracle database doesn't provide the following privileges for the DBA role:

- ALTER DATABASE
- ALTER SYSTEM
- CREATE ANY DIRECTORY
- DROP ANY DIRECTORY
- GRANT ANY PRIVILEGE
- GRANT ANY ROLE

Use the master user account for administrative tasks such as creating additional user accounts in the database. You can't use SYS, SYSTEM, and other Oracle-supplied administrative accounts.

**Limitations of a single-tenant CDB**

The following options aren't supported for the single-tenant configuration of the multitenant architecture:

- Database Activity Streams
- Oracle Enterprise Manager
- Oracle Enterprise Manager Agent
- Oracle Label Security

The following operations work in a single-tenant CDB, but no customer-visible mechanism can detect the current status of the operations:

- [Enabling and disabling block change tracking](p. 1919)
- [Enabling auditing for the SYS.AUD$ table](p. 1896)

**Note**

Auditing information isn't available from within the PDB.

**Deprecation of TLS 1.0 and 1.1 Transport Layer Security**

Transport Layer Security protocol versions 1.0 and 1.1 (TLS 1.0 and TLS 1.1) are deprecated. In accordance with security best practices, Oracle has deprecated the use of TLS 1.0 and TLS 1.1. To meet your security requirements, RDS for Oracle strongly recommends that you use TLS 1.2 instead.
Connecting to your RDS for Oracle DB instance

After Amazon RDS provisions your Oracle DB instance, you can use any standard SQL client application to log in to your DB instance. Because RDS is a managed service, you can't log in as SYS or SYSTEM. For more information, see RDS for Oracle users and privileges (p. 1812).

In this topic, you learn how to use Oracle SQL Developer or SQL*Plus to connect to an RDS for Oracle DB instance. For an example that walks you through the process of creating and connecting to a sample DB instance, see Creating and connecting to an Oracle DB instance (p. 222).

Topics

- Finding the endpoint of your RDS for Oracle DB instance (p. 1822)
- Connecting to your DB instance using Oracle SQL developer (p. 1824)
- Connecting to your DB instance using SQL*Plus (p. 1826)
- Considerations for security groups (p. 1827)
- Considerations for process architecture (p. 1827)
- Troubleshooting connections to your Oracle DB instance (p. 1827)
- Modifying connection properties using sqlnet.ora parameters (p. 1828)

Finding the endpoint of your RDS for Oracle DB instance

Each Amazon RDS DB instance has an endpoint, and each endpoint has the DNS name and port number for the DB instance. To connect to your DB instance using a SQL client application, you need the DNS name and port number for your DB instance.

You can find the endpoint for a DB instance using the Amazon RDS console or the AWS CLI.

Note

If you are using Kerberos authentication, see Connecting to Oracle with Kerberos authentication (p. 1847).

Console

To find the endpoint using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the console, choose the AWS Region of your DB instance.
3. Find the DNS name and port number for your DB instance.
   a. Choose Databases to display a list of your DB instances.
   b. Choose the Oracle DB instance name to display the instance details.
   c. On the Connectivity & security tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.
To find the endpoint of an Oracle DB instance by using the AWS CLI, call the `describe-db-instances` command.

**Example To find the endpoint using the AWS CLI**

```bash
aws rds describe-db-instances
```

Search for `Endpoint` in the output to find the DNS name and port number for your DB instance. The `Address` line in the output contains the DNS name. The following is an example of the JSON endpoint output.

```json
"Endpoint": {
   "HostedZoneId": "Z1PVIF0B656C1W",
   "Port": 3306,
   "Address": "myinstance.123456789012.us-west-2.rds.amazonaws.com"
}
```
Connecting to your DB instance using Oracle SQL developer

In this procedure, you connect to your DB instance by using Oracle SQL Developer. To download a standalone version of this utility, see the Oracle SQL developer downloads page.

To connect to your DB instance, you need its DNS name and port number. For information about finding the DNS name and port number for a DB instance, see Finding the endpoint of your RDS for Oracle DB instance (p. 1822).

To connect to a DB instance using SQL developer

1. Start Oracle SQL Developer.
2. On the Connections tab, choose the add (+) icon.

   ![Oracle SQL Developer: Start Page](image)

   ![Connections](image)

3. In the New/Select Database Connection dialog box, provide the information for your DB instance:
   - For Connection Name, enter a name that describes the connection, such as Oracle-RDS.
   - For Username, enter the name of the database administrator for the DB instance.
   - For Password, enter the password for the database administrator.
   - For Hostname, enter the DNS name of the DB instance.
   - For Port, enter the port number.
• For SID, enter the DB name. You can find the DB name on the Configuration tab of your database details page.

The completed dialog box should look similar to the following.

4. Choose Connect.

5. You can now start creating your own databases and running queries against your DB instance and databases as usual. To run a test query against your DB instance, do the following:

   a. In the Worksheet tab for your connection, enter the following SQL query.

   ```sql
   SELECT NAME FROM V$DATABASE;
   ```

   b. Choose the execute icon to run the query.

   SQL Developer returns the database name.
Connecting to your DB instance using SQL*Plus

You can use a utility like SQL*Plus to connect to an Amazon RDS DB instance running Oracle. To download Oracle Instant Client, which includes a standalone version of SQL*Plus, see Oracle Instant Client Downloads.

To connect to your DB instance, you need its DNS name and port number. For information about finding the DNS name and port number for a DB instance, see Finding the endpoint of your RDS for Oracle DB instance (p. 1822).

Example To connect to an Oracle DB instance using SQL*Plus

In the following examples, substitute the user name of your DB instance administrator. Also, substitute the DNS name for your DB instance, and then include the port number and the Oracle SID. The SID value is the name of the DB instance's database that you specified when you created the DB instance, and not the name of the DB instance.

For Linux, macOS, or Unix:

```
sqlplus 'user_name@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=dns_name)(PORT=port))(CONNECT_DATA=(SID=database_name)))'
```

For Windows:

```
sqlplus user_name@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=dns_name)(PORT=port))(CONNECT_DATA=(SID=database_name)))
```

You should see output similar to the following.

```
SQL*Plus: Release 12.1.0.2.0 Production on Mon Aug 21 09:42:20 2017
```

After you enter the password for the user, the SQL prompt appears.
SQL>

**Note**
The shorter format connection string (EZ Connect), such as `sqlplus USER/PASSWORD@longer-than-63-chars-rds-endpoint-here:1521/database-identifier`, might encounter a maximum character limit, so you we recommend that you don't use it to connect.

**Considerations for security groups**

For you to connect to your DB instance, it must be associated with a security group that contains the necessary IP addresses and network configuration. Your DB instance might use the default security group. If you assigned a default, nonconfigured security group when you created the DB instance, the firewall prevents connections. For information about creating a new security group, see [Controlling access with security groups](p. 2697).

After you create the new security group, you modify your DB instance to associate it with the security group. For more information, see [Modifying an Amazon RDS DB instance](p. 401).

You can enhance security by using SSL to encrypt connections to your DB instance. For more information, see [Oracle Secure Sockets Layer](p. 2084).

**Considerations for process architecture**

Server processes handle user connections to an Oracle DB instance. By default, the Oracle DB instance uses dedicated server processes. With dedicated server processes, each server process services only one user process. You can optionally configure shared server processes. With shared server processes, each server process can service multiple user processes.

You might consider using shared server processes when a high number of user sessions are using too much memory on the server. You might also consider shared server processes when sessions connect and disconnect very often, resulting in performance issues. There are also disadvantages to using shared server processes. For example, they can strain CPU resources, and they are more complicated to configure and administer.

For more information about dedicated and shared server processes, see [About dedicated and shared server processes](in the Oracle documentation). For more information about configuring shared server processes on an RDS for Oracle DB instance, see [How do I configure Amazon RDS for Oracle database to work with shared servers?](in the Knowledge Center).

**Troubleshooting connections to your Oracle DB instance**

The following are issues you might encounter when you try to connect to your Oracle DB instance.

<table>
<thead>
<tr>
<th>Issue</th>
<th>Troubleshooting suggestions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unable to connect to your DB instance.</td>
<td>For a newly created DB instance, the DB instance has a status of creating until it is ready to use. When the state changes to available, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new DB instance is available.</td>
</tr>
<tr>
<td>Unable to connect to your DB instance.</td>
<td>If you can't send or receive communications over the port that you specified when you created the DB instance, you can't connect to the DB instance. Check with your network administrator to verify that the</td>
</tr>
</tbody>
</table>
### Issue | Troubleshooting suggestions
---|---
Unable to connect to your DB instance. | The access rules enforced by your local firewall and the IP addresses you authorized to access your DB instance in the security group for the DB instance might not match. The problem is most likely the inbound or outbound rules on your firewall. You can add or edit an inbound rule in the security group. For **Source**, choose *My IP*. This allows access to the DB instance from the IP address detected in your browser. For more information, see [Amazon VPC VPCs and Amazon RDS](p. 2705). For more information about security groups, see [Controlling access with security groups](p. 2697).

| Connect failed because target host or object does not exist – Oracle, Error: ORA-12545 | Make sure that you specified the server name and port number correctly. For **Server name**, enter the DNS name from the console. For information about finding the DNS name and port number for a DB instance, see [Finding the endpoint of your RDS for Oracle DB instance](p. 1822).

| Invalid username/password; logon denied – Oracle, Error: ORA-01017 | You were able to reach the DB instance, but the connection was refused. This is usually caused by providing an incorrect user name or password. Verify the user name and password, and then retry.

| TNS:listener does not currently know of SID given in connect descriptor - Oracle, ERROR: ORA-12505 | Ensure the correct SID is entered. The SID is the same as your DB name. Find the DB name in the **Configuration** tab of the **Databases** page for your instance. You can also find the DB name using the AWS CLI:

```bash
aws rds describe-db-instances --query 'DBInstances[*].[DBInstanceIdentifier,DBName]' --output text
```

For more information on connection issues, see [Can’t connect to Amazon RDS DB instance](p. 2744).

### Modifying connection properties using sqlnet.ora parameters

The sqlnet.ora file includes parameters that configure Oracle Net features on Oracle database servers and clients. Using the parameters in the sqlnet.ora file, you can modify properties for connections in and out of the database.

For more information about why you might set sqlnet.ora parameters, see [Configuring profile parameters](p. 2696) in the Oracle documentation.

### Setting sqlnet.ora parameters

Amazon RDS for Oracle parameter groups include a subset of sqlnet.ora parameters. You set them in the same way that you set other Oracle parameters. The `sqlnetora.` prefix identifies which
parameters are sqlnet.ora parameters. For example, in an Oracle parameter group in Amazon RDS, the `default_sdu_size` sqlnet.ora parameter is `sqlnetora.default_sdu_size`.

For information about managing parameter groups and setting parameter values, see Working with parameter groups (p. 347).

**Supported sqlnet.ora parameters**

Amazon RDS supports the following sqlnet.ora parameters. Changes to dynamic sqlnet.ora parameters take effect immediately.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Valid values</th>
<th>Static/Dynamic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sqlnetora.default_sdu_size</code></td>
<td>Oracle 12c – 512 to 2097152</td>
<td>Dynamic</td>
<td>The session data unit (SDU) size, in bytes. The SDU is the amount of data that is put in a buffer and sent across the network at one time.</td>
</tr>
<tr>
<td><code>sqlnetora.diag_adr_enabled</code></td>
<td>ON, OFF</td>
<td>Dynamic</td>
<td>A value that enables or disables Automatic Diagnostic Repository (ADR) tracing. ON specifies that ADR file tracing is used. OFF specifies that non-ADR file tracing is used.</td>
</tr>
<tr>
<td><code>sqlnetora.recv_buf_size</code></td>
<td>8192 to 268435456</td>
<td>Dynamic</td>
<td>The buffer space limit for receive operations of sessions, supported by the TCP/IP, TCP/IP with SSL, and SDP protocols.</td>
</tr>
<tr>
<td><code>sqlnetora.send_buf_size</code></td>
<td>8192 to 268435456</td>
<td>Dynamic</td>
<td>The buffer space limit for send operations of sessions, supported by the TCP/IP, TCP/IP with SSL, and SDP protocols.</td>
</tr>
<tr>
<td><code>sqlnetora.sqlnet.allowed_logon_version_client</code></td>
<td>8, 10, 11, 12</td>
<td>Dynamic</td>
<td>Minimum authentication protocol version allowed for clients, and servers acting as clients, to establish a connection to Oracle DB instances.</td>
</tr>
<tr>
<td><code>sqlnetora.sqlnet.allowed_logon_version_server</code></td>
<td>8, 9, 10, 11, 12, 12a</td>
<td>Dynamic</td>
<td>Minimum authentication protocol version allowed to establish a connection to Oracle DB instances.</td>
</tr>
<tr>
<td><code>sqlnetora.sqlnet.expire_time</code></td>
<td>0 to 1440</td>
<td>Dynamic</td>
<td>Time interval, in minutes, to send a check to verify that client-server connections are active.</td>
</tr>
<tr>
<td><code>sqlnetora.sqlnet.inbound_connect_timeout</code></td>
<td>0 or 10 to 7200</td>
<td>Dynamic</td>
<td>Time, in seconds, for a client to connect with the database server and provide the necessary authentication information.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Valid values</td>
<td>Static/Dynamic</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>--------------</td>
<td>----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>sqlnetora.sqlnet.outbound_connect_timeout</td>
<td>0 or 10 to 7200</td>
<td>Dynamic</td>
<td>Time, in seconds, for a client to establish an Oracle Net connection to the DB instance.</td>
</tr>
<tr>
<td>sqlnetora.sqlnet.recv_timeout</td>
<td>0 or 10 to 7200</td>
<td>Dynamic</td>
<td>Time, in seconds, for a database server to wait for client data after establishing a connection.</td>
</tr>
<tr>
<td>sqlnetora.sqlnet.send_timeout</td>
<td>0 or 10 to 7200</td>
<td>Dynamic</td>
<td>Time, in seconds, for a database server to complete a send operation to clients after establishing a connection.</td>
</tr>
<tr>
<td>sqlnetora.tcp.connect_timeout</td>
<td>0 or 10 to 7200</td>
<td>Dynamic</td>
<td>Time, in seconds, for a client to establish a TCP connection to the database server.</td>
</tr>
<tr>
<td>sqlnetora.trace_level_server</td>
<td>0, 4, 10, 16, OFF, USER, ADMIN, SUPPORT</td>
<td>Dynamic</td>
<td>For non-ADR tracing, turns server tracing on at a specified level or turns it off.</td>
</tr>
</tbody>
</table>

The default value for each supported sqlnet.ora parameter is the Oracle default for the release. For information about default values for Oracle Database 12c, see Parameters for the sqlnet.ora file in the Oracle Database 12c documentation.

**Viewing sqlnet.ora parameters**

You can view sqlnet.ora parameters and their settings using the AWS Management Console, the AWS CLI, or a SQL client.

**Viewing sqlnet.ora parameters using the console**

For information about viewing parameters in a parameter group, see Working with parameter groups (p. 347).

In Oracle parameter groups, the sqlnetora. prefix identifies which parameters are sqlnet.ora parameters.

**Viewing sqlnet.ora parameters using the AWS CLI**

To view the sqlnet.ora parameters that were configured in an Oracle parameter group, use the AWS CLI describe-db-parameters command.

To view the all of the sqlnet.ora parameters for an Oracle DB instance, call the AWS CLI download-db-log-file-portion command. Specify the DB instance identifier, the log file name, and the type of output.

**Example**

The following code lists all of the sqlnet.ora parameters for mydbinstance.

For Linux, macOS, or Unix:
aws rds download-db-log-file-portion \
   --db-instance-identifier mydbinstance \
   --log-file-name trace/sqlnet-parameters \
   --output text

For Windows:

aws rds download-db-log-file-portion ^
   --db-instance-identifier mydbinstance ^
   --log-file-name trace/sqlnet-parameters ^
   --output text

**Viewing sqlnet.ora parameters using a SQL client**

After you connect to the Oracle DB instance in a SQL client, the following query lists the sqlnet.ora parameters.

```
SELECT * FROM TABLE
   (rdsadmin.rds_file_util.read_text_file(
      p_directory => 'BDUMP',
      p_filename  => 'sqlnet-parameters'));
```

For information about connecting to an Oracle DB instance in a SQL client, see [Connecting to your RDS for Oracle DB instance](p. 1822).
Securing Oracle DB instance connections

Amazon RDS for Oracle supports SSL/TLS encrypted connections and also the Oracle Native Network Encryption (NNE) option to encrypt connections between your application and your Oracle DB instance. For more information about the Oracle Native Network Encryption option, see Oracle native network encryption (p. 2073).

Topics
- Using SSL with an RDS for Oracle DB instance (p. 1832)
- Updating applications to connect to Oracle DB instances using new SSL/TLS certificates (p. 1832)
- Using native network encryption with an RDS for Oracle DB instance (p. 1835)
- Configuring Kerberos authentication for Amazon RDS for Oracle (p. 1835)
- Configuring UTL_HTTP access using certificates and an Oracle wallet (p. 1848)

Using SSL with an RDS for Oracle DB instance

Secure Sockets Layer (SSL) is an industry-standard protocol for securing network connections between client and server. After SSL version 3.0, the name was changed to Transport Layer Security (TLS), but we still often refer to the protocol as SSL. Amazon RDS supports SSL encryption for Oracle DB instances. Using SSL, you can encrypt a connection between your application client and your Oracle DB instance. SSL support is available in all AWS Regions for Oracle.

To enable SSL encryption for an Oracle DB instance, add the Oracle SSL option to the option group associated with the DB instance. Amazon RDS uses a second port, as required by Oracle, for SSL connections. Doing this allows both clear text and SSL-encrypted communication to occur at the same time between a DB instance and an Oracle client. For example, you can use the port with clear text communication to communicate with other resources inside a VPC while using the port with SSL-encrypted communication to communicate with resources outside the VPC.

For more information, see Oracle Secure Sockets Layer (p. 2084).

Note
You can't use both SSL and Oracle native network encryption (NNE) on the same DB instance. Before you can use SSL encryption, you must disable any other connection encryption.

Updating applications to connect to Oracle DB instances using new SSL/TLS certificates

As of January 13, 2023, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB instances.

Important
When you change the certificate for an Amazon RDS for Oracle DB instance, only the database listener is restarted. The DB instance isn't restarted. Existing database connections are unaffected, but new connections will encounter errors for a brief period while the listener is restarted.

Note
For client applications that use SSL/TLS to connect to your DB instances, you must update your client application trust stores to include the new CA certificates.
After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate (p. 2613). For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2608). For information about using SSL/TLS with Oracle DB instances, see Oracle Secure Sockets Layer (p. 2084).

Topics
- Finding out whether applications connect using SSL (p. 1833)
- Updating your application trust store (p. 1833)
- Example Java code for establishing SSL connections (p. 1834)

Finding out whether applications connect using SSL

If your Oracle DB instance uses an option group with the SSL option added, you might be using SSL. Check this by following the instructions in Listing the options and option settings for an option group (p. 339). For information about the SSL option, see Oracle Secure Sockets Layer (p. 2084).

Check the listener log to determine whether there are SSL connections. The following is sample output in a listener log.

```
date time * (CONNECT_DATA=(CID=(PROGRAM=program) (HOST=host)(USER=user))(SID=sid)) *
(ADDRESS=(PROTOCOL=tcps)(HOST=host)(PORT=port)) * establish * ORCL * 0
```

When PROTOCOL has the value tcps for an entry, it shows an SSL connection. However, when HOST is 127.0.0.1, you can ignore the entry. Connections from 127.0.0.1 are a local management agent on the DB instance. These connections aren't external SSL connections. Therefore, you have applications connecting using SSL if you see listener log entries where PROTOCOL is tcps and HOST is not 127.0.0.1.

To check the listener log, you can publish the log to Amazon CloudWatch Logs. For more information, see Publishing Oracle logs to Amazon CloudWatch Logs (p. 927).

Updating your application trust store

You can update the trust store for applications that use SQL*Plus or JDBC for SSL/TLS connections.

Updating your application trust store for SQL*Plus

You can update the trust store for applications that use SQL*Plus for SSL/TLS connections.

Note

When you update the trust store, you can retain older certificates in addition to adding the new certificates.

To update the trust store for SQL*Plus applications

1. Download the new root certificate that works for all AWS Regions and put the file in the ssl_wallet directory.

   For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2608).

