To avoid needing to specify the schema name, add the tiger schema to your search path using the following command.

```sql
SET search_path=public,tiger;
```
Test the tiger schema by using the following SELECT statement.

```sql
SELECT address, streetname, streettypeabbrev, zip
FROM normalize_address('1 Devonshire Place, Boston, MA 02109') AS na;
```

<table>
<thead>
<tr>
<th>address</th>
<th>streetname</th>
<th>streettypeabbrev</th>
<th>zip</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Devonshire</td>
<td>Pl</td>
<td>02109</td>
</tr>
</tbody>
</table>

(1 row)

To learn more about this extension, see [Tiger Geocoder](#) in the PostGIS documentation.

Test access to the topology schema by using the following SELECT statement. This calls the `createtopology` function to register a new topology object (my_new_topo) with the specified spatial reference identifier (26986) and default tolerance (0.5). To learn more, see [CreateTopology](#) in the PostGIS documentation.

```sql
SELECT topology.createtopology('my_new_topo',26986,0.5);
```

<table>
<thead>
<tr>
<th>createtopology</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>

(1 row)

**Step 6: Upgrade the PostGIS extension**

Each new release of PostgreSQL supports one or more versions of the PostGIS extension compatible with that release. Upgrading the PostgreSQL engine to a new version doesn't automatically upgrade the PostGIS extension. Before upgrading the PostgreSQL engine, you typically upgrade PostGIS to the newest available version for the current PostgreSQL version. For details, see [PostGIS extension versions](#).

After the PostgreSQL engine upgrade, you then upgrade the PostGIS extension again, to the version supported for the newly upgraded PostgreSQL engine version. For more information about upgrading the PostgreSQL engine, see [How to perform a major version upgrade](#).

You can check for available PostGIS extension version updates on your RDS for PostgreSQL DB instance at any time. To do so, run the following command. This function is available with PostGIS 2.5.0 and higher versions.
SELECT postGIS_extensions_upgrade();

If your application doesn't support the latest PostGIS version, you can install an older version of PostGIS that's available in your major version as follows.

CREATE EXTENSION postgis VERSION "2.5.5";

If you want to upgrade to a specific PostGIS version from an older version, you can also use the following command.

ALTER EXTENSION postgis UPDATE TO "2.5.5";

Depending on the version that you're upgrading from, you might need to use this function again. The result of the first run of the function determines if an additional upgrade function is needed. For example, this is the case for upgrading from PostGIS 2 to PostGIS 3. For more information, see Upgrading PostGIS 2 to PostGIS 3.

If you upgraded this extension to prepare for a major version upgrade of the PostgreSQL engine, you can continue with other preliminary tasks. For more information, see How to perform a major version upgrade.

PostGIS extension versions

We recommend that you install the versions of all extensions such as PostGIS as listed in Extension versions for Amazon RDS for PostgreSQL in the Amazon RDS for PostgreSQL Release Notes. To get a list of versions that are available in your release, use the following command.

SELECT * FROM pg_available_extension_versions WHERE name='postgis';

You can find version information in the following sections in the Amazon RDS for PostgreSQL Release Notes:

- PostgreSQL version 15 extensions supported on Amazon RDS
- PostgreSQL version 14 extensions supported on Amazon RDS
- PostgreSQL version 13 extensions supported on Amazon RDS
- PostgreSQL version 12 extensions supported on Amazon RDS
• PostgreSQL version 11 extensions supported on Amazon RDS
• PostgreSQL version 10 extensions supported on Amazon RDS
• PostgreSQL version 9.6.x extensions supported on Amazon RDS

Upgrading PostGIS 2 to PostGIS 3

Starting with version 3.0, the PostGIS raster functionality is now a separate extension, postgis_raster. This extension has its own installation and upgrade path. This removes dozens of functions, data types, and other artifacts required for raster image processing from the core postgis extension. That means that if your use case doesn't require raster processing, you don't need to install the postgis_raster extension.

In the following upgrade example, the first upgrade command extracts raster functionality into the postgis_raster extension. A second upgrade command is then required to upgrade postgres_raster to the new version.

To upgrade from PostGIS 2 to PostGIS 3

1. Identify the default version of PostGIS that's available to the PostgreSQL version on your RDS for PostgreSQL DB instance. To do so, run the following query.

   ```sql
   SELECT * FROM pg_available_extensions
   WHERE default_version > installed_version;
   
   name | default_version | installed_version | comment
   ----------------+-----------------+-------------------+------------------------------------------------------------
   +------------------------------------------------------------
   postgis | 3.1.4 | 2.3.7 | PostGIS geometry and geography spatial types and functions
   (1 row)
   ```

2. Identify the versions of PostGIS installed in each database on your RDS for PostgreSQL DB instance. In other words, query each user database as follows.

   ```sql
   SELECT
       e.extname AS "Name",
       e.extversion AS "Version",
       n.nspname AS "Schema",
       c.description AS "Description"
   FROM pg_catalog.pg_extension e
   ```
LEFT JOIN pg_catalog.pg_namespace n ON n.oid = e.extnamespace
LEFT JOIN pg_catalog.pg_description c ON c.objoid = e.oid
AND c.classoid = 'pg_catalog.pg_extension'::pg_catalog.regclass
WHERE
e.extname LIKE '%postgis%'
ORDER BY
1;
Name  | Version | Schema | Description
---------+---------+--------+---------------------------------------------------------------------
+---------------------------------------------------------------+
postgis | 2.3.7   | public | PostGIS geometry, geography, and raster spatial types and functions
(1 row)

This mismatch between the default version (PostGIS 3.1.4) and the installed version (PostGIS 2.3.7) means that you need to upgrade the PostGIS extension.

ALTER EXTENSION postgis UPDATE;
ALTER EXTENSION
WARNING: unpackaging raster
WARNING: PostGIS Raster functionality has been unpackaged

3. Run the following query to verify that the raster functionality is now in its own package.

SELECT
  probin,
  count(*)
FROM
  pg_proc
WHERE
  probin LIKE '%postgis%'
GROUP BY
  probin;
probin | count
--------------------+-------
$libdir/rtpostgis-2.3 | 107
$libdir/postgis-3    | 487
(2 rows)

The output shows that there's still a difference between versions. The PostGIS functions are version 3 (postgis-3), while the raster functions (rtpostgis) are version 2 (rtpostgis-2.3). To complete the upgrade, you run the upgrade command again, as follows.
postgres=> SELECT postgis_extensions_upgrade();

You can safely ignore the warning messages. Run the following query again to verify that the upgrade is complete. The upgrade is complete when PostGIS and all related extensions aren't marked as needing upgrade.

SELECT postgis_full_version();

4. Use the following query to see the completed upgrade process and the separately packaged extensions, and verify that their versions match.

SELECT
    e.extname AS "Name",
    e.extversion AS "Version",
    n.nspname AS "Schema",
    c.description AS "Description"
FROM
    pg_catalog.pg_extension e
LEFT JOIN pg_catalog.pg_namespace n ON n.oid = e.extnamespace
LEFT JOIN pg_catalog.pg_description c ON c.objoid = e.oid
    AND c.classoid = 'pg_catalog.pg_extension'::pg_catalog.regclass
WHERE
    e.extname LIKE '%postgis%'
ORDER BY
    1;

<table>
<thead>
<tr>
<th>Name</th>
<th>Version</th>
<th>Schema</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>postgis</td>
<td>3.1.5</td>
<td>public</td>
<td>PostGIS geometry, geography, and raster spatial types and functions</td>
</tr>
<tr>
<td>postgis_raster</td>
<td>3.1.5</td>
<td>public</td>
<td>PostGIS raster types and functions</td>
</tr>
</tbody>
</table>

The output shows that the PostGIS 2 extension was upgraded to PostGIS 3, and both postgis and the now separate postgis_raster extension are version 3.1.5.

After this upgrade completes, if you don't plan to use the raster functionality, you can drop the extension as follows.
DROP EXTENSION postgis_raster;
Working with the supported foreign data wrappers for Amazon RDS for PostgreSQL

A foreign data wrapper (FDW) is a specific type of extension that provides access to external data. For example, the oracle_fdw extension allows your RDS for PostgreSQL DB cluster to work with Oracle databases. As another example, by using the PostgreSQL native postgres_fdw extension you can access data stored in PostgreSQL DB instances external to your RDS for PostgreSQL DB instance.

Following, you can find information about several supported PostgreSQL foreign data wrappers.

Topics

- Using the log_fdw extension to access the DB log using SQL
- Using the postgres_fdw extension to access external data
- Working with MySQL databases by using the mysql_fdw extension
- Working with Oracle databases by using the oracle_fdw extension
- Working with SQL Server databases by using the tds_fdw extension

Using the log_fdw extension to access the DB log using SQL

RDS for PostgreSQL DB instance supports the log_fdw extension, which you can use to access your database engine log using a SQL interface. The log_fdw extension provides two functions that make it easy to create foreign tables for database logs:

- `list_postgres_log_files` – Lists the files in the database log directory and the file size in bytes.
- `create_foreign_table_for_log_file(table_name text, server_name text, log_file_name text)` – Builds a foreign table for the specified file in the current database.

All functions created by log_fdw are owned by rds_superuser. Members of the rds_superuser role can grant access to these functions to other database users.

By default, the log files are generated by Amazon RDS in stderr (standard error) format, as specified in log_destination parameter. There are only two options for this parameter, stderr and csvlog (comma-separated values, CSV). If you add the csvlog option to the parameter, Amazon RDS generates both stderr and csvlog logs. This can affect the storage capacity on
your DB cluster, so you need to be aware of the other parameters that affect log handling. For more information, see Setting the log destination (stderr, csvlog).

One benefit of generating csvlog logs is that the log_fdw extension lets you build foreign tables with the data neatly split into several columns. To do this, your instance needs to be associated with a custom DB parameter group so that you can change the setting for log_destination. For more information about how to do so, see Working with parameters on your RDS for PostgreSQL DB instance.

The following example assumes that the log_destination parameter includes csvlog.

**To use the log_fdw extension**

1. Install the log_fdw extension.

   ```sql
   postgres=> CREATE EXTENSION log_fdw;
   CREATE EXTENSION
   ```

2. Create the log server as a foreign data wrapper.

   ```sql
   postgres=> CREATE SERVER log_server FOREIGN DATA WRAPPER log_fdw;
   CREATE SERVER
   ```

3. Select all from a list of log files.

   ```sql
   postgres=> SELECT * FROM list_postgres_log_files() ORDER BY 1;
   ```

   A sample response is as follows.

<table>
<thead>
<tr>
<th>file_name</th>
<th>file_size_bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>postgresql.log.2023-08-09-22.csv</td>
<td>1111</td>
</tr>
<tr>
<td>postgresql.log.2023-08-09-23.csv</td>
<td>1172</td>
</tr>
<tr>
<td>postgresql.log.2023-08-10-00.csv</td>
<td>1744</td>
</tr>
<tr>
<td>postgresql.log.2023-08-10-01.csv</td>
<td>1102</td>
</tr>
</tbody>
</table>
   (4 rows)

4. Create a table with a single 'log_entry' column for the selected file.

   ```sql
   postgres=> SELECT create_foreign_table_for_log_file('my_postgres_error_log', 'log_server', 'postgresql.log.2023-08-09-22.csv');
   ```
The response provides no detail other than that the table now exists.

```
+-----------------------------+
|                             |
| (1 row)                     |
+-----------------------------+
```

5. Select a sample of the log file. The following code retrieves the log time and error message description.

```
postgres=> SELECT log_time, message FROM my_postgres_error_log ORDER BY 1;
```

A sample response is as follows.

```
<table>
<thead>
<tr>
<th>log_time</th>
<th>message</th>
</tr>
</thead>
<tbody>
<tr>
<td>-------------------------</td>
<td>---------------------------------------------------</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.172</td>
<td>ending log output to stderr</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.175</td>
<td>database system was interrupted; last known up</td>
</tr>
<tr>
<td></td>
<td>at 2023-08-09 22:43:34 UTC</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.223</td>
<td>checkpoint record is at 0/90002E0</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.223</td>
<td>redo record is at 0/90002A8; shutdown FALSE</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.223</td>
<td>next transaction ID: 0/1879; next OID: 24578</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.223</td>
<td>next MultiXactId: 1; next MultiXactOffset: 0</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.223</td>
<td>oldest unfrozen transaction ID: 1822, in</td>
</tr>
<tr>
<td></td>
<td>database 1</td>
</tr>
<tr>
<td></td>
<td>(7 rows)</td>
</tr>
</tbody>
</table>
```

Using the **postgres_fdw** extension to access external data

You can access data in a table on a remote database server with the **postgres_fdw** extension. If you set up a remote connection from your PostgreSQL DB instance, access is also available to your read replica.

**To use postgres_fdw to access a remote database server**

1. Install the postgres_fdw extension.

   ```
   CREATE EXTENSION postgres_fdw;
   ```

2. Create a foreign data server using CREATE SERVER.
CREATE SERVER foreign_server
FOREIGN DATA WRAPPER postgres_fdw
OPTIONS (host 'xxx.xx.xxx.xx', port '5432', dbname 'foreign_db');

3. Create a user mapping to identify the role to be used on the remote server.

CREATE USER MAPPING FOR local_user
SERVER foreign_server
OPTIONS (user 'foreign_user', password 'password');

4. Create a table that maps to the table on the remote server.

CREATE FOREIGN TABLE foreign_table (id integer NOT NULL, data text)
SERVER foreign_server
OPTIONS (schema_name 'some_schema', table_name 'some_table');

Working with MySQL databases by using the mysql_fdw extension

To access a MySQL-compatible database from your RDS for PostgreSQL DB instance, you can install and use the mysql_fdw extension. This foreign data wrapper lets you work with RDS for MySQL, Aurora MySQL, MariaDB, and other MySQL-compatible databases. The connection from RDS for PostgreSQL DB instance to the MySQL database is encrypted on a best-effort basis, depending on the client and server configurations. However, you can enforce encryption if you like. For more information, see Using encryption in transit with the extension.

The mysql_fdw extension is supported on Amazon RDS for PostgreSQL version 14.2, 13.6, and higher releases. It supports selects, inserts, updates, and deletes from an RDS for PostgreSQL DB to tables on a MySQL-compatible database instance.

Topics

- Setting up your RDS for PostgreSQL DB to use the mysql_fdw extension
- Example: Working with an RDS for MySQL database from RDS for PostgreSQL
- Using encryption in transit with the extension
Setting up your RDS for PostgreSQL DB to use the mysql_fdw extension

Setting up the mysql_fdw extension on your RDS for PostgreSQL DB instance involves loading the extension in your DB instance and then creating the connection point to the MySQL DB instance. For that task, you need to have the following details about the MySQL DB instance:

- Hostname or endpoint. For an RDS for MySQL DB instance, you can find the endpoint by using the Console. Choose the Connectivity & security tab and look in the "Endpoint and port" section.
- Port number. The default port number for MySQL is 3306.
- Name of the database. The DB identifier.

You also need to provide access on the security group or the access control list (ACL) for the MySQL port, 3306. Both the RDS for PostgreSQL DB instance and the RDS for MySQL DB instance need access to port 3306. If access isn't configured correctly, when you try to connect to MySQL-compatible table you see an error message similar to the following:

```
ERROR: failed to connect to MySQL: Can't connect to MySQL server on 'hostname.aws-region.rds.amazonaws.com:3306' (110)
```

In the following procedure, you (as the rds_superuser account) create the foreign server. You then grant access to the foreign server to specific users. These users then create their own mappings to the appropriate MySQL user accounts to work with the MySQL DB instance.

To use mysql_fdw to access a MySQL database server

1. Connect to your PostgreSQL DB instance using an account that has the rds_superuser role. If you accepted the defaults when you created your RDS for PostgreSQL DB instance, the user name is postgres, and you can connect using the psql command line tool as follows:

   ```
   psql --host=your-DB-instance.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   ```

2. Install the mysql_fdw extension as follows:

   ```
   postgres=> CREATE EXTENSION mysql_fdw;
   CREATE EXTENSION
   ```
After the extension is installed on your RDS for PostgreSQL DB instance, you set up the foreign server that provides the connection to a MySQL database.

**To create the foreign server**

Perform these tasks on the RDS for PostgreSQL DB instance. The steps assume that you're connected as a user with `rds_superuser` privileges, such as `postgres`.

1. Create a foreign server in the RDS for PostgreSQL DB instance:

   ```sql
   postgres=\> CREATE SERVER mysql-db FOREIGN DATA WRAPPER mysql_fdw OPTIONS (host 'db-name.111122223333.aws-region.rds.amazonaws.com', port '3306');
   CREATE SERVER
   ```

2. Grant the appropriate users access to the foreign server. These should be non-administrator users, that is, users without the `rds_superuser` role.

   ```sql
   postgres=\> GRANT USAGE ON FOREIGN SERVER mysql-db to user1;
   GRANT
   ```

PostgreSQL users create and manage their own connections to the MySQL database through the foreign server.

**Example: Working with an RDS for MySQL database from RDS for PostgreSQL**

Suppose that you have a simple table on an RDS for PostgreSQL DB instance. Your RDS for PostgreSQL users want to query (SELECT), INSERT, UPDATE, and DELETE items on that table. Assume that the `mysql_fdw` extension was created on your RDS for PostgreSQL DB instance, as detailed in the preceding procedure. After you connect to the RDS for PostgreSQL DB instance as a user that has `rds_superuser` privileges, you can proceed with the following steps.

1. On the RDS for PostgreSQL DB instance, create a foreign server:

   ```sql
   test=> CREATE SERVER mysqldb FOREIGN DATA WRAPPER mysql_fdw OPTIONS (host 'your-DB.aws-region.rds.amazonaws.com', port '3306');
   CREATE SERVER
   ```

2. Grant usage to a user who doesn't have `rds_superuser` permissions, for example, `user1`:

   ```sql
   test=> GRANT USAGE ON FOREIGN SERVER mysqldb TO user1;
   ```
3. Connect as user1, and then create a mapping to the MySQL user:

```
CREATE USER MAPPING FOR user1 SERVER mysqlberg OPTIONS (username 'myuser', password 'mypassword');
```

4. Create a foreign table linked to the MySQL table:

```
CREATE FOREIGN TABLE mytab (a int, b text) SERVER mysqlberg OPTIONS (dbname 'test', table_name '');
```

5. Run a simple query against the foreign table:

```
SELECT * FROM mytab;
```

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>apple</td>
</tr>
</tbody>
</table>

(1 row)

6. You can add, change, and remove data from the MySQL table. For example:

```
INSERT INTO mytab values (2, 'mango');
```

Run the SELECT query again to see the results:

```
SELECT * FROM mytab ORDER BY 1;
```

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>apple</td>
</tr>
<tr>
<td>2</td>
<td>mango</td>
</tr>
</tbody>
</table>

(2 rows)

**Using encryption in transit with the extension**

The connection to MySQL from RDS for PostgreSQL uses encryption in transit (TLS/SSL) by default. However, the connection falls back to non-encrypted when the client and server configuration...
You can enforce encryption for all outgoing connections by specifying the REQUIRE_SSL option on the RDS for MySQL user accounts. This same approach also works for MariaDB and Aurora MySQL user accounts.

For MySQL user accounts configured to REQUIRE_SSL, the connection attempt fails if a secure connection can't be established.

To enforce encryption for existing MySQL database user accounts, you can use the ALTER_USER command. The syntax varies, depending on the MySQL version, as shown in the following table. For more information, see ALTER_USER in MySQL Reference Manual.

<table>
<thead>
<tr>
<th>MySQL 5.7, MySQL 8.0</th>
<th>MySQL 5.6</th>
</tr>
</thead>
</table>
| ALTER USER 'user'@'%' REQUIRE SSL; | GRANT USAGE ON *.* to 'user'@'%'
REQUIRE SSL; |

For more information about the mysql_fdw extension, see the mysql_fdw documentation.

**Working with Oracle databases by using the oracle_fdw extension**

To access an Oracle database from your RDS for PostgreSQL DB instance you can install and use the oracle_fdw extension. This extension is a foreign data wrapper for Oracle databases. To learn more about this extension, see the oracle_fdw documentation.

The oracle_fdw extension is supported on RDS for PostgreSQL 12.7, 13.3, and higher versions.

**Topics**

- Turning on the oracle_fdw extension
- Example: Using a foreign server linked to an Amazon RDS for Oracle database
- Working with encryption in transit
- Understanding the pg_user_mappings view and permissions

**Turning on the oracle_fdw extension**

To use the oracle_fdw extension, perform the following procedure.
To turn on the oracle_fdw extension

- Run the following command using an account that has rds_superuser permissions.

  ```sql
  CREATE EXTENSION oracle_fdw;
  ```

Example: Using a foreign server linked to an Amazon RDS for Oracle database

The following example shows the use of a foreign server linked to an Amazon RDS for Oracle database.

To create a foreign server linked to an RDS for Oracle database

1. Note the following on the RDS for Oracle DB instance:
   - Endpoint
   - Port
   - Database name

2. Create a foreign server.

   ```sql
   test=> CREATE SERVER oradb FOREIGN DATA WRAPPER oracle_fdw OPTIONS (dbserver '//endpoint:port/DB_name');
   CREATE SERVER
   ```

3. Grant usage to a user who doesn't have rds_superuser privileges, for example user1.

   ```sql
   test=> GRANT USAGE ON FOREIGN SERVER oradb TO user1;
   GRANT
   ```

4. Connect as user1, and create a mapping to an Oracle user.

   ```sql
   test=> CREATE USER MAPPING FOR user1 SERVER oradb OPTIONS (user 'oracleuser', password 'mypassword');
   CREATE USER MAPPING
   ```

5. Create a foreign table linked to an Oracle table.

   ```sql
   test=> CREATE FOREIGN TABLE mytab (a int) SERVER oradb OPTIONS (table 'MYTABLE');
   CREATE FOREIGN TABLE
   ```
6. Query the foreign table.

```
test=> SELECT * FROM mytab;
     a
   ---
     1
   (1 row)
```

If the query reports the following error, check your security group and access control list (ACL) to make sure that both instances can communicate.

```
ERROR: connection for foreign table "mytab" cannot be established
DETAIL: ORA-12170: TNS:Connect timeout occurred
```

**Working with encryption in transit**

PostgreSQL-to-Oracle encryption in transit is based on a combination of client and server configuration parameters. For an example using Oracle 21c, see [About the Values for Negotiating Encryption and Integrity](https://docs.oracle.com/en/database/oracle/oracle-database/21/cdtna/oracle-native-network-encryption.html) in the Oracle documentation. The client used for oracle_fdw on Amazon RDS is configured with ACCEPTED, meaning that the encryption depends on the Oracle database server configuration.

If your database is on RDS for Oracle, see [Oracle native network encryption](https://docs.oracle.com/en/database/oracle/oracle-database/21/cdtna/oracle-native-network-encryption.html) to configure the encryption.

**Understanding the pg_user_mappings view and permissions**

The PostgreSQL catalog `pg_user_mapping` stores the mapping from an RDS for PostgreSQL user to the user on a foreign data (remote) server. Access to the catalog is restricted, but you use the `pg_user_mappings` view to see the mappings. In the following, you can find an example that shows how permissions apply with an example Oracle database, but this information applies more generally to any foreign data wrapper.

In the following output, you can find roles and permissions mapped to three different example users. Users `rdssu1` and `rdssu2` are members of the `rds_superuser` role, and `user1` isn't. The example uses the `psql` metacommand `\du` to list existing roles.

```
test=> \du
```
All users, including users that have rds_superuser privileges, are allowed to view their own user mappings (umoptions) in the pg_user_mappings table. As shown in the following example, when rdssu1 tries to obtain all user mappings, an error is raised even though rdssu1 rds_superuser privileges:

```sql
test=> SELECT * FROM pg_user_mapping;
ERROR: permission denied for table pg_user_mapping
```

Following are some examples.

```sql
test=> SET SESSION AUTHORIZATION rdssu1;
SET

```
```sql
test=> SELECT * FROM pg_user_mappings;
```
```sql
umid  | srvid | srvname | umuser | usename    |            umoptions
-------+-------+---------+--------+------------+----------------------------------
   16414 |   16411 |   oradb  |  16412 |     user1   |
   16423 |   16411 |   oradb  |  16421 |     rdssu1  | {user=oracleuser,password=mypwd}
   16424 |   16411 |   oradb  |  16422 |     rdssu2  |
(3 rows)
```
```sql
test=> SET SESSION AUTHORIZATION rdssu2;
SET

```
```sql
test=> SELECT * FROM pg_user_mappings;
```
```sql
umid  | srvid | srvname | umuser | usename    |            umoptions
-------+-------+---------+--------+------------+----------------------------------
   16414 |   16411 |   oradb  |  16412 |     user1   |
   16423 |   16411 |   oradb  |  16421 |     rdssu1  | {user=oracleuser,password=mypwd}
   16424 |   16411 |   oradb  |  16422 |     rdssu2  |
(3 rows)
```
```sql
test=> SET SESSION AUTHORIZATION user1;
```
Because of implementation differences between `information_schema._pg_user_mappings` and `pg_catalog.pg_user_mappings`, a manually created `rds_superuser` requires additional permissions to view passwords in `pg_catalog.pg_user_mappings`.

No additional permissions are required for an `rds_superuser` to view passwords in `information_schema._pg_user_mappings`.

Users who don't have the `rds_superuser` role can view passwords in `pg_user_mappings` only under the following conditions:

- The current user is the user being mapped and owns the server or holds the USAGE privilege on it.
- The current user is the server owner and the mapping is for PUBLIC.

**Working with SQL Server databases by using the tds_fdw extension**

You can use the PostgreSQL `tds_fdw` extension to access databases that support the tabular data stream (TDS) protocol, such as Sybase and Microsoft SQL Server databases. This foreign data wrapper lets you connect from your RDS for PostgreSQL DB instance to databases that use the TDS protocol, including Amazon RDS for Microsoft SQL Server. For more information, see [tds-fdw/tds_fdw](https://github.com/postgres_fdw/tds_fdw) documentation on GitHub.

The `tds_fdw` extension is supported on Amazon RDS for PostgreSQL version 14.2, 13.6, and higher releases.

**Setting up your Aurora PostgreSQL DB to use the tds_fdw extension**

In the following procedures, you can find an example of setting up and using the `tds_fdw` with an RDS for PostgreSQL DB instance. Before you can connect to a SQL Server database using `tds_fdw`, you need to get the following details for the instance:
• Hostname or endpoint. For an RDS for SQL Server DB instance, you can find the endpoint by using the Console. Choose the Connectivity & security tab and look in the "Endpoint and port" section.

• Port number. The default port number for Microsoft SQL Server is 1433.

• Name of the database. The DB identifier.

You also need to provide access on the security group or the access control list (ACL) for the SQL Server port, 1433. Both the RDS for PostgreSQL DB instance and the RDS for SQL Server DB instance need access to port 1433. If access isn't configured correctly, when you try to query the Microsoft SQL Server you see the following error message:

```
ERROR: DB-Library error: DB #: 20009, DB Msg: Unable to connect:
Adaptive Server is unavailable or does not exist (mssql2019.aws-region.rds.amazonaws.com), OS #: 0, OS Msg: Success, Level: 9
```

**To use tds_fdw to connect to a SQL Server database**

1. Connect to your PostgreSQL DB instance using an account that has the `rds_superuser` role:

   ```
   psql --host=your-DB-instance.aws-region.rds.amazonaws.com --port=5432 --username=test --password
   ```

2. Install the `tds_fdw` extension:

   ```
   test=> CREATE EXTENSION tds_fdw;
   CREATE EXTENSION
   ```

After the extension is installed on your RDS for PostgreSQL DB instance, you set up the foreign server.

**To create the foreign server**

Perform these tasks on the RDS for PostgreSQL DB instance using an account that has `rds_superuser` privileges.

1. Create a foreign server in the RDS for PostgreSQL DB instance:
To access non-ASCII data on the SQL Server side, create a server link with the character_set option in the RDS for PostgreSQL DB instance:

```
CREATE SERVER sqlserverdb FOREIGN DATA WRAPPER tds_fdw OPTIONS (servername 'mssql2019.aws-region.rds.amazonaws.com', port '1433', database 'tds_fdw_testing', character_set 'UTF-8');
```

2. Grant permissions to a user who doesn't have `rds_superuser` role privileges, for example, user1:

```
GRANT USAGE ON FOREIGN SERVER sqlserverdb TO user1;
```

3. Connect as user1 and create a mapping to a SQL Server user:

```
CREATE USER MAPPING FOR user1 SERVER sqlserverdb OPTIONS (username 'sqlserveruser', password 'password');
```

4. Create a foreign table linked to a SQL Server table:

```
CREATE FOREIGN TABLE mytab (a int) SERVER sqlserverdb OPTIONS (table 'MYTABLE');
```

5. Query the foreign table:

```
SELECT * FROM mytab;
```

```
a
---
1
(1 row)
```
Using encryption in transit for the connection

The connection from RDS for PostgreSQL to SQL Server uses encryption in transit (TLS/SSL) depending on the SQL Server database configuration. If the SQL Server isn't configured for encryption, the RDS for PostgreSQL client making the request to the SQL Server database falls back to unencrypted.

You can enforce encryption for the connection to RDS for SQL Server DB instances by setting the `rds.force_ssl` parameter. To learn how, see Forcing connections to your DB instance to use SSL. For more information about SSL/TLS configuration for RDS for SQL Server, see Using SSL with a Microsoft SQL Server DB instance.
Working with Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL is an open source development kit for building PostgreSQL extensions. It allows you to build high performance PostgreSQL extensions and safely run them on your RDS for PostgreSQL DB instance. By using Trusted Language Extensions (TLE) for PostgreSQL, you can create PostgreSQL extensions that follow the documented approach for extending PostgreSQL functionality. For more information, see Packaging Related Objects into an Extension in the PostgreSQL documentation.

One key benefit of TLE is that you can use it in environments that don't provide access to the file system underlying the PostgreSQL instance. Previously, installing a new extension required access to the file system. TLE removes this constraint. It provides a development environment for creating new extensions for any PostgreSQL database, including those running on your RDS for PostgreSQL DB instances.

TLE is designed to prevent access to unsafe resources for the extensions that you create using TLE. Its runtime environment limits the impact of any extension defect to a single database connection. TLE also gives database administrators fine-grained control over who can install extensions, and it provides a permissions model for running them.

TLE is supported on the following RDS for PostgreSQL versions:

- Version 15.2 and higher 15 versions.
- Version 14.5 and higher 14 versions.
- Version 13.12 and higher 13 versions.

The Trusted Language Extensions development environment and runtime are packaged as the pg_tle PostgreSQL extension, version 1.0.1. It supports creating extensions in JavaScript, Perl, Tcl, PL/pgSQL, and SQL. You install the pg_tle extension in your RDS for PostgreSQL DB instance in the same way that you install other PostgreSQL extensions. After the pg_tle is set up, developers can use it to create new PostgreSQL extensions, known as TLE extensions.

In the following topics, you can find information about how to set up Trusted Language Extensions and how to get started creating your own TLE extensions.

**Topics**

- Terminology
Terminology

To help you better understand Trusted Language Extensions, view the following glossary for terms used in this topic.

**Trusted Language Extensions for PostgreSQL**

*Trusted Language Extensions for PostgreSQL* is the official name of the open source development kit that's packaged as the pg_tle extension. It's available for use on any PostgreSQL system. For more information, see [aws/pg_tle](https://github.com/aws/pg_tle) on GitHub.

**Trusted Language Extensions**

*Trusted Language Extensions* is the short name for Trusted Language Extensions for PostgreSQL. This shortened name and its abbreviation (TLE) are also used in this documentation.

**trusted language**

A trusted language is a programming or scripting language that has specific security attributes. For example, trusted languages typically restrict access to the file system, and they limit use of specified networking properties. The TLE development kit is designed to support trusted languages. PostgreSQL supports several different languages that are used to create trusted or untrusted extensions. For an example, see [Trusted and Untrusted PL/Perl](https://www.postgresql.org/docs/current/pl-orm.html) in the PostgreSQL documentation. When you create an extension using Trusted Language Extensions, the extension inherently uses trusted language mechanisms.
TLE extension

A TLE extension is a PostgreSQL extension that's been created by using the Trusted Language Extensions (TLE) development kit.

Requirements for using Trusted Language Extensions for PostgreSQL

The following are requirements for setting up and using the TLE development kit.

- **RDS for PostgreSQL versions** – Trusted Language Extensions is supported on RDS for PostgreSQL versions 13.12 and higher, 14.5 and higher, and 15.2 and higher versions only.
  - If you need to upgrade your RDS for PostgreSQL instance, see [Upgrading the PostgreSQL DB engine for Amazon RDS](#).
  - If you don't yet have an Amazon RDS DB instance running PostgreSQL, you can create one. For more information, see RDS for PostgreSQL DB instance, see [Creating and connecting to a PostgreSQL DB instance](#).

- **Requires rds_superuser privileges** – To set up and configure the pg_tle extension, your database user role must have the permissions of the rds_superuser role. By default, this role is granted to the postgres user that creates the RDS for PostgreSQL DB instance.

- **Requires a custom DB parameter group** – Your RDS for PostgreSQL DB instance must be configured with a custom DB parameter group.
  - If your RDS for PostgreSQL DB instance isn't configured with a custom DB parameter group, you should create one and associate it with your RDS for PostgreSQL DB instance. For a short summary of steps, see [Creating and applying a custom DB parameter group](#).
  - If your RDS for PostgreSQL DB instance is already configured using a custom DB parameter group, you can set up Trusted Language Extensions. For details, see [Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance](#).

Creating and applying a custom DB parameter group

Use the following steps to create a custom DB parameter group and configure your RDS for PostgreSQL DB instance to use it.
To create a custom DB parameter group and use it with your RDS for PostgreSQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Parameter groups from the Amazon RDS menu.
3. Choose Create parameter group.
4. In the Parameter group details page, enter the following information.
   - For Parameter group family, choose postgres14.
   - For Type, choose DB Parameter Group.
   - For Group name, give your parameter group a meaningful name in the context of your operations.
   - For Description, enter a useful description so that others on your team can easily find it.
5. Choose Create. Your custom DB parameter group is created in your AWS Region. You can now modify your RDS for PostgreSQL DB instance to use it by following the next steps.
6. Choose Databases from the Amazon RDS menu.
7. Choose the RDS for PostgreSQL DB instance that you want to use with TLE from among those listed, and then choose Modify.
8. In the Modify DB instance settings page, find Database options in the Additional configuration section and choose your custom DB parameter group from the selector.
9. Choose Continue to save the change.
10. Choose Apply immediately so that you can continue setting up the RDS for PostgreSQL DB instance to use TLE.

To continue setting up your system for Trusted Language Extensions, see Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance.

For more information working with DB parameter groups, see Working with DB parameter groups in a DB instance.
AWS CLI

You can avoid specifying the --region argument when you use CLI commands by configuring your AWS CLI with your default AWS Region. For more information, see Configuration basics in the AWS Command Line Interface User Guide.

To create a custom DB parameter group and use it with your RDS for PostgreSQL DB instance

1. Use the create-db-parameter-group AWS CLI command to create a custom DB parameter group based on postgres14 for your AWS Region.

For Linux, macOS, or Unix:

```bash
aws rds create-db-parameter-group
  --region aws-region
  --db-parameter-group-name custom-params-for-pg-tle
  --db-parameter-group-family postgres14
  --description "My custom DB parameter group for Trusted Language Extensions"
```

For Windows:

```bash
aws rds create-db-parameter-group ^
  --region aws-region ^
  --db-parameter-group-name custom-params-for-pg-tle ^
  --db-parameter-group-family postgres14 ^
  --description "My custom DB parameter group for Trusted Language Extensions"
```

Your custom DB parameter group is available in your AWS Region, so you can modify RDS for PostgreSQL DB instance to use it.

2. Use the modify-db-instance AWS CLI command to apply your custom DB parameter group to your RDS for PostgreSQL DB instance. This command immediately reboots the active instance.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance
  --region aws-region
  --db-instance-identifier your-instance-name
  --db-parameter-group-name custom-params-for-pg-tle
  --apply-immediately
```
For Windows:

```
aws rds modify-db-instance ^
--region aws-region ^
--db-instance-identifier your-instance-name ^
--db-parameter-group-name custom-params-for-pg-tle ^
--apply-immediately
```

To continue setting up your system for Trusted Language Extensions, see Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance.

For more information, see Working with parameter groups.

**Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance**

The following steps assume that your RDS for PostgreSQL DB instance is associated with a custom DB parameter group. You can use the AWS Management Console or the AWS CLI for these steps.

When you set up Trusted Language Extensions in your RDS for PostgreSQL DB instance, you install it in a specific database for use by the database users who have permissions on that database.

**Console**

**To set up Trusted Language Extensions**

Perform the following steps using an account that's a member of the rds_superuser group (role).

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose your RDS for PostgreSQL DB instance.
3. Open the Configuration tab for your RDS for PostgreSQL DB instance. Among the Instance details, find the Parameter group link.
4. Choose the link to open the custom parameters associated with your RDS for PostgreSQL DB instance.
5. In the Parameters search field, type shared_pre to find the shared_preload_libraries parameter.
6. Choose **Edit parameters** to access the property values.

7. Add `pg_tle` to the list in the **Values** field. Use a comma to separate items in the list of values.

8. Reboot the RDS for PostgreSQL DB instance so that your change to the `shared_preload_libraries` parameter takes effect.

9. When the instance is available, verify that `pg_tle` has been initialized. Use `psql` to connect to the RDS for PostgreSQL DB instance, and then run the following command.

   ```sql
   SHOW shared_preload_libraries;
   shared_preload_libraries
   --------------------------
   rdsutils, pg_tle
   (1 row)
   ```

10. With the `pg_tle` extension initialized, you can now create the extension.

    ```sql
    CREATE EXTENSION pg_tle;
    ```

    You can verify that the extension is installed by using the following `psql` metacommand.

    ```sql
    labdb=> \dx
    List of installed extensions
    Name   | Version | Schema    | Description
   ---------+---------+-----------+--------------------------------------------
    pg_tle  | 1.0.1   | pgtle     | Trusted-Language Extensions for PostgreSQL
    plpgsql | 1.0     | pg_catalog| PL/pgSQL procedural language
    ```
11. Grant the pgtle_admin role to the primary user name that you created for your RDS for PostgreSQL DB instance when you set it up. If you accepted the default, it's postgres.

```
labdb=> GRANT pgtle_admin TO postgres;
GRANT ROLE
```

You can verify that the grant has occurred by using the psql metacommand as shown in the following example. Only the pgtle_admin and postgres roles are shown in the output. For more information, see Understanding the rds_superuser role.

```
labdb=> \du
List of roles
Role name    |           Attributes            |               Member of
-----------------+---------------------------------+----------------------------------------+
+-----------------------------------
pgtle_admin     | Cannot login                     | {}  
postgres        | Create role, Create DB          +| {rds_superuser,pgtle_admin}
| Password valid until infinity    |...  |
```

12. Close the psql session using the \q metacommand.

```
\q
```

To get started creating TLE extensions, see Example: Creating a trusted language extension using SQL.

**AWS CLI**

You can avoid specifying the --region argument when you use CLI commands by configuring your AWS CLI with your default AWS Region. For more information, see Configuration basics in the AWS Command Line Interface User Guide.

**To set up Trusted Language Extensions**

1. Use the modify-db-parameter-group AWS CLI command to add pg_tle to the shared_preload_libraries parameter.

```
aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
```
2. Use the **reboot-db-instance** AWS CLI command to reboot the RDS for PostgreSQL DB instance and initialize the `pg_tle` library.

```
aws rds reboot-db-instance \
  --db-instance-identifier your-instance \
  --region aws-region
```

3. When the instance is available, you can verify that `pg_tle` has been initialized. Use `psql` to connect to the RDS for PostgreSQL DB instance, and then run the following command.

```
SHOW shared_preload_libraries;
shared_preload_libraries
--------------------------
 rdsutils,pg_tle
(1 row)
```

With `pg_tle` initialized, you can now create the extension.

```
CREATE EXTENSION pg_tle;
```

4. Grant the `pgtle_admin` role to the primary user name that you created for your RDS for PostgreSQL DB instance when you set it up. If you accepted the default, it's `postgres`.

```
GRANT pgtle_admin TO postgres;
GRANT ROLE
```

5. Close the `psql` session as follows.

```
labdb=> \q
```

To get started creating TLE extensions, see [Example: Creating a trusted language extension using SQL](#).
Overview of Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL is a PostgreSQL extension that you install in your RDS for PostgreSQL DB instance in the same way that you set up other PostgreSQL extensions. In the following image of an example database in the pgAdmin client tool, you can view some of the components that comprise the pg_tle extension.

You can see the following details.

1. The Trusted Language Extensions (TLE) for PostgreSQL development kit is packaged as the pg_tle extension. As such, pg_tle is added to the available extensions for the database in which it's installed.

2. TLE has its own schema, pgtle. This schema contains helper functions (3) for installing and managing the extensions that you create.
3. TLE provides over a dozen helper functions for installing, registering, and managing your extensions. To learn more about these functions, see Functions reference for Trusted Language Extensions for PostgreSQL.

Other components of the pg_tle extension include the following:

- **The pgtle_admin role** – The pgtle_admin role is created when the pg_tle extension is installed. This role is privileged and should be treated as such. We strongly recommend that you follow the principle of least privilege when granting the pgtle_admin role to database users. In other words, grant the pgtle_admin role only to database users that are allowed to create, install, and manage new TLE extensions, such as postgres.

- **The pgtle.feature_info table** – The pgtle.feature_info table is a protected table that contains information about your TLEs, hooks, and the custom stored procedures and functions that they use. If you have pgtle_admin privileges, you use the following Trusted Language Extensions functions to add and update that information in the table.
  - `pgtle.register_feature`
  - `pgtle.register_feature_if_not_exists`
  - `pgtle.unregister_feature`
  - `pgtle.unregister_feature_if_exists`

### Creating TLE extensions for RDS for PostgreSQL

You can install any extensions that you create with TLE in any RDS for PostgreSQL DB instance that has the pg_tle extension installed. The pg_tle extension is scoped to the PostgreSQL database in which it's installed. The extensions that you create using TLE are scoped to the same database.

Use the various pgtle functions to install the code that makes up your TLE extension. The following Trusted Language Extensions functions all require the pgtle_admin role.

- `pgtle.install_extension`
- `pgtle.install_update_path`
- `pgtle.register_feature`
- `pgtle.register_feature_if_not_exists`
- `pgtle.set_default_version`
- `pgtle.uninstall_extension(name)`
Example: Creating a trusted language extension using SQL

The following example shows you how to create a TLE extension named pg_distance that contains a few SQL functions for calculating distances using different formulas. In the listing, you can find the function for calculating the Manhattan distance and the function for calculating the Euclidean distance. For more information about the difference between these formulas, see Taxicab geometry and Euclidean geometry in Wikipedia.

You can use this example in your own RDS for PostgreSQL DB instance if you have the pg_tle extension set up as detailed in Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance.

Note
You need to have the privileges of the pgtle_admin role to follow this procedure.

To create the example TLE extension

The following steps use an example database named labdb. This database is owned by the postgres primary user. The postgres role also has the permissions of the pgtle_admin role.

1. Use psql to connect to RDS for PostgreSQL DB instance.

   ```bash
   psql --host=db-instance-123456789012.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
   ```

2. Create a TLE extension named pg_distance by copying the following code and pasting it into your psql session console.

   ```sql
   SELECT pgtle.install_extension
   ```
CREATE FUNCTION dist(x1 float8, y1 float8, x2 float8, y2 float8, norm int) RETURNS float8 AS $$
SELECT (abs(x2 - x1) ^ norm + abs(y2 - y1) ^ norm) ^ (1::float8 / norm);
$$ LANGUAGE SQL;

CREATE FUNCTION manhattan_dist(x1 float8, y1 float8, x2 float8, y2 float8) RETURNS float8 AS $$
SELECT dist(x1, y1, x2, y2, 1);
$$ LANGUAGE SQL;

CREATE FUNCTION euclidean_dist(x1 float8, y1 float8, x2 float8, y2 float8) RETURNS float8 AS $$
SELECT dist(x1, y1, x2, y2, 2);
$$ LANGUAGE SQL;

You see the output, such as the following.

install_extension
---------------
t (1 row)

The artifacts that make up the pg_distance extension are now installed in your database. These artifacts include the control file and the code for the extension, which are items that need to be present so that the extension can be created using the CREATE EXTENSION command. In other words, you still need to create the extension to make its functions available to database users.

3. To create the extension, use the CREATE EXTENSION command as you do for any other extension. As with other extensions, the database user needs to have the CREATE permissions in the database.
CREATE EXTENSION pg_distance;

4. To test the pg_distance TLE extension, you can use it to calculate the Manhattan distance between four points.

labdb=> SELECT manhattan_dist(1, 1, 5, 5);
8

To calculate the Euclidean distance between the same set of points, you can use the following.

labdb=> SELECT euclidean_dist(1, 1, 5, 5);
5.656854249492381

The pg_distance extension loads the functions in the database and makes them available to any users with permissions on the database.

Modifying your TLE extension

To improve query performance for the functions packaged in this TLE extension, add the following two PostgreSQL attributes to their specifications.

- IMMUTABLE – The IMMUTABLE attribute ensures that the query optimizer can use optimizations to improve query response times. For more information, see Function Volatility Categories in the PostgreSQL documentation.
- PARALLEL SAFE – The PARALLEL SAFE attribute is another attribute that allows PostgreSQL to run the function in parallel mode. For more information, see CREATE FUNCTION in the PostgreSQL documentation.

In the following example, you can see how the pgtle.install_update_path function is used to add these attributes to each function to create a version 0.2 of the pg_distance TLE extension. For more information about this function, see pgtle.install_update_path. You need to have the pgtle_admin role to perform this task.

To update an existing TLE extension and specify the default version

1. Connect to RDS for PostgreSQL DB instance using psql or another client tool, such as pgAdmin.
2. Modify the existing TLE extension by copying the following code and pasting it into your `psql` session console.

```sql
SELECT pgtle.install_update_path
(    
  'pg_distance',
  '0.1',
  '0.2',
  $pg_tle$

CREATE OR REPLACE FUNCTION dist(x1 float8, y1 float8, x2 float8, y2 float8, norm int)
  RETURNS float8
AS $$
  SELECT (abs(x2 - x1) ^ norm + abs(y2 - y1) ^ norm) ^ (1::float8 / norm);
$$ LANGUAGE SQL IMMUTABLE PARALLEL SAFE;

CREATE OR REPLACE FUNCTION manhattan_dist(x1 float8, y1 float8, x2 float8, y2 float8)
  RETURNS float8
AS $$
  SELECT dist(x1, y1, x2, y2, 1);
$$ LANGUAGE SQL IMMUTABLE PARALLEL SAFE;

CREATE OR REPLACE FUNCTION euclidean_dist(x1 float8, y1 float8, x2 float8, y2 float8)
  RETURNS float8
AS $$
  SELECT dist(x1, y1, x2, y2, 2);
$$ LANGUAGE SQL IMMUTABLE PARALLEL SAFE;

$pg_tle$
);
```

You see a response similar to the following.

```
install_update_path
---------------------
t
(1 row)
```
You can make this version of the extension the default version, so that database users don’t have to specify a version when they create or update the extension in their database.

3. To specify that the modified version (version 0.2) of your TLE extension is the default version, use the `pgtle.set_default_version` function as shown in the following example.

```sql
SELECT pgtle.set_default_version('pg_distance', '0.2');
```

For more information about this function, see `pgtle.set_default_version`.

4. With the code in place, you can update the installed TLE extension in the usual way, by using `ALTER EXTENSION ... UPDATE` command, as shown here:

```sql
ALTER EXTENSION pg_distance UPDATE;
```

### Dropping your TLE extensions from a database

You can drop your TLE extensions by using the `DROP EXTENSION` command in the same way that you do for other PostgreSQL extensions. Dropping the extension doesn’t remove the installation files that make up the extension, which allows users to re-create the extension. To remove the extension and its installation files, do the following two-step process.

**To drop the TLE extension and remove its installation files**

1. Use `psql` or another client tool to connect to the RDS for PostgreSQL DB instance.

   ```bash
   psql --host=.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=dbname
   ```

2. Drop the extension as you would any PostgreSQL extension.

   ```sql
   DROP EXTENSION your-TLE-extension
   ```

   For example, if you create the `pg_distance` extension as detailed in Example: Creating a trusted language extension using SQL, you can drop the extension as follows.

   ```sql
   DROP EXTENSION pg_distance;
   ```
You see output confirming that the extension has been dropped, as follows.

```
DROP EXTENSION
```

At this point, the extension is no longer active in the database. However, its installation files and control file are still available in the database, so database users can create the extension again if they like.

- If you want to leave the extension files intact so that database users can create your TLE extension, you can stop here.
- If you want to remove all files that make up the extension, continue to the next step.

3. To remove all installation files for your extension, use the `pgtle.uninstall_extension` function. This function removes all the code and control files for your extension.

```
SELECT pgtle.uninstall_extension('your-tle-extension-name');
```

For example, to remove all `pg_distance` installation files, use the following command.

```
SELECT pgtle.uninstall_extension('pg_distance');
```

```
uninstall_extension
---------------------
t (1 row)
```

**Uninstalling Trusted Language Extensions for PostgreSQL**

If you no longer want to create your own TLE extensions using TLE, you can drop the `pg_tle` extension and remove all artifacts. This action includes dropping any TLE extensions in the database and dropping the `pgtle` schema.

**To drop the `pg_tle` extension and its schema from a database**

1. Use `psql` or another client tool to connect to the RDS for PostgreSQL DB instance.

```
psql --host=.11112223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=dbname
```
2. Drop the `pg_tle` extension from the database. If the database has your own TLE extensions still running in the database, you need to also drop those extensions. To do so, you can use the CASCADE keyword, as shown in the following.

   ```sql
   DROP EXTENSION pg_tle CASCADE;
   ```

   If the `pg_tle` extension isn't still active in the database, you don't need to use the CASCADE keyword.

3. Drop the `pgtle` schema. This action removes all the management functions from the database.

   ```sql
   DROP SCHEMA pgtle CASCADE;
   ```

   The command returns the following when the process completes.

   ```sql
   DROP SCHEMA
   ```

   The `pg_tle` extension, its schema and functions, and all artifacts are removed. To create new extensions using TLE, go through the setup process again. For more information, see Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance.

### Using PostgreSQL hooks with your TLE extensions

A **hook** is a callback mechanism available in PostgreSQL that allows developers to call custom functions or other routines during regular database operations. The TLE development kit supports PostgreSQL hooks so that you can integrate custom functions with PostgreSQL behavior at runtime. For example, you can use a hook to associate the authentication process with your own custom code, or to modify the query planning and execution process for your specific needs.

Your TLE extensions can use hooks. If a hook is global in scope, it applies across all databases. Therefore, if your TLE extension uses a global hook, then you need to create your TLE extension in all databases that your users can access.

When you use the `pg_tle` extension to build your own Trusted Language Extensions, you can use the available hooks from a SQL API to build out the functions of your extension. You should register any hooks with `pg_tle`. For some hooks, you might also need to set various configuration parameters. For example, the passcode check hook can be set to on, off, or require. For more
information about specific requirements for available pg_tle hooks, see [Hooks reference for Trusted Language Extensions for PostgreSQL](#).

**Example: Creating an extension that uses a PostgreSQL hook**

The example discussed in this section uses a PostgreSQL hook to check the password provided during specific SQL operations and prevents database users from setting their passwords to any of those contained in the `password_check.bad_passwords` table. The table contains the top-ten most commonly used, but easily breakable choices for passwords.

To set up this example in your RDS for PostgreSQL DB instance, you must have already installed Trusted Language Extensions. For details, see [Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance](#).

