1. If the source and destination DB instances use a default DB parameter group, you need to create a custom DB parameter using the appropriate version for your instances. You do this so you can change values for several parameters. For more information, see Working with parameter groups (p. 295).

2. In the custom DB parameter group, change values for the following parameters:

   • `shared_preload_libraries` – Add `pg_transport` to the list of libraries.

   • `pg_transport.num_workers` – The default value is 3. Increase or reduce this value as needed for your database. For a 200 GB database, we recommend no larger than 8. Keep in mind that if you increase the default value for this parameter, you should also increase the value of `max_worker_processes`.

   • `pg_transport.work_mem` – The default value is either 128 MB or 256 MB, depending on the PostgreSQL version. The default setting can typically be left unchanged.

   • `max_worker_processes` – The value of this parameter needs to be set using the following calculation:
This value is required on the destination to handle various background worker processes involved in the transport. To learn more about max_worker_processes, see Resource Consumption in the PostgreSQL documentation.

For more information about pg_transport parameters, see Transportable databases parameter reference (p. 1934).

3. Reboot the source RDS for PostgreSQL DB instance and the destination instance so that the settings for the parameters take effect.

4. Connect to your RDS for PostgreSQL source DB instance.

```bash
psql --host=source-instance.1112223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
```

5. Remove extraneous extensions from the public schema of the DB instance. Only the pg_transport extension is allowed during the actual transport operation.

6. Install the pg_transport extension as follows:

```sql
postgres=> CREATE EXTENSION pg_transport;
CREATE EXTENSION
```

7. Connect to your RDS for PostgreSQL destination DB instance. Remove any extraneous extensions, and then install the pg_transport extension.

```sql
postgres=> CREATE EXTENSION pg_transport;
CREATE EXTENSION
```

### Transporting a PostgreSQL database to the destination from the source

After you complete the process described in Setting up to transport a PostgreSQL database (p. 1930), you can start the transport. To do so, run the transport.import_from_server function on the destination DB instance. In the syntax following you can find the function parameters.

```sql
SELECT transport.import_from_server(  'source-db-instance-endpoint',  'source-db-instance-port',  'source-db-instance-user',  'source-user-password',  'source-database-name',  'destination-user-password',  false);
```

The false value shown in the example tells the function that this is not a dry run. To test your transport setup, you can specify true for the dry_run option when you call the function, as shown following:

```sql
postgres=> SELECT transport.import_from_server(  'docs-lab-source-db.666666666666.aws-region.rds.amazonaws.com', 5432,  'postgres', '********', 'labdb', '******', true);
```

INFO: Starting dry-run of import of database "labdb".
INFO: Created connections to remote database (took 0.03 seconds).
INFO: Checked remote cluster compatibility (took 0.05 seconds).
INFO: Dry-run complete (took 0.08 seconds total).
import_from_server
--------------------
(1 row)

The INFO lines are output because the pg_transport.timing parameter is set to its default value, true. Set the dry_run to false when you run the command and the source database is imported to the destination, as shown following:

INFO: Starting import of database "labdb".
INFO: Created connections to remote database (took 0.02 seconds).
INFO: Marked remote database as read only (took 0.13 seconds).
INFO: Checked remote cluster compatibility (took 0.03 seconds).
INFO: Signaled creation of PITR blackout window (took 2.01 seconds).
INFO: Applied remote database schema pre-data (took 0.50 seconds).
INFO: Created connections to local cluster (took 0.01 seconds).
INFO: Locked down destination database (took 0.00 seconds).
INFO: Completed transfer of database files (took 0.24 seconds).
INFO: Completed clean up (took 1.02 seconds).
INFO: Physical transport complete (took 3.97 seconds total).
import_from_server
--------------------
(1 row)

This function requires that you provide database user passwords. Thus, we recommend that you change the passwords of the user roles you used after transport is complete. Or, you can use SQL bind variables to create temporary user roles. Use these temporary roles for the transport and then discard the roles afterwards.

If your transport isn't successful, you might see an error message similar to the following:

pg_transport.num_workers=8 25% of files transported failed to download file data

The "failed to download file data" error message indicates that the number of worker processes isn't set correctly for the size of the database. You might need to increase or decrease the value set for pg_transport.num_workers. Each failure reports the percentage of completion, so you can see the impact of your changes. For example, changing the setting from 8 to 4 in one case resulted in the following:

pg_transport.num_workers=4 75% of files transported failed to download file data

Keep in mind that the max_worker_processes parameter is also taken into account during the transport process. In other words, you might need to modify both pg_transport.num_workers and max_worker_processes to successfully transport the database. The example shown finally worked when the pg_transport.num_workers was set to 2:

pg_transport.num_workers=2 100% of files transported

For more information about the transport.import_from_server function and its parameters, see Transportable databases function reference (p. 1933).

What happens during database transport

The PostgreSQL transportable databases feature uses a pull model to import the database from the source DB instance to the destination. The transport.import_from_server function creates the in-
transit database on the destination DB instance. The in-transit database is inaccessible on the destination DB instance for the duration of the transport.

When transport begins, all current sessions on the source database are ended. Any databases other than the source database on the source DB instance aren't affected by the transport.

The source database is put into a special read-only mode. While it's in this mode, you can connect to the source database and run read-only queries. However, write-enabled queries and some other types of commands are blocked. Only the specific source database that is being transported is affected by these restrictions.

During transport, you can't restore the destination DB instance to a point in time. This is because the transport isn't transactional and doesn't use the PostgreSQL write-ahead log to record changes. If the destination DB instance has automatic backups enabled, a backup is automatically taken after transport completes. Point-in-time restores are available for times after the backup finishes.

If the transport fails, the pg_transport extension attempts to undo all changes to the source and destination DB instances. This includes removing the destination's partially transported database. Depending on the type of failure, the source database might continue to reject write-enabled queries. If this happens, use the following command to allow write-enabled queries.

```
ALTER DATABASE db-name SET default_transaction_read_only = false;
```

### Transportable databases function reference

The transport.import_from_server function transports a PostgreSQL database by importing it from a source DB instance to a destination DB instance. It does this by using a physical database connection transport mechanism.

Before starting the transport, this function verifies that the source and the destination DB instances are the same version and are compatible for the migration. It also confirms that the destination DB instance has enough space for the source.

#### Syntax

```python
transport.import_from_server(
    host text,
    port int,
    username text,
    password text,
    database text,
    local_password text,
    dry_run bool
)
```

#### Return Value

None.

#### Parameters

You can find descriptions of the transport.import_from_server function parameters in the following table.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>The endpoint of the source DB instance.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>port</td>
<td>An integer representing the port of the source DB instance. PostgreSQL DB instances often use port 5432.</td>
</tr>
<tr>
<td>username</td>
<td>The user of the source DB instance. This user must be a member of the rds_superuser role.</td>
</tr>
<tr>
<td>password</td>
<td>The user password of the source DB instance.</td>
</tr>
<tr>
<td>database</td>
<td>The name of the database in the source DB instance to transport.</td>
</tr>
<tr>
<td>local_password</td>
<td>The local password of the current user for the destination DB instance. This user must be a member of the rds_superuser role.</td>
</tr>
<tr>
<td>dry_run</td>
<td>An optional Boolean value specifying whether to perform a dry run. The default is false, which means the transport proceeds. To confirm compatibility between the source and destination DB instances without performing the actual transport, set dry_run to true.</td>
</tr>
</tbody>
</table>

Example

For an example, see Transporting a PostgreSQL database to the destination from the source (p. 1931).

Transportable databases parameter reference

Several parameters control the behavior of the pg_transport extension. Following, you can find descriptions of these parameters.

**pg_transport.num_workers**

The number of workers to use for the transport process. The default is 3. Valid values are 1–32. Even the largest database transports typically require fewer than 8 workers. The value of this setting on the destination DB instance is used by both destination and source during transport.

**pg_transport.timing**

Specifies whether to report timing information during the transport. The default is true, meaning that timing information is reported. We recommend that you leave this parameter set to true so you can monitor progress. For example output, see Transporting a PostgreSQL database to the destination from the source (p. 1931).

**pg_transport.work_mem**

The maximum amount of memory to allocate for each worker. The default is 131072 kilobytes (KB) or 262144 KB (256 MB), depending on the PostgreSQL version. The minimum value is 64 megabytes (65536 KB). Valid values are in kilobytes (KBs) as binary base-2 units, where 1 KB = 1024 bytes.

The transport might use less memory than is specified in this parameter. Even large database transports typically require less than 256 MB (262144 KB) of memory per worker.
Exporting data from an RDS for PostgreSQL DB instance to Amazon S3

You can query data from an RDS for PostgreSQL DB instance and export it directly into files stored in an Amazon S3 bucket. To do this, you first install the RDS for PostgreSQL aws_s3 extension. This extension provides you with the functions that you use to export the results of queries to Amazon S3. Following, you can find out how to install the extension and how to export data to Amazon S3.

You can export from a provisioned or an Aurora Serverless v2 DB instance. These steps aren't supported for Aurora Serverless v1.

**Note**
Cross-account export to Amazon S3 isn't supported.

All currently available versions of RDS for PostgreSQL support exporting data to Amazon Simple Storage Service. For detailed version information, see Amazon RDS for PostgreSQL updates in the Amazon RDS for PostgreSQL Release Notes.

If you don’t have a bucket set up for your export, see the following topics the Amazon Simple Storage Service User Guide.

- Setting up Amazon S3
- Create a bucket

The upload to Amazon S3 uses server-side encryption by default. If you are using encryption, the Amazon S3 bucket must be encrypted with an AWS managed key. Currently, you can’t export data to a bucket that's encrypted with a customer managed key.

**Note**
You can save DB snapshot data to Amazon S3 using the AWS Management Console, AWS CLI, or Amazon RDS API. For more information, see Exporting DB snapshot data to Amazon S3 (p. 516).

**Topics**
- Installing the aws_s3 extension (p. 1935)
- Overview of exporting data to Amazon S3 (p. 1936)
- Specifying the Amazon S3 file path to export to (p. 1937)
- Setting up access to an Amazon S3 bucket (p. 1938)
- Exporting query data using the aws_s3.query_export_to_s3 function (p. 1941)
- Troubleshooting access to Amazon S3 (p. 1943)
- Function reference (p. 1943)

**Installing the aws_s3 extension**

Before you can use Amazon Simple Storage Service with your RDS for PostgreSQL DB instance, you need to install the aws_s3 extension. This extension provides functions for exporting data from an RDS for PostgreSQL DB instance to an Amazon S3 bucket. It also provides functions for importing data from an Amazon S3. For more information, see Importing data from Amazon S3 into an RDS for PostgreSQL DB instance (p. 1916). The aws_s3 extension depends on some of the helper functions in the aws_commons extension, which is installed automatically when needed.
To install the aws_s3 extension

1. Use psql (or pgAdmin) to connect to the RDS for PostgreSQL DB instance as a user that has rds_superuser privileges. If you kept the default name during the setup process, you connect as postgres.

   ```bash
   psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres
   ```

2. To install the extension, run the following command.

   ```bash
   postgres=> CREATE EXTENSION aws_s3 CASCADE;
   NOTICE: installing required extension "aws_commons"
   CREATE EXTENSION
   ```

3. To verify that the extension is installed, you can use the psql \dx metacommand.

   ```bash
   postgres=> \dx
   List of installed extensions
   Name     | Version |   Schema   |                 Description
   -------------------------------+---------+------------+---------------------------------------------
   aws_commons | 1.2     | public     | Common data types across AWS services
   aws_s3      | 1.1     | public     | AWS S3 extension for importing data from S3
   plpgsql     | 1.0     | pg_catalog | PL/pgSQL procedural language
   (3 rows)
   ```

The functions for importing data from Amazon S3 and exporting data to Amazon S3 are now available to use.

Verify that your RDS for PostgreSQL version supports exports to Amazon S3

You can verify that your RDS for PostgreSQL version supports export to Amazon S3 by using the describe-db-engine-versions command. The following example verifies support for version 10.14.

```bash
aws rds describe-db-engine-versions --region us-east-1 ^
--engine postgres --engine-version 10.14 | grep s3Export
```

If the output includes the string "s3Export", then the engine supports Amazon S3 exports. Otherwise, the engine doesn't support them.

Overview of exporting data to Amazon S3

To export data stored in an RDS for PostgreSQL database to an Amazon S3 bucket, use the following procedure.

To export RDS for PostgreSQL data to S3

1. Identify an Amazon S3 file path to use for exporting data. For details about this process, see Specifying the Amazon S3 file path to export to (p. 1937).

2. Provide permission to access the Amazon S3 bucket.

   To export data to an Amazon S3 file, give the RDS for PostgreSQL DB instance permission to access the Amazon S3 bucket that the export will use for storage. Doing this includes the following steps:

   1. Create an IAM policy that provides access to an Amazon S3 bucket that you want to export to.
2. Create an IAM role.
3. Attach the policy you created to the role you created.
4. Add this IAM role to your DB instance.

For details about this process, see Setting up access to an Amazon S3 bucket (p. 1938).

3. Identify a database query to get the data. Export the query data by calling the `aws_s3.query_export_to_s3` function.

After you complete the preceding preparation tasks, use the `aws_s3.query_export_to_s3` function to export query results to Amazon S3. For details about this process, see Exporting query data using the `aws_s3.query_export_to_s3` function (p. 1941).

### Specifying the Amazon S3 file path to export to

Specify the following information to identify the location in Amazon S3 where you want to export data to:

- **Bucket name** – A bucket is a container for Amazon S3 objects or files.

  For more information on storing data with Amazon S3, see Create a bucket and View an object in the Amazon Simple Storage Service User Guide.

- **File path** – The file path identifies where the export is stored in the Amazon S3 bucket. The file path consists of the following:
  - An optional path prefix that identifies a virtual folder path.
  - A file prefix that identifies one or more files to be stored. Larger exports are stored in multiple files, each with a maximum size of approximately 6 GB. The additional file names have the same file prefix but with `_partXX` appended. The `XX` represents 2, then 3, and so on.

  For example, a file path with an exports folder and a query-1-export file prefix is `/exports/query-1-export`.

- **AWS Region (optional)** – The AWS Region where the Amazon S3 bucket is located. If you don't specify an AWS Region value, then Amazon RDS saves your files into Amazon S3 in the same AWS Region as the exporting DB instance.

  **Note**
  Currently, the AWS Region must be the same as the region of the exporting DB instance.

  For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones (p. 79).

To hold the Amazon S3 file information about where the export is to be stored, you can use the `aws_commons.create_s3_uri` function to create an `aws_commons._s3_uri_1` composite structure as follows.

```sql
psql=> SELECT aws_commons.create_s3_uri(
    'sample-bucket',
    'sample-filepath',
    'us-west-2'
) AS s3_uri_1 \gset
```

You later provide this `s3_uri_1` value as a parameter in the call to the `aws_s3.query_export_to_s3` function. For examples, see Exporting query data using the `aws_s3.query_export_to_s3` function (p. 1941).
Setting up access to an Amazon S3 bucket

To export data to Amazon S3, give your PostgreSQL DB instance permission to access the Amazon S3 bucket that the files are to go in.

To do this, use the following procedure.

To give a PostgreSQL DB instance access to Amazon S3 through an IAM role

1. Create an IAM policy.

   This policy provides the bucket and object permissions that allow your PostgreSQL DB instance to access Amazon S3.

   As part of creating this policy, take the following steps:

   a. Include in the policy the following required actions to allow the transfer of files from your PostgreSQL DB instance to an Amazon S3 bucket:
      
      - s3:PutObject
      - s3:AbortMultipartUpload

   b. Include the Amazon Resource Name (ARN) that identifies the Amazon S3 bucket and objects in the bucket. The ARN format for accessing Amazon S3 is: `arn:aws:s3:::your-s3-bucket/*`

   For more information on creating an IAM policy for Amazon RDS for PostgreSQL, see Creating and using an IAM policy for IAM database access (p. 2198). See also Tutorial: Create and attach your first customer managed policy in the IAM User Guide.

   The following AWS CLI command creates an IAM policy named `rds-s3-export-policy` with these options. It grants access to a bucket named `your-s3-bucket`.

   **Warning**

   We recommend that you set up your database within a private VPC that has endpoint policies configured for accessing specific buckets. For more information, see Using endpoint policies for Amazon S3 in the Amazon VPC User Guide.

   We strongly recommend that you do not create a policy with all-resource access. This access can pose a threat for data security. If you create a policy that gives `s3:PutObject` access to all resources using "Resource":"*", then a user with export privileges can export data to all buckets in your account. In addition, the user can export data to any publicly writable bucket within your AWS Region.

   After you create the policy, note the Amazon Resource Name (ARN) of the policy. You need the ARN for a subsequent step when you attach the policy to an IAM role.

   ```
   aws iam create-policy --policy-name rds-s3-export-policy --policy-document '{
   "Version": "2012-10-17",
   "Statement": [
   {
   "Sid": "s3export",
   "Action": [
   "s3:PutObject",
   "s3:AbortMultipartUpload"
   ],
   "Effect": "Allow",
   "Resource": ["arn:aws:s3:::your-s3-bucket/*"]
   }
   ]
   }
   '}
   ```
2. Create an IAM role.

You do this so Amazon RDS can assume this IAM role on your behalf to access your Amazon S3 buckets. For more information, see Creating a role to delegate permissions to an IAM user in the IAM User Guide.

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the policy, be sure to use the `aws:SourceArn` global condition context key with the full ARN of the resource. The following example shows how to do so using the AWS CLI command to create a role named `rds-s3-export-role`.

**Example**

For Linux, macOS, or Unix:

```bash
aws iam create-role  \
  --role-name rds-s3-export-role  \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
          "StringEquals": {
            "aws:SourceAccount": "111122223333",
          }
        }
      }
    ]
  }'
```

For Windows:

```bash
aws iam create-role ^
  --role-name rds-s3-export-role ^
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
          "StringEquals": {
            "aws:SourceAccount": "111122223333",
          }
        }
      }
    ]
  }'
```

1939
3. Attach the IAM policy that you created to the IAM role that you created.

   The following AWS CLI command attaches the policy created earlier to the role named rds-s3-export-role. Replace your-policy-arn with the policy ARN that you noted in an earlier step.

   ```
   aws iam attach-role-policy  --policy-arn your-policy-arn  --role-name rds-s3-export-role
   ```

4. Add the IAM role to the DB instance. You do so by using the AWS Management Console or AWS CLI, as described following.

**Console**

To add an IAM role for a PostgreSQL DB instance using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the PostgreSQL DB instance name to display its details.
3. On the Connectivity & security tab, in the Manage IAM roles section, choose the role to add under Add IAM roles to this instance.
4. Under Feature, choose s3Export.
5. Choose Add role.

**AWS CLI**

To add an IAM role for a PostgreSQL DB instance using the CLI

• Use the following command to add the role to the PostgreSQL DB instance named my-db-instance. Replace your-role-arn with the role ARN that you noted in a previous step. Use s3Export for the value of the --feature-name option.

   **Example**

   For Linux, macOS, or Unix:

   ```
   aws rds add-role-to-db-instance \ 
   --db-instance-identifier my-db-instance \ 
   --feature-name s3Export \ 
   --role-arn your-role-arn \ 
   --region your-region
   ```

   For Windows:

   ```
   aws rds add-role-to-db-instance
   ```
Exporting query data using the aws_s3.query_export_to_s3 function

Export your PostgreSQL data to Amazon S3 by calling the `aws_s3.query_export_to_s3` function.