2. Run the following command to update the Oracle wallet.
Using new SSL/TLS certificates

3. Run the following command to confirm that the wallet was updated successfully.

```
prompt> orapki wallet display -wallet $ORACLE_HOME/ssl_wallet
```

Your output should contain the following.

```
Trusted Certificates:
Subject: CN=Amazon RDS Root 2019 CA,OU=Amazon RDS,O=Amazon Web Services, L=Seattle,ST=Washington,C=US
```

**Updating your application trust store for JDBC**

You can update the trust store for applications that use JDBC for SSL/TLS connections.

For information about downloading the root certificate, see [Using SSL/TLS to encrypt a connection to a DB instance](p. 2608).

For sample scripts that import certificates, see [Sample script for importing certificates into your trust store](p. 2620).

**Example Java code for establishing SSL connections**

The following code example shows how to set up the SSL connection using JDBC.

```java
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;
import java.util.Properties;

public class OracleSslConnectionTest {
    private static final String DB_SERVER_NAME = "<dns-name-provided-by-amazon-rds>";
    private static final Integer SSL_PORT = "<ssl-option-port-configured-in-option-group>";
    private static final String DB_SID = "<oracle-sid>";
    private static final String DB_USER = "<user name>";
    private static final String DB_PASSWORD = "<password>";
    // This key store has only the prod root ca.
    private static final String KEY_STORE_FILE_PATH = "<file-path-to-keystore>";
    private static final String KEY_STORE_PASS = "<keystore-password>";

    public static void main(String[] args) throws SQLException {
        final Properties properties = new Properties();
        final String connectionString = String.format(
            "jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCPS)(HOST=%s)(PORT=%d))
            (CONNECT_DATA=(SID=%s))", DB_SERVER_NAME, SSL_PORT, DB_SID);
        properties.put("user", DB_USER);
        properties.put("password", DB_PASSWORD);
        properties.put("oracle.jdbc.2EE13Compliant", "true");
        properties.put("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
        properties.put("javax.net.ssl.trustStoreType", "JKS");
        properties.put("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);
        final Connection connection = DriverManager.getConnection(connectionString,
            properties);
    }
```
// If no exception, that means handshake has passed, and an SSL connection can be opened
}

Important
After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-rsa2048-g1 certificates. For instructions, see step 3 in Updating your CA certificate by modifying your DB instance (p. 2614).

Using native network encryption with an RDS for Oracle DB instance

Oracle Database offers two ways to encrypt data over the network: native network encryption (NNE) and Transport Layer Security (TLS). NNE is a proprietary Oracle security feature, whereas TLS is an industry standard. RDS for Oracle supports NNE for all editions of Oracle Database.

NNE has the following advantages over TLS:

- You can control NNE on the client and server using settings in the NNE option:
  - SQLNET.ALLOW_weak_CRYPTO_CLIENTS and SQLNET.ALLOW_weak_CRYPTO
  - SQLNET.CRYPTO_CHECKSUM_CLIENT and SQLNET.CRYPTO_CHECKSUM_SERVER
  - SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT and SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER
  - SQLNET.ENCRIPTION_CLIENT and SQLNET.ENCRIPTION_SERVER
  - SQLNET.ENCRIPTION_TYPES_CLIENT and SQLNET.ENCRIPTION_TYPES_SERVER
- In most cases, you don't need to configure your client or server. In contrast, TSL requires you to configure both client and server.
- No certificates are required. In TLS, the server requires a certificate (which eventually expires), and the client requires a trusted root certificate for the certificate authority that issued the server’s certificate.

To enable NNE encryption for an Oracle DB instance, add the Oracle NNE option to the option group associated with the DB instance. For more information, see Oracle native network encryption (p. 2073).

Note
You can’t use both NNE and TLS on the same DB instance.

Configuring Kerberos authentication for Amazon RDS for Oracle

You can use Kerberos authentication to authenticate users when they connect to your Amazon RDS for Oracle DB instance. In this configuration, your DB instance works with AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD. When users authenticate with an RDS for Oracle DB instance joined to the trusting domain, authentication requests are forwarded to the directory that you create with AWS Directory Service.

Keeping all of your credentials in the same directory can save you time and effort. You have a centralized place for storing and managing credentials for multiple database instances. A directory can also improve your overall security profile.
Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of RDS for Oracle with Kerberos authentication, see Kerberos authentication (p. 141).

Note

Kerberos authentication isn't supported for DB instance classes that are deprecated for RDS for Oracle DB instances. For more information, see RDS for Oracle instance classes (p. 1812).

Topics

• Setting up Kerberos authentication for Oracle DB instances (p. 1836)
• Managing a DB instance in a domain (p. 1845)
• Connecting to Oracle with Kerberos authentication (p. 1847)

Setting up Kerberos authentication for Oracle DB instances

Use AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD, to set up Kerberos authentication for an Oracle DB instance. To set up Kerberos authentication, complete the following steps:

• Step 1: Create a directory using the AWS Managed Microsoft AD (p. 1836)
• Step 2: Create a trust (p. 1840)
• Step 3: Configure IAM permissions for Amazon RDS (p. 1840)
• Step 4: Create and configure users (p. 1842)
• Step 5: Enable cross-VPC traffic between the directory and the DB instance (p. 1842)
• Step 6: Create or modify an Oracle DB instance (p. 1842)
• Step 7: Create Kerberos authentication Oracle logins (p. 1844)
• Step 8: Configure an Oracle client (p. 1845)

Note

During the setup, RDS creates an Oracle database user named managed_service_user@example.com with the CREATE SESSION privilege, where example.com is your domain name. This user corresponds to the user that Directory Service creates inside your Managed Active Directory. Periodically, RDS uses the credentials provided by the Directory Service to log in to your Oracle database. Afterwards, RDS immediately destroys the ticket cache.

Step 1: Create a directory using the AWS Managed Microsoft AD

AWS Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and Domain Name System (DNS) servers on your behalf. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

• Sets up an Active Directory within the VPC.
• Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.
Note
Be sure to save this password. AWS Directory Service doesn't store it. You can reset it, but you can't retrieve it.

- Creates a security group for the directory controllers.

When you launch an AWS Managed Microsoft AD, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU has the NetBIOS name that you typed when you created your directory and is located in the domain root. The domain root is owned and managed by AWS.

The Admin account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
- Create additional OUs and containers
- Delegate authority
- Restore deleted objects from the Active Directory Recycle Bin
- Run AD and DNS Windows PowerShell modules on the Active Directory Web Service

The Admin account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders)
- View DNS event logs
- View security event logs

To create the directory, use the AWS Management Console, the AWS CLI, or the AWS Directory Service API. Make sure to open the relevant outbound ports on the directory security group so that the directory can communicate with the Oracle DB instance.

To create a directory with AWS Managed Microsoft AD

2. In the navigation pane, choose Directories and choose Set up Directory.
3. Choose AWS Managed Microsoft AD. AWS Managed Microsoft AD is the only option that you can currently use with Amazon RDS.
4. Enter the following information:

   **Directory DNS name**
   
   The fully qualified name for the directory, such as corp.example.com.

   **Directory NetBIOS name**
   
   The short name for the directory, such as CORP.

   **Directory description**
   
   (Optional) A description for the directory.

   **Admin password**
   
   The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.
The directory administrator password can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:

- Lowercase letters (a–z)
- Uppercase letters (A–Z)
- Numbers (0–9)
- Non-alphanumeric characters (~!@#$%^&*_+-=\|(){}[]:;"'<>,.?/)  

**Confirm password**

The administrator password retyped.

5. Choose **Next**.

6. Enter the following information in the **Networking** section and then choose **Next**:

   **VPC**

   The VPC for the directory. Create the Oracle DB instance in this same VPC.

   **Subnets**

   Subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Review the directory information and make any necessary changes. When the information is correct, choose **Create directory**.
It takes several minutes for the directory to be created. When it has been successfully created, the *Status* value changes to *Active*.

To see information about your directory, choose the directory name in the directory listing. Note the *Directory ID* value because you need this value when you create or modify your Oracle DB instance.
Step 2: Create a trust

If you plan to use AWS Managed Microsoft AD only, move on to Step 3: Configure IAM permissions for Amazon RDS (p. 1840).

To get Kerberos authentication using an on-premises or self-hosted Microsoft Active Directory, create a forest trust or external trust. The trust can be one-way or two-way. For more information about setting up forest trusts using AWS Directory Service, see When to create a trust relationship in the AWS Directory Service Administration Guide.

Step 3: Configure IAM permissions for Amazon RDS

To call AWS Directory Service for you, Amazon RDS requires an IAM role that uses the managed IAM policy AmazonRDSDirectoryServiceAccess. This role allows Amazon RDS to make calls to the AWS Directory Service.

**Note**
For the role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the correct AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Activating and deactivating AWS STS in an AWS Region in the IAM User Guide.

Creating an IAM role

When you create a DB instance using the AWS Management Console, and the console user has the iam:CreateRole permission, the console creates rds-direcotoryservice-kerberos-
access-role automatically. Otherwise, you must create the IAM role manually. When you create an IAM role manually, choose Directory Service, and attach the AWS managed policy AmazonRDSDirectoryServiceAccess to it.

For more information about creating IAM roles for a service, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

**Note**
The IAM role used for Windows Authentication for RDS for Microsoft SQL Server can't be used for RDS for Oracle.

### Creating an IAM trust policy manually

Optionally, you can create resource policies with the required permissions instead of using the managed IAM policy AmazonRDSDirectoryServiceAccess. Specify both directoryservice.rds.amazonaws.com and rds.amazonaws.com as principals.

To limit the permissions that Amazon RDS gives another service for a specific resource, we recommend using the **aws:SourceArn** and **aws:SourceAccount** global condition context keys in resource policies. The most effective way to protect against the confused deputy problem is to use the **aws:SourceArn** global condition context key with the full ARN of an Amazon RDS resource. For more information, see Preventing cross-service confused deputy problems (p. 2657).

The following example shows how you can use the **aws:SourceArn** and **aws:SourceAccount** global condition context keys in Amazon RDS to prevent the confused deputy problem.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "",
            "Effect": "Allow",
            "Principal": {
                "Service": [
                    "directoryservice.rds.amazonaws.com",
                    "rds.amazonaws.com"
                ],
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:rds:us-east-1:123456789012:db:mydbinstance"
                },
                "StringEquals": {
                    "aws:SourceAccount": "123456789012"
                }
            }
        }
    ]
}
```

The role must also have the following IAM policy.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "ds:DescribeDirectories",
                "ds:AuthorizeApplication",
                "ds:UnauthorizeApplication",
                "ds:GetAuthorizedApplicationDetails"
            ],
```
Step 4: Create and configure users

You can create users with the Active Directory Users and Computers tool, which is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. In this case, users are individual people or entities that have access to your directory.

To create users in an AWS Directory Service directory, you must be connected to a Windows-based Amazon EC2 instance that is a member of the AWS Directory Service directory. At the same time, you must be logged in as a user that has privileges to create users. For more information about creating users in your Microsoft Active Directory, see Manage users and groups in AWS Managed Microsoft AD in the AWS Directory Service Administration Guide.

Step 5: Enable cross-VPC traffic between the directory and the DB instance

If you plan to locate the directory and the DB instance in the same VPC, skip this step and move on to Step 6: Create or modify an Oracle DB instance (p. 1842).

If you plan to locate the directory and the DB instance in different AWS accounts or VPCs, configure cross-VPC traffic using VPC peering or AWS Transit Gateway. The following procedure enables traffic between VPCs using VPC peering. Follow the instructions in What is VPC peering? in the Amazon Virtual Private Cloud Peering Guide.

To enable cross-VPC traffic using VPC peering

1. Set up appropriate VPC routing rules to ensure that network traffic can flow both ways.
2. Ensure that the DB instance's security group can receive inbound traffic from the directory's security group. For more information, see Best practices for AWS Managed Microsoft AD in the AWS Directory Service Administration Guide.
3. Ensure that there is no network access control list (ACL) rule to block traffic.

If a different AWS account owns the directory, you must share the directory.

To share the directory between AWS accounts

1. Start sharing the directory with the AWS account that the DB instance will be created in by following the instructions in Tutorial: Sharing your AWS Managed Microsoft AD directory for seamless EC2 Domain-join in the AWS Directory Service Administration Guide.
2. Sign in to the AWS Directory Service console using the account for the DB instance, and ensure that the domain has the SHARED status before proceeding.
3. While signed into the AWS Directory Service console using the account for the DB instance, note the Directory ID value. You use this directory ID to join the DB instance to the domain.

Step 6: Create or modify an Oracle DB instance

Create or modify an Oracle DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new Oracle DB instance using the console, the create-db-instance CLI command, or the CreateDBInstance RDS API operation.

For instructions, see Creating an Amazon RDS DB instance (p. 300).
• Modify an existing Oracle DB instance using the console, the `modify-db-instance` CLI command, or the `ModifyDBInstance` RDS API operation.

For instructions, see Modifying an Amazon RDS DB instance (p. 401).

• Restore an Oracle DB instance from a DB snapshot using the console, the `restore-db-instance-from-db-snapshot` CLI command, or the `RestoreDBInstanceFromDBSnapshot` RDS API operation.

For instructions, see Restoring from a DB snapshot (p. 615).

• Restore an Oracle DB instance to a point-in-time using the console, the `restore-db-instance-to-point-in-time` CLI command, or the `RestoreDBInstanceToPointInTime` RDS API operation.

For instructions, see Restoring a DB instance to a specified time (p. 660).

Kerberos authentication is only supported for Oracle DB instances in a VPC. The DB instance can be in the same VPC as the directory, or in a different VPC. When you create or modify the DB instance, do the following:

• Provide the domain identifier (`d-*` identifier) that was generated when you created your directory.
• Provide the name of the IAM role that you created.
• Ensure that the DB instance security group can receive inbound traffic from the directory security group and send outbound traffic to the directory.

When you use the console to create a DB instance, choose Password and Kerberos authentication in the Database authentication section. Choose Browse Directory and then select the directory, or choose Create a new directory.

When you use the console to modify or restore a DB instance, choose the directory in the Kerberos authentication section, or choose Create a new directory.
When you use the AWS CLI, the following parameters are required for the DB instance to be able to use the directory that you created:

- For the --domain parameter, use the domain identifier ("d-*" identifier) generated when you created the directory.
- For the --domain-iam-role-name parameter, use the role you created that uses the managed IAM policy AmazonRDSDirectoryServiceAccess.

For example, the following CLI command modifies a DB instance to use a directory.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \\
  --db-instance-identifier mydbinstance \\
  --domain d-ID \\
  --domain-iam-role-name role-name
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --domain d-ID ^
  --domain-iam-role-name role-name
```

Important

If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

Note

`MANAGED_SERVICE_USER` is a service account whose name is randomly generated by Directory Service for RDS. During the Kerberos authentication setup, RDS for Oracle creates a user with the same name and assigns it the CREATE SESSION privilege. The Oracle DB user is identified externally as `MANAGED_SERVICE_USER@EXAMPLE.COM`, where `EXAMPLE.COM` is the name of your domain. Periodically, RDS uses the credentials provided by the Directory Service to log in to your Oracle database. Afterward, RDS immediately destroys the ticket cache.

**Step 7: Create Kerberos authentication Oracle logins**

Use the Amazon RDS master user credentials to connect to the Oracle DB instance as you do any other DB instance. The DB instance is joined to the AWS Managed Microsoft AD domain. Thus, you can provision Oracle logins and users from the Microsoft Active Directory users and groups in your domain. To manage database permissions, you grant and revoke standard Oracle permissions to these logins.

**To allow a Microsoft Active Directory user to authenticate with Oracle**

1. Connect to the Oracle DB instance using your Amazon RDS master user credentials.
2. Create an externally authenticated user in Oracle database.

   In the following example, replace `KRUSER@CORP.EXAMPLE.COM` with the user name and domain name.

   ```sql
   CREATE USER "KRUSER@CORP.EXAMPLE.COM" IDENTIFIED EXTERNALLY;
   GRANT CREATE SESSION TO "KRUSER@CORP.EXAMPLE.COM";
   ```

Users (both humans and applications) from your domain can now connect to the Oracle DB instance from a domain joined client machine using Kerberos authentication.
Step 8: Configure an Oracle client

To configure an Oracle client, meet the following requirements:

- Create a configuration file named krb5.conf (Linux) or krb5.ini (Windows) to point to the domain. Configure the Oracle client to use this configuration file.
- Verify that traffic can flow between the client host and AWS Directory Service over DNS port 53 over TCP/UDP, Kerberos ports (88 and 464 for managed AWS Directory Service) over TCP, and LDAP port 389 over TCP.
- Verify that traffic can flow between the client host and the DB instance over the database port.

Following is sample content for AWS Managed Microsoft AD.

```
[libdefaults]
default_realm = EXAMPLE.COM
[realms]
EXAMPLE.COM = {
    kdc = example.com
    admin_server = example.com
}
[domain_realm]
.example.com = CORP.EXAMPLE.COM
example.com = CORP.EXAMPLE.COM
```

Following is sample content for on-premise Microsoft AD. In your krb5.conf or krb5.ini file, replace `on-prem-ad-server-name` with the name of your on-premises AD server.

```
[libdefaults]
default_realm = ONPREM.COM
[realms]
AWSAD.COM = {
    kdc = awsad.com
    admin_server = awsad.com
}
ONPREM.COM = {
    kdc = `on-prem-ad-server-name`
    admin_server = `on-prem-ad-server-name`
}
[domain_realm]
.awsad.com = AWSAD.COM
awsad.com = AWSAD.COM
.onprem.com = ONPREM.COM
onprem.com = ONPREM.COM
```

**Note**

After you configure your krb5.ini or krb5.conf file, we recommend that you reboot the server.

The following is sample sqlnet.ora content for a SQL*Plus configuration:

```
SQLNET.AUTHENTICATION_SERVICES=(KERBEROS5PRE,KERBEROS5)
SQLNET.KERBEROS5_CONF=path_to_krb5.conf_file
```

For an example of a SQL Developer configuration, see [Document 1609359.1](https://support.oracle.com) from Oracle Support.

**Managing a DB instance in a domain**

You can use the console, the CLI, or the RDS API to manage your DB instance and its relationship with your Microsoft Active Directory. For example, you can associate a Microsoft Active Directory to enable Kerberos authentication. You can also disassociate a Microsoft Active Directory to disable Kerberos authentication.
authentication. You can also move a DB instance to be externally authenticated by one Microsoft Active Directory to another.

For example, using the CLI, you can do the following:

- To reattempt enabling Kerberos authentication for a failed membership, use the `modify-db-instance` CLI command and specify the current membership's directory ID for the `--domain` option.
- To disable Kerberos authentication on a DB instance, use the `modify-db-instance` CLI command and specify none for the `--domain` option.
- To move a DB instance from one domain to another, use the `modify-db-instance` CLI command and specify the domain identifier of the new domain for the `--domain` option.

Viewing the status of domain membership

After you create or modify your DB instance, the DB instance becomes a member of the domain. You can view the status of the domain membership for the DB instance in the console or by running the `describe-db-instances` CLI command. The status of the DB instance can be one of the following:

- **kerberos-enabled** – The DB instance has Kerberos authentication enabled.
- **enabling-kerberos** – AWS is in the process of enabling Kerberos authentication on this DB instance.
- **pending-enable-kerberos** – Enabling Kerberos authentication is pending on this DB instance.
- **pending-maintenance-enable-kerberos** – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- **pending-disable-kerberos** – Disabling Kerberos authentication is pending on this DB instance.
- **pending-maintenance-disable-kerberos** – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- **enable-kerberos-failed** – A configuration problem has prevented AWS from enabling Kerberos authentication on the DB instance. Correct the configuration problem before reissuing the command to modify the DB instance.
- **disabling-kerberos** – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. If the attempt to enable Kerberos authentication fails when you create or modify a DB instance, make sure that you're using the correct IAM role. Then modify the DB instance to join the domain.

**Note**

Only Kerberos authentication with Amazon RDS for Oracle sends traffic to the domain's DNS servers. All other DNS requests are treated as outbound network access on your DB instances running Oracle. For more information about outbound network access with Amazon RDS for Oracle, see Setting up a custom DNS server (p. 1881).

Force-rotating Kerberos keys

A secret key is shared between AWS Managed Microsoft AD and Amazon RDS for Oracle DB instance. This key is rotated automatically every 45 days. You can use the following Amazon RDS procedure to force the rotation of this key.