**To set up the password-check hook example**

1. Use `psql` to connect to RDS for PostgreSQL DB instance.

   ```
   psql --host=db-instance-123456789012.aws-region.rds.amazonaws.com
   --port=5432 --username=postgres --password --dbname=labdb
   ```

2. Copy the code from the [Password-check hook code listing](#) and paste it into your database.

   ```
   SELECT pgtle.install_extension ('my_password_check_rules',
   '1.0',
   'Do not let users use the 10 most commonly used passwords',
   $$_pgtle_$_
   CREATE SCHEMA password_check;
   REVOKE ALL ON SCHEMA password_check FROM PUBLIC;
   GRANT USAGE ON SCHEMA password_check TO PUBLIC;
   CREATE TABLE password_check.bad_passwords (plaintext) AS
   VALUES
   ('123456'),
   ('password'),
   ('12345678'),
   ('qwerty'),
   ('123456789'),
   ('12345'),
   ('1234'),
   ('111111'),
   ```
CREATE UNIQUE INDEX ON password_check.bad_passwords (plaintext);

CREATE FUNCTION password_check.passcheck_hook(username text, password text, password_type pgtle.password_types, valid_until timestamptz, valid_null boolean) RETURNS void AS $$
DECLARE
    invalid bool := false;
BEGIN
    IF password_type = 'PASSWORD_TYPE_MD5' THEN
        SELECT EXISTS(
            SELECT 1
            FROM password_check.bad_passwords bp
            WHERE ('md5' || md5(bp.plaintext || username)) = password
        ) INTO invalid;
        IF invalid THEN
            RAISE EXCEPTION 'Cannot use passwords from the common password dictionary';
        END IF;
    ELSIF password_type = 'PASSWORD_TYPE_PLAINTEXT' THEN
        SELECT EXISTS(
            SELECT 1
            FROM password_check.bad_passwords bp
            WHERE bp.plaintext = password
        ) INTO invalid;
        IF invalid THEN
            RAISE EXCEPTION 'Cannot use passwords from the common password dictionary';
        END IF;
    END IF;
END
$$ LANGUAGE plpgsql SECURITY DEFINER;

GRANT EXECUTE ON FUNCTION password_check.passcheck_hook TO PUBLIC;

SELECT pgtle.register_feature('password_check.passcheck_hook', 'passcheck');
$_pgtle_$
);

When the extension has been loaded into your database, you see the output such as the following.
3. While still connected to the database, you can now create the extension.

```sql
CREATE EXTENSION my_password_check_rules;
```

4. You can confirm that the extension has been created in the database by using the following `psql` metacommand.

```
\dx
```

<table>
<thead>
<tr>
<th>Name</th>
<th>Version</th>
<th>Schema</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>my_password_check_rules</td>
<td>1.0</td>
<td>public</td>
<td>Prevent use of any of the top-ten most common bad passwords</td>
</tr>
<tr>
<td>pg_tle</td>
<td>1.0.1</td>
<td>pgtle</td>
<td>Trusted-Language Extensions for PostgreSQL</td>
</tr>
<tr>
<td>plpgsql</td>
<td>1.0</td>
<td>pg_catalog</td>
<td>PL/pgSQL procedural language</td>
</tr>
</tbody>
</table>

(3 rows)

5. Open another terminal session to work with the AWS CLI. You need to modify your custom DB parameter group to turn on the password-check hook. To do so, use the `modify-db-parameter-group` CLI command as shown in the following example.

```
aws rds modify-db-parameter-group \
  --region aws-region \
  --db-parameter-group-name your-custom-parameter-group \
  --parameters "ParameterName=pgtle.enable_password_check,ParameterValue=on,ApplyMethod=immediate"
```

When the parameter is successfully turned on, you see the output such as the following.

```
{
  "DBParameterGroupName": "docs-lab-parameters-for-tle"
}
```
It might take a few minutes for the change to the parameter group setting to take effect. This parameter is dynamic, however, so you don't need to restart the RDS for PostgreSQL DB instance for the setting to take effect.

6. Open the psql session and query the database to verify that the password_check hook has been turned on.

```
labdb=> SHOW pgtle.enable_password_check;
pgtle.enable_password_check
-----------------------------
on
(1 row)
```

The password-check hook is now active. You can test it by creating a new role and using one of the bad passwords, as shown in the following example.

```
CREATE ROLE test_role PASSWORD 'password';
ERROR: Cannot use passwords from the common password dictionary
CONTEXT:  PL/pgSQL function
password_check.passcheck_hook(text,text,pgtle.password_types,timestamptz,boolean) line 21 at RAISE
SQL statement "SELECT password_check.passcheck_hook(
    $1::pg_catalog.text,
    $2::pg_catalog.text,
    $3::pgtle.password_types,
    $4::pg_catalog.timestamptz,
    $5::pg_catalog.bool)"
```

The output has been formatted for readability.

The following example shows that psql interactive metacommand \password behavior is also affected by the password_check hook.

```
postgres=> SET password_encryption TO 'md5';
SET
postgres=> \password
Enter new password for user "postgres":*****
Enter it again:*****
ERROR: Cannot use passwords from the common password dictionary
```
The example code shown here defines the specification for the `my_password_check_rules` TLE extension. When you copy this code and paste it into your database, the code for the `my_password_check_rules` extension is loaded into the database, and the `password_check` hook is registered for use by the extension.

```sql
SELECT pgtle.install_extension ('my_password_check_rules', '1.0', 'Do not let users use the 10 most commonly used passwords',
                           'my_password_check_rules',
                           '1.0',
                           'Do not let users use the 10 most commonly used passwords',
                           $pgtle$
CREATE SCHEMA password_check;
REVOKE ALL ON SCHEMA password_check FROM PUBLIC;
GRANT USAGE ON SCHEMA password_check TO PUBLIC;
CREATE TABLE password_check.bad_passwords (plaintext) AS
VALUES
  ('123456'),
  ('password'),
  ('12345678'),
  ('qwerty'),
  ('123456789'),
  ('12345'),
  ('1234'),
  ('111111'),
  ('1234576'),
  ('dragon');
CREATE UNIQUE INDEX ON password_check.bad_passwords (plaintext);

CREATE FUNCTION password_check.passcheck_hook(username text, password text,
password_type pgtle.password_types, valid_until timestamptz, valid_null boolean)
RETURNS void AS $$
```

    invalid bool := false;
BEGIN
    IF password_type = 'PASSWORD_TYPE_MD5' THEN
        SELECT EXISTS(
            SELECT 1
            FROM password_check.bad_passwords bp
            WHERE ('md5' || md5(bp.plaintext || username)) = password
        ) INTO invalid;
        IF invalid THEN
            RAISE EXCEPTION 'Cannot use passwords from the common password dictionary';
        END IF;
    ELSIF password_type = 'PASSWORD_TYPE_PLAINTEXT' THEN
        SELECT EXISTS(
            SELECT 1
            FROM password_check.bad_passwords bp
            WHERE bp.plaintext = password
        ) INTO invalid;
        IF invalid THEN
            RAISE EXCEPTION 'Cannot use passwords from the common password dictionary';
        END IF;
    END IF;
END
$$ LANGUAGE plpgsql SECURITY DEFINER;

GRANT EXECUTE ON FUNCTION password_check.passcheck_hook TO PUBLIC;

SELECT pgtle.register_feature('password_check.passcheck_hook', 'passcheck');
$_pgtle_$
);

Using Custom Data Types in TLE

PostgreSQL supports commands to register new base types (also known as scalar types) for efficiently handling complex data structures in your database. A base type allows you to customize how the data is stored internally, and how to convert it to and from an external textual representation. These custom data types are helpful when extending PostgreSQL to support functional domains where a built-in type such as number or text can't provide sufficient search semantics.
RDS for PostgreSQL enables you to create custom data types in your trusted language extension and define functions that support SQL and index operations for these new data types. Custom data types are available for the following versions:

- RDS for PostgreSQL 15.4 and higher 15 versions
- RDS for PostgreSQL 14.9 and higher 14 versions
- RDS for PostgreSQL 13.12 and higher 13 versions

For more information, see [Trusted Language Base types](#).

**Functions reference for Trusted Language Extensions for PostgreSQL**

View the following reference documentation about functions available in Trusted Language Extensions for PostgreSQL. Use these functions to install, register, update, and manage your TLE extensions, that is, the PostgreSQL extensions that you develop using the Trusted Language Extensions development kit.

**Topics**

- `pgtle.available_extensions`
- `pgtle.available_extension_versions`
- `pgtle.extension_update_paths`
- `pgtle.install_extension`
- `pgtle.install_update_path`
- `pgtle.register_feature`
- `pgtle.register_feature_if_not_exists`
- `pgtle.set_default_version`
- `pgtle.uninstall_extension(name)`
- `pgtle.uninstall_extension(name, version)`
- `pgtle.uninstall_extension_if_exists`
- `pgtle.uninstall_update_path`
- `pgtle.uninstall_update_path_if_exists`
- `pgtle.unregister_feature`
- `pgtle.unregister_feature_if_exists`
pgtle.available_extensions

The pgtle.available_extensions function is a set-returning function. It returns all available TLE extensions in the database. Each returned row contains information about a single TLE extension.

**Function prototype**

```sql
pgtle.available_extensions()
```

**Role**

None.

**Arguments**

None.

**Output**

- name – The name of the TLE extension.
- default_version – The version of the TLE extension to use when CREATE EXTENSION is called without a version specified.
- description – A more detailed description about the TLE extension.

**Usage example**

```sql
SELECT * FROM pgtle.available_extensions();
```

pgtle.available_extension_versions

The available_extension_versions function is a set-returning function. It returns a list of all available TLE extensions and their versions. Each row contains information about a specific version of the given TLE extension, including whether it requires a specific role.

**Function prototype**

```sql
pgtle.available_extension_versions()
```
Role

None.

Arguments

None.

Output

- name – The name of the TLE extension.
- version – The version of the TLE extension.
- superuser – This value is always false for your TLE extensions. The permissions needed to create the TLE extension or update it are the same as for creating other objects in the given database.
- trusted – This value is always false for a TLE extension.
- relocatable – This value is always false for a TLE extension.
- schema – Specifies the name of the schema in which the TLE extension is installed.
- requires – An array containing the names of other extensions needed by this TLE extension.
- description – A detailed description of the TLE extension.

For more information about output values, see Packaging Related Objects into an Extension > Extension Files in the PostgreSQL documentation.

Usage example

```sql
SELECT * FROM pgtle.available_extension_versions();
```

`pgtle.extension_update_paths`

The `extension_update_paths` function is a set-returning function. It returns a list of all the possible update paths for a TLE extension. Each row includes the available upgrades or downgrades for that TLE extension.

Function prototype

```sql
pgtle.extension_update_paths(name)
```
Role
None.

Arguments
name – The name of the TLE extension from which to get upgrade paths.

Output
• source – The source version for an update.
• target – The target version for an update.
• path – The upgrade path used to update a TLE extension from source version to target version, for example, 0.1--0.2.

Usage example

```
SELECT * FROM pgtle.extension_update_paths('your-TLE');
```

`pgtle.install_extension`

The `install_extension` function lets you install the artifacts that make up your TLE extension in the database, after which it can be created using the `CREATE EXTENSION` command.

Function prototype

```
pgtle.install_extension(name text, version text, description text, ext text, requires text[] DEFAULT NULL::text[])
```

Role
None.

Arguments
• name – The name of the TLE extension. This value is used when calling CREATE EXTENSION.
• version – The version of the TLE extension.
• description – A detailed description about the TLE extension. This description is displayed in the comment field in `pgtle.available_extensions()`.
• ext – The contents of the TLE extension. This value contains objects such as functions.
• requires – An optional parameter that specifies dependencies for this TLE extension. The pg_tle extension is automatically added as a dependency.

Many of these arguments are the same as those that are included in an extension control file for installing a PostgreSQL extension on the file system of a PostgreSQL instance. For more information, see the Extension Files in Packaging Related Objects into an Extension in the PostgreSQL documentation.

**Output**

This function returns OK on success and NULL on error.

- OK – The TLE extension has been successfully installed in the database.
- NULL – The TLE extension hasn't been successfully installed in the database.

**Usage example**

```sql
SELECT pgtle.install_extension(
    'pg_tle_test',
    '0.1',
    'My first pg_tle extension',
    $pgtle$
    CREATE FUNCTION my_test()
    RETURNS INT
    AS $$
    SELECT 42;
    $$ LANGUAGE SQL IMMUTABLE;
$pgtle$
);
```

**pgtle.install_update_path**

The install_update_path function provides an update path between two different versions of a TLE extension. This function allows users of your TLE extension to update its version by using the ALTER EXTENSION ... UPDATE syntax.

**Function prototype**

```sql
pgtle.install_update_path(name text, fromvers text, tovers text, ext text)
```
Role

pgtle_admin

Arguments

- name – The name of the TLE extension. This value is used when calling CREATE EXTENSION.
- fromvers – The source version of the TLE extension for the upgrade.
- tovers – The destination version of the TLE extension for the upgrade.
- ext – The contents of the update. This value contains objects such as functions.

Output

None.

Usage example

```sql
SELECT pgtle.install_update_path('pg_tle_test', '0.1', '0.2',
    $pgtle$
    CREATE OR REPLACE FUNCTION my_test()
    RETURNS INT
    AS $$
    SELECT 21;
    $$ LANGUAGE SQL IMMUTABLE;
    $pgtle$
);```

pgtle.register_feature

The register_feature function adds the specified internal PostgreSQL feature to the pgtle.feature_info table. PostgreSQL hooks are an example of an internal PostgreSQL feature. The Trusted Language Extensions development kit supports the use of PostgreSQL hooks. Currently, this function supports the following feature.

- passcheck – Registers the password-check hook with your procedure or function that customizes PostgreSQL’s password-check behavior.
Function prototype

```sql
pgtle.register_feature(proc regproc, feature pg_tle_feature)
```

Role

`pgtle_admin`

Arguments

- `proc` – The name of a stored procedure or function to use for the feature.
- `feature` – The name of the `pg_tle` feature (such as `passcheck`) to register with the function.

Output

None.

Usage example

```sql
SELECT pgtle.register_feature('pw_hook', 'passcheck');
```

`pgtle.register_feature_if_not_exists`

The `pgtle.register_feature_if_not_exists` function adds the specified PostgreSQL feature to the `pgtle.feature_info` table and identifies the TLE extension or other procedure or function that uses the feature. For more information about hooks and Trusted Language Extensions, see [Using PostgreSQL hooks with your TLE extensions](#).

Function prototype

```sql
pgtle.register_feature_if_not_exists(proc regproc, feature pg_tle_feature)
```

Role

`pgtle_admin`

Arguments

- `proc` – The name of a stored procedure or function that contains the logic (code) to use as a feature for your TLE extension. For example, the `pw_hook` code.
• feature – The name of the PostgreSQL feature to register for the TLE function. Currently, the only available feature is the passcheck hook. For more information, see Password-check hook (passcheck).

Output

Returns true after registering the feature for the specified extension. Returns false if the feature is already registered.

Usage example

```sql
SELECT pgtle.register_feature_if_not_exists('pw_hook', 'passcheck');
```

pgtle.set_default_version

The set_default_version function lets you specify a default_version for your TLE extension. You can use this function to define an upgrade path and designate the version as the default for your TLE extension. When database users specify your TLE extension in the CREATE EXTENSION and ALTER EXTENSION ... UPDATE commands, that version of your TLE extension is created in the database for that user.

This function returns true on success. If the TLE extension specified in the name argument doesn't exist, the function returns an error. Similarly, if the version of the TLE extension doesn't exist, it returns an error.

Function prototype

```sql
pgtle.set_default_version(name text, version text)
```

Role

pgtle_admin

Arguments

• name – The name of the TLE extension. This value is used when calling CREATE EXTENSION.
• version – The version of the TLE extension to set the default.
Output

- true – When setting default version succeeds, the function returns true.
- ERROR – Returns an error message if a TLE extension with the specified name or version doesn't exist.

Usage example

```
SELECT * FROM pgtle.set_default_version('my-extension', '1.1');
```

`pgtle.uninstall_extension(name)`

The `uninstall_extension` function removes all versions of a TLE extension from a database. This function prevents future calls of CREATE EXTENSION from installing the TLE extension. If the TLE extension doesn't exist in the database, an error is raised.

The `uninstall_extension` function won't drop a TLE extension that's currently active in the database. To remove a TLE extension that's currently active, you need to explicitly call DROP EXTENSION to remove it.

Function prototype

```
pgtle.uninstall_extension(extname text)
```

Role

`pgtle_admin`

Arguments

- `extname` – The name of the TLE extension to uninstall. This name is the same as the one used with CREATE EXTENSION to load the TLE extension for use in a given database.

Output

None.

Usage example

```
SELECT * FROM pgtle.uninstall_extension('pg_tle_test');
```
pgtle.uninstall_extension(name, version)

The uninstall_extension(name, version) function removes the specified version of the TLE extension from the database. This function prevents CREATE EXTENSION and ALTER EXTENSION from installing or updating a TLE extension to the specified version. This function also removes all update paths for the specified version of the TLE extension. This function won't uninstall the TLE extension if it's currently active in the database. You must explicitly call DROP EXTENSION to remove the TLE extension. To uninstall all versions of a TLE extension, see pgtle.uninstall_extension(name).

Function prototype

pgtle.uninstall_extension(extname text, version text)

Role

pgtle_admin

Arguments

- extname – The name of the TLE extension. This value is used when calling CREATE EXTENSION.
- version – The version of the TLE extension to uninstall from the database.

Output

None.

Usage example

SELECT * FROM pgtle.uninstall_extension('pg_tle_test', '0.2');

pgtle.uninstall_extension_if_exists

The uninstall_extension_if_exists function removes all versions of a TLE extension from a given database. If the TLE extension doesn't exist, the function returns silently (no error message is raised). If the specified extension is currently active within a database, this function doesn't drop it. You must explicitly call DROP EXTENSION to remove the TLE extension before using this function to uninstall its artifacts.
Function prototype

```sql
pgtle.uninstall_extension_if_exists(extname text)
```

**Role**

```
pgtle_admin
```

**Arguments**

- `extname` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.

**Output**

The `uninstall_extension_if_exists` function returns `true` after uninstalling the specified extension. If the specified extension doesn't exist, the function returns `false`.

- `true` – Returns `true` after uninstalling the TLE extension.
- `false` – Returns `false` when the TLE extension doesn't exist in the database.

**Usage example**

```sql
SELECT * FROM pgtle.uninstall_extension_if_exists('pg_tle_test');
```

*pgtle.uninstall_update_path*

The `uninstall_update_path` function removes the specific update path from a TLE extension. This prevents `ALTER EXTENSION ... UPDATE TO` from using this as an update path.

If the TLE extension is currently being used by one of the versions on this update path, it remains in the database.

If the update path specified doesn't exist, this function raises an error.

**Function prototype**

```sql
pgtle.uninstall_update_path(extname text, fromvers text, tovers text)
```

**Role**

```
pgtle_admin
```
Arguments

- extname – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- fromvers – The source version of the TLE extension used on the update path.
- tovers – The destination version of the TLE extension used on the update path.

Output

None.

Usage example

```sql
SELECT * FROM pgtle.uninstall_update_path('pg_tle_test', '0.1', '0.2');
```

`pgtle.uninstall_update_path_if_exists`

The `uninstall_update_path_if_exists` function is similar to `uninstall_update_path` in that it removes the specified update path from a TLE extension. However, if the update path doesn't exist, this function doesn't raise an error message. Instead, the function returns `false`.

Function prototype

```sql
pgtle.uninstall_update_path_if_exists(extname text, fromvers text, tovers text)
```

Role

`pgtle_admin`

Arguments

- extname – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- fromvers – The source version of the TLE extension used on the update path.
- tovers – The destination version of the TLE extension used on the update path.

Output

- `true` – The function has successfully updated the path for the TLE extension.
- `false` – The function wasn't able to update the path for the TLE extension.
Usage example

```sql
SELECT * FROM pgtle.uninstall_update_path_if_exists('pg_tle_test', '0.1', '0.2');
```

**pgtle.unregister_feature**

The `unregister_feature` function provides a way to remove functions that were registered to use `pg_tle` features, such as hooks. For information about registering a feature, see `pgtle.register_feature`.

**Function prototype**

```sql
pgtle.unregister_feature(proc regproc, feature pg_tle_features)
```

**Role**

`pgtle_admin`

**Arguments**

- `proc` – The name of a stored function to register with a `pg_tle` feature.
- `feature` – The name of the `pg_tle` feature to register with the function. For example, `passcheck` is a feature that can be registered for use by the trusted language extensions that you develop. For more information, see Password-check hook (passcheck).

**Output**

None.

Usage example

```sql
SELECT * FROM pgtle.unregister_feature('pw_hook', 'passcheck');
```

**pgtle.unregister_feature_if_exists**

The `unregister_feature_if_exists` function provides a way to remove functions that were registered to use `pg_tle` features, such as hooks. For more information, see Using PostgreSQL hooks with your TLE extensions. Returns `true` after successfully unregistering the feature. Returns `false` if the feature wasn't registered.
For information about registering pg_tle features for your TLE extensions, see
\texttt{pgtle.register_feature}.

\textbf{Function prototype}

\begin{verbatim}
pgtle.unregister_feature_if_exists('proc regproc', 'feature pg_tle_features')
\end{verbatim}

\textbf{Role}

\texttt{pgtle_admin}

\textbf{Arguments}

- \texttt{proc} – The name of the stored function that was registered to include a pg_tle feature.
- \texttt{feature} – The name of the pg_tle feature that was registered with the trusted language extension.

\textbf{Output}

Returns true or false, as follows.

- \texttt{true} – The function has successfully unregistered the feature from extension.
- \texttt{false} – The function wasn't able to unregister the feature from the TLE extension.

\textbf{Usage example}

\begin{verbatim}
SELECT * FROM pgtle.unregister_feature_if_exists('pw_hook', 'passcheck');
\end{verbatim}

\textbf{Hooks reference for Trusted Language Extensions for PostgreSQL}

Trusted Language Extensions for PostgreSQL supports PostgreSQL hooks. A \textit{hook} is an internal callback mechanism available to developers for extending PostgreSQL's core functionality. By using hooks, developers can implement their own functions or procedures for use during various database operations, thereby modifying PostgreSQL's behavior in some way. For example, you can use a \texttt{passcheck} hook to customize how PostgreSQL handles the passwords supplied when creating or changing passwords for users (roles).

View the following documentation to learn about the hooks available for your TLE extensions.
Password-check hook (passcheck)

The passcheck hook is used to customize PostgreSQL behavior during the password-checking process for the following SQL commands and psql metacommand.

- `CREATE ROLE username ... PASSWORD` – For more information, see [CREATE ROLE](#) in the PostgreSQL documentation.
- `ALTER ROLE username ... PASSWORD` – For more information, see [ALTER ROLE](#) in the PostgreSQL documentation.
- `\password username` – This interactive psql metacommand securely changes the password for the specified user by hashing the password before transparently using the `ALTER ROLE ... PASSWORD` syntax. The metacommand is a secure wrapper for the `ALTER ROLE ... PASSWORD` command, thus the hook applies to the behavior of the psql metacommand.

For an example, see [Password-check hook code listing](#).

Function prototype

```sql
passcheck_hook(username text, password text, password_type pgtle.password_types,
                valid_until timestamptz, valid_null boolean)
```

Arguments

A passcheck hook function takes the following arguments.

- `username` – The name (as text) of the role (username) that's setting a password.
- `password` – The plaintext or hashed password. The password entered should match the type specified in `password_type`.
- `password_type` – Specify the `pgtle.password_type` format of the password. This format can be one of the following options.
  - `PASSWORD_TYPE_PLAINTEXT` – A plaintext password.
  - `PASSWORD_TYPE_MD5` – A password that's been hashed using MD5 (message digest 5) algorithm.
• PASSWORD_TYPE_SCRAM_SHA_256 – A password that's been hashed using SCRAM-SHA-256 algorithm.
• valid_until – Specify the time when the password becomes invalid. This argument is optional. If you use this argument, specify the time as a timestamptz value.
• valid_null – If this Boolean is set to true, the valid_until option is set to NULL.

Configuration

The function pgtle.enable_password_check controls whether the passcheck hook is active. The passcheck hook has three possible settings.
• off – Turns off the passcheck password-check hook. This is the default value.
• on – Turns on the passcode password-check hook so that passwords are checked against the table.
• require – Requires a password check hook to be defined.

Usage notes

To turn the passcheck hook on or off, you need to modify the custom DB parameter group for your RDS for PostgreSQL DB instance.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group \ 
   --region aws-region \ 
   --db-parameter-group-name your-custom-parameter-group \ 
   --parameters "ParameterName=pgtle.enable_password_check,ParameterValue=on,ApplyMethod=immediate"
```

For Windows:

```bash
aws rds modify-db-parameter-group ^
   --region aws-region ^
   --db-parameter-group-name your-custom-parameter-group ^
   --parameters "ParameterName=pgtle.enable_password_check,ParameterValue=on,ApplyMethod=immediate"
```
Code examples for Amazon RDS using AWS SDKs

The following code examples show how to use Amazon RDS with an AWS software development kit (SDK).

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

*Cross-service examples* are sample applications that work across multiple AWS services.

For a complete list of AWS SDK developer guides and code examples, see [Using this service with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Get started

**Hello Amazon RDS**

The following code examples show how to get started using Amazon RDS.

**.NET**

**AWS SDK for .NET**

```csharp
using System;
using System.Threading.Tasks;
using Amazon.RDS;
using Amazon.RDS.Model;

namespace RDSActions;
```
public static class HelloRds
{
    static async Task Main(string[] args)
    {
        var rdsClient = new AmazonRDSClient();

        Console.WriteLine("Hello Amazon RDS! Following are some of your DB instances:");
        Console.WriteLine();

        // You can use await and any of the async methods to get a response.
        // Let's get the first twenty DB instances.
        var response = await rdsClient.DescribeDBInstancesAsync(

• Cross-service examples for Amazon RDS using AWS SDKs
  • Create an Aurora Serverless work item tracker

**Actions for Amazon RDS using AWS SDKs**

The following code examples demonstrate how to perform individual Amazon RDS actions with AWS SDKs. These excerpts call the Amazon RDS API and are code excerpts from larger programs that must be run in context. Each example includes a link to GitHub, where you can find instructions for setting up and running the code.

The following examples include only the most commonly used actions. For a complete list, see the Amazon Relational Database Service (Amazon RDS) API Reference.

**Examples**

• Create an Amazon RDS DB instance using an AWS SDK
• Create an Amazon RDS DB parameter group using an AWS SDK
• Create a snapshot of an Amazon RDS DB instance using an AWS SDK
• Create an authentication token for IAM authentication to an Amazon RDS database using an AWS SDK
• Delete an Amazon RDS DB instance using an AWS SDK
• Delete an Amazon RDS DB parameter group using an AWS SDK
• Describe Amazon RDS DB instances using an AWS SDK
• Describe Amazon RDS DB parameter groups using an AWS SDK
Create an Amazon RDS DB instance using an AWS SDK

The following code examples show how to create an Amazon RDS DB instance and wait for it to become available.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Get started with DB instances

AWS SDK for .NET

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```csharp
/// <summary>
/// Create an RDS DB instance with a particular set of properties. Use the action DescribeDBInstancesAsync to determine when the DB instance is ready to use.
/// </summary>
/// <param name="dbName">Name for the DB instance.</param>
```

Note
/// <param name="dbInstanceIdentifier">DB instance identifier.</param>
/// <param name="parameterGroupName">DB parameter group to associate with the instance.</param>
/// <param name="dbEngine">The engine for the DB instance.</param>
/// <param name="dbEngineVersion">Version for the DB instance.</param>
/// <param name="instanceClass">Class for the DB instance.</param>
/// <param name="allocatedStorage">The amount of storage in gibibytes (GiB) to allocate to the DB instance.</param>
/// <param name="adminName">Admin user name.</param>
/// <param name="adminPassword">Admin user password.</param>
/// <returns>DB instance object.</returns>
public async Task<DBInstance> CreateDBInstance(string dbName, string dbInstanceIdentifier,
    string parameterGroupName, string dbEngine, string dbEngineVersion, string instanceClass, int allocatedStorage, string adminName, string adminPassword)
{
    var response = await _amazonRDS.CreateDBInstanceAsync(new CreateDBInstanceRequest()
    {
        DBName = dbName,
        DBInstanceIdentifier = dbInstanceIdentifier,
        DBParameterGroupName = parameterGroupName,
        Engine = dbEngine,
        EngineVersion = dbEngineVersion,
        DBInstanceClass = instanceClass,
        AllocatedStorage = allocatedStorage,
        MasterUsername = adminName,
        MasterUserPassword = adminPassword
    });

    return response.DBInstance;
}

  client.CreateDBInstance(request);

if (outcome.IsSuccess()) {
    std::cout << "The DB instance creation has started."
    << std::endl;
} else {
    std::cerr << "Error with RDS::CreateDBInstance. "
    << outcome.GetError().GetMessage()
    << std::endl;
    cleanUpResources(PARAMETER_GROUP_NAME, "", client);
    return false;
}
```
• For API details, see CreateDBInstance in AWS SDK for C++ API Reference.

CLI

AWS CLI

To create a DB instance

The following create-db-instance example uses the required options to launch a new DB instance.

```
aws rds create-db-instance \
  --db-instance-identifier test-mysql-instance \
  --db-instance-class db.t3.micro \
  --engine mysql \
  --master-username admin \
  --master-user-password secret99 \
  --allocated-storage 20
```

Output:

```

Create an authentication token for IAM authentication to an Amazon RDS database using an AWS SDK

The following code example shows how to create an authentication token for IAM authentication.

Java

**SDK for Java 2.x**

```
public class GenerateRDSAuthToken {
    public static void main(String[] args) {
        final String usage = ""
            "Usage:
                \n                <dbInstanceIdentifier> <masterUsername>

                Where:
                \n                dbInstanceIdentifier - The database instance identifier.
                masterUsername - The master user name.
            ""

        if (args.length != 2) {
            System.out.println(usage);
            System.exit(1);
        }
    }

    public void generateAuthToken(String dbInstanceIdentifier, String masterUsername) {
        // Generate the authentication token
    }
}
```

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Use the RdsUtilities class to generate an authentication token.
String dbInstanceIdentifier = args[0];
String masterUsername = args[1];
Region region = Region.US_WEST_2;
RdsClient rdsClient = RdsClient.builder()
  .region(region)
  .build();

String token = getAuthToken(rdsClient, dbInstanceIdentifier, masterUsername);
  System.out.println("The token response is " + token);
}

public static String getAuthToken(RdsClient rdsClient, String dbInstanceIdentifier, String masterUsername) {

RdsUtilities utilities = rdsClient.utilities();
try {
  GenerateAuthenticationTokenRequest tokenRequest =
    GenerateAuthenticationTokenRequest.builder()
      .credentialsProvider(ProfileCredentialsProvider.create())
      .username(masterUsername)
      .port(3306)
      .hostname(dbInstanceIdentifier)
      .build();

  return utilities.generateAuthenticationToken(tokenRequest);
} catch (RdsException e) {
  System.out.println(e.getLocalizedMessage());
  System.exit(1);
}
return "";
}

```cpp
Aws::Client::ClientConfiguration clientConfig;
// Optional: Set to the AWS Region (overrides config file).
// clientConfig.region = "us-east-1";

Aws::RDS::RDSClient client(clientConfig);

Aws::RDS::Model::DeleteDBInstanceRequest request;
request.SetDBInstanceIdentifier(dbInstanceIdentifier);
request.SetSkipFinalSnapshot(true);
request.SetDeleteAutomatedBackups(true);

Aws::RDS::Model::DeleteDBInstanceOutcome outcome =
    client.DeleteDBInstance(request);

if (outcome.IsSuccess()) {
    std::cout << "DB instance deletion has started."
    << std::endl;
} else {
    std::cerr << "Error with RDS::DeleteDBInstance. "
    << outcome.GetError().GetMessage()
    << std::endl;
    result = false;
}
```

- For API details, see DeleteDBInstance in AWS SDK for C++ API Reference.
### AWS CLI

**To delete a DB instance**

The following `delete-db-instance` example deletes the specified DB instance after creating a final DB snapshot named `test-instance-final-snap`.

```bash
aws rds delete-db-instance
   --db-instance-identifier test-instance
   --final-db-snapshot-identifier test-instance-final-snap
```

Output:

```json
{
   "DBInstance": {
      "DBInstanceIdentifier": "test-instance",
      "DBInstanceStatus": "deleting",
      ...some output truncated...
   }
}
```

- For API details, see [DeleteDBInstance](https://docs.aws.amazon.com/cli/latest/reference/rds/delete-db-instance.html) in *AWS CLI Command Reference*.

### Go

**SDK for Go V2**

**Note**

### Describe Amazon RDS DB parameter groups using an AWS SDK

The following code examples show how to describe Amazon RDS DB parameter groups.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Get started with DB instances](https://docs.aws.amazon.com/sdk-for-ruby/api/latest/api/Guides/GettingStarted.html)

#### .NET

**AWS SDK for .NET**

```csharp
/// <summary>
/// Get descriptions of DB parameter groups.
/// </summary>
/// <param name="name">Optional name of the DB parameter group to describe.</param>
/// <returns>The list of DB parameter group descriptions.</returns>
```
```csharp
public async Task<List<DBParameterGroup>> DescribeDBParameterGroups(string name = null)
{
    var response = await _amazonRDS.DescribeDBParameterGroupsAsync(
        new DescribeDBParameterGroupsRequest()
        {
            DBParameterGroupName = name
        });
    return response.DBParameterGroups;
}
```

- For API details, see [DescribeDBParameterGroups](https://docs.aws.amazon.com/sdk-for-net/latest/awssdk-reference/services/rds.html#rds-AmazonRDS-DescribeDBParameterGroups) in *AWS SDK for .NET API Reference*.

### C++

**SDK for C++**

```c++
Aws::Client::ClientConfiguration clientConfig;
// Optional: Set to the AWS Region (overrides config file).
// clientConfig.region = "us-east-1";

Aws::RDS::RDSClient client(clientConfig);

Aws::RDS::Model::DescribeDBParameterGroupsRequest request;
request.SetDBParameterGroupName(PARAMETER_GROUP_NAME);

Aws::RDS::Model::DescribeDBParameterGroupsOutcome outcome =
    client.DescribeDBParameterGroups(request);

if (outcome.IsSuccess()) {
    std::cout << "DB parameter group named " << PARAMETER_GROUP_NAME << " already exists." << std::endl;
    dbParameterGroupFamily = outcome.GetResult().GetDBParameterGroups()[0].GetDBParameterGroupFamily();
}
```

---

Describe DB parameter groups

[4284](#)
else {
    std::cerr << "Error with RDS::DescribeDBParameterGroups. " << outcome.GetError().GetMessage() << std::endl;
    return false;
}

- For API details, see DescribeDBParameterGroups in AWS SDK for C++ API Reference.

**CLI**

**AWS CLI**

**To describe your DB parameter group**

The following describe-db-parameter-groups example retrieves details about your DB parameter groups.

```
aws rds describe-db-parameter-groups
```

Output:

```json
{
    "DBParameterGroups": [
    {
        "DBParameterGroupName": "default.aurora-mysql5.7",
        "DBParameterGroupFamily": "aurora-mysql5.7",
        "Description": "Default parameter group for aurora-mysql5.7",
        "DBParameterGroupArn": "arn:aws:rds:us-east-1:123456789012:pg:default.aurora-mysql5.7"
    },
    {
        "DBParameterGroupName": "default.aurora-postgresql9.6",
        "DBParameterGroupFamily": "aurora-postgresql9.6",
        "Description": "Default parameter group for aurora-postgresql9.6",
        "DBParameterGroupArn": "arn:aws:rds:us-east-1:123456789012:pg:default.aurora-postgresql9.6"
    }
    ]
}
```
"DBParameterGroupName": "default.aurora5.6",
"DBParameterGroupFamily": "aurora5.6",
"Description": "Default parameter group for aurora5.6",
"DBParameterGroupArn": "arn:aws:rds:us-east-1:123456789012:pg:default.aurora5.6"
},
{
  "DBParameterGroupName": "default.mariadb10.1",
  "DBParameterGroupFamily": "mariadb10.1",
  "Description": "Default parameter group for mariadb10.1",

**Describe snapshots of Amazon RDS DB instances using an AWS SDK**

The following code examples show how to describe snapshots of Amazon RDS DB instances.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- **Get started with DB instances**

**.NET**

**AWS SDK for .NET**

```csharp
/// <summary>
/// Return a list of DB snapshots for a particular DB instance.
/// </summary>
/// <param name="dbInstanceIdentifier">DB instance identifier.</param>
/// <returns>List of DB snapshots.</returns>
public async Task<List<DBSnapshot>> DescribeDBSnapshots(string dbInstanceIdentifier)
{
    var results = new List<DBSnapshot>();
    var snapshotsPaginator = _amazonRDS.Paginators.DescribeDBSnapshots(
        new DescribeDBSnapshotsRequest()
        {
            DBInstanceIdentifier = dbInstanceIdentifier
        });

    // Get the entire list using the paginator.
    await foreach (var snapshots in snapshotsPaginator.DBSnapshots)
```
```
results.Add(snapshot);
return results;
```

- For API details, see [DescribeDBSnapshots](#) in *AWS SDK for .NET API Reference*.

### C++

**SDK for C++**

```
Aws::Client::ClientConfiguration clientConfig;
// Optional: Set to the AWS Region (overrides config file).
// clientConfig.region = "us-east-1";

Aws::RDS::RDSClient client(clientConfig);

Aws::RDS::Model::DescribeDBSnapshotsRequest request;
request.SetDBSnapshotIdentifier(snapshotID);

Aws::RDS::Model::DescribeDBSnapshotsOutcome outcome =
    client.DescribeDBSnapshots(request);

if (outcome.IsSuccess()) {
    snapshot = outcome.GetResult().GetDBSnapshots()[0];
} else {
    std::cerr << "Error with RDS::DescribeDBSnapshots. " <<
        outcome.GetError().GetMessage() << std::endl;
    cleanUpResources(PARAMETER_GROUP_NAME, DB_INSTANCE_IDENTIFIER,
        client);
    return false;
}
```

**CLI**

**AWS CLI**

**Example 1: To describe a DB snapshot for a DB instance**

The following `describe-db-snapshots` example retrieves the details of a DB snapshot for a DB instance.

```
aws rds describe-db-snapshots \
    --db-snapshot-identifier mydbsnapshot
```

**Output:**

```json
{
    "DBSnapshots": [
        {
            "DBSnapshotIdentifier": "mydbsnapshot",
            "DBInstanceIdentifier": "mysqldb",
            "SnapshotCreateTime": "2018-02-08T22:28:08.598Z",
            "Engine": "mysql",
            "AllocatedStorage": 20,
            "Status": "available",
            "Port": 3306,
            "AvailabilityZone": "us-east-1f",
            "VpcId": "vpc-6594f31c",
            "InstanceCreateTime": "2018-02-08T22:24:55.973Z",
            "MasterUsername": "mysqladmin",
            "EngineVersion": "5.6.37",
            "LicenseModel": "general-public-license",
            "SnapshotType": "manual",
            "OptionGroupName": "default:mysql-5-6",
            "PercentProgress": 100,
            "StorageType": "gp2",
            "Encrypted": false,
            "DBSnapshotArn": "arn:aws:rds:us-east-1:123456789012:snapshot:mydbsnapshot",
        }
    ]
}
```
For more information, see Creating a DB Snapshot in the Amazon RDS User Guide.

Example 2: To find the number of manual snapshots taken

The following describe-db-snapshots example uses the length operator in the --query option to return the number of manual snapshots that have been taken in a particular AWS Region.

```bash
aws rds describe-db-snapshots \
    --snapshot-type manual \
    --query "length(*[].{DBSnapshots:SnapshotType})" \
    --region eu-central-1
```

Output:

```
35
```

For more information, see Creating a DB Snapshot in the Amazon RDS User Guide.

- For API details, see DescribeDBSnapshots in AWS CLI Command Reference.

SDK versions.
Modify an Amazon RDS DB instance using an AWS SDK

The following code examples show how to modify an Amazon RDS DB instance.

**CLI**

**AWS CLI**

To modify a DB instance

The following `modify-db-instance` example associates an option group and a parameter group with a compatible Microsoft SQL Server DB instance. The `--apply-immediately` parameter causes the option and parameter groups to be associated immediately, instead of waiting until the next maintenance window.

```bash
aws rds modify-db-instance \
    --db-instance-identifier database-2 \
    --option-group-name test-se-2017 \
    --db-parameter-group-name test-sqlserver-se-2017 \
    --apply-immediately
```

**Output:**

```json
{
    "DBInstance": {
        "DBInstanceIdentifier": "database-2",
        "DBInstanceClass": "db.r4.large",
        "Engine": "sqlserver-se",
        "DBInstanceStatus": "available",
        ...
    },
    "DBParameterGroups": [
        {
            "DBParameterGroupName": "test-sqlserver-se-2017",
            "ParameterApplyStatus": "applying"
        }
    ],
    "AvailabilityZone": "us-west-2d",
    ...
}
```

"MultiAZ": true,
For more information, see Modifying an Amazon RDS DB Instance in the Amazon RDS User Guide.

- For API details, see ModifyDBInstance in AWS CLI Command Reference.

Java

### Reboot an Amazon RDS DB instance using an AWS SDK

The following code examples show how to reboot an Amazon RDS DB instance.

**CLI**

**AWS CLI**

**To reboot a DB instance**

The following `reboot-db-instance` example starts a reboot of the specified DB instance.

```
aws rds reboot-db-instance \
    --db-instance-identifier test-mysql-instance
```

**Output:**

```
{
    "DBInstance": {
        "DBInstanceIdentifier": "test-mysql-instance",
        "DBInstanceClass": "db.t3.micro",
        "Engine": "mysql",
        "DBInstanceStatus": "rebooting",
        "MasterUsername": "admin",
        "Endpoint": {
            "Address": "test-mysql-instance.############.us-west-2.rds.amazonaws.com",
            "Port": 3306,
            "HostedZoneId": "Z1PVIF0EXAMPLE"
        }
```

---

*Reboot a DB instance*

### SDK for Kotlin

`suspend fun getAccountAttributes() {`

```kotlin
    RdsClient { region = "us-west-2" }.use { rdsClient ->
        val response = rdsClient.describeAccountAttributes(DescribeAccountAttributesRequest {})
        response.accountQuotas?.forEach { quotas ->
            val response = response.accountQuotas
            println("Name is: ${quotas.accountQuotaName}")
            println("Max value is ${quotas.max}")
        }
    }
}
```

For a complete list of AWS SDK developer guides and code examples, see [Using this service with an AWS SDK](https://docs.aws.amazon.com/sdk-for-kotlin/api/latest/class/com.amazonaws.rds.RdsClient.describeAccountAttributes.html). This topic also includes information about getting started and details about previous SDK versions.

### Update parameters in an Amazon RDS DB parameter group using an AWS SDK

The following code examples show how to update parameters in an Amazon RDS DB parameter group.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Get started with DB instances](https://docs.aws.amazon.com/sdk-for-kotlin/api/latest/class/com.amazonaws.rds.RdsClient.describeAccountAttributes.html)
Update parameters in a DB parameter group

### Note
There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws/aws-code-examples).

```csharp
/// <summary>
/// Update a DB parameter group. Use the action DescribeDBParameterGroupsAsync
/// to determine when the DB parameter group is ready to use.
/// </summary>
/// <param name="name">Name of the DB parameter group.</param>
/// <param name="parameters">List of parameters. Maximum of 20 per request.</param>
/// <returns>The updated DB parameter group name.</returns>
public async Task<string> ModifyDBParameterGroup(
    string name, List<Parameter> parameters)
{
    var response = await _amazonRDS.ModifyDBParameterGroupAsync(
        new ModifyDBParameterGroupRequest() {
            DBParameterGroupName = name,
            Parameters = parameters,
        });
    return response.DBParameterGroupName;
}
```

- For API details, see [ModifyDBParameterGroup](https://docs.aws.amazon.com/sdk-for-net/v3/api/aws-clt-modifydbparametergroup.html) in *AWS SDK for .NET API Reference*. 
**SDK for C++**

```cpp
Aws::Client::ClientConfiguration clientConfig;
// Optional: Set to the AWS Region (overrides config file).
// clientConfig.region = "us-east-1";

Aws::RDS::RDSClient client(clientConfig);

Aws::RDS::Model::ModifyDBParameterGroupRequest request;
request.SetDBParameterGroupName(PARAMETER_GROUP_NAME);
request.SetParameters(updateParameters);

Aws::RDS::Model::ModifyDBParameterGroupOutcome outcome =
    client.ModifyDBParameterGroup(request);

if (outcome.IsSuccess()) {
    std::cout << "The DB parameter group was successfully modified." << std::endl;
} else {
    std::cerr << "Error with RDS::ModifyDBParameterGroup. " <<
              outcome.GetError().GetMessage() << std::endl;
}
```

- For API details, see [ModifyDBParameterGroup](https://aws-sdk_cpp.github.io/awssdk/awssdkcpp/enums.html#ModifyDBParameterGroup) in *AWS SDK for C++ API Reference*.

---

**CLI**

**AWS CLI**

To modify a DB parameter group
The following `modify-db-parameter-group` example changes the value of the `clr enabled` parameter in a DB parameter group. The `--apply-immediately` parameter causes the DB parameter group to be modified immediately, instead of waiting until the next maintenance window.

```
aws rds modify-db-parameter-group \
   --db-parameter-group-name test-sqlserver-se-2017 \
   --parameters "ParameterName='clr enabled',ParameterValue=1,ApplyMethod=immediate"
```

Output:

```
{
   "DBParameterGroupName": "test-sqlserver-se-2017"
}
```

For more information, see Modifying Parameters in a DB Parameter Group in the Amazon RDS User Guide.

- For API details, see ModifyDBParameterGroup in AWS CLI Command Reference.

Go

**SDK for Go V2**

```go
type DbInstances struct {
   RdsClient *rds.Client
}
```

// UpdateParameters updates parameters in a named DB parameter group.

---

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
func (instances *DbInstances) UpdateParameters(parameterGroupName string, params []types.Parameter) error {
    _, err := instances.RdsClient.ModifyDBParameterGroup(context.TODO(),
    &rds.ModifyDBParameterGroupInput{
        DBParameterGroupName: aws.String(parameterGroupName),
        Parameters:            params,
    })
    if err != nil {
        log.Printf("Couldn't update parameters in %v: %v\n", parameterGroupName, err)
        return err
    } else {
        return nil
    }
}

**Scenarios for Amazon RDS using AWS SDKs**

The following code examples show you how to implement common scenarios in Amazon RDS with AWS SDKs. These scenarios show you how to accomplish specific tasks by calling multiple functions
within Amazon RDS. Each scenario includes a link to GitHub, where you can find instructions on how to set up and run the code.

Examples

- [Get started with Amazon RDS DB instances using an AWS SDK](#)

**Get started with Amazon RDS DB instances using an AWS SDK**

The following code examples show how to:

- Create a custom DB parameter group and set parameter values.
- Create a DB instance that's configured to use the parameter group. The DB instance also contains a database.
- Take a snapshot of the instance.
- Delete the instance and parameter group.

**.NET**

**AWS SDK for .NET**

---

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

---

Run an interactive scenario at a command prompt.

```csharp
/// <summary>
/// Scenario for RDS DB instance example.
/// </summary>
public class RDSInstanceScenario
{
    /*
     * Before running this .NET code example, set up your development environment, including your credentials.
     */

    This .NET example performs the following tasks:
```
1. Returns a list of the available DB engine families using the DescribeDBEngineVersionsAsync method.
2. Selects an engine family and creates a custom DB parameter group using the CreateDBParameterGroupAsync method.
3. Gets the parameter groups using the DescribeDBParameterGroupsAsync method.
4. Gets parameters in the group using the DescribeDBParameters method.
5. Parses and displays parameters in the group.
6. Modifies both the auto_increment_offset and auto_increment_increment parameters using the ModifyDBParameterGroupAsync method.
7. Gets and displays the updated parameters using the DescribeDBParameters method with a source of "user".
8. Gets a list of allowed engine versions using the DescribeDBEngineVersionsAsync method.
9. Displays and selects from a list of micro instance classes available for the selected engine and version.
10. Creates an RDS DB instance that contains a MySql database and uses the parameter group using the CreateDBInstanceAsync method.
11. Waits for DB instance to be ready using the DescribeDBInstancesAsync method.
12. Prints out the connection endpoint string for the new DB instance.
13. Creates a snapshot of the DB instance using the CreateDBSnapshotAsync method.
14. Waits for DB snapshot to be ready using the DescribeDBSnapshots method.
15. Deletes the DB instance using the DeleteDBInstanceAsync method.
16. Waits for DB instance to be deleted using the DescribeDbInstances method.
17. Deletes the parameter group using the DeleteDBParameterGroupAsync method.

Go

SDK for Go V2

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario at a command prompt.

```go
// GetStartedInstances is an interactive example that shows you how to use the AWS SDK for Go
// with Amazon Relation Database Service (Amazon RDS) to do the following:
//
// 1. Create a custom DB parameter group and set parameter values.
// 2. Create a DB instance that is configured to use the parameter group. The DB instance
// also contains a database.
// 3. Take a snapshot of the DB instance.
// 4. Delete the DB instance and parameter group.

/**
 * Before running this Java (v2) code example, set up your development environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * This example requires an AWS Secrets Manager secret that contains the database credentials. If you do not create a secret, this example will not work. For details, see:
 *
 * https://docs.aws.amazon.com/secretsmanager/latest/userguide/integrating_how-services-use-secrets_RS.html
 *
 * This Java example performs these tasks:
 *
 * 1. Returns a list of the available DB engines.
 * 2. Selects an engine family and create a custom DB parameter group.
 * 3. Gets the parameter groups.
 * 4. Gets parameters in the group.
 * 5. Modifies the auto_increment_offset parameter.
 * 6. Gets and displays the updated parameters.
 * 7. Gets a list of allowed engine versions.
 * 8. Gets a list of micro instance classes available for the selected engine.
 * 9. Creates an RDS database instance that contains a MySql database and uses...
/* the parameter group.
 * 10. Waits for the DB instance to be ready and prints out the connection
 * endpoint value.
 * 11. Creates a snapshot of the DB instance.
 * 12. Waits for an RDS DB snapshot to be ready.
 * 13. Deletes the RDS DB instance.
 * 14. Deletes the parameter group.
 */

Kotlin

SDK for Kotlin

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

/**
 * Before running this code example, set up your development environment, including your credentials.
 
For more information, see the following documentation topic:

https://docs.aws.amazon.com/sdk-for-kotlin/latest/developer-guide/setup.html
This example requires an AWS Secrets Manager secret that contains the database credentials. If you do not create a secret, this example will not work. For more details, see:

https://docs.aws.amazon.com/secretsmanager/latest/userguide/integrating_how-services-use-secrets_RS.html

This example performs the following tasks:

1. Returns a list of the available DB engines by invoking the DescribeDbEngineVersions method.
2. Selects an engine family and create a custom DB parameter group by invoking the createDBParameterGroup method.
3. Gets the parameter groups by invoking the DescribeDbParameterGroups method.
4. Gets parameters in the group by invoking the DescribeDbParameters method.
5. Modifies both the auto_increment_offset and auto_increment_increment parameters by invoking the modifyDbParameterGroup method.
6. Gets and displays the updated parameters.
7. Gets a list of allowed engine versions by invoking the describeDbEngineVersions method.
8. Gets a list of micro instance classes available for the selected engine.
9. Creates an Amazon Relational Database Service (Amazon RDS) database instance that contains a MySQL database and uses the parameter group.
10. Waits for DB instance to be ready and prints out the connection endpoint value.
11. Creates a snapshot of the DB instance.
12. Waits for the DB snapshot to be ready.
13. Deletes the DB instance.
14. Deletes the parameter group.

*/

    """
    Displays connection information about a DB instance and tips on how to
    connect to it.
    
    :param db_inst: The DB instance to display.
    """

Get started with DB instances
You can now connect to your database using your favorite MySQL client.

One way to connect is by using the 'mysql' shell on an Amazon EC2 instance:

that is running in the same VPC as your DB instance. Pass the endpoint, port, and administrator user name to 'mysql' and enter your password when prompted:

```python
f"\n\nmysql -h {db_inst['Endpoint']['Address']} -P {db_inst['Endpoint']['Port']} "
    f"-u {db_inst['MasterUsername']} -p"

print(  
    "For more information, see the User Guide for Amazon RDS:\n"
)
print("-" * 88)
```

Serverless examples for Amazon RDS using AWS SDKs

The following code examples show how to use Amazon RDS with AWS SDKs.

Examples

- Connecting to an Amazon RDS database in a Lambda function

Connecting to an Amazon RDS database in a Lambda function

The following code example shows how to implement a Lambda function that connects to an RDS database. The function makes a simple database request and returns the result.

JavaScript

SDK for JavaScript (v2)

```javascript
/*
Node.js code here.
*/
// ES6+ example
import { Signer } from '@aws-sdk/rds-signer';
import mysql from 'mysql2/promise';
async function createAuthToken() {

```
// Define connection authentication parameters
const dbinfo = {
    hostname: process.env.ProxyHostName,
    port: process.env.Port,
    username: process.env.DBUserName,
    region: process.env.AWS_REGION,
}

// Create RDS Signer object
const signer = new Signer(dbinfo);

// Request authorization token from RDS, specifying the username
const token = await signer.getAuthToken();
return token;
}

async function dbOps() {
    // Obtain auth token
    const token = await createAuthToken();
    // Define connection configuration
    let connectionConfig = {
        host: process.env.ProxyHostName,
        user: process.env.DBUserName,
        password: token,
        database: process.env.DBName,
        ssl: 'Amazon RDS'
    }
    // Create the connection to the DB
    const conn = await mysql.createConnection(connectionConfig);
    // Obtain the result of the query
    const [res,] = await conn.execute('select ?+? as sum', [3, 2]);
    return res;
}

export const handler = async (event) => {
    // Execute database flow
    const result = await dbOps();
    // Return result
    return {
        statusCode: 200,

### Cross-service examples for Amazon RDS using AWS SDKs

The following sample applications use AWS SDKs to combine Amazon RDS with other AWS services. Each example includes a link to GitHub, where you can find instructions on how to set up and run the application.