**Topics**
- **Prerequisites** (p. 1941)
- Calling `aws_s3.query_export_to_s3` (p. 1941)
- Exporting to a CSV file that uses a custom delimiter (p. 1942)
- Exporting to a binary file with encoding (p. 1943)

**Prerequisites**

Before you use the `aws_s3.query_export_to_s3` function, be sure to complete the following prerequisites:

- Install the required PostgreSQL extensions as described in Overview of exporting data to Amazon S3 (p. 1936).
- Determine where to export your data to Amazon S3 as described in Specifying the Amazon S3 file path to export to (p. 1937).
- Make sure that the DB instance has export access to Amazon S3 as described in Setting up access to an Amazon S3 bucket (p. 1938).

The examples following use a database table called `sample_table`. These examples export the data into a bucket called `sample-bucket`. The example table and data are created with the following SQL statements in `psql`.

```sql
psql=> CREATE TABLE sample_table (bid bigint PRIMARY KEY, name varchar(80));
psql=> INSERT INTO sample_table (bid, name) VALUES (1, 'Monday'), (2, 'Tuesday'), (3, 'Wednesday');
```

**Calling aws_s3.query_export_to_s3**

The following shows the basic ways of calling the `aws_s3.query_export_to_s3` function.

These examples use the variable `s3_uri_1` to identify a structure that contains the information identifying the Amazon S3 file. Use the `aws_commons.create_s3_uri` function to create the structure.

```sql
psql=> SELECT aws_commons.create_s3_uri(
    'sample-bucket',
    'sample-filepath',
    'us-west-2'
) AS s3_uri_1 \gset
```
Although the parameters vary for the following two `aws_s3.query_export_to_s3` function calls, the results are the same for these examples. All rows of the `sample_table` table are exported into a bucket called `sample-bucket`.

```
psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM sample_table', :'s3_uri_1');
psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM sample_table', :'s3_uri_1',
   options :='format text');
```

The parameters are described as follows:

- `'SELECT * FROM sample_table'` – The first parameter is a required text string containing an SQL query. The PostgreSQL engine runs this query. The results of the query are copied to the S3 bucket identified in other parameters.

- `:'s3_uri_1'` – This parameter is a structure that identifies the Amazon S3 file. This example uses a variable to identify the previously created structure. You can instead create the structure by including the `aws_commons.create_s3_uri` function call inline within the `aws_s3.query_export_to_s3` function call as follows.

```
SELECT * from aws_s3.query_export_to_s3('select * from sample_table',
   aws_commons.create_s3_uri('sample-bucket', 'sample-filepath', 'us-west-2')
);
```

- `options :='format text'` – The options parameter is an optional text string containing PostgreSQL COPY arguments. The copy process uses the arguments and format of the PostgreSQL COPY command.

If the file specified doesn't exist in the Amazon S3 bucket, it's created. If the file already exists, it's overwritten. The syntax for accessing the exported data in Amazon S3 is the following.

```
s3-region://bucket-name[/path-prefix]/file-prefix
```

Larger exports are stored in multiple files, each with a maximum size of approximately 6 GB. The additional file names have the same file prefix but with `_partXX` appended. The `XX` represents 2, then 3, and so on. For example, suppose that you specify the path where you store data files as the following.

```
s3-us-west-2://my-bucket/my-prefix
```

If the export has to create three data files, the Amazon S3 bucket contains the following data files.

```
s3-us-west-2://my-bucket/my-prefix
s3-us-west-2://my-bucket/my-prefix_part2
s3-us-west-2://my-bucket/my-prefix_part3
```

For the full reference for this function and additional ways to call it, see `aws_s3.query_export_to_s3` (p. 1943). For more about accessing files in Amazon S3, see **View an object** in the Amazon Simple Storage Service User Guide.

### Exporting to a CSV file that uses a custom delimiter

The following example shows how to call the `aws_s3.query_export_to_s3` function to export data to a file that uses a custom delimiter. The example uses arguments of the PostgreSQL COPY command to specify the comma-separated value (CSV) format and a colon `:` delimiter.
Troubleshooting access to Amazon S3

If you encounter connection problems when attempting to export data to Amazon S3, first confirm that the outbound access rules for the VPC security group associated with your DB instance permit network connectivity. Specifically, the security group must have a rule that allows the DB instance to send TCP traffic to port 443 and to any IPv4 addresses (0.0.0.0/0). For more information, see Provide access to your DB instance in your VPC by creating a security group (p. 156).

• Troubleshooting Amazon RDS identity and access (p. 2222)
• Troubleshooting Amazon S3 in the Amazon Simple Storage Service User Guide
• Troubleshooting Amazon S3 and IAM in the IAM User Guide

Function reference

Functions

• aws_s3.query_export_to_s3 (p. 1943)
• aws_commons.create_s3_uri (p. 1945)

aws_s3.query_export_to_s3

Exports a PostgreSQL query result to an Amazon S3 bucket. The aws_s3 extension provides the aws_s3.query_export_to_s3 function.

The two required parameters are query and s3_info. These define the query to be exported and identify the Amazon S3 bucket to export to. An optional parameter called options provides for defining various export parameters. For examples of using the aws_s3.query_export_to_s3 function, see Exporting query data using the aws_s3.query_export_to_s3 function (p. 1941).

Syntax

aws_s3.query_export_to_s3(
    query text,
    s3_info aws_commons._s3_uri_1,
    options text
)
Input parameters

query

A required text string containing an SQL query that the PostgreSQL engine runs. The results of this
query are copied to an S3 bucket identified in the s3_info parameter.

s3_info

An aws_commons._s3_uri_1 composite type containing the following information about the S3
object:
  • bucket – The name of the Amazon S3 bucket to contain the file.
  • file_path – The Amazon S3 file name and path.
  • region – The AWS Region that the bucket is in. For a listing of AWS Region names and associated
    values, see Regions, Availability Zones, and Local Zones (p. 79).

Currently, this value must be the same AWS Region as that of the exporting DB instance. The
default is the AWS Region of the exporting DB instance.

To create an aws_commons._s3_uri_1 composite structure, see the
aws_commons.create_s3_uri (p. 1945) function.

options

An optional text string containing arguments for the PostgreSQL COPY command. These arguments
specify how the data is to be copied when exported. For more details, see the PostgreSQL COPY
documentation.

Alternate input parameters

To help with testing, you can use an expanded set of parameters instead of the s3_info parameter.
Following are additional syntax variations for the aws_s3.query_export_to_s3 function.

Instead of using the s3_info parameter to identify an Amazon S3 file, use the combination of the
bucket, file_path, and region parameters.

aws_s3.query_export_to_s3(
  query text,
  bucket text,
  file_path text,
  region text,
  options text
)

query

A required text string containing an SQL query that the PostgreSQL engine runs. The results of this
query are copied to an S3 bucket identified in the s3_info parameter.

bucket

A required text string containing the name of the Amazon S3 bucket that contains the file.

file_path

A required text string containing the Amazon S3 file name including the path of the file.

region

An optional text string containing the AWS Region that the bucket is in. For a listing of AWS Region
names and associated values, see Regions, Availability Zones, and Local Zones (p. 79).
Currently, this value must be the same AWS Region as that of the exporting DB instance. The default is the AWS Region of the exporting DB instance.

**options**

An optional text string containing arguments for the PostgreSQL COPY command. These arguments specify how the data is to be copied when exported. For more details, see the PostgreSQL COPY documentation.

**Output parameters**

```
aws_s3.query_export_to_s3(
    OUT rows_uploaded bigint,
    OUT files_uploaded bigint,
    OUT bytes_uploaded bigint
)
```

**rows_uploaded**

The number of table rows that were successfully uploaded to Amazon S3 for the given query.

**files_uploaded**

The number of files uploaded to Amazon S3. Files are created in sizes of approximately 6 GB. Each additional file created has _partXX appended to the name. The XX represents 2, then 3, and so on as needed.

**bytes_uploaded**

The total number of bytes uploaded to Amazon S3.

**Examples**

```
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'sample-bucket', 'sample-filepath');
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'sample-bucket', 'sample-filepath','us-west-2');
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'sample-bucket', 'sample-filepath','us-west-2','format text');
```

**aws_commons.create_s3_uri**

Creates an aws_commons._s3_uri_1 structure to hold Amazon S3 file information. You use the results of the aws_commons.create_s3_uri function in the s3_info parameter of the aws_s3.query_export_to_s3 (p. 1943) function. For an example of using the aws_commons.create_s3_uri function, see Specifying the Amazon S3 file path to export to (p. 1937).

**Syntax**

```
aws_commons.create_s3_uri(
    bucket text,
    file_path text,
    region text
)
```
**Input parameters**

*bucket*

A required text string containing the Amazon S3 bucket name for the file.

*file_path*

A required text string containing the Amazon S3 file name including the path of the file.

*region*

A required text string containing the AWS Region that the file is in. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones (p. 79).
Invoking an AWS Lambda function from an RDS for PostgreSQL DB instance

AWS Lambda is an event-driven compute service that lets you run code without provisioning or managing servers. It's available for use with many AWS services, including RDS for PostgreSQL. For example, you can use Lambda functions to process event notifications from a database, or to load data from files whenever a new file is uploaded to Amazon S3. To learn more about Lambda, see What is AWS Lambda? in the AWS Lambda Developer Guide.

**Note**
Invoking an AWS Lambda function is supported in these RDS for PostgreSQL versions:

- 14.1 and higher minor versions
- 13.2 and higher minor versions
- 12.6 and higher minor versions

Setting up RDS for PostgreSQL to work with Lambda functions is a multi-step process involving AWS Lambda, IAM, your VPC, and your RDS for PostgreSQL DB instance. Following, you can find summaries of the necessary steps.

For more information about Lambda functions, see Getting started with Lambda and AWS Lambda foundations in the AWS Lambda Developer Guide.

**Topics**

- Step 1: Configure your RDS for PostgreSQL DB instance for outbound connections to AWS Lambda (p. 1947)
- Step 2: Configure IAM for your RDS for PostgreSQL DB instance and AWS Lambda (p. 1948)
- Step 3: Install the aws_lambda extension for an RDS for PostgreSQL DB instance (p. 1949)
- Step 4: Use Lambda helper functions with your RDS for PostgreSQL DB instance (Optional) (p. 1950)
- Step 5: Invoke a Lambda function from your RDS for PostgreSQL DB instance (p. 1950)
- Step 6: Grant other users permission to invoke Lambda functions (p. 1951)
- Examples: Invoking Lambda functions from your RDS for PostgreSQL DB instance (p. 1952)
- Lambda function error messages (p. 1954)
- AWS Lambda function reference (p. 1955)

**Step 1: Configure your RDS for PostgreSQL DB instance for outbound connections to AWS Lambda**

Lambda functions always run inside an Amazon VPC that’s owned by the AWS Lambda service. Lambda applies network access and security rules to this VPC and it maintains and monitors the VPC automatically. Your RDS for PostgreSQL DB instance sends network traffic to the Lambda service’s VPC. How you configure this depends on whether your DB instance is public or private.

- **Public RDS for PostgreSQL DB instance** – A DB instance is public if it's located in a public subnet on your VPC, and if the instance's "PubliclyAccessible" property is true. To find the value of this property, you can use the describe-db-instances AWS CLI command. Or, you can use the AWS Management Console to open the Connectivity & security tab and check that Publicly accessible is Yes. To verify that the instance is in the public subnet of your VPC, you can use the AWS Management Console or the AWS CLI.

1947
To set up access to Lambda, you use the AWS Management Console or the AWS CLI to create an outbound rule on your VPC's security group. The outbound rule specifies that TCP can use port 443 to send packets to any IPv4 addresses (0.0.0.0/0).

- **Private RDS for PostgreSQL DB instance** – In this case, the instance's "PubliclyAccessible" property is false or it's in a private subnet. To allow the instance to work with Lambda, you can use a Network Address Translation (NAT) gateway. For more information, see NAT gateways. Or, you can configure your VPC with a VPC endpoint for Lambda. For more information, see VPC endpoints in the Amazon VPC User Guide. The endpoint responds to calls made by your RDS for PostgreSQL DB instance to your Lambda functions. The VPC endpoint uses its own private DNS resolution. RDS for PostgreSQL can't use the Lambda VPC endpoint until you change the value of the rds.custom_dns_resolution from its default value of 0 (not enabled) to 1. To do so:
  - Create a custom DB parameter group.
  - Change the value of the rds.custom_dns_resolution parameter from its default of 0 to 1.
  - Modify your DB instance to use your custom DB parameter group.
  - Reboot the instance to have the modified parameter take effect.

Your VPC can now interact with the AWS Lambda VPC at the network level. Next, you configure the permissions using IAM.

### Step 2: Configure IAM for your RDS for PostgreSQL DB instance and AWS Lambda

Invoking Lambda functions from your RDS for PostgreSQL DB instance requires certain privileges. To configure the necessary privileges, we recommend that you create an IAM policy that allows invoking Lambda functions, assign that policy to a role, and then apply the role to your DB instance. This approach gives the DB instance privileges to invoke the specified Lambda function on your behalf. The following steps show you how to do this using the AWS CLI.

**To configure IAM permissions for using your Amazon RDS instance with Lambda**

1. Use the `create-policy` AWS CLI command to create an IAM policy that allows your RDS for PostgreSQL DB instance to invoke the specified Lambda function. (The statement ID (Sid) is an optional description for your policy statement and has no effect on usage.) This policy gives your DB instance the minimum permissions needed to invoke the specified Lambda function.

```bash
aws iam create-policy --policy-name rds-lambda-policy --policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowAccessToExampleFunction",
            "Effect": "Allow",
            "Action": "lambda:InvokeFunction",
        }
    ]
}
```

Alternatively, you can use the predefined AWSLambdaRole policy that allows you to invoke any of your Lambda functions. For more information, see Identity-based IAM policies for Lambda

2. Use the `create-role` AWS CLI command to create an IAM role that the policy can assume at runtime.

```bash
aws iam create-role --role-name rds-lambda-role --assume-role-policy-document '{
    "Version": "2012-10-17",
}
```
Step 3: Install the extension

3. Apply the policy to the role by using the `attach-role-policy` AWS CLI command.

    ```bash
    aws iam attach-role-policy
    --policy-arn arn:aws:iam::444455556666:policy/rds-lambda-policy
    --role-name rds-lambda-role --region aws-region
    ```

4. Apply the role to your RDS for PostgreSQL DB instance by using the `add-role-to-db-instance` AWS CLI command. This last step allows your DB instance's database users to invoke Lambda functions.

    ```bash
    aws rds add-role-to-db-instance
    --db-cluster-identifier my-cluster-name
    --feature-name Lambda
    --role-arn arn:aws:iam::444455556666:role/rds-lambda-role
    --region aws-region
    ```

With the VPC and the IAM configurations complete, you can now install the `aws_lambda` extension. (Note that you can install the extension at any time, but until you set up the correct VPC support and IAM privileges, the `aws_lambda` extension adds nothing to your RDS for PostgreSQL DB instance's capabilities.)

**Step 3: Install the `aws_lambda` extension for an RDS for PostgreSQL DB instance**

To use AWS Lambda with your RDS for PostgreSQL DB instance, the `aws_lambda` PostgreSQL extension to your RDS for PostgreSQL. This extension provides your RDS for PostgreSQL DB instance with the ability to call Lambda functions from PostgreSQL.

**To install the `aws_lambda` extension in your RDS for PostgreSQL DB instance**

Use the PostgreSQL `psql` command-line or the pgAdmin tool to connect to your RDS for PostgreSQL DB instance.

1. Connect to your RDS for PostgreSQL DB instance as a user with `rds_superuser` privileges. The default `postgres` user is shown in the example.

    ```bash
    psql -h instance.444455556666.aws-region.rds.amazonaws.com -U postgres -p 5432
    ```

2. Install the `aws_lambda` extension. The `aws_commons` extension is also required. It provides helper functions to `aws_lambda` and many other Aurora extensions for PostgreSQL. If it's not already on your RDS for PostgreSQLDB instance, it's installed with `aws_lambda` as shown following.

    ```sql
    CREATE EXTENSION IF NOT EXISTS aws_lambda CASCADE;
    NOTICE: installing required extension "aws_commons"
    CREATE EXTENSION
    ```
The `aws.lambda` extension is installed in your DB instance. You can now create convenience structures for invoking your Lambda functions.

**Step 4: Use Lambda helper functions with your RDS for PostgreSQL DB instance (Optional)**

You can use the helper functions in the `aws_commons` extension to prepare entities that you can more easily invoke from PostgreSQL. To do this, you need to have the following information about your Lambda functions:

- **Function name** – The name, Amazon Resource Name (ARN), version, or alias of the Lambda function. The IAM policy created in [Step 2: Configure IAM for your instance and Lambda](p. 1948) requires the ARN, so we recommend that you use your function’s ARN.
- **AWS Region** – (Optional) The AWS Region where the Lambda function is located if it’s not in the same Region as your RDS for PostgreSQL DB instance.

To hold the Lambda function name information, you use the `aws_commons.create_lambda_function_arn` (p. 1957) function. This helper function creates an `aws_commons._lambda_function_arn_1` composite structure with the details needed by the invoke function. Following, you can find three alternative approaches to setting up this composite structure.

```sql
SELECT aws_commons.create_lambda_function_arn(
    'my-function',
    'aws-region'
) AS aws_lambda_arn_1 \gset
```

```sql
SELECT aws_commons.create_lambda_function_arn(
    '111122223333:function:my-function',
    'aws-region'
) AS lambda_partial_arn_1 \gset
```

```sql
SELECT aws_commons.create_lambda_function_arn(
) AS lambda_arn_1 \gset
```

Any of these values can be used in calls to the `aws.lambda.invoke` (p. 1955) function. For examples, see [Step 5: Invoke a Lambda function from your RDS for PostgreSQL DB instance](p. 1950).

**Step 5: Invoke a Lambda function from your RDS for PostgreSQL DB instance**

The `aws.lambda.invoke` function behaves synchronously or asynchronously, depending on the `invocation_type`. The two alternatives for this parameter are `RequestResponse` (the default) and `Event`, as follows.

- **RequestResponse** – This invocation type is *synchronous*. It's the default behavior when the call is made without specifying an invocation type. The response payload includes the results of the `aws.lambda.invoke` function. Use this invocation type when your workflow requires receiving results from the Lambda function before proceeding.
- **Event** – This invocation type is *asynchronous*. The response doesn't include a payload containing results. Use this invocation type when your workflow doesn't need a result from the Lambda function to continue processing.
As a simple test of your setup, you can connect to your DB instance using psql and invoke an example function from the command line. Suppose that you have one of the basic functions set up on your Lambda service, such as the simple Python function shown in the following screenshot.

To invoke an example function

1. Connect to your DB instance using psql or pgAdmin.

   ```
   psql -h instance.4444555666.aws-region.rds.amazonaws.com -U postgres -p 5432
   ```

2. Invoke the function using its ARN.

   ```
   SELECT * from aws_lambda.invoke(aws_commons.create_lambda_function_arn('arn:aws:lambda:aws-region:4444555666:function:simple', 'us-west-1'), '{"body": "Hello from Postgres!"}':::json );
   ```

   The response looks as follows.

<table>
<thead>
<tr>
<th>status_code</th>
<th>payload</th>
<th>executed_version</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>{&quot;statusCode&quot;: 200, &quot;body&quot;: &quot;Hello from Lambda!&quot;}</td>
<td>$LATEST</td>
</tr>
</tbody>
</table>

   If your invocation attempt doesn't succeed, see Lambda function error messages (p. 1954).