```sql
SELECT rdsadmin.rdsadmin_kerberos_auth_tasks.rotate_kerberos_keytab AS TASK_ID FROM DUAL;
```

**Note**

In a read replica configuration, this procedure is available only on the source DB instance and not on the read replica.
The `SELECT` statement returns the ID of the task in a `VARCHAR2` data type. You can view the status of an ongoing task in a bdump file. The bdump files are located in the `/rdsdbdata/log/trace` directory. Each bdump file name is in the following format.

```
dbtask-task-id.log
```

You can view the result by displaying the task's output file.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-task-id.log'));
```

Replace `task-id` with the task ID returned by the procedure.

**Note**
Tasks are executed asynchronously.

### Connecting to Oracle with Kerberos authentication

This section assumes that you have set up your Oracle client as described in Step 8: Configure an Oracle client (p. 1845). To connect to the Oracle DB with Kerberos authentication, log in using the Kerberos authentication type. For example, after launching Oracle SQL Developer, choose **Kerberos Authentication** as the authentication type, as shown following.

![Kerberos Authentication](image)

To connect to Oracle with Kerberos authentication with SQL*Plus:

1. At a command prompt, run the following command:

```
kinit username
```

Replace `username` with the user name and, at the prompt, enter the password stored in the Microsoft Active Directory for the user.

2. Open SQL*Plus and connect using the DNS name and port number for the Oracle DB instance.

For more information about connecting to an Oracle DB instance in SQL*Plus, see Connecting to your DB instance using SQL*Plus (p. 1826).
Configuring UTL_HTTP access using certificates and an Oracle wallet

Amazon RDS supports outbound network access on your Oracle DB instances. To connect your DB instance to the network, you can use the following PL/SQL packages:

**UTL_HTTP**

This package makes HTTP calls from SQL and PL/SQL. You can use it to access data on the Internet over HTTP. For more information, see [UTL_HTTP](#) in the Oracle documentation.

**UTL_TCP**

This package provides TCP/IP client-side access functionality in PL/SQL. This package is useful to PL/SQL applications that use Internet protocols and email. For more information, see [UTL_TCP](#) in the Oracle documentation.

**UTL_SMTP**

This package provides interfaces to the SMTP commands that enable a client to dispatch emails to an SMTP server. For more information, see [UTL_SMTP](#) in the Oracle documentation.

Before configuring your instance for network access, review the following requirements and considerations:

- To use SMTP with the UTL_MAIL option, see [Oracle UTL_MAIL](#) (p. 2115).
- The Domain Name Server (DNS) name of the remote host can be any of the following:
  - Publicly resolvable.
  - The endpoint of an Amazon RDS DB instance.
  - Resolvable through a custom DNS server. For more information, see [Setting up a custom DNS server](#) (p. 1881).
  - The private DNS name of an Amazon EC2 instance in the same VPC or a peered VPC. In this case, make sure that the name is resolvable through a custom DNS server. Alternatively, to use the DNS provided by Amazon, you can enable the `enableDnsSupport` attribute in the VPC settings and enable DNS resolution support for the VPC peering connection. For more information, see [DNS support in your VPC](#) and [Modifying your VPC peering connection](#).
- To connect securely to remote SSL/TLS resources, we recommend that you create and upload customized Oracle wallets. By using the Amazon S3 integration with Amazon RDS for Oracle feature, you can download a wallet from Amazon S3 into Oracle DB instances. For information about Amazon S3 integration for Oracle, see [Amazon S3 integration](#) (p. 2008).
- You can establish database links between Oracle DB instances over an SSL/TLS endpoint if the Oracle SSL option is configured for each instance. No further configuration is required. For more information, see [Oracle Secure Sockets Layer](#) (p. 2084).

By completing the following tasks, you can configure UTL_HTTP.REQUEST to work with websites that require client authentication certificates during the SSL handshake. You can also configure password authentication for UTL_HTTP access to websites by modifying the Oracle wallet generation commands and the `DBMS_NETWORK_ACL_ADMIN.APPEND_WALLET_ACE` procedure. For more information, see [DBMS_NETWORK_ACL_ADMIN](#) in the Oracle Database documentation.

**Note**

You can adapt the following tasks for UTL_SMTP, which enables you to send emails over SSL/TLS (including [Amazon Simple Email Service](#)).

**Topics**
Step 1: Get the root certificate for a website

For the RDS for Oracle instance to make secure connections to a website, add the root CA certificate. Amazon RDS uses the root certificate to sign the website certificate to the Oracle wallet.

You can get the root certificate in various ways. For example, you can do the following:

1. Use a web server to visit the website secured by the certificate.
2. Download the root certificate that was used for signing.

For AWS services, root certificates typically reside in the Amazon trust services repository.

Step 2: Create an Oracle wallet

Create an Oracle wallet that contains both the web server certificates and the client authentication certificates. The RDS Oracle instance uses the web server certificate to establish a secure connection to the website. The website needs the client certificate to authenticate the Oracle database user.

You might want to configure secure connections without using client certificates for authentication. In this case, you can skip the Java keystore steps in the following procedure.

To create an Oracle wallet

1. Place the root and client certificates in a single directory, and then change into this directory.
2. Convert the .p12 client certificate to the Java keystore.
   
   Note
   If you’re not using client certificates for authentication, you can skip this step.

   The following example converts the client certificate named client_certificate.p12 to the Java keystore named client_keystore.jks. The keystore is then included in the Oracle wallet. The keystore password is P12PASSWORD.

   orapki wallet pkcs12_to_jks -wallet ./.client_certificate.p12 -jksKeyStoreLoc ./.client_keystore.jks -jksKeyStorepwd P12PASSWORD

3. Create a directory for your Oracle wallet that is different from the certificate directory.

   The following example creates the directory /tmp/wallet.

   mkdir -p /tmp/wallet

4. Create an Oracle wallet in your wallet directory.

   The following example sets the Oracle wallet password to P12PASSWORD, which is the same password used by the Java keystore in a previous step. Using the same password is convenient, but not necessary. The -auto_login parameter turns on the automatic login feature, so that you don’t need to specify a password every time you want to access it.
Note
Specify a password other than the prompt shown here as a security best practice.

```
orapki wallet create -wallet /tmp/wallet -pwd P12PASSWORD -auto_login
```

5. Add the Java keystore to your Oracle wallet.

**Note**
If you're not using client certificates for authentication, you can skip this step.

The following example adds the keystore `client_keystore.jks` to the Oracle wallet named `/tmp/wallet`. In this example, you specify the same password for the Java keystore and the Oracle wallet.

```
orapki wallet jks_to_pkcs12 -wallet /tmp/wallet -pwd P12PASSWORD -keystore ./client_keystore.jks -jkspwd P12PASSWORD
```

6. Add the root certificate for your target website to the Oracle wallet.

The following example adds a certificate named `Root_CA.cer`.

```
orapki wallet add -wallet /tmp/wallet -trusted_cert -cert ./Root_CA.cer -pwd P12PASSWORD
```

7. Add any intermediate certificates.

The following example adds a certificate named `Intermediate.cer`. Repeat this step as many times as need to load all intermediate certificates.

```
orapki wallet add -wallet /tmp/wallet -trusted_cert -cert ./Intermediate.cer -pwd P12PASSWORD
```

8. Confirm that your newly created Oracle wallet has the required certificates.

```
orapki wallet display -wallet /tmp/wallet -pwd P12PASSWORD
```

**Step 3: Download your Oracle wallet to your RDS for Oracle instance**

In this step, you upload your Oracle wallet to Amazon S3, and then download the wallet from Amazon S3 to your RDS for Oracle instance.

**To download your Oracle wallet to your RDS for Oracle DB instance**

1. Complete the prerequisites for Amazon S3 integration with Oracle, and add the `S3_INTEGRATION` option to your Oracle DB instance. Ensure that the IAM role for the option has access to the Amazon S3 bucket you are using.

   For more information, see [Amazon S3 integration](p. 2008).

2. Log in to your DB instance as the master user, and then create an Oracle directory to hold the Oracle wallet.

   The following example creates an Oracle directory named `WALLET_DIR`.

   ```
   EXEC rdsadmin.rdsadmin_util.create_directory('WALLET_DIR');
   ```
3. Upload the Oracle wallet to your Amazon S3 bucket.

   You can use any supported upload technique.

4. If you’re re-uploading an Oracle wallet, delete the existing wallet. Otherwise, skip to the next step.

   The following example removes the existing wallet, which is named `cwallet.sso`.

   ```sql
   EXEC UTL_FILE.FREMOVE ('WALLET_DIR', 'cwallet.sso');
   ```

5. Download the Oracle wallet from your Amazon S3 bucket to the Oracle DB instance.

   The following example downloads the wallet named `cwallet.sso` from the Amazon S3 bucket named `my_s3_bucket` to the DB instance directory named `WALLET_DIR`.

   ```sql
   SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
   p_bucket_name => 'my_s3_bucket',
   p_s3_prefix => 'cwallet.sso',
   p_directory_name => 'WALLET_DIR'
   ) AS TASK_ID FROM DUAL;
   ```

6. (Optional) Download a password-protected Oracle wallet.

   Download this wallet only if you want to require a password for every use of the wallet. The following example downloads password-protected wallet `ewallet.p12`.

   ```sql
   SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
   p_bucket_name => 'my_s3_bucket',
   p_s3_prefix => 'ewallet.p12',
   p_directory_name => 'WALLET_DIR'
   ) AS TASK_ID FROM DUAL;
   ```

7. Check the status of your DB task.

   Substitute the task ID returned from the preceding steps for `dbtask-1234567890123-4567.log` in the following example.

   ```sql
   SELECT TEXT FROM
   TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-1234567890123-4567.log'));
   ```

8. Check the contents of the directory that you’re using to store the Oracle wallet.

   ```sql
   SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory => 'WALLET_DIR'));
   ```

   For more information, see [Listing files in a DB instance directory](p. 1943).

### Step 4: Grant user permissions for the Oracle wallet

You can either create a new database user or configure an existing user. In either case, you must configure the user to access the Oracle wallet for secure connections and client authentication using certificates.

#### To grant user permissions for the Oracle wallet

1. Log in your RDS for Oracle DB instance as the master user.
2. If you don’t want to configure an existing database user, create a new user. Otherwise, skip to the next step.

   The following example creates a database user named `my-user`.

   ```sql
   CREATE USER my-user IDENTIFIED BY my-user-pwd;
   GRANT CONNECT TO my-user;
   ```

3. Grant permission to your database user on the directory containing your Oracle wallet.

   The following example grants read access to user `my-user` on directory `WALLET_DIR`.

   ```sql
   GRANT READ ON DIRECTORY WALLET_DIR TO my-user;
   ```

4. Grant permission to your database user to use the UTL_HTTP package.

   The following PL/SQL program grants UTL_HTTP access to user `my-user`.

   ```sql
   BEGIN
   rdsadmin.rdsadmin_util.grant_sys_object('UTL_HTTP', UPPER('my-user'));
   END;
   ```

5. Grant permission to your database user to use the UTL_FILE package.

   The following PL/SQL program grants UTL_FILE access to user `my-user`.

   ```sql
   BEGIN
   rdsadmin.rdsadmin_util.grant_sys_object('UTL_FILE', UPPER('my-user'));
   END;
   ```

---

**Step 5: Configure access to a website from your DB instance**

In this step, you configure your Oracle database user so that it can connect to your target website using UTL_HTTP, your uploaded Oracle Wallet, and the client certificate. For more information, see Configuring Access Control to an Oracle Wallet in the Oracle Database documentation.

**To configure access to a website from your RDS for Oracle DB instance**

1. Log in your RDS for Oracle DB instance as the master user.
2. Create a Host Access Control Entry (ACE) for your user and the target website on a secure port.

   The following example configures `my-user` to access `secret.encrypted-website.com` on secure port 443.

   ```sql
   BEGIN
   DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
   host       => 'secret.encrypted-website.com',
   lower_port => 443,
   upper_port => 443,
   ace        => xs$ace_type(privilege_list => xs$name_list('http'),
                               principal_name => 'my-user',
                               principal_type => xs_acl.ptype_db));
   END;
   ```
For more information, see Configuring Access Control for External Network Services in the Oracle Database documentation.

3. (Optional) Create an ACE for your user and target website on the standard port.

You might need to use the standard port if some web pages are served from the standard web server port (80) instead of the secure port (443).

BEGIN
DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(  
  host       => 'secret.encrypted-website.com',  
  lower_port => 80,  
  upper_port => 80,  
  ace        => xs$ace_type(privilege_list => xs$name_list('http'),  
                         principal_name => 'my-user',  
                         principal_type => xs_acl.ptype_db));
END;
/

4. Confirm that the access control entries exist.

SET LINESIZE 150
COLUMN HOST FORMAT A40
COLUMN ACL FORMAT A50
SELECT HOST, LOWER_PORT, UPPER_PORT, ACL
FROM DBA_NETWORK_ACLS
ORDER BY HOST;

5. Grant permission to your database user to use the UTL_HTTP package.

The following PL/SQL program grants UTL_HTTP access to user my-user.

BEGIN
  rdsadmin.rdsadmin_util.grant_sys_object('UTL_HTTP', UPPER('my-user'));
END;
/

6. Confirm that related access control lists exist.

SET LINESIZE 150
COLUMN ACL FORMAT A50
COLUMN PRINCIPAL FORMAT A20
COLUMN PRIVILEGE FORMAT A10
SELECT ACL, PRINCIPAL, PRIVILEGE, IS_GRANT,
     TO_CHAR(START_DATE, 'DD-MON-YYYY') AS START_DATE,
     TO_CHAR(END_DATE, 'DD-MON-YYYY') AS END_DATE
FROM DBA_NETWORK_ACL_PRIVILEGES
ORDER BY ACL, PRINCIPAL, PRIVILEGE;

7. Grant permission to your database user to use certificates for client authentication and your Oracle wallet for connections.

   Note
   If you’re not using client certificates for authentication, you can skip this step.

DECLARE
  l_wallet_path all_directories.directory_path%type;
BEGIN
  SELECT DIRECTORY_PATH
Step 6: Test connections from your DB instance to a website

In this step, you configure your database user so that it can connect to the website using UTL_HTTP, your uploaded Oracle Wallet, and the client certificate.

To configure access to a website from your RDS for Oracle DB instance

1. Log in your RDS for Oracle DB instance as a database user with UTL_HTTP permissions.
2. Confirm that a connection to your target website can resolve the host address.
   
   The following example gets the host address from secret.encrypted-website.com.

   ```sql
   SELECT UTL_INADDR.GET_HOST_ADDRESS(host => 'secret.encrypted-website.com') FROM DUAL;
   ``

3. Test a failed connection.

   The following query fails because UTL_HTTP requires the location of the Oracle wallet with the certificates.

   ```sql
   SELECT UTL_HTTP.REQUEST('secret.encrypted-website.com') FROM DUAL;
   ``

4. Test website access by using UTL_HTTP.SET_WALLET and selecting from DUAL.

   ```sql
   DECLARE
   l_wallet_path all_directories.directory_path%type;
   BEGIN
   SELECT DIRECTORY_PATH INTO l_wallet_path FROM ALL_DIRECTORIES
   WHERE UPPER(DIRECTORY_NAME) = 'WALLET_DIR';
   UTL_HTTP.SET_WALLET('file:' || l_wallet_path);
   END;
   /
   SELECT UTL_HTTP.REQUEST('secret.encrypted-website.com') FROM DUAL;
   ``

5. (Optional) Test website access by storing your query in a variable and using EXECUTE IMMEDIATE.

   ```sql
   DECLARE
   l_wallet_path all_directories.directory_path%type;
   v_webpage_sql VARCHAR2(1000);
   v_results VARCHAR2(32767);
   BEGIN
   SELECT DIRECTORY_PATH INTO l_wallet_path FROM ALL_DIRECTORIES
   WHERE UPPER(DIRECTORY_NAME) = 'WALLET_DIR';
   UTL_HTTP.SET_WALLET('file:' || l_wallet_path);
   END;
   /
   DECLARE
   v_webpage_sql VARCHAR2(1000);
   v_results VARCHAR2(32767);
   BEGIN
   SELECT DIRECTORY_PATH INTO l_wallet_path FROM ALL_DIRECTORIES
   WHERE UPPER(DIRECTORY_NAME) = 'WALLET_DIR';
   UTL_HTTP.SET_WALLET('file:' || l_wallet_path);
   END;
   /
   SELECT UTL_HTTP.REQUEST('secret.encrypted-website.com') FROM DUAL;
   ```
6. (Optional) Find the file system location of your Oracle wallet directory.

```sql
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory => 'WALLET_DIR'));
```

Use the output from the previous command to make an HTTP request. For example, if the directory is `rdsdbdata/userdirs/01`, run the following query.

```sql
SELECT UTL_HTTP.REQUEST('https://secret.encrypted-website.com/', '', 'file://rdsdbdata/userdirs/01')
FROM   DUAL;
```
Working with CDBs in RDS for Oracle

In the Oracle multitenant architecture, a container database (CDB) can include customer-created pluggable databases (PDBs). For more information about CDBs, see Introduction to the Multitenant Architecture in the Oracle Database documentation.

Overview of RDS for Oracle CDBs

You can create an RDS for Oracle DB instance as a container database (CDB) when you run Oracle Database 19c or higher. A CDB differs from a non-CDB because it can contain pluggable databases (PDBs). A PDB is a portable collection of schemas and objects that appears to an application as a separate database.

Starting with Oracle Database 21c, all databases are CDBs. If your DB instance runs Oracle Database 19c, you can create either a CDB or a non-CDB. A non-CDB uses the traditional Oracle database architecture and can't contain PDBs. You can convert an Oracle Database 19c non-CDB to a CDB, but you can't convert a CDB to a non-CDB. You can only upgrade a CDB to a CDB.

Single-tenant configuration

RDS for Oracle supports the single-tenant configuration of the Oracle multitenant architecture. This means that an RDS for Oracle DB instance can contain only one PDB. You name the PDB when you create your DB instance. The CDB name defaults to RDSCDB and can't be changed.

In RDS for Oracle, your client application interacts with the PDB rather than the CDB. Your experience with a PDB is mostly identical to your experience with a non-CDB. You use the same Amazon RDS APIs in the single-tenant configuration as you do in the non-CDB architecture. You can't access the CDB itself.

Creation and conversion options in a CDB

Although Oracle Database 21c supports only CDBs, Oracle Database 19c supports both CDBs and non-CDBs. The following table shows the different options for creating and converting CDBs and non-CDBs.

<table>
<thead>
<tr>
<th>Release</th>
<th>Database creation options</th>
<th>Architecture conversion options</th>
<th>Major version upgrade targets</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle Database 21c</td>
<td>CDB only</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>Release</td>
<td>Database creation options</td>
<td>Architecture conversion options</td>
<td>Major version upgrade targets</td>
</tr>
<tr>
<td>------------------</td>
<td>---------------------------</td>
<td>----------------------------------------------</td>
<td>-------------------------------</td>
</tr>
<tr>
<td>Oracle Database 19c</td>
<td>CDB or non-CDB</td>
<td>Non-CDB to CDB (April 2021 RU or higher)</td>
<td>21c CDB (from 19c CDB only)</td>
</tr>
<tr>
<td>Oracle Database 12c (desupported)</td>
<td>Non-CDB only</td>
<td>N/A</td>
<td>19c non-CDB</td>
</tr>
</tbody>
</table>

As shown in the preceding table, you can't directly upgrade a non-CDB to a CDB in a new major version. But you can convert an Oracle Database 19c non-CDB to an Oracle Database 19c CDB, and then upgrade the Oracle Database 19c CDB to an Oracle Database 21c CDB. For more information, see Converting an RDS for Oracle non-CDB to a CDB (p. 1860).

**User accounts and privileges in a CDB**

In the Oracle multitenant architecture, all user accounts are either *common users* or *local users*. A CDB common user is a database user whose single identity and password are known in the CDB root and in every existing and future PDB. In contrast, a local user exists only in a single PDB.

The RDS master user is a local user account in the PDB, which you name when you create your DB instance. If you create new user accounts, these users will also be local users residing in the PDB. You can't use any user accounts to create new PDBs or modify the state of the existing PDB.

The *rdsadmin* user is a common user account. You can run RDS for Oracle packages that exist in this account, but you can't log in as *rdsadmin*. For more information, see About Common Users and Local Users in the Oracle documentation.

**Parameter group families in a CDB**

CDBs have their own parameter group families and default parameter values. The CDB parameter group families are as follows:

- oracle-ee-cdb-21
- oracle-se2-cdb-21
- oracle-ee-cdb-19
- oracle-se2-cdb-19

You specify parameters at the CDB level rather than the PDB level. The PDB inherits parameter settings from the CDB. For more information about setting parameters, see Working with parameter groups (p. 347). For best practices, see Working with DB parameter groups (p. 297).

**PDB portability in a CDB**

Your CDB can contain only a single PDB. You can't unplug this PDB or plug in a different PDB. To move data into or out of your CDB, use the same techniques as for a non-CDB. For more information about migrating data, see Importing data into Oracle on Amazon RDS (p. 1963).

**Configuring an RDS for Oracle CDB**

Configuring a CDB is similar to configuring a non-CDB.

**Topics**

- Creating an RDS for Oracle CDB instance (p. 1858)
- Connecting to a PDB in your RDS for Oracle CDB (p. 1857)
Creating an RDS for Oracle CDB instance

In RDS for Oracle, creating a CDB is almost identical to creating a non-CDB. The difference is that you choose the Multitenant architecture when creating your DB instance. To create a CDB, use the AWS Management Console, the AWS CLI, or the RDS API.

Console

To create a CDB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the CDB instance.
3. In the navigation pane, choose Databases.
4. Choose Create database.
5. In Choose a database creation method, select Standard Create.
6. In Engine options, choose Oracle.
7. For Database management type, choose Amazon RDS.
8. For Architecture settings, choose Multitenant architecture.
9. Choose the settings that you want based on the options listed in Settings for DB instances (p. 308).
   Note the following:
   • For Master username, enter the name for a local user in your PDB. You can't use the master username to log in to the CDB root.
   • For Initial database name, enter the name of your PDB. You can't name the CDB, which has the default name RDSCDB.
10. Choose Create database.

AWS CLI

To create a DB instance by using the AWS CLI, call the create-db-instance command with the following parameters:

- --db-instance-identifier
- --db-instance-class
- --engine { oracle-ee-cdb | oracle-se2-cdb }
- --master-username
- --master-user-password
- --allocated-storage
- --backup-retention-period

For information about each setting, see Settings for DB instances (p. 308).

This following example creates an RDS for Oracle DB instance named my-cdb-inst. The PDB is named mypdb.

Example

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance \
```
Configuring a CDB

```
--engine oracle-ee-cdb
--db-instance-identifier my-cdb-inst
--db-name mypdb
--allocated-storage 250
--db-instance-class db.t3.large
--master-username pdb_admin
--master-user-password masteruserpassword
--backup-retention-period 3
```

For Windows:

```
aws rds create-db-instance
--engine oracle-ee-cdb
--db-instance-identifier my-cdb-inst
--db-name mypdb
--allocated-storage 250
--db-instance-class db.t3.large
--master-username pdb_admin
--master-user-password masteruserpassword
--backup-retention-period 3
```

**Note**

Specify a password other than the prompt shown here as a security best practice.