**Examples**

- [Create an Aurora Serverless work item tracker](#)

### Create an Aurora Serverless work item tracker

The following code examples show how to create a web application that tracks work items in an Amazon Aurora Serverless database and uses Amazon Simple Email Service (Amazon SES) to send reports.

**.NET**

**AWS SDK for .NET**

Shows how to use the AWS SDK for .NET to create a web application that tracks work items in an Amazon Aurora database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with a RESTful .NET backend.

- Integrate a React web application with AWS services.
- List, add, update, and delete items in an Aurora table.
- Send an email report of filtered work items using Amazon SES.
- Deploy and manage example resources with the included AWS CloudFormation script.
For complete source code and instructions on how to set up and run, see the full example on GitHub.

**Services used in this example**

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

**C++**

**SDK for C++**

Shows how to create a web application that tracks and reports on work items stored in an Amazon Aurora Serverless database.

For complete source code and instructions on how to set up a C++ REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on GitHub.

**Services used in this example**

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

**Java**

**SDK for Java 2.x**

Shows how to create a web application that tracks and reports on work items stored in an Amazon RDS database.

For complete source code and instructions on how to set up a Spring REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on GitHub.
For complete source code and instructions on how to set up and run an example that uses the JDBC API, see the full example on GitHub.

**Services used in this example**

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

**JavaScript**

**SDK for JavaScript (v3)**

Shows how to use the AWS SDK for JavaScript (v3) to create a web application that tracks work items in an Amazon Aurora database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with an Express Node.js backend.

- Integrate a React.js web application with AWS services.
- List, add, and update items in an Aurora table.
- Send an email report of filtered work items by using Amazon SES.
- Deploy and manage example resources with the included AWS CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

**Services used in this example**

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES
Kotlin

SDK for Kotlin

Shows how to create a web application that tracks and reports on work items stored in an Amazon RDS database.

For complete source code and instructions on how to set up a Spring REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

PHP

SDK for PHP

Shows how to use the AWS SDK for PHP to create a web application that tracks work items in an Amazon RDS database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with a RESTful PHP backend.

- Integrate a React.js web application with AWS services.
- List, add, update, and delete items in an Amazon RDS table.
- Send an email report of filtered work items using Amazon SES.
- Deploy and manage example resources with the included AWS CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
Python

SDK for Python (Boto3)

Shows how to use the AWS SDK for Python (Boto3) to create a REST service that tracks work items in an Amazon Aurora Serverless database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses the Flask web framework to handle HTTP routing and integrates with a React webpage to present a fully functional web application.

- Build a Flask REST service that integrates with AWS services.
- Read, write, and update work items that are stored in an Aurora Serverless database.
- Create an AWS Secrets Manager secret that contains database credentials and use it to authenticate calls to the database.
- Use Amazon SES to send email reports of work items.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

For a complete list of AWS SDK developer guides and code examples, see Using this service with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.
Security in Amazon RDS

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS compliance programs. To learn about the compliance programs that apply to Amazon RDS, see AWS services in scope by compliance program.

- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your organization's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Amazon RDS. The following topics show you how to configure Amazon RDS to meet your security and compliance objectives. You also learn how to use other AWS services that help you monitor and secure your Amazon RDS resources.

You can manage access to your Amazon RDS resources and your databases on a DB instance. The method you use to manage access depends on what type of task the user needs to perform with Amazon RDS:

- Run your DB instance in a virtual private cloud (VPC) based on the Amazon VPC service for the greatest possible network access control. For more information about creating a DB instance in a VPC, see Amazon VPC VPCs and Amazon RDS.

- Use AWS Identity and Access Management (IAM) policies to assign permissions that determine who is allowed to manage Amazon RDS resources. For example, you can use IAM to determine who is allowed to create, describe, modify, and delete DB instances, tag resources, or modify security groups.
Use security groups to control what IP addresses or Amazon EC2 instances can connect to your databases on a DB instance. When you first create a DB instance, its firewall prevents any database access except through rules specified by an associated security group.

Use Secure Socket Layer (SSL) or Transport Layer Security (TLS) connections with DB instances running the Db2, MySQL, MariaDB, PostgreSQL, Oracle, or Microsoft SQL Server database engines. For more information on using SSL/TLS with a DB instance, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.

Use Amazon RDS encryption to secure your DB instances and snapshots at rest. Amazon RDS encryption uses the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your DB instance. For more information, see Encrypting Amazon RDS resources.

Use network encryption and transparent data encryption with Oracle DB instances; for more information, see Oracle native network encryption and Oracle Transparent Data Encryption.

Use the security features of your DB engine to control who can log in to the databases on a DB instance. These features work just as if the database was on your local network.

Note
You have to configure security only for your use cases. You don't have to configure security access for processes that Amazon RDS manages. These include creating backups, replicating data between a primary DB instance and a read replica, and other processes.

For more information on managing access to Amazon RDS resources and your databases on a DB instance, see the following topics.

Topics

- Database authentication with Amazon RDS
- Password management with Amazon RDS and AWS Secrets Manager
- Data protection in Amazon RDS
- Identity and access management for Amazon RDS
- Logging and monitoring in Amazon RDS
- Compliance validation for Amazon RDS
- Resilience in Amazon RDS
- Infrastructure security in Amazon RDS
Database authentication with Amazon RDS

Amazon RDS supports several ways to authenticate database users.

Password, Kerberos, and IAM database authentication use different methods of authenticating to the database. Therefore, a specific user can log in to a database using only one authentication method.

For PostgreSQL, use only one of the following role settings for a user of a specific database:

- To use IAM database authentication, assign the `rds_iam` role to the user.
- To use Kerberos authentication, assign the `rds_ad` role to the user.
- To use password authentication, don't assign either the `rds_iam` or `rds_ad` roles to the user.

Don't assign both the `rds_iam` and `rds_ad` roles to a user of a PostgreSQL database either directly or indirectly by nested grant access. If the `rds_iam` role is added to the master user, IAM authentication takes precedence over password authentication so the master user has to log in as an IAM user.

⚠️ **Important**

We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

**Topics**

- Password authentication
- IAM database authentication
• **Kerberos authentication**

**Password authentication**

With *password authentication*, your database performs all administration of user accounts. You create users with SQL statements such as `CREATE USER`, with the appropriate clause required by the DB engine for specifying passwords. For example, in MySQL the statement is `CREATE USER name IDENTIFIED BY password`, while in PostgreSQL, the statement is `CREATE USER name WITH PASSWORD password`.

With password authentication, your database controls and authenticates user accounts. If a DB engine has strong password management features, they can enhance security. Database authentication might be easier to administer using password authentication when you have small user communities. Because clear text passwords are generated in this case, integrating with AWS Secrets Manager can enhance security.

For information about using Secrets Manager with Amazon RDS, see [Creating a basic secret](#) and [Rotating secrets for supported Amazon RDS databases](#) in the *AWS Secrets Manager User Guide*. For information about programmatically retrieving your secrets in your custom applications, see [Retrieving the secret value](#) in the *AWS Secrets Manager User Guide*.

**IAM database authentication**

You can authenticate to your DB instance using AWS Identity and Access Management (IAM) database authentication. IAM database authentication works with MySQL and PostgreSQL. With this authentication method, you don't need to use a password when you connect to a DB instance. Instead, you use an authentication token.

For more information about IAM database authentication, including information about availability for specific DB engines, see [IAM database authentication for MariaDB, MySQL, and PostgreSQL](#).

**Kerberos authentication**

Amazon RDS supports external authentication of database users using Kerberos and Microsoft Active Directory. Kerberos is a network authentication protocol that uses tickets and symmetric-key cryptography to eliminate the need to transmit passwords over the network. Kerberos has been built into Active Directory and is designed to authenticate users to network resources, such as databases.
Amazon RDS support for Kerberos and Active Directory provides the benefits of single sign-on and centralized authentication of database users. You can keep your user credentials in Active Directory. Active Directory provides a centralized place for storing and managing credentials for multiple DB instances.

You can make it possible for your database users to authenticate against DB instances in two ways. They can use credentials stored either in AWS Directory Service for Microsoft Active Directory or in your on-premises Active Directory.

Microsoft SQL Server and PostgreSQL DB instances support one- and two-way forest trust relationships. Oracle DB instances support one- and two-way external and forest trust relationships. For more information, see When to create a trust relationship in the AWS Directory Service Administration Guide.

For information about Kerberos authentication with a specific DB engine, see the following:

- Working with AWS Managed Active Directory with RDS for SQL Server
- Using Kerberos authentication for MySQL
- Configuring Kerberos authentication for Amazon RDS for Oracle
- Using Kerberos authentication with Amazon RDS for PostgreSQL

⚠️ Note

Currently, Kerberos authentication isn't supported for MariaDB DB instances.
Password management with Amazon RDS and AWS Secrets Manager

Amazon RDS integrates with Secrets Manager to manage master user passwords for your DB instances and Multi-AZ DB clusters.

**Topics**

- Limitations for Secrets Manager integration with Amazon RDS
- Overview of managing master user passwords with AWS Secrets Manager
- Benefits of managing master user passwords with Secrets Manager
- Permissions required for Secrets Manager integration
- Enforcing RDS management of the master user password in AWS Secrets Manager
- Managing the master user password for a DB instance with Secrets Manager
- Managing the master user password for a Multi-AZ DB cluster with Secrets Manager
- Rotating the master user password secret for a DB instance
- Rotating the master user password secret for a Multi-AZ DB cluster
- Viewing the details about a secret for a DB instance
- Viewing the details about a secret for a Multi-AZ DB cluster
- Region and version availability

**Limitations for Secrets Manager integration with Amazon RDS**

Managing master user passwords with Secrets Manager isn't supported for the following features:

- For all DB engines except for RDS for SQL Server, creating a read replica when the source DB or DB cluster manages credentials with Secrets Manager
- Amazon RDS Blue/Green Deployments
- Amazon RDS Custom
- Oracle Data Guard switchover
- RDS for Oracle with CDB
Overview of managing master user passwords with AWS Secrets Manager

With AWS Secrets Manager, you can replace hard-coded credentials in your code, including database passwords, with an API call to Secrets Manager to retrieve the secret programmatically. For more information about Secrets Manager, see the AWS Secrets Manager User Guide.

When you store database secrets in Secrets Manager, your AWS account incurs charges. For information about pricing, see AWS Secrets Manager Pricing.

You can specify that RDS manages the master user password in Secrets Manager for an Amazon RDS DB instance or Multi-AZ DB cluster when you perform one of the following operations:

- Create the DB instance
- Create the Multi-AZ DB cluster
- Modify the DB instance
- Modify the Multi-AZ DB cluster
- Restore the DB instance from Amazon S3

When you specify that RDS manages the master user password in Secrets Manager, RDS generates the password and stores it in Secrets Manager. You can interact directly with the secret to retrieve the credentials for the master user. You can also specify a customer managed key to encrypt the secret, or use the KMS key that is provided by Secrets Manager.

RDS manages the settings for the secret and rotates the secret every seven days by default. You can modify some of the settings, such as the rotation schedule. If you delete a DB instance that manages a secret in Secrets Manager, the secret and its associated metadata are also deleted.

To connect to a DB instance or Multi-AZ DB cluster with the credentials in a secret, you can retrieve the secret from Secrets Manager. For more information, see Retrieve secrets from AWS Secrets Manager and Connect to a SQL database with credentials in an AWS Secrets Manager secret in the AWS Secrets Manager User Guide.

Benefits of managing master user passwords with Secrets Manager

Managing RDS master user passwords with Secrets Manager provides the following benefits:

- RDS automatically generates database credentials.
• RDS automatically stores and manages database credentials in AWS Secrets Manager.
• RDS rotates database credentials regularly, without requiring application changes.
• Secrets Manager secures database credentials from human access and plain text view.
• Secrets Manager allows retrieval of database credentials in secrets for database connections.
• Secrets Manager allows fine-grained control of access to database credentials in secrets using IAM.
• You can optionally separate database encryption from credentials encryption with different KMS keys.
• You can eliminate manual management and rotation of database credentials.
• You can monitor database credentials easily with AWS CloudTrail and Amazon CloudWatch.

For more information about the benefits of Secrets Manager, see the AWS Secrets Manager User Guide.

Permissions required for Secrets Manager integration

Users must have the required permissions to perform operations related to Secrets Manager integration. You can create IAM policies that grant permissions to perform specific API operations on the specified resources they need. You can then attach those policies to the IAM permission sets or roles that require those permissions. For more information, see Identity and access management for Amazon RDS.

For create, modify, or restore operations, the user who specifies that Amazon RDS manages the master user password in Secrets Manager must have permissions to perform the following operations:

• kms:DescribeKey
• secretsmanager:CreateSecret
• secretsmanager:TagResource

For create, modify, or restore operations, the user who specifies the customer managed key to encrypt the secret in Secrets Manager must have permissions to perform the following operations:

• kms:Decrypt
• kms:GenerateDataKey
• kms:CreateGrant

For modify operations, the user who rotates the master user password in Secrets Manager must have permissions to perform the following operation:

• secretsmanager:RotateSecret

Enforcing RDS management of the master user password in AWS Secrets Manager

You can use IAM condition keys to enforce RDS management of the master user password in AWS Secrets Manager. The following policy doesn’t allow users to create or restore DB instances or DB clusters unless the master user password is managed by RDS in Secrets Manager.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Deny",
         "Action": ["rds:CreateDBInstance", "rds:CreateDBCluster",
                     "rds:RestoreDBInstanceFromS3", "rds:RestoreDBClusterFromS3"],
         "Resource": "*",
         "Condition": {
            "Bool": {
               "rds:ManageMasterUserPassword": false
            }
         }
      }
   ]
}
```

Note

This policy enforces password management in AWS Secrets Manager at creation. However, you can still disable Secrets Manager integration and manually set a master password by modifying the instance.
To prevent this, include `rds:ModifyDBInstance, rds:ModifyDBCluster` in the action block of the policy. Be aware, this prevents the user from applying any further modifications to existing instances that don't have Secrets Manager integration enabled.

For more information about using condition keys in IAM policies, see [Policy condition keys for Amazon RDS](#) and [Example policies: Using condition keys](#).

### Managing the master user password for a DB instance with Secrets Manager

You can configure RDS management of the master user password in Secrets Manager when you perform the following actions:

- [Creating an Amazon RDS DB instance](#)
- [Modifying an Amazon RDS DB instance](#)
- [Restoring a backup into a MySQL DB instance](#)

You can use the RDS console, the AWS CLI, or the RDS API to perform these actions.

#### Console

Follow the instructions for creating or modifying a DB instance with the RDS console:

- [Creating a DB instance](#)
- [Modifying an Amazon RDS DB instance](#)
- [Importing data from Amazon S3 to a new MySQL DB instance](#)

When you use the RDS console to perform one of these operations, you can specify that the master user password is managed by RDS in Secrets Manager. To do so when you are creating or restoring a DB instance, select **Manage master credentials in AWS Secrets Manager** in **Credential settings**. When you are modifying a DB instance, select **Manage master credentials in AWS Secrets Manager** in **Settings**.

The following image is an example of the **Manage master credentials in AWS Secrets Manager** setting when you are creating or restoring a DB instance.
When you select this option, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.
You can choose to encrypt the secret with a KMS key that Secrets Manager provides or with a customer managed key that you create. After RDS is managing the database credentials for a DB instance, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements. For more information about the available settings when you are creating a DB instance, see Settings for DB instances. For more information about the available settings when you are modifying a DB instance, see Settings for DB instances.

AWS CLI

To manage the master user password with RDS in Secrets Manager, specify the --manage-master-user-password option in one of the following AWS CLI commands:

- create-db-instance
- modify-db-instance
- restore-db-instance-from-s3

When you specify the --manage-master-user-password option in these commands, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the --master-user-secret-kms-key-id option to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN.

After RDS is managing the database credentials for a DB instance, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements. For more information about the available settings when you are creating a DB instance, see Settings for DB instances. For more information about the available settings when you are modifying a DB instance, see Settings for DB instances.

This example creates a DB instance and specifies that RDS manages the master user password in Secrets Manager. The secret is encrypted using the KMS key that is provided by Secrets Manager.

Example

For Linux, macOS, or Unix:
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --engine mysql \
    --engine-version 8.0.30 \
    --db-instance-class db.r5b.large \
    --allocated-storage 200 \
    --manage-master-user-password

For Windows:

aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --engine mysql ^
    --engine-version 8.0.30 ^
    --db-instance-class db.r5b.large ^
    --allocated-storage 200 ^
    --manage-master-user-password

RDS API

To specify that RDS manages the master user password in Secrets Manager, set the ManageMasterUserPassword parameter to true in one of the following RDS API operations:

- CreateDBInstance
- ModifyDBInstance
- RestoreDBInstanceFromS3

When you set the ManageMasterUserPassword parameter to true in one of these operations, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the MasterUserSecretKmsKeyId parameter to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN. After RDS is managing the database credentials for a DB instance, you can't change the KMS key that is used to encrypt the secret.
Managing the master user password for a Multi-AZ DB cluster with Secrets Manager

You can configure RDS management of the master user password in Secrets Manager when you perform the following actions:

- Creating a Multi-AZ DB cluster
- Modifying a Multi-AZ DB cluster

You can use the RDS console, the AWS CLI, or the RDS API to perform these actions.

Console

Follow the instructions for creating or modifying a Multi-AZ DB cluster with the RDS console:

- Creating a DB cluster
- Modifying a Multi-AZ DB cluster

When you use the RDS console to perform one of these operations, you can specify that the master user password is managed by RDS in Secrets Manager. To do so when you are creating a DB cluster, select Manage master credentials in AWS Secrets Manager in Credential settings. When you are modifying a DB cluster, select Manage master credentials in AWS Secrets Manager in Settings.

The following image is an example of the Manage master credentials in AWS Secrets Manager setting when you are creating a DB cluster.
When you select this option, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.
You can choose to encrypt the secret with a KMS key that Secrets Manager provides or with a customer managed key that you create. After RDS is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements.

For more information about the available settings when you are creating a Multi-AZ DB cluster, see Settings for creating Multi-AZ DB clusters. For more information about the available settings when you are modifying a Multi-AZ DB cluster, see Settings for modifying Multi-AZ DB clusters.

AWS CLI

To specify that RDS manages the master user password in Secrets Manager, specify the --manage-master-user-password option in one of the following commands:

- create-db-cluster
- modify-db-cluster

When you specify the --manage-master-user-password option in these commands, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the --master-user-secret-kms-key-id option to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN.

After RDS is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements.

For more information about the available settings when you are creating a Multi-AZ DB cluster, see Settings for creating Multi-AZ DB clusters. For more information about the available settings when you are modifying a Multi-AZ DB cluster, see Settings for modifying Multi-AZ DB clusters.

This example creates a Multi-AZ DB cluster and specifies that RDS manages the password in Secrets Manager. The secret is encrypted using the KMS key that is provided by Secrets Manager.

Example

For Linux, macOS, or Unix:
For Windows:

```bash
aws rds create-db-cluster ^
  --db-cluster-identifier mysql-multi-az-db-cluster ^
  --engine mysql ^
  --engine-version 8.0.28 ^
  --backup-retention-period 1 ^
  --allocated-storage 4000 ^
  --storage-type io1 ^
  --iops 10000 ^
  --db-cluster-instance-class db.r6gd.xlarge ^
  --manage-master-user-password
```

### RDS API

To specify that RDS manages the master user password in Secrets Manager, set the `ManageMasterUserPassword` parameter to `true` in one of the following operations:

- [CreateDBCluster](#)
- [ModifyDBCluster](#)

When you set the `ManageMasterUserPassword` parameter to `true` in one of these operations, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `MasterUserSecretKmsKeyId` parameter to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN.
After RDS is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

**Rotating the master user password secret for a DB instance**

When RDS rotates a master user password secret, Secrets Manager generates a new secret version for the existing secret. The new version of the secret contains the new master user password. Amazon RDS changes the master user password for the DB instance to match the password for the new secret version.

You can rotate a secret immediately instead of waiting for a scheduled rotation. To rotate a master user password secret in Secrets Manager, modify the DB instance. For information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](#).

You can rotate a master user password secret immediately with the RDS console, the AWS CLI, or the RDS API. The new password is always 28 characters long and contains at least one upper and lowercase character, one number, and one punctuation.

**Console**

To rotate a master user password secret using the RDS console, modify the DB instance and select **Rotate secret immediately** in Settings.
Follow the instructions for modifying a DB instance with the RDS console in Modifying an Amazon RDS DB instance. You must choose **Apply immediately** on the confirmation page.

**AWS CLI**

To rotate a master user password secret using the AWS CLI, use the `modify-db-instance` command and specify the `--rotate-master-user-password` option. You must specify the `--apply-immediately` option when you rotate the master password.

This example rotates a master user password secret.

**Example**

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --rotate-master-user-password \
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --rotate-master-user-password ^
  --apply-immediately
```

**RDS API**

You can rotate a master user password secret using the `ModifyDBInstance` operation and setting the `RotateMasterUserPassword` parameter to `true`. You must set the `ApplyImmediately` parameter to `true` when you rotate the master password.

**Rotating the master user password secret for a Multi-AZ DB cluster**

When RDS rotates a master user password secret, Secrets Manager generates a new secret version for the existing secret. The new version of the secret contains the new master user password. Amazon RDS changes the master user password for the Multi-AZ DB cluster to match the password for the new secret version.
You can rotate a secret immediately instead of waiting for a scheduled rotation. To rotate a master user password secret in Secrets Manager, modify the Multi-AZ DB cluster. For information about modifying a Multi-AZ DB cluster, see Modifying a Multi-AZ DB cluster.

You can rotate a master user password secret immediately with the RDS console, the AWS CLI, or the RDS API. The new password is always 28 characters long and contains at least one upper and lowercase character, one number, and one punctuation.

**Console**

To rotate a master user password secret using the RDS console, modify the Multi-AZ DB cluster and select **Rotate secret immediately** in **Settings**.

Follow the instructions for modifying a Multi-AZ DB cluster with the RDS console in Modifying a Multi-AZ DB cluster. You must choose Apply immediately on the confirmation page.
AWS CLI

To rotate a master user password secret using the AWS CLI, use the `modify-db-cluster` command and specify the `--rotate-master-user-password` option. You must specify the `--apply-immediately` option when you rotate the master password.

This example rotates a master user password secret.

Example

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster \
  --db-cluster-identifier mydbcluster \
  --rotate-master-user-password \
  --apply-immediately
```

For Windows:

```bash
aws rds modify-db-cluster ^
  --db-cluster-identifier mydbcluster ^
  --rotate-master-user-password ^
  --apply-immediately
```

RDS API

You can rotate a master user password secret using the `ModifyDBCluster` operation and setting the `RotateMasterUserPassword` parameter to `true`. You must set the `ApplyImmediately` parameter to `true` when you rotate the master password.

Viewing the details about a secret for a DB instance

You can retrieve your secrets using the console (https://console.aws.amazon.com/secretsmanager/) or the AWS CLI (`get-secret-value` Secrets Manager command).

You can find the Amazon Resource Name (ARN) of a secret managed by RDS in Secrets Manager with the RDS console, the AWS CLI, or the RDS API.
To view the details about a secret managed by RDS in Secrets Manager

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the name of the DB instance to show its details.
4. Choose the Configuration tab.

In Master Credentials ARN, you can view the secret ARN.
You can follow the Manage in Secrets Manager link to view and manage the secret in the Secrets Manager console.

**AWS CLI**

You can use the [describe-db-instances](https://docs.aws.amazon.com/cli/latest/reference/rds/describe-db-instances.html) RDS CLI command to find the following information about a secret managed by RDS in Secrets Manager:
• SecretArn – The ARN of the secret
• SecretStatus – The status of the secret

The possible status values include the following:
• creating – The secret is being created.
• active – The secret is available for normal use and rotation.
• rotating – The secret is being rotated.
• impaired – The secret can be used to access database credentials, but it can't be rotated.
   A secret might have this status if, for example, permissions are changed so that RDS can no longer access
   the secret or the KMS key for the secret.

When a secret has this status, you can correct the condition that caused the status. If you correct the
condition that caused status, the status remains impaired until the next rotation. Alternatively, you can
modify the DB instance to turn off automatic management of database credentials, and then modify the
DB instance again to turn on automatic management of database credentials. To modify the DB instance,
use the --manage-master-user-password option in the modify-db-instance command.
• KmsKeyId – The ARN of the KMS key that is used to encrypt the secret

Specify the --db-instance-identifier option to show output for a specific DB instance. This example
shows the output for a secret that is used by a DB instance.

Example

```bash
aws rds describe-db-instances --db-instance-identifier mydbinstance
```

Following is sample output for a secret:

```json
"MasterUserSecret": {
    "SecretArn": "arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!db-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx",
    "SecretStatus": "active",
    "KmsKeyId": "arn:aws:kms:eu-west-1:123456789012:key/0987dcb-09fe-87dc-65ba-ab0987654321"
}
```
When you have the secret ARN, you can view details about the secret using the `get-secret-value` Secrets Manager CLI command.

This example shows the details for the secret in the previous sample output.

**Example**

For Linux, macOS, or Unix:

```bash
aws secretsmanager get-secret-value \
   --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!db-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

For Windows:

```bash
aws secretsmanager get-secret-value ^
   --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!db-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

**RDS API**

You can view the ARN, status, and KMS key for a secret managed by RDS in Secrets Manager by using the `DescribeDBInstances` operation and setting the `DBInstanceIdentifier` parameter to a DB instance identifier. Details about the secret are included in the output.

When you have the secret ARN, you can view details about the secret using the `GetSecretValue` Secrets Manager operation.

**Viewing the details about a secret for a Multi-AZ DB cluster**

You can retrieve your secrets using the console ([https://console.aws.amazon.com/secretsmanager/](https://console.aws.amazon.com/secretsmanager/)) or the AWS CLI (`get-secret-value` Secrets Manager command).

You can find the Amazon Resource Name (ARN) of a secret managed by RDS in Secrets Manager with the RDS console, the AWS CLI, or the RDS API.

**Console**

**To view the details about a secret managed by RDS in Secrets Manager**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.

3. Choose the name of the Multi-AZ DB cluster to show its details.

4. Choose the **Configuration** tab.

In **Master Credentials ARN**, you can view the secret ARN.

![Image showing the configuration tab with Master Credentials ARN highlighted](image_url)

```
Cluster

```

- Viewing the details about a secret for a Multi-AZ DB cluster
You can follow the Manage in Secrets Manager link to view and manage the secret in the Secrets Manager console.

**AWS CLI**

You can use the RDS AWS CLI `describe-db-clusters` command to find the following information about a secret managed by RDS in Secrets Manager:

- **SecretArn** – The ARN of the secret
- **SecretStatus** – The status of the secret

The possible status values include the following:

- **creating** – The secret is being created.
- **active** – The secret is available for normal use and rotation.
- **rotating** – The secret is being rotated.
- **impaired** – The secret can be used to access database credentials, but it can't be rotated. A secret might have this status if, for example, permissions are changed so that RDS can no longer access the secret or the KMS key for the secret.

When a secret has this status, you can correct the condition that caused the status. If you correct the condition that caused status, the status remains impaired until the next rotation. Alternatively, you can modify the DB cluster to turn off automatic management of database credentials, and then modify the DB cluster again to turn on automatic management of database credentials. To modify the DB cluster, use the `--manage-master-user-password` option in the `modify-db-cluster` command.

- **KmsKeyId** – The ARN of the KMS key that is used to encrypt the secret

Specify the `--db-cluster-identifier` option to show output for a specific DB cluster. This example shows the output for a secret that is used by a DB cluster.

**Example**

```bash
aws rds describe-db-clusters --db-cluster-identifier mydbcluster
```

The following sample shows the output for a secret:
"MasterUserSecret": {
  "SecretArn": "arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx",
  "SecretStatus": "active",
  "KmsKeyId": "arn:aws:kms:eu-west-1:123456789012:key/0987dcba-09fe-87dc-65ba-ab0987654321"
}

When you have the secret ARN, you can view details about the secret using the `get-secret-value` Secrets Manager CLI command.

This example shows the details for the secret in the previous sample output.

**Example**

For Linux, macOS, or Unix:

```bash
aws secretsmanager get-secret-value \
  --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

For Windows:

```bash
aws secretsmanager get-secret-value ^
  --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

**RDS API**

You can view the ARN, status, and KMS key for a secret managed by RDS in Secrets Manager using the DescribeDBClusters RDS operation and setting the `DBClusterIdentifier` parameter to a DB cluster identifier. Details about the secret are included in the output.

When you have the secret ARN, you can view details about the secret using the `GetSecretValue` Secrets Manager operation.

**Region and version availability**

Feature availability and support varies across specific versions of each database engine and across AWS Regions. For more information about version and Region availability with Secrets Manager integration with Amazon RDS, see [Secrets Manager integration](https://docs.aws.amazon.com/secretsmanager/latest/userguide/).
Data protection in Amazon RDS

The AWS shared responsibility model applies to data protection in Amazon Relational Database Service. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see the AWS Shared Responsibility Model and GDPR blog post on the AWS Security Blog.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual users with AWS IAM Identity Center or AWS Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with AWS CloudTrail.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a Name field. This includes when you work with Amazon RDS or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Protecting data using encryption

You can enable encryption for database resources. You can also encrypt connections to DB instances.

Topics

- Encrypting Amazon RDS resources
- AWS KMS key management
- Using SSL/TLS to encrypt a connection to a DB instance or cluster
- Rotating your SSL/TLS certificate

Encrypting Amazon RDS resources

Amazon RDS can encrypt your Amazon RDS DB instances. Data that is encrypted at rest includes the underlying storage for DB instances, its automated backups, read replicas, and snapshots.

Amazon RDS encrypted DB instances use the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your Amazon RDS DB instances. After your data is encrypted, Amazon RDS handles authentication of access and decryption of your data transparently with a minimal impact on performance. You don't need to modify your database client applications to use encryption.

Note

For encrypted and unencrypted DB instances, data that is in transit between the source and the read replicas is encrypted, even when replicating across AWS Regions.

- Encrypting a DB instance
- Determining whether encryption is turned on for a DB instance
- Availability of Amazon RDS encryption
- Encryption in transit
- Limitations of Amazon RDS encrypted DB instances
Overview of encrypting Amazon RDS resources

Amazon RDS encrypted DB instances provide an additional layer of data protection by securing your data from unauthorized access to the underlying storage. You can use Amazon RDS encryption to increase data protection of your applications deployed in the cloud, and to fulfill compliance requirements for encryption at rest.

For an Amazon RDS encrypted DB instance, all logs, backups, and snapshots are encrypted. Amazon RDS uses an AWS KMS key to encrypt these resources. For more information about KMS keys, see AWS KMS keys in the AWS Key Management Service Developer Guide and AWS KMS key management. If you copy an encrypted snapshot, you can use a different KMS key to encrypt the target snapshot than the one that was used to encrypt the source snapshot.

A read replica of an Amazon RDS encrypted instance must be encrypted using the same KMS key as the primary DB instance when both are in the same AWS Region. If the primary DB instance and read replica are in different AWS Regions, you encrypt the read replica using the KMS key for that AWS Region.

You can use an AWS managed key, or you can create customer managed keys. To manage the customer managed keys used for encrypting and decrypting your Amazon RDS resources, you use the AWS Key Management Service (AWS KMS). AWS KMS combines secure, highly available hardware and software to provide a key management system scaled for the cloud. Using AWS KMS, you can create customer managed keys and define the policies that control how these customer managed keys can be used. AWS KMS supports CloudTrail, so you can audit KMS key usage to verify that customer managed keys are being used appropriately. You can use your customer managed keys with Amazon Aurora and supported AWS services such as Amazon S3, Amazon EBS, and Amazon Redshift. For a list of services that are integrated with AWS KMS, see AWS Service Integration.

Amazon RDS also supports encrypting an Oracle or SQL Server DB instance with Transparent Data Encryption (TDE). TDE can be used with RDS encryption at rest, although using TDE and RDS encryption at rest simultaneously might slightly affect the performance of your database. You must manage different keys for each encryption method. For more information on TDE, see Oracle Transparent Data Encryption or Support for Transparent Data Encryption in SQL Server.

Encrypting a DB instance

To encrypt a new DB instance, choose Enable encryption on the Amazon RDS console. For information on creating a DB instance, see Creating an Amazon RDS DB instance.
If you use the `create-db-instance` AWS CLI command to create an encrypted DB instance, set the `--storage-encrypted` parameter. If you use the `CreateDBInstance` API operation, set the `StorageEncrypted` parameter to true.

When you create an encrypted DB instance, you can choose a customer managed key or the AWS managed key for Amazon RDS to encrypt your DB instance. If you don't specify the key identifier for a customer managed key, Amazon RDS uses the AWS managed key for your new DB instance. Amazon RDS creates an AWS managed key for Amazon RDS for your AWS account. Your AWS account has a different AWS managed key for Amazon RDS for each AWS Region.

For more information about KMS keys, see [AWS KMS keys](https://docs.aws.amazon.com/kms/latest/developerguide/) in the *AWS Key Management Service Developer Guide*.

Once you have created an encrypted DB instance, you can't change the KMS key used by that DB instance. Therefore, be sure to determine your KMS key requirements before you create your encrypted DB instance.

If you use the AWS CLI `create-db-instance` command to create an encrypted DB instance with a customer managed key, set the `--kms-key-id` parameter to any key identifier for the KMS key. If you use the Amazon RDS API `CreateDBInstance` operation, set the `KmsKeyId` parameter to any key identifier for the KMS key. To use a customer managed key in a different AWS account, specify the key ARN or alias ARN.

⚠️ **Important**

Amazon RDS can lose access to the KMS key for a DB instance. For example, RDS loses access when the KMS key isn't enabled, or when RDS access to a KMS key is revoked. In these cases, the encrypted DB instance goes into `inaccessible-encryption-credentials-recoverable` state. The DB instance remains in this state for seven days. When you start the DB instance during that time, it checks if the KMS key is active and recovers the DB instance if it is. Restart the DB instance using the AWS CLI command `start-db-instance` or AWS Management Console.

If the DB instance isn't recovered, then it goes into the terminal `inaccessible-encryption-credentials` state. In this case, you can only restore the DB instance from a backup. We strongly recommend that you always turn on backups for encrypted DB instances to guard against the loss of encrypted data in your databases.
Determining whether encryption is turned on for a DB instance

You can use the AWS Management Console, AWS CLI, or RDS API to determine whether encryption at rest is turned on for a DB instance.

Console

To determine whether encryption at rest is turned on for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the name of the DB instance that you want to check to view its details.
4. Choose the Configuration tab, and check the Encryption value under Storage.

It shows either Enabled or Not enabled.

AWS CLI

To determine whether encryption at rest is turned on for a DB instance by using the AWS CLI, call the describe-db-instances command with the following option:
• --db-instance-identifier – The name of the DB instance.

The following example uses a query to return either TRUE or FALSE regarding encryption at rest for the mydb DB instance.

Example

```bash
aws rds describe-db-instances --db-instance-identifier mydb --query "*[].{StorageEncrypted:StorageEncrypted}" --output text
```

RDS API

To determine whether encryption at rest is turned on for a DB instance by using the Amazon RDS API, call the `DescribeDBInstances` operation with the following parameter:

• `DBInstanceIdentifier` – The name of the DB instance.

Availability of Amazon RDS encryption

Amazon RDS encryption is currently available for all database engines and storage types, except for SQL Server Express Edition.

Amazon RDS encryption is available for most DB instance classes. The following table lists DB instance classes that *don't support* Amazon RDS encryption:

<table>
<thead>
<tr>
<th>Instance type</th>
<th>Instance class</th>
</tr>
</thead>
<tbody>
<tr>
<td>General purpose (M1)</td>
<td>db.m1.small</td>
</tr>
<tr>
<td></td>
<td>db.m1.medium</td>
</tr>
<tr>
<td></td>
<td>db.m1.large</td>
</tr>
<tr>
<td></td>
<td>db.m1.xlarge</td>
</tr>
<tr>
<td>Memory optimized (M2)</td>
<td>db.m2.xlarge</td>
</tr>
<tr>
<td></td>
<td>db.m2.2xlarge</td>
</tr>
<tr>
<td></td>
<td>db.m2.4xlarge</td>
</tr>
</tbody>
</table>
Encryption in transit

AWS provides secure and private connectivity between DB instances of all types. In addition, some instance types use the offload capabilities of the underlying Nitro System hardware to automatically encrypt in-transit traffic between instances. This encryption uses Authenticated Encryption with Associated Data (AEAD) algorithms, with 256-bit encryption. There is no impact on network performance. To support this additional in-transit traffic encryption between instances, the following requirements must be met:

- The instances use the following instance types:
  - **General purpose**: M6i, M6id, M6in, M6idn, M7g
  - **Memory optimized**: R6i, R6id, R6in, R6idn, R7g, X2idn, X2iedn, X2iez
- The instances are in the same AWS Region.
- The instances are in the same VPC or peered VPCs, and the traffic does not pass through a virtual network device or service, such as a load balancer or a transit gateway.

Limitations of Amazon RDS encrypted DB instances

The following limitations exist for Amazon RDS encrypted DB instances:

- You can only encrypt an Amazon RDS DB instance when you create it, not after the DB instance is created.

  However, because you can encrypt a copy of an unencrypted snapshot, you can effectively add encryption to an unencrypted DB instance. That is, you can create a snapshot of your DB instance, and then create an encrypted copy of that snapshot. You can then restore a DB instance from the encrypted snapshot, and thus you have an encrypted copy of your original DB instance. For more information, see Copying a DB snapshot.

- You can't turn off encryption on an encrypted DB instance.
- You can't create an encrypted snapshot of an unencrypted DB instance.
- A snapshot of an encrypted DB instance must be encrypted using the same KMS key as the DB instance.
• You can't have an encrypted read replica of an unencrypted DB instance or an unencrypted read replica of an encrypted DB instance.

• Encrypted read replicas must be encrypted with the same KMS key as the source DB instance when both are in the same AWS Region.

• You can't restore an unencrypted backup or snapshot to an encrypted DB instance.

• To copy an encrypted snapshot from one AWS Region to another, you must specify the KMS key in the destination AWS Region. This is because KMS keys are specific to the AWS Region that they are created in.

The source snapshot remains encrypted throughout the copy process. Amazon RDS uses envelope encryption to protect data during the copy process. For more information about envelope encryption, see Envelope encryption in the AWS Key Management Service Developer Guide.

• You can't unencrypt an encrypted DB instance. However, you can export data from an encrypted DB instance and import the data into an unencrypted DB instance.

**AWS KMS key management**

Amazon RDS automatically integrates with AWS Key Management Service (AWS KMS) for key management. Amazon RDS uses envelope encryption. For more information about envelope encryption, see Envelope encryption in the AWS Key Management Service Developer Guide.

You can use two types of AWS KMS keys to encrypt your DB instances.

• If you want full control over a KMS key, you must create a customer managed key. For more information about customer managed keys, see Customer managed keys in the AWS Key Management Service Developer Guide.

You can't share a snapshot that has been encrypted using the AWS managed key of the AWS account that shared the snapshot.

• AWS managed keys are KMS keys in your account that are created, managed, and used on your behalf by an AWS service that is integrated with AWS KMS. By default, the RDS AWS managed key (aws/rds) is used for encryption. You can't manage, rotate, or delete the RDS AWS managed key. For more information about AWS managed keys, see AWS managed keys in the AWS Key Management Service Developer Guide.
To manage KMS keys used for Amazon RDS encrypted DB instances, use the [AWS Key Management Service (AWS KMS)](https://aws.amazon.com/kms/) in the [AWS KMS console](https://console.aws.amazon.com/kms), the AWS CLI, or the AWS KMS API. To view audit logs of every action taken with an AWS managed or customer managed key, use [AWS CloudTrail](https://aws.amazon.com/cloudtrail/). For more information about key rotation, see [Rotating AWS KMS keys](https).

⚠️ **Important**

If you turn off or revoke permissions to a KMS key used by an RDS database, RDS puts your database into a terminal state when access to the KMS key is required. This change could be immediate, or deferred, depending on the use case that required access to the KMS key. In this state, the DB instance is no longer available, and the current state of the database can't be recovered. To restore the DB instance, you must re-enable access to the KMS key for RDS, and then restore the DB instance from the latest available backup.

**Authorizing use of a customer managed key**

When RDS uses a customer managed key in cryptographic operations, it acts on behalf of the user who is creating or changing the RDS resource.

To create an RDS resource using a customer managed key, a user must have permissions to call the following operations on the customer managed key:

- `kms:CreateGrant`
- `kms:DescribeKey`

You can specify these required permissions in a key policy, or in an IAM policy if the key policy allows it.

You can make the IAM policy stricter in various ways. For example, if you want to allow the customer managed key to be used only for requests that originate in RDS, you can use the `kms:ViaService condition key` with the `rds.<region>.amazonaws.com` value. Also, you can use the keys or values in the [Amazon RDS encryption context](https://docs.aws.amazon.com/rds/latest/userguide/rds-data-key.html) as a condition for using the customer managed key for encryption.

For more information, see [Allowing users in other accounts to use a KMS key](https://docs.aws.amazon.com/kms/latest/userguide/how-to-share-kms-keys.html) in the [AWS Key Management Service Developer Guide](https://docs.aws.amazon.com/kms/latest/userguide/) and [Key policies in AWS KMS](https://docs.aws.amazon.com/kms/latest/userguide/key-policies.html).
Amazon RDS encryption context

When RDS uses your KMS key, or when Amazon EBS uses the KMS key on behalf of RDS, the service specifies an encryption context. The encryption context is additional authenticated data (AAD) that AWS KMS uses to ensure data integrity. When an encryption context is specified for an encryption operation, the service must specify the same encryption context for the decryption operation. Otherwise, decryption fails. The encryption context is also written to your AWS CloudTrail logs to help you understand why a given KMS key was used. Your CloudTrail logs might contain many entries describing the use of a KMS key, but the encryption context in each log entry can help you determine the reason for that particular use.

At minimum, Amazon RDS always uses the DB instance ID for the encryption context, as in the following JSON-formatted example:

```json
{ "aws:rds:db-id": "db-CQYSMDPBRZ7BPMH7Y3RTDG5QY" }
```

This encryption context can help you identify the DB instance for which your KMS key was used.

When your KMS key is used for a specific DB instance and a specific Amazon EBS volume, both the DB instance ID and the Amazon EBS volume ID are used for the encryption context, as in the following JSON-formatted example:

```json
{
    "aws:rds:db-id": "db-BRG7VYS3SVIFQW7234EJQ0M5RQ",
    "aws:ebs:id": "vol-ad8c6542"
}
```

Using SSL/TLS to encrypt a connection to a DB instance or cluster

You can use Secure Socket Layer (SSL) or Transport Layer Security (TLS) from your application to encrypt a connection to a database running MariaDB, Microsoft SQL Server, MySQL, Oracle, or PostgreSQL.

SSL/TLS connections provide a layer of security by encrypting data that moves between your client and DB instance or cluster. Optionally, your SSL/TLS connection can perform server identity verification by validating the server certificate installed on your database. To require server identity verification, follow this general process:

1. Choose the certificate authority (CA) that signs the DB server certificate, for your database. For more information about certificate authorities, see Certificate authorities.
2. Download a certificate bundle to use when you are connecting to the database. To download a certificate bundle, see Certificate bundles for all AWS Regions and Certificate bundles for specific AWS Regions.

   **Note**
   
   All certificates are only available for download using SSL/TLS connections.

3. Connect to the database using your DB engine's process for implementing SSL/TLS connections. Each DB engine has its own process for implementing SSL/TLS. To learn how to implement SSL/TLS for your database, follow the link that corresponds to your DB engine:
   - [Using SSL/TLS with an RDS for Db2 DB instance](#)
   - [Using SSL/TLS with a MariaDB DB instance](#)
   - [Using SSL with a Microsoft SQL Server DB instance](#)
   - [Using SSL/TLS with a MySQL DB instance](#)
   - [Using SSL with an RDS for Oracle DB instance](#)
   - [Using SSL with a PostgreSQL DB instance](#)

**Certificate authorities**

The **certificate authority (CA)** is the certificate that identifies the root CA at the top of the certificate chain. The CA signs the **DB server certificate**, which is installed on each DB instance. The DB server certificate identifies the DB instance as a trusted server.
Amazon RDS provides the following CAs to sign the DB server certificate for a database.

<table>
<thead>
<tr>
<th>Certificate authority (CA)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rds-ca-2019</td>
<td>Uses a certificate authority with RSA 2048 private key algorithm and SHA256 signing algorithm. This CA expires in 2024 and doesn't support automatic server certificate rotation. If you are using this CA and want to keep the same standard, we recommend that you switch to the rds-ca-rsa2048-g1 CA.</td>
</tr>
<tr>
<td>rds-ca-rsa2048-g1</td>
<td>Uses a certificate authority with RSA 2048 private key algorithm and SHA256 signing algorithm in most AWS Regions. In the AWS GovCloud (US) Regions, this CA uses a certificate authority with RSA 2048 private key algorithm and SHA384 signing algorithm.</td>
</tr>
</tbody>
</table>
Certificate authority (CA) | Description
--- | ---
 | This CA remains valid for longer than the rds-ca-2019 CA. This CA supports automatic server certificate rotation.
rds-ca-rsa4096-g1 | Uses a certificate authority with RSA 4096 private key algorithm and SHA384 signing algorithm. This CA supports automatic server certificate rotation.
rds-ca-ecc384-g1 | Uses a certificate authority with ECC 384 private key algorithm and SHA384 signing algorithm. This CA supports automatic server certificate rotation.

**Note**

If you are using the AWS CLI, you can see the validities of the certificate authorities listed above by using *describe-certificates*.

These CA certificates are included in the regional and global certificate bundle. When you use the rds-ca-rsa2048-g1, rds-ca-rsa4096-g1, or rds-ca-ecc384-g1 CA with a database, RDS manages the DB server certificate on the database. RDS rotates the DB server certificate automatically before it expires.

**Setting the CA for your database**

You can set the CA for a database when you perform the following tasks:

- **Create a DB instance or Multi-AZ DB cluster** – You can set the CA when you create a DB instance or cluster. For instructions, see the section called “Creating a DB instance” or the section called “Creating a Multi-AZ DB cluster”.

- **Modify a DB instance or Multi-AZ DB cluster** – You can set the CA for a DB instance or cluster by modifying it. For instructions, see the section called “Modifying a DB instance” or the section called “Modifying a Multi-AZ DB cluster”.
Note

The default CA is set to rds-ca-rsa2048-g1. You can override the default CA for your AWS account by using the `modify-certificates` command.

The available CAs depend on the DB engine and DB engine version. When you use the AWS Management Console, you can choose the CA using the **Certificate authority** setting, as shown in the following image.

The console only shows the CAs that are available for the DB engine and DB engine version. If you're using the AWS CLI, you can set the CA for a DB instance using the `create-db-instance` or `modify-db-instance` command. You can set the CA for a Multi-AZ DB cluster using the `create-db-cluster` or `modify-db-cluster` command.

If you're using the AWS CLI, you can see the available CAs for your account by using the `describe-certificates` command. This command also shows the expiration date for each CA in `ValidTill` in the output. You can find the CAs that are available for a specific DB engine and DB engine version using the `describe-db-engine-versions` command.

The following example shows the CAs available for the default RDS for PostgreSQL DB engine version.

```bash
aws rds describe-db-engine-versions --default-only --engine postgres
```

Your output is similar to the following. The available CAs are listed in `SupportedCACertificateIdentifiers`. The output also shows whether the DB engine version supports rotating the certificate without restart in `SupportsCertificateRotationWithoutRestart`.