**Step 6: Grant other users permission to invoke Lambda functions**

At this point in the procedures, only you as rds_superuser can invoke your Lambda functions. To allow other users to invoke any functions that you create, you need to grant them permission.

**To grant others permission to invoke Lambda functions**

1. Connect to your DB instance using psql or pgAdmin.
Examples: Invoking Lambda functions

Following, you can find several examples of calling the `aws_lambda.invoke` function. Most all the examples use the composite structure `aws_lambda_arn_1` that you create in Step 4: Use Lambda helper functions with your RDS for PostgreSQL DB instance (Optional) to simplify passing the function details. For an example of asynchronous invocation, see Example: Asynchronous (Event) invocation of Lambda functions (p. 1953). All the other examples listed use synchronous invocation.

To learn more about Lambda invocation types, see Invoking Lambda functions in the AWS Lambda Developer Guide. For more information about `aws_lambda_arn_1`, see `aws_commons.create_lambda_function_arn` (p. 1957).

Examples list
- Example: Synchronous (RequestResponse) invocation of Lambda functions (p. 1952)
- Example: Asynchronous (Event) invocation of Lambda functions (p. 1953)
- Example: Capturing the Lambda execution log in a function response (p. 1953)
- Example: Including client context in a Lambda function (p. 1953)
- Example: Invoking a specific version of a Lambda function (p. 1953)

Example: Synchronous (RequestResponse) invocation of Lambda functions

Following are two examples of a synchronous Lambda function invocation. The results of these `aws_lambda.invoke` function calls are the same.

```
SELECT * FROM aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"}::json);
```

```
SELECT * FROM aws_lambda.invoke(':aws_lambda_arn_1', '{"body": "Hello from Postgres!"}::json, 'RequestResponse');
```

The parameters are described as follows:
- `:'aws_lambda_arn_1'` – This parameter identifies the composite structure created in Step 4: Use Lambda helper functions with your RDS for PostgreSQL DB instance (Optional) (p. 1950), with the `aws_commons.create_lambda_function_arn` helper function. You can also create this structure inline within your `aws_lambda.invoke` call as follows.

```
SELECT * FROM aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-function', 'aws-region'), '{"body": "Hello from Postgres!"}::json
```
• '{"body": "Hello from PostgreSQL!"}::json' – The JSON payload to pass to the Lambda function.
• 'RequestResponse' – The Lambda invocation type.

Example: Asynchronous (Event) invocation of Lambda functions

Following is an example of an asynchronous Lambda function invocation. The Event invocation type schedules the Lambda function invocation with the specified input payload and returns immediately. Use the Event invocation type in certain workflows that don't depend on the results of the Lambda function.

```sql
SELECT * FROM aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"}::json, 'Event');
```

Example: Capturing the Lambda execution log in a function response

You can include the last 4 KB of the execution log in the function response by using the log_type parameter in your `aws_lambda.invoke` function call. By default, this parameter is set to None, but you can specify Tail to capture the results of the Lambda execution log in the response, as shown following.

```sql
SELECT *, select convert_from(decode(log_result, 'base64'), 'utf-8') as log FROM aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"}::json, 'RequestResponse', 'Tail');
```

Set the `aws_lambda.invoke` function's log_type parameter to Tail to include the execution log in the response. The default value for the log_type parameter is None.

The log_result that's returned is a base64 encoded string. You can decode the contents using a combination of the decode and convert_from PostgreSQL functions.

For more information about log_type, see `aws_lambda.invoke` (p. 1955).

Example: Including client context in a Lambda function

The `aws_lambda.invoke` function has a context parameter that you can use to pass information separate from the payload, as shown following.

```sql
SELECT *, convert_from(decode(log_result, 'base64'), 'utf-8') as log FROM aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"}::json, 'RequestResponse', 'Tail');
```

To include client context, use a JSON object for the `aws_lambda.invoke` (p. 1955) function's context parameter.

For more information about the context parameter, see the `aws_lambda.invoke` (p. 1955) reference.

Example: Invoking a specific version of a Lambda function

You can specify a particular version of a Lambda function by including the qualifier parameter with the `aws_lambda.invoke` call. Following, you can find an example that does this using 'custom_version' as an alias for the version.
Lambda function error messages

In the following list you can find information about error messages, with possible causes and solutions.

- **VPC configuration issues**

  VPC configuration issues can raise the following error messages when trying to connect:

  ```
  ERROR:  invoke API failed
  DETAIL:  AWS Lambda client returned 'Unable to connect to endpoint'.
  CONTEXT:  SQL function "invoke" statement 1
  ```

  A common cause for this error is improperly configured VPC security group. Make sure you have an outbound rule for TCP open on port 443 of your VPC security group so that your VPC can connect to the Lambda VPC.

  If your DB instance is private, check the private DNS setup for your VPC. Make sure that you set the rds.custom_dns_resolution parameter to 1 and setup AWS PrivateLink as outlined in Step 1: Configure your RDS for PostgreSQL DB instance for outbound connections to AWS Lambda (p. 1947). For more information, see Interface VPC endpoints (AWS PrivateLink).

- **Lack of permissions needed to invoke Lambda functions**

  If you see either of the following error messages, the user (role) invoking the function doesn't have proper permissions.

  ```
  ERROR:  permission denied for schema aws_lambda
  ```

  ```
  ERROR:  permission denied for function invoke
  ```

  A user (role) must be given specific grants to invoke Lambda functions. For more information, see Step 6: Grant other users permission to invoke Lambda functions (p. 1951).

- **Improper handling of errors in your Lambda functions**

  If a Lambda function throws an exception during request processing, aws_lambda.invoke fails with a PostgreSQL error such as the following.

  ```
  ERROR:  lambda invocation failed
  ```
Be sure to handle errors in your Lambda functions or in your PostgreSQL application.

AWS Lambda function reference

Following is the reference for the functions to use for invoking Lambda functions with RDS for PostgreSQL.

**Functions**

- `aws_lambda.invoke` (p. 1955)
- `aws_commons.create_lambda_function_arn` (p. 1957)

**aws_lambda.invoke**

Runs a Lambda function for an RDS for PostgreSQL DB instance.

For more details about invoking Lambda functions, see also `Invoke` in the *AWS Lambda Developer Guide*.

**Syntax**

**JSON**

```json
aws_lambda.invoke(
    IN function_name TEXT,
    IN payload JSON,
    IN region TEXT DEFAULT NULL,
    IN invocation_type TEXT DEFAULT 'RequestResponse',
    IN log_type TEXT DEFAULT 'None',
    IN context JSON DEFAULT NULL,
    IN qualifier VARCHAR(128) DEFAULT NULL,
    OUT status_code INT,
    OUT payload JSON,
    OUT executed_version TEXT,
    OUT log_result TEXT)
```

```json
aws_lambda.invoke(
    IN function_name aws_commons._lambda_function_arn_1,
    IN payload JSON,
    IN invocation_type TEXT DEFAULT 'RequestResponse',
    IN log_type TEXT DEFAULT 'None',
    IN context JSON DEFAULT NULL,
    IN qualifier VARCHAR(128) DEFAULT NULL,
    OUT status_code INT,
    OUT payload JSON,
    OUT executed_version TEXT,
    OUT log_result TEXT)
```

**JSONB**

```json
aws_lambda.invoke(
    IN function_name TEXT,
    IN payload JSONB,
    IN region TEXT DEFAULT NULL,
    IN invocation_type TEXT DEFAULT 'RequestResponse',
    IN log_type TEXT DEFAULT 'None',
    IN context JSONB DEFAULT NULL,
    IN qualifier VARCHAR(128) DEFAULT NULL,
```

1955
OUT status_code INT,
OUT payload JSONB,
OUT executed_version TEXT,
OUT log_result TEXT)

aws_lambda.invoke(
IN function_name aws_commons._lambda_function_arn_1,
IN payload JSONB,
IN invocation_type TEXT DEFAULT 'RequestResponse',
IN log_type TEXT DEFAULT 'None',
IN context JSONB DEFAULT NULL,
IN qualifier VARCHAR(128) DEFAULT NULL,
OUT status_code INT,
OUT payload JSONB,
OUT executed_version TEXT,
OUT log_result TEXT
)

Input parameters

function_name

The identifying name of the Lambda function. The value can be the function name, an ARN, or a partial ARN. For a listing of possible formats, see Lambda function name formats in the AWS Lambda Developer Guide.

payload

The input for the Lambda function. The format can be JSON or JSONB. For more information, see JSON Types in the PostgreSQL documentation.

region

(Optional) The Lambda Region for the function. By default, RDS resolves the AWS Region from the full ARN in the function_name or it uses the RDS for PostgreSQL DB instance Region. If this Region value conflicts with the one provided in the function_name ARN, an error is raised.

invocation_type

The invocation type of the Lambda function. The value is case-sensitive. Possible values include the following:

- RequestResponse – The default. This type of invocation for a Lambda function is synchronous and returns a response payload in the result. Use the RequestResponse invocation type when your workflow depends on receiving the Lambda function result immediately.
- Event – This type of invocation for a Lambda function is asynchronous and returns immediately without a returned payload. Use the Event invocation type when you don’t need results of the Lambda function before your workflow moves on.
- DryRun – This type of invocation tests access without running the Lambda function.

log_type

The type of Lambda log to return in the log_result output parameter. The value is case-sensitive. Possible values include the following:

- Tail – The returned log_result output parameter will include the last 4 KB of the execution log.
- None – No Lambda log information is returned.

custom

Client context in JSON or JSONB format. Fields to use include than custom and env.
qualifier

A qualifier that identifies a Lambda function's version to be invoked. If this value conflicts with one provided in the function_name ARN, an error is raised.

Output parameters

status_code

An HTTP status response code. For more information, see Lambda Invoke response elements in the AWS Lambda Developer Guide.

payload

The information returned from the Lambda function that ran. The format is in JSON or JSONB.

executed_version

The version of the Lambda function that ran.

log_result

The execution log information returned if the log_type value is Tail when the Lambda function was invoked. The result contains the last 4 KB of the execution log encoded in Base64.

aws_commons.create_lambda_function_arn

Creates an aws_commons._lambda_function_arn_1 structure to hold Lambda function name information. You can use the results of the aws_commons.create_lambda_function_arn function in the function_name parameter of the aws_lambda.invoke aws_lambda.invoke (p. 1955) function.

Syntax

```sql
aws_commons.create_lambda_function_arn(
    function_name TEXT,
    region TEXT DEFAULT NULL
) RETURNS aws_commons._lambda_function_arn_1
```

Input parameters

function_name

A required text string containing the Lambda function name. The value can be a function name, a partial ARN, or a full ARN.

region

An optional text string containing the AWS Region that the Lambda function is in. For a listing of Region names and associated values, see Regions, Availability Zones, and Local Zones (p. 79).

Working with PostgreSQL features supported by Amazon RDS for PostgreSQL

Amazon RDS for PostgreSQL supports many of the most common PostgreSQL features. For example, PostgreSQL has an autovacuum feature that performs routine maintenance on the database. The
The autovacuum feature is active by default. Although you can turn off this feature, we highly recommend that you keep it on. Understanding this feature and what you can do to make sure it works as it should is a basic task of any DBA. For more information about the autovacuum, see Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL (p. 1977). To learn more about other common DBA tasks, Common DBA tasks for Amazon RDS for PostgreSQL (p. 1967).

RDS for PostgreSQL also supports extensions that add important functionality to the DB instance. For example, you can use the PostGIS extension to work with spatial data, or use the pg_cron extension to schedule maintenance from within the instance. For more information about PostgreSQL extensions, see Using PostgreSQL extensions with Amazon RDS for PostgreSQL (p. 2046).

Foreign data wrappers are a specific type of extension designed to let your RDS for PostgreSQL DB instance work with other commercial databases or data types. For more information about foreign data wrappers supported by RDS for PostgreSQL, see Working with the supported foreign data wrappers for Amazon RDS for PostgreSQL (p. 2088).

Following, you can find information about some other features supported by RDS for PostgreSQL.

Topics
- Custom data types and enumerations with RDS for PostgreSQL (p. 1958)
- Event triggers for RDS for PostgreSQL (p. 1959)
- Huge pages for RDS for PostgreSQL (p. 1959)
- Performing logical replication for Amazon RDS for PostgreSQL (p. 1960)
- RAM disk for the stats_temp_directory (p. 1961)
- Tablespace for RDS for PostgreSQL (p. 1962)
- RDS for PostgreSQL collations for EBCDIC and other mainframe migrations (p. 1962)

## Custom data types and enumerations with RDS for PostgreSQL

PostgreSQL supports creating custom data types and working with enumerations. For more information about creating and working with enumerations and other data types, see Enumerated types in the PostgreSQL documentation.

The following is an example of creating a type as an enumeration and then inserting values into a table.

```sql
CREATE TYPE rainbow AS ENUM ('red', 'orange', 'yellow', 'green', 'blue', 'purple');
CREATE TABLE t1 (colors rainbow);
INSERT INTO t1 VALUES ('red'), ('orange');
SELECT * from t1;
colors
--------
red
orange
(2 rows)
postgres=> ALTER TYPE rainbow RENAME VALUE 'red' TO 'crimson';
ALTER TYPE
postgres=> SELECT * from t1;
colors
--------
crimson
orange
(2 rows)
```
Event triggers for RDS for PostgreSQL

All current PostgreSQL versions support event triggers, and so do all available versions of RDS for PostgreSQL. You can use the main user account (default, postgres) to create, modify, rename, and delete event triggers. Event triggers are at the DB instance level, so they can apply to all databases on an instance.

For example, the following code creates an event trigger that prints the current user at the end of every data definition language (DDL) command.

```sql
CREATE OR REPLACE FUNCTION raise_notice_func()
RETURNS event_trigger
 LANGUAGE plpgsql AS
$$
BEGIN
RAISE NOTICE 'In trigger function: %', current_user;
END;
$$;
CREATE EVENT TRIGGER event_trigger_1
ON ddl_command_end
EXECUTE PROCEDURE raise_notice_func();
```

For more information about PostgreSQL event triggers, see Event triggers in the PostgreSQL documentation.

There are several limitations to using PostgreSQL event triggers on Amazon RDS. These include the following:

- You can't create event triggers on read replicas. You can, however, create event triggers on a read replica source. The event triggers are then copied to the read replica. The event triggers on the read replica don't fire on the read replica when changes are pushed from the source. However, if the read replica is promoted, the existing event triggers fire when database operations occur.
- To perform a major version upgrade to a PostgreSQL DB instance that uses event triggers, make sure to delete the event triggers before you upgrade the instance.

Huge pages for RDS for PostgreSQL

Huge pages are a memory management feature that reduces overhead when a DB instance is working with large contiguous chunks of memory, such as that used by shared buffers. This PostgreSQL feature is supported by all currently available RDS for PostgreSQL versions. You allocate huge pages for your application by using calls to `mmap` or `SYSV` shared memory. RDS for PostgreSQL supports both 4-KB and 2-MB page sizes.

You can turn huge pages on or off by changing the value of the `huge_pages` parameter. The feature is turned on by default for all DB instance classes other than micro, small, and medium DB instance classes.

**Note**

Huge pages aren't supported for db.m1, db.m2, and db.m3 DB instance classes.

RDS for PostgreSQL uses huge pages based on the available shared memory. If the DB instance can't use huge pages due to shared memory constraints, Amazon RDS prevents the DB instance from starting. In this case, Amazon RDS sets the status of the DB instance to an incompatible parameters state. If this occurs, you can set the `huge_pages` parameter to off to allow Amazon RDS to start the DB instance.

The `shared_buffers` parameter is key to setting the shared memory pool that is required for using huge pages. The default value for the `shared_buffers` parameter uses a database parameters macro.
This macro sets a percentage of the total 8 KB pages available for the DB instance's memory. When you use huge pages, those pages are located with the huge pages. Amazon RDS puts a DB instance into an incompatible parameters state if the shared memory parameters are set to require more than 90 percent of the DB instance memory.

To learn more about PostgreSQL memory management, see Resource Consumption in the PostgreSQL documentation.

Performing logical replication for Amazon RDS for PostgreSQL

Starting with version 10.4, RDS for PostgreSQL supports the publication and subscription SQL syntax that was introduced in PostgreSQL 10. To learn more, see Logical replication in the PostgreSQL documentation.

**Note**

In addition to the native PostgreSQL logical replication feature introduced in PostgreSQL 10, RDS for PostgreSQL also supports the `pglogical` extension. For more information, see Using `pglogical` to synchronize data across instances (p. 2068).

Following, you can find information about setting up logical replication for an RDS for PostgreSQL DB instance.

**Topics**

- Understanding logical replication and logical decoding (p. 1960)
- Working with logical replication slots (p. 1961)

**Understanding logical replication and logical decoding**

RDS for PostgreSQL supports the streaming of write-ahead log (WAL) changes using PostgreSQL's logical replication slots. It also supports using logical decoding. You can set up logical replication slots on your instance and stream database changes through these slots to a client such as `pg_recvlogical`. You create logical replication slots at the database level, and they support replication connections to a single database.

The most common clients for PostgreSQL logical replication are AWS Database Migration Service or a custom-managed host on an Amazon EC2 instance. The logical replication slot has no information about the receiver of the stream. Also, there's no requirement that the target be a replica database. If you set up a logical replication slot and don't read from the slot, data can be written and quickly fill up your DB instance's storage.

You turn on PostgreSQL logical replication and logical decoding for Amazon RDS with a parameter, a replication connection type, and a security role. The client for logical decoding can be any client that can establish a replication connection to a database on a PostgreSQL DB instance.

**To turn on logical decoding for an RDS for PostgreSQL DB instance**

1. Make sure that the user account that you're using has these roles:
   - The `rds_superuser` role so you can turn on logical replication
   - The `rds_replication` role to grant permissions to manage logical slots and to stream data using logical slots

2. Set the `rds.logical_replication` static parameter to 1. As part of applying this parameter, also set the parameters `wal_level`, `max_wal_senders`, `max_replication_slots`, and `max_connections`. These parameter changes can increase WAL generation, so set the `rds.logical_replication` parameter only when you are using logical slots.
3. Reboot the DB instance for the static rds.logical_replication parameter to take effect.
4. Create a logical replication slot as explained in the next section. This process requires that you specify a decoding plugin. Currently, RDS for PostgreSQL supports the test_decoding and wal2json output plugins that ship with PostgreSQL.

For more information on PostgreSQL logical decoding, see the PostgreSQL documentation.

### Working with logical replication slots

You can use SQL commands to work with logical slots. For example, the following command creates a logical slot named test_slot using the default PostgreSQL output plugin test_decoding.

```sql
SELECT * FROM pg_create_logical_replication_slot('test_slot', 'test_decoding');
```

```
slot_name    | xlog_position
-------------+---------------
regression_slot | 0/1681970     
(1 row)
```

To list logical slots, use the following command.

```sql
SELECT * FROM pg_replication_slots;
```

To drop a logical slot, use the following command.

```sql
SELECT pg_drop_replication_slot('test_slot');
```

(1 row)

For more examples on working with logical replication slots, see Logical decoding examples in the PostgreSQL documentation.