This command produces output similar to the following.

```
{
  "DBInstance": {
    "DBInstanceIdentifier": "my-cdb-inst",
    "DBInstanceClass": "db.t3.large",
    "Engine": "oracle-ee-cdb",
    "DBInstanceStatus": "creating",
    "MasterUsername": "pdb_user",
    "DBName": "MYPDB",
    "AllocatedStorage": 250,
    "PreferredBackupWindow": "04:59-05:29",
    "BackupRetentionPeriod": 3,
    "DBSecurityGroups": [],
    "VpcSecurityGroups": [
      {
        "VpcSecurityGroupId": "sg-0a2bcd3e",
        "Status": "active"
      }
    ],
    "DBParameterGroups": [
      {
        "DBParameterGroupName": "default.oracle-ee-cdb-19",
        "ParameterApplyStatus": "in-sync"
      }
    ],
    "DBSubnetGroup": {
      "DBSubnetGroupName": "default",
      "DBSubnetGroupDescription": "default",
      "VpcId": "vpc-1234567a",
      "SubnetGroupStatus": "Complete",
      ...
    }
  }
}
```

**RDS API**

To create a DB instance by using the Amazon RDS API, call the `CreateDBInstance` operation.

For information about each setting, see [Settings for DB instances](p. 308).
Connecting to a PDB in your RDS for Oracle CDB

You can use a utility like SQL*Plus to connect to a PDB. To download Oracle Instant Client, which includes a standalone version of SQL*Plus, see Oracle Instant Client Downloads.

To connect SQL*Plus to your PDB, you need the following information:

- Database user name and password
- Endpoint for your DB instance
- Port number

For information about finding the preceding information, see Finding the endpoint of your RDS for Oracle DB instance (p. 1822).

**Example To connect to your PDB using SQL*Plus**

In the following examples, substitute your master user for `master_user_name`. Also, substitute the endpoint for your DB instance, and then include the port number and the Oracle SID. The SID value is the name of the PDB that you specified when you created your DB instance, and not the DB instance identifier.

For Linux, macOS, or Unix:

```
sqlplus 'master_user_name@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=endpoint)(PORT=port))(CONNECT_DATA=(SID=pdb_name)))'
```

For Windows:

```
sqlplus master_user_name@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=endpoint)(PORT=port))(CONNECT_DATA=(SID=pdb_name)))
```

You should see output similar to the following.

```
SQL*Plus: Release 19.0.0.0.0 Production on Mon Aug 21 09:42:20 2021
```

After you enter the password for the user, the SQL prompt appears.

```
SQL>
```

**Note**

The shorter format connection string (Easy connect or EZCONNECT), such as `sqlplus username/password@LONGER-THAN-63-CHARS-RDS-ENDPOINT-HERE:1521/database-identifier`, might encounter a maximum character limit and should not be used to connect.

Back up and restore a CDB

DB snapshots work the same way in the multitenant and non-multitenant architecture. The only difference is that when you restore a DB snapshot, you can only rename the PDB, not the CDB. The CDB is always named RDSCDB. For more information, see Oracle Database considerations (p. 616).

Converting an RDS for Oracle non-CDB to a CDB

You can change the architecture of an Oracle database from the traditional non-CDB architecture to the multitenant architecture. When you upgrade your database engine version, you can't change the
Converting a non-CDB to a CDB

To upgrade an Oracle Database 19c non-CDB to an Oracle Database 21c CDB, you first need to convert the non-CDB to a CDB, and then upgrade the 19c CDB to a 21c CDB.

The non-CDB conversion operation has the following requirements:

- Make sure that you specify oracle-ee-cdb or oracle-se2-cdb for the engine type. These are the only supported values.
- Make sure that your DB engine runs Oracle Database 19c with an April 2021 or later RU.

The operation has the following limitations:

- You can't convert a CDB to a non-CDB. You can only convert a non-CDB to a CDB.
- You can't convert a primary or replica database that has Oracle Data Guard enabled.
- You can't upgrade the DB engine version and convert a non-CDB to a CDB in the same operation.
- The considerations for option and parameter groups are the same as for upgrading the DB engine. For more information, see Considerations for Oracle DB upgrades (p. 2126).

**Console**

**To convert a non-CDB to a CDB**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where your DB instance resides.
3. In the navigation pane, choose Databases, and then choose the non-CDB instance that you want to convert to a CDB instance.
4. Choose Modify.
5. For Architecture settings, select Multitenant architecture.
6. (Optional) For DB parameter group, choose a new parameter group for your CDB instance. The same parameter group considerations apply when converting a DB instance as when upgrading a DB instance. For more information, see Parameter group considerations (p. 2127).
7. (Optional) For Option group, choose a new option group for your CDB instance. The same option group considerations apply when converting a DB instance as when upgrading a DB instance. For more information, see Option group considerations (p. 2126).
8. When all the changes are as you want them, choose Continue and check the summary of modifications.
9. (Optional) Choose Apply immediately to apply the changes immediately. Choosing this option can cause downtime in some cases. For more information, see Using the Apply Immediately setting (p. 402).
10. On the confirmation page, review your changes. If they are correct, choose Modify DB instance.

Or choose Back to edit your changes or Cancel to cancel your changes.

**AWS CLI**

To convert the non-CDB on your DB instance to a CDB, set --engine to oracle-ee-cdb or oracle-se2-cdb in the AWS CLI command modify-db-instance.

The following example converts the DB instance named my-non-cdb and specifies a custom option group and parameter group.
Example

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \n   --db-instance-identifier my-non-cdb \n   --engine oracle-ee-cdb \n   --option-group-name custom-option-group \n   --db-parameter-group-name custom-parameter-group
```

For Windows:

```bash
aws rds modify-db-instance ^
   --db-instance-identifier my-non-cdb ^
   --engine oracle-ee-cdb ^
   --option-group-name custom-option-group ^
   --db-parameter-group-name custom-parameter-group
```

RDS API

To convert a non-CDB to a CDB, specify Engine in the RDS API operation `ModifyDBInstance`.

Upgrading your CDB

You can upgrade a CDB to a different Oracle Database release. For example, you can upgrade an Oracle Database 19c CDB to an Oracle Database 21c CDB. You can't change the database architecture during an upgrade. Thus, you can't upgrade a non-CDB to a CDB or upgrade a CDB to a non-CDB.

The procedure for upgrading a CDB to a CDB is the same as for upgrading a non-CDB to a non-CDB. For more information, see [Upgrading the RDS for Oracle DB engine (p. 2119)](#).
Administering your Oracle DB instance

Following are the common management tasks that you perform with an Amazon RDS DB instance. Some tasks are the same for all RDS DB instances. Other tasks are specific to RDS for Oracle.

The following tasks are common to all RDS databases, but Oracle has special considerations. For example, connect to an Oracle Database using the Oracle clients SQL*Plus and SQL Developer.

<table>
<thead>
<tr>
<th>Task area</th>
<th>Relevant documentation</th>
</tr>
</thead>
</table>
| Instance classes, storage, and PIOPS | RDS for Oracle instance classes (p. 1812)

</tbody>
</table>

Following, you can find a description for Amazon RDS–specific implementations of common DBA tasks for RDS Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. Also, RDS restricts access to certain system procedures and tables that require advanced privileges. In many of the tasks, you run the `rdsadmin` package, which is an Amazon RDS–specific tool that enables you to administer your database.

The following are common DBA tasks for DB instances running Oracle:

- **System tasks** (p. 1871)

<table>
<thead>
<tr>
<th>Task</th>
<th>Amazon RDS method</th>

**Oracle method:**
Various stored package procedures
Performing common system tasks for Oracle DB instances

Following, you can find how to perform certain common DBA tasks related to the system on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and restricts access to certain system procedures and tables that require advanced privileges.

Topics
- Disconnecting a session (p. 1871)
- Terminating a session (p. 1872)
- Canceling a SQL statement in a session (p. 1873)
- Enabling and disabling restricted sessions (p. 1874)
- Flushing the shared pool (p. 1874)
- Flushing the buffer cache (p. 1875)
- Flushing the database smart flash cache (p. 1875)
- Granting SELECT or EXECUTE privileges to SYS objects (p. 1875)
- Revoking SELECT or EXECUTE privileges on SYS objects (p. 1877)
- Granting privileges to non-master users (p. 1877)
- Creating custom functions to verify passwords (p. 1878)
- Setting up a custom DNS server (p. 1881)
- Setting and unsetting system diagnostic events (p. 1882)

Disconnecting a session

To disconnect the current session by ending the dedicated server process, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.disconnect`. The disconnect procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sid</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The session identifier.</td>
</tr>
<tr>
<td>serial</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The serial number of the session.</td>
</tr>
</tbody>
</table>
The following example disconnects a session.

```sql
begin
  rdsadmin.rdsadmin_util.disconnect(
    sid => sid,
    serial => serial_number);
end;
/
```

To get the session identifier and the session serial number, query the V$SESSION view. The following example gets all sessions for the user AWSUSER.

```sql
SELECT SID, SERIAL#, STATUS FROM V$SESSION WHERE USERNAME = 'AWSUSER';
```

The database must be open to use this method. For more information about disconnecting a session, see ALTER SYSTEM in the Oracle documentation.

## Terminating a session

To terminate a session, use the Amazon RDS procedure rdsadmin.rdsadmin_util.kill. The kill procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sid</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The session identifier.</td>
</tr>
<tr>
<td>serial</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The serial number of the session.</td>
</tr>
</tbody>
</table>
| method         | varchar   | null    | No       | Valid values are 'IMMEDIATE' or 'PROCESS'. If you specify IMMEDIATE, it has the same effect as running the following statement:  
**ALTER SYSTEM KILL SESSION 'sid,serial#' IMMEDIATE**  
If you specify PROCESS, you terminate the processes associated with a session. Only specify PROCESS if terminating the session using IMMEDIATE was unsuccessful. |
To get the session identifier and the session serial number, query the V$SESSION view. The following example gets all sessions for the user **AWSUSER**.

```
SELECT SID, SERIAL#, STATUS FROM V$SESSION WHERE USERNAME = 'AWSUSER';
```

The following example terminates a session.

```
BEGIN
    rdsadmin.rdsadmin_util.kill(
        sid => sid,
        serial => serial_number,
        method => 'IMMEDIATE');
END;
/
```

The following example terminates the processes associated with a session.

```
BEGIN
    rdsadmin.rdsadmin_util.kill(
        sid => sid,
        serial => serial_number,
        method => 'PROCESS');
END;
/
```

### Canceling a SQL statement in a session

To cancel a SQL statement in a session, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.cancel`.

**Note**
This procedure is supported for Oracle Database 19c (19.0.0) and all higher major and minor versions of RDS for Oracle.

The `cancel` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sid</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The session identifier.</td>
</tr>
<tr>
<td>serial</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The serial number of the session.</td>
</tr>
<tr>
<td>sql_id</td>
<td>varchar2</td>
<td>null</td>
<td>No</td>
<td>The SQL identifier of the SQL statement.</td>
</tr>
</tbody>
</table>

The following example cancels a SQL statement in a session.

```
begin
    rdsadmin.rdsadmin_util.cancel(
        sid => sid,
        serial => serial_number,
        sql_id => sql_id);
end;
/
```

To get the session identifier, the session serial number, and the SQL identifier of a SQL statement, query the V$SESSION view. The following example gets all sessions and SQL identifiers for the user **AWSUSER**.
select SID, SERIAL#, SQL_ID, STATUS from V$SESSION where USERNAME = 'AWSUSER';

**Enabling and disabling restricted sessions**

To enable and disable restricted sessions, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.restricted_session`. The `restricted_session` procedure has the following parameters:

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Yes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_enable</code></td>
<td>boolean</td>
<td>true</td>
<td>No</td>
<td>Set to true to enable restricted sessions, false to disable restricted sessions.</td>
</tr>
</tbody>
</table>

The following example shows how to enable and disable restricted sessions.

```sql
/* Verify that the database is currently unrestricted. */
SELECT LOGINS FROM V$INSTANCE;

LOGINS
-------
ALLOWED

/* Enable restricted sessions */
EXEC rdsadmin.rdsadmin_util.restricted_session(p_enable => true);

/* Verify that the database is now restricted. */
SELECT LOGINS FROM V$INSTANCE;

LOGINS
-------
RESTRICTED

/* Disable restricted sessions */
EXEC rdsadmin.rdsadmin_util.restricted_session(p_enable => false);

/* Verify that the database is now unrestricted again. */
SELECT LOGINS FROM V$INSTANCE;

LOGINS
-------
ALLOWED
```

**Flushing the shared pool**

To flush the shared pool, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.flush_shared_pool`. The `flush_shared_pool` procedure has no parameters.
The following example flushes the shared pool.

```
EXEC rdsadmin.rdsadmin_util.flush_shared_pool;
```

### Flushing the buffer cache

To flush the buffer cache, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.flush_buffer_cache`. The `flush_buffer_cache` procedure has no parameters.

The following example flushes the buffer cache.

```
EXEC rdsadmin.rdsadmin_util.flush_buffer_cache;
```

### Flushing the database smart flash cache

To flush the database smart flash cache, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.flush_flash_cache`. The `flush_flash_cache` procedure has no parameters. The following example flushes the database smart flash cache.

```
EXEC rdsadmin.rdsadmin_util.flush_flash_cache;
```

For more information about using the database smart flash cache with RDS for Oracle, see [Storing temporary data in an RDS for Oracle instance store](p. 1952).

### Granting SELECT or EXECUTE privileges to SYS objects

Usually you transfer privileges by using roles, which can contain many objects. To grant privileges to a single object, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.grant_sys_object`. The procedure grants only privileges that the master user has already been granted through a role or direct grant.

The `grant_sys_object` procedure has the following parameters.

**Important**

For all parameter values, use uppercase unless you created the user with a case-sensitive identifier. For example, if you run `CREATE USER myuser` or `CREATE USER MYUSER`, the data dictionary stores `MYUSER`. However, if you use double quotes in `CREATE USER "MyUser"`, the data dictionary stores `MyUser`.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_obj_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the object to grant privileges for. The object can be a directory, function, package, procedure, sequence, table, or view. Object names must be spelled exactly as they appear in DBA_OBJECTS. Most system objects are defined in uppercase, so we</td>
</tr>
</tbody>
</table>
### System tasks

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_grantee</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the object to grant privileges to. The object can be a schema or a role.</td>
</tr>
<tr>
<td>p_privilege</td>
<td>varchar2</td>
<td>null</td>
<td>Yes</td>
<td>—</td>
</tr>
<tr>
<td>p_grant_option</td>
<td>boolean</td>
<td>false</td>
<td>No</td>
<td>Set to true to use the with grant option. The p_grant_option parameter is supported for 12.1.0.2.v4 and later, all 12.2.0.1 versions, and all 19.0.0 versions.</td>
</tr>
</tbody>
</table>

The following example grants select privileges on an object named `V_$SESSION` to a user named USER1.

```
begin
  rdsadmin.rdsadmin_util.grant_sys_object(
    p_obj_name  => 'V_$SESSION',
    p_grantee   => 'USER1',
    p_privilege => 'SELECT');
end;
/
```

The following example grants select privileges on an object named `V_$SESSION` to a user named USER1 with the grant option.

```
begin
  rdsadmin.rdsadmin_util.grant_sys_object(
    p_obj_name   => 'V_$SESSION',
    p_grantee    => 'USER1',
    p_privilege  => 'SELECT',
    p_grant_option => true);
end;
/
```

To be able to grant privileges on an object, your account must have those privileges granted to it directly with the grant option, or via a role granted using with admin option. In the most common case, you may want to grant SELECT on a DBA view that has been granted to the SELECT_CATALOG_ROLE role. If that role isn't already directly granted to your user using with admin option, then you can't transfer the privilege. If you have the DBA privilege, then you can grant the role directly to another user.

The following example grants the SELECT_CATALOG_ROLE and EXECUTE_CATALOG_ROLE to USER1. Since the with admin option is used, USER1 can now grant access to SYS objects that have been granted to SELECT_CATALOG_ROLE.

```
GRANT SELECT_CATALOG_ROLE TO USER1 WITH ADMIN OPTION;
GRANT EXECUTE_CATALOG_ROLE TO USER1 WITH ADMIN OPTION;
```

Objects already granted to PUBLIC do not need to be re-granted. If you use the grant_sys_object procedure to re-grant access, the procedure call succeeds.
Revoking SELECT or EXECUTE privileges on SYS objects

To revoke privileges on a single object, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.revoke_sys_object`. The procedure only revokes privileges that the master account has already been granted through a role or direct grant.

The `revoke_sys_object` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_obj_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the object to revoke privileges for. The object can be a directory, function, package, procedure, sequence, table, or view. Object names must be spelled exactly as they appear in <code>DBA_OBJECTS</code>. Most system objects are defined in upper case, so we recommend you try that first.</td>
</tr>
<tr>
<td>p_revokee</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the object to revoke privileges for. The object can be a schema or a role.</td>
</tr>
<tr>
<td>p_privilege</td>
<td>varchar2</td>
<td>null</td>
<td>Yes</td>
<td>—</td>
</tr>
</tbody>
</table>

The following example revokes select privileges on an object named `V_$SESSION` from a user named `USER1`.

```sql
begin
  rdsadmin.rdsadmin_util.revoke_sys_object(
    p_obj_name  => 'V_$SESSION',
    p_revokee   => 'USER1',
    p_privilege => 'SELECT');
end;
/
```

Granting privileges to non-master users

You can grant select privileges for many objects in the SYS schema by using the `SELECT_CATALOG_ROLE` role. The `SELECT_CATALOG_ROLE` role gives users SELECT privileges on data dictionary views. The following example grants the role `SELECT_CATALOG_ROLE` to a user named `user1`.