```
{

```
"DBEngineVersions": [  
  
  
  "DBParameterGroupFamily": "postgres13",
  "DBEngineDescription": "PostgreSQL",
  "DBEngineVersionDescription": "PostgreSQL 13.4-R1",
  "ValidUpgradeTarget": [],
  "SupportsLogExportsToCloudwatchLogs": false,
  "SupportsRead Replica": true,
  "SupportedFeatureNames": [     "Lambda"
  ],
  "Status": "available",
  "SupportsParallelQuery": false,
  "SupportsGlobal Databases": false,
  "Supports Babelfish": false,
  "SupportsCertificateRotation Without Restart": true,
  "SupportedCACertificateIdentifiers": [     "rds-ca-2019",
    "rds-ca-rsa2048-g1",
    "rds-ca-ecc384-g1",
    "rds-ca-rsa4096-g1"
  ]
  
  ]
  ]
]

DB server certificate validities

The validity of DB server certificate depends on the DB engine and DB engine version. If the DB engine version supports rotating the certificate without restart, the validity of the DB server certificate is 1 year. Otherwise the validity is 3 years.

For more information about DB server certificate rotation, see [Automatic server certificate rotation](#).

Viewing the CA for your DB instance

You can view the details about the CA for a database by viewing the [Connectivity & security](#) tab in the console, as in the following image.
If you're using the AWS CLI, you can view the details about the CA for a DB instance by using the `describe-db-instances` command. You can view the details about the CA for a Multi-AZ DB cluster by using the `describe-db-clusters` command.

To check the contents of your CA certificate bundle, use the following command:

```
keytool -printcert -v -file global-bundle.pem
```

### Certificate bundles for all AWS Regions

If your application is on Microsoft Windows and requires a PKCS7 file, you can download the PKCS7 certificate bundle. This bundle contains both the intermediate and root certificates at [https://truststore.pki.rds.amazonaws.com/global/global-bundle.p7b](https://truststore.pki.rds.amazonaws.com/global/global-bundle.p7b).

### Note

Amazon RDS Proxy uses certificates from the AWS Certificate Manager (ACM). If you're using RDS Proxy, you don't need to download Amazon RDS certificates or update applications that use RDS Proxy connections. For more information, see [Using TLS/SSL with RDS Proxy](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/Connecting.Client.TLS.SSL.Production.html).
## Certificate bundles for specific AWS Regions

To get a certificate bundle that contains both the intermediate and root certificates for an AWS Region, download it from the link for the AWS Region in the following table.

<table>
<thead>
<tr>
<th>AWS Region</th>
<th>Certificate bundle (PEM)</th>
<th>Certificate bundle (PKCS7)</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1-bundle.pem</td>
<td>us-east-1-bundle.p7b</td>
</tr>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2-bundle.pem</td>
<td>us-east-2-bundle.p7b</td>
</tr>
<tr>
<td>US West (N. California)</td>
<td>us-west-1-bundle.pem</td>
<td>us-west-1-bundle.p7b</td>
</tr>
<tr>
<td>US West (Oregon)</td>

**AWS GovCloud (US) certificates**

If your application is on Microsoft Windows and requires a PKCS7 file, you can download the PKCS7 certificate bundle. This bundle contains both the intermediate and root certificates at [https://truststore.pki.us-gov-west-1.rds.amazonaws.com/global/global-bundle.p7b](https://truststore.pki.us-gov-west-1.rds.amazonaws.com/global/global-bundle.p7b).

To get a certificate bundle that contains both the intermediate and root certificates for an AWS GovCloud (US) Region, download from the link for the AWS GovCloud (US) Region in the following table.
<table>
<thead>
<tr>
<th>AWS GovCloud (US) Region</th>
<th>Certificate bundle (PEM)</th>
<th>Certificate bundle (PKCS7)</th>
</tr>
</thead>
</table>

**Rotating your SSL/TLS certificate**

Amazon RDS Certificate Authority certificates rds-ca-2019 are set to expire in August, 2024. If you use or plan to use Secure Sockets Layer (SSL) or Transport Layer Security (TLS) with certificate verification to connect to your RDS DB instances or Multi-AZ DB clusters, consider using one of the new CA certificates rds-ca-rsa2048-g1, rds-ca-rsa4096-g1 or rds-ca-ecc384-g1. If you currently do not use SSL/TLS with certificate verification, you might still have an expired CA certificate and must update them to a new CA certificate if you plan to use SSL/TLS with certificate verification to connect to your RDS databases.

Follow these instructions to complete your updates. Before you update your DB instances or Multi-AZ DB clusters to use the new CA certificate, make sure that you update your clients or applications connecting to your RDS databases.

Amazon RDS provides new CA certificates as an AWS security best practice. For information about the new certificates and the supported AWS Regions, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#).

---

**Note**

Amazon RDS Proxy uses certificates from the AWS Certificate Manager (ACM). If you're using RDS Proxy, when you rotate your SSL/TLS certificate, you don't need to update applications that use RDS Proxy connections. For more information, see [Using TLS/SSL with RDS Proxy](#).

---

**Note**

If you're using a Go version 1.15 application with a DB instance or Multi-AZ DB cluster that was created or updated to the rds-ca-2019 certificate prior to July 28, 2020, you must update the certificate again. Update the certificate to rds-ca-rsa2048-g1, rds-ca-rsa4096-
g1, or rds-ca-ecc384-g1 depending on your engine. Run the modify-db-instance command for a DB instance, or the modify-db-cluster command for a Multi-AZ DB cluster, using the new CA certificate identifier. You can find the CAs that are available for a specific DB engine and DB engine version using the describe-db-engine-versions command.

If you created your database or updated its certificate after July 28, 2020, no action is required. For more information, see Go GitHub issue #39568.

Topics

- Updating your CA certificate by modifying your DB instance or cluster
- Updating your CA certificate by applying maintenance
- Automatic server certificate rotation
- Sample script for importing certificates into your trust store

Updating your CA certificate by modifying your DB instance or cluster

The following example updates your CA certificate from rds-ca-2019 to rds-ca-rsa2048-g1. You can choose a different certificate. For more information, see Certificate authorities.

To update your CA certificate by modifying your DB instance or cluster

1. Download the new SSL/TLS certificate as described in Using SSL/TLS to encrypt a connection to a DB instance or cluster.
2. Update your applications to use the new SSL/TLS certificate.

The methods for updating applications for new SSL/TLS certificates depend on your specific applications. Work with your application developers to update the SSL/TLS certificates for your applications.

For information about checking for SSL/TLS connections and updating applications for each DB engine, see the following topics:

- Updating applications to connect to MariaDB instances using new SSL/TLS certificates
- Updating applications to connect to Microsoft SQL Server DB instances using new SSL/TLS certificates
- Updating applications to connect to MySQL DB instances using new SSL/TLS certificates
• Updating applications to connect to Oracle DB instances using new SSL/TLS certificates

• Updating applications to connect to PostgreSQL DB instances using new SSL/TLS certificates

For a sample script that updates a trust store for a Linux operating system, see Sample script for importing certificates into your trust store.

Note

The certificate bundle contains certificates for both the old and new CA, so you can upgrade your application safely and maintain connectivity during the transition period. If you are using the AWS Database Migration Service to migrate a database to a DB instance or cluster, we recommend using the certificate bundle to ensure connectivity during the migration.

3. Modify the DB instance or Multi-AZ DB cluster to change the CA from rds-ca-2019 to rds-ca-rsa2048-g1. To check if your database requires a restart to update the CA certificates, use the describe-db-engine-versions command and check the SupportsCertificateRotationWithoutRestart flag.

Important

If you are experiencing connectivity issues after certificate expiry, use the apply immediately option by specifying Apply immediately in the console or by specifying the --apply-immediately option using the AWS CLI. By default, this operation is scheduled to run during your next maintenance window.

To set an override for your instance CA that’s different from the default RDS CA, use the modify-certificates CLI command.

You can use the AWS Management Console or the AWS CLI to change the CA certificate from rds-ca-2019 to rds-ca-rsa2048-g1 for a DB instance or Multi-AZ DB cluster.

Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance or Multi-AZ DB cluster that you want to modify.

3. Choose Modify.

![Modify button in the RDS management console]

4. In the Connectivity section, choose rds-ca-rsa2048-g1.

![Certificate authority list]

5. Choose Continue and check the summary of modifications.

6. To apply the changes immediately, choose Apply immediately.

7. On the confirmation page, review your changes. If they are correct, choose Modify DB Instance or Modify cluster to save your changes.

⚠️ Important

When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

Or choose Back to edit your changes or Cancel to cancel your changes.
AWS CLI

To use the AWS CLI to change the CA from `rds-ca-2019` to `rds-ca-rsa2048-g1` for a DB instance or Multi-AZ DB cluster, call the `modify-db-instance` or `modify-db-cluster` command. Specify the DB instance or cluster identifier and the `--ca-certificate-identifier` option.

Use the `--apply-immediately` parameter to apply the update immediately. By default, this operation is scheduled to run during your next maintenance window.

⚠️ Important

When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

Example

DB instance

The following example modifies `mydbinstance` by setting the CA certificate to `rds-ca-rsa2048-g1`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --ca-certificate-identifier rds-ca-rsa2048-g1
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --ca-certificate-identifier rds-ca-rsa2048-g1
```

⚠️ Note

If your instance requires reboot, you can use the `modify-db-instance` CLI command and specify the `--no-certificate-rotation-restart` option.
Example

Multi-AZ DB cluster

The following example modifies mydbcluster by setting the CA certificate to rds-ca-rsa2048-g1.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster \
   --db-cluster-identifier mydbcluster \
   --ca-certificate-identifier rds-ca-rsa2048-g1
```

For Windows:

```bash
aws rds modify-db-cluster ^
   --db-cluster-identifier mydbcluster ^
   --ca-certificate-identifier rds-ca-rsa2048-g1
```

Updating your CA certificate by applying maintenance

Perform the following steps to update your CA certificate by applying maintenance.

To update your CA certificate by applying maintenance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Certificate update.
The **Databases requiring certificate update** page appears.

<table>
<thead>
<tr>
<th>Database</th>
<th>Status</th>
<th>CA Authority</th>
<th>CA Expiration Date</th>
<th>Role</th>
<th>Restart Required</th>
<th>Scheduled Changes</th>
<th>Maintenance</th>
</tr>
</thead>
<tbody>
<tr>
<td>database-1</td>
<td>Available</td>
<td>rds-ca-2019</td>
<td>June 30, 2024, 10:26 (UTC-07:00)</td>
<td>Instance</td>
<td>No</td>
<td>No</td>
<td>March 03</td>
</tr>
<tr>
<td>database-2</td>
<td>Available</td>
<td>rds-ca-2019</td>
<td>June 30, 2024, 10:26 (UTC-07:00)</td>
<td>Multi-AZ DB cluster</td>
<td>No</td>
<td>No</td>
<td>March 07</td>
</tr>
</tbody>
</table>
3. Choose the DB instance or Multi-AZ DB cluster that you want to update.

You can schedule the certificate rotation for your next maintenance window by choosing Schedule. Apply the rotation immediately by choosing Apply now.

4. a. If you choose Schedule, you are prompted to confirm the CA certificate rotation. This prompt also states the scheduled window for your update.
b. If you choose Apply now, you are prompted to confirm the CA certificate rotation.
Before scheduling the CA certificate rotation on your database, update any client applications that use SSL/TLS and the server certificate to connect. These updates are specific to your DB engine. After you have updated these client applications, you can confirm the CA certificate rotation.

To continue, choose the check box, and then choose **Confirm**.

5. Repeat steps 3 and 4 for each DB instance and cluster that you want to update.
Automatic server certificate rotation

If your CA supports automatic server certificate rotation, RDS automatically handles the rotation of the DB server certificate. RDS uses the same root CA for this automatic rotation, so you don't need to download a new CA bundle. See Certificate authorities.

The rotation and validity of your DB server certificate depend on your DB engine:

- If your DB engine supports rotation without restart, RDS automatically rotates the DB server certificate without requiring any action from you. RDS attempts to rotate your DB server certificate in your preferred maintenance window at the DB server certificate half life. The new DB server certificate is valid for 12 months.
- If your DB engine doesn't support rotation without restart, RDS notifies you about a maintenance event at least 6 months before the DB server certificate expires. The new DB server certificate is valid for 36 months.

Use the describe-db-engine-versions command and inspect the SupportsCertificateRotationWithoutRestart flag to identify whether the DB engine version supports rotating the certificate without restart. For more information, see Setting the CA for your database.

Sample script for importing certificates into your trust store

The following are sample shell scripts that import the certificate bundle into a trust store.

Each sample shell script uses keytool, which is part of the Java Development Kit (JDK). For information about installing the JDK, see JDK Installation Guide.

Topics

- Sample script for importing certificates on Linux
- Sample script for importing certificates on macOS

Sample script for importing certificates on Linux

The following is a sample shell script that imports the certificate bundle into a trust store on a Linux operating system.

```bash
mydir=tmp/certs
```
if [ ! -e "${mydir}" ]
then
    mkdir -p "${mydir}"
fi

truststore=${mydir}/rds-truststore.jks
storepassword=changeit

awk 'split_after == 1 {n++;split_after=0} /-----END CERTIFICATE-----/ {split_after=1}
{print > "rds-ca-" n+1 " .pem"}' < ${mydir}/global-bundle.pem
for CERT in rds-ca-*; do
    alias=$(openssl x509 -noout -text -in $CERT | perl -ne 'next unless /Subject:/;
s/.*(CN|=CN = )//; print')
    echo "Importing $alias"
    keytool -import -file ${CERT} -alias "$alias" -storepass ${storepassword} -keystore ${truststore} -noprompt
    rm $CERT
done

rm ${mydir}/global-bundle.pem

echo "Trust store content is:"
keytool -list -v -keystore "$truststore" -storepass ${storepassword} | grep Alias | cut -d " " -f3- | while read alias
do
    expiry=`keytool -list -v -keystore "$truststore" -storepass ${storepassword} -alias "$alias" | grep Valid | perl -ne 'if(/until: (.*?)\n/) { print "$1\n"; }'`
    echo " Certificate $alias expires in '$expiry'
done

Sample script for importing certificates on macOS

The following is a sample shell script that imports the certificate bundle into a trust store on macOS.

mydir=tmp/certs
if [ ! -e "${mydir}" ]
then
mkdir -p "${mydir}"
fi

truststore=${mydir}/rds-truststore.jks
storepassword=changeit
split -p "-----BEGIN CERTIFICATE-----" ${mydir}/global-bundle.pem rds-ca-
for CERT in rds-ca-*; do
  alias=$(openssl x509 -noout -text -in $CERT | perl -ne 'next unless /Subject:/; s/.*(CN=|CN = )//; print')
  echo "Importing $alias"
  keytool -import -file $CERT -alias "$alias" -storepass $storepassword -keystore $truststore -noprompt
  rm $CERT
done
rm ${mydir}/global-bundle.pem
echo "Trust store content is: "
keytool -list -v -keystore "$truststore" -storepass $storepassword | grep Alias | cut -d " " -f3- | while read alias
do
  expiry=`keytool -list -v -keystore "$truststore" -storepass $storepassword -alias "$alias" | grep Valid | perl -ne 'if(/until: (.*)\n/) { print "$1\n"; }'`
  echo " Certificate $alias expires in "$expiry"
done

**Internetwork traffic privacy**

Connections are protected both between Amazon RDS and on-premises applications and between Amazon RDS and other AWS resources within the same AWS Region.

**Traffic between service and on-premises clients and applications**

You have two connectivity options between your private network and AWS:

- An AWS Site-to-Site VPN connection. For more information, see [What is AWS Site-to-Site VPN?](#)
• An AWS Direct Connect connection. For more information, see What is AWS Direct Connect?

You get access to Amazon RDS through the network by using AWS-published API operations. Clients must support the following:

• Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.

• Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.
Identity and access management for Amazon RDS

AWS Identity and Access Management ( IAM ) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be authenticated ( signed in ) and authorized ( have permissions ) to use Amazon RDS resources. IAM is an AWS service that you can use with no additional charge.

Topics
- Audience
- Authenticating with identities
- Managing access using policies
- How Amazon RDS works with IAM
- Identity-based policy examples for Amazon RDS
- AWS managed policies for Amazon RDS
- Amazon RDS updates to AWS managed policies
- Preventing cross-service confused deputy problems
- IAM database authentication for MariaDB, MySQL, and PostgreSQL
- Troubleshooting Amazon RDS identity and access

Audience

How you use AWS Identity and Access Management ( IAM ) differs, depending on the work you do in Amazon RDS.

Service user – If you use the Amazon RDS service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more Amazon RDS features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in Amazon RDS, see Troubleshooting Amazon RDS identity and access.

Service administrator – If you’re in charge of Amazon RDS resources at your company, you probably have full access to Amazon RDS. It’s your job to determine which Amazon RDS features and resources your employees should access. You must then submit requests to your administrator to change the permissions of your service users. Review the information on this page to understand
the basic concepts of IAM. To learn more about how your company can use IAM with Amazon RDS, see How Amazon RDS works with IAM.

Administrator – If you're an administrator, you might want to learn details about how you can write policies to manage access to Amazon RDS. To view example Amazon RDS identity-based policies that you can use in IAM, see Identity-based policy examples for Amazon RDS.

Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. You must be authenticated (signed in to AWS) as the AWS account root user, as an IAM user, or by assuming an IAM role.

You can sign in to AWS as a federated identity by using credentials provided through an identity source. AWS IAM Identity Center (IAM Identity Center) users, your company's single sign-on authentication, and your Google or Facebook credentials are examples of federated identities. When you sign in as a federated identity, your administrator previously set up identity federation using IAM roles. When you access AWS by using federation, you are indirectly assuming a role.

Depending on the type of user you are, you can sign in to the AWS Management Console or the AWS access portal. For more information about signing in to AWS, see How to sign in to your AWS account in the AWS Sign-In User Guide.

If you access AWS programmatically, AWS provides a software development kit (SDK) and a command line interface (CLI) to cryptographically sign your requests by using your credentials. If you don't use AWS tools, you must sign requests yourself. For more information about using the recommended method to sign requests yourself, see Signing AWS API requests in the IAM User Guide.

Regardless of the authentication method that you use, you might be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see Multi-factor authentication in the AWS IAM Identity Center User Guide and Using multi-factor authentication (MFA) in AWS in the IAM User Guide.

AWS account root user

When you create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account root user and is accessed by signing in with the email address and password that you used to create the account.
We strongly recommend that you don't use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see Tasks that require root user credentials in the IAM User Guide.

**Federated identity**

As a best practice, require human users, including users that require administrator access, to use federation with an identity provider to access AWS services by using temporary credentials.

A federated identity is a user from your enterprise user directory, a web identity provider, the AWS Directory Service, the Identity Center directory, or any user that accesses AWS services by using credentials provided through an identity source. When federated identities access AWS accounts, they assume roles, and the roles provide temporary credentials.

For centralized access management, we recommend that you use AWS IAM Identity Center. You can create users and groups in IAM Identity Center, or you can connect and synchronize to a set of users and groups in your own identity source for use across all your AWS accounts and applications. For information about IAM Identity Center, see What is IAM Identity Center? in the AWS IAM Identity Center User Guide.

**IAM users and groups**

An IAM user is an identity within your AWS account that has specific permissions for a single person or application. Where possible, we recommend relying on temporary credentials instead of creating IAM users who have long-term credentials such as passwords and access keys. However, if you have specific use cases that require long-term credentials with IAM users, we recommend that you rotate access keys. For more information, see Rotate access keys regularly for use cases that require long-term credentials in the IAM User Guide.

An IAM group is an identity that specifies a collection of IAM users. You can't sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named IAMAdmins and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see When to create an IAM user (instead of a role) in the IAM User Guide.
You can authenticate to your DB instance using IAM database authentication.

IAM database authentication works with the following DB engines:

- RDS for MariaDB
- RDS for MySQL
- RDS for PostgreSQL

For more information about authenticating to your DB instance using IAM, see IAM database authentication for MariaDB, MySQL, and PostgreSQL.

IAM roles

An IAM role is an identity within your AWS account that has specific permissions. It is similar to a user, but is not associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by switching roles. You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see Using IAM roles in the IAM User Guide.

IAM roles with temporary credentials are useful in the following situations:

- **Temporary user permissions** – A user can assume an IAM role to temporarily take on different permissions for a specific task.

- **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see Creating a role for a third-party Identity Provider in the IAM User Guide. If you use IAM Identity Center, you configure a permission set. To control what your identities can access after they authenticate, IAM Identity Center correlates the permission set to a role in IAM. For information about permissions sets, see Permission sets in the AWS IAM Identity Center User Guide.

- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.
• **Cross-service access** – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.

• **Principal permissions** – When you use an IAM user or role to perform actions in AWS, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other AWS services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see [Forward access sessions](#).

• **Service role** – A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see [Creating a role to delegate permissions to an AWS service](#) in the IAM User Guide.

• **Service-linked role** – A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

• **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see [Using an IAM role to grant permissions to applications running on Amazon EC2 instances](#) in the IAM User Guide.

To learn whether to use IAM roles, see [When to create an IAM role (instead of a user)](#) in the IAM User Guide.

**Managing access using policies**

You control access in AWS by creating policies and attaching them to IAM identities or AWS resources. A policy is an object in AWS that, when associated with an identity or resource, defines
their permissions. AWS evaluates these policies when an entity (root user, user, or IAM role) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see Overview of JSON policies in the IAM User Guide.

An administrator can use policies to specify who has access to AWS resources, and what actions they can perform on those resources. Every IAM entity (permission set or role) starts with no permissions. In other words, by default, users can do nothing, not even change their own password. To give a user permission to do something, an administrator must attach a permissions policy to a user. Or the administrator can add the user to a group that has the intended permissions. When an administrator gives permissions to a group, all users in that group are granted those permissions.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the iam:GetRole action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

**Identity-based policies**

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as a permission set or role. These policies control what actions that identity can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Creating IAM policies in the IAM User Guide.

Identity-based policies can be further categorized as inline policies or managed policies. Inline policies are embedded directly into a single permission set or role. Managed policies are standalone policies that you can attach to multiple permission sets and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see Choosing between managed policies and inline policies in the IAM User Guide.

For information about AWS managed policies that are specific to Amazon RDS, see AWS managed policies for Amazon RDS.

**Other policy types**

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.
• **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (permission set or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the permission set or role in the Principal field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see [Permissions boundaries for IAM entities](#) in the [IAM User Guide](#).

• **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for grouping and centrally managing multiple AWS accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each AWS account root user. For more information about Organizations and SCPs, see [How SCPs work](#) in the [AWS Organizations User Guide](#).

• **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's permissions are the intersection of the permission sets or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see [Session policies](#) in the [IAM User Guide](#).

### Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see [Policy evaluation logic](#) in the [IAM User Guide](#).

### How Amazon RDS works with IAM

Before you use IAM to manage access to Amazon RDS, you should understand what IAM features are available to use with Amazon RDS.
### IAM features you can use with Amazon RDS

<table>
<thead>
<tr>
<th>IAM feature</th>

To get a high-level view of how Amazon RDS and other AWS services work with IAM, see [AWS services that work with IAM](https://docs.aws.amazon.com/IAM/latest/userguide/services-that-work-with-iam.html) in the IAM User Guide.

**Topics**

- Amazon RDS identity-based policies
- Resource-based policies within Amazon RDS
- Policy actions for Amazon RDS
- Policy resources for Amazon RDS
- Policy condition keys for Amazon RDS
- Access control lists (ACLs) in Amazon RDS
- Attribute-based access control (ABAC) in policies with Amazon RDS tags
Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see [Creating IAM policies](#) in the [IAM User Guide](#).

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. You can't specify the principal in an identity-based policy because it applies to the user or role to which it is attached. To learn about all of the elements that you can use in a JSON policy, see [IAM JSON policy elements reference](#) in the [IAM User Guide](#).

### Identity-based policy examples for Amazon RDS

To view examples of Amazon RDS identity-based policies, see [Identity-based policy examples for Amazon RDS](#).

### Resource-based policies within Amazon RDS

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must [specify a principal](#)
in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. Adding a cross-account principal to a resource-based policy is only half of establishing the trust relationship. When the principal and the resource are in different AWS accounts, an IAM administrator in the trusted account must also grant the principal entity (user or role) permission to access the resource. They grant permission by attaching an identity-based policy to the entity. However, if a resource-based policy grants access to a principal in the same account, no additional identity-based policy is required. For more information, see [How IAM roles differ from resource-based policies](https://docs.aws.amazon.com/IAM/latest/UserGuide Identities.html) in the IAM User Guide.

**Policy actions for Amazon RDS**

| Supports policy actions | Yes |

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Action element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated AWS API operation. There are some exceptions, such as permission-only actions that don't have a matching API operation. There are also some operations that require multiple actions in a policy. These additional actions are called dependent actions.

Include actions in a policy to grant permissions to perform the associated operation.

Policy actions in Amazon RDS use the following prefix before the action: `rds:`. For example, to grant someone permission to describe DB instances with the Amazon RDS DescribeDBInstances API operation, you include the `rds:DescribeDBInstances` action in their policy. Policy statements must include either an Action or NotAction element. Amazon RDS defines its own set of actions that describe tasks that you can perform with this service.

To specify multiple actions in a single statement, separate them with commas as follows.

```json
"Action": [
    "rds:action1",
    "rds:action2"
]
```
You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word Describe, include the following action.

"Action": "rds:Describe*"

**Policy resources for Amazon RDS**

| Supports policy resources | Yes |

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The Resource JSON policy element specifies the object or objects to which the action applies. Statements must include either a Resource or a NotResource element. As a best practice, specify a resource using its [Amazon Resource Name (ARN)](https://docs.aws.amazon.com/RDS/latest/UserGuide/Service-Authorization-Reference.html#Service-Authorization-Reference). You can do this for actions that support a specific resource type, known as resource-level permissions.

For actions that don't support resource-level permissions, such as listing operations, use a wildcard (*) to indicate that the statement applies to all resources.

"Resource": "*"

The DB instance resource has the following Amazon Resource Name (ARN).

```
arn:${Partition}:rds:${Region}:${Account}:${ResourceType}/${Resource}
```

For more information about the format of ARNs, see [Amazon Resource Names (ARNs) and AWS service namespaces](https://docs.aws.amazon.com/RDS/latest/UserGuide/Service-Authorization-Reference.html#Service-Authorization-Reference).

For example, to specify the dbtest DB instance in your statement, use the following ARN.

To specify all DB instances that belong to a specific account, use the wildcard (*).
Some RDS API operations, such as those for creating resources, can't be performed on a specific resource. In those cases, use the wildcard (*).

Many Amazon RDS API operations involve multiple resources. For example, `CreateDBInstance` creates a DB instance. You can specify that an user must use a specific security group and parameter group when creating a DB instance. To specify multiple resources in a single statement, separate the ARNs with commas.

To see a list of Amazon RDS resource types and their ARNs, see Resources Defined by Amazon RDS in the Service Authorization Reference. To learn with which actions you can specify the ARN of each resource, see Actions Defined by Amazon RDS.

**Policy condition keys for Amazon RDS**

<table>
<thead>
<tr>
<th>Supports service-specific policy condition keys</th>
<th>Yes</th>
</tr>
</thead>
</table>

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Condition element (or Condition block) lets you specify conditions in which a statement is in effect. The Condition element is optional. You can create conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request.

If you specify multiple Condition elements in a statement, or multiple keys in a single Condition element, AWS evaluates them using a logical AND operation. If you specify multiple values for a single condition key, AWS evaluates the condition using a logical OR operation. All of the conditions must be met before the statement's permissions are granted.
You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see IAM policy elements: variables and tags in the IAM User Guide.

AWS supports global condition keys and service-specific condition keys. To see all AWS global condition keys, see AWS global condition context keys in the IAM User Guide.

Amazon RDS defines its own set of condition keys and also supports using some global condition keys. To see all AWS global condition keys, see AWS global condition context keys in the IAM User Guide.

All RDS API operations support the aws:RequestedRegion condition key.

To see a list of Amazon RDS condition keys, see Condition Keys for Amazon RDS in the Service Authorization Reference. To learn with which actions and resources you can use a condition key, see Actions Defined by Amazon RDS.

**Access control lists (ACLs) in Amazon RDS**

| Supports access control lists (ACLs) | No |

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

**Attribute-based access control (ABAC) in policies with Amazon RDS tags**

| Supports attribute-based access control (ABAC) tags in policies | Yes |

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes. In AWS, these attributes are called tags. You can attach tags to IAM entities (users or roles) and to many AWS resources. Tagging entities and resources is the first step of ABAC. Then you design ABAC policies to allow operations when the principal's tag matches the tag on the resource that they are trying to access.
ABAC is helpful in environments that are growing rapidly and helps with situations where policy management becomes cumbersome.

To control access based on tags, you provide tag information in the condition element of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is Yes for the service. If a service supports all three condition keys for only some resource types, then the value is Partial.

For more information about ABAC, see What is ABAC? in the IAM User Guide. To view a tutorial with steps for setting up ABAC, see Use attribute-based access control (ABAC) in the IAM User Guide.

For more information about tagging Amazon RDS resources, see Specifying conditions: Using custom tags. To view an example identity-based policy for limiting access to a resource based on the tags on that resource, see Grant permission for actions on a resource with a specific tag with two different values.

Using temporary credentials with Amazon RDS

| Supports temporary credentials | Yes |

Some AWS services don't work when you sign in using temporary credentials. For additional information, including which AWS services work with temporary credentials, see AWS services that work with IAM in the IAM User Guide.

You are using temporary credentials if you sign in to the AWS Management Console using any method except a user name and password. For example, when you access AWS using your company's single sign-on (SSO) link, that process automatically creates temporary credentials. You also automatically create temporary credentials when you sign in to the console as a user and then switch roles. For more information about switching roles, see Switching to a role (console) in the IAM User Guide.

You can manually create temporary credentials using the AWS CLI or AWS API. You can then use those temporary credentials to access AWS. AWS recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see Temporary security credentials in IAM.
Cross-service principal permissions for Amazon RDS

| Supports principal permissions | Yes |

When you use an IAM user or role to perform actions in AWS, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other AWS services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see Forward access sessions.

Service roles for Amazon RDS

| Supports service roles | Yes |

A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

⚠️ Warning

Changing the permissions for a service role might break Amazon RDS functionality. Edit service roles only when Amazon RDS provides guidance to do so.

Service-linked roles for Amazon RDS

| Supports service-linked roles | Yes |

A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.
For details about using Amazon RDS service-linked roles, see Using service-linked roles for Amazon RDS.

Identity-based policy examples for Amazon RDS

By default, permission sets and roles don't have permission to create or modify Amazon RDS resources. They also can't perform tasks using the AWS Management Console, AWS CLI, or AWS API. An administrator must create IAM policies that grant permission sets and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the permission sets or roles that require those permissions.

To learn how to create an IAM identity-based policy using these example JSON policy documents, see Creating policies on the JSON tab in the IAM User Guide.

Topics

- Policy best practices
- Using the Amazon RDS console
- Allow users to view their own permissions
- Allow a user to create DB instances in an AWS account
- Permissions required to use the console
- Allow a user to perform any describe action on any RDS resource
- Allow a user to create a DB instance that uses the specified DB parameter group and subnet group
- Grant permission for actions on a resource with a specific tag with two different values
- Prevent a user from deleting a DB instance
- Deny all access to a resource
- Example policies: Using condition keys
- Specifying conditions: Using custom tags

Policy best practices

Identity-based policies determine whether someone can create, access, or delete Amazon RDS resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:
• **Get started with AWS managed policies and move toward least-privilege permissions** – To get started granting permissions to your users and workloads, use the *AWS managed policies* that grant permissions for many common use cases. They are available in your AWS account. We recommend that you reduce permissions further by defining AWS customer managed policies that are specific to your use cases. For more information, see [AWS managed policies](https://aws.amazon.com/documentation/iam/user-guide/aws-managed-policies/) or [AWS managed policies for job functions](https://aws.amazon.com/documentation/iam/user-guide/aws-managed-policies-job-functions/) in the *IAM User Guide*.

• **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. For more information about using IAM to apply permissions, see [Policies and permissions in IAM](https://aws.amazon.com/documentation/iam/user-guide/policies-and-permissions-in-iam/) in the *IAM User Guide*.

• **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific AWS service, such as AWS CloudFormation. For more information, see [IAM JSON policy elements: Condition](https://aws.amazon.com/documentation/iam/user-guide/iam-json-policy-conditions/) in the *IAM User Guide*.

• **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see [IAM Access Analyzer policy validation](https://aws.amazon.com/documentation/iam/user-guide/iam-access-analyzer-policy-validation/) in the *IAM User Guide*.

• **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or a root user in your AWS account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see [Configuring MFA-protected API access](https://aws.amazon.com/documentation/iam/user-guide/configuring-mfa-protected-api-access/) in the *IAM User Guide*.

### Using the Amazon RDS console

To access the Amazon RDS console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the Amazon RDS resources in your AWS account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won't function as intended for entities (users or roles) with that policy.
You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that you're trying to perform.

To ensure that those entities can still use the Amazon RDS console, also attach the following AWS managed policy to the entities.

```
AmazonRDSReadOnlyAccess
```

For more information, see Adding permissions to a user in the IAM User Guide.

**Allow users to view their own permissions**

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ViewOwnUserInfo",
      "Effect": "Allow",
      "Action": [
        "iam:GetUserPolicy",
        "iam:ListGroupsForUser",
        "iam:ListAttachedUserPolicies",
        "iam:ListUserPolicies",
        "iam:GetUser"
      ],
      "Resource": ["arn:aws:iam::*:user/${aws:username}" ]
    },
    {
      "Sid": "NavigateInConsole",
      "Effect": "Allow",
      "Action": [
        "iam:GetGroupPolicy",
        "iam:GetPolicyVersion",
        "iam:GetPolicy",
        "iam:ListAttachedGroupPolicies",
        "iam:ListGroupPolicies",
        "iam:ListGroupPolicyVersions",
```
Allow a user to create DB instances in an AWS account

The following is an example policy that allows the user with the ID 123456789012 to create DB instances for your AWS account. The policy requires that the name of the new DB instance begin with test. The new DB instance must also use the MySQL database engine and the db.t2.micro DB instance class. In addition, the new DB instance must use an option group and a DB parameter group that starts with default, and it must use the default subnet group.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowCreateDBInstanceOnly",
            "Effect": "Allow",
            "Action": [
                "rds:CreateDBInstance"
            ],
            "Resource": [
                "arn:aws:rds:*:123456789012:db:test*",
                "arn:aws:rds:*:123456789012:og:default*",
                "arn:aws:rds:*:123456789012:pg:default*",
                "arn:aws:rds:*:123456789012:subgrp:default"
            ],
            "Condition": {
                "StringEquals": {
                    "rds:DatabaseEngine": "mysql",
                    "rds:DatabaseClass": "db.t2.micro"
                }
            }
        }
    ]
}
```

The policy includes a single statement that specifies the following permissions for the user:
• The policy allows the user to create a DB instance using the CreateDBInstance API operation (this also applies to the create-db-instance AWS CLI command and the AWS Management Console).

• The Resource element specifies that the user can perform actions on or with resources. You specify resources using an Amazon Resources Name (ARN). This ARN includes the name of the service that the resource belongs to (rds), the AWS Region (* indicates any region in this example), the AWS account number (123456789012 is the account number in this example), and the type of resource. For more information about creating ARNs, see Working with Amazon Resource Names (ARNs) in Amazon RDS.

The Resource element in the example specifies the following policy constraints on resources for the user:

• The DB instance identifier for the new DB instance must begin with test (for example, testCustomerData1, test-region2-data).
• The option group for the new DB instance must begin with default.
• The DB parameter group for the new DB instance must begin with default.
• The subnet group for the new DB instance must be the default subnet group.

• The Condition element specifies that the DB engine must be MySQL and the DB instance class must be db.t2.micro. The Condition element specifies the conditions when a policy should take effect. You can add additional permissions or restrictions by using the Condition element. For more information about specifying conditions, see Policy condition keys for Amazon RDS. This example specifies the rds:DatabaseEngine and rds:DatabaseClass conditions. For information about the valid condition values for rds:DatabaseEngine, see the list under the Engine parameter in CreateDBInstance. For information about the valid condition values for rds:DatabaseClass, see Supported DB engines for DB instance classes.

The policy doesn't specify the Principal element because in an identity-based policy you don't specify the principal who gets the permission. When you attach policy to a user, the user is the implicit principal. When you attach a permission policy to an IAM role, the principal identified in the role's trust policy gets the permissions.

To see a list of Amazon RDS actions, see Actions Defined by Amazon RDS in the Service Authorization Reference.
Permissions required to use the console

For a user to work with the console, that user must have a minimum set of permissions. These permissions allow the user to describe the Amazon RDS resources for their AWS account and to provide other related information, including Amazon EC2 security and network information.

If you create an IAM policy that is more restrictive than the minimum required permissions, the console doesn't function as intended for users with that IAM policy. To ensure that those users can still use the console, also attach the AmazonRDSReadOnlyAccess managed policy to the user, as described in Managing access using policies.

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the Amazon RDS API.

The following policy grants full access to all Amazon RDS resources for the root AWS account:

```
AmazonRDSFullAccess
```

Allow a user to perform any describe action on any RDS resource

The following permissions policy grants permissions to a user to run all of the actions that begin with Describe. These actions show information about an RDS resource, such as a DB instance. The wildcard character (*) in the Resource element indicates that the actions are allowed for all Amazon RDS resources owned by the account.

```
{  
   "Version": "2012-10-17",  
   "Statement": [  
      {  
         "Sid": "AllowRDSDescribe",  
         "Effect": "Allow",  
         "Action": "rds:Describe*",  
         "Resource": "*"  
      }  
   ]  
}
```
Allow a user to create a DB instance that uses the specified DB parameter group and subnet group

The following permissions policy grants permissions to allow a user to only create a DB instance that must use the `mydbpg` DB parameter group and the `mydbsubnetgroup` DB subnet group.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": "rds:CreateDBInstance",
            "Resource": [
                "arn:aws:rds:*:*:pg:mydbpg",
                "arn:aws:rds:*:*:subgrp:mydbsubnetgroup"
            ]
        }
    ]
}
```

Grant permission for actions on a resource with a specific tag with two different values

You can use conditions in your identity-based policy to control access to Amazon RDS resources based on tags. The following policy allows permission to perform the `CreateDBSnapshot` API operation on DB instances with either the `stage` tag set to `development` or `test`.

```json
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid":"AllowAnySnapshotName",
            "Effect":"Allow",
            "Action": ["rds:CreateDBSnapshot"],
            "Resource":"arn:aws:rds:*:123456789012:snapshot:*"
        },
        {
            "Sid":"AllowDevTestToCreateSnapshot",
            "Effect": "Allow",
            "Action": ["rds:CreateDBSnapshot"],
            "Resource": "arn:aws:rds:*:123456789012:snapshot:*"
        }
    ]
}
```
The following policy allows permission to perform the ModifyDBInstance API operation on DB instances with either the stage tag set to development or test.

```json
{
  "Version":"2012-10-17",
  "Statement":[
    {
      "Sid":"AllowChangingParameterOptionSecurityGroups",
      "Effect":"Allow",
      "Action":[
        "rds:ModifyDBInstance"
      ],
      "Resource": [*
        "arn:aws:rds::*:123456789012:pg:*",
        "arn:aws:rds::*:123456789012:secgrp:*",
        "arn:aws:rds::*:123456789012:og:*"
      ]
    },
    {
      "Sid":"AllowDevTestToModifyInstance",
      "Effect":"Allow",
      "Action":[
        "rds:ModifyDBInstance"
      ],
      "Resource":"arn:aws:rds::*:123456789012:db:*",
      "Condition":{
        "StringEquals":{
          "rds:db-tag/stage":[
            "development",
            "test"
          ]
        }
      }
    }
  ]
}
```
Prevent a user from deleting a DB instance

The following permissions policy grants permissions to prevent a user from deleting a specific DB instance. For example, you might want to deny the ability to delete your production DB instances to any user that is not an administrator.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "DenyDelete1",
         "Effect": "Deny",
         "Action": "rds:DeleteDBInstance",
      }
   ]
}
```

Deny all access to a resource

You can explicitly deny access to a resource. Deny policies take precedence over allow policies. The following policy explicitly denies a user the ability to manage a resource:

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Deny",
         "Action": "rds:*",
      }
   ]
}
```
Example policies: Using condition keys

Following are examples of how you can use condition keys in Amazon RDS IAM permissions policies.

**Example 1: Grant permission to create a DB instance that uses a specific DB engine and isn't MultiAZ**

The following policy uses an RDS condition key and allows a user to create only DB instances that use the MySQL database engine and don't use MultiAZ. The Condition element indicates the requirement that the database engine is MySQL.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowMySQLCreate",
            "Effect": "Allow",
            "Action": "rds:CreateDBInstance",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "rds:DatabaseEngine": "mysql"
                },
                "Bool": {
                    "rds:MultiAz": false
                }
            }
        }
    ]
}
```

**Example 2: Explicitly deny permission to create DB instances for certain DB instance classes and create DB instances that use Provisioned IOPS**

The following policy explicitly denies permission to create DB instances that use the DB instance classes r3.8xlarge and m4.10xlarge, which are the largest and most expensive DB instance
Explicitly denying permission supersedes any other permissions granted. This ensures that identities to not accidentally get permission that you never want to grant.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DenyLargeCreate",
            "Effect": "Deny",
            "Action": "rds:CreateDBInstance",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "rds:DatabaseClass": [
                        "db.r3.8xlarge",
                        "db.m4.10xlarge"
                    ]
                }
            }
        },
        {
            "Sid": "DenyPIOPSCreate",
            "Effect": "Deny",
            "Action": "rds:CreateDBInstance",
            "Resource": "*",
            "Condition": {
                "NumericNotEquals": {
                    "rds:Piops": "0"
                }
            }
        }
    ]
}
```

**Example 3: Limit the set of tag keys and values that can be used to tag a resource**

The following policy uses an RDS condition key and allows the addition of a tag with the key stage to be added to a resource with the values test, qa, and production.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowStageTag",
            "Effect": "Allow",
            "Action": "rds:CreateDBInstance",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "rds:Stage": "test",
                    "rds:Stage": "qa",
                    "rds:Stage": "production"
                }
            }
        }
    ]
}
```
Specifying conditions: Using custom tags

Amazon RDS supports specifying conditions in an IAM policy using custom tags.

For example, suppose that you add a tag named environment to your DB instances with values such as beta, staging, production, and so on. If you do, you can create a policy that restricts certain users to DB instances based on the environment tag value.

Note

Custom tag identifiers are case-sensitive.

The following table lists the RDS tag identifiers that you can use in a Condition element.

<table>
<thead>
<tr>
<th>RDS tag identifier</th>
<th>Applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>db-tag</td>
<td>DB instances, including read replicas</td>
</tr>
<tr>
<td>RDS tag identifier</td>
<td>Applies to</td>
</tr>
<tr>
<td>--------------------</td>
<td>------------------------------</td>
</tr>
<tr>
<td>snapshot-tag</td>
<td>DB snapshots</td>
</tr>
<tr>
<td>ri-tag</td>
<td>Reserved DB instances</td>
</tr>
<tr>
<td>og-tag</td>
<td>DB option groups</td>
</tr>
<tr>
<td>pg-tag</td>
<td>DB parameter groups</td>
</tr>
<tr>
<td>subgrp-tag</td>
<td>DB subnet groups</td>
</tr>
<tr>
<td>es-tag</td>
<td>Event subscriptions</td>
</tr>
<tr>
<td>cluster-tag</td>
<td>DB clusters</td>
</tr>
<tr>
<td>cluster-pg-tag</td>
<td>DB cluster parameter groups</td>
</tr>
<tr>
<td>cluster-snapshot-tag</td>
<td>DB cluster snapshots</td>
</tr>
</tbody>
</table>

The syntax for a custom tag condition is as follows:

"Condition":{"StringEquals":{"rds:rds-tag-identifier/tag-name": ["value"]} }

For example, the following Condition element applies to DB instances with a tag named environment and a tag value of production.

"Condition":{"StringEquals":{"rds:db-tag/environment": ["production"]} }

For information about creating tags, see Tagging Amazon RDS resources.

⚠️ Important

If you manage access to your RDS resources using tagging, we recommend that you secure access to the tags for your RDS resources. You can manage access to tags by creating policies for the AddTagsToResource and RemoveTagsFromResource actions. For example, the following policy denies users the ability to add or remove tags for all resources. You can then create policies to allow specific users to add or remove tags.

```json
{

```
To see a list of Amazon RDS actions, see Actions Defined by Amazon RDS in the Service Authorization Reference.

Example policies: Using custom tags

Following are examples of how you can use custom tags in Amazon RDS IAM permissions policies. For more information about adding tags to an Amazon RDS resource, see Working with Amazon Resource Names (ARNs) in Amazon RDS.

Note

All examples use the us-west-2 region and contain fictitious account IDs.

Example 1: Grant permission for actions on a resource with a specific tag with two different values

The following policy allows permission to perform the CreateDBSnapshot API operation on DB instances with either the stage tag set to development or test.

```json
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Sid":"AllowAnySnapshotName",
         "Effect":"Allow",
         "Action": [ "rds:CreateDBSnapshot" ],
         "Resource": "*"
      }
   ]
}
```
"Action"[:
   "rds:CreateDBSnapshot"
],
"Resource":"arn:aws:rds:*:123456789012:snapshot:*"
},
{
   "Sid":"AllowDevTestToCreateSnapshot",
   "Effect":"Allow",
   "Action"[:
       "rds:CreateDBSnapshot"
],
   "Resource":"arn:aws:rds:*:123456789012:db:*",
   "Condition":{
       "StringEquals":{
           "rds:db-tag/stage"[:
               "development",
               "test"
           ]
       }
   }
}
]
]

The following policy allows permission to perform the ModifyDBInstance API operation on DB instances with either the stage tag set to development or test.

{
   "Version":"2012-10-17",
   "Statement":[
       {
           "Sid":"AllowChangingParameterOptionSecurityGroups",
           "Effect":"Allow",
           "Action"[:
               "rds:ModifyDBInstance"
           ],
           "Resource": [ 
               "arn:aws:rds:*:123456789012:pg:*",
               "arn:aws:rds:*:123456789012:secgrp:*",
               "arn:aws:rds:*:123456789012:og:*"
           ]
       },
       {
           "Sid": "IDAMonitoringAllowListSnapshot",
           "Effect": "Allow",
           "Action": [
               "rds:CreateDBSnapshot"
           ],
           "Resource": "arn:aws:rds:*:123456789012:db:*"
       }
   ]
}
Example 2: Explicitly deny permission to create a DB instance that uses specified DB parameter groups

The following policy explicitly denies permission to create a DB instance that uses DB parameter groups with specific tag values. You might apply this policy if you require that a specific customer-created DB parameter group always be used when creating DB instances. Policies that use Deny are most often used to restrict access that was granted by a broader policy.

Explicitly denying permission supersedes any other permissions granted. This ensures that identities to not accidentally get permission that you never want to grant.

```json
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Sid":"DenyProductionCreate",
         "Effect":"Deny",
         "Action":"rds:CreateDBInstance",
         "Resource":"arn:aws:rds:*:123456789012:pg:*",
         "Condition":{
            "StringEquals":{
               "rds:pg-tag/usage":"prod"
            }
         }
      }
   ]
}
```
Example 3: Grant permission for actions on a DB instance with an instance name that is prefixed with a user name

The following policy allows permission to call any API (except to AddTagsToResource or RemoveTagsFromResource) on a DB instance that has a DB instance name that is prefixed with the user's name and that has a tag called stage equal to devo or that has no tag called stage.

The Resource line in the policy identifies a resource by its Amazon Resource Name (ARN). For more information about using ARNs with Amazon RDS resources, see Working with Amazon Resource Names (ARNs) in Amazon RDS.

```json
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Sid":"AllowFullDevAccessNoTags",
         "Effect":"Allow",
         "NotAction": [
            "rds:AddTagsToResource",
            "rds:RemoveTagsFromResource"
         ],
         "Resource":"arn:aws:rds:*:123456789012:db:${aws:username}*",
         "Condition": {
            "StringEqualsIfExists": {
               "rds:db-tag/stage":"devo"
            }
         }
      }
   ]
}
```
AWS managed policies for Amazon RDS

To add permissions to permission sets and roles, it's easier to use AWS managed policies than to write policies yourself. It takes time and expertise to create IAM customer managed policies that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see AWS managed policies in the IAM User Guide.

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (permission sets and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services don't remove permissions from an AWS managed policy, so policy updates don't break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the ReadOnlyAccess AWS managed policy provides read-only access to all AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see AWS managed policies for job functions in the IAM User Guide.

Topics

- AWS managed policy: AmazonRDSReadOnlyAccess
- AWS managed policy: AmazonRDSFullAccess
- AWS managed policy: AmazonRDSDataFullAccess
- AWS managed policy: AmazonRDSEnhancedMonitoringRole
- AWS managed policy: AmazonRDSPerformanceInsightsReadOnly
- AWS managed policy: AmazonRDSPerformanceInsightsFullAccess
- AWS managed policy: AmazonRDSDirectoryServiceAccess
- AWS managed policy: AmazonRDSRolePolicy
- AWS managed policy: AmazonRDSCustomServiceRolePolicy
- AWS managed policy: AmazonRDSCustomInstanceProfileRolePolicy
AWS managed policy: AmazonRDSReadOnlyAccess

This policy allows read-only access to Amazon RDS through the AWS Management Console.

Permissions details

This policy includes the following permissions:

- rds – Allows principals to describe Amazon RDS resources and list the tags for Amazon RDS resources.
- cloudwatch – Allows principals to get Amazon CloudWatch metric statistics.
- ec2 – Allows principals to describe Availability Zones and networking resources.
- logs – Allows principals to describe CloudWatch Logs log streams of log groups, and get CloudWatch Logs log events.
- devops-guru – Allows principals to describe resources that have Amazon DevOps Guru coverage, which is specified either by CloudFormation stack names or resource tags.

For more information about this policy, including the JSON policy document, see AmazonRDSReadOnlyAccess in the AWS Managed Policy Reference Guide.

AWS managed policy: AmazonRDSFullAccess

This policy provides full access to Amazon RDS through the AWS Management Console.

Permissions details

This policy includes the following permissions:

- rds – Allows principals full access to Amazon RDS.
- application-autoscaling – Allows principals describe and manage Application Auto Scaling scaling targets and policies.
- cloudwatch – Allows principals get CloudWatch metric statics and manage CloudWatch alarms.
- ec2 – Allows principals to describe Availability Zones and networking resources.
- logs – Allows principals to describe CloudWatch Logs log streams of log groups, and get CloudWatch Logs log events.
- outposts – Allows principals to get AWS Outposts instance types.
• **pi** – Allows principals to get Performance Insights metrics.

• **sns** – Allows principals to Amazon Simple Notification Service (Amazon SNS) subscriptions and topics, and to publish Amazon SNS messages.

• **devops-guru** – Allows principals to describe resources that have Amazon DevOps Guru coverage, which is specified either by CloudFormation stack names or resource tags.

For more information about this policy, including the JSON policy document, see [AmazonRDSFullAccess](#) in the *AWS Managed Policy Reference Guide*.

**AWS managed policy: AmazonRDSDataFullAccess**

This policy allows full access to use the Data API and the query editor on Aurora Serverless clusters in a specific AWS account. This policy allows the AWS account to get the value of a secret from AWS Secrets Manager.

You can attach the AmazonRDSDataFullAccess policy to your IAM identities.

**Permissions details**

This policy includes the following permissions:

• **dbqms** – Allows principals to access, create, delete, describe, and update queries. The Database Query Metadata Service (dbqms) is an internal-only service. It provides your recent and saved queries for the query editor on the AWS Management Console for multiple AWS services, including Amazon RDS.

• **rds-data** – Allows principals to run SQL statements on Aurora Serverless databases.

• **secretsmanager** – Allows principals to get the value of a secret from AWS Secrets Manager.

For more information about this policy, including the JSON policy document, see [AmazonRDSDataFullAccess](#) in the *AWS Managed Policy Reference Guide*.

**AWS managed policy: AmazonRDSEnhancedMonitoringRole**

This policy provides access to Amazon CloudWatch Logs for Amazon RDS Enhanced Monitoring.

**Permissions details**

This policy includes the following permissions:
• **logs** – Allows principals to create CloudWatch Logs log groups and retention policies, and to create and describe CloudWatch Logs log streams of log groups. It also allows principals to put and get CloudWatch Logs log events.

For more information about this policy, including the JSON policy document, see AmazonRDSEnhancedMonitoringRole in the *AWS Managed Policy Reference Guide*.

**AWS managed policy: AmazonRDSPerformanceInsightsReadOnly**

This policy provides read-only access to Amazon RDS Performance Insights for Amazon RDS DB instances and Amazon Aurora DB clusters.

This policy now includes **Sid** (statement ID) as an identifier for the policy statement.

**Permissions details**

This policy includes the following permissions:

• **rds** – Allows principals to describe Amazon RDS DB instances and Amazon Aurora DB clusters.

• **pi** – Allows principals make calls to the Amazon RDS Performance Insights API and access Performance Insights metrics.

For more information about this policy, including the JSON policy document, see AmazonRDSPerformanceInsightsReadOnly in the *AWS Managed Policy Reference Guide*.

**AWS managed policy: AmazonRDSPerformanceInsightsFullAccess**

This policy provides full access to Amazon RDS Performance Insights for Amazon RDS DB instances and Amazon Aurora DB clusters.

This policy now includes **Sid** (statement ID) as an identifier for the policy statement.

**Permissions details**

This policy includes the following permissions:

• **rds** – Allows principals to describe Amazon RDS DB instances and Amazon Aurora DB clusters.

• **pi** – Allows principals make calls to the Amazon RDS Performance Insights API, and create, view, and delete performance analysis reports.
• **cloudwatch** – Allows principals to list all the Amazon CloudWatch metrics, and get metric data and statistics.

For more information about this policy, including the JSON policy document, see [AmazonRDSPerformanceInsightsFullAccess](https://aws.amazon.com/aws-managed-policies/AmazonRDSPerformanceInsightsFullAccess) in the *AWS Managed Policy Reference Guide*.

**AWS managed policy: AmazonRDSDirectoryServiceAccess**

This policy allows Amazon RDS to make calls to the AWS Directory Service.

**Permissions details**

This policy includes the following permission:

- **ds** – Allows principals to describe AWS Directory Service directories and control authorization to AWS Directory Service directories.

For more information about this policy, including the JSON policy document, see [AmazonRDSDirectoryServiceAccess](https://aws.amazon.com/aws-managed-policies/AmazonRDSDirectoryServiceAccess) in the *AWS Managed Policy Reference Guide*.

**AWS managed policy: AmazonRDSServiceRolePolicy**

You can't attach the AmazonRDSServiceRolePolicy policy to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to perform actions on your behalf. For more information, see [Service-linked role permissions for Amazon RDS](https://docs.aws.amazon.com/rdsc2rlb/latest/securityguide/security-groups.html).

**AWS managed policy: AmazonRDSCustomServiceRolePolicy**

You can't attach the AmazonRDSCustomServiceRolePolicy policy to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to perform actions on your behalf. For more information, see [Service-linked role permissions for Amazon RDS Custom](https://docs.aws.amazon.com/rdsc2rlb/latest/securityguide/service-linked-roles.html).

**AWS managed policy: AmazonRDSCustomInstanceProfileRolePolicy**

You shouldn't attach AmazonRDSCustomInstanceProfileRolePolicy to your IAM entities. It should only be attached to an instance profile role that is used to grant permissions to your Amazon RDS Custom DB instance to perform various automation actions and database management tasks. Pass the instance profile as `custom-iam-instance-profile` parameter during the RDS Custom instance creation and RDS Custom associates this instance profile to your DB instance.
Permissions details

This policy includes the following permissions:

- **ssm, ssmmessages, ec2messages**: Allows RDS Custom to communicate, execute automation and maintain agents on the DB instance through Systems Manager.
- **ec2, s3**: Allows RDS Custom to perform backup operations on the DB instance that provides point-in-time restore capabilities.
- **secretsmanager**: Allows RDS Custom to manage DB instance specific secrets created by RDS Custom.
- **cloudwatch, logs**: Allows RDS Custom to upload DB instance metrics and logs to CloudWatch through CloudWatch agent.
- **events, sqs**: Allows RDS Custom to send and receive status information about the DB instance.
- **kms**: Allows RDS Custom to use an instance-specific KMS key to perform encryption of secrets and S3 objects that RDS Custom manages.

For more information about this policy, including the JSON policy document, see [AmazonRDSCustomInstanceProfileRolePolicy](https://aws.amazon.com/managedpolicy/amazonrdscustominstanceprofilerolepolicy) in the *AWS Managed Policy Reference Guide*. 
## Amazon RDS updates to AWS managed policies

View details about updates to AWS managed policies for Amazon RDS since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the Amazon RDS [Document history] page.

Preventing cross-service confused deputy problems

The *confused deputy problem* is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem.

Cross-service impersonation can occur when one service (the *calling service*) calls another service (the *called service*). The calling service can be manipulated to use its permissions to act on another customer's resources in a way that it shouldn't have permission to access. To prevent this, AWS provides tools that can help you protect your data for all services with service principals that have been given access to resources in your account. For more information, see [The confused deputy problem](#) in the *IAM User Guide*.

To limit the permissions that Amazon RDS gives another service for a specific resource, we recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource policies.

In some cases, the `aws:SourceArn` value doesn't contain the account ID, for example when you use the Amazon Resource Name (ARN) for an Amazon S3 bucket. In these cases, make sure to use both global condition context keys to limit permissions. In some cases, you use both global condition context keys and the `aws:SourceArn` value contains the account ID. In these cases, make sure that the `aws:SourceAccount` value and the account in the `aws:SourceArn` use the same account ID when they're used in the same policy statement. If you want only one resource to be associated with the cross-service access, use `aws:SourceArn`. If you want to allow any resource in the specified AWS account to be associated with the cross-service use, use `aws:SourceAccount`.

Make sure that the value of `aws:SourceArn` is an ARN for an Amazon RDS resource type. For more information, see [Working with Amazon Resource Names (ARNs) in Amazon RDS](#).

The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition context key with the full ARN of the resource. In some cases, you might not know the full ARN of the resource or you might be specifying multiple resources. In these cases, use the `aws:SourceArn` global context condition key with wildcards (*) for the unknown portions of the ARN. An example is `arn:aws:rds:*:123456789012:*`.

The following example shows how you can use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in Amazon RDS to prevent the confused deputy problem.
For more examples of policies that use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys, see the following sections:

IAM database authentication for MariaDB, MySQL, and PostgreSQL

You can authenticate to your DB instance using AWS Identity and Access Management (IAM) database authentication. IAM database authentication works with MariaDB, MySQL, and PostgreSQL. With this authentication method, you don't need to use a password when you connect to a DB instance. Instead, you use an authentication token.

An authentication token is a unique string of characters that Amazon RDS generates on request. Authentication tokens are generated using AWS Signature Version 4. Each token has a lifetime of 15 minutes. You don't need to store user credentials in the database, because authentication is managed externally using IAM. You can also still use standard database authentication. The token is only used for authentication and doesn't affect the session after it is established.

IAM database authentication provides the following benefits:

- Network traffic to and from the database is encrypted using Secure Socket Layer (SSL) or Transport Layer Security (TLS). For more information about using SSL/TLS with Amazon RDS, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.
- You can use IAM to centrally manage access to your database resources, instead of managing access individually on each DB instance.
- For applications running on Amazon EC2, you can use profile credentials specific to your EC2 instance to access your database instead of a password, for greater security.

In general, consider using IAM database authentication when your applications create fewer than 200 connections per second, and you don't want to manage usernames and passwords directly in your application code.

The AWS JDBC Driver for MySQL supports IAM database authentication. For more information, see AWS IAM Database Authentication in the AWS JDBC Driver for MySQL GitHub repository.

Topics

- Region and version availability
- CLI and SDK support
- Limitations for IAM database authentication
- Recommendations for IAM database authentication
- Unsupported AWS global condition context keys
• Enabling and disabling IAM database authentication
• Creating and using an IAM policy for IAM database access
• Creating a database account using IAM authentication
• Connecting to your DB instance using IAM authentication

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability with Amazon RDS and IAM database authentication, see IAM database authentication.

CLI and SDK support

IAM database authentication is available for the AWS CLI and for the following language-specific AWS SDKs:

• AWS SDK for .NET
• AWS SDK for C++
• AWS SDK for Go
• AWS SDK for Java
• AWS SDK for JavaScript
• AWS SDK for PHP
• AWS SDK for Python (Boto3)
• AWS SDK for Ruby

Limitations for IAM database authentication

When using IAM database authentication, the following limitations apply:

• The maximum number of connections per second for your DB instance might be limited depending on its DB instance class and your workload. IAM authentication can fail in case of resource exhaustion during peak DB loads.
• Currently, IAM database authentication doesn't support all global condition context keys.

For more information about global condition context keys, see AWS global condition context keys in the IAM User Guide.
• For PostgreSQL, if the IAM role (rds_iam) is added to a user (including the RDS master user), IAM authentication takes precedence over password authentication, so the user must log in as an IAM user.

• For PostgreSQL, Amazon RDS does not support enabling both IAM and Kerberos authentication methods at the same time.

• For PostgreSQL, you cannot use IAM authentication to establish a replication connection.

• You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

Recommendations for IAM database authentication

We recommend the following when using IAM database authentication:

• Use IAM database authentication when your application requires fewer than 200 new IAM database authentication connections per second.

The database engines that work with Amazon RDS don't impose any limits on authentication attempts per second. However, when you use IAM database authentication, your application must generate an authentication token. Your application then uses that token to connect to the DB instance. If you exceed the limit of maximum new connections per second, then the extra overhead of IAM database authentication can cause connection throttling.

Consider using connection pooling in your applications to mitigate constant connection creation. This can reduce the overhead from IAM DB authentication and allow your applications to reuse existing connections. Alternatively, consider using RDS Proxy for these use cases. RDS Proxy has additional costs. See RDS Proxy pricing.

• The size of an IAM database authentication token depends on many things including the number of IAM tags, IAM service policies, ARN lengths, as well as other IAM and database properties. The minimum size of this token is generally about 1 KB but can be larger. Since this token is used as the password in the connection string to the database using IAM authentication, you should ensure that your database driver (e.g., ODBC) and/or any tools do not limit or otherwise truncate this token due to its size. A truncated token will cause the authentication validation done by the database and IAM to fail.

• If you are using temporary credentials when creating an IAM database authentication token, the temporary credentials must still be valid when using the IAM database authentication token to make a connection request.
Unsupported AWS global condition context keys

IAM database authentication does not support the following subset of AWS global condition context keys.

- aws:Referer
- aws:SourceIp
- aws:SourceVpc
- aws:SourceVpce
- aws:UserAgent
- aws:VpcSourceIp

Enabling and disabling IAM database authentication

By default, IAM database authentication is disabled on DB instances. You can enable or disable IAM database authentication using the AWS Management Console, AWS CLI, or the API.

You can enable IAM database authentication when you perform one of the following actions:

- To create a new DB instance with IAM database authentication enabled, see [Creating an Amazon RDS DB instance](https://docs.aws.amazon.com/rds/latest/userguide/iam-create-instance.html).
- To modify a DB instance to enable IAM database authentication, see [Modifying an Amazon RDS DB instance](https://docs.aws.amazon.com/rds/latest/userguide/iam-create-instance.html).
- To restore a DB instance from a snapshot with IAM database authentication enabled, see [Restoring from a DB snapshot](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/CHAP_Governance.html).
- To restore a DB instance to a point in time with IAM database authentication enabled, see [Restoring a DB instance to a specified time](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/CHAP_Governance.html).

IAM authentication for PostgreSQL DB instances requires that the SSL value be 1. You can't enable IAM authentication for a PostgreSQL DB instance if the SSL value is 0. You can't change the SSL value to 0 if IAM authentication is enabled for a PostgreSQL DB instance.
Console

Each creation or modification workflow has a Database authentication section, where you can enable or disable IAM database authentication. In that section, choose Password and IAM database authentication to enable IAM database authentication.

To enable or disable IAM database authentication for an existing DB instance

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB instance that you want to modify.

   Note
   Make sure that the DB instance is compatible with IAM authentication. Check the compatibility requirements in Region and version availability.

4. Choose Modify.
5. In the Database authentication section, choose Password and IAM database authentication to enable IAM database authentication. Choose Password authentication or Password and Kerberos authentication to disable IAM authentication.
6. Choose Continue.
7. To apply the changes immediately, choose Immediately in the Scheduling of modifications section.
8. Choose Modify DB instance.

AWS CLI

To create a new DB instance with IAM authentication by using the AWS CLI, use the create-db-instance command. Specify the --enable-iam-database-authentication option, as shown in the following example.