After you create the logical replication slot, you can start streaming. The following example shows how logical decoding is controlled over the streaming replication protocol. This example uses the program pg_recvlogical, which is included in the PostgreSQL distribution. Doing this requires that client authentication is set up to allow replication connections.

```
pg_recvlogical -d postgres --slot test_slot -U postgres
              --host "instance-name.111122223333.aws-region.rds.amazonaws.com
              -f - --start
```

To see the contents of the pg_replication_origin_status view, query the pg_show_replication_origin_status function.

```sql
SELECT * FROM pg_show_replication_origin_status();
```

```
local_id | external_id | remote_lsn | local_lsn
----------+-------------+------------+-----------
(0 rows)
```

### RAM disk for the stats_temp_directory

You can use the RDS for PostgreSQL parameter rds.pg_stat_ramdisk_size to specify the system memory allocated to a RAM disk for storing the PostgreSQL stats_temp_directory. The RAM disk parameter is available for all PostgreSQL versions on Amazon RDS.
Under certain workloads, setting this parameter can improve performance and decrease I/O requirements. For more information about the stats_temp_directory, see the PostgreSQL documentation.

To set up a RAM disk for your stats_temp_directory, set the rds.pg_stat_ramdisk_size parameter to an integer literal value in the parameter group used by your DB instance. This parameter denotes MB, so you must use an integer value. Expressions, formulas, and functions aren't valid for the rds.pg_stat_ramdisk_size parameter. Be sure to reboot the DB instance so that the change takes effect. For information about setting parameters, see Working with parameter groups (p. 295).

For example, the following AWS CLI command sets the RAM disk parameter to 256 MB.

```
aws rds modify-db-parameter-group
  --db-parameter-group-name pg-95-ramdisk-testing
  --parameters "ParameterName=rds.pg_stat_ramdisk_size, ParameterValue=256,
  ApplyMethod=pending-reboot"
```

After you reboot, run the following command to see the status of the stats_temp_directory.

```
postgres=> SHOW stats_temp_directory;
```

The command should return the following.

```
stats_temp_directory
-----------------------------
/rdsdbramdisk/pg_stat_tmp
(1 row)
```

### Tablespace for RDS for PostgreSQL

RDS for PostgreSQL supports tablespaces for compatibility. Because all storage is on a single logical volume, you can't use tablespaces for I/O splitting or isolation. Our benchmarks and experience indicate that a single logical volume is the best setup for most use cases.

To create and use tablespaces with your RDS for PostgreSQL DB instance requires the rds_superuser role. Your RDS for PostgreSQL DB instance's main user account (default name, postgres) is a member of this role. For more information, see Understanding PostgreSQL roles and permissions (p. 1967).

If you specify a file name when you create a tablespace, the path prefix is /rdsdbdata/db/base/tablespace. The following example places tablespace files in /rdsdbdata/db/base/tablespace/data. This example assumes that a dbadmin user (role) exists and that it's been granted the rds_superuser role needed to work with tablespaces.

```
postgres=> CREATE TABLESPACE act_data
  OWNER dbadmin
  LOCATION '/data';
CREATED TABLESPACE
```

To learn more about PostgreSQL tablespaces, see Tablespace in the PostgreSQL documentation.

### RDS for PostgreSQL collations for EBCDIC and other mainframe migrations

RDS for PostgreSQL versions 10 and higher include ICU version 60.2, which is based on Unicode 10.0 and includes collations from the Unicode Common Locale Data Repository, CLDR 32. These software
internationalization libraries ensure that character encodings are presented in a consistent way, regardless of operating system or platform. For more information about Unicode CLDR-32, see the CLDR 32 Release Note on the Unicode CLDR website. You can learn more about the internationalization components for Unicode (ICU) at the ICU Technical Committee (ICU-TC) website. For information about ICU-60, see Download ICU 60.

Starting with version 14.3, RDS for PostgreSQL also includes collations that help with data integration and conversion from EBCDIC-based systems. The extended binary coded decimal interchange code or **EBCDIC** encoding is commonly used by mainframe operating systems. These Amazon RDS-provided collations are narrowly defined to sort only those Unicode characters that directly map to EBCDIC code pages. The characters are sorted in EBCDIC code-point order to allow for data validation after conversion. These collations don't include denormalized forms, nor do they include Unicode characters that don't directly map to a character on the source EBCDIC code page.

The character mappings between EBCDIC code pages and Unicode code points are based on tables published by IBM. The complete set is available from IBM as a compressed file for download. RDS for PostgreSQL used these mappings with tools provided by the ICU to create the collations listed in the tables in this section. The collation names include a language and country as required by the ICU. However, EBCDIC code pages don't specify languages, and some EBCDIC code pages cover multiple countries. That means that the language and country portion of the collation names in the table are arbitrary, and they don't need to match the current locale. In other words, the code page number is the most important part of the collation name in this table. You can use any of the collations listed in the following tables in any RDS for PostgreSQL database.

- **Unicode to EBCDIC collations table** – Some mainframe data migration tools internally use LATIN1 or LATIN9 to encode and process data. Such tools use round-trip schemes to preserve data integrity and support reverse conversion. The collations in this table can be used by tools that process data using LATIN1 encoding, which doesn't require special handling.
- **Unicode to LATIN9 collations table** – You can use these collations in any RDS for PostgreSQL database.

In the following table, you find collations available in RDS for PostgreSQL that map EBCDIC code pages to Unicode code points. We recommend that you use the collations in this table for application development that requires sorting based on the ordering of IBM code pages.

<table>
<thead>
<tr>
<th>PostgreSQL collation name</th>
<th>Description of code-page mapping and sort order</th>
</tr>
</thead>
<tbody>
<tr>
<td>da-DK-cp277-x-icu</td>
<td>Unicode characters that directly map to IBM EBCDIC Code Page 277 (per conversion tables) are sorted in IBM CP 277 code point order</td>
</tr>
<tr>
<td>de-DE-cp273-x-icu</td>
<td>Unicode characters that directly map to IBM EBCDIC Code Page 273 (per conversion tables) are sorted in IBM CP 273 code point order</td>
</tr>
<tr>
<td>en-GB-cp285-x-icu</td>
<td>Unicode characters that directly map to IBM EBCDIC Code Page 285 (per conversion tables) are sorted in IBM CP 285 code point order</td>
</tr>
<tr>
<td>en-US-cp037-x-icu</td>
<td>Unicode characters that directly map to IBM EBCDIC Code Page 037 (per conversion tables) are sorted in IBM CP 37 code point order</td>
</tr>
<tr>
<td>es-ES-cp284-x-icu</td>
<td>Unicode characters that directly map to IBM EBCDIC Code Page 284 (per conversion tables) are sorted in IBM CP 284 code point order</td>
</tr>
<tr>
<td>PostgreSQL collation name</td>
<td>Description of code-page mapping and sort order</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------</td>
</tr>
<tr>
<td>fi-FI-cp278-x-icu</td>
<td>Unicode characters that directly map to IBM EBCDIC Code Page 278 (per conversion tables) are sorted in IBM CP 278 code point order</td>
</tr>
<tr>
<td>fr-FR-cp297-x-icu</td>
<td>Unicode characters that directly map to IBM EBCDIC Code Page 297 (per conversion tables) are sorted in IBM CP 297 code point order</td>
</tr>
<tr>
<td>it-IT-cp280-x-icu</td>
<td>Unicode characters that directly map to IBM EBCDIC Code Page 280 (per conversion tables) are sorted in IBM CP 280 code point order</td>
</tr>
<tr>
<td>nl-BE-cp500-x-icu</td>
<td>Unicode characters that directly map to IBM EBCDIC Code Page 500 (per conversion tables) are sorted in IBM CP 500 code point order</td>
</tr>
</tbody>
</table>

Amazon RDS provides a set of additional collations that sort Unicode code points that map to LATIN9 characters using the tables published by IBM, in the order of the original code points according to the EBCDIC code page of the source data.

<table>
<thead>
<tr>
<th>PostgreSQL collation name</th>
<th>Description of code-page mapping and sort order</th>
</tr>
</thead>
<tbody>
<tr>
<td>da-DK-cp1142m-x-icu</td>
<td>Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1142 (per conversion tables) are sorted in IBM CP 1142 code point order</td>
</tr>
<tr>
<td>de-DE-cp1141m-x-icu</td>
<td>Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1141 (per conversion tables) are sorted in IBM CP 1141 code point order</td>
</tr>
<tr>
<td>en-GB-cp1146m-x-icu</td>
<td>Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1146 (per conversion tables) are sorted in IBM CP 1146 code point order</td>
</tr>
<tr>
<td>en-US-cp1140m-x-icu</td>
<td>Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1140 (per conversion tables) are sorted in IBM CP 1140 code point order</td>
</tr>
<tr>
<td>es-ES-cp1145m-x-icu</td>
<td>Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1145 (per conversion tables) are sorted in IBM CP 1145 code point order</td>
</tr>
<tr>
<td>fi-Fi-cp1143m-x-icu</td>
<td>Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1143 (per conversion tables) are sorted in IBM CP 1143 code point order</td>
</tr>
<tr>
<td>fr-FR-cp1147m-x-icu</td>
<td>Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1147 (per conversion tables) are sorted in IBM CP 1147 code point order</td>
</tr>
</tbody>
</table>
**PostgreSQL collation name** | **Description of code-page mapping and sort order**
---|---
1147 (per conversion tables) are sorted in IBM CP 1147 code point order | it-IT-cp1144m-x-icu
Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1144 (per conversion tables) are sorted in IBM CP 1144 code point order | nl-BE-cp1148m-x-icu
Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1148 (per conversion tables) are sorted in IBM CP 1148 code point order

In the following, you can find an example of using an RDS for PostgreSQL collation.

```sql
db1=> SELECT pg_import_system_collations('pg_catalog');

<table>
<thead>
<tr>
<th>pg_import_system_collations</th>
</tr>
</thead>
<tbody>
<tr>
<td>36</td>
</tr>
</tbody>
</table>

db1=> SELECT 'œ' < 'a' col1;
<table>
<thead>
<tr>
<th>col1</th>
</tr>
</thead>
<tbody>
<tr>
<td>t</td>
</tr>
</tbody>
</table>

db1=> SELECT 'œ' < 'a' COLLATE "da-DK-cp277-x-icu" col1;
<table>
<thead>
<tr>
<th>col1</th>
</tr>
</thead>
<tbody>
<tr>
<td>f</td>
</tr>
</tbody>
</table>
```

We recommend that you use the collations in the [Unicode to EBCDIC collations table](https://aws.amazon.com/rds-postgresql/collations/) and in the [Unicode to LATIN9 collations table](https://aws.amazon.com/rds-postgresql/collations/) for application development that requires sorting based on the ordering of IBM code pages. The following collations (suffixed with the letter "b") are also visible in `pg_collation`, but are intended for use by mainframe data integration and migration tools at AWS that map code pages with specific code point shifts and require special handling in collation. In other words, the following collations aren't recommended for use.

- da-DK-277b-x-icu
- da-DK-1142b-x-icu
- de-DE-cp273b-x-icu
- de-DE-cp1141b-x-icu
- en-GB-cp1146b-x-icu
- en-GB-cp285b-x-icu
- en-US-cp037b-x-icu
- en-US-cp1140b-x-icu
- es-ES-cp1145b-x-icu
- es-ES-cp284b-x-icu
- fi-FI-cp1143b-x-icu
- fr-FR-cp1147b-x-icu
- fr-FR-cp297b-x-icu
- it-IT-cp1144b-x-icu
- it-IT-cp280b-x-icu
- nl-BE-cp1148b-x-icu
• nl-BE-cp500b-x-icu

To learn more about migrating applications from mainframe environments to AWS, see What is AWS Mainframe Modernization?

For more information about managing collations in PostgreSQL, see Collation Support in the PostgreSQL documentation.
Common DBA tasks for Amazon RDS for PostgreSQL

Database administrators (DBAs) perform a variety of tasks when administering an Amazon RDS for PostgreSQL DB instance. If you're a DBA already familiar with PostgreSQL, you need to be aware of some of the important differences between running PostgreSQL on your hardware and RDS for PostgreSQL. For example, because it's a managed service, Amazon RDS doesn't allow shell access to your DB instances. That means that you don't have direct access to `pg_hba.conf` and other configuration files. For RDS for PostgreSQL, changes that are typically made to the PostgreSQL configuration file of an on-premises instance are made to a custom DB parameter group associated with the RDS for PostgreSQL DB instance. For more information, see Working with parameter groups (p. 295).

You also can’t access log files in the same way that you do with an on-premises PostgreSQL instance. To learn more about logging, see RDS for PostgreSQL database log files (p. 752).

As another example, you don’t have access to the PostgreSQL superuser account. On RDS for PostgreSQL, the `rds_superuser` role is the most highly privileged role, and it's granted to `postgres` at set up time. Whether you're familiar with using PostgreSQL on-premises or completely new to RDS for PostgreSQL, we recommend that you understand the `rds_superuser` role, and how to work with roles, users, groups, and permissions. For more information, see Understanding PostgreSQL roles and permissions (p. 1967).

Following are some common DBA tasks for RDS for PostgreSQL.

**Topics**
- Understanding PostgreSQL roles and permissions (p. 1967)
- Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL (p. 1977)
- Working with logging mechanisms supported by RDS for PostgreSQL (p. 1985)
- Using pgBadger for log analysis with PostgreSQL (p. 1986)
- Working with parameters on your RDS for PostgreSQL DB instance (p. 1986)

**Understanding PostgreSQL roles and permissions**

When you create an RDS for PostgreSQL DB instance using the AWS Management Console, an administrator account is created at the same time. By default, its name is `postgres`, as shown in the following screenshot:
You can choose another name rather than accept the default (postgres). If you do, the name you choose must start with a letter and be between 1 and 16 alphanumeric characters. For simplicity's sake, we refer to this main user account by its default value (postgres) throughout this guide.

If you use the create-db-instance AWS CLI rather than the AWS Management Console, you create the name by passing it with the master-username parameter in the command. For more information, see Creating an Amazon RDS DB instance (p. 236).

Whether you use the AWS Management Console, the AWS CLI, or the Amazon RDS API, and whether you use the default postgres name or choose a different name, this first database user account is a member of the rds_superuser group and has rds_superuser privileges.

**Topics**
- Understanding the rds_superuser role (p. 1968)
- Controlling user access to the PostgreSQL database (p. 1969)
- Delegating and controlling user password management (p. 1971)
- Using SCRAM for PostgreSQL password encryption (p. 1972)

### Understanding the rds_superuser role

In PostgreSQL, a role can define a user, a group, or a set of specific permissions granted to a group or user for various objects in the database. PostgreSQL commands to CREATE USER and CREATE GROUP have been replaced by the more general, CREATE ROLE with specific properties to distinguish database users. A database user can be thought of as a role with the LOGIN privilege.

**Note**
The CREATE USER and CREATE GROUP commands can still be used. For more information, see Database Roles in the PostgreSQL documentation.

The postgres user is the most highly privileged database user on your RDS for PostgreSQL DB instance. It has the characteristics defined by the following CREATE ROLE statement.

```
CREATE ROLE postgres WITH LOGIN NOSUPERUSER INHERIT CREATEDB CREATEROLE NOREPLICATION VALID UNTIL 'infinity'
```

The properties NOSUPERUSER, NOREPLICATION, INHERIT, and VALID UNTIL 'infinity' are the default options for CREATE ROLE, unless otherwise specified.

By default, postgres has privileges granted to the rds_superuser role. The rds_superuser role allows the postgres user to do the following:

- Add extensions that are available for use with Amazon RDS. For more information, see Working with PostgreSQL features supported by Amazon RDS for PostgreSQL (p. 1957)
- Create roles for users and grant privileges to users. For more information, see CREATE ROLE and GRANT in the PostgreSQL documentation.
- Create databases. For more information, see CREATE DATABASE in the PostgreSQL documentation.
- Grant rds_superuser privileges to user roles that don't have these privileges, and revoke privileges as needed. We recommend that you grant this role only to those users who perform superuser tasks. In other words, you can grant this role to database administrators (DBAs) or system administrators.
- Grant (and revoke) the rds_replication role to database users that don't have the rds_superuser role.
- Grant (and revoke) the rds_password role to database users that don't have the rds_superuser role.
Obtain status information about all database connections by using the pg_stat_activity view. When needed, rds_superuser can stop any connections by using pg_terminate_backend or pg_cancel_backend.

In the CREATE ROLE postgres... statement, you can see that the postgres user role specifically disallows PostgreSQL superuser permissions. RDS for PostgreSQL is a managed service, so you can’t access the host OS, and you can’t connect using the PostgreSQL superuser account. Many of the tasks that require superuser access on a stand-alone PostgreSQL are managed automatically by Amazon RDS.

For more information about granting privileges, see GRANT in the PostgreSQL documentation.

The rds_superuser role is one of several predefined roles in an RDS for PostgreSQL DB instance.

Note
In PostgreSQL 13 and earlier releases, predefined roles are known as default roles.

In the following list, you find some of the other predefined roles that are created automatically for a new RDS for PostgreSQL DB instance. Predefined roles and their privileges can’t be changed. You can’t drop, rename, or modify privileges for these predefined roles. Attempting to do so results in an error.

• rds_password – A role that can change passwords and set up password constraints for database users. The rds_superuser role is granted this role by default, and can grant the role to database users. For more information, see Controlling user access to the PostgreSQL database (p. 1969).

• rdsadmin – A role that’s created to handle many of the management tasks that the administrator with superuser privileges would perform on a standalone PostgreSQL database. This role is used internally by RDS for PostgreSQL for many management tasks.

• rdstopmgr – A role that’s used internally by Amazon RDS to support Multi-AZ deployments.

To see all predefined roles, you can connect to your RDS for PostgreSQL DB instance and use the psq1 \du metacommand. The output looks as follows:

<table>
<thead>
<tr>
<th>Role name</th>
<th>Attributes</th>
<th>Member of</th>
</tr>
</thead>
<tbody>
<tr>
<td>postgres</td>
<td>Create role, Create DB</td>
<td>{rds_superuser}</td>
</tr>
<tr>
<td></td>
<td>Password valid until infinity</td>
<td></td>
</tr>
<tr>
<td>rds_superuser</td>
<td>Cannot login</td>
<td>{pg_monitor,pg_signal_backend,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>rds_replication,rds_password}</td>
</tr>
</tbody>
</table>

In the output, you can see that rds_superuser isn’t a database user role (it can’t login), but it has the privileges of many other roles. You can also see that database user postgres is a member of the rds_superuser role. As mentioned previously, postgres is the default value in the Amazon RDS console’s Create database page. If you chose another name, that name is shown in the list of roles instead.

Controlling user access to the PostgreSQL database

New databases in PostgreSQL are always created with a default set of privileges in the database’s public schema that allow all database users and roles to create objects. These privileges allow database users to connect to the database, for example, and create temporary tables while connected.

To better control user access to the databases instances that you create on your RDS for PostgreSQL DB instance, we recommend that you revoke these default public privileges. After doing so, you then grant specific privileges for database users on a more granular basis, as shown in the following procedure.
To set up roles and privileges for a new database instance

Suppose you’re setting up a database on a newly created RDS for PostgreSQL DB instance for use by several researchers, all of whom need read-write access to the database.

1. Use psql (or pgAdmin) to connect to your RDS for PostgreSQL DB instance:

```bash
psql --host=your-db-instance.666666666666.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
```

When prompted, enter your password. The psql client connects and displays the default administrative connection database, postgres=>, as the prompt.