```sql
GRANT SELECT_CATALOG_ROLE TO user1;
```

You can grant EXECUTE privileges for many objects in the SYS schema by using the `EXECUTE_CATALOG_ROLE` role. The `EXECUTE_CATALOG_ROLE` role gives users EXECUTE privileges for packages and procedures in the data dictionary. The following example grants the role `EXECUTE_CATALOG_ROLE` to a user named `user1`.

```sql
GRANT EXECUTE_CATALOG_ROLE TO user1;
```
GRANT EXECUTE_CATALOG_ROLE TO user1;

The following example gets the permissions that the roles SELECT_CATALOG_ROLE and EXECUTE_CATALOG_ROLE allow.

```sql
SELECT *
FROM ROLE_TAB_PRIVS
WHERE ROLE IN ('SELECT_CATALOG_ROLE','EXECUTE_CATALOG_ROLE')
ORDER BY ROLE, TABLE_NAME ASC;
```

The following example creates a non-master user named user1, grants the CREATE SESSION privilege, and grants the SELECT privilege on a database named sh.sales.

```sql
CREATE USER user1 IDENTIFIED BY PASSWORD;
GRANT CREATE SESSION TO user1;
GRANT SELECT ON sh.sales TO user1;
```

Creating custom functions to verify passwords

You can create a custom password verification function in the following ways:

- To use standard verification logic, and to store your function in the SYS schema, use the `create_verify_function` procedure.
- To use custom verification logic, or to avoid storing your function in the SYS schema, use the `create_passthrough_verify_fcn` procedure.

The `create_verify_function` procedure

You can create a custom function to verify passwords by using the Amazon RDS procedure `rdsadmin.rdsadmin_password_verify.create_verify_function`. The `create_verify_function` procedure is supported for version 12.0.2.v5 and all higher major and minor versions of RDS for Oracle.

The `create_verify_function` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_verify_function_name</td>
<td>varchar2</td>
<td></td>
<td>Yes</td>
<td>The name for your custom function. This function is created for you in the SYS schema. You assign this function to user profiles.</td>
</tr>
<tr>
<td>p_min_length</td>
<td>number</td>
<td>8</td>
<td>No</td>
<td>The minimum number of characters required.</td>
</tr>
<tr>
<td>p_max_length</td>
<td>number</td>
<td>256</td>
<td>No</td>
<td>The maximum number of characters allowed.</td>
</tr>
<tr>
<td>p_min_letters</td>
<td>number</td>
<td>1</td>
<td>No</td>
<td>The minimum number of letters required.</td>
</tr>
<tr>
<td>p_min_uppercase</td>
<td>number</td>
<td>0</td>
<td>No</td>
<td>The minimum number of uppercase letters required.</td>
</tr>
</tbody>
</table>
### System tasks

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_min_lowercase</td>
<td>number</td>
<td>0</td>
<td>No</td>
<td>The minimum number of lowercase letters required.</td>
</tr>
<tr>
<td>p_min_digits</td>
<td>number</td>
<td>1</td>
<td>No</td>
<td>The minimum number of digits required.</td>
</tr>
<tr>
<td>p_min_special</td>
<td>number</td>
<td>0</td>
<td>No</td>
<td>The minimum number of special characters required.</td>
</tr>
<tr>
<td>p_min_different_chars</td>
<td>number</td>
<td>3</td>
<td>No</td>
<td>The minimum number of different characters required between the old and new password.</td>
</tr>
<tr>
<td>p_disallow_username</td>
<td>boolean</td>
<td>true</td>
<td>No</td>
<td>Set to true to disallow the user name in the password.</td>
</tr>
<tr>
<td>p_disallow_reverse</td>
<td>boolean</td>
<td>true</td>
<td>No</td>
<td>Set to true to disallow the reverse of the user name in the password.</td>
</tr>
<tr>
<td>p_disallow_db_name</td>
<td>boolean</td>
<td>true</td>
<td>No</td>
<td>Set to true to disallow the database or server name in the password.</td>
</tr>
<tr>
<td>p_disallow_simple_strings</td>
<td>boolean</td>
<td>true</td>
<td>No</td>
<td>Set to true to disallow simple strings as the password.</td>
</tr>
<tr>
<td>p_disallow_whitespace</td>
<td>boolean</td>
<td>false</td>
<td>No</td>
<td>Set to true to disallow white space characters in the password.</td>
</tr>
<tr>
<td>p_disallow_at_sign</td>
<td>boolean</td>
<td>false</td>
<td>No</td>
<td>Set to true to disallow the @ character in the password.</td>
</tr>
</tbody>
</table>

You can create multiple password verification functions.

There are restrictions on the name of your custom function. Your custom function can’t have the same name as an existing system object. The name can be no more than 30 characters long. Also, the name must include one of the following strings: PASSWORD, VERIFY, COMPLEXITY, ENFORCE, or STRENGTH.

The following example creates a function named CUSTOM_PASSWORD_FUNCTION. The function requires that a password has at least 12 characters, 2 uppercase characters, 1 digit, and 1 special character, and that the password disallows the @ character.

```ruby
begin
    rdsadmin.rdsadmin_password_verify.create_verify_function(
        p_verify_function_name => 'CUSTOM_PASSWORD_FUNCTION',
        p_min_length           => 12,
        p_min_uppercase        => 2,
        p_min_digits           => 1,
        p_min_special          => 1,
        p_disallow_at_sign     => true);
end;
```
To see the text of your verification function, query DBA_SOURCE. The following example gets the text of a custom password function named CUSTOM_PASSWORD_FUNCTION.

```sql
COL TEXT FORMAT a150
SELECT TEXT
FROM DBA_SOURCE
WHERE OWNER = 'SYS'
AND NAME = 'CUSTOM_PASSWORD_FUNCTION'
ORDER BY LINE;
```

To associate your verification function with a user profile, use `alter profile`. The following example associates a verification function with the DEFAULT user profile.

```sql
ALTER PROFILE DEFAULT LIMIT PASSWORD_VERIFY_FUNCTION CUSTOM_PASSWORD_FUNCTION;
```

To see what user profiles are associated with what verification functions, query DBA_PROFILES. The following example gets the profiles that are associated with the custom verification function named CUSTOM_PASSWORD_FUNCTION.

```sql
SELECT * FROM DBA_PROFILES WHERE RESOURCE_NAME = 'PASSWORD' AND LIMIT = 'CUSTOM_PASSWORD_FUNCTION';
```

<table>
<thead>
<tr>
<th>PROFILE</th>
<th>RESOURCE_NAME</th>
<th>RESOURCE</th>
<th>LIMIT</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT</td>
<td>PASSWORD_VERIFY_FUNCTION</td>
<td>PASSWORD</td>
<td></td>
</tr>
<tr>
<td>CUSTOM_PASSWORD_FUNCTION</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The following example gets all profiles and the password verification functions that they are associated with.

```sql
SELECT * FROM DBA_PROFILES WHERE RESOURCE_NAME = 'PASSWORD_VERIFY_FUNCTION';
```

<table>
<thead>
<tr>
<th>PROFILE</th>
<th>RESOURCE_NAME</th>
<th>RESOURCE</th>
<th>LIMIT</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT</td>
<td>PASSWORD_VERIFY_FUNCTION</td>
<td>PASSWORD</td>
<td></td>
</tr>
<tr>
<td>CUSTOM_PASSWORD_FUNCTION</td>
<td>PASSWORD_VERIFY_FUNCTION</td>
<td>PASSWORD</td>
<td></td>
</tr>
<tr>
<td>RDSADMIN</td>
<td>PASSWORD_VERIFY_FUNCTION</td>
<td>PASSWORD</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The `create_passthrough_verify_fcn` procedure

The `create_passthrough_verify_fcn` procedure is supported for version 12.1.0.2.v7 and all higher major and minor versions of RDS for Oracle.

You can create a custom function to verify passwords by using the Amazon RDS procedure `rdsadmin.rdsadmin_password_verify.create_passthrough_verify_fcn`. The `create_passthrough_verify_fcn` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_verify_function_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name for your custom verification function. This is a wrapper function that is created for you in the</td>
</tr>
</tbody>
</table>
The following example creates a password verification function that uses the logic from the function named PASSWORD_LOGIC_EXTRA_STRONG.

```sql
begin
   rdsadmin.rdsadmin_password_verify.create_passthrough_verify_fcn(
      p_verify_function_name => 'CUSTOM_PASSWORD_FUNCTION',
      p_target_owner         => 'TEST_USER',
      p_target_function_name => 'PASSWORD_LOGIC_EXTRA_STRONG');
end;
/
```

To associate the verification function with a user profile, use `alter profile`. The following example associates the verification function with the DEFAULT user profile.

```sql
ALTER PROFILE DEFAULT LIMIT PASSWORD_VERIFY_FUNCTION CUSTOM_PASSWORD_FUNCTION;
```

### Setting up a custom DNS server

Amazon RDS supports outbound network access on your DB instances running Oracle. For more information about outbound network access, including prerequisites, see Configuring UTL_HTTP access using certificates and an Oracle wallet (p. 1848).

Amazon RDS Oracle allows Domain Name Service (DNS) resolution from a custom DNS server owned by the customer. You can resolve only fully qualified domain names from your Amazon RDS DB instance through your custom DNS server.

After you set up your custom DNS name server, it takes up to 30 minutes to propagate the changes to your DB instance. After the changes are propagated to your DB instance, all outbound network traffic requiring a DNS lookup queries your DNS server over port 53.

To set up a custom DNS server for your Amazon RDS for Oracle DB instance, do the following:

- From the DHCP options set attached to your virtual private cloud (VPC), set the domain-name-servers option to the IP address of your DNS name server. For more information, see DHCP options sets.
Note
The domain-name-servers option accepts up to four values, but your Amazon RDS DB instance uses only the first value.

- Ensure that your DNS server can resolve all lookup queries, including public DNS names, Amazon EC2 private DNS names, and customer-specific DNS names. If the outbound network traffic contains any DNS lookups that your DNS server can't handle, your DNS server must have appropriate upstream DNS providers configured.
- Configure your DNS server to produce User Datagram Protocol (UDP) responses of 512 bytes or less.
- Configure your DNS server to produce Transmission Control Protocol (TCP) responses of 1024 bytes or less.
- Configure your DNS server to allow inbound traffic from your Amazon RDS DB instances over port 53. If your DNS server is in an Amazon VPC, the VPC must have a security group that contains inbound rules that permit UDP and TCP traffic on port 53. If your DNS server is not in an Amazon VPC, it must have appropriate firewall allow-listing to permit UDP and TCP inbound traffic on port 53.

For more information, see Security groups for your VPC and Adding and removing rules.
- Configure the VPC of your Amazon RDS DB instance to allow outbound traffic over port 53. Your VPC must have a security group that contains outbound rules that allow UDP and TCP traffic on port 53.

For more information, see Security groups for your VPC and Adding and removing rules.
- The routing path between the Amazon RDS DB instance and the DNS server has to be configured correctly to allow DNS traffic.
  - If the Amazon RDS DB instance and the DNS server are not in the same VPC, a peering connection has to be set up between them. For more information, see What is VPC peering?

Setting and unsetting system diagnostic events
To set and unset diagnostic events at the session level, you can use the Oracle SQL statement ALTER SESSION SET EVENTS. However, to set events at the system level you can't use Oracle SQL. Instead, use the system event procedures in the rdsadmin.rdsadmin_util package. The system event procedures are available in the following engine versions:

- All Oracle Database 21c versions
- 19.0.0.0.ru-2020-10.rur-2020-10.r1 and higher Oracle Database 19c versions

For more information, see Version 19.0.0.0.ru-2020-10.rur-2020-10.r1 in the Amazon RDS for Oracle Release Notes.
- 12.2.0.1.ru-2020-10.rur-2020-10.r1 and higher Oracle Database 12c Release 2 (12.2.0.1) versions

For more information, see Version 12.2.0.1.ru-2020-10.rur-2020-10.r1 in the Amazon RDS for Oracle Release Notes.
- 12.1.0.2.V22 and higher Oracle Database 12c Release 1 (12.1.0.2) versions

For more information, see Version 12.1.0.2.v22 in the Amazon RDS for Oracle Release Notes.

Important
Internally, the rdsadmin.rdsadmin_util package sets events by using the ALTER SYSTEM SET EVENTS statement. This ALTER SYSTEM statement isn't documented in the Oracle Database documentation. Some system diagnostic events can generate large amounts of tracing information, cause contention, or affect database availability. We recommend that you test specific diagnostic events in your nonproduction database, and only set events in your production database under guidance of Oracle Support.
Listing allowed system diagnostic events

To list the system events that you can set, use the Amazon RDS procedure rdsadmin.rdsadmin_util.list_allowed_system_events. This procedure accepts no parameters.

The following example lists all system events that you can set.

```
SET SERVEROUTPUT ON
EXEC rdsadmin.rdsadmin_util.list_allowed_system_events;
```

The following sample output lists event numbers and their descriptions. Use the Amazon RDS procedures set_system_event to set these events and unset_system_event to unset them.

```
604   - error occurred at recursive SQL level
942   - table or view does not exist
1401  - inserted value too large for column
1403  - no data found
1410  - invalid ROWID
1422  - exact fetch returns more than requested number of rows
1426  - numeric overflow
1427  - single-row subquery returns more than one row
1476  - divisor is equal to zero
1483  - invalid length for DATE or NUMBER bind variable
1489  - result of string concatenation is too long
1652  - unable to extend temp segment by in tablespace
1858  - a non-numeric character was found where a numeric was expected
4031  - unable to allocate bytes of shared memory ("","",'',"")
6502  - PL/SQL: numeric or value error
10027 - Specify Deadlock Trace Information to be Dumped
10046 - enable SQL statement timing
10053 - CBO Enable optimizer trace
10173 - Dynamic Sampling time-out error
10442 - enable trace of kst for ORA-01555 diagnostics
12008 - error in materialized view refresh path
12012 - error on auto execute of job
12504 - TNS:listener was not given the SERVICE_NAME in CONNECT_DATA
14400 - inserted partition key does not map to any partition
31693 - Table data object failed to load/unload and is being skipped due to error:
```

**Note**
The list of the allowed system events can change over time. To make sure that you have the most recent list of eligible events, use rdsadmin.rdsadmin_util.list_allowed_system_events.

Setting system diagnostic events

To set a system event, use the Amazon RDS procedure rdsadmin.rdsadmin_util.set_system_event. You can only set events listed in the output of rdsadmin.rdsadmin_util.list_allowed_system_events. The set_system_event procedure accepts the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_event</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The system event number. The value must be one of the event numbers reported by list_allowed_system_events.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Data type</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------</td>
<td>---------</td>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>p_level</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The event level. See the Oracle Database documentation or Oracle Support for descriptions of different level values.</td>
</tr>
</tbody>
</table>

The procedure set_system_event constructs and runs the required ALTER SYSTEM SET EVENTS statements according to the following principles:

- The event type (context or errorstack) is determined automatically.
- A statement in the form ALTER SYSTEM SET EVENTS 'event LEVEL event_level' sets the context events. This notation is equivalent to ALTER SYSTEM SET EVENTS 'event TRACE NAME CONTEXT FOREVER, LEVEL event_level'.
- A statement in the form ALTER SYSTEM SET EVENTS 'event ERRORSTACK (event_level)' sets the error stack events. This notation is equivalent to ALTER SYSTEM SET EVENTS 'event TRACE NAME ERRORSTACK LEVEL event_level'.

The following example sets event 942 at level 3, and event 10442 at level 10. Sample output is included:

```
SQL> SET SERVEROUTPUT ON
SQL> EXEC rdsadmin.rdsadmin_util.set_system_event(942,3);
Setting system event 942 with: alter system set events '942 errorstack (3)'
PL/SQL procedure successfully completed.
SQL> EXEC rdsadmin.rdsadmin_util.set_system_event(10442,10);
Setting system event 10442 with: alter system set events '10442 level 10'
PL/SQL procedure successfully completed.
```

### Listing system diagnostic events that are set

To list the system events that are currently set, use the Amazon RDS procedure rdsadmin.rdsadmin_util.list_set_system_events. This procedure reports only events set at system level by set_system_event.

The following example lists the active system events:

```
SET SERVEROUTPUT ON
EXEC rdsadmin.rdsadmin_util.list_set_system_events;
```

The following sample output shows the list of events, the event type, the level at which the events are currently set, and the time when the event was set.

```
942 errorstack (3) - set at 2020-11-03 11:42:27
10442 level 10 - set at 2020-11-03 11:42:41
PL/SQL procedure successfully completed.
```

### Unsetting system diagnostic events

To unset a system event, use the Amazon RDS procedure rdsadmin.rdsadmin_util.unset_system_event. You can only unset events listed in the output of
rdsadmin.rdsadmin_util.list_allowed_system_events. The unset_system_event procedure accepts the following parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_event</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The system event number. The value must be one of the event numbers reported by list_allowed_system_events.</td>
</tr>
</tbody>
</table>

The following example unsets events 942 and 10442. Sample output is included.

```
SQL> SET SERVEROUTPUT ON
SQL> EXEC rdsadmin.rdsadmin_util.unset_system_event(942);
Unsetting system event 942 with: alter system set events '942 off'
PL/SQL procedure successfully completed.

SQL> EXEC rdsadmin.rdsadmin_util.unset_system_event(10442);
Unsetting system event 10442 with: alter system set events '10442 off'
PL/SQL procedure successfully completed.
```

Performing common database tasks for Oracle DB instances

Following, you can find how to perform certain common DBA tasks related to databases on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. Amazon RDS also restricts access to some system procedures and tables that require advanced privileges.

Topics

- Changing the global name of a database (p. 1886)
- Creating and sizing tablespaces (p. 1886)
- Setting the default tablespace (p. 1887)
- Setting the default temporary tablespace (p. 1887)
- Creating a temporary tablespace on the instance store (p. 1887)
- Adding a tempfile to the instance store on a read replica (p. 1888)
- Dropping tempfiles on a read replica (p. 1888)
- Checkpointing a database (p. 1889)
- Setting distributed recovery (p. 1889)
- Setting the database time zone (p. 1889)
- Working with Oracle external tables (p. 1890)
- Generating performance reports with Automatic Workload Repository (AWR) (p. 1891)
- Adjusting database links for use with DB instances in a VPC (p. 1895)
- Setting the default edition for a DB instance (p. 1895)
- Enabling auditing for the SYS.AUD$ table (p. 1896)
- Disabling auditing for the SYS.AUD$ table (p. 1896)
- Cleaning up interrupted online index builds (p. 1897)
• Skipping corrupt blocks (p. 1897)
• Resizing tablespace, data files, and temp files (p. 1899)
• Purging the recycle bin (p. 1902)
• Setting the default displayed values for full redaction (p. 1903)

Changing the global name of a database

To change the global name of a database, use the Amazon RDS procedure rdsadmin.rdsadmin_util.rename_global_name. The rename_global_name procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_new_global_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The new global name for the database.</td>
</tr>
</tbody>
</table>

The database must be open for the name change to occur. For more information about changing the global name of a database, see ALTER DATABASE in the Oracle documentation.

The following example changes the global name of a database to new_global_name.

```sql
EXEC rdsadmin.rdsadmin_util.rename_global_name(p_new_global_name => 'new_global_name');
```

Creating and sizing tablespaces

Amazon RDS only supports Oracle Managed Files (OMF) for data files, log files, and control files. When you create data files and log files, you can't specify the physical file names.

By default, if you don't specify a data file size, tablespaces are created with the default of AUTOEXTEND ON, and no maximum size. In the following example, the tablespace users1 is autoextensible.

```sql
CREATE TABLESPACE users1;
```

Because of these default settings, tablespaces can grow to consume all allocated storage. We recommend that you specify an appropriate maximum size on permanent and temporary tablespaces, and that you carefully monitor space usage.

The following example creates a tablespace named users2 with a starting size of 1 gigabyte. Because a data file size is specified, but AUTOEXTEND ON isn't specified, the tablespace isn't autoextensible.

```sql
CREATE TABLESPACE users2 DATAFILE SIZE 1G;
```

The following example creates a tablespace named users3 with a starting size of 1 gigabyte, autoextend turned on, and a maximum size of 10 gigabytes.

```sql
CREATE TABLESPACE users3 DATAFILE SIZE 1G AUTOEXTEND ON MAXSIZE 10G;
```

The following example creates a temporary tablespace named temp01.