```
aws rds create-db-instance
   --db-instance-identifier mydbinstance
   --db-instance-class db.m3.medium
   --engine MySQL
   --allocated-storage 20
   --master-username masterawsuser
```
To update an existing DB instance to have or not have IAM authentication, use the AWS CLI command `modify-db-instance`. Specify either the `--enable-iam-database-authentication` or `--no-enable-iam-database-authentication` option, as appropriate.

**Note**
Make sure that the DB instance is compatible with IAM authentication. Check the compatibility requirements in [Region and version availability](#).

By default, Amazon RDS performs the modification during the next maintenance window. If you want to override this and enable IAM DB authentication as soon as possible, use the `--apply-immediately` parameter.

The following example shows how to immediately enable IAM authentication for an existing DB instance.

```
aws rds modify-db-instance
  --db-instance-identifier mydbinstance
  --apply-immediately
  --enable-iam-database-authentication
```

If you are restoring a DB instance, use one of the following AWS CLI commands:

- `restore-db-instance-to-point-in-time`
- `restore-db-instance-from-db-snapshot`

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the `--enable-iam-database-authentication` or `--no-enable-iam-database-authentication` option, as appropriate.

**RDS API**

To create a new DB instance with IAM authentication by using the API, use the API operation `CreateDBInstance`. Set the `EnableIAMDatabaseAuthentication` parameter to `true`. 
To update an existing DB instance to have IAM authentication, use the API operation `ModifyDBInstance`. Set the `EnableIAMDatabaseAuthentication` parameter to `true` to enable IAM authentication, or `false` to disable it.

### Note
Make sure that the DB instance is compatible with IAM authentication. Check the compatibility requirements in [Region and version availability](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/Concepts.Regions.AmazonRDS.html).

If you are restoring a DB instance, use one of the following API operations:

- `RestoreDBInstanceFromDBSnapshot`
- `RestoreDBInstanceToPointInTime`

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the `EnableIAMDatabaseAuthentication` parameter to `true` to enable IAM authentication, or `false` to disable it.

### Creating and using an IAM policy for IAM database access

To allow a user or role to connect to your DB instance, you must create an IAM policy. After that, you attach the policy to a permissions set or role.

### Note
To learn more about IAM policies, see [Identity and access management for Amazon RDS](https://docs.aws.amazon.com/IAM/latest/userguide/using-policy-examples.html).

The following example policy allows a user to connect to a DB instance using IAM database authentication.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "rds-db:connect"
            ]
        }
    ]
}
```
A user with administrator permissions can access DB instances without explicit permissions in an IAM policy. If you want to restrict administrator access to DB instances, you can create an IAM role with the appropriate, lesser privileged permissions and assign it to the administrator.

Don't confuse the rds-db: prefix with other RDS API operation prefixes that begin with rds:. You use the rds-db: prefix and the rds-db:connect action only for IAM database authentication. They aren't valid in any other context.

The example policy includes a single statement with the following elements:

- **Effect** – Specify `Allow` to grant access to the DB instance. If you don't explicitly allow access, then access is denied by default.
- **Action** – Specify `rds-db:connect` to allow connections to the DB instance.
- **Resource** – Specify an Amazon Resource Name (ARN) that describes one database account in one DB instance. The ARN format is as follows.

```python
arn:aws:rds-db:region:account-id:dbuser:DbiResourceId/db-user-name
```

In this format, replace the following:
• **region** is the AWS Region for the DB instance. In the example policy, the AWS Region is `us-east-2`.

• **account-id** is the AWS account number for the DB instance. In the example policy, the account number is `1234567890`. The user must be in the same account as the account for the DB instance.

To perform cross-account access, create an IAM role with the policy shown above in the account for the DB instance and allow your other account to assume the role.

• **DbiResourceId** is the identifier for the DB instance. This identifier is unique to an AWS Region and never changes. In the example policy, the identifier is `db-ABCDEFGHIJKL01234`.

To find a DB instance resource ID in the AWS Management Console for Amazon RDS, choose the DB instance to see its details. Then choose the **Configuration** tab. The **Resource ID** is shown in the **Configuration** section.

Alternatively, you can use the AWS CLI command to list the identifiers and resource IDs for all of your DB instance in the current AWS Region, as shown following.

```
aws rds describe-db-instances --query "DBInstances[*].
[DBInstanceIdentifier,DbiResourceId]"
```

If you are using Amazon Aurora, specify a **DbClusterResourceId** instead of a **DbiResourceId**. For more information, see [Creating and using an IAM policy for IAM database access](https://docs.aws.amazon.com/aurora/latest/userguide/iam-authentication.html) in the *Amazon Aurora User Guide*.

![Note](https://docs.aws.amazon.com/autoscaling/ec2/latest/userguide/ps-note.png)  
If you are connecting to a database through RDS Proxy, specify the proxy resource ID, such as `prx-ABCDEFGHIJKL01234`. For information about using IAM database authentication with RDS Proxy, see [Connecting to a proxy using IAM authentication](https://docs.aws.amazon.com/elasticache/latest/maintenance/index.html).

• **db-user-name** is the name of the database account to associate with IAM authentication. In the example policy, the database account is `db_user`.

IAM database authentication
You can construct other ARNs to support various access patterns. The following policy allows access to two different database accounts in a DB instance.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["rds-db:connect"],
            "Resource": [
            ]
        }
    ]
}
```

The following policy uses the "*" character to match all DB instances and database accounts for a particular AWS account and AWS Region.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["rds-db:connect"],
            "Resource": [
            ]
        }
    ]
}
```
The following policy matches all of the DB instances for a particular AWS account and AWS Region. However, the policy only grants access to DB instances that have a jane_doe database account.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["rds-db:connect"],
        ]
    ]
}
```

The user or role has access to only those databases that the database user does. For example, suppose that your DB instance has a database named dev, and another database named test. If the database user jane_doe has access only to dev, any users or roles that access that DB instance with the jane_doe user also have access only to dev. This access restriction is also true for other database objects, such as tables, views, and so on.

An administrator must create IAM policies that grant entities permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the permission sets or roles that require those permissions. For examples of policies, see Identity-based policy examples for Amazon RDS.

**Attaching an IAM policy to a permission set or role**

After you create an IAM policy to allow database authentication, you need to attach the policy to a permission set or role. For a tutorial on this topic, see [Create and attach your first customer managed policy](#) in the IAM User Guide.

As you work through the tutorial, you can use one of the policy examples shown in this section as a starting point and tailor it to your needs. At the end of the tutorial, you have a permission set with an attached policy that can make use of the rds-db:connect action.
Note
You can map multiple permission sets or roles to the same database user account. For example, suppose that your IAM policy specified the following resource ARN.

```
arn:aws:rds-db:us-east-2:123456789012:dbuser:db-12ABC34DEFG5HIJ6KLMNOP78QR/jane_doe
```

If you attach the policy to Jane, Bob, and Diego, then each of those users can connect to the specified DB instance using the jane_doe database account.

Creating a database account using IAM authentication

With IAM database authentication, you don’t need to assign database passwords to the user accounts you create. If you remove a user that is mapped to a database account, you should also remove the database account with the DROP USER statement.

Note
The user name used for IAM authentication must match the case of the user name in the database.

Topics
- Using IAM authentication with MariaDB and MySQL
- Using IAM authentication with PostgreSQL

Using IAM authentication with MariaDB and MySQL

With MariaDB and MySQL, authentication is handled by AWSAuthenticationPlugin—an AWS-provided plugin that works seamlessly with IAM to authenticate your users. Connect to the DB instance as the master user or a different user who can create users and grant privileges. After connecting, issue the CREATE USER statement, as shown in the following example.

```
CREATE USER jane_doe IDENTIFIED WITH AWSAuthenticationPlugin AS 'RDS';
```
The IDENTIFIED WITH clause allows MariaDB and MySQL to use the AWSAuthenticationPlugin to authenticate the database account (jane_doe). The AS 'RDS' clause refers to the authentication method. Make sure the specified database user name is the same as a resource in the IAM policy for IAM database access. For more information, see Creating and using an IAM policy for IAM database access.

⚠️ **Note**

If you see the following message, it means that the AWS-provided plugin is not available for the current DB instance.

`ERROR 1524 (HY000): Plugin 'AWSAuthenticationPlugin' is not loaded`

To troubleshoot this error, verify that you are using a supported configuration and that you have enabled IAM database authentication on your DB instance. For more information, see Region and version availability and Enabling and disabling IAM database authentication.

After you create an account using AWSAuthenticationPlugin, you manage it in the same way as other database accounts. For example, you can modify account privileges with GRANT and REVOKE statements, or modify various account attributes with the ALTER USER statement.

Database network traffic is encrypted using SSL/TLS when using IAM. To allow SSL connections, modify the user account with the following command.

```
ALTER USER 'jane_doe'@'%' REQUIRE SSL;
```

**Using IAM authentication with PostgreSQL**

To use IAM authentication with PostgreSQL, connect to the DB instance as the master user or a different user who can create users and grant privileges. After connecting, create database users and then grant them the rds_iam role as shown in the following example.

```
CREATE USER db_userx;
GRANT rds_iam TO db_userx;
```
Make sure the specified database user name is the same as a resource in the IAM policy for IAM database access. For more information, see Creating and using an IAM policy for IAM database access.

Connecting to your DB instance using IAM authentication

With IAM database authentication, you use an authentication token when you connect to your DB instance. An authentication token is a string of characters that you use instead of a password. After you generate an authentication token, it’s valid for 15 minutes before it expires. If you try to connect using an expired token, the connection request is denied.

Every authentication token must be accompanied by a valid signature, using AWS signature version 4. (For more information, see Signature Version 4 signing process in the AWS General Reference.) The AWS CLI and an AWS SDK, such as the AWS SDK for Java or AWS SDK for Python (Boto3), can automatically sign each token you create.

You can use an authentication token when you connect to Amazon RDS from another AWS service, such as AWS Lambda. By using a token, you can avoid placing a password in your code. Alternatively, you can use an AWS SDK to programmatically create and programmatically sign an authentication token.

After you have a signed IAM authentication token, you can connect to an Amazon RDS DB instance. Following, you can find out how to do this using either a command line tool or an AWS SDK, such as the AWS SDK for Java or AWS SDK for Python (Boto3).

For more information, see the following blog posts:

- Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL
- Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL

Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication
Topics

• Connecting to your DB instance using IAM authentication from the command line: AWS CLI and mysql client

• Connecting to your DB instance using IAM authentication from the command line: AWS CLI and psql client

• Connecting to your DB instance using IAM authentication and the AWS SDK for .NET

• Connecting to your DB instance using IAM authentication and the AWS SDK for Go

• Connecting to your DB instance using IAM authentication and the AWS SDK for Java

• Connecting to your DB instance using IAM authentication and the AWS SDK for Python (Boto3)

Connecting to your DB instance using IAM authentication from the command line: AWS CLI and mysql client

You can connect from the command line to an Amazon RDS DB instance with the AWS CLI and mysql command line tool as described following.

Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

• Enabling and disabling IAM database authentication

• Creating and using an IAM policy for IAM database access

• Creating a database account using IAM authentication

Note

For information about connecting to your database using SQL Workbench/J with IAM authentication, see the blog post Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL.

Topics

• Generating an IAM authentication token

• Connecting to a DB instance
Generating an IAM authentication token

The following example shows how to get a signed authentication token using the AWS CLI.

```bash
aws rds generate-db-auth-token
  --hostname rdsmysql.123456789012.us-west-2.rds.amazonaws.com
  --port 3306
  --region us-west-2
  --username jane_doe
```

In the example, the parameters are as follows:

- `--hostname` – The host name of the DB instance that you want to access
- `--port` – The port number used for connecting to your DB instance
- `--region` – The AWS Region where the DB instance is running
- `--username` – The database account that you want to access

The first several characters of the token look like the following.

```
rdsmysql.123456789012.us-west-2.rds.amazonaws.com:3306/?
Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```

⚠️ **Note**

You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

Connecting to a DB instance

The general format for connecting is shown following.

```bash
mysql --host=hostName --port=portNumber --ssl-ca=full_path_to_ssl_certificate --enable-cleartext-plugin --user=userName --password=authToken
```

The parameters are as follows:

- `--host` – The host name of the DB instance that you want to access
- `--port` – The port number used for connecting to your DB instance
• `--ssl-ca` – The full path to the SSL certificate file that contains the public key

For more information about SSL/TLS support for MariaDB, see [Using SSL/TLS with a MariaDB DB instance](#).

For more information about SSL/TLS support for MySQL, see [Using SSL/TLS with a MySQL DB instance](#).

To download an SSL certificate, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#).

• `--enable-cleartext-plugin` – A value that specifies that `AWSAuthenticationPlugin` must be used for this connection

If you are using a MariaDB client, the `--enable-cleartext-plugin` option isn’t required.

• `--user` – The database account that you want to access

• `--password` – A signed IAM authentication token

The authentication token consists of several hundred characters. It can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows one way to perform this workaround. In the example, `/sample_dir/` is the full path to the SSL certificate file that contains the public key.

```bash
RDSHOST="mysqldb.123456789012.us-east-1.rds.amazonaws.com"
TOKEN="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 3306 --region us-west-2 --username jane_doe )"

mysql --host=$RDSHOST --port=3306 --ssl-ca=/sample_dir/global-bundle.pem --enable-cleartext-plugin --user=jane_doe --password=$TOKEN
```

When you connect using `AWSAuthenticationPlugin`, the connection is secured using SSL. To verify this, type the following at the `mysql>` command prompt.

```bash
show status like 'Ssl%';
```

The following lines in the output show more details.

```
+-----------------------------+-----------------------------+
| IAM database authentication |
+-----------------------------+-----------------------------+
```
If you want to connect to a DB instance through a proxy, see [Connecting to a proxy using IAM authentication](#).

**Connecting to your DB instance using IAM authentication from the command line: AWS CLI and psql client**

You can connect from the command line to an Amazon RDS for PostgreSQL DB instance with the AWS CLI and psql command line tool as described following.

**Prerequisites**

The following are prerequisites for connecting to your DB instance using IAM authentication:

- [Enabling and disabling IAM database authentication](#)
- [Creating and using an IAM policy for IAM database access](#)
- [Creating a database account using IAM authentication](#)

---

### Note

For information about connecting to your database using pgAdmin with IAM authentication, see the blog post [Using IAM authentication to connect with pgAdmin](#), [Amazon Aurora PostgreSQL](#), or [Amazon RDS for PostgreSQL](#).

---

**Topics**

- IAM database authentication
Generating an IAM authentication token

The authentication token consists of several hundred characters so it can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows how to use the AWS CLI to get a signed authentication token using the `generate-db-auth-token` command, and store it in a `PGPASSWORD` environment variable.

```bash
export RDSHOST="rdspostgres.123456789012.us-west-2.rds.amazonaws.com"
export PGPASSWORD="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --region us-west-2 --username jane_doe )"
```

In the example, the parameters to the `generate-db-auth-token` command are as follows:

- `--hostname` – The host name of the DB instance that you want to access
- `--port` – The port number used for connecting to your DB instance
- `--region` – The AWS Region where the DB instance is running
- `--username` – The database account that you want to access

The first several characters of the generated token look like the following.

```
rdspostgres.123456789012.us-west-2.rds.amazonaws.com:5432/?
Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```

**Note**
You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

Connecting to an Amazon RDS PostgreSQL instance

The general format for using `psql` to connect is shown following.

```bash
IAM database authentication
```

---

*Amazon Relational Database Service User Guide*

- Generating an IAM authentication token
- Connecting to an Amazon RDS PostgreSQL instance
The parameters are as follows:

- **host** – The host name of the DB instance that you want to access
- **port** – The port number used for connecting to your DB instance
- **sslmode** – The SSL mode to use
  
  When you use **sslmode=verify-full**, the SSL connection verifies the DB instance endpoint against the endpoint in the SSL certificate.
- **sslrootcert** – The full path to the SSL certificate file that contains the public key

For more information, see [Using SSL with a PostgreSQL DB instance](#).

To download an SSL certificate, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#).

- **dbname** – The database that you want to access
- **user** – The database account that you want to access
- **password** – A signed IAM authentication token

**Note**

You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

The following example shows using psql to connect. In the example, psql uses the environment variable RDSHOST for the host and the environment variable PGPASSWORD for the generated token. Also, `/sample_dir/` is the full path to the SSL certificate file that contains the public key.

```bash
export RDSHOST="rdspostgres.123456789012.us-west-2.rds.amazonaws.com"
export PGPASSWORD="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --region us-west-2 --username jane_doe )"
```
If you want to connect to a DB instance through a proxy, see [Connecting to a proxy using IAM authentication](#).

### Connecting to your DB instance using IAM authentication and the AWS SDK for .NET

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for .NET as described following.

#### Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- [Enabling and disabling IAM database authentication](#)
- [Creating and using an IAM policy for IAM database access](#)
- [Creating a database account using IAM authentication](#)

#### Examples

The following code examples show how to generate an authentication token, and then use it to connect to a DB instance.

To run this code example, you need the [AWS SDK for .NET](https://aws.amazon.com/sdk-for-net/), found on the AWS site. The `AWSSDK.CORE` and the `AWSSDK.RDS` packages are required. To connect to a DB instance, use the .NET database connector for the DB engine, such as `MySqlConnector` for MariaDB or MySQL, or `Npgsql` for PostgreSQL.

This code connects to a MariaDB or MySQL DB instance. Modify the values of the following variables as needed:

- `server` – The endpoint of the DB instance that you want to access
- `user` – The database account that you want to access
- `database` – The database that you want to access
- `port` – The port number used for connecting to your DB instance
- `SslMode` – The SSL mode to use

```
psql "host=$RDSHOST port=5432 sslmode=verify-full sslrootcert=/sample_dir/global-bundle.pem dbname=DBName user=jane_doe password=$PGPASSWORD"
```
When you use `SslMode=Required`, the SSL connection verifies the DB instance endpoint against the endpoint in the SSL certificate.

- **SslCa** – The full path to the SSL certificate for Amazon RDS

To download a certificate, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#).

---

### Note

You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

```csharp
using System;
using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;
using Amazon;

namespace ubuntu
{
    class Program
    {
        static void Main(string[] args)
        {
            var pwd = Amazon.RDS.Util.RDSAuthTokenGenerator.GenerateAuthToken(RegionEndpoint.USEast1,
                "mysqldb.123456789012.us-east-1.rds.amazonaws.com", 3306, "jane_doe");
            // for debug only
            Console.Write("{0}\n", pwd);  //this verifies the token is generated

            MySqlConnection conn = new MySqlConnection($"server=mysqldb.123456789012.us-east-1.rds.amazonaws.com;user=jane_doe;database=mydB;port=3306;password={pwd};SslMode=Required;");
            conn.Open();

            // Define a query
            MySqlCommand sampleCommand = new MySqlCommand("SHOW DATABASES;", conn);

            // Execute a query
            MySqlDataReader mysqlDataRdr = sampleCommand.ExecuteReader();
        }
    }
}
```
// Read all rows and output the first column in each row
while (mysqlDataRdr.Read())
    Console.WriteLine(mysqlDataRdr[0]);

mysqlDataRdr.Close();
// Close connection
conn.Close();

This code connects to a PostgreSQL DB instance.

Modify the values of the following variables as needed:

- **Server** – The endpoint of the DB instance that you want to access
- **User ID** – The database account that you want to access
- **Database** – The database that you want to access
- **Port** – The port number used for connecting to your DB instance
- **SSL Mode** – The SSL mode to use

When you use **SSL Mode=Required**, the SSL connection verifies the DB instance endpoint against the endpoint in the SSL certificate.

- **Root Certificate** – The full path to the SSL certificate for Amazon RDS

To download a certificate, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#).

---

**Note**

You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

```csharp
using System;
using Npgsql;
using Amazon.RDS.Util;

namespace ConsoleApp1
{
```
class Program
{
    static void Main(string[] args)
    {
        var pwd = RDSAuthTokenGenerator.GenerateAuthToken("postgresmydb.123456789012.us-east-1.rds.amazonaws.com", 5432, "jane_doe");
        // for debug only Console.Write("{0}\n", pwd); //this verifies the token is generated
        NpgsqlConnection conn = new NpgsqlConnection($"Server=postgresmydb.123456789012.us-east-1.rds.amazonaws.com;User Id=jane_doe;Password={pwd};Database=mydb;SSL Mode=Require;Root Certificate=full_path_to_ssl_certificate");
        conn.Open();
        // Define a query
        NpgsqlCommand cmd = new NpgsqlCommand("select count(*) FROM pg_user", conn);
        // Execute a query
        NpgsqlDataReader dr = cmd.ExecuteReader();
        // Read all rows and output the first column in each row
        while (dr.Read())
            Console.Write("{0}\n", dr[0]);
        // Close connection
        conn.Close();
    }
}

If you want to connect to a DB instance through a proxy, see Connecting to a proxy using IAM authentication.

Connecting to your DB instance using IAM authentication and the AWS SDK for Go

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for Go as described following.

Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:
- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

Examples

To run these code examples, you need the [AWS SDK for Go](https://aws.amazon.com/sdk-for-go/), found on the AWS site.

Modify the values of the following variables as needed:

- `dbName` – The database that you want to access
- `dbUser` – The database account that you want to access
- `dbHost` – The endpoint of the DB instance that you want to access
- `dbPort` – The port number used for connecting to your DB instance
- `region` – The AWS Region where the DB instance is running

In addition, make sure the imported libraries in the sample code exist on your system.

**Note**

You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

**Important**

The examples in this section use the following code to provide credentials that access a database from a local environment:

```go
creds := credentials.NewEnvCredentials()
```

If you are accessing a database from an AWS service, such as Amazon EC2 or Amazon ECS, you can replace the code with the following code:

```go
sess := session.Must(session.NewSession())
creds := sess.Config.Credentials
```

If you make this change, make sure you add the following import:
```
"github.com/aws/aws-sdk-go/aws/session"
```
Connecting using IAM authentication and the AWS SDK for Go V2

You can connect to a DB instance using IAM authentication and the AWS SDK for Go V2.

The following code examples show how to generate an authentication token, and then use it to connect to a DB instance.

This code connects to a MariaDB or MySQL DB instance.

```go
package main

import (
    "context"
    "database/sql"
    "fmt"
    
    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/feature/rds/auth"
    _ "github.com/go-sql-driver/mysql"
)

func main() {
    var dbName string = "DatabaseName"
    var dbUser string = "DatabaseUser"
    var dbHost string = "mysql$db.123456789012.us-east-1.rds.amazonaws.com"
    var dbPort int = 3306
    var dbEndpoint string = fmt.Sprintf("%s:%d", dbHost, dbPort)
    var region string = "us-east-1"

    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        panic("configuration error: " + err.Error())
    }

    authenticationToken, err := auth.BuildAuthToken(
        context.TODO(), dbEndpoint, region, dbUser, cfg.Credentials)
    if err != nil {
        // Handle error
    }
}
```
This code connects to a PostgreSQL DB instance.

golang

package main

import (  
    "context"  
    "database/sql"  
    "fmt"  
    "github.com/aws/aws-sdk-go-v2/config"  
    "github.com/aws/aws-sdk-go-v2/feature/rds/auth"  
    _ "github.com/lib/pq"
)

func main() {
    var dbName string = "DatabaseName"  
    var dbUser string = "DatabaseUser"  
    var dbHost string = "postgresmydb.123456789012.us-east-1.rds.amazonaws.com"  
    var dbPort int = 5432  
    var dbEndpoint string = fmt.Sprintf("%s:%d", dbHost, dbPort)  
    var region string = "us-east-1"

    cfg, err := config.LoadDefaultConfig(context.TODO())  
    if err != nil {
        panic(err)
    }

    dsn := fmt.Sprintf("%s:%s@tcp(%s)/%s?tls=true&allowCleartextPasswords=true", 
        dbUser, authToken, dbEndpoint, dbName,
    )

    db, err := sql.Open("mysql", dsn)  
    if err != nil {
        panic(err)
    }

    err = db.Ping()  
    if err != nil {
        panic(err)
    }
}
If you want to connect to a DB instance through a proxy, see Connecting to a proxy using IAM authentication.

Connecting using IAM authentication and the AWS SDK for Go V1.

You can connect to a DB instance using IAM authentication and the AWS SDK for Go V1.

The following code examples show how to generate an authentication token, and then use it to connect to a DB instance.

This code connects to a MariaDB or MySQL DB instance.

```go
package main

import (
    "database/sql"
    "fmt"
    "log"
)

func main() {
    panic("configuration error: " + err.Error())
}

authenticationToken, err := auth.BuildAuthToken(
    context.TODO(), dbEndpoint, region, dbUser, cfg.Credentials)
if err != nil {
    panic("failed to create authentication token: " + err.Error())
}

dsn := fmt.Sprintf("host=%s port=%d user=%s password=%s dbname=%s",
    dbHost, dbPort, dbUser, authenticationToken, dbName,
)

db, err := sql.Open("postgres", dsn)
if err != nil {
    panic(err)
}

err = db.Ping()
if err != nil {
    panic(err)
}
}
```
func main() {
    dbName := "app"
    dbUser := "jane_doe"
    dbHost := "mysql.db.123456789012.us-east-1.rds.amazonaws.com"
    dbPort := 3306
    dbEndpoint := fmt.Sprintf("%s:%d", dbHost, dbPort)
    region := "us-east-1"

    creds := credentials.NewEnvCredentials()
    authToken, err := rdsutils.BuildAuthToken(dbEndpoint, region, dbUser, creds)
    if err != nil {
        panic(err)
    }

    dsn := fmt.Sprintf("%s:%s@tcp(%s)/%s?tls=true&allowCleartextPasswords=true", dbUser, authToken, dbEndpoint, dbName,
    )

    db, err := sql.Open("mysql", dsn)
    if err != nil {
        panic(err)
    }

    err = db.Ping()
    if err != nil {
        panic(err)
    }
}

This code connects to a PostgreSQL DB instance.
func main() {
    dbName := "app"
    dbUser := "jane_doe"
    dbHost := "postgresmydb.123456789012.us-east-1.rds.amazonaws.com"
    dbPort := 5432
    dbEndpoint := fmt.Sprintf("%s:%d", dbHost, dbPort)
    region := "us-east-1"
    creds := credentials.NewEnvCredentials()
    authToken, err := rdsutils.BuildAuthToken(dbEndpoint, region, dbUser, creds)
    if err != nil {
        panic(err)
    }
    dsn := fmt.Sprintf("host=%s port=%d user=%s password=%s dbname=%s",
        dbHost, dbPort, dbUser, authToken, dbName,
    )
    db, err := sql.Open("postgres", dsn)
    if err != nil {
        panic(err)
    }
    err = db.Ping()
    if err != nil {
        panic(err)
    }
}

If you want to connect to a DB instance through a proxy, see [Connecting to a proxy using IAM authentication](#).

**Connecting to your DB instance using IAM authentication and the AWS SDK for Java**

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for Java as described following.

**Prerequisites**

The following are prerequisites for connecting to your DB instance using IAM authentication:
Generating an IAM authentication token

If you are writing programs using the AWS SDK for Java, you can get a signed authentication token using the RdsIamAuthTokenGenerator class. Using this class requires that you provide AWS credentials. To do this, you create an instance of the DefaultAWSCredentialsProviderChain class. DefaultAWSCredentialsProviderChain uses the first AWS access key and secret key that it finds in the default credential provider chain. For more information about AWS access keys, see Managing access keys for users.

⚠️ **Note**
You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

After you create an instance of RdsIamAuthTokenGenerator, you can call the getAuthToken method to obtain a signed token. Provide the AWS Region, host name, port number, and user name. The following code example illustrates how to do this.

```java
package com.amazonaws.codesamples;

import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.services.rds.auth.GetIamAuthTokenRequest;
import com.amazonaws.services.rds.auth.RdsIamAuthTokenGenerator;

public class GenerateRDSAuthToken {
```
Manually constructing an IAM authentication token

In Java, the easiest way to generate an authentication token is to use `RdsIamAuthTokenGenerator`. This class creates an authentication token for you, and then signs it using AWS signature version 4. For more information, see Signature version 4 signing process in the AWS General Reference.

However, you can also construct and sign an authentication token manually, as shown in the following code example.

```java
import com.amazonaws.SdkClientException;

package com.amazonaws.codesamples;

public static void main(String[] args) {
    String region = "us-west-2";
    String hostname = "rdsmysql.123456789012.us-west-2.rds.amazonaws.com";
    String port = "3306";
    String username = "jane_doe";

    System.out.println(generateAuthToken(region, hostname, port, username));
}

static String generateAuthToken(String region, String hostName, String port, String username) {
    RdsIamAuthTokenGenerator generator = RdsIamAuthTokenGenerator.builder()
            .credentials(new DefaultAWSCredentialsProviderChain())
            .region(region)
            .build();

    String authToken = generator.getAuthToken(
            GetIamAuthTokenRequest.builder()
                    .hostname(hostName)
                    .port(Integer.parseInt(port))
                    .userName(username)
                    .build());

    return authToken;
}
```

            + e.getMessage(), e);
    }
}
Connecting to a DB instance

The following code example shows how to generate an authentication token, and then use it to connect to an instance running MariaDB or MySQL.

To run this code example, you need the AWS SDK for Java, found on the AWS site. In addition, you need the following:

- MySQL Connector/J. This code example was tested with mysql-connector-java-5.1.33-bin.jar.
- An intermediate certificate for Amazon RDS that is specific to an AWS Region. (For more information, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.) At runtime, the class loader looks for the certificate in the same directory as this Java code example, so that the class loader can find it.

- Modify the values of the following variables as needed:
  - RDS_INSTANCE_HOSTNAME – The host name of the DB instance that you want to access.
  - RDS_INSTANCE_PORT – The port number used for connecting to your PostgreSQL DB instance.
  - REGION_NAME – The AWS Region where the DB instance is running.
  - DB_USER – The database account that you want to access.
  - SSL_CERTIFICATE – An SSL certificate for Amazon RDS that is specific to an AWS Region.

To download a certificate for your AWS Region, see Using SSL/TLS to encrypt a connection to a DB instance or cluster. Place the SSL certificate in the same directory as this Java program file, so that the class loader can find the certificate at runtime.

This code example obtains AWS credentials from the default credential provider chain.

⚠️ Note

Specify a password for DEFAULT_KEY_STORE_PASSWORD other than the prompt shown here as a security best practice.

        KeyStore ks = KeyStore.getInstance(KEY_STORE_TYPE, KEY_STORE_PROVIDER);
        ks.load(null);
        ks.setCertificateEntry("rootCaCertificate", rootX509Certificate);
        ks.store(fos, DEFAULT_KEY_STORE_PASSWORD.toCharArray());
    }
}
```
If you want to connect to a DB instance through a proxy, see Connecting to a proxy using IAM authentication.

Connecting to your DB instance using IAM authentication and the AWS SDK for Python (Boto3)

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for Python (Boto3) as described following.

Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

In addition, make sure the imported libraries in the sample code exist on your system.

Examples

The code examples use profiles for shared credentials. For information about the specifying credentials, see Credentials in the AWS SDK for Python (Boto3) documentation.

The following code examples show how to generate an authentication token, and then use it to connect to a DB instance.

To run this code example, you need the AWS SDK for Python (Boto3), found on the AWS site.
Modify the values of the following variables as needed:

- **ENDPOINT** – The endpoint of the DB instance that you want to access
- **PORT** – The port number used for connecting to your DB instance
- **USER** – The database account that you want to access
- **REGION** – The AWS Region where the DB instance is running
- **DBNAME** – The database that you want to access
- **SSLCERTIFICATE** – The full path to the SSL certificate for Amazon RDS

For ssl_ca, specify an SSL certificate. To download an SSL certificate, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.

**Note**

You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

This code connects to a MariaDB or MySQL DB instance.

Before running this code, install the PyMySQL driver by following the instructions in the Python Package Index.

```python
import pymysql
import sys
import boto3
import os

ENDPOINT="mysqldb.123456789012.us-east-1.rds.amazonaws.com"
PORT="3306"
USER="jane_doe"
REGION="us-east-1"
DBNAME="mydb"
os.environ['LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN'] = '1'

# gets the credentials from .aws/credentials
session = boto3.Session(profile_name='default')
client = session.client('rds')
```
token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USER, Region=REGION)

try:
    conn = pymysql.connect(host=ENDPOINT, user=USER, passwd=token, port=PORT, 
                         database=DBNAME, ssl_ca='SSLCERTIFICATE')
    cur = conn.cursor()
    cur.execute("""SELECT now()""")
    query_results = cur.fetchall()
    print(query_results)
except Exception as e:
    print("Database connection failed due to {}").format(e)

This code connects to a PostgreSQL DB instance.

Before running this code, install psycopg2 by following the instructions in Psycopg documentation.

import psycopg2
import sys
import boto3
import os
ENDPOINT="postgresmydb.123456789012.us-east-1.rds.amazonaws.com"
PORT="5432"
USER="jane_doe"
REGION="us-east-1"
DBNAME="mydb"

#gets the credentials from .aws/credentials
session = boto3.Session(profile_name='RDSCreds')
client = session.client('rds')

token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USER, Region=REGION)

try:
    conn = psycopg2.connect(host=ENDPOINT, port=PORT, database=DBNAME, user=USER, 
                            password=token, sslrootcert="SSLCERTIFICATE")
    cur = conn.cursor()
    cur.execute("""SELECT now()""")
query_results = cur.fetchall()
print(query_results)
except Exception as e:
    print("Database connection failed due to {}".format(e))

If you want to connect to a DB instance through a proxy, see Connecting to a proxy using IAM authentication.

Troubleshooting Amazon RDS identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with Amazon RDS and IAM.

Topics

- I'm not authorized to perform an action in Amazon RDS
- I'm not authorized to perform iam:PassRole
- I want to allow people outside of my AWS account to access my Amazon RDS resources

I'm not authorized to perform an action in Amazon RDS

If the AWS Management Console tells you that you're not authorized to perform an action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your sign-in credentials.

The following example error occurs when the mateojackson user tries to use the console to view details about a widget but does not have rds:GetWidget permissions.

User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform:
    rds:GetWidget on resource: my-example-widget

In this case, Mateo asks his administrator to update his policies to allow him to access the my-example-widget resource using the rds:GetWidget action.

I'm not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the iam:PassRole action, then you must contact your administrator for assistance. Your administrator is the person that provided you
with your sign-in credentials. Ask that person to update your policies to allow you to pass a role to Amazon RDS.

Some AWS services allow you to pass an existing role to that service, instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when a user named marymajor tries to use the console to perform an action in Amazon RDS. However, the action requires the service to have permissions granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform:
iam:PassRole
```

In this case, Mary asks her administrator to update her policies to allow her to perform the iam:PassRole action.

**I want to allow people outside of my AWS account to access my Amazon RDS resources**

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Amazon RDS supports these features, see [How Amazon RDS works with IAM](https://docs.aws.amazon.com/rds/latest/userguide/using-iam.html).
- To learn how to provide access to your resources across AWS accounts that you own, see [Providing access to an IAM user in another AWS account that you own](https://docs.aws.amazon.com/iam/latest/userguide/idp-create-account-policy.html) in the IAM User Guide.
- To learn how to provide access to your resources to third-party AWS accounts, see [Providing access to AWS accounts owned by third parties](https://docs.aws.amazon.com/iam/latest/userguide/idp-create-account-policy.html) in the IAM User Guide.
- To learn how to provide access through identity federation, see [Providing access to externally authenticated users (identity federation)](https://docs.aws.amazon.com/iam/latest/userguide/using-iam-identity-provider.html) in the IAM User Guide.
- To learn the difference between using roles and resource-based policies for cross-account access, see [How IAM roles differ from resource-based policies](https://docs.aws.amazon.com/iam/latest/userguide/using-iam-account-access.html) in the IAM User Guide.
Logging and monitoring in Amazon RDS

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon RDS and your AWS solutions. You should collect monitoring data from all of the parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. AWS provides several tools for monitoring your Amazon RDS resources and responding to potential incidents:

**Amazon CloudWatch Alarms**

Using Amazon CloudWatch alarms, you watch a single metric over a time period that you specify. If the metric exceeds a given threshold, a notification is sent to an Amazon SNS topic or AWS Auto Scaling policy. CloudWatch alarms do not invoke actions because they are in a particular state. Rather the state must have changed and been maintained for a specified number of periods.

**AWS CloudTrail Logs**

CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon RDS. CloudTrail captures all API calls for Amazon RDS as events, including calls from the console and from code calls to Amazon RDS API operations. Using the information collected by CloudTrail, you can determine the request that was made to Amazon RDS, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see [Monitoring Amazon RDS API calls in AWS CloudTrail](#).

**Enhanced Monitoring**

Amazon RDS provides metrics in real time for the operating system (OS) that your DB instance runs on. You can view the metrics for your DB instance using the console, or consume the Enhanced Monitoring JSON output from Amazon CloudWatch Logs in a monitoring system of your choice. For more information, see [Monitoring OS metrics with Enhanced Monitoring](#).

**Amazon RDS Performance Insights**

Performance Insights expands on existing Amazon RDS monitoring features to illustrate your database's performance and help you analyze any issues that affect it. With the Performance Insights dashboard, you can visualize the database load and filter the load by waits, SQL statements, hosts, or users. For more information, see [Monitoring DB load with Performance Insights on Amazon RDS](#).
Database Logs

You can view, download, and watch database logs using the AWS Management Console, AWS CLI, or RDS API. For more information, see Monitoring Amazon RDS log files.

Amazon RDS Recommendations

Amazon RDS provides automated recommendations for database resources. These recommendations provide best practice guidance by analyzing DB instance configuration, usage, and performance data. For more information, see Viewing and responding to Amazon RDS recommendations.

Amazon RDS Event Notification

Amazon RDS uses the Amazon Simple Notification Service (Amazon SNS) to provide notification when an Amazon RDS event occurs. These notifications can be in any notification form supported by Amazon SNS for an AWS Region, such as an email, a text message, or a call to an HTTP endpoint. For more information, see Working with Amazon RDS event notification.

AWS Trusted Advisor

Trusted Advisor draws upon best practices learned from serving hundreds of thousands of AWS customers. Trusted Advisor inspects your AWS environment and then makes recommendations when opportunities exist to save money, improve system availability and performance, or help close security gaps. All AWS customers have access to five Trusted Advisor checks. Customers with a Business or Enterprise support plan can view all Trusted Advisor checks.

Trusted Advisor has the following Amazon RDS-related checks:

- Amazon RDS Idle DB Instances
- Amazon RDS Security Group Access Risk
- Amazon RDS Backups
- Amazon RDS Multi-AZ

For more information on these checks, see Trusted Advisor best practices (checks).

For more information about monitoring Amazon RDS, see Monitoring metrics in an Amazon RDS instance.
Compliance validation for Amazon RDS

Third-party auditors assess the security and compliance of Amazon RDS as part of multiple AWS compliance programs. These include SOC, PCI, FedRAMP, HIPAA, and others.

For a list of AWS services in scope of specific compliance programs, see AWS services in scope by compliance program. For general information, see AWS compliance programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading reports in AWS Artifact.

Your compliance responsibility when using Amazon RDS is determined by the sensitivity of your data, your organization’s compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- **Security and compliance quick start guides** – These deployment guides discuss architectural considerations and provide steps for deploying security- and compliance-focused baseline environments on AWS.
- **Architecting for HIPAA Security and Compliance on Amazon Web Services** – This whitepaper describes how companies can use AWS to create HIPAA-compliant applications.
- **AWS compliance resources** – This collection of workbooks and guides that might apply to your industry and location.
- **AWS Config** – This AWS service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- **AWS Security Hub** – This AWS service provides a comprehensive view of your security state within AWS. Security Hub uses security controls to evaluate your AWS resources and to check your compliance against security industry standards and best practices. For a list of supported services and controls, see Security Hub controls reference.
Resilience in Amazon RDS

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see [AWS global infrastructure](#).

In addition to the AWS global infrastructure, Amazon RDS offers features to help support your data resiliency and backup needs.

Backup and restore

Amazon RDS creates and saves automated backups of your DB instance. Amazon RDS creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases.

Amazon RDS creates automated backups of your DB instance during the backup window of your DB instance. Amazon RDS saves the automated backups of your DB instance according to the backup retention period that you specify. If necessary, you can recover your database to any point in time during the backup retention period. You can also back up your DB instance manually, by manually creating a DB snapshot.

You can create a DB instance by restoring from this DB snapshot as a disaster recovery solution if the source DB instance fails.

For more information, see [Backing up, restoring, and exporting data](#).

Replication

Amazon RDS uses the MariaDB, MySQL, Oracle, and PostgreSQL DB engines' built-in replication functionality to create a special type of DB instance called a read replica from a source DB instance. Updates made to the source DB instance are asynchronously copied to the read replica. You can reduce the load on your source DB instance by routing read queries from your applications to the read replica. Using read replicas, you can elastically scale out beyond the capacity constraints of a single DB instance for read-heavy database workloads. You can promote a read replica to a
standalone instance as a disaster recovery solution if the source DB instance fails. For some DB engines, Amazon RDS also supports other replication options.

For more information, see Working with DB instance read replicas.

**Failover**

Amazon RDS provides high availability and failover support for DB instances using Multi-AZ deployments. Amazon RDS uses several different technologies to provide failover support. Multi-AZ deployments for Oracle, PostgreSQL, MySQL, and MariaDB DB instances use Amazon's failover technology. SQL Server DB instances use SQL Server Database Mirroring (DBM).

For more information, see Configuring and managing a Multi-AZ deployment.
Infrastructure security in Amazon RDS

As a managed service, Amazon Relational Database Service is protected by AWS global network security. For information about AWS security services and how AWS protects infrastructure, see AWS Cloud Security. To design your AWS environment using the best practices for infrastructure security, see Infrastructure Protection in Security Pillar AWS Well-Architected Framework.

You use AWS published API calls to access Amazon RDS through the network. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

In addition, Amazon RDS offers features to help support infrastructure security.

Security groups

Security groups control the access that traffic has in and out of a DB instance. By default, network access is turned off to a DB instance. You can specify rules in a security group that allow access from an IP address range, port, or security group. After ingress rules are configured, the same rules apply to all DB instances that are associated with that security group.

For more information, see Controlling access with security groups.

Public accessibility

When you launch a DB instance inside a virtual private cloud (VPC) based on the Amazon VPC service, you can turn on or off public accessibility for that DB instance. To designate whether the DB instance that you create has a DNS name that resolves to a public IP address, you use the Public accessibility parameter. By using this parameter, you can designate whether there is public access to the DB instance. You can modify a DB instance to turn on or off public accessibility by modifying the Public accessibility parameter.
For more information, see [Hiding a DB instance in a VPC from the internet](https://aws.amazon.com/rds/userguide/#hiding-a-db-instance-in-a-vpc-from-the-internet).

⚠️ **Note**

If your DB instance is in a VPC but isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see [Internetwork traffic privacy](https://aws.amazon.com/rds/userguide/#internetwork-traffic-privacy).
Amazon RDS API and interface VPC endpoints (AWS PrivateLink)

You can establish a private connection between your VPC and Amazon RDS API endpoints by creating an *interface VPC endpoint*. Interface endpoints are powered by *AWS PrivateLink*.

AWS PrivateLink enables you to privately access Amazon RDS API operations without an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. DB instances in your VPC don't need public IP addresses to communicate with Amazon RDS API endpoints to launch, modify, or terminate DB instances. Your DB instances also don't need public IP addresses to use any of the available RDS API operations. Traffic between your VPC and Amazon RDS doesn't leave the Amazon network.

Each interface endpoint is represented by one or more elastic network interfaces in your subnets. For more information on elastic network interfaces, see *Elastic network interfaces* in the *Amazon EC2 User Guide*.

For more information about VPC endpoints, see *Interface VPC endpoints (AWS PrivateLink)* in the *Amazon VPC User Guide*. For more information about RDS API operations, see *Amazon RDS API Reference*.

You don't need an interface VPC endpoint to connect to a DB instance. For more information, see *Scenarios for accessing a DB instance in a VPC*.

**Considerations for VPC endpoints**

Before you set up an interface VPC endpoint for Amazon RDS API endpoints, ensure that you review *Interface endpoint properties and limitations* in the *Amazon VPC User Guide*.

All RDS API operations relevant to managing Amazon RDS resources are available from your VPC using AWS PrivateLink.

VPC endpoint policies are supported for RDS API endpoints. By default, full access to RDS API operations is allowed through the endpoint. For more information, see *Controlling access to services with VPC endpoints* in the *Amazon VPC User Guide*.

**Availability**

Amazon RDS API currently supports VPC endpoints in the following AWS Regions:
- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Canada West (Calgary)
- China (Beijing)
- China (Ningxia)
- Europe (Frankfurt)
- Europe (Zurich)
- Europe (Ireland)
- Europe (London)
- Europe (Paris)
- Europe (Stockholm)
- Europe (Milan)
- Israel (Tel Aviv)
- Middle East (Bahrain)
- South America (São Paulo)
- AWS GovCloud (US-East)
- AWS GovCloud (US-West)
Creating an interface VPC endpoint for Amazon RDS API

You can create a VPC endpoint for the Amazon RDS API using either the Amazon VPC console or the AWS Command Line Interface (AWS CLI). For more information, see Creating an interface endpoint in the Amazon VPC User Guide.

Create a VPC endpoint for Amazon RDS API using the service name com.amazonaws.region.rds.

Excluding AWS Regions in China, if you enable private DNS for the endpoint, you can make API requests to Amazon RDS with the VPC endpoint using its default DNS name for the AWS Region, for example rds.us-east-1.amazonaws.com. For the China (Beijing) and China (Ningxia) AWS Regions, you can make API requests with the VPC endpoint using rds-api.cn-north-1.amazonaws.com.cn and rds-api.cn-northwest-1.amazonaws.com.cn, respectively.

For more information, see Accessing a service through an interface endpoint in the Amazon VPC User Guide.

Creating a VPC endpoint policy for Amazon RDS API

You can attach an endpoint policy to your VPC endpoint that controls access to Amazon RDS API. The policy specifies the following information:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

For more information, see Controlling access to services with VPC endpoints in the Amazon VPC User Guide.

Example: VPC endpoint policy for Amazon RDS API actions

The following is an example of an endpoint policy for Amazon RDS API. When attached to an endpoint, this policy grants access to the listed Amazon RDS API actions for all principals on all resources.