2. To prevent database users from creating objects in the public schema, do the following:

   ```
   postgres=> REVOKE CREATE ON SCHEMA public FROM PUBLIC;
   REVOKE
   ```

3. Next, you create a new database instance:

   ```
   postgres=> CREATE DATABASE lab_db;
   CREATE DATABASE
   ```

4. Revoke all privileges from the PUBLIC schema on this new database.

   ```
   postgres=> REVOKE ALL ON DATABASE lab_db FROM public;
   REVOKE
   ```

5. Create a role for database users.

   ```
   postgres=> CREATE ROLE lab_tech;
   CREATE ROLE
   ```

6. Give database users that have this role the ability to connect to the database.

   ```
   postgres=> GRANT CONNECT ON DATABASE lab_db TO lab_tech;
   GRANT
   ```

7. Grant all users with the lab_tech role all privileges on this database.

   ```
   postgres=> GRANT ALL PRIVILEGES ON DATABASE lab_db TO lab_tech;
   GRANT
   ```

8. Create database users, as follows:

   ```
   postgres=> CREATE ROLE lab_user1 LOGIN PASSWORD 'change_me';
   CREATE ROLE
   postgres=> CREATE ROLE lab_user2 LOGIN PASSWORD 'change_me';
   CREATE ROLE
   ```

9. Grant these two users the privileges associated with the lab_tech role:

   ```
   postgres=> GRANT lab_tech TO lab_user1;
   GRANT ROLE
   postgres=> GRANT lab_tech TO lab_user2;
   GRANT ROLE
   ```
At this point, lab_user1 and lab_user2 can connect to the lab_db database. This example doesn't follow best practices for enterprise usage, which might include creating multiple database instances, different schemas, and granting limited permissions. For more complete information and additional scenarios, see Managing PostgreSQL Users and Roles.

For more information about privileges in PostgreSQL databases, see the GRANT command in the PostgreSQL documentation.

**Delegating and controlling user password management**

As a DBA, you might want to delegate the management of user passwords. Or, you might want to prevent database users from changing their passwords or reconfiguring password constraints, such as password lifetime. To ensure that only the database users that you choose can change password settings, you can turn on the restricted password management feature. When you activate this feature, only those database users that have been granted the `rds_password` role can manage passwords.

**Note**

To use restricted password management, your RDS for PostgreSQL DB instance must be running PostgreSQL 10.6 or higher.

By default, this feature is off, as shown in the following:

```sql
postgres=> SHOW rds.restrict_password_commands;
 rds.restrict_password_commands
---------------
 off
(1 row)
```

To turn on this feature, you use a custom parameter group and change the setting for `rds.restrict_password_commands` to 1. Be sure to reboot your RDS for PostgreSQL DB instance so that the setting takes effect.

With this feature active, `rds_password` privileges are needed for the following SQL commands:

```sql
CREATE ROLE myrole WITH PASSWORD 'mypassword';
CREATE ROLE myrole WITH PASSWORD 'mypassword' VALID UNTIL '2023-01-01';
ALTER ROLE myrole WITH PASSWORD 'mypassword' VALID UNTIL '2023-01-01';
ALTER ROLE myrole WITH PASSWORD 'mypassword';
ALTER ROLE myrole VALID UNTIL '2023-01-01';
ALTER ROLE myrole RENAME TO myrole2;
```

Renaming a role (`ALTER ROLE myrole RENAME TO newname`) is also restricted if the password uses the MD5 hashing algorithm.

With this feature active, attempting any of these SQL commands without the `rds_password` role permissions generates the following error:

```
ERROR: must be a member of rds_password to alter passwords
```

We recommend that you grant the `rds_password` to only a few roles that you use solely for password management. If you grant `rds_password` privileges to database users that don't have `rds_superuser` privileges, you need to also grant them the `CREATEROLE` attribute.

Make sure that you verify password requirements such as expiration and needed complexity on the client side. If you use your own client-side utility for password related changes, the utility needs to be a member of `rds_password` and have `CREATE ROLE` privileges.
Using SCRAM for PostgreSQL password encryption

The Salted Challenge Response Authentication Mechanism (SCRAM) is an alternative to PostgreSQL's default message digest (MD5) algorithm for encrypting passwords. The SCRAM authentication mechanism is considered more secure than MD5. To learn more about these two different approaches to securing passwords, see Password Authentication in the PostgreSQL documentation.

We recommend that you use SCRAM rather than MD5 as the password encryption scheme for your RDS for PostgreSQL DB instance. It's a cryptographic challenge-response mechanism that uses the scram-sha-256 algorithm for password authentication and encryption.

You might need to update libraries for your client applications to support SCRAM. For example, JDBC versions before 42.2.0 don't support SCRAM. For more information, see PostgreSQL JDBC Driver in the PostgreSQL JDBC Driver documentation. For a list of other PostgreSQL drivers and SCRAM support, see List of drivers in the PostgreSQL documentation.

Note
RDS for PostgreSQL version 13.1 and higher support scram-sha-256. These versions also let you configure your DB instance to require SCRAM, as discussed in the following procedures.

Setting up RDS for PostgreSQL DB instance to require SCRAM

you can require the RDS for PostgreSQL DB instance to accept only passwords that use the scram-sha-256 algorithm.

Important
For existing RDS Proxies with PostgreSQL databases, if you modify the database authentication to use SCRAM only, the proxy becomes unavailable for up to 60 seconds. To avoid the issue, do one of the following:

• Ensure that the database allows both SCRAM and MD5 authentication.
• To use only SCRAM authentication, create a new proxy, migrate your application traffic to the new proxy, then delete the proxy previously associated with the database.

Before making changes to your system, be sure you understand the complete process, as follows:

• Get information about all roles and password encryption for all database users.
• Double-check the parameter settings for your RDS for PostgreSQL DB instance for the parameters that control password encryption.
• If your RDS for PostgreSQL DB instance uses a default parameter group, you need to create a custom DB parameter group and apply it to your RDS for PostgreSQL DB instance so that you can modify parameters when needed. If your RDS for PostgreSQL DB instance uses a custom parameter group, you can modify the necessary parameters later in the process, as needed.
• Change the password_encryption parameter to scram-sha-256.
• Notify all database users that they need to update their passwords. Do the same for your postgres account. The new passwords are encrypted and stored using the scram-sha-256 algorithm.
• Verify that all passwords are encrypted using as the type of encryption.
• If all passwords use scram-sha-256, you can change the rds.accepted_password_auth_method parameter from md5+scram to scram-sha-256.

Warning
After you change rds.accepted_password_auth_method to scram-sha-256 alone, any users (roles) with md5–encrypted passwords can't connect.
Getting ready to require SCRAM for your RDS for PostgreSQL DB instance

Before making any changes to your RDS for PostgreSQL DB instance, check all existing database user accounts. Also, check the type of encryption used for passwords. You can do these tasks by using the rds_tools extension. This extension is supported on RDS for PostgreSQL 13.1 and higher releases.

To get a list of database users (roles) and password encryption methods

1. Use psql to connect to your RDS for PostgreSQL DB instance, as shown in the following.

   ```bash
   psql --host=host-url.amazonaws.com --port=port --username=username --password
   ```

2. Install the rds_tools extension.

   ```bash
   postgres=> CREATE EXTENSION rds_tools;
   ```

3. Get a listing of roles and encryption.

   ```bash
   postgres=> SELECT * FROM rds_tools.role_password_encryption_type();
   ```

You see output similar to the following.

<table>
<thead>
<tr>
<th>rolname</th>
<th>encryption_type</th>
</tr>
</thead>
<tbody>
<tr>
<td>pg_monitor</td>
<td></td>
</tr>
<tr>
<td>pg_read_all_settings</td>
<td></td>
</tr>
<tr>
<td>pg_read_all_stats</td>
<td></td>
</tr>
<tr>
<td>pg_stat_scan_tables</td>
<td></td>
</tr>
<tr>
<td>pg_signal_backend</td>
<td></td>
</tr>
<tr>
<td>lab_tester</td>
<td>md5</td>
</tr>
<tr>
<td>user_465</td>
<td>md5</td>
</tr>
<tr>
<td>postgres</td>
<td>md5</td>
</tr>
<tr>
<td>(8 rows)</td>
<td></td>
</tr>
</tbody>
</table>

Creating a custom DB parameter group

**Note**
If your RDS for PostgreSQL DB instance already uses a custom parameter group, you don't need to create a new one.

For an overview of parameter groups for Amazon RDS, see Working with parameters on your RDS for PostgreSQL DB instance (p. 1986).

The password encryption type used for passwords is set in one parameter, password_encryption. The encryption that the RDS for PostgreSQL DB instance allows is set in another parameter, rds.accepted_password_auth_method. Changing either of these from the default values requires that you create a custom DB parameter group and apply it to your instance.

You can also use the AWS Management Console or the RDS API to create a custom DB parameter group. For more information, see

You can now associate the custom parameter group with your DB instance.
To create a custom DB parameter group

1. Use the `create-db-parameter-group` CLI command to create the custom DB parameter group. This example uses `postgres13` as the source for this custom parameter group.

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group --db-parameter-group-name 'docs-lab-scram-passwords' --db-parameter-group-family postgres13 --description 'Custom parameter group for SCRAM'
```

For Windows:

```
aws rds create-db-parameter-group --db-parameter-group-name "docs-lab-scram-passwords" --db-parameter-group-family postgres13 --description "Custom DB parameter group for SCRAM"
```

2. Use the `modify-db-instance` CLI command to apply this custom parameter group to your RDS for PostgreSQL DB cluster.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance --db-instance-identifier 'your-instance-name' --db-parameter-group-name "docs-lab-scram-passwords"
```

For Windows:

```
aws rds modify-db-instance --db-instance-identifier "your-instance-name" --db-parameter-group-name "docs-lab-scram-passwords"
```

To resynchronize your RDS for PostgreSQL DB instance with your custom DB parameter group, you need to reboot the primary and all other instances of the cluster. To minimize impact to your users, schedule this to occur during your regular maintenance window.

Configuring password encryption to use SCRAM

The password encryption mechanism used by an RDS for PostgreSQL DB instance is set in the DB parameter group in the `password_encryption` parameter. Allowed values are `unset`, `md5`, or `scram-sha-256`. The default value depends on the RDS for PostgreSQL version, as follows:

- RDS for PostgreSQL 14 – No default value (unset)
- RDS for PostgreSQL 13 – Default is `md5`

With a custom DB parameter group attached to your RDS for PostgreSQL DB instance, you can modify values for the password encryption parameter.
To change password encryption setting to scram-sha-256

- Change the value of password encryption to scram-sha-256, as shown following. The change can be applied immediately because the parameter is dynamic, so a restart isn't required for the change to take effect.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group --db-parameter-group-name 'docs-lab-scram-passwords' --parameters 'ParameterName=password_encryption,ParameterValue=scram-sha-256,ApplyMethod=immediate'
```

For Windows:

```bash
aws rds modify-db-parameter-group --db-parameter-group-name ^
"docs-lab-scram-passwords" --parameters ^
"ParameterName=password_encryption,ParameterValue=scram-sha-256,ApplyMethod=immediate"
```

Migrating passwords for user roles to SCRAM

You can migrate passwords for user roles to SCRAM as described following.

To migrate database user (role) passwords from MD5 to SCRAM

1. Log in as the administrator user (default user name, postgres) as shown following.

```bash
psql --host=\db-name\111122223333.\aws-region.\rds.amazonaws.com --port=5432 --username=postgres --password
```

2. Check the setting of the password_encryption parameter on your RDS for PostgreSQL DB instance by using the following command.

```bash
postgres=> SHOW password_encryption;
password_encryption
---------------------
md5
(1 row)
```

3. Change the value of this parameter to scram-sha-256. This is a dynamic parameter, so you don't need to reboot the instance after making this change. Check the value again to make sure that it's now set to scram-sha-256, as follows.

```bash
postgres=> SHOW password_encryption;
password_encryption
---------------------
scram-sha-256
(1 row)
```

4. Notify all database users to change their passwords. Be sure to also change your own password for account postgres (the database user with rds_superuser privileges).

```bash
labdb=> ALTER ROLE postgres WITH LOGIN PASSWORD 'change_me';
ALTER ROLE
```

5. Repeat the process for all databases on your RDS for PostgreSQL DB instance.
Changing parameter to require SCRAM

This is the final step in the process. After you make the change in the following procedure, any user accounts (roles) that still use md5 encryption for passwords can’t log in to the RDS for PostgreSQL DB instance.

The rds.accepted_password_auth_method specifies the encryption method that the RDS for PostgreSQL DB instance accepts for a user password during the login process. The default value is md5+scram, meaning that either method is accepted. In the following image, you can find the default setting for this parameter.

<table>
<thead>
<tr>
<th>Name</th>
<th>Values</th>
<th>Allowed values</th>
<th>Modifiable</th>
<th>Source</th>
<th>Apply type</th>
</tr>
</thead>
<tbody>
<tr>
<td>password_encryption</td>
<td>scram-sha-256</td>
<td>md5, scram-sha-256</td>
<td>true</td>
<td>system</td>
<td>dynamic</td>
</tr>
<tr>
<td>rds.accepted_password_auth_method</td>
<td>md5+scram</td>
<td>md5+scram [scram]</td>
<td>true</td>
<td>system</td>
<td>dynamic</td>
</tr>
</tbody>
</table>

The allowed values for this parameter are md5+scram or scram alone. Changing this parameter value to scram makes this a requirement.

To change the parameter value to require SCRAM authentication for passwords

1. Verify that all database user passwords for all databases on your RDS for PostgreSQL DB instance use scram-sha-256 for password encryption. To do so, query rds_tools for the role (user) and encryption type, as follows.

   postgres=> SELECT * FROM rds_tools.role_password_encryption_type();
   roiname | encryption_type
   --------+-----------------+--------+-----------------------+
   pg_monitor |                 | scram-sha-256 |
   pg_read_all_settings |                 | scram-sha-256 |
   pg_read_all_stats |                 | scram-sha-256 |
   pg_stat_scan_tables |                 | scram-sha-256 |
   pg_signal_backend |                 | scram-sha-256 |
   lab_tester | scram-sha-256 |        |
   user_465 | scram-sha-256 |        |
   postgres | scram-sha-256 |        |
   ( rows)

2. Repeat the query across all DB instances in your RDS for PostgreSQL DB instance.

   If all passwords use scram-sha-256, you can proceed.

3. Change the value of the accepted password authentication to scram-sha-256, as follows.

   For Linux, macOS, or Unix:

   ```shell
   aws rds modify-db-parameter-group --db-parameter-group-name 'docs-lab-scram-passwords'
   \--parameters
   'ParameterName=rds.accepted_password_auth_method,ParameterValue=scram,ApplyMethod=immediate'
   ```

   For Windows:

   ```shell
   aws rds modify-db-parameter-group --db-parameter-group-name "docs-lab-scram-passwords"
   ^\--parameters
   "ParameterName=rds.accepted_password_auth_method,ParameterValue=scram,ApplyMethod=immediate"
   ```
Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL

We strongly recommend that you use the autovacuum feature to maintain the health of your PostgreSQL DB instance. Autovacuum automates the start of the VACUUM and the ANALYZE commands. It checks for tables with a large number of inserted, updated, or deleted tuples. After this check, it reclaims storage by removing obsolete data or tuples from the PostgreSQL database.

By default, autovacuum is turned on for the Amazon RDS for PostgreSQL DB instances that you create using any of the default PostgreSQL DB parameter groups. These include default.postgres10, default.postgres11, and so on. All default PostgreSQL DB parameter groups have an rds.adaptive_autovacuum parameter that's set to 1, thus activating the feature. Other configuration parameters associated with the autovacuum feature are also set by default. Because these defaults are somewhat generic, you can benefit from tuning some of the parameters associated with the autovacuum feature for your specific workload.

Following, you can find more information about the autovacuum and how to tune some of its parameters on your RDS for PostgreSQL DB instance. For high-level information, see Best practices for working with PostgreSQL (p. 230).

Topics
- Allocating memory for autovacuum (p. 1977)
- Reducing the likelihood of transaction ID wraparound (p. 1978)
- Determining if the tables in your database need vacuuming (p. 1978)
- Determining which tables are currently eligible for autovacuum (p. 1979)
- Determining if autovacuum is currently running and for how long (p. 1980)
- Performing a manual vacuum freeze (p. 1981)
- Reindexing a table when autovacuum is running (p. 1982)
- Other parameters that affect autovacuum (p. 1983)
- Setting table-level autovacuum parameters (p. 1984)
- Logging autovacuum and vacuum activities (p. 1984)

Allocating memory for autovacuum

One of the most important parameters influencing autovacuum performance is the maintenance_work_mem parameter. This parameter determines how much memory that you allocate for autovacuum to use to scan a database table and to hold all the row IDs that are going to be vacuumed. If you set the value of the maintenance_work_mem parameter too low, the vacuum process might have to scan the table multiple times to complete its work. Such multiple scans can have a negative impact on performance.

When doing calculations to determine the maintenance_work_mem parameter value, keep in mind two things:

- The default unit is kilobytes (KB) for this parameter.
- The maintenance_work_mem parameter works in conjunction with the autovacuum_max_workers parameter. If you have many small tables, allocate more autovacuum_max_workers and less maintenance_work_mem. If you have large tables (say, larger than 100 GB), allocate more memory and fewer worker processes. You need to have enough memory allocated to succeed on your biggest table. Each autovacuum_max_workers can use the memory that you allocate. Thus, make sure that the combination of worker processes and memory equal the total memory that you want to allocate.
In general terms, for large hosts set the `maintenance_work_mem` parameter to a value between one and two gigabytes (between 1,048,576 and 2,097,152 KB). For extremely large hosts, set the parameter to a value between two and four gigabytes (between 2,097,152 and 4,194,304 KB). The value that you set for this parameter depends on the workload. Amazon RDS has updated its default for this parameter to be kilobytes calculated as follows.

\[
\text{GREATEST}\left(\frac{\text{DBInstanceClassMemory}}{63963136} \times 1024, 65536\right).
\]

### Reducing the likelihood of transaction ID wraparound

In some cases, parameter group settings related to autovacuum might not be aggressive enough to prevent transaction ID wraparound. To address this, RDS for PostgreSQL provides a mechanism that adapts the autovacuum parameter values automatically. Adaptive autovacuum parameter tuning is a feature for RDS for PostgreSQL. A detailed explanation of TransactionID wraparound is found in the PostgreSQL documentation.

Adaptive autovacuum parameter tuning is turned on by default for RDS for PostgreSQL instances with the dynamic parameter `rds.adaptive_autovacuum` set to ON. We strongly recommend that you keep this turned on. However, to turn off adaptive autovacuum parameter tuning, set the `rds.adaptive_autovacuum` parameter to 0 or OFF.

Transaction ID wraparound is still possible even when Amazon RDS tunes the autovacuum parameters. We encourage you to implement an Amazon CloudWatch alarm for transaction ID wraparound. For more information, see the post Implement an early warning system for transaction ID wraparound in RDS for PostgreSQL on the AWS Database Blog.

With adaptive autovacuum parameter tuning turned on, Amazon RDS begins adjusting autovacuum parameters when the CloudWatch metric `MaximumUsedTransactionIDs` reaches the value of the `autovacuum_freeze_max_age` parameter or 500,000,000, whichever is greater.

Amazon RDS continues to adjust parameters for autovacuum if a table continues to trend toward transaction ID wraparound. Each of these adjustments dedicates more resources to autovacuum to avoid wraparound. Amazon RDS updates the following autovacuum-related parameters:

- `autovacuum_vacuum_cost_delay`
- `autovacuum_vacuum_cost_limit`
- `autovacuum_work_mem`
- `autovacuum_naptime`

RDS modifies these parameters only if the new value makes autovacuum more aggressive. The parameters are modified in memory on the DB instance. The values in the parameter group aren’t changed. To view the current in-memory settings, use the PostgreSQL `SHOW` SQL command.

When Amazon RDS modifies any of these autovacuum parameters, it generates an event for the affected DB instance. This event is visible on the AWS Management Console and through the Amazon RDS API. After the `MaximumUsedTransactionIDs` CloudWatch metric returns below the threshold, Amazon RDS resets the autovacuum-related parameters in memory back to the values specified in the parameter group. It then generates another event corresponding to this change.

### Determining if the tables in your database need vacuuming

You can use the following query to show the number of unvacuumed transactions in a database. The `datfrozenxid` column of a database's `pg_database` row is a lower bound on the normal transaction IDs appearing in that database. This column is the minimum of the per-table `relfrozenxid` values within the database.
SELECT datname, age(datfrozenxid) FROM pg_database ORDER BY age(datfrozenxid) desc limit 20;

For example, the results of running the preceding query might be the following.

<table>
<thead>
<tr>
<th>datname</th>
<th>age</th>
</tr>
</thead>
<tbody>
<tr>
<td>mydb</td>
<td>1771757888</td>
</tr>
<tr>
<td>template0</td>
<td>1721757888</td>
</tr>
<tr>
<td>template1</td>
<td>1721757888</td>
</tr>
<tr>
<td>rdsadmin</td>
<td>1694088527</td>
</tr>
<tr>
<td>postgres</td>
<td>1693881061</td>
</tr>
</tbody>
</table>

(5 rows)

When the age of a database reaches 2 billion transaction IDs, transaction ID (XID) wraparound occurs and the database becomes read-only. You can use this query to produce a metric and run a few times a day. By default, autovacuum is set to keep the age of transactions to no more than 200,000,000 (autovacuum_freeze_max_age).

A sample monitoring strategy might look like this:

- Set the autovacuum_freeze_max_age value to 200 million transactions.
- If a table reaches 500 million unvacuumed transactions, that triggers a low-severity alarm. This isn't an unreasonable value, but it can indicate that autovacuum isn't keeping up.
- If a table ages to 1 billion, this should be treated as an alarm to take action on. In general, you want to keep ages closer to autovacuum_freeze_max_age for performance reasons. We recommend that you investigate using the recommendations that follow.
- If a table reaches 1.5 billion unvacuumed transactions, that triggers a high-severity alarm. Depending on how quickly your database uses transaction IDs, this alarm can indicate that the system is running out of time to run autovacuum. In this case, we recommend that you resolve this immediately.

If a table is constantly breaching these thresholds, modify your autovacuum parameters further. By default, using VACUUM manually (which has cost-based delays disabled) is more aggressive than using the default autovacuum, but it is also more intrusive to the system as a whole.

We recommend the following:

- Be aware and turn on a monitoring mechanism so that you are aware of the age of your oldest transactions.

  For information on creating a process that warns you about transaction ID wraparound, see the AWS Database Blog post Implement an early warning system for transaction ID wraparound in Amazon RDS for PostgreSQL.

- For busier tables, perform a manual vacuum freeze regularly during a maintenance window, in addition to relying on autovacuum. For information on performing a manual vacuum freeze, see Performing a manual vacuum freeze (p. 1981).

## Determining which tables are currently eligible for autovacuum

Often, it is one or two tables in need of vacuuming. Tables whose relfrozenxid value is greater than the number of transactions in autovacuum_freeze_max_age are always targeted by autovacuum. Otherwise, if the number of tuples made obsolete since the last VACUUM exceeds the vacuum threshold, the table is vacuumed.

The autovacuum threshold is defined as:
Determining if autovacuum is currently running and for how long

If you need to manually vacuum a table, make sure to determine if autovacuum is currently running. If it is, you might need to adjust parameters to make it run more efficiently, or turn off autovacuum temporarily so that you can manually run VACUUM.

Use the following query to determine if autovacuum is running, how long it has been running, and if it is waiting on another session.