```sql
CREATE TEMPORARY TABLESPACE temp01;
```
We recommend that you don't use smallfile tablespaces because you can't resize smallfile tablespaces with RDS for Oracle. However, you can add a data file to a smallfile tablespace. To determine whether a tablespace is bigfile or smallfile, query the `DBA_TABLESPACES` as follows.

```
SELECT TABLESPACE NAME, BIGFILE FROM DBA_TABLESPACES;
```

You can resize a bigfile tablespace by using `ALTER TABLESPACE`. You can specify the size in kilobytes (K), megabytes (M), gigabytes (G), or terabytes (T). The following example resizes a bigfile tablespace named `users_bf` to 200 MB.

```
ALTER TABLESPACE users_bf RESIZE 200M;
```

The following example adds an additional data file to a smallfile tablespace named `users_sf`.

```
ALTER TABLESPACE users_sf ADD DATAFILE SIZE 100000M AUTOEXTEND ON NEXT 250m MAXSIZE UNLIMITED;
```

### Setting the default tablespace

To set the default tablespace, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_default_tablespace`. The `alter_default_tablespace` procedure has the following parameters.

```
Parameter name | Data type | Default | Required | Description
----------------|-----------|---------|----------|----------------
tablespace_name | varchar   | —       | Yes      | The name of the default tablespace.
```

The following example sets the default tablespace to `users2`:

```
EXEC rdsadmin.rdsadmin_util.alter_default_tablespace(tablespace_name => 'users2');
```

### Setting the default temporary tablespace

To set the default temporary tablespace, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_default_temp_tablespace`. The `alter_default_temp_tablespace` procedure has the following parameters.

```
Parameter name | Data type | Default | Required | Description
----------------|-----------|---------|----------|----------------
tablespace_name | varchar   | —       | Yes      | The name of the default temporary tablespace.
```

The following example sets the default temporary tablespace to `temp01`.

```
EXEC rdsadmin.rdsadmin_util.alter_default_temp_tablespace(tablespace_name => 'temp01');
```

### Creating a temporary tablespace on the instance store

To create a temporary tablespace on the instance store, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.create_inst_store_tmp_tblspace`. The `create_inst_store_tmp_tblspace` procedure has the following parameters.
### Database tasks

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_tablespace_name</td>
<td>varchar</td>
<td>—</td>
<td>Yes</td>
<td>The name of the temporary tablespace.</td>
</tr>
</tbody>
</table>

The following example creates the temporary tablespace `temp01` in the instance store.

```sql
EXEC rdsadmin.rdsadmin_util.create_inst_store_tmp_tblspace(p_tablespace_name => 'temp01');
```

**Important**

When you run `rdsadmin_util.create_inst_store_tmp_tblspace`, the newly created temporary tablespace is not automatically set as the default temporary tablespace. To set it as the default, see [Setting the default temporary tablespace (p. 1887)](#).

For more information, see [Storing temporary data in an RDS for Oracle instance store (p. 1952)](#).

### Adding a tempfile to the instance store on a read replica

When you create a temporary tablespace on a primary DB instance, the read replica doesn't create tempfiles. Assume that an empty temporary tablespace exists on your read replica for either of the following reasons:

- You dropped a tempfile from the tablespace on your read replica. For more information, see [Dropping tempfiles on a read replica (p. 1888)](#).
- You created a new temporary tablespace on the primary DB instance. In this case, RDS for Oracle synchronizes the metadata to the read replica.

You can add a tempfile to the empty temporary tablespace, and store the tempfile in the instance store. To create a tempfile in the instance store, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.add_inst_store_tempfile`. You can use this procedure only on a read replica. The procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_tablespace_name</td>
<td>varchar</td>
<td>—</td>
<td>Yes</td>
<td>The name of the temporary tablespace on your read replica.</td>
</tr>
</tbody>
</table>

In the following example, the empty temporary tablespace `temp01` exists on your read replica. Run the following command to create a tempfile for this tablespace, and store it in the instance store.

```sql
EXEC rdsadmin.rdsadmin_util.add_inst_store_tempfile(p_tablespace_name => 'temp01');
```

For more information, see [Storing temporary data in an RDS for Oracle instance store (p. 1952)](#).

### Dropping tempfiles on a read replica

You can't drop an existing temporary tablespace on a read replica. You can change the tempfile storage on a read replica from Amazon EBS to the instance store, or from the instance store to Amazon EBS. To achieve these goals, do the following:

1. Drop the current tempfiles in the temporary tablespace on the read replica.
2. Create new tempfiles on different storage.
To drop the tempfiles, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.drop_replica_tempfiles`. You can use this procedure only on read replicas. The `drop_replica_tempfiles` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_tablespace_name</td>
<td>varchar</td>
<td>—</td>
<td>Yes</td>
<td>The name of the temporary tablespace on your read replica.</td>
</tr>
</tbody>
</table>

Assume that a temporary tablespace named `temp01` resides in the instance store on your read replica. Drop all tempfiles in this tablespace by running the following command.

```
EXEC rdsadmin.rdsadmin_util.drop_replica_tempfiles(p_tablespace_name => 'temp01');
```

For more information, see [Storing temporary data in an RDS for Oracle instance store (p. 1952)](#).

**Checkpointing a database**

To checkpoint the database, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.checkpoint`. The `checkpoint` procedure has no parameters.

The following example checkpoints the database.

```
EXEC rdsadmin.rdsadmin_util.checkpoint;
```

**Setting distributed recovery**

To set distributed recovery, use the Amazon RDS procedures `rdsadmin.rdsadmin_util.enable_distr_recovery` and `disable_distr_recovery`. The procedures have no parameters.

The following example enables distributed recovery.

```
EXEC rdsadmin.rdsadmin_util.enable_distr_recovery;
```

The following example disables distributed recovery.

```
EXEC rdsadmin.rdsadmin_util.disable_distr_recovery;
```

**Setting the database time zone**

You can set the time zone of your Amazon RDS Oracle database in the following ways:

- **The Timezone option**

  The Timezone option changes the time zone at the host level and affects all date columns and values such as SYSDATE. For more information, see [Oracle time zone (p. 2103)](#).

- **The Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_db_time_zone`**

  The `alter_db_time_zone` procedure changes the time zone for only certain data types, and doesn’t change SYSDATE. There are additional restrictions on setting the time zone listed in the [Oracle documentation](#).
The alter_db_time_zone procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_new_tz</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The new time zone as a named region or an absolute offset from Coordinated Universal Time (UTC). Valid offsets range from -12:00 to +14:00.</td>
</tr>
</tbody>
</table>

The following example changes the time zone to UTC plus three hours.

```
EXEC rdsadmin.rdsadmin_util.alter_db_time_zone(p_new_tz => '+3:00');
```

The following example changes the time zone to the Africa/Algiers time zone.

```
EXEC rdsadmin.rdsadmin_util.alter_db_time_zone(p_new_tz => 'Africa/Algiers');
```

After you alter the time zone by using the alter_db_time_zone procedure, reboot your DB instance for the change to take effect. For more information, see Rebooting a DB instance (p. 436). For information about upgrading time zones, see Time zone considerations (p. 2127).

### Working with Oracle external tables

Oracle external tables are tables with data that is not in the database. Instead, the data is in external files that the database can access. By using external tables, you can access data without loading it into the database. For more information about external tables, see Managing external tables in the Oracle documentation.

With Amazon RDS, you can store external table files in directory objects. You can create a directory object, or you can use one that is predefined in the Oracle database, such as the DATA_PUMP_DIR directory. For information about creating directory objects, see Creating and dropping directories in the main data storage space (p. 1942). You can query the ALL_DIRECTORIES view to list the directory objects for your Amazon RDS Oracle DB instance.

**Note**
Directory objects point to the main data storage space (Amazon EBS volume) used by your instance. The space used—along with data files, redo logs, audit, trace, and other files—counts against allocated storage.

You can move an external data file from one Oracle database to another by using the DBMS_FILE_TRANSFER package or the UTL_FILE package. The external data file is moved from a directory on the source database to the specified directory on the destination database. For information about using DBMS_FILE_TRANSFER, see Importing using Oracle Data Pump (p. 1964).

After you move the external data file, you can create an external table with it. The following example creates an external table that uses the emp_xt_file1.txt file in the USER_DIR1 directory.

```
CREATE TABLE emp_xt (emp_id NUMBER,
                     first_name VARCHAR2(50),
                     last_name VARCHAR2(50),
```
Suppose that you want to move data that is in an Amazon RDS Oracle DB instance into an external data file. In this case, you can populate the external data file by creating an external table and selecting the data from the table in the database. For example, the following SQL statement creates the `orders_xt` external table by querying the `orders` table in the database.

```
CREATE TABLE orders_xt
ORGANIZATION EXTERNAL
(
    TYPE ORACLE_DATAPUMP
    DEFAULT DIRECTORY DATA_PUMP_DIR
    LOCATION ('orders_xt.dmp')
) AS SELECT * FROM orders;
```

In this example, the data is populated in the `orders_xt.dmp` file in the `DATA_PUMP_DIR` directory.

**Generating performance reports with Automatic Workload Repository (AWR)**

To gather performance data and generate reports, Oracle recommends Automatic Workload Repository (AWR). AWR requires Oracle Database Enterprise Edition and a license for the Diagnostics and Tuning packs. To enable AWR, set the `CONTROL_MANAGEMENT_PACK_ACCESS` initialization parameter to either `DIAGNOSTIC` or `DIAGNOSTIC+TUNING`.

**Working with AWR reports in RDS**

To generate AWR reports, you can run scripts such as `awrrpt.sql`. These scripts are installed on the database host server. In Amazon RDS, you don't have direct access to the host. However, you can get copies of SQL scripts from another installation of Oracle Database.

You can also use AWR by running procedures in the `SYSDBMS_WORKLOAD_REPOSITORY` PL/SQL package. You can use this package to manage baselines and snapshots, and also to display ASH and AWR reports. For example, to generate an AWR report in text format run the `DBMS_WORKLOAD_REPOSITORY.AWR_REPORT_TEXT` procedure. However, you can't reach these AWR reports from the AWS Management Console.

When working with AWR, we recommend using the `rdsadmin.rdsadmin_diagnostic_util` procedures. You can use these procedures to generate the following:

- AWR reports
- Active Session History (ASH) reports
- Automatic Database Diagnostic Monitor (ADDM) reports
- Oracle Data Pump Export dump files of AWR data
The `rdsadmin_diagnostic_util` procedures save the reports to the DB instance file system. You can access these reports from the console. You can also access reports using the `rdsadmin.rds_file_util` procedures, and you can access reports that are copied to Amazon S3 using the S3 Integration option. For more information, see Reading files in a DB instance directory (p. 1943) and Amazon S3 integration (p. 2008).

You can use the `rdsadmin_diagnostic_util` procedures in the following Amazon RDS for Oracle DB engine versions:

- All Oracle Database 21c versions
- 19.0.0.0.ru-2020-04.rur-2020-04.r1 and higher Oracle Database 19c versions
- 12.2.0.1.ru-2020-04.rur-2020-04.r1 and higher Oracle Database 12c Release 2 (12.2) versions
- 12.1.0.2.v20 and higher Oracle Database 12c Release 1 (12.1) versions

For a blog that explains how to work with diagnostic reports in a replication scenario, see Generate AWR reports for Amazon RDS for Oracle read replicas.

### Common parameters for the diagnostic utility package

You typically use the following parameters when managing AWR and ADDM with the `rdsadmin_diagnostic_util` package.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>begin_snap_id</td>
<td>NUMBER</td>
<td>—</td>
<td>Yes</td>
<td>The ID of the beginning snapshot.</td>
</tr>
<tr>
<td>end_snap_id</td>
<td>NUMBER</td>
<td>—</td>
<td>Yes</td>
<td>The ID of the ending snapshot.</td>
</tr>
<tr>
<td>dump_directory</td>
<td>VARCHAR</td>
<td>BDUMP</td>
<td>No</td>
<td>The directory to write the report or export file to. If you specify a nondefault directory, the user that runs the <code>rdsadmin_diagnostic_util</code> procedures must have write permissions for the directory.</td>
</tr>
<tr>
<td>p_tag</td>
<td>VARCHAR2</td>
<td>—</td>
<td>No</td>
<td>A string that can be used to distinguish between backups to indicate the purpose or usage of backups, such as incremental or daily. You can specify up to 30 characters. Valid characters are a-z, A-Z, 0-9, an underscore (_), a dash (-), and a period (.). The tag is not case-sensitive. RMAN always stores tags in uppercase, regardless of the case used when entering them. Tags don't need to be unique, so multiple backups can have the same tag. If you don't specify a tag, RMAN assigns a default tag automatically using the format <code>TAGYYYYMMDDTHHMMSS</code>, where <code>YYYY</code> is the year, <code>MM</code> is the month, <code>DD</code> is the day, <code>HH</code> is the hour (in 24-hour format), <code>MM</code> is the minutes, and <code>SS</code> is the seconds. The date and time indicate when RMAN started the backup. For example, a backup with the default tag <code>TAG20190927T214517</code> indicates a backup that started on 2019-09-27 at 21:45:17. The <code>p_tag</code> parameter is supported for the following RDS for Oracle DB engine versions:</td>
</tr>
</tbody>
</table>

- **Oracle Database 21c (21.0.0)**
Generating an AWR report

To generate an AWR report, use the `rdsadmin.rdsadmin_diagnostic_util.awr_report` procedure.

The following example generates a AWR report for the snapshot range 101–106. The output text file is named `awrrpt_101_106.txt`. You can access this report from the AWS Management Console.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.awr_report(101,106,'TEXT');
```
The following example generates an HTML report for the snapshot range 63–65. The output HTML file is named awrrpt_63_65.html. The procedure writes the report to the nondefault database directory named AWR_RPT_DUMP.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.awr_report(63,65,'HTML','AWR_RPT_DUMP');
```

### Extracting AWR data into a dump file

To extract AWR data into a dump file, use the `rdsadmin.rdsadmin_diagnostic_util.awr_extract` procedure.

The following example extracts the snapshot range 101–106. The output dump file is named awrextract_101_106.dmp. You can access this file through the console.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.awr_extract(101,106);
```

The following example extracts the snapshot range 63–65. The output dump file is named awrextract_63_65.dmp. The file is stored in the nondefault database directory named AWR_RPT_DUMP.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.awr_extract(63,65,'AWR_RPT_DUMP');
```

### Generating an ADDM report

To generate an ADDM report, use the `rdsadmin.rdsadmin_diagnostic_util.addm_report` procedure.

The following example generates an ADDM report for the snapshot range 101–106. The output text file is named addmrpt_101_106.txt. You can access the report through the console.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.addm_report(101,106);
```

The following example generates an ADDM report for the snapshot range 63–65. The output text file is named addmrpt_63_65.txt. The file is stored in the nondefault database directory named ADDM_RPT_DUMP.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.addm_report(63,65,'ADDM_RPT_DUMP');
```

### Generating an ASH report

To generate an ASH report, use the `rdsadmin.rdsadmin_diagnostic_util.ash_report` procedure.

The following example generates an ASH report that includes the data from 14 minutes ago until the current time. The name of the output file uses the format `ashrpt begin_time end_time.txt`, where `begin_time` and `end_time` use the format `YYYYMMDDHH24MISS`. You can access the file through the console.

```
BEGIN
    rdsadmin.rdsadmin_diagnostic_util.ash_report(
        begin_time     =>     SYSDATE-14/1440,
        end_time       =>     SYSDATE,
        report_type    =>     'TEXT');
END
```
The following example generates an ASH report that includes the data from November 18, 2019, at 6:07 PM through November 18, 2019, at 6:15 PM. The name of the output HTML report is `ashrpt_20190918180700_20190918181500.html`. The report is stored in the nondefault database directory named `AWR_RPT_DUMP`.

```
BEGIN
  rdsadmin.rdsadmin_diagnostic_util.ash_report(
    begin_time     =>    TO_DATE('2019-09-18 18:07:00', 'YYYY-MM-DD HH24:MI:SS'),
    end_time       =>    TO_DATE('2019-09-18 18:15:00', 'YYYY-MM-DD HH24:MI:SS'),
    report_type    =>    'html',
    dump_directory =>    'AWR_RPT_DUMP');
END;
```

**Accessing AWR reports from the console or CLI**

To access AWR reports or export dump files, you can use the AWS Management Console or AWS CLI. For more information, see [Downloading a database log file](p. 896).

**Adjusting database links for use with DB instances in a VPC**

To use Oracle database links with Amazon RDS DB instances inside the same virtual private cloud (VPC) or peered VPCs, the two DB instances should have a valid route between them. Verify the valid route between the DB instances by using your VPC routing tables and network access control list (ACL).

The security group of each DB instance must allow ingress to and egress from the other DB instance. The inbound and outbound rules can refer to security groups from the same VPC or a peered VPC. For more information, see [Updating your security groups to reference peered VPC security groups](p. 1881).

If you have configured a custom DNS server using the DHCP Option Sets in your VPC, your custom DNS server must be able to resolve the name of the database link target. For more information, see [Setting up a custom DNS server](p. 1881).

For more information about using database links with Oracle Data Pump, see [Importing using Oracle Data Pump](p. 1964).

**Setting the default edition for a DB instance**

You can redefine database objects in a private environment called an edition. You can use edition-based redefinition to upgrade an application’s database objects with minimal downtime.

You can set the default edition of an Amazon RDS Oracle DB instance using the Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_default_edition`.

The following example sets the default edition for the Amazon RDS Oracle DB instance to `RELEASE_V1`.

```
EXEC rdsadmin.rdsadmin_util.alter_default_edition('RELEASE_V1');
```

The following example sets the default edition for the Amazon RDS Oracle DB instance back to the Oracle default.

```
EXEC rdsadmin.rdsadmin_util.alter_default_edition('ORA$BASE');
```
For more information about Oracle edition-based redefinition, see About editions and edition-based redefinition in the Oracle documentation.

### Enabling auditing for the SYS.AUD$ table

To enable auditing on the database audit trail table SYS.AUD$, use the Amazon RDS procedure `rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table`. The only supported audit property is `ALL`. You can't audit or not audit individual statements or operations.

Enabling auditing is supported for Oracle DB instances running the following versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2)
- Oracle Database 12c Release 1 (12.1.0.2.v14) and later

The `audit_all_sys_aud_table` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_by_access</td>
<td>boolean</td>
<td>true</td>
<td>No</td>
<td>Set to <code>true</code> to audit BY ACCESS. Set to <code>false</code> to audit BY SESSION.</td>
</tr>
</tbody>
</table>

**Note**

In a single-tenant CDB, the following operations work, but no customer-visible mechanism can detect the current status of the operations. Auditing information isn't available from within the PDB. For more information, see Limitations of a single-tenant CDB (p. 1821).

The following query returns the current audit configuration for SYS.AUD$ for a database:

```
SELECT * FROM DBA_OBJ_AUDIT_OPTS WHERE OWNER='SYS' AND OBJECT_NAME='AUD$';
```

The following commands enable audit of `ALL` on SYS.AUD$ BY ACCESS.

```
EXEC rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table;
EXEC rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table(p_by_access => true);
```

The following command enables audit of `ALL` on SYS.AUD$ BY SESSION.