```json
{
    "Statement":[
```
Example: VPC endpoint policy that denies all access from a specified AWS account

The following VPC endpoint policy denies AWS account 123456789012 all access to resources using the endpoint. The policy allows all actions from other accounts.

```json
{
   "Statement": [
      {
         "Action": "*",
         "Effect": "Allow",
         "Resource": "*",
         "Principal": "*"
      },
      {
         "Action": "*",
         "Effect": "Deny",
         "Resource": "*",
         "Principal": {
            "AWS": [
               "123456789012"
            ]
         }
      }
   ]
}
```

Security best practices for Amazon RDS

Use AWS Identity and Access Management (IAM) accounts to control access to Amazon RDS API operations, especially operations that create, modify, or delete Amazon RDS resources.
Such resources include DB instances, security groups, and parameter groups. Also use IAM to control actions that perform common administrative actions such as backing up and restoring DB instances.

- Create an individual user for each person who manages Amazon RDS resources, including yourself. Don't use AWS root credentials to manage Amazon RDS resources.
- Grant each user the minimum set of permissions required to perform his or her duties.
- Use IAM groups to effectively manage permissions for multiple users.
- Rotate your IAM credentials regularly.
- Configure AWS Secrets Manager to automatically rotate the secrets for Amazon RDS. For more information, see Rotating your AWS Secrets Manager secrets in the AWS Secrets Manager User Guide. You can also retrieve the credential from AWS Secrets Manager programmatically. For more information, see Retrieving the secret value in the AWS Secrets Manager User Guide.

For more information about Amazon RDS security, see Security in Amazon RDS. For more information about IAM, see AWS Identity and Access Management. For information on IAM best practices, see IAM best practices.

AWS Security Hub uses security controls to evaluate resource configurations and security standards to help you comply with various compliance frameworks. For more information about using Security Hub to evaluate RDS resources, see Amazon Relational Database Service controls in the AWS Security Hub User Guide.

You can monitor your usage of RDS as it relates to security best practices by using Security Hub. For more information, see What is AWS Security Hub?

Use the AWS Management Console, the AWS CLI, or the RDS API to change the password for your master user. If you use another tool, such as a SQL client, to change the master user password, it might result in privileges being revoked for the user unintentionally.

## Controlling access with security groups

VPC security groups control the access that traffic has in and out of a DB instance. By default, network access is turned off for a DB instance. You can specify rules in a security group that allow access from an IP address range, port, or security group. After ingress rules are configured, the same rules apply to all DB instances that are associated with that security group. You can specify up to 20 rules in a security group.
Overview of VPC security groups

Each VPC security group rule makes it possible for a specific source to access a DB instance in a VPC that is associated with that VPC security group. The source can be a range of addresses (for example, 203.0.113.0/24), or another VPC security group. By specifying a VPC security group as the source, you allow incoming traffic from all instances (typically application servers) that use the source VPC security group. VPC security groups can have rules that govern both inbound and outbound traffic. However, the outbound traffic rules typically don't apply to DB instances. Outbound traffic rules apply only if the DB instance acts as a client. For example, outbound traffic rules apply to an Oracle DB instance with outbound database links. You must use the Amazon EC2 API or the Security Group option on the VPC console to create VPC security groups.

When you create rules for your VPC security group that allow access to the instances in your VPC, you must specify a port for each range of addresses that the rule allows access for. For example, if you want to turn on Secure Shell (SSH) access for instances in the VPC, create a rule allowing access to TCP port 22 for the specified range of addresses.

You can configure multiple VPC security groups that allow access to different ports for different instances in your VPC. For example, you can create a VPC security group that allows access to TCP port 80 for web servers in your VPC. You can then create another VPC security group that allows access to TCP port 3306 for RDS for MySQL DB instances in your VPC.

For more information on VPC security groups, see Security groups in the Amazon Virtual Private Cloud User Guide.

⚠️ Note

If your DB instance is in a VPC but isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy.

Security group scenario

A common use of a DB instance in a VPC is to share data with an application server running in an Amazon EC2 instance in the same VPC, which is accessed by a client application outside the VPC. For this scenario, you use the RDS and VPC pages on the AWS Management Console or the RDS and EC2 API operations to create the necessary instances and security groups:
1. Create a VPC security group (for example, sg-0123ec2example) and define inbound rules that use the IP addresses of the client application as the source. This security group allows your client application to connect to EC2 instances in a VPC that uses this security group.

2. Create an EC2 instance for the application and add the EC2 instance to the VPC security group (sg-0123ec2example) that you created in the previous step.

3. Create a second VPC security group (for example, sg-6789rdsexample) and create a new rule by specifying the VPC security group that you created in step 1 (sg-0123ec2example) as the source.

4. Create a new DB instance and add the DB instance to the VPC security group (sg-6789rdsexample) that you created in the previous step. When you create the DB instance, use the same port number as the one specified for the VPC security group (sg-6789rdsexample) rule that you created in step 3.

The following diagram shows this scenario.
For detailed instructions about configuring a VPC for this scenario, see Tutorial: Create a VPC for use with a DB instance (IPv4 only). For more information about using a VPC, see Amazon VPC VPCs and Amazon RDS.

Creating a VPC security group

You can create a VPC security group for a DB instance by using the VPC console. For information about creating a security group, see Provide access to your DB instance in your VPC by creating a security group and Security groups in the Amazon Virtual Private Cloud User Guide.
Associating a security group with a DB instance

You can associate a security group with a DB instance by using Modify on the RDS console, the ModifyDBInstance Amazon RDS API, or the modify-db-instance AWS CLI command.

The following CLI example associates a specific VPC security group and removes DB security groups from the DB instance

```bash
aws rds modify-db-instance --db-instance-identifier dbName --vpc-security-group-ids sg-ID
```

For information about modifying a DB instance, see Modifying an Amazon RDS DB instance. For security group considerations when you restore a DB instance from a DB snapshot, see Security group considerations.

⚠️ Note

The RDS console displays different security group rule names for your database if the Port value is configured to a non-default value.

Master user account privileges

When you create a new DB instance, the default master user that you use gets certain privileges for that DB instance. You can't change the master user name after the DB instance is created.

⚠️ Important

We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

⚠️ Note

If you accidentally delete the permissions for the master user, you can restore them by modifying the DB instance and setting a new master user password. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.
The following table shows the privileges and database roles the master user gets for each of the database engines.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>System privilege</th>
<th>Database role</th>
</tr>
</thead>
<tbody>
<tr>
<td>Db2</td>
<td>The master user is assigned to the masterdba group and assigned the master_user_role.</td>

</tr>
</tbody>
</table>

Master user account privileges
Using service-linked roles for Amazon RDS

Amazon RDS uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Amazon RDS. Service-linked roles are predefined by Amazon RDS and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes using Amazon RDS easier because you don't have to manually add the necessary permissions. Amazon RDS defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon RDS can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete the roles only after first deleting their related resources. This protects your Amazon RDS resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS services that work with IAM and look for the services that have Yes in the Service-Linked Role column. Choose a Yes with a link to view the service-linked role documentation for that service.

Service-linked role permissions for Amazon RDS

Amazon RDS uses the service-linked role named AWSServiceRoleForRDS to allow Amazon RDS to call AWS services on behalf of your DB instances.

The AWSServiceRoleForRDS service-linked role trusts the following services to assume the role:

- rds.amazonaws.com

This service-linked role has a permissions policy attached to it called AmazonRDSServiceRolePolicy that grants it permissions to operate in your account. The role permissions policy allows Amazon RDS to complete the following actions on the specified resources:

For more information about this policy, including the JSON policy document, see AmazonRDSServiceRolePolicy in the AWS Managed Policy Reference Guide.
Note

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message: **Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.** Make sure you have the following permissions enabled:

```json
{
    "Action": "iam:CreateServiceLinkedRole",
    "Effect": "Allow",
    "Resource": "arn:aws:iam::*:role/aws-service-role/rds.amazonaws.com/AWSServiceRoleForRDS",
    "Condition": {
        "StringLike": {
            "iam:AWSServiceName": "rds.amazonaws.com"
        }
    }
}
```

For more information, see [Service-linked role permissions](https://docs.aws.amazon.com/iam/latest/userguide/service-linked-roles.html) in the *IAM User Guide*.

---

Creating a service-linked role for Amazon RDS

You don't need to manually create a service-linked role. When you create a DB instance, Amazon RDS creates the service-linked role for you.

**Important**

If you were using the Amazon RDS service before December 1, 2017, when it began supporting service-linked roles, then Amazon RDS created the AWSServiceRoleForRDS role in your account. To learn more, see [A new role appeared in my AWS account](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/USER_AWS-SERVICE-ROLE-NEW-RDS.html).

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a DB instance, Amazon RDS creates the service-linked role for you again.
Editing a service-linked role for Amazon RDS

Amazon RDS does not allow you to edit the AWSServiceRoleForRDS service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the IAM User Guide.

Deleting a service-linked role for Amazon RDS

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must delete all of your DB instances before you can delete the service-linked role.

Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first confirm that the role has no active sessions and remove any resources used by the role.

To check whether the service-linked role has an active session in the IAM console

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane of the IAM console, choose Roles. Then choose the name (not the check box) of the AWSServiceRoleForRDS role.
3. On the Summary page for the chosen role, choose the Access Advisor tab.
4. On the Access Advisor tab, review recent activity for the service-linked role.

Note

If you are unsure whether Amazon RDS is using the AWSServiceRoleForRDS role, you can try to delete the role. If the service is using the role, then the deletion fails and you can view the AWS Regions where the role is being used. If the role is being used, then you must wait for the session to end before you can delete the role. You cannot revoke the session for a service-linked role.

If you want to remove the AWSServiceRoleForRDS role, you must first delete all of your DB instances.
Deleting all of your instances

Use one of these procedures to delete each of your instances.

To delete an instance (console)

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the instance that you want to delete.
4. For Actions, choose Delete.
5. If you are prompted for Create final Snapshot?, choose Yes or No.
6. If you chose Yes in the previous step, for Final snapshot name enter the name of your final snapshot.
7. Choose Delete.

To delete an instance (CLI)

See delete-db-instance in the AWS CLI Command Reference.

To delete an instance (API)

See DeleteDBInstance in the Amazon RDS API Reference.

You can use the IAM console, the IAM CLI, or the IAM API to delete the AWSServiceRoleForRDS service-linked role. For more information, see Deleting a service-linked role in the IAM User Guide.

Service-linked role permissions for Amazon RDS Custom

Amazon RDS Custom uses the service-linked role named AWSServiceRoleForRDSCustom to allow RDS Custom to call AWS services on behalf of your DB instances and DB clusters.

The AWSServiceRoleForRDSCustom service-linked role trusts the following services to assume the role:

- custom.rds.amazonaws.com

This service-linked role has a permissions policy attached to it called AmazonRDSCustomServiceRolePolicy that grants it permissions to operate in your account.
The role permissions policy allows RDS Custom to complete the following actions on the specified resources:

For more information about this policy, including the JSON policy document, see AmazonRDSCustomServiceRolePolicy in the AWS Managed Policy Reference Guide.

Creating, editing, or deleting the service-linked role for RDS Custom works the same as for Amazon RDS. For more information, see Service-linked role permissions for Amazon RDS.

Note

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message:

Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.

Make sure you have the following permissions enabled:

```
{
    "Action": "iam:CreateServiceLinkedRole",
    "Effect": "Allow",
    "Resource": "arn:aws:iam::*:role/aws-service-role/custom.rds.amazonaws.com/AmazonRDSCustomServiceRolePolicy",
    "Condition": {
        "StringLike": {
            "iam:AWSServiceName": "custom.rds.amazonaws.com"
        }
    }
}
```

For more information, see Service-linked role permissions in the IAM User Guide.
Amazon VPC VPCs and Amazon RDS

Amazon Virtual Private Cloud (Amazon VPC) makes it possible for you to launch AWS resources, such as Amazon RDS DB instances, into a virtual private cloud (VPC).

When you use a VPC, you have control over your virtual networking environment. You can choose your own IP address range, create subnets, and configure routing and access control lists. There is no additional cost to run your DB instance in a VPC.

Accounts have a default VPC. All new DB instances are created in the default VPC unless you specify otherwise.

Topics

• Working with a DB instance in a VPC
• Updating the VPC for a DB instance
• Scenarios for accessing a DB instance in a VPC
• Tutorial: Create a VPC for use with a DB instance (IPv4 only)
• Tutorial: Create a VPC for use with a DB instance (dual-stack mode)
• Moving a DB instance not in a VPC into a VPC

Following, you can find a discussion about VPC functionality relevant to Amazon RDS DB instances. For more information about Amazon VPC, see Amazon VPC Getting Started Guide and Amazon VPC User Guide.

Working with a DB instance in a VPC

Your DB instance is in a virtual private cloud (VPC). A VPC is a virtual network that is logically isolated from other virtual networks in the AWS Cloud. Amazon VPC makes it possible for you to launch AWS resources, such as an Amazon RDS DB instance or Amazon EC2 instance, into a VPC. The VPC can either be a default VPC that comes with your account or one that you create. All VPCs are associated with your AWS account.

Your default VPC has three subnets that you can use to isolate resources inside the VPC. The default VPC also has an internet gateway that can be used to provide access to resources inside the VPC from outside the VPC.

For a list of scenarios involving Amazon RDS DB instances in a VPC and outside of a VPC, see Scenarios for accessing a DB instance in a VPC.
Topics

- Working with a DB instance in a VPC
- Working with DB subnet groups
- Shared subnets
- Amazon RDS IP addressing
- Hiding a DB instance in a VPC from the internet
- Creating a DB instance in a VPC

In the following tutorials, you can learn to create a VPC that you can use for a common Amazon RDS scenario:

- Tutorial: Create a VPC for use with a DB instance (IPv4 only)
- Tutorial: Create a VPC for use with a DB instance (dual-stack mode)

**Working with a DB instance in a VPC**

Here are some tips on working with a DB instance in a VPC:

- Your VPC must have at least two subnets. These subnets must be in two different Availability Zones in the AWS Region where you want to deploy your DB instance. A subnet is a segment of a VPC's IP address range that you can specify and that you can use to group DB instances based on your security and operational needs.

  For Multi-AZ deployments, defining a subnet for two or more Availability Zones in an AWS Region allows Amazon RDS to create a new standby in another Availability Zone as needed. Make sure to do this even for Single-AZ deployments, just in case you want to convert them to Multi-AZ deployments at some point.

  **Note**

  The DB subnet group for a Local Zone can have only one subnet.

- If you want your DB instance in the VPC to be publicly accessible, make sure to turn on the VPC attributes DNS hostnames and DNS resolution.

- Your VPC must have a DB subnet group that you create. You create a DB subnet group by specifying the subnets you created. Amazon RDS chooses a subnet and an IP address within that
subnet group to associate with your DB instance. The DB instance uses the Availability Zone that contains the subnet.

- Your VPC must have a VPC security group that allows access to the DB instance.

For more information, see Scenarios for accessing a DB instance in a VPC.

- The CIDR blocks in each of your subnets must be large enough to accommodate spare IP addresses for Amazon RDS to use during maintenance activities, including failover and compute scaling. For example, a range such as 10.0.0.0/24 and 10.0.1.0/24 is typically large enough.

- A VPC can have an instance tenancy attribute of either default or dedicated. All default VPCs have the instance tenancy attribute set to default, and a default VPC can support any DB instance class.

If you choose to have your DB instance in a dedicated VPC where the instance tenancy attribute is set to dedicated, the DB instance class of your DB instance must be one of the approved Amazon EC2 dedicated instance types. For example, the r5.large EC2 dedicated instance corresponds to the db.r5.large DB instance class. For information about instance tenancy in a VPC, see Dedicated instances in the Amazon Elastic Compute Cloud User Guide.

For more information about the instance types that can be in a dedicated instance, see Amazon EC2 dedicated instances on the EC2 pricing page.

**Note**

When you set the instance tenancy attribute to dedicated for a DB instance, it doesn't guarantee that the DB instance will run on a dedicated host.

- When an option group is assigned to a DB instance, it's associated with the DB instance's VPC. This linkage means that you can't use the option group assigned to a DB instance if you attempt to restore the DB instance into a different VPC.

- If you restore a DB instance into a different VPC, make sure to either assign the default option group to the DB instance, assign an option group that is linked to that VPC, or create a new option group and assign it to the DB instance. With persistent or permanent options, such as Oracle TDE, you must create a new option group that includes the persistent or permanent option when restoring a DB instance into a different VPC.
Working with DB subnet groups

Subnets are segments of a VPC's IP address range that you designate to group your resources based on security and operational needs. A DB subnet group is a collection of subnets (typically private) that you create in a VPC and that you then designate for your DB instances. By using a DB subnet group, you can specify a particular VPC when creating DB instances using the AWS CLI or RDS API. If you use the console, you can choose the VPC and subnet groups you want to use.

Each DB subnet group should have subnets in at least two Availability Zones in a given AWS Region. When creating a DB instance in a VPC, you choose a DB subnet group for it. From the DB subnet group, Amazon RDS chooses a subnet and an IP address within that subnet to associate with the DB instance. The DB uses the Availability Zone that contains the subnet.

If the primary DB instance of a Multi-AZ deployment fails, Amazon RDS can promote the corresponding standby and later create a new standby using an IP address of the subnet in one of the other Availability Zones.

The subnets in a DB subnet group are either public or private. The subnets are public or private, depending on the configuration that you set for their network access control lists (network ACLs) and routing tables. For a DB instance to be publicly accessible, all of the subnets in its DB subnet group must be public. If a subnet that's associated with a publicly accessible DB instance changes from public to private, it can affect DB instance availability.

To create a DB subnet group that supports dual-stack mode, make sure that each subnet that you add to the DB subnet group has an Internet Protocol version 6 (IPv6) CIDR block associated with it. For more information, see Amazon RDS IP addressing and Migrating to IPv6 in the Amazon VPC User Guide.

ℹ️ Note

The DB subnet group for a Local Zone can have only one subnet.

When Amazon RDS creates a DB instance in a VPC, it assigns a network interface to your DB instance by using an IP address from your DB subnet group. However, we strongly recommend that you use the Domain Name System (DNS) name to connect to your DB instance. We recommend this because the underlying IP address changes during failover.
Note

For each DB instance that you run in a VPC, make sure to reserve at least one address in each subnet in the DB subnet group for use by Amazon RDS for recovery actions.

Shared subnets

You can create a DB instance in a shared VPC.

Some considerations to keep in mind while using shared VPCs:

- You can move a DB instance from a shared VPC subnet to a non-shared VPC subnet and vice-versa.
- Participants in a shared VPC must create a security group in the VPC to allow them to create a DB instance.
- Owners and participants in a shared VPC can access the database by using SQL queries. However, only the creator of a resource can make any API calls on the resource.

Amazon RDS IP addressing

IP addresses enable resources in your VPC to communicate with each other, and with resources over the internet. Amazon RDS supports both IPv4 and IPv6 addressing protocols. By default, Amazon RDS and Amazon VPC use the IPv4 addressing protocol. You can't turn off this behavior. When you create a VPC, make sure to specify an IPv4 CIDR block (a range of private IPv4 addresses). You can optionally assign an IPv6 CIDR block to your VPC and subnets, and assign IPv6 addresses from that block to DB instances in your subnet.

Support for the IPv6 protocol expands the number of supported IP addresses. By using the IPv6 protocol, you ensure that you have sufficient available addresses for the future growth of the internet. New and existing RDS resources can use IPv4 and IPv6 addresses within your VPC. Configuring, securing, and translating network traffic between the two protocols used in different parts of an application can cause operational overhead. You can standardize on the IPv6 protocol for Amazon RDS resources to simplify your network configuration.

Topics

- IPv4 addresses
• **IPv6 addresses**

• **Dual-stack mode**

### IPv4 addresses

When you create a VPC, you must specify a range of IPv4 addresses for the VPC in the form of a CIDR block, such as `10.0.0.0/16`. A **DB subnet group** defines the range of IP addresses in this CIDR block that a DB instance can use. These IP addresses can be private or public.

A private IPv4 address is an IP address that’s not reachable over the internet. You can use private IPv4 addresses for communication between your DB instance and other resources, such as Amazon EC2 instances, in the same VPC. Each DB instance has a private IP address for communication in the VPC.

A public IP address is an IPv4 address that’s reachable from the internet. You can use public addresses for communication between your DB instance and resources on the internet, such as a SQL client. You control whether your DB instance receives a public IP address.

For a tutorial that shows you how to create a VPC with only private IPv4 addresses that you can use for a common Amazon RDS scenario, see [Tutorial: Create a VPC for use with a DB instance (IPv4 only)](#).

### IPv6 addresses

You can optionally associate an IPv6 CIDR block with your VPC and subnets, and assign IPv6 addresses from that block to the resources in your VPC. Each IPv6 address is globally unique.

The IPv6 CIDR block for your VPC is automatically assigned from Amazon’s pool of IPv6 addresses. You can’t choose the range yourself.

When connecting to an IPv6 address, make sure that the following conditions are met:

• The client is configured so that client to database traffic over IPv6 is allowed.

• RDS security groups used by the DB instance are configured correctly so that client to database traffic over IPv6 is allowed.

• The client operating system stack allows traffic on the IPv6 address, and operating system drivers and libraries are configured to choose the correct default DB instance endpoint (either IPv4 or IPv6).
For more information about IPv6, see IP Addressing in the Amazon VPC User Guide.

Dual-stack mode

When a DB instance can communicate over both the IPv4 and IPv6 addressing protocols, it's running in dual-stack mode. So, resources can communicate with the DB instance over IPv4, IPv6, or both. RDS disables Internet Gateway access for IPv6 endpoints of private dual-stack mode DB instances. RDS does this to ensure that your IPv6 endpoints are private and can only be accessed from within your VPC.

Topics

• Dual-stack mode and DB subnet groups
• Working with dual-stack mode DB instances
• Modifying IPv4-only DB instances to use dual-stack mode
• Region and version availability
• Limitations for dual-stack network DB instances

For a tutorial that shows you how to create a VPC with both IPv4 and IPv6 addresses that you can use for a common Amazon RDS scenario, see Tutorial: Create a VPC for use with a DB instance (dual-stack mode).

Dual-stack mode and DB subnet groups

To use dual-stack mode, make sure that each subnet in the DB subnet group that you associate with the DB instance has an IPv6 CIDR block associated with it. You can create a new DB subnet group or modify an existing DB subnet group to meet this requirement. After a DB instance is in dual-stack mode, clients can connect to it normally. Make sure that client security firewalls and RDS DB instance security groups are accurately configured to allow traffic over IPv6. To connect, clients use the DB instance's endpoint. Client applications can specify which protocol is preferred when connecting to a database. In dual-stack mode, the DB instance detects the client's preferred network protocol, either IPv4 or IPv6, and uses that protocol for the connection.

If a DB subnet group stops supporting dual-stack mode because of subnet deletion or CIDR disassociation, there's a risk of an incompatible network state for DB instances that are associated with the DB subnet group. Also, you can't use the DB subnet group when you create a new dual-stack mode DB instance.
To determine whether a DB subnet group supports dual-stack mode by using the AWS Management Console, view the **Network type** on the details page of the DB subnet group. To determine whether a DB subnet group supports dual-stack mode by using the AWS CLI, run the `describe-db-subnet-groups` command and view `SupportedNetworkTypes` in the output.

Read replicas are treated as independent DB instances and can have a network type that's different from the primary DB instance. If you change the network type of a read replica's primary DB instance, the read replica isn't affected. When you are restoring a DB instance, you can restore it to any network type that's supported.

**Working with dual-stack mode DB instances**

When you create or modify a DB instance, you can specify dual-stack mode to allow your resources to communicate with your DB instance over IPv4, IPv6, or both.

When you use the AWS Management Console to create or modify a DB instance, you can specify dual-stack mode in the **Network type** section. The following image shows the **Network type** section in the console.

![Network type section](image)

When you use the AWS CLI to create or modify a DB instance, set the `--network-type` option to `DUAL` to use dual-stack mode. When you use the RDS API to create or modify a DB instance, set the `NetworkType` parameter to `DUAL` to use dual-stack mode. When you are modifying the network type of a DB instance, downtime is possible. If dual-stack mode isn't supported by the specified DB engine version or DB subnet group, the `NetworkTypeNotSupported` error is returned.

For more information about creating a DB instance, see [Creating an Amazon RDS DB instance](#). For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](#).

To determine whether a DB instance is in dual-stack mode by using the console, view the **Network type** on the **Connectivity & security** tab for the DB instance.

**Modifying IPv4-only DB instances to use dual-stack mode**

You can modify an IPv4-only DB instance to use dual-stack mode. To do so, change the network type of the DB instance. The modification might result in downtime.
It is recommended that you change the network type of your Amazon RDS DB instances during a maintenance window. Currently, setting the network type of new instances to dual-stack mode isn't supported. You can set network type manually by using the `modify-db-instance` command.

Before modifying a DB instance to use dual-stack mode, make sure that its DB subnet group supports dual-stack mode. If the DB subnet group associated with the DB instance doesn't support dual-stack mode, specify a different DB subnet group that supports it when you modify the DB instance. Modifying the DB subnet group of a DB instance can cause downtime.

If you modify the DB subnet group of a DB instance before you change the DB instance to use dual-stack mode, make sure that the DB subnet group is valid for the DB instance before and after the change.

For RDS for PostgreSQL, RDS for MySQL, RDS for Oracle, and RDS for MariaDB Single-AZ instances, we recommend that you run the `modify-db-instance` command with only the `--network-type` parameter set to `DUAL` to change the network to dual-stack mode. Adding other parameters along with the `--network-type` parameter in the same API call could result in downtime. To modify multiple parameters, ensure that the network type modification is successfully completed before sending another `modify-db-instance` request with other parameters.

Network type modifications for RDS for PostgreSQL, RDS for MySQL, RDS for Oracle, and RDS for MariaDB Multi-AZ DB instances cause a brief downtime and trigger a failover if you only use the `--network-type` parameter or if you combine parameters in a `modify-db-instance` command.

Network type modifications on RDS for SQL Server Single-AZ or Multi-AZ DB instances cause downtime if you only use the `--network-type` parameter or if you combine parameters in a `modify-db-instance` command. Network type modifications cause failover in an SQL Server Multi-AZ instance.

If you can't connect to the DB instance after the change, make sure that the client and database security firewalls and route tables are accurately configured to allow traffic to the database on the selected network (either IPv4 or IPv6). You might also need to modify operating system parameter, libraries, or drivers to connect using an IPv6 address.

When you modify a DB instance to use dual-stack mode, there can't be a pending change from a Single-AZ deployment to a Multi-AZ deployment, or from a Multi-AZ deployment to a Single-AZ deployment.
To modify an IPv4-only DB instance to use dual-stack mode

1. Modify a DB subnet group to support dual-stack mode, or create a DB subnet group that supports dual-stack mode:
   a. Associate an IPv6 CIDR block with your VPC.

      For instructions, see  Add an IPv6 CIDR block to your VPC in the Amazon VPC User Guide.

   b. Attach the IPv6 CIDR block to all of the subnets in your the DB subnet group.

      For instructions, see  Add an IPv6 CIDR block to your subnet in the Amazon VPC User Guide.

   c. Confirm that the DB subnet group supports dual-stack mode.

      If you are using the AWS Management Console, select the DB subnet group, and make sure that the Supported network types value is Dual, IPv4.

      If you are using the AWS CLI, run the describe-db-subnet-groups command, and make sure that the SupportedNetworkType value for the DB instance is Dual, IPv4.

2. Modify the security group associated with the DB instance to allow IPv6 connections to the database, or create a new security group that allows IPv6 connections.

   For instructions, see  Security group rules in the Amazon VPC User Guide.

3. Modify the DB instance to support dual-stack mode. To do so, set the Network type to Dual-stack mode.

   If you are using the console, make sure that the following settings are correct:

   - **Network type** – Dual-stack mode

   - **DB subnet group** – The DB subnet group that you configured in a previous step

   - **Security group** – The security that you configured in a previous step
If you are using the AWS CLI, make sure that the following settings are correct:

- `--network-type` – dual
- `--db-subnet-group-name` – The DB subnet group that you configured in a previous step
- `--vpc-security-group-ids` – The VPC security group that you configured in a previous step

For example:

```
aws rds modify-db-instance --db-instance-identifier my-instance --network-type "DUAL"
```

4. Confirm that the DB instance supports dual-stack mode.

If you are using the console, choose the Connectivity & security tab for the DB instance. On that tab, make sure that the Network type value is **Dual-stack mode**.

If you are using the AWS CLI, run the `describe-db-instances` command, and make sure that the NetworkType value for the DB instance is dual.

Run the `dig` command on the DB instance endpoint to identify the IPv6 address associated with it.