```
SELECT datname, usename, pid, state, wait_event, current_timestamp - xact_start AS xact_runtime, query
FROM pg_stat_activity
WHERE upper(query) LIKE '%VACUUM%'
ORDER BY xact_start;
```

After running the query, you should see output similar to the following.

```
<table>
<thead>
<tr>
<th>datname</th>
<th>usename</th>
<th>pid</th>
<th>state</th>
<th>wait_event</th>
<th>xact_runtime</th>
<th>query</th>
</tr>
</thead>
<tbody>
<tr>
<td>mydb</td>
<td>rdsadmin</td>
<td>16473</td>
<td>active</td>
<td></td>
<td>33 days 16:32:11.600656</td>
<td>autovacuum: VACUUM ANALYZE public.mytable1 (to prevent wraparound)</td>
</tr>
</tbody>
</table>
```

Vacuum-threshold = vacuum-base-threshold + vacuum-scale-factor * number-of-tuples

While you are connected to your database, run the following query to see a list of tables that autovacuum sees as eligible for vacuuming.

```
WITH vbt AS (SELECT setting AS autovacuum_vacuum_threshold FROM pg_settings WHERE name = 'autovacuum_vacuum_threshold'),
vsf AS (SELECT setting AS autovacuum_vacuum_scale_factor FROM pg_settings WHERE name = 'autovacuum_vacuum_scale_factor'),
fma AS (SELECT setting AS autovacuum_freeze_max_age FROM pg_settings WHERE name = 'autovacuum_freeze_max_age'),
sto AS (select opt_oid, split_part(setting,'=','') as param, split_part(setting, '=' , 2) as value from (select oid opt_oid, unnest(reloptions) setting from pg_class) opt)
SELECT '"'||ns.nspname||'"."'||c.relname||'"' as relation,
pg_size_pretty(pg_table_size(c.oid)) as table_size,
age(relfrozenxid) as xid_age,
coalesce(cfma.value::float, autovacuum_freeze_max_age::float) autovacuum_freeze_max_age,
(coalesce(cvbt.value::float, autovacuum_vacuum_threshold::float) +
coalesce(cvsf.value::float,autovacuum_vacuum_scale_factor::float)) * c.reltuples
AS autovacuum_vacuum_tuples, n_dead_tup as dead_tuples
FROM pg_class c join pg_namespace ns on ns.oid = c.relnamespace
join pg_stat_all_tables stat on stat.relid = c.oid join vbt on (1=1) join vsf on (1=1) join fma on (1=1)
left join sto cvbt on cvbt.param = 'autovacuum_vacuum_threshold' and c.oid = cvbt.opt_oid
left join sto cvsf on cvsf.param = 'autovacuum_vacuum_scale_factor' and c.oid = cvsf.opt_oid
left join sto cfma on cfma.param = 'autovacuum_freeze_max_age' and c.oid = cfma.opt_oid
WHERE c.relkind = 'r' and nspname <> 'pg_catalog'
AND (age(refrozeinid) <= coalesce(cfma.value::float, autovacuum_freeze_max_age::float)
OR coalesce(cvbt.value::float, autovacuum_vacuum_threshold::float) +
coalesce(cvsf.value::float,autovacuum_vacuum_scale_factor::float)) * c.reltuples <= n_dead_tup)
ORDER BY age(refrozeinid) DESC LIMIT 50;
```
mydb    | rdsadmin | 22553 | active |            | 14 days 09:15:34.073141 | autovacuum:

|          |       |        |            |                         | FROM 
pg_stat_activity
  + |          |       |        |            |                         | WHERE query
like '%VACUUM%'
  + |          |       |        |            |                         | ORDER BY
xact_start;

Several issues can cause a long-running autovacuum session (that is, multiple days long). The most common issue is that your `maintenance_work_mem` parameter value is set too low for the size of the table or rate of updates.

We recommend that you use the following formula to set the `maintenance_work_mem` parameter value.

\[
\text{GREATEST} \left( \frac{\text{DBInstanceClassMemory}}{63963136} \times 1024, 65536 \right)
\]

Short running autovacuum sessions can also indicate problems:

- It can indicate that there aren't enough `autovacuum_max_workers` for your workload. In this case, you need to indicate the number of workers.
- It can indicate that there is an index corruption (autovacuum crashes and restarts on the same relation but makes no progress). In this case, run a manual `vacuum freeze verbose table` to see the exact cause.

### Performing a manual vacuum freeze

You might want to perform a manual vacuum on a table that has a vacuum process already running. This is useful if you have identified a table with an age approaching 2 billion transactions (or above any threshold you are monitoring).

The following steps are guidelines, with several variations to the process. For example, during testing, suppose that you find that the `maintenance_work_mem` parameter value is set too small and that you need to take immediate action on a table. However, perhaps you don't want to bounce the instance at the moment. Using the queries in previous sections, you determine which table is the problem and notice a long running autovacuum session. You know that you need to change the `maintenance_work_mem` parameter setting, but you also need to take immediate action and vacuum the table in question. The following procedure shows what to do in this situation.

### To manually perform a vacuum freeze

1. Open two sessions to the database containing the table you want to vacuum. For the second session, use "screen" or another utility that maintains the session if your connection is dropped.
2. In session one, get the process ID (PID) of the autovacuum session running on the table.
   
   Run the following query to get the PID of the autovacuum session.

   ```sql
   SELECT datname, usename, pid, current_timestamp - xact_start
   ```
3. In session two, calculate the amount of memory that you need for this operation. In this example, we determine that we can afford to use up to 2 GB of memory for this operation, so we set `maintenance_work_mem` for the current session to 2 GB.

```
SET maintenance_work_mem='2 GB';
```

4. In session two, issue a `vacuum freeze verbose` command for the table. The verbose setting is useful because, although there is no progress report for this in PostgreSQL currently, you can see activity.

```
\timing on
Timing is on.
vacuum freeze verbose pgbench_branches;
```

```
INFO:  vacuuming "public.pgbench_branches"
INFO:  index "pgbench_branches_pkey" now contains 50 row versions in 2 pages
DETAIL:  0 index row versions were removed.
0 index pages have been deleted, 0 are currently reusable.
CPU 0.00s/0.00u sec elapsed 0.00 sec.
INFO:  index "pgbench_branches_test_index" now contains 50 row versions in 2 pages
DETAIL:  0 index row versions were removed.
0 index pages have been deleted, 0 are currently reusable.
INFO:  "pgbench_branches": found 0 removable, 50 nonremovable row versions
    in 43 out of 43 pages
DETAIL:  0 dead row versions cannot be removed yet.
There were 9347 unused item pointers.
0 pages are entirely empty.
CPU 0.00s/0.00u sec elapsed 0.00 sec.
VACUUM
Time: 2.765 ms
```

5. In session one, if autovacuum was blocking the vacuum session, you see in `pg_stat_activity` that waiting is "T" for your vacuum session. In this case, you need to end the autovacuum process as follows.

```
SELECT pg_terminate_backend('the_pid');
```

At this point, your session begins. It's important to note that autovacuum restarts immediately because this table is probably the highest on its list of work.

6. Initiate your `vacuum freeze verbose` command in session two, and then end the autovacuum process in session one.

### Reindexing a table when autovacuum is running

If an index has become corrupt, autovacuum continues to process the table and fails. If you attempt a manual vacuum in this situation, you receive an error message like the following.

```
postgres=> vacuum freeze pgbench_branches;
ERROR:  index "pgbench_branches_test_index" contains unexpected zero page at block 30521
HINT:  Please REINDEX it.
```
When the index is corrupted and autovacuum is attempting to run on the table, you contend with an already running autovacuum session. When you issue a `REINDEX` command, you take out an exclusive lock on the table. Write operations are blocked, and also read operations that use that specific index.

**To reindex a table when autovacuum is running on the table**

1. Open two sessions to the database containing the table that you want to vacuum. For the second session, use "screen" or another utility that maintains the session if your connection is dropped.
2. In session one, get the PID of the autovacuum session running on the table.

   Run the following query to get the PID of the autovacuum session.

   ```sql
   SELECT datname, usename, pid, current_timestamp - xact_start AS xact_runtime, query
   FROM pg_stat_activity WHERE upper(query) like '%VACUUM%' ORDER BY xact_start;
   ```

3. In session two, issue the reindex command.

   ```sql
   \timing on
   Timing is on.
   reindex index pgbench_branches_test_index;
   REINDEX
   Time: 9.966 ms
   ```

4. In session one, if autovacuum was blocking the process, you see in `pg_stat_activity` that waiting is "T" for your vacuum session. In this case, you end the autovacuum process.

   ```sql
   SELECT pg_terminate_backend('the_pid');
   ```

   At this point, your session begins. It's important to note that autovacuum restarts immediately because this table is probably the highest on its list of work.

5. Initiate your command in session two, and then end the autovacuum process in session 1.

**Other parameters that affect autovacuum**

The following query shows the values of some of the parameters that directly affect autovacuum and its behavior. The autovacuum parameters are described fully in the PostgreSQL documentation.

```sql
SELECT name, setting, unit, short_desc
FROM pg_settings
WHERE name IN ('autovacuum_max_workers', 'autovacuum_analyze_scale_factor', 'autovacuum_naptime', 'autovacuum_analyze_threshold', 'autovacuum_analyze_scale_factor', 'autovacuum_vacuum_threshold', 'autovacuum_vacuum_scale_factor', 'autovacuum_vacuum_threshold', 'autovacuum_vacuum_cost_delay', 'autovacuum_vacuum_cost_limit', 'vacuum_cost_limit', 'autovacuum_freeze_max_age', 'maintenance_work_mem', 'vacuum_freeze_min_age');
```

While these all affect autovacuum, some of the most important ones are:
Amazon Relational Database Service User Guide
Working with the PostgreSQL autovacuum

- `maintenance_work_mem`
- `autovacuum_freeze_max_age`
- `autovacuum_max_workers`
- `autovacuum_vacuum_cost_delay`
- `autovacuum_vacuum_cost_limit`

### Setting table-level autovacuum parameters

You can set autovacuum-related storage parameters at a table level, which can be better than altering the behavior of the entire database. For large tables, you might need to set aggressive settings and you might not want to make autovacuum behave that way for all tables.

The following query shows which tables currently have table-level options in place.

```sql
SELECT relname, reloptions
FROM pg_class
WHERE reloptions IS NOT null;
```

An example where this might be useful is on tables that are much larger than the rest of your tables. Suppose that you have one 300-GB table and 30 other tables less than 1 GB. In this case, you might set some specific parameters for your large table so you don't alter the behavior of your entire system.

```sql
ALTER TABLE mytable set (autovacuum_vacuum_cost_delay=0);
```

Doing this turns off the cost-based autovacuum delay for this table at the expense of more resource usage on your system. Normally, autovacuum pauses for `autovacuum_vacuum_cost_delay` each time `autovacuum_cost_limit` is reached. For more details, see the PostgreSQL documentation about cost-based vacuuming.

### Logging autovacuum and vacuum activities

Information about autovacuum activities is sent to the `postgresql.log` based on the level specified in the `rds.force_autovacuum_logging_level` parameter. Following are the values allowed for this parameter and the PostgreSQL versions for which that value is the default setting:

- `disabled` (PostgreSQL 10, PostgreSQL 9.6)
- `debug5`, `debug4`, `debug3`, `debug2`, `debug1`
- `info` (PostgreSQL 12, PostgreSQL 11)
- `notice`
- `warning` (PostgreSQL 14, PostgreSQL 13)
- `error`, `log`, `fatal`, `panic`

The `rds.force_autovacuum_logging_level` works with the `log_autovacuum_min_duration` parameter. The `log_autovacuum_min_duration` parameter's value is the threshold (in milliseconds) above which autovacuum actions get logged. A setting of `-1` logs nothing, while a setting of 0 logs all actions. As with `rds.force_autovacuum_logging_level`, default values for `log_autovacuum_min_duration` are version dependent, as follows:

- 10000 ms – PostgreSQL 14, PostgreSQL 13, PostgreSQL 12, and PostgreSQL 11
- (empty) – No default value for PostgreSQL 10 and PostgreSQL 9.6

1984
We recommend that you set `rds.force_autovacuum_logging_level` to `WARNING`. We also recommend that you set `log_autovacuum_min_duration` to a value from 1000 to 5000. A setting of 5000 logs activity that takes longer than 5,000 milliseconds. Any setting other than -1 also logs messages if the autovacuum action is skipped because of a conflicting lock or concurrently dropped relations. For more information, see Automatic Vacuuming in the PostgreSQL documentation.

To troubleshoot issues, you can change the `rds.force_autovacuum_logging_level` parameter to one of the debug levels, from debug1 up to debug5 for the most verbose information. We recommend that you use debug settings for short periods of time and for troubleshooting purposes only. To learn more, see When to log in the PostgreSQL documentation.

**Note**

PostgreSQL allows the `rds_superuser` account to view autovacuum sessions in `pg_stat_activity`. For example, you can identify and end an autovacuum session that is blocking a command from running, or running slower than a manually issued vacuum command.

### Working with logging mechanisms supported by RDS for PostgreSQL

There are several parameters, extensions, and other configurable items that you can set to log activities that occur on your PostgreSQL DB instance. These include the following:

- The `log_statement` parameter can be used to log user activity in your PostgreSQL database. To learn more about RDS for PostgreSQL logging and how to monitor the logs, see RDS for PostgreSQL database log files (p. 752).
- The `rds.force_admin_logging_level` parameter logs actions by the Amazon RDS internal user (`rdsadmin`) in the databases on the DB instance. It writes the output to the PostgreSQL error log. Allowed values are disabled, debug5, debug4, debug3, debug2, debug1, info, notice, warning, error, log, fatal, and panic. The default value is disabled.
- The `rds.force_autovacuum_logging_level` parameter can be set to capture various autovacuum operations in the PostgreSQL error log. For more information, see Logging autovacuum and vacuum activities (p. 1984).
- The PostgreSQL Audit (pgAudit) extension can be installed and configured to capture activities at the session level or at the object level. For more information, see Using pgAudit to log database activity (p. 2052).
- The `log_fdw` extension makes it possible for you to access the database engine log using SQL. For more information, see Using the log_fdw extension to access the DB log using SQL (p. 2088).
- The `pg_stat_statements` library is specified as the default for the `shared_preload_libraries` parameter in RDS for PostgreSQL version 10 and higher. It's this library that you can use to analyze running queries. Be sure that `pg_stat_statements` is set in your DB parameter group. For more information about monitoring your RDS for PostgreSQL DB instance using the information that this library provides, see SQL statistics for RDS PostgreSQL (p. 667).
- The `log_hostname` parameter captures to the log the hostname of each client connection. For RDS for PostgreSQL version 12 and higher versions, this parameter is set to off by default. If you turn it on, be sure to monitor session connection times. When turned on, the service uses the domain name system (DNS) reverse lookup request to get the hostname of the client that's making the connection and add it to the PostgreSQL log. This has a noticeable impact during session connection. We recommend that you turn on this parameter for troubleshooting purposes only.

In general terms, the point of logging is so that the DBA can monitor, tune performance, and troubleshoot. Many of the logs are uploaded automatically to Amazon CloudWatch or Performance Insights. Here, they're sorted and grouped to provide complete metrics for your DB instance. To learn more about Amazon RDS monitoring and metrics, see Monitoring metrics in an Amazon RDS instance (p. 545).
Using pgBadger for log analysis with PostgreSQL

You can use a log analyzer such as pgBadger to analyze PostgreSQL logs. The pgBadger documentation states that the %l pattern (the log line for the session or process) should be a part of the prefix. However, if you provide the current RDS log_line_prefix as a parameter to pgBadger it should still produce a report.

For example, the following command correctly formats an Amazon RDS for PostgreSQL log file dated 2014-02-04 using pgBadger.