```
EXEC rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table(p_by_access => false);
```

For more information, see [AUDIT (traditional auditing)](https://docs.oracle.com/cd/E11882_01/server.112/e26086/index.html) in the Oracle documentation.

### Disabling auditing for the SYS.AUD$ table

To disable auditing on the database audit trail table SYS.AUD$, use the Amazon RDS procedure `rdsadmin.rdsadmin_master_util.noaudit_all_sys_aud_table`. This procedure takes no parameters.

The following query returns the current audit configuration for SYS.AUD$ for a database:
SELECT * FROM DBA_OBJ_AUDIT_OPTS WHERE OWNER='SYS' AND OBJECT_NAME='AUD$';

The following command disables audit of ALL on SYS.AUD$.

EXEC rdsadmin.rdsadmin_master_util.noaudit_all_sys_aud_table;

For more information, see NOAUDIT (traditional auditing) in the Oracle documentation.

### Cleaning up interrupted online index builds

To clean up failed online index builds, use the Amazon RDS procedure `rdsadmin.rdsadmin_dbms_repair.online_index_clean`.

The `online_index_clean` procedure has the following parameters:

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_id</td>
<td>binary_integer</td>
<td>ALL_INDEX_ID</td>
<td>No</td>
<td>The object ID of the index. Typically, you can use the object ID from the ORA-08104 error text.</td>
</tr>
<tr>
<td>wait_for_lock</td>
<td>binary_integer</td>
<td>rdsadmin.rdsadmin_dbms_repair.lock_wait</td>
<td>No</td>
<td>Specify rdsadmin.rdsadmin_dbms_repair.lock_nowait to try to get a lock on the underlying object but not retry if the lock fails. Specify rdsadmin.rdsadmin_dbms_repair.lock_nowait to try to get a lock on the underlying object but not retry if the lock fails.</td>
</tr>
</tbody>
</table>

The following example cleans up a failed online index build:

```sql
declare
    is_clean boolean;
begin
    is_clean := rdsadmin.rdsadmin_dbms_repair.online_index_clean(
        object_id     => 1234567890,
        wait_for_lock => rdsadmin.rdsadmin_dbms_repair.lock_nowait
    );
end;
/
```

For more information, see ONLINE_INDEX_CLEAN function in the Oracle documentation.

### Skipping corrupt blocks

To skip corrupt blocks during index and table scans, use the `rdsadmin.rdsadmin_dbms_repair` package.
The following procedures wrap the functionality of the `sys.dbms_repair.admin_table` procedure and take no parameters:

- `rdsadmin.rdsadmin_dbms_repair.create_repair_table`
- `rdsadmin.rdsadmin_dbms_repair.create_orphan_keys_table`
- `rdsadmin.rdsadmin_dbms_repair.drop_repair_table`
- `rdsadmin.rdsadmin_dbms_repair.drop_orphan_keys_table`
- `rdsadmin.rdsadmin_dbms_repair.purge_repair_table`
- `rdsadmin.rdsadmin_dbms_repair.purge_orphan_keys_table`

The following procedures take the same parameters as their counterparts in the `DBMS_REPAIR` package for Oracle databases:

- `rdsadmin.rdsadmin_dbms_repair.check_object`
- `rdsadmin.rdsadmin_dbms_repair.dump_orphan_keys`
- `rdsadmin.rdsadmin_dbms_repair.fix_corrupt_blocks`
- `rdsadmin.rdsadmin_dbms_repair.rebuild_freelists`
- `rdsadmin.rdsadmin_dbms_repair.segment_fix_status`
- `rdsadmin.rdsadmin_dbms_repair.skip_corrupt_blocks`

For more information about handling database corruption, see `DBMS_REPAIR` in the Oracle documentation.

**Example Responding to corrupt blocks**

This example shows the basic workflow for responding to corrupt blocks. Your steps will depend on the location and nature of your block corruption.

**Important**

Before attempting to repair corrupt blocks, review the `DBMS_REPAIR` documentation carefully.

**To skip corrupt blocks during index and table scans**

1. Run the following procedures to create repair tables if they don't already exist.

   ```sql
   EXEC rdsadmin.rdsadmin_dbms_repair.create_repair_table;
   EXEC rdsadmin.rdsadmin_dbms_repair.create_orphan_keys_table;
   ```

2. Run the following procedures to check for existing records and purge them if appropriate.

   ```sql
   SELECT COUNT(*) FROM SYS.REPAIR_TABLE;
   SELECT COUNT(*) FROM SYS.ORPHAN_KEY_TABLE;
   SELECT COUNT(*) FROM SYS.DBA_REPAIR_TABLE;
   SELECT COUNT(*) FROM SYS.DBA_ORPHAN_KEY_TABLE;
   EXEC rdsadmin.rdsadmin_dbms_repair.purge_repair_table;
   EXEC rdsadmin.rdsadmin_dbms_repair.purge_orphan_keys_table;
   ```

3. Run the following procedure to check for corrupt blocks.

   ```sql
   SET SERVEROUTPUT ON
   DECLARE v_num_corrupt INT;
   BEGIN
     v_num_corrupt := 0;
     rdsadmin.rdsadmin_dbms_repair.check_object (
Resizing tablespace, data files, and temp files

By default, Oracle tablespaces are created with auto-extend turned on and no maximum size. Because of these default settings, tablespaces can sometimes grow too large. We recommend that you specify
an appropriate maximum size on permanent and temporary tablespaces, and that you carefully monitor space usage.

**Resizing permanent tablespaces**

To resize a permanent tablespace in an RDS for Oracle DB instance, use any of the following Amazon RDS procedures:

- `rdsadmin.rdsadmin_util.resize_datafile`
- `rdsadmin.rdsadmin_util.autoextend_datafile`

The `resize_datafile` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_data_file_id</code></td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The identifier of the data file to resize.</td>
</tr>
<tr>
<td><code>p_size</code></td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The size of the data file. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G).</td>
</tr>
</tbody>
</table>

The `autoextend_datafile` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_data_file_id</code></td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The identifier of the data file to resize.</td>
</tr>
<tr>
<td><code>p_autoextend_state</code></td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The state of the autoextension feature. Specify ON to extend the data file automatically and OFF to turn off autoextension.</td>
</tr>
<tr>
<td><code>p_next</code></td>
<td>varchar2</td>
<td>—</td>
<td>No</td>
<td>The size of the next data file increment. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G).</td>
</tr>
<tr>
<td><code>p_maxsize</code></td>
<td>varchar2</td>
<td>—</td>
<td>No</td>
<td>The maximum disk space allowed for automatic extension. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G). You can specify UNLIMITED to remove the file size limit.</td>
</tr>
</tbody>
</table>

The following example resizes data file 4 to 500 MB.
The following example turns off autoextension for data file 4. It also turns on autoextension for data file 5, with an increment of 128 MB and no maximum size.

```sql
EXEC rdsadmin.rdsadmin_util.resize_datafile(4,'500M');
EXEC rdsadmin.rdsadmin_util.autoextend_datafile(4,'OFF');
EXEC rdsadmin.rdsadmin_util.autoextend_datafile(5,'ON','128M','UNLIMITED');
```

### Resizing temporary tablespaces

To resize a temporary tablespace in an RDS for Oracle DB instance, including a read replica, use any of the following Amazon RDS procedures:

- `rdsadmin.rdsadmin_util.resize_temp_tablespace`
- `rdsadmin.rdsadmin_util.resize_tempfile`
- `rdsadmin.rdsadmin_util.autoextend_tempfile`

The `resize_temp_tablespace` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_temp_tablespace_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the temporary tablespace to resize.</td>
</tr>
<tr>
<td>p_size</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The size of the tablespace. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G).</td>
</tr>
</tbody>
</table>

The `resize_tempfile` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_temp_file_id</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The identifier of the temp file to resize.</td>
</tr>
<tr>
<td>p_size</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The size of the temp file. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G).</td>
</tr>
</tbody>
</table>

The `autoextend_tempfile` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_temp_file_id</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The identifier of the temp file to resize.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Data type</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------</td>
<td>---------</td>
<td>----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>p_autoextend_state</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The state of the autoextension feature. Specify ON to extend the temp file automatically and OFF to turn off autoextension.</td>
</tr>
<tr>
<td>p_next</td>
<td>varchar2</td>
<td>—</td>
<td>No</td>
<td>The size of the next temp file increment. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G).</td>
</tr>
<tr>
<td>p_maxsize</td>
<td>varchar2</td>
<td>—</td>
<td>No</td>
<td>The maximum disk space allowed for automatic extension. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G). You can specify UNLIMITED to remove the file size limit.</td>
</tr>
</tbody>
</table>

The following examples resize a temporary tablespace named TEMP to the size of 4 GB.

```sql
EXEC rdsadmin.rdsadmin_util.resize_temp_tablespace('TEMP','4G');
EXEC rdsadmin.rdsadmin_util.resize_temp_tablespace('TEMP','4096000000');
```

The following example resizes a temporary tablespace based on the temp file with the file identifier 1 to the size of 2 MB.

```sql
EXEC rdsadmin.rdsadmin_util.resize_tempfile(1,'2M');
```

The following example turns off autoextension for temp file 1. It also sets the maximum autoextension size of temp file 2 to 10 GB, with an increment of 100 MB.

```sql
EXEC rdsadmin.rdsadmin_util.autoextend_tempfile(1,'OFF');
EXEC rdsadmin.rdsadmin_util.autoextend_tempfile(2,'ON','100M','10G');
```

For more information about read replicas for Oracle DB instances see Working with read replicas for Amazon RDS for Oracle (p. 1989).

**Purging the recycle bin**

When you drop a table, your Oracle database doesn't immediately remove its storage space. The database renames the table and places it and any associated objects in a recycle bin. Purging the recycle bin removes these items and releases their storage space.

To purge the entire recycle bin, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.purge_dba_recyclebin`. However, this procedure can't purge the recycle bin of SYS and RDSADMIN objects. If you need to purge these objects, contact AWS Support.

The following example purges the entire recycle bin.
Setting the default displayed values for full redaction

To change the default displayed values for full redaction on your Amazon RDS Oracle instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.dbms_redact_upd_full_rdct_val`. Note that you create a redaction policy with the `DBMS_REDACT` PL/SQL package, as explained in the Oracle Database documentation. The `dbms_redact_upd_full_rdct_val` procedure specifies the characters to display for different data types affected by an existing policy.

The `dbms_redact_upd_full_rdct_val` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_number_val</td>
<td>number</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the NUMBER data type.</td>
</tr>
<tr>
<td>p_binfloat_val</td>
<td>binary_float</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the BINARY_FLOAT data type.</td>
</tr>
<tr>
<td>p_bindouble_val</td>
<td>binary_double</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the BINARY_DOUBLE data type.</td>
</tr>
<tr>
<td>p_char_val</td>
<td>char</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the CHAR data type.</td>
</tr>
<tr>
<td>p_varchar_val</td>
<td>varchar2</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the VARCHAR2 data type.</td>
</tr>
<tr>
<td>p_nchar_val</td>
<td>nchar</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the NCHAR data type.</td>
</tr>
<tr>
<td>pnvarchar_val</td>
<td>nvarchar2</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the NVARCHAR2 data type.</td>
</tr>
<tr>
<td>p_date_val</td>
<td>date</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the DATE data type.</td>
</tr>
<tr>
<td>p_ts_val</td>
<td>timestamp</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the TIMESTAMP data type.</td>
</tr>
<tr>
<td>p_tswtz_val</td>
<td>timestamp with time zone</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the TIMESTAMP WITH TIME ZONE data type.</td>
</tr>
<tr>
<td>p_blob_val</td>
<td>blob</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the BLOB data type.</td>
</tr>
</tbody>
</table>
## Performing common log-related tasks for Oracle DB instances

Following, you can find how to perform certain common DBA tasks related to logging on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and restricts access to certain system procedures and tables that require advanced privileges.

For more information, see [Oracle database log files](p. 924).

### Topics

- Setting force logging (p. 1905)
- Setting supplemental logging (p. 1905)
- Switching online log files (p. 1906)
- Adding online redo logs (p. 1906)
- Dropping online redo logs (p. 1907)
- Resizing online redo logs (p. 1907)
- Retaining archived redo logs (p. 1909)
- Accessing online and archived redo logs (p. 1910)
- Downloading archived redo logs from Amazon S3 (p. 1911)
Setting force logging

In force logging mode, Oracle logs all changes to the database except changes in temporary tablespaces and temporary segments (NOLOGGING clauses are ignored). For more information, see Specifying FORCE LOGGING mode in the Oracle documentation.

To set force logging, use the Amazon RDS procedure rdsadmin.rdsadmin_util.force_logging. The force_logging procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Yes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_enable</td>
<td>boolean</td>
<td>true</td>
<td>No</td>
<td>Set to true to put the database in force logging mode, false to remove the database from force logging mode.</td>
</tr>
</tbody>
</table>

The following example puts the database in force logging mode.

EXEC rdsadmin.rdsadmin_util.force_logging(p_enable => true);

Setting supplemental logging

If you enable supplemental logging, LogMiner has the necessary information to support chained rows and clustered tables. For more information, see Supplemental logging in the Oracle documentation.

Oracle Database doesn't enable supplemental logging by default. To enable and disable supplemental logging, use the Amazon RDS procedure rdsadmin.rdsadmin_util.alter_supplemental_logging. For more information about how Amazon RDS manages the retention of archived redo logs for Oracle DB instances, see Retaining archived redo logs (p. 1909).

The alter_supplemental_logging procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_action</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>'ADD' to add supplemental logging, 'DROP' to drop supplemental logging.</td>
</tr>
<tr>
<td>p_type</td>
<td>varchar2</td>
<td>null</td>
<td>No</td>
<td>The type of supplemental logging. Valid values are 'ALL', 'FOREIGN KEY', 'PRIMARY KEY', 'UNIQUE', or PROCEDURAL.</td>
</tr>
</tbody>
</table>

The following example enables supplemental logging.

begin
  rdsadmin.rdsadmin_util.alter_supplemental_logging(
    p_action => 'ADD');
end
The following example enables supplemental logging for all fixed-length maximum size columns.

```sql
begin
rdsadmin.rdsadmin_util.alter_supplemental_logging(
    p_action => 'ADD',
    p_type   => 'ALL');
end;
/
```

The following example enables supplemental logging for primary key columns.

```sql
begin
rdsadmin.rdsadmin_util.alter_supplemental_logging(
    p_action => 'ADD',
    p_type   => 'PRIMARY KEY');
end;
/
```

### Switching online log files

To switch log files, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.switch_logfile`. The `switch_logfile` procedure has no parameters.

The following example switches log files.

```sql
EXEC rdsadmin.rdsadmin_util.switch_logfile;
```

### Adding online redo logs

An Amazon RDS DB instance running Oracle starts with four online redo logs, 128 MB each. To add additional redo logs, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.add_logfile`.

The `add_logfile` procedure has the following parameters.

**Note**
The parameters are mutually exclusive.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bytes</td>
<td>positive</td>
<td>null</td>
<td>No</td>
<td>The size of the log file in bytes.</td>
</tr>
<tr>
<td>p_size</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The size of the log file. You can specify the size in kilobytes (K), megabytes (M), or gigabytes (G).</td>
</tr>
</tbody>
</table>

The following command adds a 100 MB log file.

```sql
EXEC rdsadmin.rdsadmin_util.add_logfile(p_size => '100M');
```
Dropping online redo logs

To drop redo logs, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.drop_logfile`. The `drop_logfile` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grp</td>
<td>positive</td>
<td></td>
<td>Yes</td>
<td>The group number of the log.</td>
</tr>
</tbody>
</table>

The following example drops the log with group number 3.

```sql
EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 3);
```

You can only drop logs that have a status of unused or inactive. The following example gets the statuses of the logs.

```sql
SELECT GROUP#, STATUS FROM V$LOG;
```

<table>
<thead>
<tr>
<th>GROUP#</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>CURRENT</td>
</tr>
<tr>
<td>2</td>
<td>INACTIVE</td>
</tr>
<tr>
<td>3</td>
<td>INACTIVE</td>
</tr>
<tr>
<td>4</td>
<td>UNUSED</td>
</tr>
</tbody>
</table>

Resizing online redo logs

An Amazon RDS DB instance running Oracle starts with four online redo logs, 128 MB each. The following example shows how you can use Amazon RDS procedures to resize your logs from 128 MB each to 512 MB each.

```sql
/* Query V$LOG to see the logs. */
/* You start with 4 logs of 128 MB each. */
SELECT GROUP#, BYTES, STATUS FROM V$LOG;
```

<table>
<thead>
<tr>
<th>GROUP#</th>
<th>BYTES</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>134217728</td>
<td>INACTIVE</td>
</tr>
<tr>
<td>2</td>
<td>134217728</td>
<td>CURRENT</td>
</tr>
<tr>
<td>3</td>
<td>134217728</td>
<td>INACTIVE</td>
</tr>
<tr>
<td>4</td>
<td>134217728</td>
<td>INACTIVE</td>
</tr>
</tbody>
</table>

```sql
/* Add four new logs that are each 512 MB */
EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);
EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);
EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);
EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);
```

```sql
/* Query V$LOG to see the logs. */
/* Now there are 8 logs. */
```
SELECT GROUP#, BYTES, STATUS FROM V$LOG;

GROUP#     BYTES      STATUS

  8        536870912  UNUSED

Retaining archived redo logs

You can retain archived redo logs locally on your DB instance for use with products like Oracle LogMiner (DBMS_LOGMNR). After you have retained the redo logs, you can use LogMiner to analyze the logs. For more information, see Using LogMiner to analyze redo log files in the Oracle documentation.

To retain archived redo logs, use the Amazon RDS procedure rdsadmin.rdsadmin_util.set_configuration. The set_configuration procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>varchar</td>
<td>—</td>
<td>Yes</td>
<td>The name of the configuration to update.</td>
</tr>
<tr>
<td>value</td>
<td>varchar</td>
<td>—</td>
<td>Yes</td>
<td>The value for the configuration.</td>
</tr>
</tbody>
</table>

The following example retains 24 hours of redo logs.

begin
    rdsadmin.rdsadmin_util.set_configuration(
        name  => 'archivelog retention hours',
        value => '24');
end;
/
commit;

Note
The commit is required for the change to take effect.

To view how long archived redo logs are kept for your DB instance, use the Amazon RDS procedure rdsadmin.rdsadmin_util.show_configuration.
The following example shows the log retention time.

```sql
set serveroutput on
EXEC rdsadmin.rdsadmin_util.show_configuration;
```

The output shows the current setting for `archivelog retention` hours. The following output shows that archived redo logs are kept for 48 hours.

<table>
<thead>
<tr>
<th>NAME</th>
<th>VALUE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>archivelog retention hours</td>
<td>48</td>
<td>ArchiveLog expiration specifies the duration in hours before archive/redo log files are automatically deleted.</td>
</tr>
</tbody>
</table>

Because the archived redo logs are retained on your DB instance, ensure that your DB instance has enough allocated storage for the retained logs. To determine how much space your DB instance has used in the last X hours, you can run the following query, replacing X with the number of hours.

```sql
SELECT SUM(BLOCKS * BLOCK_SIZE) bytes
FROM V$ARCHIVED_LOG
WHERE FIRST_TIME >= SYSDATE-(X/24) AND DEST_ID=1;
```

RDS for Oracle only generates archived redo logs when the backup retention period of your DB instance is greater than zero. By default the backup retention period is greater than zero.

When the archived log retention period expires, RDS for Oracle removes the archived redo logs from your DB instance. To support restoring your DB instance to a point in time, Amazon RDS retains the archived redo logs outside of your DB instance based on the backup retention period. To modify the backup retention period, see [Modifying an Amazon RDS DB instance](p. 401).

**Note**

In some cases, you might be using JDBC on Linux to download archived redo logs and experience long latency times and connection resets. In such cases, the issues might be caused by the default random number generator setting on your Java client. We recommend setting your JDBC drivers to use a nonblocking random number generator.

### Accessing online and archived redo logs

You might want to access your online and archived redo log files for mining with external tools such as GoldenGate, Attunity, Informatica, and others. To access these files, do the following:

1. Create directory objects that provide read-only access to the physical file paths.

   ```sql```
   Use rdsadmin.rdsadmin_master_util.create_archivelog_dir and rdsadmin.rdsadmin_master_util.create_onlinelog_dir.
   ```

2. Read the files using PL/SQL.

   You can read the files by using PL/SQL. For more information about reading files from directory objects, see [Listing files in a DB instance directory](p. 1943) and [Reading files in a DB instance directory](p. 1943).

Accessing transaction logs is supported for the following releases:

- Oracle Database 21c
- Oracle Database 19c
- Oracle Database 12c Release 2 (12.2.0.1)
Oracle Database 12c Release 1 (12.1)

The following code creates directories that provide read-only access to your online and archived redo log files:

**Important**
This code also revokes the DROP ANY DIRECTORY privilege.

```sql
EXEC rdsadmin.rdsadmin_master_util.create_archivelog_dir;
EXEC rdsadmin.rdsadmin_master_util.create_onlinelog_dir;
```

The following code drops the directories for your online and archived redo log files.

```sql
EXEC rdsadmin.rdsadmin_master_util.drop_archivelog_dir;
EXEC rdsadmin.rdsadmin_master_util.drop_onlinelog_dir;
```

The following code grants and revokes the DROP ANY DIRECTORY privilege.

```sql
EXEC rdsadmin.rdsadmin_master_util.revoke_drop_any_directory;
EXEC rdsadmin.rdsadmin_master_util.grant_drop_any_directory;
```

**Downloading archived redo logs from Amazon S3**

You can download archived redo logs on your DB instance using the `rdsadmin.rdsadmin_archive_log_download` package. If archived redo logs are no longer on your DB instance, you might want to download them again from Amazon S3. Then you can mine the logs or use them to recover or replicate your database.