```
dig db-instance-endpoint AAAA
```

Use the DB instance endpoint, not the IPv6 address, to connect to the DB instance.

### Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability with dual-stack mode, see [Dual-stack mode](#).

### Limitations for dual-stack network DB instances

The following limitations apply to dual-stack network DB instances:
• DB instances can't use the IPv6 protocol exclusively. They can use IPv4 exclusively, or they can use the IPv4 and IPv6 protocol (dual-stack mode).

• Amazon RDS doesn't support native IPv6 subnets.

• DB instances that use dual-stack mode must be private. They can't be publicly accessible.

• Dual-stack mode doesn't support the db.m3 and db.r3 DB instance classes.

• For RDS for SQL Server, dual-stack mode DB instances that use Always On AGs availability group listener endpoints only present IPv4 addresses.

• You can't use RDS Proxy with dual-stack mode DB instances.

• You can't use dual-stack mode with RDS on AWS Outposts DB instances.

• You can't use dual-stack mode with DB instances in a Local Zone.

### Hiding a DB instance in a VPC from the internet

One common Amazon RDS scenario is to have a VPC in which you have an EC2 instance with a public-facing web application and a DB instance with a database that isn't publicly accessible. For example, you can create a VPC that has a public subnet and a private subnet. Amazon EC2 instances that function as web servers can be deployed in the public subnet. The DB instances are deployed in the private subnet. In such a deployment, only the web servers have access to the DB instances. For an illustration of this scenario, see [A DB instance in a VPC accessed by an EC2 instance in the same VPC](#).

When you launch a DB instance inside a VPC, the DB instance has a private IP address for traffic inside the VPC. This private IP address isn't publicly accessible. You can use the Public access option to designate whether the DB instance also has a public IP address in addition to the private IP address. If the DB instance is designated as publicly accessible, its DNS endpoint resolves to the private IP address from within the VPC. It resolves to the public IP address from outside of the VPC. Access to the DB instance is ultimately controlled by the security group it uses. That public access is not permitted if the security group assigned to the DB instance doesn't include inbound rules that permit it. In addition, for a DB instance to be publicly accessible, the subnets in its DB subnet group must have an internet gateway. For more information, see [Can't connect to Amazon RDS DB instance](#).

You can modify a DB instance to turn on or off public accessibility by modifying the Public access option. The following illustration shows the Public access option in the Additional connectivity configuration section. To set the option, open the Additional connectivity configuration section in the Connectivity section.
Connectivity

Virtual private cloud (VPC)  Info
VPC that defines the virtual networking environment for this DB instance.

Default VPC (vpc-2aed394c)  ▼

Only VPCs with a corresponding DB subnet group are listed.

After a database is created, you can’t change its VPC.

Subnet group  Info
DB subnet group that defines which subnets and IP ranges the DB cluster can use in the VPC you selected.

Additional configuration

For information about modifying a DB instance to set the Public access option, see Modifying an Amazon RDS DB instance.
Creating a DB instance in a VPC

The following procedures help you create a DB instance in a VPC. To use the default VPC, you can begin with step 2, and use the VPC and DB subnet group have already been created for you. If you want to create an additional VPC, you can create a new VPC.

Note

If you want your DB instance in the VPC to be publicly accessible, you must update the DNS information for the VPC by enabling the VPC attributes DNS hostnames and DNS resolution. For information about updating the DNS information for a VPC instance, see Updating DNS support for your VPC.

Follow these steps to create a DB instance in a VPC:

- **Step 1: Create a VPC**
- **Step 2: Create a DB subnet group**
- **Step 3: Create a VPC security group**
- **Step 4: Create a DB instance in the VPC**

**Step 1: Create a VPC**

Create a VPC with subnets in at least two Availability Zones. You use these subnets when you create a DB subnet group. If you have a default VPC, a subnet is automatically created for you in each Availability Zone in the AWS Region.

For more information, see Create a VPC with private and public subnets, or see Create a VPC in the Amazon VPC User Guide.

**Step 2: Create a DB subnet group**

A DB subnet group is a collection of subnets (typically private) that you create for a VPC and that you then designate for your DB instances. A DB subnet group allows you to specify a particular VPC when you create DB instances using the AWS CLI or RDS API. If you use the console, you can just choose the VPC and subnets you want to use. Each DB subnet group must have at least one subnet in at least two Availability Zones in the AWS Region. As a best practice, each DB subnet group should have at least one subnet for every Availability Zone in the AWS Region.
For Multi-AZ deployments, defining a subnet for all Availability Zones in an AWS Region enables Amazon RDS to create a new standby replica in another Availability Zone if necessary. You can follow this best practice even for Single-AZ deployments, because you might convert them to Multi-AZ deployments in the future.

For a DB instance to be publicly accessible, the subnets in the DB subnet group must have an internet gateway. For more information about internet gateways for subnets, see [Connect to the internet using an internet gateway](#) in the *Amazon VPC User Guide*.

**Note**

The DB subnet group for a Local Zone can have only one subnet.

When you create a DB instance in a VPC, you can choose a DB subnet group. Amazon RDS chooses a subnet and an IP address within that subnet to associate with your DB instance. If no DB subnet groups exist, Amazon RDS creates a default subnet group when you create a DB instance. Amazon RDS creates and associates an Elastic Network Interface to your DB instance with that IP address. The DB instance uses the Availability Zone that contains the subnet.

For Multi-AZ deployments, defining a subnet for two or more Availability Zones in an AWS Region allows Amazon RDS to create a new standby in another Availability Zone should the need arise. You need to do this even for Single-AZ deployments, just in case you want to convert them to Multi-AZ deployments at some point.

In this step, you create a DB subnet group and add the subnets that you created for your VPC.

**To create a DB subnet group**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Subnet groups**.
3. Choose **Create DB Subnet Group**.
4. For **Name**, type the name of your DB subnet group.
5. For **Description**, type a description for your DB subnet group.
6. For **VPC**, choose the default VPC or the VPC that you created.
7. In the **Add subnets** section, choose the Availability Zones that include the subnets from **Availability Zones**, and then choose the subnets from **Subnets**.
Create DB Subnet Group

To create a new subnet group, give it a name and a description, and choose an existing VPC. You will then be able to add subnets related to that VPC.

**Subnet group details**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>You won’t be able to modify the name after your subnet group has been created.</td>
</tr>
<tr>
<td></td>
<td>mydbsubnetgroup</td>
</tr>
<tr>
<td>Description</td>
<td>Must contain from 1 to 255 characters. Alphanumeric characters, spaces, hyphens, underscores, and periods are allowed.</td>
</tr>
<tr>
<td></td>
<td>My DB Subnet Group</td>
</tr>
<tr>
<td>VPC</td>
<td>Choose a VPC identifier that corresponds to the subnets you want to use for your DB subnet group. You won’t be able to choose a different VPC identifier after your subnet group has been created.</td>
</tr>
<tr>
<td></td>
<td>tutorial-vpc (vpc-068fe388385afc014)</td>
</tr>
</tbody>
</table>

**Add subnets**

**Availability Zones**
Choose the Availability Zones that include the subnets you want to add.

- Choose an availability zone

<table>
<thead>
<tr>
<th>Availability zone</th>
<th>Subnet ID</th>
<th>CIDR block</th>
</tr>
</thead>
<tbody>
<tr>
<td>us-east-1a</td>
<td>subnet-079bd4b8953ae1dd</td>
<td>10.0.0.0/24</td>
</tr>
<tr>
<td>us-east-1c</td>
<td>subnet-057e85b72c46fdd9a</td>
<td>10.0.1.0/24</td>
</tr>
</tbody>
</table>

**Select subnets**

- subnet-079bd4b8953ae1dd (10.0.0.0/24)
- subnet-057e85b72c46fdd9a (10.0.1.0/24)
Note
If you have enabled a Local Zone, you can choose an Availability Zone group on the Create DB subnet group page. In this case, choose the Availability Zone group, Availability Zones, and Subnets.

8. Choose Create.

Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see details, including all of the subnets associated with the group, in the details pane at the bottom of the window.

Step 3: Create a VPC security group

Before you create your DB instance, you can create a VPC security group to associate with your DB instance. If you don't create a VPC security group, you can use the default security group when you create a DB instance. For instructions on how to create a security group for your DB instance, see Create a VPC security group for a private DB instance, or see Control traffic to resources using security groups in the Amazon VPC User Guide.

Step 4: Create a DB instance in the VPC

In this step, you create a DB instance and use the VPC name, the DB subnet group, and the VPC security group you created in the previous steps.

Note
If you want your DB instance in the VPC to be publicly accessible, you must enable the VPC attributes DNS hostnames and DNS resolution. For more information, see DNS attributes for your VPC in the Amazon VPC User Guide.

For details on how to create a DB instance, see Creating an Amazon RDS DB instance.

When prompted in the Connectivity section, enter the VPC name, the DB subnet group, and the VPC security group.
Updating the VPC for a DB instance

You can use the AWS Management Console to move your DB instance to a different VPC.

For information about modifying a DB instance, see Modifying an Amazon RDS DB instance. In the Connectivity section of the modify page, shown following, enter the new DB subnet group for DB subnet group. The new subnet group must be a subnet group in a new VPC.

You can't change the VPC for a DB instance if the following conditions apply:

- The DB instance is in multiple Availability Zones. You can convert the DB instance to a single Availability Zone, move it to a new VPC, and then convert it back to a Multi-AZ DB instance. For more information, see Configuring and managing a Multi-AZ deployment.

- The DB instance has one or more read replicas. You can remove the read replicas, move the DB instance to a new VPC, and then add the read replicas again. For more information, see Working with DB instance read replicas.

- The DB instance is a read replica. You can promote the read replica, and then move the standalone DB instance to a new VPC. For more information, see Promoting a read replica to be a standalone DB instance.

- The subnet group in the target VPC doesn't have subnets in the DB instance's the Availability Zone. You can add subnets in the DB instance's Availability Zone to the DB subnet group, and then move the DB instance to the new VPC. For more information, see Working with DB subnet groups.

Scenarios for accessing a DB instance in a VPC

Amazon RDS supports the following scenarios for accessing a DB instance in a VPC:
- An EC2 instance in the same VPC
- An EC2 instance in a different VPC
- A client application through the internet
- A private network

**A DB instance in a VPC accessed by an EC2 instance in the same VPC**

A common use of a DB instance in a VPC is to share data with an application server that is running in an EC2 instance in the same VPC.

The following diagram shows this scenario.
The simplest way to manage access between EC2 instances and DB instances in the same VPC is to do the following:

- Create a VPC security group for your DB instances to be in. This security group can be used to restrict access to the DB instances. For example, you can create a custom rule for this security group. This might allow TCP access using the port that you assigned to the DB instance when you created it and an IP address you use to access the DB instance for development or other purposes.

- Create a VPC security group for your EC2 instances (web servers and clients) to be in. This security group can, if needed, allow access to the EC2 instance from the internet by using the VPC's routing table. For example, you can set rules on this security group to allow TCP access to the EC2 instance over port 22.

- Create custom rules in the security group for your DB instances that allow connections from the security group you created for your EC2 instances. These rules might allow any member of the security group to access the DB instances.

There is an additional public and private subnet in a separate Availability Zone. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easy to switch to a Multi-AZ DB instance deployment in the future.

For a tutorial that shows you how to create a VPC with both public and private subnets for this scenario, see Tutorial: Create a VPC for use with a DB instance (IPv4 only).

Tip

You can set up network connectivity between an Amazon EC2 instance and a DB instance automatically when you create the DB instance. For more information, see .

To create a rule in a VPC security group that allows connections from another security group, do the following:

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc.
2. In the navigation pane, choose Security groups.
3. Choose or create a security group for which you want to allow access to members of another security group. In the preceding scenario, this is the security group that you use for your DB instances. Choose the **Inbound rules** tab, and then choose **Edit inbound rules**.

4. On the **Edit inbound rules** page, choose **Add rule**.

5. For **Type**, choose the entry that corresponds to the port you used when you created your DB instance, such as **MYSQL/Aurora**.

6. In the **Source** box, start typing the ID of the security group, which lists the matching security groups. Choose the security group with members that you want to have access to the resources protected by this security group. In the scenario preceding, this is the security group that you use for your EC2 instance.

7. If required, repeat the steps for the TCP protocol by creating a rule with **All TCP** as the **Type** and your security group in the **Source** box. If you intend to use the UDP protocol, create a rule with **All UDP** as the **Type** and your security group in **Source**.

8. Choose **Save rules**.

The following screen shows an inbound rule with a security group for its source.

For more information about connecting to the DB instance from your EC2 instance, see [Connecting to an Amazon RDS DB instance](#).

**A DB instance in a VPC accessed by an EC2 instance in a different VPC**

When your DB instances is in a different VPC from the EC2 instance you are using to access it, you can use VPC peering to access the DB instance.

The following diagram shows this scenario.
A VPC peering connection is a networking connection between two VPCs that enables you to route traffic between them using private IP addresses. Resources in either VPC can communicate with each other as if they are within the same network. You can create a VPC peering connection between your own VPCs, with a VPC in another AWS account, or with a VPC in a different AWS Region. To learn more about VPC peering, see VPC peering in the Amazon Virtual Private Cloud User Guide.

**A DB instance in a VPC accessed by a client application through the internet**

To access a DB instances in a VPC from a client application through the internet, you configure a VPC with a single public subnet, and an internet gateway to enable communication over the internet.

The following diagram shows this scenario.
We recommend the following configuration:

- A VPC of size /16 (for example CIDR: 10.0.0.0/16). This size provides 65,536 private IP addresses.
- A subnet of size /24 (for example CIDR: 10.0.0.0/24). This size provides 256 private IP addresses.
- An Amazon RDS DB instance that is associated with the VPC and the subnet. Amazon RDS assigns an IP address within the subnet to your DB instance.
- An internet gateway which connects the VPC to the internet and to other AWS products.
- A security group associated with the DB instance. The security group's inbound rules allow your client application to access to your DB instance.

For information about creating a DB instances in a VPC, see Creating a DB instance in a VPC.

A DB instance in a VPC accessed by a private network

If your DB instance isn't publicly accessible, you have the following options for accessing it from a private network:

- An AWS Site-to-Site VPN connection. For more information, see What is AWS Site-to-Site VPN?
- An AWS Direct Connect connection. For more information, see What is AWS Direct Connect?
- An AWS Client VPN connection. For more information, see What is AWS Client VPN?

The following diagram shows a scenario with an AWS Site-to-Site VPN connection.
For more information, see [Internetwork traffic privacy](#).
A common scenario includes a DB instance in a virtual private cloud (VPC) based on the Amazon VPC service. This VPC shares data with a web server that is running in the same VPC. In this tutorial, you create the VPC for this scenario.

The following diagram shows this scenario. For information about other scenarios, see Scenarios for accessing a DB instance in a VPC.

Your DB instance needs to be available only to your web server, and not to the public internet. Thus, you create a VPC with both public and private subnets. The web server is hosted in the public subnet, so that it can reach the public internet. The DB instance is hosted in a private subnet. The web server can connect to the DB instance because it is hosted within the same VPC. But the DB instance isn't available to the public internet, providing greater security.
This tutorial configures an additional public and private subnet in a separate Availability Zone. These subnets aren't used by the tutorial. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easier to switch to a Multi-AZ DB instance deployment in the future.

This tutorial describes configuring a VPC for Amazon RDS DB instances. For a tutorial that shows you how to create a web server for this VPC scenario, see Tutorial: Create a web server and an Amazon RDS DB instance. For more information about Amazon VPC, see Amazon VPC Getting Started Guide and Amazon VPC User Guide.

Tip
You can set up network connectivity between an Amazon EC2 instance and a DB instance automatically when you create the DB instance. The network configuration is similar to the one described in this tutorial. For more information, see Configure automatic network connectivity with an EC2 instance.

Create a VPC with private and public subnets

Use the following procedure to create a VPC with both public and private subnets.

To create a VPC and subnets

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the top-right corner of the AWS Management Console, choose the Region to create your VPC in. This example uses the US West (Oregon) Region.
3. In the upper-left corner, choose VPC dashboard. To begin creating a VPC, choose Create VPC.
4. For Resources to create under VPC settings, choose VPC and more.
5. For the VPC settings, set these values:

   - Name tag auto-generation – tutorial
   - IPv4 CIDR block – 10.0.0.0/16
   - IPv6 CIDR block – No IPv6 CIDR block
   - Tenancy – Default
   - Number of Availability Zones (AZs) – 2
   - Customize AZs – Keep the default values.
• Number of public subnet – 2
• Number of private subnets – 2
• Customize subnets CIDR blocks – Keep the default values.
• NAT gateways ($) – None
• VPC endpoints – None
• DNS options – Keep the default values.

Note
Amazon RDS requires at least two subnets in two different Availability Zones to support Multi-AZ DB instance deployments. This tutorial creates a Single-AZ deployment, but the requirement makes it easier to convert to a Multi-AZ DB instance deployment in the future.

6. Choose Create VPC.

Create a VPC security group for a public web server

Next, you create a security group for public access. To connect to public EC2 instances in your VPC, you add inbound rules to your VPC security group. These allow traffic to connect from the internet.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose VPC Dashboard, choose Security Groups, and then choose Create security group.
3. On the Create security group page, set these values:
   - Security group name: tutorial-securitygroup
   - Description: Tutorial Security Group
   - VPC: Choose the VPC that you created earlier, for example: vpc-identifier (tutorial-vpc)
4. Add inbound rules to the security group.
   a. Determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH). To determine your public IP address, in a different browser window or tab,
you can use the service at [https://checkip.amazonaws.com](https://checkip.amazonaws.com). An example of an IP address is 203.0.113.25/32.

In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, find the range of IP addresses used by client computers.

### Warning

If you use 0.0.0.0/0 for SSH access, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances using SSH.

b. In the **Inbound rules** section, choose **Add rule**.

c. Set the following values for your new inbound rule to allow SSH access to your Amazon EC2 instance. If you do this, you can connect to your Amazon EC2 instance to install the web server and other utilities. You also connect to your EC2 instance to upload content for your web server.

   - **Type:** SSH
   - **Source:** The IP address or range from Step a, for example: 203.0.113.25/32.

d. Choose **Add rule**.

e. Set the following values for your new inbound rule to allow HTTP access to your web server:

   - **Type:** HTTP
   - **Source:** 0.0.0.0/0

5. Choose **Create security group** to create the security group.

   Note the security group ID because you need it later in this tutorial.
Create a VPC security group for a private DB instance

To keep your DB instance private, create a second security group for private access. To connect to private DB instances in your VPC, you add inbound rules to your VPC security group that allow traffic from your web server only.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose VPC Dashboard, choose Security Groups, and then choose Create security group.
3. On the Create security group page, set these values:
   - Security group name: tutorial-db-securitygroup
   - Description: Tutorial DB Instance Security Group
   - VPC: Choose the VPC that you created earlier, for example: vpc-identifier (tutorial-vpc)
4. Add inbound rules to the security group.
   a. In the Inbound rules section, choose Add rule.
   b. Set the following values for your new inbound rule to allow MySQL traffic on port 3306 from your Amazon EC2 instance. If you do this, you can connect from your web server to your DB instance. By doing so, you can store and retrieve data from your web application to your database.
      - Type: MySQL/Aurora
      - Source: The identifier of the tutorial-securitygroup security group that you created previously in this tutorial, for example: sg-9edd5cfb.
5. Choose Create security group to create the security group.

Create a DB subnet group

A DB subnet group is a collection of subnets that you create in a VPC and that you then designate for your DB instances. A DB subnet group makes it possible for you to specify a particular VPC when creating DB instances.

To create a DB subnet group

1. Identify the private subnets for your database in the VPC.
a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

b. Choose VPC Dashboard, and then choose Subnets.

c. Note the subnet IDs of the subnets named tutorial-subnet-private1-us-west-2a and tutorial-subnet-private2-us-west-2b.

You need the subnet IDs when you create your DB subnet group.

2. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.

Make sure that you connect to the Amazon RDS console, not to the Amazon VPC console.

3. In the navigation pane, choose Subnet groups.

4. Choose Create DB subnet group.

5. On the Create DB subnet group page, set these values in Subnet group details:

   - Name: tutorial-db-subnet-group
   - Description: Tutorial DB Subnet Group
   - VPC: tutorial-vpc (vpc-identifier)

6. In the Add subnets section, choose the Availability Zones and Subnets.

   For this tutorial, choose us-west-2a and us-west-2b for the Availability Zones. For Subnets, choose the private subnets you identified in the previous step.

7. Choose Create.

   Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see details in the details pane at the bottom of the window. These details include all of the subnets associated with the group.

Note

If you created this VPC to complete Tutorial: Create a web server and an Amazon RDS DB instance, create the DB instance by following the instructions in Create an Amazon RDS DB instance.
Deleting the VPC

After you create the VPC and other resources for this tutorial, you can delete them if they are no longer needed.

ℹ️ Note
If you added resources in the VPC that you created for this tutorial, you might need to delete these before you can delete the VPC. For example, these resources might include Amazon EC2 instances or Amazon RDS DB instances. For more information, see Delete your VPC in the Amazon VPC User Guide.

To delete a VPC and related resources

1. Delete the DB subnet group.
   a. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   b. In the navigation pane, choose Subnet groups.
   c. Select the DB subnet group you want to delete, such as tutorial-db-subnet-group.
   d. Choose Delete, and then choose Delete in the confirmation window.

2. Note the VPC ID.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose VPC Dashboard, and then choose VPCs.
   c. In the list, identify the VPC that you created, such as tutorial-vpc.
   d. Note the VPC ID of the VPC that you created. You need the VPC ID in later steps.

3. Delete the security groups.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose VPC Dashboard, and then choose Security Groups.
   c. Select the security group for the Amazon RDS DB instance, such as tutorial-db-securitygroup.
   d. For Actions, choose Delete security groups, and then choose Delete on the confirmation page.
e. On the Security Groups page, select the security group for the Amazon EC2 instance, such as tutorial-securitygroup.
f. For Actions, choose Delete security groups, and then choose Delete on the confirmation page.

4. Delete the VPC.

a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
b. Choose VPC Dashboard, and then choose VPCs.
c. Select the VPC you want to delete, such as tutorial-vpc.
d. For Actions, choose Delete VPC.

The confirmation page shows other resources that are associated with the VPC that will also be deleted, including the subnets associated with it.

e. On the confirmation page, enter delete, and then choose Delete.
Tutorial: Create a VPC for use with a DB instance (dual-stack mode)

A common scenario includes a DB instance in a virtual private cloud (VPC) based on the Amazon VPC service. This VPC shares data with a public Amazon EC2 instance that is running in the same VPC.

In this tutorial, you create the VPC for this scenario that works with a database running in dual-stack mode. Dual-stack mode to enable connection over the IPv6 addressing protocol. For more information about IP addressing, see Amazon RDS IP addressing.

Dual-stack network instances are supported in most regions. For more information see Region and version availability. To see the limitations of dual-stack mode, see Limitations for dual-stack network DB instances.

The following diagram shows this scenario.
Your DB instance needs to be available only to your Amazon EC2 instance, and not to the public internet. Thus, you create a VPC with both public and private subnets. The Amazon EC2 instance is hosted in the public subnet, so that it can reach the public internet. The DB instance is hosted in a private subnet. The Amazon EC2 instance can connect to the DB instance because it's hosted within the same VPC. However, the DB instance is not available to the public internet, providing greater security.

This tutorial configures an additional public and private subnet in a separate Availability Zone. These subnets aren't used by the tutorial. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easy to switch to a Multi-AZ DB instance deployment in the future.

For information about other scenarios, see Scenarios for accessing a DB instance in a VPC.
To create a DB instance that uses dual-stack mode, specify **Dual-stack mode** for the **Network type** setting. You can also modify a DB instance with the same setting. For more information, see [Creating an Amazon RDS DB instance](#) and [Modifying an Amazon RDS DB instance](#).

This tutorial describes configuring a VPC for Amazon RDS DB instances. For more information about Amazon VPC, see [Amazon VPC User Guide](#).

**Create a VPC with private and public subnets**

Use the following procedure to create a VPC with both public and private subnets.

**To create a VPC and subnets**

1. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
2. In the upper-right corner of the AWS Management Console, choose the Region to create your VPC in. This example uses the US East (Ohio) Region.
3. In the upper-left corner, choose **VPC dashboard**. To begin creating a VPC, choose **Create VPC**.
4. For **Resources to create** under **VPC settings**, choose **VPC and more**.
5. For the remaining **VPC settings**, set these values:
   - **Name tag auto-generation** – **tutorial-dual-stack**
   - **IPv4 CIDR block** – 10.0.0.0/16
   - **IPv6 CIDR block** – Amazon-provided IPv6 CIDR block
   - **Tenancy** – Default
   - **Number of Availability Zones (AZs)** – 2
   - **Customize AZs** – Keep the default values.
   - **Number of public subnet** – 2
   - **Number of private subnets** – 2
   - **Customize subnets CIDR blocks** – Keep the default values.
   - **NAT gateways ($)** – None
   - **Egress only internet gateway** – No
   - **VPC endpoints** – None
   - **DNS options** – Keep the default values.
Amazon RDS requires at least two subnets in two different Availability Zones to support Multi-AZ DB instance deployments. This tutorial creates a Single-AZ deployment, but the requirement makes it easy to convert to a Multi-AZ DB instance deployment in the future.

Note

6. Choose Create VPC.

Create a VPC security group for a public Amazon EC2 instance

Next, you create a security group for public access. To connect to public EC2 instances in your VPC, add inbound rules to your VPC security group that allow traffic to connect from the internet.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose VPC Dashboard, choose Security Groups, and then choose Create security group.
3. On the Create security group page, set these values:
   - Security group name: tutorial-dual-stack-securitygroup
   - Description: Tutorial Dual-Stack Security Group
   - VPC: Choose the VPC that you created earlier, for example: vpc-identifier (tutorial-dual-stack-vpc)
4. Add inbound rules to the security group.
   a. Determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH).

   An example of an Internet Protocol version 4 (IPv4) address is 203.0.113.25/32.
   An example of an Internet Protocol version 6 (IPv6) address range is 2001:db8:1234:1a00::/64.

   In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, find the range of IP addresses used by client computers.
Warning

If you use 0.0.0.0/0 for IPv4 or ::0 for IPv6, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances.

b. In the Inbound rules section, choose Add rule.

c. Set the following values for your new inbound rule to allow Secure Shell (SSH) access to your Amazon EC2 instance. If you do this, you can connect to your EC2 instance to install SQL clients and other applications. Specify an IP address so you can access your EC2 instance:

- **Type:** SSH
- **Source:** The IP address or range from step a. An example of an IPv4 IP address is 203.0.113.25/32. An example of an IPv6 IP address is 2001:DB8::/32.

5. Choose Create security group to create the security group.

Note the security group ID because you need it later in this tutorial.

Create a VPC security group for a private DB instance

To keep your DB instance private, create a second security group for private access. To connect to private DB instances in your VPC, add inbound rules to your VPC security group. These allow traffic from your Amazon EC2 instance only.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose VPC Dashboard, choose Security Groups, and then choose Create security group.
3. On the Create security group page, set these values:

- **Security group name:** tutorial-dual-stack-db-securitygroup
- **Description:** Tutorial Dual-Stack DB Instance Security Group
• **VPC:** Choose the VPC that you created earlier, for example: `vpc-identifier (tutorial-dual-stack-vpc)`

4. Add inbound rules to the security group:
   a. In the **Inbound rules** section, choose **Add rule**.
   b. Set the following values for your new inbound rule to allow MySQL traffic on port 3306 from your Amazon EC2 instance. If you do, you can connect from your EC2 instance to your DB instance. Doing this means that you can send data from your EC2 instance to your database.
      • **Type:** MySQL/Aurora
      • **Source:** The identifier of the `tutorial-dual-stack-securitygroup` security group that you created previously in this tutorial, for example `sg-9edd5cfb`.

5. To create the security group, choose **Create security group**.

---

**Create a DB subnet group**

*A DB subnet group* is a collection of subnets that you create in a VPC and that you then designate for your DB instances. By using a DB subnet group, you can specify a particular VPC when creating DB instances. To create a DB subnet group that is DUAL compatible, all subnets must be DUAL compatible. To be DUAL compatible, a subnet must have an IPv6 CIDR associated with it.

**To create a DB subnet group**

1. Identify the private subnets for your database in the VPC.
   a. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
   b. Choose **VPC Dashboard**, and then choose **Subnets**.
   c. Note the subnet IDs of the subnets named `tutorial-dual-stack-subnet-private1-us-west-2a` and `tutorial-dual-stack-subnet-private2-us-west-2b`.

      You will need the subnet IDs when you create your DB subnet group.

2. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).

   Make sure that you connect to the Amazon RDS console, not to the Amazon VPC console.

3. In the navigation pane, choose **Subnet groups**.

4. Choose **Create DB subnet group**.
5. On the **Create DB subnet group** page, set these values in **Subnet group details**:

   - **Name**: tutorial-dual-stack-db-subnet-group
   - **Description**: Tutorial Dual-Stack DB Subnet Group
   - **VPC**: tutorial-dual-stack-vpc (vpc-identifier)

6. In the **Add subnets** section, choose values for the **Availability Zones** and **Subnets** options.

   For this tutorial, choose **us-east-2a** and **us-east-2b** for the **Availability Zones**. For **Subnets**, choose the private subnets you identified in the previous step.

7. Choose **Create**.

Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see its details. These include the supported addressing protocols and all of the subnets associated with the group and the network type supported by the DB subnet group.

**Create an Amazon EC2 instance in dual-stack mode**

To create an Amazon EC2 instance, follow the instructions in [Launch an instance using the new launch instance wizard](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/launch-an-instance.html) in the *Amazon EC2 User Guide for Linux Instances*.

On the **Configure Instance Details** page, set these values and keep the other values as their defaults:

- **Network** – Choose an existing VPC with both public and private subnets, such as **tutorial-dual-stack-vpc** (vpc-identifier) created in [Create a VPC with private and public subnets](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/VPC-Create.html).
- **Subnet** – Choose an existing public subnet, such as **subnet-identifier** | tutorial-dual-stack-subnet-public1-us-east-2a | us-east-2a created in [Create a VPC security group for a public Amazon EC2 instance](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/VPC-SecurityGroup.html).
- **Auto-assign Public IP** – Choose Enable.
- **Auto-assign IPv6 IP** – Choose Enable.
- **Firewall (security groups)** – Choose Select an existing security group.
- **Common security groups** – Choose an existing security group, such as the tutorial-securitygroup created in [Create a VPC security group for a public Amazon EC2 instance](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/VPC-SecurityGroup.html). Make sure that the security group that you choose includes inbound rules for Secure Shell (SSH) and HTTP access.
Create a DB instance in dual-stack mode

In this step, you create a DB instance that runs in dual-stack mode.

To create a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the upper-right corner of the console, choose the AWS Region where you want to create the DB instance. This example uses the US East (Ohio) Region.

3. In the navigation pane, choose Databases.

4. Choose Create database.

5. On the Create database page, make sure that the Standard create option is chosen, and then choose the MySQL DB engine type.

6. In the Connectivity section, set these values:

   - **Network type** – Choose Dual-stack mode.
   - **Virtual private cloud (VPC)** – Choose an existing VPC with both public and private subnets, such as tutorial-dual-stack-vpc (vpc-identifier) created in Create a VPC with private and public subnets.
     
     The VPC must have subnets in different Availability Zones.
   - **DB subnet group** – Choose a DB subnet group for the VPC, such as tutorial-dual-stack-db-subnet-group created in Create a DB subnet group.
   - **Public access** – Choose No.
   - **VPC security group (firewall)** – Select Choose existing.
   - **Existing VPC security groups** – Choose an existing VPC security group that is configured for private access, such as tutorial-dual-stack-db-securitygroup created in Create a VPC security group for a private DB instance.
Remove other security groups, such as the default security group, by choosing the X associated with each.

- **Availability Zone** – Choose **us-west-2a**.
  
  To avoid cross-AZ traffic, make sure the DB instance and the EC2 instance are in the same Availability Zone.

7. For the remaining sections, specify your DB instance settings. For information about each setting, see [Settings for DB instances](#).

### Connect to your Amazon EC2 instance and DB instance

After you create your Amazon EC2 instance and DB instance in dual-stack mode, you can connect to each one using the IPv6 protocol. To connect to an Amazon EC2 instance using the IPv6 protocol, follow the instructions in [Connect to your Linux instance](#) in the *Amazon EC2 User Guide for Linux Instances*.

To connect to your RDS for MySQL DB instance from the Amazon EC2 instance, follow the instructions in [Connect to a MySQL DB instance](#).

### Deleting the VPC

After you create the VPC and other resources for this tutorial, you can delete them if they are no longer needed.

If you added resources in the VPC that you created for this tutorial, you might need to delete these before you can delete the VPC. Examples of resources are Amazon EC2 instances or DB instances. For more information, see [Delete your VPC](#) in the *Amazon VPC User Guide*.

### To delete a VPC and related resources

1. Delete the DB subnet group:
   
   a. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
   
   b. In the navigation pane, choose **Subnet groups**.
   
   c. Select the DB subnet group to delete, such as **tutorial-db-subnet-group**.
   
   d. Choose **Delete**, and then choose **Delete** in the confirmation window.

2. Note the VPC ID:
a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

b. Choose VPC Dashboard, and then choose VPCs.

c. In the list, identify the VPC you created, such as tutorial-dual-stack-vpc.

d. Note the VPC ID value of the VPC that you created. You need this VPC ID in subsequent steps.

3. Delete the security groups:

a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

b. Choose VPC Dashboard, and then choose Security Groups.

c. Select the security group for the Amazon RDS DB instance, such as tutorial-dual-stack-db-securitygroup.

d. For Actions, choose Delete security groups, and then choose Delete on the confirmation page.

e. On the Security Groups page, select the security group for the Amazon EC2 instance, such as tutorial-dual-stack-securitygroup.

f. For Actions, choose Delete security groups, and then choose Delete on the confirmation page.

4. Delete the NAT gateway:

a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

b. Choose VPC Dashboard, and then choose NAT Gateways.

c. Select the NAT gateway of the VPC that you created. Use the VPC ID to identify the correct NAT gateway.

d. For Actions, choose Delete NAT gateway.

e. On the confirmation page, enter delete, and then choose Delete.

5. Delete the VPC:

a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

b. Choose VPC Dashboard, and then choose VPCs.

c. Select the VPC that you want to delete, such as tutorial-dual-stack-vpc.

d. For Actions, choose Delete VPC.

The confirmation page shows other resources that are associated with the VPC that will also be deleted, including the subnets associated with it.
6. Release the Elastic IP addresses:
   
a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
b. Choose EC2 Dashboard, and then choose Elastic IPs.
c. Select the Elastic IP address that you want to release.
d. For Actions, choose Release Elastic IP addresses.
e. On the confirmation page, choose Release.
Moving a DB instance not in a VPC into a VPC

Some legacy DB instances on the EC2-Classic platform are not in a VPC. If your DB instance is not in a VPC, you can use the AWS Management Console to easily move your DB instance into a VPC. Before you can move a DB instance not in a VPC, into a VPC, you must create the VPC.

EC2-Classic was retired on August 15, 2022. If you haven’t migrated from EC2-Classic to a VPC, we recommend that you migrate as soon as possible. For more information, see Migrate from EC2-Classic to a VPC in the Amazon EC2 User Guide and the blog EC2-Classic Networking is Retiring – Here’s How to Prepare.

⚠️ Important
If you are a new Amazon RDS customer, if you have never created a DB instance before, or if you are creating a DB instance in an AWS Region you have not used before, in almost all cases you are on the EC2-VPC platform and have a default VPC. For information about working with DB instances in a VPC, see Working with a DB instance in a VPC.

Follow these steps to create a VPC for your DB instance.

- **Step 1: Create a VPC**
- **Step 2: Create a DB subnet group**
- **Step 3: Create a VPC security group**

After you create the VPC, follow these steps to move your DB instance into the VPC.

- **Updating the VPC for a DB instance**

We highly recommend that you create a backup of your DB instance immediately before the migration. Doing so ensures that you can restore the data if the migration fails. For more information, see Backing up, restoring, and exporting data.

The following are some limitations to moving your DB instance into the VPC.
• **Previous generation DB instance classes** – Previous generation DB instance classes might not be supported on the VPC platform. When moving a DB instance to a VPC, choose a db.m3 or db.r3 DB instance class. After you move the DB instance to a VPC, you can scale the DB instance to use a later DB instance class. For a full list of VPC supported instance classes, see Amazon RDS instance types.

• **Multi-AZ** – Moving a Multi-AZ DB instance not in a VPC into a VPC is not currently supported. To move your DB instance to a VPC, first modify the DB instance so that it is a single-AZ deployment. Change the Multi-AZ deployment setting to No. After you move the DB instance to a VPC, modify it again to make it a Multi-AZ deployment. For more information, see Modifying an Amazon RDS DB instance.

• **Read replicas** – Moving a DB instance with read replicas not in a VPC into a VPC is not currently supported. To move your DB instance to a VPC, first delete all of its read replicas. After you move the DB instance to a VPC, recreate the read replicas. For more information, see Working with DB instance read replicas.

• **Option groups** – If you move your DB instance to a VPC, and the DB instance is using a custom option group, change the option group that is associated with your DB instance. Option groups are platform-specific, and moving to a VPC is a change in platform. To use a custom option group in this case, assign the default VPC option group to the DB instance, assign an option group that is used by other DB instances in the VPC you are moving to, or create a new option group and assign it to the DB instance. For more information, see Working with option groups.

**Alternatives for moving a DB instance not in a VPC into a VPC with minimal downtime**

Using the following alternatives, you can move a DB instance not in a VPC into a VPC with minimal downtime. These alternatives cause minimum disruption to the source DB instance and allow it to serve user traffic during the migration. However, the time required to migrate to a VPC will vary based on the database size and the live workload characteristics.

• **AWS Database Migration Service (AWS DMS)** – AWS DMS enables the live migration of data while keeping the source DB instance fully operational, but it replicates only a limited set of DDL statements. AWS DMS doesn't propagate items such as indexes, users, privileges, stored procedures, and other database changes not directly related to table data. In addition, AWS DMS doesn't automatically use RDS snapshots for the initial DB instance creation, which can increase migration time. For more information, see AWS Database Migration Service.
• **DB snapshot restore or point-in-time recovery** – You can move a DB instance to a VPC by restoring a snapshot of the DB instance or by restoring a DB instance to a point in time. For more information, see [Restoring from a DB snapshot](#) and [Restoring a DB instance to a specified time](#).
Quotas and constraints for Amazon RDS

Following, you can find a description of the resource quotas and naming constraints for Amazon RDS.

Topics
- Quotas in Amazon RDS
- Naming constraints in Amazon RDS
- Maximum number of database connections
- File size limits in Amazon RDS

Quotas in Amazon RDS

Each AWS account has quotas, for each AWS Region, on the number of Amazon RDS resources that can be created. After a quota for a resource has been reached, additional calls to create that resource fail with an exception.

The following table lists the resources and their quotas per AWS Region.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Adjust</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Authorizations per DB security group</td>
<td>Each supported Region: 20</td>
<td>No</td>
<td>Number of security group authorizations per DB security group</td>
</tr>
<tr>
<td>Custom engine versions</td>
<td>Each supported Region: 40</td>
<td>Yes</td>
<td>The maximum number of custom engine versions allowed in this account in the current Region</td>
</tr>
<tr>
<td>DB cluster parameter groups</td>
<td>Each supported Region: 50</td>
<td>No</td>
<td>The maximum number of DB cluster parameter groups</td>
</tr>
<tr>
<td>DB clusters</td>
<td>Each supported Region: 40</td>
<td>Yes</td>
<td>The maximum number of Aurora clusters allowed</td>
</tr>
<tr>
<td>Name</td>
<td>Default</td>
<td>Adjust</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------------------</td>
<td>----------------------------------------------</td>
<td>--------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DB instances</td>
<td>Each supported Region: 40</td>
<td>Yes</td>
<td>The maximum number of DB instances allowed in this account in the current Region</td>
</tr>
<tr>
<td>DB subnet groups</td>
<td>Each supported Region: 50</td>
<td>Yes</td>
<td>The maximum number of DB subnet groups</td>
</tr>
<tr>
<td>Data API HTTP request body size</td>
<td>Each supported Region: 4 Megabytes</td>
<td>No</td>
<td>The maximum size allowed for the HTTP request body.</td>
</tr>
<tr>
<td>Data API maximum concurrent cluster-secrets</td>
<td>Each supported Region: 30</td>
<td>No</td>
<td>The maximum number of unique pairs of Aurora Serverless DB clusters and secrets in concurrent Data API requests for the current account and AWS Region.</td>
</tr>
<tr>
<td>Data API maximum concurrent requests</td>
<td>Each supported Region: 500</td>
<td>No</td>
<td>The maximum number of Data API requests to an Aurora Serverless DB cluster that use the same secret and can be processed at the same time. Additional requests are queued and processed as in-process requests complete.</td>
</tr>
<tr>
<td>Name</td>
<td>Default</td>
<td>Adjust</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------</td>
<td>----------------------------------</td>
<td>--------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Data API maximum result set size</td>
<td>Each supported Region: 1 Megabytes</td>
<td>No</td>
<td>The maximum size of the database result set that can be returned by the Data API.</td>
</tr>
<tr>
<td>Data API maximum size of JSON response string</td>
<td>Each supported Region: 10 Megabytes</td>
<td>No</td>
<td>The maximum size of the simplified JSON response string returned by the RDS Data API.</td>
</tr>
<tr>
<td>Data API requests per second</td>
<td>Each supported Region: 1,000 per second</td>
<td>No</td>
<td>The maximum number of requests to the Data API per second allowed in this account in the current AWS Region.</td>
</tr>
<tr>
<td>Event subscriptions</td>
<td>Each supported Region: 20</td>
<td>Yes</td>
<td>The maximum number of event subscriptions</td>
</tr>
<tr>
<td>IAM roles per DB cluster</td>
<td>Each supported Region: 5</td>
<td>Yes</td>
<td>The maximum number of IAM roles associated with a DB cluster</td>
</tr>
<tr>
<td>IAM roles per DB instance</td>
<td>Each supported Region: 5</td>
<td>Yes</td>
<td>The maximum number of IAM roles associated with a DB instance</td>
</tr>
<tr>
<td>Manual DB cluster snapshots</td>
<td>Each supported Region: 100</td>
<td>Yes</td>
<td>The maximum number of manual DB cluster snapshots</td>
</tr>
<tr>
<td>Manual DB instance snapshots</td>
<td>Each supported Region: 100</td>
<td>Yes</td>
<td>The maximum number of manual DB instance snapshots</td>
</tr>
<tr>
<td>Name</td>
<td>Default</td>
<td>Adjust</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>----------------------------------</td>
<td>--------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Option groups</td>
<td>Each supported Region: 20</td>
<td>Yes</td>
<td>The maximum number of option groups</td>
</tr>
<tr>
<td>Parameter groups</td>
<td>Each supported Region: 50</td>
<td>Yes</td>
<td>The maximum number of parameter groups</td>
</tr>
<tr>
<td>Proxies</td>
<td>Each supported Region: 20</td>
<td>Yes</td>
<td>The maximum number of proxies allowed in this account in the current AWS Region</td>
</tr>
<tr>
<td>Read replicas per primary</td>
<td>Each supported Region: 15</td>
<td>Yes</td>
<td>The maximum number of read replicas per primary DB instance. This quota cant be adjusted for Amazon Aurora.</td>
</tr>
<tr>
<td>Reserved DB instances</td>
<td>Each supported Region: 40</td>
<td>Yes</td>
<td>The maximum number of reserved DB instances allowed in this account in the current AWS Region</td>
</tr>
<tr>
<td>Rules per security group</td>
<td>Each supported Region: 20</td>
<td>No</td>
<td>The maximum number of rules per DB security group</td>
</tr>
<tr>
<td>Security groups</td>
<td>Each supported Region: 25</td>
<td>Yes</td>
<td>The maximum number of DB security groups</td>
</tr>
<tr>
<td>Security groups (VPC)</td>
<td>Each supported Region: 5</td>
<td>No</td>
<td>The maximum number of DB security groups per Amazon VPC</td>
</tr>
<tr>
<td>Subnets per DB subnet group</td>
<td>Each supported Region: 20</td>
<td>No</td>
<td>The maximum number of subnets per DB subnet group</td>
</tr>
<tr>
<td>Name</td>
<td>Default</td>
<td>Adjust</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>----------------------------------------------</td>
<td>----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Tags per resource</td>
<td>Each supported Region: 50</td>
<td>No</td>
<td>The maximum number of tags per Amazon RDS resource</td>
</tr>
<tr>
<td>Total storage for all DB instances</td>
<td>Each supported Region: 100,000 Gigabytes</td>
<td>Yes</td>
<td>The maximum total storage (in GB) on EBS volumes for all Amazon RDS DB instances added together. This quota does not apply to Amazon Aurora, which has a maximum cluster volume of 128 TiB for each DB cluster.</td>
</tr>
</tbody>
</table>

**Note**

By default, you can have up to a total of 40 DB instances. RDS DB instances, Aurora DB instances, Amazon Neptune instances, and Amazon DocumentDB instances apply to this quota.

The following limitations apply to the Amazon RDS DB instances:

- 10 for each SQL Server edition (Enterprise, Standard, Web, and Express) under the "license-included" model
- 10 for Oracle under the "license-included" model
- 40 for Db2 under the "bring-your-own-license" (BYOL) licensing model
- 40 for MySQL, MariaDB, or PostgreSQL
- 40 for Oracle under the "bring-your-own-license" (BYOL) licensing model

If your application requires more DB instances, you can request additional DB instances by opening the **Service Quotas console**. In the navigation pane, choose **AWS services**. Choose **Amazon Relational Database Service (Amazon RDS)**, choose a quota, and follow...
the directions to request a quota increase. For more information, see [Requesting a quota increase](#) in the *Service Quotas User Guide*.

For RDS for Oracle and RDS for SQL Server, the read replica limit is 5 per source database for each Region.

Backups managed by AWS Backup are considered manual DB snapshots, but don't count toward the manual snapshot quota. For information about AWS Backup, see the [AWS Backup Developer Guide](#).

If you use any RDS API operations and exceed the default quota for the number of calls per second, the Amazon RDS API issues an error like the following one.

ClientError: An error occurred (ThrottlingException) when calling the `API_name` operation: Rate exceeded.

Here, reduce the number of calls per second. The quota is meant to cover most use cases. If higher limits are needed, request a quota increase by contacting AWS Support. Open the [AWS Support Center](#) page, sign in if necessary, and choose *Create case*. Choose *Service limit increase*. Complete and submit the form.

**Note**

This quota can't be changed in the Amazon RDS Service Quotas console.

### Naming constraints in Amazon RDS

The following table describes naming constraints in Amazon RDS.

<table>
<thead>
<tr>
<th>Resource or item</th>
<th>Constraints</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB instance identifier</td>
<td>Identifiers have these naming constraints:</td>
</tr>
<tr>
<td></td>
<td>• Must contain 1–63 alphanumeric characters or hyphens.</td>
</tr>
<tr>
<td></td>
<td>• First character must be a letter.</td>
</tr>
<tr>
<td></td>
<td>• Can't end with a hyphen or contain two consecutive hyphens.</td>
</tr>
<tr>
<td>Resource or item</td>
<td>Constraints</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>• Must be unique for all DB instances per AWS account, per AWS Region.</td>
</tr>
<tr>
<td>Database name</td>
<td>Database name constraints differ for each database engine. For more information, see the available settings when creating each DB instance.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong></td>
</tr>
<tr>
<td></td>
<td>This approach doesn't apply to SQL Server. For SQL Server, you create your databases after you create your DB instance.</td>
</tr>
<tr>
<td>Master user name</td>
<td>Master user name constraints differ for each database engine. For more information, see the available settings when creating each DB instance.</td>
</tr>
<tr>
<td>Master password</td>
<td>The password for the database master user can include any printable ASCII character except /, ', '', @, or a space. For Oracle, &amp; is an additional character limitation. The password has the following number of printable ASCII characters depending on the DB engine:</td>
</tr>
<tr>
<td></td>
<td>• Db2: 8–255</td>
</tr>
<tr>
<td></td>
<td>• MariaDB and MySQL: 8–41</td>
</tr>
<tr>
<td></td>
<td>• Oracle: 8–30</td>
</tr>
<tr>
<td></td>
<td>• SQL Server and PostgreSQL: 8–128</td>
</tr>
<tr>
<td>DB parameter group name</td>
<td>These names have these constraints:</td>
</tr>
<tr>
<td></td>
<td>• Must contain 1–255 alphanumeric characters.</td>
</tr>
<tr>
<td></td>
<td>• First character must be a letter.</td>
</tr>
<tr>
<td></td>
<td>• Hyphens are allowed, but the name cannot end with a hyphen or contain two consecutive hyphens.</td>
</tr>
</tbody>
</table>
Resource or item | Constraints
--- | ---
DB subnet group name | These names have these constraints:
  - Must contain 1–255 characters.
  - Alphanumeric characters, spaces, hyphens, underscores, and periods are allowed.

### Maximum number of database connections

The maximum number of simultaneous database connections varies by the DB engine type and the memory allocation for the DB instance class. The maximum number of connections is generally set in the parameter group associated with the DB instance. The exception is Microsoft SQL Server, where it is set in the server properties for the DB instance in SQL Server Management Studio (SSMS).

Database connections consume memory. Setting one of these parameters too high can cause a low memory condition that might cause a DB instance to be placed in the `incompatible-parameters` status. For more information, see Diagnosing and resolving incompatible parameters status for a memory limit.

If your applications frequently open and close connections, or keep a large number of long-lived connections open, we recommend that you use Amazon RDS Proxy. RDS Proxy is a fully managed, highly available database proxy that uses connection pooling to share database connections securely and efficiently. To learn more about RDS Proxy, see Using Amazon RDS Proxy.

**Note**

For Oracle, you set the maximum number of user processes and user and system sessions. For Db2, you can't set maximum connections. The limit is 64000.
### Maximum database connections

<table>
<thead>
<tr>
<th>DB engine</th>
<th>Parameter</th>
<th>Allowed values</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MariaDB and MySQL</td>
<td>max_connections</td>
<td>1–100000</td>
<td>Default for all MariaDB and MySQL versions except for MariaDB version 10.5 and 10.6: {DBInstanceClassMemory/12582880} Default for MariaDB version 10.5 and 10.6: LEAST({DBInstanceClassMemory/25165760},12000)</td>
<td>Number of simultaneous client connections allowed</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td><strong>Note</strong> In either case, if the default value calculation results in a value greater than 16,000, Amazon RDS sets the limit to 16,000 for MariaDB and MySQL DB instances.</td>
<td></td>
</tr>
<tr>
<td>Oracle</td>
<td>processes</td>
<td>80–20000</td>
<td>LEAST({DBInstanceClassMemory/9868951},20000)</td>
<td>User processes</td>
</tr>
<tr>
<td>DB engine</td>
<td>Parameter</td>
<td>Allowed values</td>
<td>Default value</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>------------------------</td>
<td>-------------------------</td>
<td>------------------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>sessions</td>
<td>100–65535</td>
<td>–</td>
<td>User and system sessions</td>
</tr>
<tr>
<td>PostgreSQL</td>
<td>max_connections</td>
<td>6–8388607</td>
<td>LEAST(DBInstanceClassMemory/9531392, 5000)</td>
<td>Maximum number of concurrent connections</td>
</tr>
<tr>
<td>SQL Server</td>
<td>Maximum number of concurrent connections</td>
<td>0–32767</td>
<td>0 (unlimited)</td>
<td>Maximum number of concurrent connections</td>
</tr>
</tbody>
</table>

`DBInstanceClassMemory` is in bytes. For details about how this value is calculated, see [Specifying DB parameters](#). Because of memory reserved for the operating system and RDS management processes, this memory size is smaller than the value in gibibytes (GiB) shown in [Hardware specifications for DB instance classes](#).

For example, some DB instance classes have 8 GiB of memory, which is 8,589,934,592 bytes. For a MySQL DB instance running on a DB instance class with 8 GiB of memory, such as db.m7g.large, the equation that uses the total memory would be \( \frac{8589934592}{12582880} = 683 \). However, the variable `DBInstanceClassMemory` automatically subtracts the amounts reserved to the operating system and the RDS processes that manage the DB instance. The remainder of the subtraction is then divided by 12,582,880. This calculation results in approximately 630 for the value of `max_connections` instead of 683. This value depends on the DB instance class and DB engine.

When a MariaDB or MySQL DB instance is running on a small DB instance class, such as db.t3.micro or db.t3.small, the total memory available is low. For these DB instance classes, RDS reserves a significant portion of the available memory, which affects the value `max_connections`. For example, the default maximum number of connections for a MySQL DB instance running on a db.t3.micro DB instance class is approximately 60. You can determine the `max_connections` value for your DB MariaDB or MySQL DB instance by connecting to it and running the following SQL command:

```sql
SHOW GLOBAL VARIABLES LIKE 'max_connections';
```
File size limits in Amazon RDS

File size limits apply to certain Amazon RDS DB instances. For more information, see the following engine-specific limits:

- [MariaDB file size limits in Amazon RDS](#)
- [MySQL file size limits in Amazon RDS](#)
- [Oracle file size limits in Amazon RDS](#)
Troubleshooting for Amazon RDS

Use the following sections to help troubleshoot problems you have with DB instances in Amazon RDS and Amazon Aurora.

Topics

• Can't connect to Amazon RDS DB instance
• Amazon RDS security issues
• Troubleshooting incompatible-network state
• Resetting the DB instance owner password
• Amazon RDS DB instance outage or reboot
• Amazon RDS DB parameter changes not taking effect
• Amazon RDS DB instance running out of storage
• Amazon RDS insufficient DB instance capacity
• Freeable memory issues in Amazon RDS
• MySQL and MariaDB issues
• Can't set backup retention period to 0

For information about debugging problems using the Amazon RDS API, see Troubleshooting applications on Amazon RDS.

Can't connect to Amazon RDS DB instance

When you can't connect to a DB instance, the following are common causes:

• **Inbound rules** – The access rules enforced by your local firewall and the IP addresses authorized to access your DB instance might not match. The problem is most likely the inbound rules in your security group.

By default, DB instances don't allow access. Access is granted through a security group associated with the VPC that allows traffic into and out of the DB instance. If necessary, add inbound and outbound rules for your particular situation to the security group. You can specify an IP address, a range of IP addresses, or another VPC security group.
When adding a new inbound rule, you can choose **My IP** for **Source** to allow access to the DB instance from the IP address detected in your browser.

For more information about setting up security groups, see [Provide access to your DB instance in your VPC by creating a security group](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/CHAP_SecurityGroups.html).

**Note**

Client connections from IP addresses within the range 169.254.0.0/16 aren't permitted. This is the Automatic Private IP Addressing Range (APIPA), which is used for local-link addressing.

**Public accessibility** – To connect to your DB instance from outside of the VPC, such as by using a client application, the instance must have a public IP address assigned to it.

To make the instance publicly accessible, modify it and choose **Yes** under **Public accessibility**. For more information, see [Hiding a DB instance in a VPC from the internet](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/CHAP_SecurityGroups.html).

**Port** – The port that you specified when you created the DB instance can't be used to send or receive communications due to your local firewall restrictions. To determine if your network allows the specified port to be used for inbound and outbound communication, check with your network administrator.

**Availability** – For a newly created DB instance, the DB instance has a status of creating until the DB instance is ready to use. When the state changes to available, you can connect to the DB instance. Depending on the size of your DB instance, it can take up to 20 minutes before an instance is available.

**Internet gateway** – For a DB instance to be publicly accessible, the subnets in its DB subnet group must have an internet gateway.

**To configure an internet gateway for a subnet**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**, and then choose the name of the DB instance.
3. In the **Connectivity & security** tab, write down the values of the VPC ID under **VPC** and the subnet ID under **Subnets**.

4. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).

5. In the navigation pane, choose **Internet Gateways**. Verify that there is an internet gateway attached to your VPC. Otherwise, choose **Create Internet Gateway** to create an internet gateway. Select the internet gateway, and then choose **Attach to VPC** and follow the directions to attach it to your VPC.

6. In the navigation pane, choose **Subnets**, and then select your subnet.

7. On the **Route Table** tab, verify that there is a route with `0.0.0.0/0` as the destination and the internet gateway for your VPC as the target.

If you're connecting to your instance using its IPv6 address, verify that there is a route for all IPv6 traffic (`::/0`) that points to the internet gateway. Otherwise, do the following:

   a. Choose the ID of the route table (`rtb-xxxxxxxx`) to navigate to the route table.
   
   b. On the **Routes** tab, choose **Edit routes**. Choose **Add route**, use `0.0.0.0/0` as the destination and the internet gateway as the target.

        For IPv6, choose **Add route**, use `::/0` as the destination and the internet gateway as the target.

   c. Choose **Save routes**.

Also, if you are trying to connect to IPv6 endpoint, make sure that client IPv6 address range is authorized to connect to the DB instance.

For more information, see [Working with a DB instance in a VPC](#).

For engine-specific connection issues, see the following topics:

- [Troubleshooting connections to your SQL Server DB instance](#)
- [Troubleshooting connections to your Oracle DB instance](#)
- [Troubleshooting connections to your RDS for PostgreSQL instance](#)
- [Maximum MySQL and MariaDB connections](#)
Testing a connection to a DB instance

You can test your connection to a DB instance using common Linux or Microsoft Windows tools.

From a Linux or Unix terminal, you can test the connection by entering the following. Replace `DB-instance-endpoint` with the endpoint and `port` with the port of your DB instance.

```
network -zv DB-instance-endpoint port
```

For example, the following shows a sample command and the return value.

```
network -zv postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 8299
```

```
Connection to postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 8299 port [tcp/v4r-data] succeeded!
```

Windows users can use Telnet to test the connection to a DB instance. Telnet actions aren't supported other than for testing the connection. If a connection is successful, the action returns no message. If a connection isn't successful, you receive an error message such as the following.

```
C:\>telnet sg-postgresql1.c6c8mntfake0.us-west-2.rds.amazonaws.com 819

Connecting To sg-postgresql1.c6c8mntfake0.us-west-2.rds.amazonaws.com...Could not open connection to the host, on port 819: Connect failed
```

If Telnet actions return success, your security group is properly configured.

**Note**

Amazon RDS doesn't accept internet control message protocol (ICMP) traffic, including ping.

Troubleshooting connection authentication

In some cases, you can connect to your DB instance but you get authentication errors. In these cases, you might want to reset the master user password for the DB instance. You can do this by modifying the RDS instance.
For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

Amazon RDS security issues

To avoid security issues, never use your master AWS user name and password for a user account. Best practice is to use your master AWS account to create users and assign those to DB user accounts. You can also use your master account to create other user accounts, if necessary.

For information about creating users, see Creating an IAM user in your AWS account. For information about creating users in AWS IAM Identity Center, see Manage identities in IAM Identity Center.

Error message "failed to retrieve account attributes, certain console functions may be impaired."

You can get this error for several reasons. It might be because your account is missing permissions, or your account hasn't been properly set up. If your account is new, you might not have waited for the account to be ready. If this is an existing account, you might lack permissions in your access policies to perform certain actions such as creating a DB instance. To fix the issue, your administrator needs to provide the necessary roles to your account. For more information, see the IAM documentation.

Troubleshooting incompatible-network state

The incompatible-network state means that the database might still be accessible at the database level but you can't modify or reboot it.

Causes

The incompatible-network state of your DB instance could be a result of one of the following actions:

- Modifying the DB instance class.
- Modifying the DB instance to use Multi-AZ DB cluster deployment.
- Replacing a host due to a maintenance event.
- Launching a replacement DB instance.
- Restoring from a snapshot backup.
• Starting a DB instance that was stopped.

Resolution

Use start-db-instance command

To fix a database that is in an incompatible-network state, follow these instructions:

2. Choose the DB instance that is in the incompatible-network state and note the DB instance identifier, VPC ID, and subnet IDs from the Connectivity & Security tab.

3. Use the AWS CLI to run the `start-db-instance` command. Specify the `--db-instance-identifier` value.

   **Note**
   
   Running this command when your database is in incompatible mode might cause some downtime.
   The `start-db-instance` command does not resolve this issue for RDS for SQL Server DB instances.

Your database status changes to Available if the command executes successfully.

If your database restarts, the DB instance might execute the last operation run on the instance before it was moved to incompatible-network state. This might move the instance back to the incompatible-network state.

If the `start-db-instance` command is unsuccessful or the instance moves back to incompatible-network state, open the Databases page in the RDS console and select the database. Navigate to the Logs & events section. The Recent events section displays further resolution steps to follow. The messages are classified as follows:

• **INTERNAL RESOURCE CHECK**: There might be issues with your internal resources.

• **DNS CHECK**: Check DNS resolution and hostnames for the VPC in the VPC console.

• **ENI CHECK**: The elastic network interface (ENI) for your database might not exist.
• **GATEWAY CHECK**: The internet gateway for your publicly available database is not attached to the VPC.

• **IP CHECK**: There are no free IP addresses in your subnets.

• **SECURITY GROUP CHECK**: There are no security groups associated with your database or the security groups are invalid.

• **SUBNET CHECK**: There are no valid subnets in your DB subnet group or there are issues with your subnet.

• **VPC CHECK**: The VPC associated with your database is invalid.

**Perform point-in-time recovery**

It is best practice to have a backup (snapshot or logical), in case your database enters incompatible-network state. See [Introduction to backups](#). If you turned on automated backups, then temporarily stop any writes to the database and perform a point-in-time recovery.

![Note]

After an instance enters the incompatible-network state, the DB instance might not be accessible to perform a logical backup.

If you didn't turn on automated backups, create a new DB instance. Then migrate the data using [AWS Database Migration Service (AWS DMS)](https://aws.amazon.com/dms), or by using a backup and restore tool.

If this does not resolve the issue, contact AWS Support for further assistance.

**Resetting the DB instance owner password**

If you get locked out of your DB instance, you can log in as the master user. Then you can reset the credentials for other administrative users or roles. If you can't log in as the master user, the AWS account owner can reset the master user password. For details of which administrative accounts or roles you might need to reset, see [Master user account privileges](#).

You can change the DB instance password by using the Amazon RDS console, the AWS CLI command `modify-db-instance`, or by using the [ModifyDBInstance](https://docs.aws.amazon.com/AmazonRDS/latest/userguide/RDS-API-modify-db-instance.html) API operation. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](https://docs.aws.amazon.com/AmazonRDS/latest/userguide/RDS-API-modify-db-instance.html).
Amazon RDS DB instance outage or reboot

A DB instance outage can occur when a DB instance is rebooted. It can also occur when the DB instance is put into a state that prevents access to it, and when the database is restarted. A reboot can occur when you manually reboot your DB instance. A reboot can also occur when you change a DB instance setting that requires a reboot before it can take effect.

A DB instance reboot occurs when you change a setting that requires a reboot, or when you manually cause a reboot. A reboot can occur immediately if you change a setting and request that the change take effect immediately. Or it can occur during the DB instance's maintenance window.

A DB instance reboot occurs immediately when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0. You then set Apply Immediately to true.
- You change the DB instance class, and Apply Immediately is set to true.
- You change the storage type from Magnetic (Standard) to General Purpose (SSD) or Provisioned IOPS (SSD), or from Provisioned IOPS (SSD) or General Purpose (SSD) to Magnetic (Standard).

A DB instance reboot occurs during the maintenance window when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0, and Apply Immediately is set to false.
- You change the DB instance class, and Apply Immediately is set to false.

When you change a static parameter in a DB parameter group, the change doesn't take effect until the DB instance associated with the parameter group is rebooted. The change requires a manual reboot. The DB instance isn't automatically rebooted during the maintenance window.

To see a table that shows DB instance actions and the effect that setting the Apply Immediately value has, see Modifying an Amazon RDS DB instance.

Amazon RDS DB parameter changes not taking effect

In some cases, you might change a parameter in a DB parameter group but don't see the changes take effect. If so, you likely need to reboot the DB instance associated with the DB parameter
When you change a dynamic parameter, the change takes effect immediately. When you change a static parameter, the change doesn't take effect until you reboot the DB instance associated with the parameter group.

You can reboot a DB instance using the RDS console. Or you can explicitly call the `RebootDBInstance` API operation. You can reboot without failover if the DB instance is in a Multi-AZ deployment. The requirement to reboot the associated DB instance after a static parameter change helps mitigate the risk of a parameter misconfiguration affecting an API call. An example of this is calling `ModifyDBInstance` to change the DB instance class. For more information, see Modifying parameters in a DB parameter group.

### Amazon RDS DB instance running out of storage

If your DB instance runs out of storage space, it might no longer be available. We highly recommend that you constantly monitor the `FreeStorageSpace` metric published in CloudWatch to make sure that your DB instance has enough free storage space.

If your database instance runs out of storage, its status changes to `storage-full`. For example, a call to the `DescribeDBInstances` API operation for a DB instance that has used up its storage outputs the following.

```shell
aws rds describe-db-instances --db-instance-identifier mydbinstance
```

```
DBINSTANCE mydbinstance 2009-12-22T23:06:11.915Z db.m5.large mysql8.0 50 sa
storage-full mydbinstance.clla4j4jgyph.us-east-1.rds.amazonaws.com 3306
us-east-1b 3
SECGROUP default active
PARAMGRP default.mysql8.0 in-sync
```

To recover from this scenario, add more storage space to your instance using the `ModifyDBInstance` API operation or the following AWS CLI command.

**For Linux, macOS, or Unix:**

```shell
aws rds modify-db-instance \
--db-instance-identifier mydbinstance \
--allocated-storage 60 \
--apply-immediately
```

**For Windows:**

```shell
``
aws rds modify-db-instance
  --db-instance-identifier mydbinstance
  --allocated-storage 60
  --apply-immediately

Now, when you describe your DB instance, you see that your DB instance has modifying status, which indicates the storage is being scaled.

aws rds describe-db-instances --db-instance-identifier mydbinstance

After storage scaling is complete, your DB instance status changes to available.

aws rds describe-db-instances --db-instance-identifier mydbinstance

You can receive notifications when your storage space is exhausted using the DescribeEvents operation. For example, in this scenario, if you make a DescribeEvents call after these operations you see the following output.

aws rds describe-events --source-type db-instance --source-identifier mydbinstance

DB instance out of storage
Amazon RDS insufficient DB instance capacity

The InsufficientDBInstanceCapacity error can be returned when you try to create, start, or modify a DB instance. It can also be returned when you try to restore a DB instance from a DB snapshot. When this error is returned, a common cause is that the specific DB instance class isn't available in the requested Availability Zone. You can try one of the following to solve the problem:

- Retry the request with a different DB instance class.
- Retry the request with a different Availability Zone.
- Retry the request without specifying an explicit Availability Zone.

For information about troubleshooting instance capacity issues for Amazon EC2, see Insufficient instance capacity in the Amazon EC2 User Guide.

For information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

Freeable memory issues in Amazon RDS

Freeable memory is the total random access memory (RAM) on a DB instance that can be made available to the database engine. It's the sum of the free operating-system (OS) memory and the available buffer and page cache memory. The database engine uses most of the memory on the host, but OS processes also use some RAM. Memory currently allocated to the database engine or used by OS processes isn't included in freeable memory. When the database engine is running out of memory, the DB instance can use the temporary space that is normally used for buffering and caching. As previously mentioned, this temporary space is included in freeable memory.

You use the FreeableMemory metric in Amazon CloudWatch to monitor the freeable memory. For more information, see Overview of monitoring metrics in Amazon RDS.

If your DB instance consistently runs low on freeable memory or uses swap space, consider scaling up to a larger DB instance class. For more information, see DB instance classes.
You can also change the memory settings. For example, on RDS for MySQL, you might adjust the size of the `innodb_buffer_pool_size` parameter. This parameter is set by default to 75 percent of physical memory. For more MySQL troubleshooting tips, see [How can I troubleshoot low freeable memory in an Amazon RDS for MySQL database?](#)

**MySQL and MariaDB issues**

You can diagnose and correct issues with MySQL and MariaDB DB instances.

Topics

- [Maximum MySQL and MariaDB connections](#)
- [Diagnosing and resolving incompatible parameters status for a memory limit](#)
- [Diagnosing and resolving lag between read replicas](#)
- [Diagnosing and resolving a MySQL or MariaDB read replication failure](#)

- [Diagnosing and resolving point-in-time restore failures](#)
- [Replication stopped error](#)
- [Read replica create fails or replication breaks with fatal error 1236](#)

**Maximum MySQL and MariaDB connections**

The maximum number of connections allowed to an RDS for MySQL or RDS for MariaDB DB instance is based on the amount of memory available for its DB instance class. A DB instance class with more memory available results in a larger number of connections available. For more information on DB instance classes, see [DB instance classes](#).

The connection limit for a DB instance is set by default to the maximum for the DB instance class. You can limit the number of concurrent connections to any value up to the maximum number of connections allowed. Use the `max_connections` parameter in the parameter group for the DB instance. For more information, see [Maximum number of database connections](#) and [Working with parameter groups](#).

You can retrieve the maximum number of connections allowed for a MySQL or MariaDB DB instance by running the following query.

```sql
SELECT @@max_connections;
```
You can retrieve the number of active connections to a MySQL or MariaDB DB instance by running the following query.

```
SHOW STATUS WHERE `variable_name` = 'Threads_connected';
```

**Diagnosing and resolving incompatible parameters status for a memory limit**

A MariaDB or MySQL DB instance can be placed in **incompatible-parameters** status for a memory limit when the following conditions are met:

- The DB instance is restarted at least three times in one hour or at least five times in one day when the DB instance status is **Available**.
- An attempt to restart the DB instance fails because a maintenance action or monitoring process couldn't restart the DB instance.
- The potential memory usage of the DB instance exceeds 1.2 times the memory allocated to its DB instance class.

When a DB instance is restarted for the third time in one hour or for the fifth time in one day, it performs a check for memory usage. The check makes a calculation of the potential memory usage of the DB instance. The value returned by the calculation is the sum of the following values:

- **Value 1** – The sum of the following parameters:
  - `innodb_additional_mem_pool_size`
  - `innodb_buffer_pool_size`
  - `innodb_log_buffer_size`
  - `key_buffer_size`
  - `query_cache_size` (MySQL version 5.7 only)
  - `tmp_table_size`
- **Value 2** – The `max_connections` parameter multiplied by the sum of the following parameters:
  - `binlog_cache_size`
  - `join_buffer_size`
  - `read_buffer_size`
  - `read_rnd_buffer_size`
• sort_buffer_size

• thread_stack

• **Value 3** – If the performance_schema parameter is enabled, then multiply the max_connections parameter by 257700.

If the performance_schema parameter is disabled, then this value is zero.

So, the value returned by the calculation is the following:

Value 1 + Value 2 + Value 3

When this value exceeds 1.2 times the memory allocated to the DB instance class used by the DB instance, the DB instance is placed in incompatible-parameters status. For information about the memory allocated to DB instance classes, see Hardware specifications for DB instance classes.

The calculation multiplies the value of the max_connections parameter by the sum of several parameters. If the max_connections parameter is set to a large value, it might cause the check to return an inordinately high value for the potential memory usage of the DB instance. In this case, consider lowering the value of the max_connections parameter.

To resolve the problem, complete the following steps:

1. Adjust the memory parameters in the DB parameter group associated with the DB instance. Do so such that the potential memory usage is lower than 1.2 times the memory allocated to its DB instance class.

   For information about setting parameters, see Modifying parameters in a DB parameter group.

2. Restart the DB instance.

   For information about setting parameters, see Starting an Amazon RDS DB instance that was previously stopped.

**Diagnosing and resolving lag between read replicas**

After you create a MySQL or MariaDB read replica and the replica is available, Amazon RDS first replicates the changes made to the source DB instance from the time the read replica create operation started. During this phase, the replication lag time for the read replica is greater than 0.
You can monitor this lag time in Amazon CloudWatch by viewing the Amazon RDS ReplicaLag metric.

The ReplicaLag metric reports the value of the Seconds_Behind_Master field of the MariaDB or MySQL SHOW REPLICA STATUS command. For more information, see SHOW REPLICA STATUS Statement in the MySQL documentation.

When the ReplicaLag metric reaches 0, the replica has caught up to the source DB instance. If the ReplicaLag metric returns -1, replication might not be active. To troubleshoot a replication error, see Diagnosing and resolving a MySQL or MariaDB read replication failure. A ReplicaLag value of -1 can also mean that the Seconds_Behind_Master value can't be determined or is NULL.

**Note**

Previous versions of MariaDB and MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MariaDB version before 10.5 or a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

The ReplicaLag metric returns -1 during a network outage or when a patch is applied during the maintenance window. In this case, wait for network connectivity to be restored or for the maintenance window to end before you check the ReplicaLag metric again.

The MySQL and MariaDB read replication technology is asynchronous. Thus, you can expect occasional increases for the BinLogDiskUsage metric on the source DB instance and for the ReplicaLag metric on the read replica. For example, consider a situation where a high volume of write operations to the source DB instance occur in parallel. At the same time, write operations to the read replica are serialized using a single I/O thread. Such a situation can lead to a lag between the source instance and read replica.

For more information about read replicas and MySQL, see Replication implementation details in the MySQL documentation. For more information about read replicas and MariaDB, see Replication overview in the MariaDB documentation.

You can reduce the lag between updates to a source DB instance and the subsequent updates to the read replica by doing the following:

- Set the DB instance class of the read replica to have a storage size comparable to that of the source DB instance.
• Make sure that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the `max_allowed_packet` parameter in the next section.

• Disable the query cache. For tables that are modified often, using the query cache can increase replica lag because the cache is locked and refreshed often. If this is the case, you might see less replica lag if you disable the query cache. You can disable the query cache by setting the `query_cache_type` parameter to 0 in the DB parameter group for the DB instance. For more information on the query cache, see **Query cache configuration**.

• Warm the buffer pool on the read replica for InnoDB for MySQL or MariaDB. For example, suppose that you have a small set of tables that are being updated often and you're using the InnoDB or XtraDB table schema. In this case, dump those tables on the read replica. Doing this causes the database engine to scan through the rows of those tables from the disk and then cache them in the buffer pool. This approach can reduce replica lag. The following shows an example.

For Linux, macOS, or Unix:

```bash
PROMPT> mysqldump \
    -h <endpoint> \
    --port=<port> \
    -u=<username> \
    -p <password> \
    database_name table1 table2 > /dev/null
```

For Windows:

```bash
PROMPT> mysqldump ^
    -h <endpoint> ^
    --port=<port> ^
    -u=<username> ^
    -p <password> ^
    database_name table1 table2 > /dev/null
```

## Diagnosing and resolving a MySQL or MariaDB read replication failure

Amazon RDS monitors the replication status of your read replicas. RDS updates the **Replication State** field of the read replica instance to **Error** if replication stops for any reason. You can review the details of the associated error thrown by the MySQL or MariaDB engines by viewing
the Replication Error field. Events that indicate the status of the read replica are also generated, including RDS-EVENT-0045, RDS-EVENT-0046, and RDS-EVENT-0057. For more information about events and subscribing to events, see Working with Amazon RDS event notification. If a MySQL error message is returned, check the error in the MySQL error message documentation. If a MariaDB error message is returned, check the error in the MariaDB error message documentation.

Common situations that can cause replication errors include the following:

- The value for the max_allowed_packet parameter for a read replica is less than the max_allowed_packet parameter for the source DB instance.

  The max_allowed_packet parameter is a custom parameter that you can set in a DB parameter group. The max_allowed_packet parameter is used to specify the maximum size of data manipulation language (DML) that can be run on the database. In some cases, the max_allowed_packet value for the source DB instance might be larger than the max_allowed_packet value for the read replica. If so, the replication process can throw an error and stop replication. The most common error is packet bigger than 'max_allowed_packet' bytes. You can fix the error by having the source and read replica use DB parameter groups with the same max_allowed_packet parameter values.

- Writing to tables on a read replica. If you're creating indexes on a read replica, you need to have the read_only parameter set to 0 to create the indexes. If you're writing to tables on the read replica, it can break replication.

- Using a nontransactional storage engine such as MyISAM. Read replicas require a transactional storage engine. Replication is only supported for the following storage engines: InnoDB for MySQL or MariaDB.

  You can convert a MyISAM table to InnoDB with the following command:

  ```sql
  alter table <schema>.<table_name> engine=innodb;
  ```

- Using unsafe nondeterministic queries such as SYSDATE(). For more information, see Determination of safe and unsafe statements in binary logging in the MySQL documentation.