```
./pgbadger -f stderr -p '%t:%r:%u@%d::[%p]:' postgresql.log.2014-02-04-00
```

Working with parameters on your RDS for PostgreSQL DB instance

In some cases, you might create an RDS for PostgreSQL DB instance without specifying a custom parameter group. If so, your DB instance is created using the default parameter group for the version of PostgreSQL that you choose. For example, suppose that you create an RDS for PostgreSQL DB instance using PostgreSQL 13.3. In this case, the DB instance is created using the values in the parameter group for PostgreSQL 13 releases, default.postgres13.

You can also create your own custom DB parameter group. You need to do this if you want to modify any settings for the RDS for PostgreSQL DB instance from their default values. To learn how, see Working with parameter groups (p. 295).

You can track the settings on your RDS for PostgreSQL DB instance in several different ways. You can use the AWS Management Console, the AWS CLI, or the Amazon RDS API. You can also query the values from the PostgreSQL pg_settings table of your instance, as shown following.

```
SELECT name, setting, boot_val, reset_val, unit
FROM pg_settings
ORDER BY name;
```

To learn more about the values returned from this query, see pg_settings in the PostgreSQL documentation.

Be especially careful when changing the settings for max_connections and shared_buffers on your RDS for PostgreSQL DB instance. For example, suppose that you modify settings for max_connections or shared_buffers and you use values that are too high for your actual workload. In this case, your RDS for PostgreSQL DB instance won't start. If this happens, you see an error such as the following in the postgres.log.

```
2018-09-18 21:13:15 UTC::@:[8097]:FATAL: could not map anonymous shared memory: Cannot allocate memory
2018-09-18 21:13:15 UTC::@:[8097]:HINT: This error usually means that PostgreSQL's request for a shared memory segment exceeded available memory or swap space. To reduce the request size (currently 351434274048 bytes), reduce PostgreSQL's shared memory usage, perhaps by reducing shared_buffers or max_connections.
```

However, you can't change any values of the settings contained in the default RDS for PostgreSQL DB parameter groups. To change settings for any parameters, first create a custom DB parameter group. Then change the settings in that custom group, and then apply the custom parameter group to your RDS for PostgreSQL DB instance. To learn more, see Working with parameter groups (p. 295).
There are two types of RDS for PostgreSQL DB parameters.

- **Static parameters** – Static parameters require that the RDS for PostgreSQL DB instance be rebooted after a change so that the new value can take effect.
- **Dynamic parameters** – Dynamic parameters don't require a reboot after changing their settings.

**Note**

If your RDS for PostgreSQL DB instance is using your own custom DB parameter group, you can change the values of dynamic parameters on the running DB instance. You can do this by using the AWS Management Console, the AWS CLI, or the Amazon RDS API.

If you have privileges to do so, you can also change parameter values by using the `ALTER DATABASE`, `ALTER ROLE`, and `SET` commands.
RDS for PostgreSQL DB instance parameter list

The following table lists some (but not all) parameters available in an RDS for PostgreSQL DB instance. To view all available parameters, you use the describe-db-parameters AWS CLI command. For example, to get the list of all parameters available in the default parameter group for RDS for PostgreSQL version 13, run the following.

```
aws rds describe-db-parameters --db-parameter-group-name default.postgres13
```

You can also use the Console. Choose Parameter groups from the Amazon RDS menu, and then choose the parameter group from those available in your AWS Region.

Tuning with wait events for RDS for PostgreSQL

Wait events are an important tuning tool for RDS for PostgreSQL. When you can find out why sessions are waiting for resources and what they are doing, you're better able to reduce bottlenecks. You can use the information in this section to find possible causes and corrective actions. This section also discusses basic PostgreSQL tuning concepts.

The wait events in this section are specific to RDS for PostgreSQL. For information about wait events for Aurora PostgreSQL, see Tuning with wait events for Aurora PostgreSQL in the Amazon Aurora User Guide.

Some wait events discussed in this section have no analogs in the open source versions of these database engines. Other wait events have the same names as events in open source engines, but behave differently.

Essential concepts for RDS for PostgreSQL tuning

Before you tune your RDS for PostgreSQL database, make sure to learn what wait events are and why they occur. Also review the basic memory and disk architecture of RDS for PostgreSQL. For a helpful architecture diagram, see the PostgreSQL wikibook.

Topics

- RDS for PostgreSQL wait events (p. 1998)
- RDS for PostgreSQL memory (p. 1998)
- RDS for PostgreSQL processes (p. 2000)
RDS for PostgreSQL wait events

A wait event is an indication that the session is waiting for a resource. For example, the wait event Client:ClientRead occurs when RDS for PostgreSQL is waiting to receive data from the client. Sessions typically wait for resources such as the following.

- Single-threaded access to a buffer, for example, when a session is attempting to modify a buffer
- A row that is currently locked by another session
- A data file read
- A log file write

For example, to satisfy a query, the session might perform a full table scan. If the data isn't already in memory, the session waits for the disk I/O to complete. When the buffers are read into memory, the session might need to wait because other sessions are accessing the same buffers. The database records the waits by using a predefined wait event. These events are grouped into categories.

By itself, a single wait event doesn't indicate a performance problem. For example, if requested data isn't in memory, reading data from disk is necessary. If one session locks a row for an update, another session waits for the row to be unlocked so that it can update it. A commit requires waiting for the write to a log file to complete. Waits are integral to the normal functioning of a database.

On the other hand, large numbers of wait events typically show a performance problem. In such cases, you can use wait event data to determine where sessions are spending time. For example, if a report that typically runs in minutes now takes hours to run, you can identify the wait events that contribute the most to total wait time. If you can determine the causes of the top wait events, you can sometimes make changes that improve performance. For example, if your session is waiting on a row that has been locked by another session, you can end the locking session.

RDS for PostgreSQL memory

RDS for PostgreSQL memory is divided into shared and local.

Topics
- Shared memory in RDS for PostgreSQL (p. 1998)
- Local memory in RDS for PostgreSQL (p. 1999)

Shared memory in RDS for PostgreSQL

RDS for PostgreSQL allocates shared memory when the instance starts. Shared memory is divided into multiple subareas. Following, you can find a description of the most important ones.

Topics
- Shared buffers (p. 1998)
- Write ahead log (WAL) buffers (p. 1999)

Shared buffers

The shared buffer pool is an RDS for PostgreSQL memory area that holds all pages that are or were being used by application connections. A page is the memory version of a disk block. The shared buffer pool caches the data blocks read from disk. The pool reduces the need to reread data from disk, making the database operate more efficiently.

Every table and index is stored as an array of pages of a fixed size. Each block contains multiple tuples, which correspond to rows. A tuple can be stored in any page.
The shared buffer pool has finite memory. If a new request requires a page that isn't in memory, and no more memory exists, RDS for PostgreSQL evicts a less frequently used page to accommodate the request. The eviction policy is implemented by a clock sweep algorithm.

The `shared_buffers` parameter determines how much memory the server dedicates to caching data.

**Write ahead log (WAL) buffers**

A *write-ahead log (WAL) buffer* holds transaction data that RDS for PostgreSQL later writes to persistent storage. Using the WAL mechanism, RDS for PostgreSQL can do the following:

- Recover data after a failure
- Reduce disk I/O by avoiding frequent writes to disk

When a client changes data, RDS for PostgreSQL writes the changes to the WAL buffer. When the client issues a `COMMIT`, the WAL writer process writes transaction data to the WAL file.

The `wal_level` parameter determines how much information is written to the WAL.

**Local memory in RDS for PostgreSQL**

Every backend process allocates local memory for query processing.

**Topics**

- Work memory area (p. 1999)
- Maintenance work memory area (p. 1999)
- Temporary buffer area (p. 1999)

**Work memory area**

The *work memory area* holds temporary data for queries that performs sorts and hashes. For example, a query with an `ORDER BY` clause performs a sort. Queries use hash tables in hash joins and aggregations.

The `work_mem` parameter the amount of memory to be used by internal sort operations and hash tables before writing to temporary disk files. The default value is 4 MB. Multiple sessions can run simultaneously, and each session can run maintenance operations in parallel. For this reason, the total work memory used can be multiples of the `work_mem` setting.

**Maintenance work memory area**

The *maintenance work memory area* caches data for maintenance operations. These operations include vacuuming, creating an index, and adding foreign keys.

The `maintenance_work_mem` parameter specifies the maximum amount of memory to be used by maintenance operations. The default value is 64 MB. A database session can only run one maintenance operation at a time.

**Temporary buffer area**

The *temporary buffer area* caches temporary tables for each database session.

Each session allocates temporary buffers as needed up to the limit you specify. When the session ends, the server clears the buffers.

The `temp_buffers` parameter sets the maximum number of temporary buffers used by each session. Before the first use of temporary tables within a session, you can change the `temp_buffers` value.
RDS for PostgreSQL processes

RDS for PostgreSQL uses multiple processes.

Topics
- Postmaster process (p. 2000)
- Backend processes (p. 2000)
- Background processes (p. 2000)

Postmaster process

The postmaster process is the first process started when you start RDS for PostgreSQL. The postmaster process has the following primary responsibilities:

- Fork and monitor background processes
- Receive authentication requests from client processes, and authenticate them before allowing the database to service requests

Backend processes

If the postmaster authenticates a client request, the postmaster forks a new backend process, also called a postgres process. One client process connects to exactly one backend process. The client process and the backend process communicate directly without intervention by the postmaster process.

Background processes

The postmaster process forks several processes that perform different backend tasks. Some of the more important include the following:

- WAL writer
  RDS for PostgreSQL writes data in the WAL (write ahead logging) buffer to the log files. The principle of write ahead logging is that the database can't write changes to the data files until after the database writes log records describing those changes to disk. The WAL mechanism reduces disk I/O, and allows RDS for PostgreSQL to use the logs to recover the database after a failure.
- Background writer
  This process periodically write dirty (modified) pages from the memory buffers to the data files. A page becomes dirty when a backend process modifies it in memory.
- Autovacuum daemon
  The daemon consists of the following:
  - The autovacuum launcher
  - The autovacuum worker processes
  When autovacuum is turned on, it checks for tables that have had a large number of inserted, updated, or deleted tuples. The daemon has the following responsibilities:
  - Recover or reuse disk space occupied by updated or deleted rows
  - Update statistics used by the planner
  - Protect against loss of old data because of transaction ID wraparound
  The autovacuum feature automates the execution of VACUUM and ANALYZE commands. VACUUM has the following variants: standard and full. Standard vacuum runs in parallel with other database operations. VACUUM FULL requires an exclusive lock on the table it is working on. Thus, it can't run in
parallel with operations that access the same table. VACUUM creates a substantial amount of I/O traffic, which can cause poor performance for other active sessions.

RDS for PostgreSQL wait events

The following table lists the wait events for RDS for PostgreSQL that most commonly indicate performance problems, and summarizes the most common causes and corrective actions.

<table>
<thead>
<tr>
<th>Wait event</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Client:ClientRead (p. 2002)</td>
<td>This event occurs when RDS for PostgreSQL is waiting to receive data from the client.</td>
</tr>
<tr>
<td>Client:ClientWrite (p. 2004)</td>
<td>This event occurs when RDS for PostgreSQL is waiting to write data to the client.</td>
</tr>
<tr>
<td>CPU (p. 2006)</td>
<td>This event occurs when a thread is active in CPU or is waiting for CPU.</td>
</tr>
<tr>
<td>IO:BufFileRead and IO:BufFileWrite (p. 2010)</td>
<td>These events occur when RDS for PostgreSQL creates temporary files.</td>
</tr>
<tr>
<td>IO:DataFileRead (p. 2015)</td>
<td>This event occurs when a connection waits on a backend process to read a required page from storage because the page isn't available in shared memory.</td>
</tr>
<tr>
<td>IO:WALWrite (p. 2022)</td>
<td>This event occurs when RDS for PostgreSQL is waiting for the write-ahead log (WAL) buffers to be written to a WAL file.</td>

<td>This event occurs when a server process has called the pg_sleep function and is waiting for the sleep timeout to expire.</td>
</tr>
<tr>
<td>(p. 2043)</td>
<td></td>
</tr>
<tr>
<td>Timeout:VacuumDelay</td>
<td>This event indicates that the vacuum process is sleeping because the estimated cost limit has been reached.</td>
</tr>
<tr>
<td>(p. 2043)</td>
<td></td>
</tr>
</tbody>
</table>

**Client:ClientRead**

The **Client:ClientRead** event occurs when RDS for PostgreSQL is waiting to receive data from the client.

**Topics**

- Supported engine versions (p. 2002)
- Context (p. 2002)
- Likely causes of increased waits (p. 2002)
- Actions (p. 2003)

**Supported engine versions**

This wait event information is supported for RDS for PostgreSQL version 10 and higher.

**Context**

An RDS for PostgreSQL DB instance is waiting to receive data from the client. The RDS for PostgreSQL DB instance must receive the data from the client before it can send more data to the client. The time that the instance waits before receiving data from the client is a **Client:ClientRead** event.

**Likely causes of increased waits**

Common causes for the **Client:ClientRead** event to appear in top waits include the following:

**Increased network latency**

There might be increased network latency between the RDS for PostgreSQL DB instance and client. Higher network latency increases the time required for DB instance to receive data from the client.

**Increased load on the client**

There might be CPU pressure or network saturation on the client. An increase in load on the client can delay transmission of data from the client to the RDS for PostgreSQL DB instance.

**Excessive network round trips**

A large number of network round trips between the RDS for PostgreSQL DB instance and the client can delay transmission of data from the client to the RDS for PostgreSQL DB instance.
Large copy operation

During a copy operation, the data is transferred from the client's file system to the RDS for PostgreSQL DB instance. Sending a large amount of data to the DB instance can delay transmission of data from the client to the DB instance.

Idle client connection

When a client connects to the RDS for PostgreSQL DB instance in an idle in transaction state, the DB instance might wait for the client to send more data or issue a command. A connection in this state can lead to an increase in Client:ClientRead events.

PgBouncer used for connection pooling

PgBouncer has a low-level network configuration setting called pkt_buf, which is set to 4,096 by default. If the workload is sending query packets larger than 4,096 bytes through PgBouncer, we recommend increasing the pkt_buf setting to 8,192. If the new setting doesn't decrease the number of Client:ClientRead events, we recommend increasing the pkt_buf setting to larger values, such as 16,384 or 32,768. If the query text is large, the larger setting can be particularly helpful.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Place the clients in the same Availability Zone and VPC subnet as the instance (p. 2003)
- Scale your client (p. 2003)
- Use current generation instances (p. 2003)
- Increase network bandwidth (p. 2004)
- Monitor for transactions in the "idle in transaction" state (p. 2004)

Place the clients in the same Availability Zone and VPC subnet as the instance

To reduce network latency and increase network throughput, place clients in the same Availability Zone and virtual private cloud (VPC) subnet as the RDS for PostgreSQL DB instance. Make sure that the clients are as geographically close to the DB instance as possible.

Scale your client

Using Amazon CloudWatch or other host metrics, determine if your client is currently constrained by CPU or network bandwidth, or both. If the client is constrained, scale your client accordingly.

Use current generation instances

In some cases, you might not be using a DB instance class that supports jumbo frames. If you're running your application on Amazon EC2, consider using a current generation instance for the client. Also, configure the maximum transmission unit (MTU) on the client operating system. This technique might reduce the number of network round trips and increase network throughput. For more information, see Jumbo frames (9001 MTU) in the Amazon EC2 User Guide for Linux Instances.

For information about DB instance classes, see DB instance classes (p. 10). To determine the DB instance class that is equivalent to an Amazon EC2 instance type, place db. before the Amazon EC2 instance type name. For example, the r5.8xlarge Amazon EC2 instance is equivalent to the db.r5.8xlarge DB instance class.
Increase network bandwidth

Use NetworkReceiveThroughput and NetworkTransmitThroughput Amazon CloudWatch metrics to monitor incoming and outgoing network traffic on the DB instance. These metrics can help you to determine if network bandwidth is sufficient for your workload.

If your network bandwidth isn't enough, increase it. If the AWS client or your DB instance is reaching the network bandwidth limits, the only way to increase the bandwidth is to increase your DB instance size. For more information, see DB instance class types (p. 10).

For more information about CloudWatch metrics, see Amazon CloudWatch metrics for Amazon RDS (p. 644).

Monitor maximums for network performance

If you are using Amazon EC2 clients, Amazon EC2 provides maximums for network performance metrics, including aggregate inbound and outbound network bandwidth. It also provides connection tracking to ensure that packets are returned as expected and link-local services access for services such as the Domain Name System (DNS). To monitor these maximums, use a current enhanced networking driver and monitor network performance for your client.

For more information, see Monitor network performance for your Amazon EC2 instance in the Amazon EC2 User Guide for Linux Instances and Monitor network performance for your Amazon EC2 instance in the Amazon EC2 User Guide for Windows Instances.

Monitor for transactions in the "idle in transaction" state

Check whether you have an increasing number of idle in transaction connections. To do this, monitor the state column in the pg_stat_activity table. You might be able to identify the connection source by running a query similar to the following.

```
select client_addr, state, count(1) from pg_stat_activity
where state like 'idle in transaction%'
group by 1,2
order by 3 desc
```

Client:ClientWrite

The Client:ClientWrite event occurs when RDS for PostgreSQL is waiting to write data to the client.

Topics
- Supported engine versions (p. 2004)
- Context (p. 2004)
- Likely causes of increased waits (p. 2005)
- Actions (p. 2005)

Supported engine versions

This wait event information is supported for RDS for PostgreSQL version 10 and higher.

Context

A client process must read all of the data received from an RDS for PostgreSQL DB cluster before the cluster can send more data. The time that the cluster waits before sending more data to the client is a Client:ClientWrite event.
Reduced network throughput between the RDS for PostgreSQL DB instance and the client can cause this event. CPU pressure and network saturation on the client can also cause this event. CPU pressure is when the CPU is fully utilized and there are tasks waiting for CPU time. Network saturation is when the network between the database and client is carrying more data than it can handle.

**Likely causes of increased waits**

Common causes for the **Client:ClientWrite** event to appear in top waits include the following:

**Increased network latency**

There might be increased network latency between the RDS for PostgreSQL DB instance and client. Higher network latency increases the time required for the client to receive the data.

**Increased load on the client**

There might be CPU pressure or network saturation on the client. An increase in load on the client delays the reception of data from the RDS for PostgreSQL DB instance.

**Large volume of data sent to the client**

The RDS for PostgreSQL DB instance might be sending a large amount of data to the client. A client might not be able to receive the data as fast as the cluster is sending it. Activities such as a copy of a large table can result in an increase in **Client:ClientWrite** events.

**Actions**

We recommend different actions depending on the causes of your wait event.

**Topics**

- Place the clients in the same Availability Zone and VPC subnet as the cluster (p. 2005)
- Use current generation instances (p. 2005)
- Reduce the amount of data sent to the client (p. 2005)
- Scale your client (p. 2006)

**Place the clients in the same Availability Zone and VPC subnet as the cluster**

To reduce network latency and increase network throughput, place clients in the same Availability Zone and virtual private cloud (VPC) subnet as the RDS for PostgreSQL DB instance.

**Use current generation instances**

In some cases, you might not be using a DB instance class that supports jumbo frames. If you're running your application on Amazon EC2, consider using a current generation instance for the client. Also, configure the maximum transmission unit (MTU) on the client operating system. This technique might reduce the number of network round trips and increase network throughput. For more information, see Jumbo frames (9001 MTU) in the *Amazon EC2 User Guide for Linux Instances*.

For information about DB instance classes, see DB instance classes (p. 10). To determine the DB instance class that is equivalent to an Amazon EC2 instance type, place db. before the Amazon EC2 instance type name. For example, the r5.8xlarge Amazon EC2 instance is equivalent to the db.r5.8xlarge DB instance class.

**Reduce the amount of data sent to the client**

When possible, adjust your application to reduce the amount of data that the RDS for PostgreSQL DB instance sends to the client. Making such adjustments relieves CPU and network contention on the client.
Scale your client

Using Amazon CloudWatch or other host metrics, determine if your client is currently constrained by CPU or network bandwidth, or both. If the client is constrained, scale your client accordingly.

CPU

This event occurs when a thread is active in CPU or is waiting for CPU.

Topics

- Supported engine versions (p. 2006)
- Context (p. 2006)
- Likely causes of increased waits (p. 2007)
- Actions (p. 2008)

Supported engine versions

This wait event information is relevant for all all versions of RDS for PostgreSQL.

Context

The central processing unit (CPU) is the component of a computer that runs instructions. For example, CPU instructions perform arithmetic operations and exchange data in memory. If a query increases the number of instructions that it performs through the database engine, the time spent running the query increases. CPU scheduling is giving CPU time to a process. Scheduling is orchestrated by the kernel of the operating system.

Topics

- How to tell when this wait occurs (p. 2006)
- DBLoadCPU metric (p. 2007)
- os.cpuUtilization metrics (p. 2007)
- Likely cause of CPU scheduling (p. 2007)

How to tell when this wait occurs

This CPU wait event indicates that a backend process is active in CPU or is waiting for CPU. You know that it's occurring when a query shows the following information:

- The pg_stat_activity.state column has the value active.
- The wait_event_type and wait_event columns in pg_stat_activity are both null.

To see the backend processes that are using or waiting on CPU, run the following query.