**Note**
You can't download archived redo logs on read replica instances.

**Downloading archived redo logs: basic steps**

The availability of your archived redo logs depends on the following retention policies:

- **Backup retention policy** – Logs inside of this policy are available in Amazon S3. Logs outside of this policy are removed.
- **Archived log retention policy** – Logs inside of this policy are available on your DB instance. Logs outside of this policy are removed.

If logs aren't on your instance but are protected by your backup retention period, use `rdsadmin.rdsadmin_archive_log_download` to download them again. RDS for Oracle saves the logs to the `/rdsdbdata/log/arch` directory on your DB instance.

**To download archived redo logs from Amazon S3**

1. Configure your retention period to ensure your downloaded archived redo logs are retained for the duration you need them. Make sure to COMMIT your change.

   RDS retains your downloaded logs according to the archived log retention policy, starting from the time the logs were downloaded. To learn how to set the retention policy, see [Retaining archived redo logs](p. 1909).

2. Wait up to 5 minutes for the archived log retention policy change to take effect.
3. Download the archived redo logs from Amazon S3 using `rdsadmin.rdsadmin_archive_log_download`

   For more information, see Downloading a single archived redo log (p. 1912) and Downloading a series of archived redo logs (p. 1912).

   **Note**
   RDS automatically checks the available storage before downloading. If the requested logs consume a high percentage of space, you receive an alert.

4. Confirm that the logs were downloaded from Amazon S3 successfully.

   You can view the status of your download task in a bdump file. The bdump files have the path name `/rdsdbdata/log/trace/dbtask-task-id.log`. In the preceding download step, you run a SELECT statement that returns the task ID in a VARCHAR2 data type. For more information, see similar examples in Monitoring the status of a file transfer (p. 2023).

**Downloading a single archived redo log**

To download a single archived redo log to the `/rdsdbdata/log/arch` directory, use `rdsadmin.rdsadmin_archive_log_download.download_log_with_seqnum`. This procedure has the following parameter:

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>seqnum</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The sequence number of the archived redo log.</td>
</tr>
</tbody>
</table>

The following example downloads the log with sequence number 20.

```
SELECT rdsadmin.rdsadmin_archive_log_download.download_log_with_seqnum(seqnum => 20) AS TASK_ID
FROM   DUAL;
```

**Downloading a series of archived redo logs**

To download a series of archived redo logs to the `/rdsdbdata/log/arch` directory, use `download_logs_in_seqnum_range`. Your download is limited to 300 logs per request. The `download_logs_in_seqnum_range` procedure has the following parameters:

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>start_seq</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The starting sequence number for the series.</td>
</tr>
<tr>
<td>end_seq</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The ending sequence number for the series.</td>
</tr>
</tbody>
</table>

The following example downloads the logs from sequence 50 to 100.

```
SELECT rdsadmin.rdsadmin_archive_log_download.download_logs_in_seqnum_range(start_seq => 50, end_seq => 100) AS TASK_ID
FROM   DUAL;
```
Performing common RMAN tasks for Oracle DB instances

In the following section, you can find how you can perform Oracle Recovery Manager (RMAN) DBA tasks on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that require advanced privileges.

Use the Amazon RDS package `rdsadmin.rdsadmin_rman_util` to perform RMAN backups of your Amazon RDS for Oracle database to disk. The `rdsadmin.rdsadmin_rman_util` package supports full and incremental database file backups, tablespace backups, and archived redo log backups.

After an RMAN backup has finished, you can copy the backup files off the Amazon RDS for Oracle DB instance host. You might do this for the purpose of restoring to a non-RDS host or for long-term storage of backups. For example, you can copy the backup files to an Amazon S3 bucket. For more information, see using Amazon S3 integration (p. 2008).

The backup files for RMAN backups remain on the Amazon RDS DB instance host until you remove them manually. You can use the UTL_FILE. FREMOVE Oracle procedure to remove files from a directory. For more information, see FREMOVE procedure in the Oracle Database documentation.

You can't use the RMAN to restore RDS for Oracle DB instances. However, you can use RMAN to restore a backup to an on-premises or Amazon EC2 instance. For more information, see the blog article Restore an Amazon RDS for Oracle instance to a self-managed instance.

Note
For backing up and restoring to another Amazon RDS for Oracle DB instance, you can continue to use the Amazon RDS backup and restore features. For more information, see Backing up and restoring (p. 590).

Topics
- Prerequisites for RMAN backups (p. 1913)
- Common parameters for RMAN procedures (p. 1914)
- Validating DB instance files (p. 1916)
- Enabling and disabling block change tracking (p. 1919)
- Crosschecking archived redo logs (p. 1920)
- Backing up archived redo logs (p. 1921)
- Performing a full database backup (p. 1926)
- Performing an incremental database backup (p. 1927)
- Backing up a tablespace (p. 1928)
- Backing up a control file (p. 1929)

Prerequisites for RMAN backups

Before backing up your database using the `rdsadmin.rdsadmin_rman_util` package, make sure that you meet the following prerequisites:

- Make sure that your RDS for Oracle database is in ARCHIVELOG mode. To enable this mode, set the backup retention period to a non-zero value.
When backing up archived redo logs or performing a full or incremental backup that includes archived redo logs, and when backing up the database, make sure that redo log retention is set to a nonzero value. Archived redo logs are required to make database files consistent during recovery. For more information, see Retaining archived redo logs (p. 1909).

Make sure that your DB instance has sufficient free space to hold the backups. When back up your database, you specify an Oracle directory object as a parameter in the procedure call. RMAN places the files in the specified directory. You can use default directories, such as DATA_PUMP_DIR, or create a new directory. For more information, see Creating and dropping directories in the main data storage space (p. 1942).

You can monitor the current free space in an RDS for Oracle instance using the CloudWatch metric FreeStorageSpace. We recommend that your free space exceeds the current size of the database, though RMAN backs up only formatted blocks and supports compression.

### Common parameters for RMAN procedures

You can use procedures in the Amazon RDS package rdsadmin.rdsadmin_rman_util to perform tasks with RMAN. Several parameters are common to the procedures in the package. The package has the following common parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_directory_name</td>
<td>varchar2</td>
<td>A valid database directory name.</td>
<td>—</td>
<td>Yes</td>
<td>The name of the directory to contain the backup files.</td>
</tr>
<tr>
<td>p_label</td>
<td>varchar2</td>
<td>a-z, A-Z, 0-9, '-', '.'</td>
<td>—</td>
<td>No</td>
<td>A unique string that is included in the backup file names.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Note: The limit is 30 characters.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>p_owner</td>
<td>varchar2</td>
<td>A valid owner of the directory specified in p_directory_name.</td>
<td>—</td>
<td>Yes</td>
<td>The owner of the directory to contain the backup files.</td>
</tr>
<tr>
<td>p_tag</td>
<td>varchar2</td>
<td>a-z, A-Z, 0-9, '-', '.'</td>
<td>NULL</td>
<td>No</td>
<td>A string that can be used to distinguish between backups to indicate the purpose or usage of backups, such as daily, weekly, or incremental-level backups.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The limit is 30 characters. The tag is not case-sensitive. Tags are always stored in uppercase, regardless of the case used when entering them.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Tags don't need to be unique, so multiple backups can have the same tag.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>If you don't specify a tag, then RMAN assigns a default tag automatically using the format {TAGYYYYMMDDTHHMMSS}, where YYYY is the year, MM is the month, DD is the day, HH is the...</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Parameter name</td>
<td>Data type</td>
<td>Valid values</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-----------</td>
<td>--------------</td>
<td>---------</td>
<td>----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>p_compress</td>
<td>boolean</td>
<td>TRUE, FALSE</td>
<td>FALSE</td>
<td>No</td>
<td>Specify TRUE to enable BASIC backup compression. Specify FALSE to disable BASIC backup compression.</td>
</tr>
<tr>
<td>p_include_archive</td>
<td>boolean</td>
<td>TRUE, FALSE</td>
<td>FALSE</td>
<td>No</td>
<td>Specify TRUE to include archived redo logs in the backup. Specify FALSE to exclude archived redo logs from the backup.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>If you include archived redo logs in the backup, set retention to one hour or greater using the rdsadmin.rdsadmin_util.set_configuration procedure. Also, call the rdsadmin.rdsadmin_rman_util.crosscheck_archivelog procedure immediately before running the backup. Otherwise, the backup might fail due to missing archived redo log files that have been deleted by Amazon RDS management procedures.</td>
</tr>
<tr>
<td>p_include_control</td>
<td>boolean</td>
<td>TRUE, FALSE</td>
<td>FALSE</td>
<td>No</td>
<td>Specify TRUE to include the control file in the backup. Specify FALSE to exclude the control file from the backup.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Data type</td>
<td>Valid values</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-----------</td>
<td>-------------------------------</td>
<td>---------</td>
<td>----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>p_optimize</td>
<td>boolean</td>
<td>TRUE, FALSE</td>
<td>TRUE</td>
<td>No</td>
<td>Specify TRUE to enable backup optimization, if archived redo logs are included, to reduce backup size. Specify FALSE to disable backup optimization.</td>
</tr>
<tr>
<td>p_parallel</td>
<td>number</td>
<td>A valid integer between 1 and 254 for Oracle Database Enterprise Edition (EE), 1 for other Oracle Database editions</td>
<td>1</td>
<td>No</td>
<td>Number of channels.</td>
</tr>
<tr>
<td>p_rman_to_dbms_output</td>
<td>boolean</td>
<td>TRUE, FALSE</td>
<td>FALSE</td>
<td>No</td>
<td>When TRUE, the RMAN output is sent to the DBMS_OUTPUT package in addition to a file in the BDUMP directory. In SQL*Plus, use SET SERVEROUTPUT ON to see the output. When FALSE, the RMAN output is only sent to a file in the BDUMP directory.</td>
</tr>
<tr>
<td>p_section_size_mb</td>
<td>number</td>
<td>A valid integer</td>
<td>NULL</td>
<td>No</td>
<td>The section size in megabytes (MB). Validates in parallel by dividing each file into the specified section size. When NULL, the parameter is ignored.</td>
</tr>
<tr>
<td>p_validation_type</td>
<td>varchar2</td>
<td>'PHYSICAL', 'PHYSICAL+LOGICAL'</td>
<td>'PHYSICAL'</td>
<td></td>
<td>The level of corruption detection. Specify 'PHYSICAL' to check for physical corruption. An example of physical corruption is a block with a mismatch in the header and footer. Specify 'PHYSICAL+LOGICAL' to check for logical inconsistencies in addition to physical corruption. An example of logical corruption is a corrupt block.</td>
</tr>
</tbody>
</table>

**Validating DB instance files**

You can use the Amazon RDS package rdsadmin.rdsadmin_rman_util to validate Amazon RDS for Oracle DB instance files, such as data files, tablespaces, control files, or server parameter files (SPFILEs).

For more information about RMAN validation, see [Validating database files and backups](#) and [VALIDATE](#) in the Oracle documentation.
Validating a DB instance (p. 1917)
Validating a tablespace (p. 1917)
Validating a control file (p. 1918)
Validating an SPFILE (p. 1918)
Validating a data file (p. 1918)

Validating a DB instance

To validate all of the relevant files used by an Amazon RDS Oracle DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_database`. This procedure uses the following common parameters for RMAN tasks:

- `p_validation_type`
- `p_parallel`
- `p_section_size_mb`
- `p_rman_to_dbms_output`

For more information, see Common parameters for RMAN procedures (p. 1914).

The following example validates the DB instance using the default values for the parameters.

```sql
EXEC rdsadmin.rdsadmin_rman_util.validate_database;
```

The following example validates the DB instance using the specified values for the parameters.

```sql
BEGIN
rdsadmin.rdsadmin_rman_util.validate_database(
    p_validation_type     => 'PHYSICAL+LOGICAL',
    p_parallel            => 4,
    p_section_size_mb     => 10,
    p_rman_to_dbms_output => FALSE);
END;
```

When the `p_rman_to_dbms_output` parameter is set to FALSE, the RMAN output is written to a file in the BDUMP directory.

To view the files in the BDUMP directory, run the following `SELECT` statement.

```sql
SELECT * FROM table(rdsadmin.rds_file_util.listdir('BDUMP')) order by mtime;
```

To view the contents of a file in the BDUMP directory, run the following `SELECT` statement.

```sql
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP', 'rds-rman-validate-nnn.txt'));
```

Replace the file name with the name of the file you want to view.

Validating a tablespace

To validate the files associated with a tablespace, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_tablespace`. 

---

1917
This procedure uses the following common parameters for RMAN tasks:

- `p_validation_type`
- `p_parallel`
- `p_section_size_mb`
- `p_rman_to_dbms_output`

For more information, see [Common parameters for RMAN procedures (p. 1914)](#).

This procedure also uses the following additional parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_tablespace_name</code></td>
<td>varchar2</td>
<td>A valid tablespace name</td>
<td>—</td>
<td>Yes</td>
<td>The name of the tablespace.</td>
</tr>
</tbody>
</table>

**Validating a control file**

To validate only the control file used by an Amazon RDS Oracle DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_current_controlfile`.

This procedure uses the following common parameter for RMAN tasks:

- `p_validation_type`
- `p_rman_to_dbms_output`

For more information, see [Common parameters for RMAN procedures (p. 1914)](#).

**Validating an SPFILE**

To validate only the server parameter file (SPFILE) used by an Amazon RDS Oracle DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_spfile`.

This procedure uses the following common parameter for RMAN tasks:

- `p_validation_type`
- `p_rman_to_dbms_output`

For more information, see [Common parameters for RMAN procedures (p. 1914)](#).

**Validating a data file**

To validate a data file, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_datafile`.

This procedure uses the following common parameters for RMAN tasks:

- `p_validation_type`
- `p_parallel`
- `p_section_size_mb`
- `p_rman_to_dbms_output`
For more information, see Common parameters for RMAN procedures (p. 1914).

This procedure also uses the following additional parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_datafile</td>
<td>varchar2</td>
<td>A valid datafile ID number or a valid datafile name including complete path</td>
<td>—</td>
<td>Yes</td>
<td>The datafile ID number (from v$datafile.file#) or the full datafile name including the path (from v$datafile.name).</td>
</tr>
<tr>
<td>p_from_block</td>
<td>number</td>
<td>A valid integer</td>
<td>NULL</td>
<td>No</td>
<td>The number of the block where the validation starts within the data file. When this is NULL, 1 is used.</td>
</tr>
<tr>
<td>p_to_block</td>
<td>number</td>
<td>A valid integer</td>
<td>NULL</td>
<td>No</td>
<td>The number of the block where the validation ends within the data file. When this is NULL, the maximum block in the data file is used.</td>
</tr>
</tbody>
</table>

### Enabling and disabling block change tracking

Block changing tracking records changed blocks in a tracking file. This technique can improve the performance of RMAN incremental backups. For more information, see Using Block Change Tracking to Improve Incremental Backup Performance in the Oracle Database documentation.

RMAN features aren't supported in a read replica. However, as part of your high availability strategy, you might choose to enable block tracking in a read-only replica using the procedure rdsadmin.rdsadmin_rman_util.enable_block_change_tracking. If you promote this read-only replica to a source DB instance, block change tracking is enabled for the new source instance. Thus, your instance can benefit from fast incremental backups.

Block change tracking procedures are supported in Enterprise Edition only for the following DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2019-01.rur-2019-01.r1 or higher (deprecated)
- Oracle Database 12c Release 1 (12.1), using 12.1.0.2.v15 or higher (deprecated)

**Note**

In a single-tenant CDB, the following operations work, but no customer-visible mechanism can detect the current status of the operations. See also Limitations of a single-tenant CDB (p. 1821).
To enable block change tracking for a DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.enable_block_change_tracking`. To disable block change tracking, use `disable_block_change_tracking`. These procedures take no parameters.

To determine whether block change tracking is enabled for your DB instance, run the following query.

```
SELECT STATUS, FILENAME FROM V$BLOCK_CHANGE_TRACKING;
```

The following example enables block change tracking for a DB instance.

```
EXEC rdsadmin.rdsadmin_rman_util.enable_block_change_tracking;
```

The following example disables block change tracking for a DB instance.

```
EXEC rdsadmin.rdsadmin_rman_util.disable_block_change_tracking;
```

### Crosschecking archived redo logs

You can crosscheck archived redo logs using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.crosscheck_archivelog`.

You can use this procedure to crosscheck the archived redo logs registered in the control file and optionally delete the expired logs records. When RMAN makes a backup, it creates a record in the control file. Over time, these records increase the size of the control file. We recommend that you remove expired records periodically.

**Note**

Standard Amazon RDS backups don't use RMAN and therefore don't create records in the control file.

This procedure uses the common parameter `p_rman_to_dbms_output` for RMAN tasks.

For more information, see [Common parameters for RMAN procedures](p. 1914).

This procedure also uses the following additional parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_delete_expired</code></td>
<td>boolean</td>
<td>TRUE, FALSE</td>
<td>TRUE</td>
<td>No</td>
<td>When <code>TRUE</code>, delete expired archived redo log records from the control file. When <code>FALSE</code>, retain the expired archived redo log records in the control file.</td>
</tr>
</tbody>
</table>

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2019-01.rur-2019-01.r1 or higher
The following example marks archived redo log records in the control file as expired, but does not delete the records.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.crosscheck_archivelog(
        p_delete_expired      => FALSE,
        p_rman_to_dbms_output => FALSE);
END;
/
```

The following example deletes expired archived redo log records from the control file.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.crosscheck_archivelog(
        p_delete_expired      => TRUE,
        p_rman_to_dbms_output => FALSE);
END;
/
```

### Backing up archived redo logs

You can use the Amazon RDS package `rdsadmin.rdsadmin_rman_util` to back up archived redo logs for an Amazon RDS Oracle DB instance.

The procedures for backing up archived redo logs are supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2019-01.rur-2019-01.r1 or higher
- Oracle Database 12c Release 1 (12.1), using 12.1.0.2.v15 or higher

- [Backing up an archived redo log from a sequence number range (p. 1925)](#)

### Backing up all archived redo logs

To back up all of the archived redo logs for an Amazon RDS Oracle DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_archivelog_all`.

This procedure uses the following common parameters for RMAN tasks:

- p_owner
- p_directory_name
- p_label
- p_parallel
- p_compress
- p_rman_to_dbms_output
• p_tag

For more information, see Common parameters for RMAN procedures (p. 1914).

The following example backs up all archived redo logs for the DB instance.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_archivelog_all(
        p_owner => 'SYS',
        p_directory_name => 'MYDIRECTORY',
        p_parallel => 4,
        p_tag => 'MY_LOG_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

Backing up an archived redo log from a date range

To back up specific archived redo logs for an Amazon RDS Oracle DB instance by specifying a date range, use the Amazon RDS procedure rdsadmin.rdsadmin_rman_util.backup_archivelog_date. The date range specifies which archived redo logs to back up.

This procedure uses the following common parameters for RMAN tasks:

• p_owner
• p_directory_name
• p_label
• p_parallel
• p_compress
• p_rman_to_dbms_output
• p_tag

For more information, see Common parameters for RMAN procedures (p. 1914).

This procedure also uses the following additional parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_from_date</td>
<td>date</td>
<td>A date that is between the start_date and next_date of an archived redo log that exists on disk. The value must be</td>
<td>—</td>
<td>Yes</td>
<td>The starting date for the archived log backups.</td>
</tr>
</tbody>
</table>
### Parameter name | Data type | Valid values | Default | Required | Description
---|---|---|---|---|---
| less than or equal to the value specified for p_to_date. | date | A date that is between the start_date and next_date of an archived redo log that exists on disk. The value must be greater than or equal to the value specified for p_from_date. | | Yes | The ending date for the archived log backups.

The following example backs up archived redo logs in the date range for the DB instance.

```sql
BEGIN
  rdsadmin.rdsadmin_rman_util.backup_archivelog_date(
    p_owner => 'SYS',
    p_directory_name => 'MYDIRECTORY',
    p_from_date => '03/01/2019 00:00:00',
    p_to_date => '03/02/2019 00:00:00',
    p_parallel => 4,
    p_tag => 'MY_LOG_BACKUP',
    p_rman_to_dbms_output => FALSE);
END;
/
```

### Backing up an archived redo log from an SCN range