The following steps can help resolve your replication error:

- If you encounter a logical error and you can safely skip the error, follow the steps described in Skipping the current replication error. Your MySQL or MariaDB DB instance must be running a version that includes the mysql_rds_skip_repl_error procedure. For more information, see mysql.rds_skip_repl_error.
• If you encounter a binary log (binlog) position issue, you can change the replica replay position with the `mysql_rds_next_master_log` command. Your MySQL or MariaDB DB instance must be running a version that supports the `mysql_rds_next_master_log` command to change the replica replay position. For version information, see `mysql.rds_next_master_log`.

• You might encounter a temporary performance issue due to high DML load. If so, you can set the `innodb_flush_log_at_trx_commit` parameter to 2 in the DB parameter group on the read replica. Doing this can help the read replica catch up, though it temporarily reduces atomicity, consistency, isolation, and durability (ACID).

• You can delete the read replica and create an instance using the same DB instance identifier. If you do this, the endpoint remains the same as that of your old read replica.

If a replication error is fixed, the Replication State changes to replicating. For more information, see Troubleshooting a MySQL read replica problem.

Creating triggers with binary logging enabled requires SUPER privilege

When trying to create triggers in an RDS for MySQL or RDS for MariaDB DB instance, you might receive the following error.

"You do not have the SUPER privilege and binary logging is enabled"

To use triggers when binary logging is enabled requires the SUPER privilege, which is restricted for RDS for MySQL and RDS for MariaDB DB instances. You can create triggers when binary logging is enabled without the SUPER privilege by setting the `log_bin_trust_function_creators` parameter to true. To set the `log_bin_trust_function_creators` to true, create a new DB parameter group or modify an existing DB parameter group.

You can create a new DB parameter group so you can create triggers in your RDS for MySQL or RDS for MariaDB DB instance with binary logging enabled. To do so, use the following CLI commands. To modify an existing parameter group, start with step 2.

**To create a new parameter group to allow triggers with binary logging enabled using the CLI**

1. Create a new parameter group.

   For Linux, macOS, or Unix:

   ```bash
   aws rds create-db-parameter-group
   ```
--db-parameter-group-name allow-triggers \ 
--db-parameter-group-family mysql8.0 \ 
--description "parameter group allowing triggers"

For Windows:

aws rds create-db-parameter-group ^
   --db-parameter-group-name allow-triggers ^
   --db-parameter-group-family mysql8.0 ^
   --description "parameter group allowing triggers"

2. Modify the DB parameter group to allow triggers.

   For Linux, macOS, or Unix:

   aws rds modify-db-parameter-group \ 
     --db-parameter-group-name allow-triggers \ 
     --parameters "ParameterName=log_bin_trust_functionCreators, ParameterValue=true, ApplyMethod=pending-reboot"

   For Windows:

   aws rds modify-db-parameter-group ^
     --db-parameter-group-name allow-triggers ^
     --parameters "ParameterName=log_bin_trust_functionCreators, ParameterValue=true, ApplyMethod=pending-reboot"

3. Modify your DB instance to use the new DB parameter group.

   For Linux, macOS, or Unix:

   aws rds modify-db-instance \ 
     --db-instance-identifier mydbinstance \ 
     --db-parameter-group-name allow-triggers \ 
     --apply-immediately

   For Windows:

   aws rds modify-db-instance ^
     --db-instance-identifier mydbinstance ^
     --db-parameter-group-name allow-triggers ^
4. For the changes to take effect, manually reboot the DB instance.

```
aws rds reboot-db-instance --db-instance-identifier mydbinstance
```

## Diagnosing and resolving point-in-time restore failures

### Restoring a DB Instance That Includes Temporary Tables

When attempting a point-in-time restore (PITR) of your MySQL or MariaDB DB instance, you might encounter the following error.

```
Database instance could not be restored because there has been incompatible database activity for restore functionality. Common examples of incompatible activity include using temporary tables, in-memory tables, or using MyISAM tables. In this case, use of Temporary table was detected.
```

PITR relies on both backup snapshots and binary logs (binlogs) from MySQL or MariaDB to restore your DB instance to a particular time. Temporary table information can be unreliable in binlogs and can cause a PITR failure. If you use temporary tables in your MySQL or MariaDB DB instance, you can lower the possibility of a PITR failure. To do so, perform more frequent backups. A PITR failure is most probable in the time between a temporary table's creation and the next backup snapshot.

### Restoring a DB Instance That Includes In-Memory Tables

You might encounter a problem when restoring a database that has in-memory tables. In-memory tables are purged during a restart. As a result, your in-memory tables might be empty after a reboot. We recommend that when you use in-memory tables, you architect your solution to handle empty tables in the event of a restart. If you're using in-memory tables with replicated DB instances, you might need to recreate the read replicas after a restart. This might be necessary if a read replica reboots and can't restore data from an empty in-memory table.

For more information about backups and PITR, see [Introduction to backups](#) and [Restoring a DB instance to a specified time](#).
Replication stopped error

When you call the `mysql.rds_skip_repl_error` command, you might receive an error message stating that replication is down or disabled.

This error message appears because replication is stopped and can't be restarted.

If you need to skip a large number of errors, the replication lag can increase beyond the default retention period for binary log files. In this case, you might encounter a fatal error due to binary log files being purged before they have been replayed on the replica. This purge causes replication to stop, and you can no longer call the `mysql.rds_skip_repl_error` command to skip replication errors.

You can mitigate this issue by increasing the number of hours that binary log files are retained on your replication source. After you have increased the binlog retention time, you can restart replication and call the `mysql.rds_skip_repl_error` command as needed.

To set the binlog retention time, use the `mysql.rds_set_configuration` procedure. Specify a configuration parameter of 'binlog retention hours' along with the number of hours to retain binlog files on the DB cluster, up to 720 (30 days). The following example sets the retention period for binlog files to 48 hours.

```sql
CALL mysql.rds_set_configuration('binlog retention hours', 48);
```

Read replica create fails or replication breaks with fatal error 1236

After changing default parameter values for a MySQL or MariaDB DB instance, you might encounter one of the following problems:

- You can't create a read replica for the DB instance.
- Replication fails with fatal error 1236.

Some default parameter values for MySQL and MariaDB DB instances help to make sure that the database is ACID compliant and read replicas are crash-safe. They do this by making sure that each commit is fully synchronized by writing the transaction to the binary log before it's committed. Changing these parameters from their default values to improve performance can cause replication to fail when a transaction hasn't been written to the binary log.

To resolve this issue, set the following parameter values:
• sync_binlog = 1
• innodb_support_xa = 1
• innodb_flush_log_at_trx_commit = 1

Can't set backup retention period to 0

There are several reasons why you might need to set the backup retention period to 0. For example, you can disable automatic backups immediately by setting the retention period to 0.

In some cases, you might set the value to 0 and receive a message saying that the retention period must be between 1 and 35. In these cases, check to make sure that you haven't set up a read replica for the instance. Read replicas require backups for managing read replica logs, and therefore you can't set a retention period of 0.
Amazon RDS API reference

In addition to the AWS Management Console and the AWS Command Line Interface (AWS CLI), Amazon RDS also provides an API. You can use the API to automate tasks for managing your DB instances and other objects in Amazon RDS.

- For an alphabetical list of API operations, see Actions.
- For an alphabetical list of data types, see Data types.
- For a list of common query parameters, see Common parameters.
- For descriptions of the error codes, see Common errors.

For more information about the AWS CLI, see AWS Command Line Interface reference for Amazon RDS.

Topics
- Using the Query API
- Troubleshooting applications on Amazon RDS

Using the Query API

The following sections briefly discuss the parameters and request authentication used with the Query API.

For general information about how the Query API works, see Query requests in the Amazon EC2 API Reference.

Query parameters

HTTP Query-based requests are HTTP requests that use the HTTP verb GET or POST and a Query parameter named Action.

Each Query request must include some common parameters to handle authentication and selection of an action.

Some operations take lists of parameters. These lists are specified using the param.\text{n} notation. Values of \text{n} are integers starting from 1.
Query request authentication

You can only send Query requests over HTTPS, and you must include a signature in every Query request. You must use either AWS signature version 4 or signature version 2. For more information, see Signature Version 4 signing process and Signature version 2 signing process.

Troubleshooting applications on Amazon RDS

Amazon RDS provides specific and descriptive errors to help you troubleshoot problems while interacting with the Amazon RDS API.

Topics

• Retrieving errors
• Troubleshooting tips

For information about troubleshooting for Amazon RDS DB instances, see Troubleshooting for Amazon RDS.

Retrieving errors

Typically, you want your application to check whether a request generated an error before you spend any time processing results. The easiest way to find out if an error occurred is to look for an Error node in the response from the Amazon RDS API.

XPath syntax provides a simple way to search for the presence of an Error node. It also provides a relatively easy way to retrieve the error code and message. The following code snippet uses Perl and the XML::XPath module to determine if an error occurred during a request. If an error occurred, the code prints the first error code and message in the response.

```perl
use XML::XPath;
my $xp = XML::XPath->new(xml =>$response);
if ( $xp->find("//Error") )
{print "There was an error processing your request:\n", " Error code: ",
 $xp->findvalue("//Error[1]/Code"), "\n", " ",
 $xp->findvalue("//Error[1]/Message"), "\n\n"; }
```
Troubleshooting tips

We recommend the following processes to diagnose and resolve problems with the Amazon RDS API:

- Verify that Amazon RDS is operating normally in the AWS Region that you're targeting by checking [http://status.aws.amazon.com](http://status.aws.amazon.com).
- Check the structure of your request.

Each Amazon RDS operation has a reference page in the *Amazon RDS API Reference*. Double-check that you are using parameters correctly. For ideas about what might be wrong, look at the sample requests or user scenarios to see if those examples do similar operations.

- Check AWS re:Post.

Amazon RDS has a development community where you can search for solutions to problems others have experienced along the way. To view the topics, go to [AWS re:Post](http://aws.amazon.com/repost).
# Document history

**Current API version:** 2014-10-31

The following table describes important changes in each release of the *Amazon RDS User Guide* after May 2018. For notification about updates to this documentation, you can subscribe to an RSS feed.

![Note]

*You can filter new Amazon RDS features on the [What's New with Database?](https://aws.amazon.com/database/modernization/new-with-database/) page. For Products, choose Amazon RDS. Then search using keywords such as **RDS Proxy** or **Oracle 2023**.*

</tbody>
</table>
RDS Custom for Oracle is available in the Middle East (UAE) Region

You can create RDS Custom for Oracle DB instances in the Middle East (UAE) Region. For a table that shows all supported AWS Regions, see RDS Custom for Oracle.

New AWS managed policy

Amazon RDS added a new managed policy named AmazonRDS Custom InstanceProfileRolePolicy to allow RDS Custom to perform automation actions and database management tasks through an EC2 instance profile. For more information, see Amazon RDS updates to AWS managed policies.

Amazon RDS supports MariaDB 10.11.7, 10.6.17, 10.5.24, and 10.4.33

You can now create Amazon RDS DB instances running MariaDB version 10.11.7, 10.6.17, 10.5.24, and 10.4.33. For more information, see MariaDB on Amazon RDS versions.

Amazon RDS Multi-AZ DB clusters support the Amazon EBS gp3 storage volume

Multi-AZ DB clusters now support gp3 SSD-based EBS volumes. For more information, see gp3 storage.
Amazon RDS support for AWS Secrets Manager in the Israel (Tel Aviv) Region

Amazon RDS supports Secrets Manager in the Israel (Tel Aviv) Region. For more information, see Password management with Amazon RDS and AWS Secrets Manager.

February 21, 2024

Amazon RDS for Db2 supports audit logging

RDS for Db2 now supports database-level audit logging. When you enable audit logging for an RDS for Db2 database, Amazon RDS records the database activity and stores the audit logs in Amazon S3. For more information, see Db2 audit logging.

February 15, 2024

Amazon RDS Extended Support

Amazon RDS now automatically enables Amazon RDS Extended Support when RDS for MySQL and RDS for PostgreSQL major engine versions in your DB instances and Multi-AZ DB clusters reach the RDS end of standard support date. For more information, see Using Amazon RDS Extended Support.

February 15, 2024

Amazon RDS supports MySQL 8.0.36

You can now create Amazon RDS DB instances running MySQL version 8.0.36. For more information, see MySQ L on Amazon RDS versions.

RDS Proxy supports Multi-AZ DB clusters

RDS Proxy now supports connecting to Multi-AZ DB clusters. For more information, see Working with Amazon RDS Proxy endpoints.

RDS Custom for Oracle is available in the AWS GovCloud (US) Regions

Amazon RDS is now available in the AWS GovCloud (US) Regions. For more information, see RDS Custom for Oracle.

Amazon RDS Optimized Writes supports the db.m5 DB instance class

Amazon RDS Optimized Writes now supports the db.m5 DB instance class. For more information, see Improving write performance with Amazon RDS Optimized Writes for MariaDB and Improving write performance with Amazon RDS Optimized Writes for MySQL.
Amazon RDS for Oracle supports the multi-tenant configuration of the CDB architecture.

With the RDS for Oracle multi-tenant feature, RDS delivers a fully managed Oracle multitenant architecture and experience for your Oracle databases. You can use RDS APIs to create multiple PDBs, called tenant databases, in a CDB. RDS offers the multi-tenant configuration of the CDB architecture as an alternative to the legacy single-tenant configuration. For more information, see Multi-tenant configuration of the CDB architecture.

Amazon RDS exports Performance Insights metrics to Amazon CloudWatch.

Performance Insights lets you export the preconfigured or custom metrics dashboards to Amazon CloudWatch. The exported metrics dashboards are available to view in the CloudWatch console. You can also export a selected Performance Insights metric widget and view the metrics data in the CloudWatch console. For more information, see Exporting Performance Insights metrics to CloudWatch.

</table>
Amazon RDS Custom for Oracle supports a nondefault Oracle SID

When you create an RDS Custom for Oracle DB instance using Oracle Database 19c, you can specify a nondefault Oracle system identifier (Oracle SID). This value is also the name of the CDB. For more information, see Multitenant architecture considerations.

RDS for SQL Server supports Self Managed Active Directory

You can now use Self Managed Active Directory to directly join your RDS for SQL Server DB instances to your Microsoft Active Directory (AD) domains. Self-managed AD domains can be on-premises or in the cloud. For more information, see Working with Self Managed Active Directory.

PostgreSQL logical replication support for Multi-AZ DB clusters

You can now use PostgreSQL logical replication with your Multi-AZ DB cluster to replicate and synchronize individual tables rather than an entire database instance. For more information, see Using PostgreSQL logical replication with Multi-AZ DB clusters.

</table>
RDS supports MariaDB 10.6.13, 10.5.20, 10.4.29, and 10.3.39

You can now create Amazon RDS DB instances running MariaDB version 10.6.13, 10.5.20, 10.4.29, and 10.3.39. For more information, see MariaDB on Amazon RDS versions.

June 15, 2023

RDS for Oracle supports transportable tablespaces

You can migrate data from an on-premises Oracle database into an RDS for Oracle DB instance using transportable tablespaces. This technique doesn't require additional licensing and is the migration technique with the least downtime. For more information, see Migrating using Oracle transportable tablespaces.

June 15, 2023

Amazon RDS supports RDS Proxy with RDS for MariaDB version 10.6

You can now create an RDS Proxy with an RDS for MariaDB version 10.6 database. For more information about RDS Proxy, see Using Amazon RDS Proxy.

June 15, 2023

RDS Custom for SQL Server supports Bring Your Own Media (BYOM)

You can now create a Custom Engine Version (CEV) using your own SQL Server media. For more information, see Bring Your Own Media with RDS Custom for SQL Server.

June 8, 2023
RDS for Oracle can convert an Oracle Database 19c non-CDB to a CDB

If your DB instance runs Oracle Database 19c with the April 2021 or higher RU, you can convert a non-CDB to a CDB (container database). After you convert the architecture, you can upgrade your 19c CDB to a 21c CDB. This step is necessary because you can't upgrade your database and convert the architecture using a single command. For more information, see Converting an RDS for Oracle non-CDB into a CDB.

Multi-AZ DB clusters available in the China Regions

Multi-AZ DB clusters are now available in the AWS Regions China (Beijing) and China (Ningxia). For more information, see Multi-AZ DB clusters.

Amazon RDS Optimized Reads support for Multi-AZ DB clusters

Amazon RDS Optimized Reads now supports Multi-AZ DB clusters. For more information, see Improving query performance for RDS for MySQL with Amazon RDS Optimized Reads and Improving query performance for RDS for PostgreSQL with Amazon RDS Optimized Reads.

Amazon DevOps Guru available for RDS for PostgreSQL

RDS for PostgreSQL alerts you to recent anomalies detected by Amazon DevOps Guru. The database details page of the console alerts you to current and anomalies that occurred in the past 24 hours. DevOps Guru publishes proactive insights with recommendations to help address issues in your RDS for PostgreSQL databases before they are predicted to happen. For more information, see How DevOps Guru for RDS works.

March 30, 2023

RDS Custom supports the Amazon EBS gp3 storage volume

RDS Custom for Oracle and RDS Custom for SQL Server both support the io1, gp2, and gp3 SSD-based EBS volumes. For more information, see General requirements for RDS Custom for Oracle and General requirements for RDS Custom for SQL Server.

</table>
Amazon RDS supports automatically setting up connectivity between an RDS database and an EC2 instance

You can use the AWS Management Console to set up connectivity between an existing RDS DB instance or Multi-AZ DB cluster and an EC2 instance. For more information, see Connecting an EC2 instance and an RDS database automatically.

AWS JDBC Driver for PostgreSQL generally available

The AWS JDBC Driver for PostgreSQL is a client driver designed for RDS for PostgreSQL. The AWS JDBC Driver for PostgreSQL is now generally available. For more information, see Connecting with the AWS JDBC Driver for PostgreSQL.

Amazon RDS for Oracle supports Oracle APEX version 21.2.v1

APEX 21.2 includes patch 33420059. For more information, see APEX version requirements.

RDS supports MySQL 5.7.39

You can now create Amazon RDS DB instances running MySQL versions 5.7.39. For more information, see MySQL on Amazon RDS versions.

RDS supports MariaDB 10.6.10

You can now create Amazon RDS DB instances running MariaDB versions 10.6.10. For more information, see MariaDB on Amazon RDS versions.

October 14, 2022

October 6, 2022

October 3, 2022

September 29, 2022

September 29, 2022
**RDS Proxy supports RDS for SQL Server**
You can now create an RDS Proxy for an RDS DB instance that runs Microsoft SQL Server version 2014 or higher. For more information about RDS Proxy, see [Using Amazon RDS Proxy](#).

**RDS supports MariaDB 10.5.17, 10.4.26, and 10.3.36**
You can now create Amazon RDS DB instances running MariaDB versions 10.5.17, 10.4.26, and 10.3.36. For more information, see [MariaDB on Amazon RDS versions](#).

**Amazon RDS for Oracle supports local instance storage for temporary data**
You can now launch Amazon RDS for Oracle on Amazon EC2 db.r5d and db.m5d instance types with the temporary tablespace and Database Smart Flash Cache (the flash cache) configured to use an instance store. By storing temporary data locally, you can achieve lower read and write latencies when compared to standard storage based on Amazon EBS. For more information, see [Storing temporary Oracle data in the instance store](#).

</tr>
<tr>
<td><strong>Amazon RDS on AWS Outposts supports scale storage and autoscaling operations</strong></td>
<td>You can now change the storage sizes of DB instances on your Outpost and use storage autoscaling. For more information, see <a href="#">Amazon RDS on AWS Outposts support for Amazon RDS features</a>.</td>
<td>May 2, 2022</td>
</tr>
</tbody>
</table>
Multi-AZ DB clusters available in additional AWS Regions

You can now create Multi-AZ DB clusters in the following Regions: Asia Pacific (Singapore) and Asia Pacific (Sydney). For more information, see Multi-AZ DB cluster deployments.

April 29, 2022

Amazon RDS supports dual-stack mode

DB instances can now run in dual-stack mode. In dual-stack mode, resources can communicate with the DB instance over IPv4, IPv6, or both. For more information, see Amazon RDS IP addressing.

April 29, 2022

Amazon RDS publishes usage metrics to Amazon CloudWatch

The AWS/Usage namespace in Amazon CloudWatch includes account-level usage metrics for your Amazon RDS service quotas. For more information, see Amazon CloudWatch usage metrics for Amazon RDS.

April 28, 2022

Amazon RDS for MySQL supports the db.m6i and db.r6i DB instance classes

You can now use the db.m6i and db.r6i DB instance classes for Amazon RDS DB instances running MySQL. For more information, see Supported DB engines for DB instance classes.

April 28, 2022

</tr>
<tr>
<td>Amazon RDS for PostgreSQL now supports PostgreSQL version 14 beta 2 in the database preview environment</td>
<td>For more about PostgreSQL version 14 beta 1, see PostgreSQL 14 beta 1 release notes. For more about PostgreSQL version 14 beta 2, see PostgreSQL 14 beta 2 release notes. For information on the Database Preview Environment, see Working with the database preview environment.</td>
</tr>
<tr>
<td>Amazon RDS supports RDS Proxy in a shared VPC</td>
<td>You can now create an RDS Proxy in a shared VPC. For more information about RDS Proxy, see &quot;Managing Connections with Amazon RDS Proxy&quot; in the Amazon RDS User Guide or the Aurora User Guide.</td>
</tr>
<tr>
<td>Amazon RDS supports MariaDB 10.2.39</td>
<td>You can now create Amazon RDS DB instances running MariaDB versions 10.2.39. For more information, see MariaDB on Amazon RDS versions.</td>
</tr>
<tr>
<td>Feature Description</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Amazon RDS for Oracle adds the TIMEZONE_FILE_AUTO UPGRADE _option</td>
<td>With this option, you can upgrade the current time zone file to the latest version on your Oracle DB instance. For more information, see Oracle time zone file autoupgrade.</td>
</tr>
<tr>
<td>Amazon RDS extends support for cross-Region automated backups</td>
<td>You can now replicate DB snapshots and transaction logs between more AWS Regions. For more information, see Replicating automated backups to another AWS Region.</td>
</tr>
<tr>
<td>Support for MySQL 5.7.34</td>
<td>You can now create Amazon RDS DB instances running MySQL version 5.7.34. For more information, see MySQL on Amazon RDS versions.</td>
</tr>
<tr>
<td>Amazon RDS on AWS Outposts supports additional RDS for PostgreSQL versions</td>
<td>RDS on Outposts now supports RDS for PostgreSQL versions 12.7 and 13.3. For more information, see Amazon RDS on AWS Outposts support for Amazon RDS features.</td>
</tr>
<tr>
<td>Amazon RDS for PostgreSQL supports oracle_fdw</td>
<td>You can now use the oracle_fdw extension to provide a foreign data wrapper for access to Oracle databases. For more information, see <a href="#">Accessing external data with the oracle_fdw extension</a>.</td>
</tr>
<tr>
<td>---------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Amazon RDS supports Oracle Management Agent (OMA) version 13.5</td>
<td>You can use Oracle Management Agent (OMA) version 13.5 with Oracle Enterprise Manager (OEM) Cloud Control 13c Release 5 and higher. Amazon RDS for Oracle installs OMA, which then communicates with your Oracle Management Service (OMS) to provide monitoring information. If you run OMS 13.5, you can manage databases by installing OMA 13.5. For more information, see <a href="#">Oracle Management Agent for Enterprise Manager Cloud Control</a>.</td>
</tr>
</tbody>
</table>
Amazon RDS for Oracle supports downloading logs from Amazon S3

If archived redo logs aren't on your instance but are protected by your backup retention period, you can use `rdsadmin.rdsadmin_archive_log_download` to download them from Amazon S3. RDS for Oracle saves the logs to the `/rdsdbdata/log/arch` directory on your DB instance. For more information, see [Downloading archived redo logs from Amazon S3](#).

July 2, 2021

Amazon RDS supports MariaDB 10.4.18 and 10.5.9

You can now create Amazon RDS DB instances running MariaDB versions 10.4.18 and 10.5.9. For more information, see [MariaDB on Amazon RDS versions](#).

June 30, 2021
Amazon RDS for Oracle supports Database Activity Streams

You can now monitor an Oracle DB instance using Database Activity Streams. An Oracle database writes audit records to the unified audit trail. When you start a database activity stream on an Oracle DB instance, Amazon Kinesis streams all activities that match the Oracle Database audit policies. For more information, see Monitoring Amazon RDS with Database Activity Streams.

Amazon RDS for Oracle introduces memory optimized instance classes

New Oracle DB instance classes are optimized for workloads that require additional memory, storage, and I/O per vCPU. For more information, see RDS for Oracle instance classes.

Support for MySQL 8.0.25

You can now create Amazon RDS DB instances running MySQL version 8.0.25. For more information, see MySQL on Amazon RDS versions.

Amazon RDS on AWS Outposts supports additional RDS for PostgreSQL versions

RDS on Outposts now supports RDS for PostgreSQL versions 12.5, 12.6, 13.1, and 13.2. For more information, see Amazon RDS on AWS Outposts support for Amazon RDS features.
Amazon RDS supports MariaDB 10.2.37 and 10.3.28
You can now create Amazon RDS DB instances running MariaDB versions 10.2.37 and 10.3.28. For more information, see MariaDB on Amazon RDS versions.

May 27, 2021

Amazon RDS for Oracle supports multitenant container database (CDB)
A multitenant architecture enables an Oracle database to be a CDB. In Oracle Database 19c, your CDB can include a single PDB. The user experience with a PDB is mostly identical to the user experience with a non-CDB. For more information, see RDS for Oracle architecture.

May 25, 2021

Amazon RDS on AWS Outposts supports Amazon RDS for SQL Server
RDS on Outposts now supports Amazon RDS for SQL Server. For more information, see Amazon RDS on AWS Outposts support for Amazon RDS features.

May 11, 2021

Amazon RDS extends support for cross-Region automated backups
You can now configure Amazon RDS database instances running Microsoft SQL Server to replicate DB snapshots and transaction logs to a different AWS Region. For more information, see Replicating automated backups to another AWS Region.

May 7, 2021
<table>

</tbody>
</table>
Amazon RDS plans to deprecate Oracle Database 18c

Oracle Database 18c (18.0.0.0) is on a deprecation path. Oracle Corporation will no longer provide patches for Oracle Database 18c after the end-of-support date. On July 1, 2021, Amazon RDS plans to begin automatically upgrading Oracle Database 18c instances to Oracle Database 19c. Before the automatic upgrades begin, we highly recommend that you manually upgrade your existing Oracle Database 18c instances to Oracle Database 19c. For more information, see Preparing for the automatic upgrade of Oracle Database 18c.

March 11, 2021

Amazon RDS has ended support for Oracle Database 11g

You can only create DB instances for Oracle Database 12c Release 1 (12.1.0.2) and later. If you have Oracle Database 11g snapshots, upgrade them to a later release. For more information, see Upgrading an Oracle DB snapshot.

March 11, 2021
Amazon RDS supports continuous backups of DB instances in AWS Backup

You can now create automated backups in AWS Backup and restore DB instances from these backups to a specified time. For more information, see Using AWS Backup to manage automated backups.

March 10, 2021

Amazon RDS supports Oracle Management Agent (OMA) version 13.4

You can use Oracle Management Agent (OMA) version 13.4 with Oracle Enterprise Manager (OEM) Cloud Control 13c Release 4 Update 9. Amazon RDS for Oracle installs OMA, which then communicates with your Oracle Management Service (OMS) to provide monitoring information. If you run OMS 13.4, you can manage databases by installing OMA 13.4. For more information, see Oracle Management Agent for Enterprise Manager Cloud Control.

March 10, 2021
RDS Proxy endpoint enhancements

You can create additional endpoints associated with each RDS proxy. Creating an endpoint in a different VPC enables cross-VPC access for the proxy. Proxies for Aurora MySQL clusters can also have read-only endpoints. These reader endpoints connect to reader DB instances in the clusters and can improve read scalability and availability for query-intensive applications. For more information about RDS Proxy, see "Managing Connections with Amazon RDS Proxy" in the Amazon RDS User Guide or the Aurora user guide.

Amazon RDS extends supports for cross-Region automated backups

You can now configure Amazon RDS database instances running PostgreSQL to replicate DB snapshots and transaction logs to a different AWS Region. For more information, see Replicating automated backups to another AWS Region.

<td>Amazon RDS extends support for exporting snapshots to Amazon S3</td>
<td>You can now export DB snapshot data to Amazon S3 in China. For more information, see <a href="#">Exporting DB snapshot data to Amazon S3</a>.</td>
<td>February 17, 2021</td>
</tr>
</tbody>
</table>
Replication filters for Amazon RDS for MariaDB and MySQL

You can configure replication filters for MySQL and MariaDB instances. Replication filters specify which databases and tables are replicated in a read replica. You can create lists of databases and tables to include or exclude for each read replica. For more information, see Configuring replication filters with MariaDB and Configuring replication filters with MySQL.

RDS for Oracle supports APEX 20.2v1

You can use APEX 20.2.v1 with all supported versions of Oracle Database. For more information, see Oracle Application Express.

Amazon RDS for SQL Server supports local instance storage for the tempdb database

You can now launch Amazon RDS for SQL Server on Amazon EC2 db.r5d and db.m5d instance types with the tempdb database configured to use an instance store. By placing tempdb data files and log files locally, you can achieve lower read and write latencies when compared to standard storage based on Amazon EBS. For more information, see Instance store support for the tempdb database on Amazon RDS for SQL Server.

</tr>
</tbody>
</table>
Support for MySQL 5.5.62
You can now create Amazon RDS DB instances running MySQL version 5.5.62. For more information, see MySQL on Amazon RDS versions.

Performance Insights supports analyzing statistics for running PostgreSQL queries
You can now analyze statistics for running queries with Performance Insights for PostgreSQL DB instances. For more information, see Statistics for PostgreSQL.

Amazon RDS extends support for storage autoscaling
You can now enable storage autoscaling when creating a read replica, restoring a DB instance to a specified time, or restoring a MySQL DB instance from an Amazon S3 backup. For more information, see Managing capacity automatically with Amazon RDS storage autoscaling.

Amazon RDS for SQL Server supports Database Mail
With Database Mail you can send email messages from your Amazon RDS for SQL Server database instance. After specifying the email recipients, you can add files or query results to the message you send. For more information, see Using Database Mail on Amazon RDS for SQL Server.

</tbody>
</table>
Amazon RDS for SQL Server supports upgrades to SQL Server 2019

You can upgrade your SQL Server DB instances to SQL Server 2019. For more information, see Upgrading the Microsoft SQL Server DB Engine.

October 6, 2020

Amazon RDS for Oracle supports specifying the national character set

The national character set, also called the NCHAR character set, is used in the NCHAR, NVARCHAR2, and NCLOB data types. When you create a database, you can specify either AL16UTF16 (default) or UTF8 as the NCHAR character set. For more information, see Oracle character sets supported in Amazon RDS.

October 2, 2020

Support for MySQL 5.7.31

You can now create Amazon RDS DB instances running MySQL version 5.7.31. For more information, see MySQL on Amazon RDS versions.

October 1, 2020

Amazon RDS for PostgreSQL supports exporting data to Amazon S3

You can query data from a PostgreSQL DB instance and export it directly into files stored in an Amazon S3 bucket. For more information, see Exporting data from an RDS for PostgreSQL DB instance to Amazon S3.

**Amazon RDS proxy**

You can reduce the overhead of connection management on your cluster, and reduce the chance of "too many connections" errors, by using the Amazon RDS Proxy. You associate each proxy with an RDS DB instance or Aurora DB cluster. Then you use the proxy endpoint in the connection string for your application. The Amazon RDS Proxy is currently in a public preview state. It supports the RDS for MySQL database engine. For more information, see [Managing connections with Amazon RDS proxy (preview)].

**Amazon RDS on AWS Outposts (preview)**

With Amazon RDS on AWS Outposts, you can create AWS-managed relational databases in your on-premises data centers. RDS on Outposts enables you to run RDS databases on AWS Outposts. For more information, see [Amazon RDS on AWS Outposts (preview)].

</table>
Support for per-second billing

Amazon RDS is now billed in 1-second increments in all AWS Regions except AWS GovCloud (US) for on-demand instances. For more information, see DB instance billing for Amazon RDS.

Support for importing data from Amazon S3 for Amazon RDS for PostgreSQL

You can now import data from Amazon S3 file into a table in an RDS PostgreSQL DB instance. For more information, see Importing Amazon S3 data into an RDS PostgreSQL DB instance.

Support for restoring 5.7 backups from Amazon S3

You can now create a backup of your MySQL version 5.7 database, store it on Amazon S3, and then restore the backup file onto a new Amazon RDS DB instance running MySQL. For more information, see Restoring a backup into a MySQL DB instance.
Support for multiple major version upgrades for Amazon RDS for PostgreSQL

With Amazon RDS for PostgreSQL, you can now choose from multiple major versions when you upgrade the DB engine. This feature enables you to skip ahead to a newer major version when you upgrade select PostgreSQL engine versions. For more information, see Upgrading the PostgreSQL DB engine.

Support for 64 TiB of storage for Amazon RDS for Oracle

You can now create Amazon RDS DB instances for Oracle with up to 64 TiB of storage and up to 80,000 provisioned IOPS. For more information, see DB instance storage.

Support for MySQL 8.0.15

You can now create Amazon RDS DB instances running MySQL version 8.0.15. For more information, see MySQL on Amazon RDS versions.

Support for MariaDB 10.3.13

You can now create Amazon RDS DB instances running MariaDB version 10.3.13. For more information, see MariaDB on Amazon RDS versions.

<tr>
<td>MariaDB supports a new major version</td>
<td>You can now create Amazon RDS DB instances running MariaDB version 10.3. For more information, see MariaDB on Amazon RDS versions.</td>
<td>October 23, 2018</td>
</tr>
<tr>
<td>Amazon RDS for Oracle supports Oracle JVM</td>
<td>Amazon RDS for Oracle now supports the Oracle Java Virtual Machine (JVM) option. For more information, see Oracle Java virtual machine.</td>
<td>October 16, 2018</td>
</tr>
<tr>
<td>Custom parameter group for restore and point in time recovery</td>
<td>You can now specify a custom parameter group when you restore a snapshot or perform a point in time recovery operation. For more information, see Restoring from a DB snapshot and Restoring a DB instance to a specified time.</td>
<td>October 15, 2018</td>
</tr>
<tr>
<td><strong>Amazon RDS for Oracle supports 32 TiB storage</strong></td>
<td>You can now create Oracle RDS DB instances with up to 32 TiB of storage. For more information, see [DB instance storage].</td>
<td>October 15, 2018</td>
</tr>
<tr>
<td><strong>Amazon RDS for MySQL supports GTIDs</strong></td>
<td>Amazon RDS for MySQL now supports global transaction identifiers (GTIDs), which are unique across all DB instances and in a replication configuration. For more information, see [Using GTID-based replication for RDS for MySQL].</td>
<td>October 10, 2018</td>
</tr>
<tr>
<td><strong>MySQL 5.7.23, 5.6.41, and 5.5.61</strong></td>
<td>You can now create Amazon RDS DB instances running MySQL versions 5.7.23, 5.6.41, and 5.5.61. For more information, see [MySQL on Amazon RDS versions].</td>
<td>October 8, 2018</td>
</tr>
<tr>
<td><strong>Amazon RDS for Oracle supports a new version of SQLT</strong></td>
<td>Amazon RDS for Oracle now supports SQLT version 12.2.180331. For more information, see [Oracle SQLT].</td>
<td>October 4, 2018</td>
</tr>
<tr>
<td><strong>Amazon RDS for PostgreSQL now supports IAM authentication</strong></td>
<td>Amazon RDS for PostgreSQL now supports IAM authentication. For more information see [IAM database authentication for MySQL and PostgreSQL].</td>
<td>September 27, 2018</td>
</tr>
</tbody>
</table>
You can enable deletion protection for your Amazon RDS DB instances

When you enable deletion protection for a DB instance, the database cannot be deleted by any user. For more information, see Deleting a DB instance.

September 26, 2018

Amazon RDS for MySQL and Amazon RDS for MariaDB support db.m5 DB instance classes

You can now create Amazon RDS DB instances running MySQL or MariaDB that use the db.m5 DB instance classes. For more information, see DB instance class.

September 18, 2018

Amazon RDS now supports upgrades to SQL Server 2017

You can upgrade your existing DB instance to SQL Server 2017 from any version except SQL Server 2008. To upgrade from SQL Server 2008, first upgrade to one of the other versions first. For information, see Upgrading the Microsoft SQL Server DB engine.

September 11, 2018

Amazon RDS for PostgreSQL now supports PostgreSQL version 11 beta 3 in the database preview environment

In this release, the Write-Ahead Log (WAL) segment size (wal_segment_size) is now set to 64MB. For more about PostgreSQL version 11 Beta 3, see PostgreSQL 11 beta 3 released. For information on the Database Preview Environment, see Working with the database preview environment.

</tr>
<tr>
<td>Added Aurora PostgreSQL HIPAA eligibility</td>
<td>Aurora PostgreSQL now supports building HIPAA compliant applications. For more information, see Working with Amazon Aurora PostgreSQL.</td>
<td>December 6, 2017</td>
</tr>
<tr>
<td>Additional AWS Regions available for Amazon Aurora with PostgreSQL compatibility</td>
<td>Amazon Aurora with PostgreSQL compatibility is now available in four new AWS Regions. For more information, see Availability for Amazon Aurora PostgreSQL.</td>
<td>November 22, 2017</td>
</tr>
<tr>
<td>Modify storage for Amazon RDS DB instances running Microsoft SQL Server</td>
<td>You can now modify the storage of your Amazon RDS DB instances running SQL Server. For more information, see Modifying an Amazon RDS DB instance.</td>
<td>November 21, 2017</td>
</tr>
<tr>
<td>Amazon RDS supports 16 TiB storage for Linux-based engines</td>
<td>You can now create MySQL, MariaDB, PostgreSQL, and Oracle RDS DB instances with up to 16 TiB of storage. For more information, see Amazon RDS DB instance storage.</td>
<td>November 21, 2017</td>
</tr>
<tr>
<td>Amazon RDS supports fast scale up of storage</td>
<td>You can now add storage to MySQL, MariaDB, PostgreSQL, and Oracle RDS DB instances in a few minutes. For more information, see Amazon RDS DB instance storage.</td>
<td>November 21, 2017</td>
</tr>
<tr>
<td>Amazon RDS supports MariaDB versions 10.1.26 and 10.0.32</td>
<td>You can now create Amazon RDS DB instances running MariaDB versions 10.1.26 and 10.0.32. For more information, see MariaDB on Amazon RDS versions.</td>
<td>November 20, 2017</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>-----------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------------</td>
</tr>
<tr>
<td>Amazon RDS for Microsoft SQL Server now supports new DB instance classes</td>
<td>You can now create Amazon RDS DB instances running SQL Server that use the db.r4 and db.m4.16xlarge DB instance classes. For more information, see <a href="https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/DB-instance-class-support.html">DB instance class support for Microsoft SQL Server</a>.</td>
<td>November 20, 2017</td>
</tr>
<tr>
<td>Amazon RDS for MySQL and MariaDB now supports new DB instance classes</td>

<td>November 20, 2017</td>
</tr>
<tr>
<td>SQL Server 2017</td>
<td>You can now create Amazon RDS DB instances running Microsoft SQL Server 2017. You can also create DB instances running SQL Server 2016 SP1 CU5. For more information, see <a href="https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/">Amazon RDS for Microsoft SQL Server</a>.</td>
<td>November 17, 2017</td>
</tr>
<tr>
<td>Restore MySQL backups from Amazon S3</td>
<td>You can now create a backup of your on-premises database, store it on Amazon S3, and then restore the backup file onto a new Amazon RDS DB instance running MySQL. For more information, see <a href="https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/DB-instance-class-support.html">Restoring a backup into a MySQL DB instance</a>.</td>
<td>November 17, 2017</td>
</tr>
<tr>
<td>Auto Scaling with Aurora Replicas</td>
<td>Amazon Aurora MySQL now supports Aurora Auto Scaling. Aurora Auto Scaling dynamically adjusts the number of Aurora Replicas based on increases or decreases in connectivity or workload. For more information, see <a href="https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/">Using Amazon Aurora Auto Scaling with Aurora replicas</a>.</td>
<td>November 17, 2017</td>
</tr>
<tr>
<td>Oracle default edition support</td>
<td>Amazon RDS for Oracle DB instances now supports setting the default edition for the DB instance. For more information, see <a href="https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/">Setting the default edition for a DB instance</a>.</td>
<td>November 3, 2017</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>--------------</td>
</tr>
<tr>
<td>Oracle DB instance file validation</td>
<td>Amazon RDS for Oracle DB instances now supports validating DB instance files with the Oracle Recovery Manager (RMAN) logical validation utility. For more information, see <a href="#">Validating database files in RDS for Oracle</a>.</td>
<td>November 3, 2017</td>
</tr>
<tr>
<td>Management Agent for OEM 13c</td>
<td>Amazon RDS for Oracle DB instances now support the Management Agent for Oracle Enterprise Manager (OEM) Cloud Control 13c. For more information, see <a href="#">Oracle Management Agent for Enterprise Manager Cloud Control</a>.</td>
<td>November 1, 2017</td>
</tr>
<tr>
<td>Storage reconfiguration for Microsoft SQL Server snapshots</td>
<td>You can now reconfigure the storage when you restore a snapshot to an Amazon RDS DB instance running Microsoft SQL Server. For more information, see <a href="#">Restoring from a DB snapshot</a>.</td>
<td>October 26, 2017</td>
</tr>
<tr>
<td>Asynchronous key prefetch for Aurora MySQL-Compatible Edition</td>
<td>Asynchronous key prefetch (AKP) improves the performance of noncached index joins, by prefetching keys in memory ahead of when they are needed. For more information, see <a href="#">Working with asynchronous key prefetch in Amazon Aurora</a>.</td>
<td>October 26, 2017</td>
</tr>
<tr>
<td>MySQL 5.7.19, 5.6.37, and 5.5.57</td>
<td>You can now create Amazon RDS DB instances running MySQL versions 5.7.19, 5.6.37, and 5.5.57. For more information, see <a href="#">MySQL on Amazon RDS versions</a>.</td>
<td>October 25, 2017</td>
</tr>
<tr>
<td>General availability of Amazon Aurora with PostgreSQL compatibility</td>
<td>Amazon Aurora with PostgreSQL compatibility makes it simple and cost-effective to set up, operate, and scale your new and existing PostgreSQL deployments, thus freeing you to focus on your business and applications. For more information, see <a href="#">Working with Amazon Aurora PostgreSQL</a>.</td>
<td>October 24, 2017</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>--------------</td>
</tr>
<tr>
<td>Amazon RDS for Oracle DB instances support new DB instance classes</td>
<td>Amazon RDS for Oracle DB instances now support memory optimized next generation (db.r4) instance classes. Amazon RDS for Oracle DB instances also now support the following new current generation instance classes: db.m4.16xlarge, db.t2.xlarge, and db.t2.2xlarge. For more information, see <a href="#">DB instance classes</a> and <a href="#">RDS for Oracle instance classes</a>.</td>
<td>October 23, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Your new and existing Reserved Instances can now cover multiple sizes in the same DB instance class. Size-flexible reserved instances are available for DB instances with the same AWS Region, database engine, and instance family, and across AZ configuration. Size-flexible reserved instances are available for the following database engines: Amazon Aurora, MariaDB, MySQL, Oracle (Bring Your Own License), PostgreSQL. For more information, see <a href="#">Size-flexible reserved DB instances</a>.</td>
<td>October 11, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use the Oracle SQLT option to tune a SQL statement for optimal performance. For more information, see <a href="#">Oracle SQLT</a>.</td>
<td>September 22, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>If you have existing manual DB snapshots of your Amazon RDS for Oracle DB instances, you can now upgrade them to a later version of the Oracle database engine. For more information, see <a href="#">Upgrading an Oracle DB snapshot</a>.</td>
<td>September 20, 2017</td>
</tr>
<tr>
<td>New feature</td>

<td>You can now use Oracle Locator to support internet and wireless service-based applications and partner-based GIS solutions with your Amazon RDS DB instances running Oracle. For more information, see <a href="#">Oracle Locator</a>.</td>
<td>September 15, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use Oracle Multimedia to store, manage, and retrieve images, audio, video, and other heterogeneous media data in your Amazon RDS DB instances running Oracle. For more information, see <a href="#">Oracle Multimedia</a>.</td>
<td>September 15, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now export audit logs from your Amazon Aurora MySQL DB clusters to Amazon CloudWatch Logs. For more information, see <a href="#">Publishing Aurora MySQL logs to Amazon CloudWatch Logs</a>.</td>
<td>September 14, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports multiple versions of Oracle Application Express (APEX) for your DB instances running Oracle. For more information, see <a href="#">Oracle Application Express (APEX)</a>.</td>
<td>September 13, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use Amazon Aurora to migrate an unencrypted or encrypted DB snapshot or MySQL DB instance to an encrypted Aurora MySQL DB cluster. For more information, see <a href="#">Migrating an RDS for MySQL snapshot to Aurora</a> and <a href="#">Migrating data from a MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica</a>.</td>
<td>September 5, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can use Amazon RDS for Microsoft SQL Server databases to build HIPAA-compliant applications. For more information, see <a href="#">Compliance program support for Microsoft SQL Server DB instances</a>.</td>
<td>August 31, 2017</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>-----------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use Amazon RDS for MariaDB databases to build HIPAA-compliant applications. For more information, see Amazon RDS for MariaDB.</td>
<td>August 31, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now create Amazon RDS DB instances running Microsoft SQL Server with allocated storage up to 16 TiB, and Provisioned IOPS to storage ranges of 1:1–50:1. For more information, see Amazon RDS DB instance storage.</td>
<td>August 22, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use Multi-AZ deployments for DB instances running Microsoft SQL Server in the EU (Frankfurt) region. For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server.</td>
<td>August 3, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now create Amazon RDS DB instances running MariaDB versions 10.1.23 and 10.0.31. For more information, see MariaDB on Amazon RDS versions.</td>
<td>July 17, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports Microsoft SQL Server Enterprise Edition with the License Included model in all AWS Regions. For more information, see Licensing Microsoft SQL Server on Amazon RDS.</td>
<td>July 13, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS for Oracle now supports Linux kernel huge pages for increased database scalability. The use of huge pages results in smaller page tables and less CPU time spent on memory management, increasing the performance of large database instances. You can use huge pages with your Amazon RDS DB instances running all editions of Oracle versions 12.1.0.2 and 11.2.0.4. For more information, see Turning on HugePages for an RDS for Oracle instance.</td>

<tr>
<td>----------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support encryption at rest (EAR) for db.t2.small and db.t2.medium DB instance classes for all non-Aurora DB engines. For more information, see <a href="#">Availability of Amazon RDS encryption</a>.</td>
<td>June 27, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Amazon Aurora in the Europe (Frankfurt) region. For more information, see <a href="#">Availability for Amazon Aurora MySQL</a>.</td>
<td>June 16, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now specify an option group when you copy a DB snapshot across AWS regions. For more information, see <a href="#">Option group considerations</a>.</td>
<td>June 12, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now copy DB snapshots created from specialized DB instances across AWS regions. You can copy snapshots from DB instances that use Oracle TDE, Microsoft SQL Server TDE, and Microsoft SQL Server Multi-AZ with Mirroring. For more information, see <a href="#">Copying a DB snapshot</a>.</td>
<td>June 12, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon Aurora now allows you to quickly and cost-effectively copy all of your databases in an Amazon Aurora DB cluster. For more information, see <a href="#">Cloning databases in an Aurora DB cluster</a>.</td>
<td>June 12, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports Microsoft SQL Server 2016 SP1 CU2. For more information, see <a href="#">Amazon RDS for Microsoft SQL Server</a>.</td>
<td>June 7, 2017</td>
</tr>
<tr>
<td>Preview</td>
<td>Public preview of Amazon Aurora with PostgreSQL Compatibility. For more information, see <a href="#">Working with Amazon Aurora PostgreSQL</a>.</td>

<tr>
<td>New feature</td>
<td>Amazon Aurora MySQL now supports spatial indexing.</td>
<td>December 14, 2016</td>
</tr>
<tr>
<td></td>
<td>Spatial indexing improves query performance on large datasets for queries that use spatial data. For more information, see <a href="#">Amazon Aurora MySQL</a> and <a href="#">spatial data</a>.</td>
<td></td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports outbound network access on your DB instances running Oracle. You can use utl_http, utl_tcp, and utl_smtp to connect from your DB instance to the network. For more information, see <a href="#">Configuring UTL_HTTP access using certificates and an Oracle wallet</a>.</td>
<td>December 5, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS has retired support for MySQL version 5.1. However, you can restore existing MySQL 5.1 snapshots to a MySQL 5.5 instance. For more information, see <a href="#">Supported storage engines for RDS for MySQL</a>.</td>
<td>November 15, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports Microsoft SQL Server 2016 RTM CU2. For more information, see <a href="#">Amazon RDS for Microsoft SQL Server</a>.</td>
<td>November 4, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports major version upgrades for DB instances running Oracle. You can now upgrade your Oracle DB instances from 11g to 12c. For more information, see <a href="#">Upgrading the RDS for Oracle DB engine</a>.</td>
<td>November 2, 2016</td>
</tr>

<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------------</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now create DB instances running Microsoft SQL Server 2014 Enterprise Edition. Amazon RDS now supports SQL Server 2014 SP2 for all editions and all regions. For more information, see <a href="#">Amazon RDS for Microsoft SQL Server</a>.</td>
<td>October 25, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon Aurora MySQL now integrates with other AWS services: You can load text or XML data into a table from an Amazon S3 bucket, or invoke an AWS Lambda function from database code. For more information, see <a href="#">Integrating Aurora MySQL with other AWS services</a>.</td>
<td>October 18, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now access the tempdb database on your Amazon RDS DB instances running Microsoft SQL Server. You can access the tempdb database by using Transact-SQL through Microsoft SQL Server Management Studio (SSMS), or any other standard SQL client application. For more information, see <a href="#">Accessing the tempdb database on Microsoft SQL Server DB instances on Amazon RDS</a>.</td>
<td>September 29, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use the UTL_MAIL package with your Amazon RDS DB instances running Oracle. For more information, see <a href="#">Oracle UTL_MAIL</a>.</td>
<td>September 20, 2016</td>
</tr>
<tr>
<td>New features</td>
<td>You can now set the time zone of your new Microsoft SQL Server DB instances to a local time zone, to match the time zone of your applications. For more information, see <a href="#">Local time zone for Microsoft SQL Server DB instances</a>.</td>
<td>September 19, 2016</td>

<tr>
<td>--------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use the Oracle Label Security option to control access to individual table rows in your Amazon RDS DB instances running Oracle Database 12c. With Oracle Label Security, you can enforce regulatory compliance with a policy-based administration model, and ensure that an access to sensitive data is restricted to only users with the appropriate clearance level. For more information, see Oracle Label Security.</td>
<td>September 8, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now connect to an Amazon Aurora DB cluster using the reader endpoint, which load-balances connections across the Aurora Replicas that are available in the DB cluster. As clients request new connections to the reader endpoint, Aurora distributes the connection requests among the Aurora Replicas in the DB cluster. This functionality can help balance your read workload across multiple Aurora Replicas in your DB cluster. For more information, see Amazon Aurora endpoints.</td>
<td>September 8, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now support the Oracle Enterprise Manager Cloud Control on your Amazon RDS DB instances running Oracle. You can enable the Management Agent on your DB instances, and share data with your Oracle Management Service (OMS). For more information, see Oracle Management Agent for Enterprise Manager Cloud Control.</td>
<td>September 1, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>This release adds support to get an ARN for a resource. For more information, see Getting an existing ARN.</td>
<td>August 23, 2016</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>--------------</td>

<tr>
<td>New feature</td>
<td>You can now assign up to 50 tags for each Amazon RDS resource, for managing your resources and tracking costs. For more information, see <a href="#">Tagging Amazon RDS resources</a>.</td>
<td>August 19, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports the License Included model for Oracle Standard Edition Two. For more information, see <a href="#">Creating an Amazon RDS DB instance</a>. You can now change the license model of your Amazon RDS DB instances running Microsoft SQL Server and Oracle. For more information, see <a href="#">Licensing Microsoft SQL Server on Amazon RDS</a> and <a href="#">RDS for Oracle licensing options</a>.</td>
<td>August 5, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports native backup and restore for Microsoft SQL Server databases using full backup files (.bak files). You can now easily migrate SQL Server databases to Amazon RDS, and import and export databases in a single, easily-portable file, using Amazon S3 for storage, and AWS KMS for encryption. For more information, see <a href="#">Importing and exporting SQL Server databases using native backup and restore</a>.</td>
<td>July 27, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now copy the source files from a MySQL database to an Amazon Simple Storage Service (Amazon S3) bucket, and then restore an Amazon Aurora DB cluster from those files. This option can be considerably faster than migrating data using mysqldump. For more information, see <a href="#">Migrating data from an external MySQL database to an Aurora MySQL DB cluster</a>.</td>
<td>July 20, 2016</td>
</tr>