```sql
SELECT * 
FROM   pg_stat_activity 
WHERE  state = 'active' 
AND    wait_event_type IS NULL 
AND    wait_event IS NULL;
```
**DBLoadCPU metric**

The Performance Insights metric for CPU is DBLoadCPU. The value for DBLoadCPU can differ from the value for the Amazon CloudWatch metric CPUUtilization. The latter metric is collected from the HyperVisor for a database instance.

**os.cpuUtilization metrics**

Performance Insights operating-system metrics provide detailed information about CPU utilization. For example, you can display the following metrics:

- `os.cpuUtilization.nice.avg`
- `os.cpuUtilization.total.avg`
- `os.cpuUtilization.wait.avg`
- `os.cpuUtilization.idle.avg`

Performance Insights reports the CPU usage by the database engine as `os.cpuUtilization.nice.avg`.

**Likely cause of CPU scheduling**

The operating system (OS) kernel handles scheduling for the CPU. When the CPU is active, a process might need to wait to get scheduled. The CPU is active while it's performing computations. It's also active while it has an idle thread that it's not running, that is, an idle thread that's waiting on memory I/O. This type of I/O dominates the typical database workload.

Processes are likely to wait to get scheduled on a CPU when the following conditions are met:

- The CloudWatch CPUUtilization metric is near 100 percent.
- The average load is greater than the number of vCPUs, indicating a heavy load. You can find the `loadAverageMinute` metric in the OS metrics section in Performance Insights.

**Likely causes of increased waits**

When the CPU wait event occurs more than normal, possibly indicating a performance problem, typical causes include the following.

**Topics**

- Likely causes of sudden spikes (p. 2007)
- Likely causes of long-term high frequency (p. 2008)
- Corner cases (p. 2008)

**Likely causes of sudden spikes**

The most likely causes of sudden spikes are as follows:

- Your application has opened too many simultaneous connections to the database. This scenario is known as a "connection storm."
- Your application workload changed in any of the following ways:
  - New queries
  - An increase in the size of your dataset
  - Index maintenance or creation
  - New functions
• New operators
• An increase in parallel query execution
• Your query execution plans have changed. In some cases, a change can cause an increase in buffers. For example, the query is now using a sequential scan when it previously used an index. In this case, the queries need more CPU to accomplish the same goal.

 Likely causes of long-term high frequency

The most likely causes of events that recur over a long period:

• Too many backend processes are running concurrently on CPU. These processes can be parallel workers.
• Queries are performing suboptimally because they need a large number of buffers.

 Corner cases

If none of the likely causes turn out to be actual causes, the following situations might be occurring:

• The CPU is swapping processes in and out.
• The CPU might be managing page table entries if the huge pages feature has been turned off. This memory management feature is turned on by default for all DB instance classes other than micro, small, and medium DB instance classes. For more information, see Huge pages for RDS for PostgreSQL (p. 1959).

 Actions

If the CPU wait event dominates database activity, it doesn't necessarily indicate a performance problem. Respond to this event only when performance degrades.

 Topics

• Investigate whether the database is causing the CPU increase (p. 2008)
• Determine whether the number of connections increased (p. 2008)
• Respond to workload changes (p. 2009)

 Investigate whether the database is causing the CPU increase

Examine the os.cpuUtilization.nice.avg metric in Performance Insights. If this value is far less than the CPU usage, nondatabase processes are the main contributor to CPU.

 Determine whether the number of connections increased

Examine the DatabaseConnections metric in Amazon CloudWatch. Your action depends on whether the number increased or decreased during the period of increased CPU wait events.

 The connections increased

If the number of connections went up, compare the number of backend processes consuming CPU to the number of vCPUs. The following scenarios are possible:

• The number of backend processes consuming CPU is less than the number of vCPUs.
  
  In this case, the number of connections isn't an issue. However, you might still try to reduce CPU utilization.
• The number of backend processes consuming CPU is greater than the number of vCPUs.

In this case, consider the following options:
• Decrease the number of backend processes connected to your database. For example, implement a connection pooling solution such as RDS Proxy. To learn more, see Using Amazon RDS Proxy (p. 961).
• Upgrade your instance size to get a higher number of vCPUs.
• Redirect some read-only workloads to reader nodes, if applicable.

The connections didn’t increase

Examine the blks_hit metrics in Performance Insights. Look for a correlation between an increase in blks_hit and CPU usage. The following scenarios are possible:

• CPU usage and blks_hit are correlated.

In this case, find the top SQL statements that are linked to the CPU usage, and look for plan changes. You can use either of the following techniques:
• Explain the plans manually and compare them to the expected execution plan.
• Look for an increase in block hits per second and local block hits per second. In the Top SQL section of Performance Insights dashboard, choose Preferences.

• CPU usage and blks_hit aren’t correlated.

In this case, determine whether any of the following occurs:
• The application is rapidly connecting to and disconnecting from the database.

Diagnose this behavior by turning on log_connections and log_disconnections, then analyzing the PostgreSQL logs. Consider using the pgbadger log analyzer. For more information, see https://github.com/darold/pgbadger.
• The OS is overloaded.

In this case, Performance Insights shows that backend processes are consuming CPU for a longer time than usual. Look for evidence in the Performance Insights os.cpuUtilization metrics or the CloudWatch CPUUtilization metric. If the operating system is overloaded, look at Enhanced Monitoring metrics to diagnose further. Specifically, look at the process list and the percentage of CPU consumed by each process.
• Top SQL statements are consuming too much CPU.

Examine statements that are linked to the CPU usage to see whether they can use less CPU. Run an EXPLAIN command, and focus on the plan nodes that have the most impact. Consider using a PostgreSQL execution plan visualizer. To try out this tool, see http://explain.dalibo.com/.

Respond to workload changes

If your workload has changed, look for the following types of changes:

New queries

Check whether the new queries are expected. If so, ensure that their execution plans and the number of executions per second are expected.

An increase in the size of the data set

Determine whether partitioning, if it’s not already implemented, might help. This strategy might reduce the number of pages that a query needs to retrieve.
Index maintenance or creation

Check whether the schedule for the maintenance is expected. A best practice is to schedule maintenance activities outside of peak activities.

New functions

Check whether these functions perform as expected during testing. Specifically, check whether the number of executions per second is expected.

New operators

Check whether they perform as expected during the testing.

An increase in running parallel queries

Determine whether any of the following situations has occurred:

- The relations or indexes involved have suddenly grown in size so that they differ significantly from \texttt{min\_parallel\_table\_scan\_size} or \texttt{min\_parallel\_index\_scan\_size}.
- Recent changes have been made to \texttt{parallel\_setup\_cost} or \texttt{parallel\_tuple\_cost}.
- Recent changes have been made to \texttt{max\_parallel\_workers} or \texttt{max\_parallel\_workers\_per\_gather}.

**IO:BufFileRead and IO:BufFileWrite**

The \texttt{IO:BufFileRead} and \texttt{IO:BufFileWrite} events occur when RDS for PostgreSQL creates temporary files. When operations require more memory than the working memory parameters currently define, they write temporary data to persistent storage. This operation is sometimes called “spilling to disk.”

**Topics**

- Supported engine versions (p. 2010)
- Context (p. 2010)
- Likely causes of increased waits (p. 2011)
- Actions (p. 2011)

**Supported engine versions**

This wait event information is supported for all versions of RDS for PostgreSQL.

**Context**

\texttt{IO:BufFileRead} and \texttt{IO:BufFileWrite} relate to the work memory area and maintenance work memory area. For more information about these local memory areas, see Resource Consumption in the PostgreSQL documentation.

The default value for \texttt{work\_mem} is 4 MB. If one session performs operations in parallel, each worker handling the parallelism uses 4 MB of memory. For this reason, set \texttt{work\_mem} carefully. If you increase the value too much, a database running many sessions might consume too much memory. If you set the value too low, RDS for PostgreSQL creates temporary files in local storage. The disk I/O for these temporary files can reduce performance.

If you observe the following sequence of events, your database might be generating temporary files:

1. Sudden and sharp decreases in availability
2. Fast recovery for the free space
You might also see a "chainsaw" pattern. This pattern can indicate that your database is creating small files constantly.

**Likely causes of increased waits**

In general, these wait events are caused by operations that consume more memory than the work_mem or maintenance_work_mem parameters allocate. To compensate, the operations write to temporary files. Common causes for the IO:BufFileRead and IO:BufFileWrite events include the following:

**Queries that need more memory than exists in the work memory area**

Queries with the following characteristics use the work memory area:

- Hash joins
- ORDER BY clause
- GROUP BY clause
- DISTINCT
- Window functions
- CREATE TABLE AS SELECT
- Materialized view refresh

**Statements that need more memory than exists in the maintenance work memory area**

The following statements use the maintenance work memory area:

- CREATE INDEX
- CLUSTER

**Actions**

We recommend different actions depending on the causes of your wait event.

**Topics**

- Identify the problem (p. 2011)
- Examine your join queries (p. 2012)
- Examine your ORDER BY and GROUP BY queries (p. 2012)
- Avoid using the DISTINCT operation (p. 2013)
- Consider using window functions instead of GROUP BY functions (p. 2013)
- Investigate materialized views and CTAS statements (p. 2014)
- Use pg_repack when you rebuild indexes (p. 2014)
- Increase maintenance_work_mem when you cluster tables (p. 2014)
- Tune memory to prevent IO:BufFileRead and IO:BufFileWrite (p. 2014)

**Identify the problem**

Assume a situation in which Performance Insights isn't turned on and you suspect that IO:BufFileRead and IO:BufFileWrite are occurring more frequently than is normal. To identify the source of the problem, you can set the log_temp_files parameter to log all queries that generate more than your specified threshold KB of temporary files. By default, log_temp_files is set to -1, which turns off this logging feature. If you set this parameter to 0, RDS for PostgreSQL logs all temporary files. If you set it to 1024, RDS for PostgreSQL logs all queries that produce temporary files.
larger than 1 MB. For more information about log_temp_files, see Error Reporting and Logging in the PostgreSQL documentation.

**Examine your join queries**

It's likely that your query uses joins. For example, the following query joins four tables.

```sql
SELECT *
FROM "order"
INNER JOIN order_item
    ON (order.id = order_item.order_id)
INNER JOIN customer
    ON (customer.id = order.customer_id)
INNER JOIN customer_address
    ON (customer_address.customer_id = customer.id AND
        order.customer_address_id = customer_address.id)
WHERE customer.id = 1234567890;
```

A possible cause of spikes in temporary file usage is a problem in the query itself. For example, a broken clause might not filter the joins properly. Consider the second inner join in the following example.

```sql
SELECT *
FROM "order"
INNER JOIN order_item
    ON (order.id = order_item.order_id)
INNER JOIN customer
    ON (customer.id = customer.id)
INNER JOIN customer_address
    ON (customer_address.customer_id = customer.id AND
        order.customer_address_id = customer_address.id)
WHERE customer.id = 1234567890;
```

The preceding query mistakenly joins customer.id to customer.id, generating a Cartesian product between every customer and every order. This type of accidental join generates large temporary files. Depending on the size of the tables, a Cartesian query can even fill up storage. Your application might have Cartesian joins when the following conditions are met:

- You see large, sharp decreases in storage availability, followed by fast recovery.
- No indexes are being created.
- No CREATE TABLE FROM SELECT statements are being issued.
- No materialized views are being refreshed.

To see whether the tables are being joined using the proper keys, inspect your query and object-relational mapping directives. Bear in mind that certain queries of your application are not called all the time, and some queries are dynamically generated.

**Examine your ORDER BY and GROUP BY queries**

In some cases, an ORDER BY clause can result in excessive temporary files. Consider the following guidelines:

- Only include columns in an ORDER BY clause when they need to be ordered. This guideline is especially important for queries that return thousands of rows and specify many columns in the ORDER BY clause.
- Considering creating indexes to accelerate ORDER BY clauses when they match columns that have the same ascending or descending order. Partial indexes are preferable because they are smaller. Smaller indexes are read and traversed more quickly.
• If you create indexes for columns that can accept null values, consider whether you want the null values stored at the end or at the beginning of the indexes.

If possible, reduce the number of rows that need to be ordered by filtering the result set. If you use WITH clause statements or subqueries, remember that an inner query generates a result set and passes it to the outside query. The more rows that a query can filter out, the less ordering the query needs to do.

• If you don’t need to obtain the full result set, use the LIMIT clause. For example, if you only want the top five rows, a query using the LIMIT clause doesn't keep generating results. In this way, the query requires less memory and temporary files.

A query that uses a GROUP BY clause can also require temporary files. GROUP BY queries summarize values by using functions such as the following:

- COUNT
- AVG
- MIN
- MAX
- SUM
- STDDEV

To tune GROUP BY queries, follow the recommendations for ORDER BY queries.

**Avoid using the DISTINCT operation**

If possible, avoid using the DISTINCT operation to remove duplicated rows. The more unnecessary and duplicated rows that your query returns, the more expensive the DISTINCT operation becomes. If possible, add filters in the WHERE clause even if you use the same filters for different tables. Filtering the query and joining correctly improves your performance and reduces resource use. It also prevents incorrect reports and results.

If you need to use DISTINCT for multiple rows of a same table, consider creating a composite index. Grouping multiple columns in an index can improve the time to evaluate distinct rows. Also, if you use RDS for PostgreSQL version 10 or higher, you can correlate statistics among multiple columns by using the CREATE STATISTICS command.

**Consider using window functions instead of GROUP BY functions**

Using GROUP BY, you change the result set, and then retrieve the aggregated result. Using window functions, you aggregate data without changing the result set. A window function uses the OVER clause to perform calculations across the sets defined by the query, correlating one row with another. You can use all the GROUP BY functions in window functions, but also use functions such as the following:

- RANK
- ARRAY_AGG
- ROW_NUMBER
- LAG
- LEAD

To minimize the number of temporary files generated by a window function, remove duplications for the same result set when you need two distinct aggregations. Consider the following query.

```
SELECT sum(salary) OVER (PARTITION BY dept ORDER BY salary DESC) as sum_salary
```
You can rewrite the query with the WINDOW clause as follows.

```
SELECT sum(salary) OVER w as sum_salary
    , avg(salary) OVER w as avg_salary
FROM empsalary
WINDOW w AS (PARTITION BY dept ORDER BY salary DESC);
```

By default, the RDS for PostgreSQL execution planner consolidates similar nodes so that it doesn't duplicate operations. However, by using an explicit declaration for the window block, you can maintain the query more easily. You might also improve performance by preventing duplication.

**Investigate materialized views and CTAS statements**

When a materialized view refreshes, it runs a query. This query can contain an operation such as GROUP BY, ORDER BY, or DISTINCT. During a refresh, you might observe large numbers of temporary files and the wait events `IO:BufFileWrite` and `IO:BufFileRead`. Similarly, when you create a table based on a `SELECT` statement, the `CREATE TABLE` statement runs a query. To reduce the temporary files needed, optimize the query.

**Use pg_repack when you rebuild indexes**

When you create an index, the engine orders the result set. As tables grow in size, and as values in the indexed column become more diverse, the temporary files require more space. In most cases, you can't prevent the creation of temporary files for large tables without modifying the maintenance work memory area. For more information about `maintenance_work_mem`, see [https://www.postgresql.org/docs/current/runtime-config-resource.html](https://www.postgresql.org/docs/current/runtime-config-resource.html) in the PostgreSQL documentation.

A possible workaround when recreating a large index is to use the pg_repack extension. For more information, see [Reorganize tables in PostgreSQL databases with minimal locks](https://pg_repack.readthedocs.io) in the pg_repack documentation. For information about setting up the extension in your RDS for PostgreSQL DB instance, see [Reducing bloat in tables and indexes with the pg_repack extension](#p.2078).

**Increase maintenance_work_mem when you cluster tables**

The CLUSTER command clusters the table specified by `table_name` based on an existing index specified by `index_name`. RDS for PostgreSQL physically recreates the table to match the order of a given index.

When magnetic storage was prevalent, clustering was common because storage throughput was limited. Now that SSD-based storage is common, clustering is less popular. However, if you cluster tables, you can still increase performance slightly depending on the table size, index, query, and so on.

If you run the CLUSTER command and observe the wait events `IO:BufFileWrite` and `IO:BufFileRead`, tune `maintenance_work_mem`. Increase the memory size to a fairly large amount. A high value means that the engine can use more memory for the clustering operation.

**Tune memory to prevent IO:BufFileRead and IO:BufFileWrite**

In some situations, you need to tune memory. Your goal is to balance memory across the following areas of consumption using the appropriate parameters, as follows.

- The `work_mem` value
- The memory remaining after discounting the `shared_buffers` value
- The maximum connections opened and in use, which is limited by `max_connections`
For more information about tuning memory, see Resource Consumption in the PostgreSQL documentation.

Increase the size of the work memory area

In some situations, your only option is to increase the memory used by your session. If your queries are correctly written and are using the correct keys for joins, consider increasing the work_mem value.

To find out how many temporary files a query generates, set log_temp_files to 0. If you increase the work_mem value to the maximum value identified in the logs, you prevent the query from generating temporary files. However, work_mem sets the maximum per plan node for each connection or parallel worker. If the database has 5,000 connections, and if each one uses 256 MiB memory, the engine needs 1.2 TiB of RAM. Thus, your instance might run out of memory.

Reserve sufficient memory for the shared buffer pool

Your database uses memory areas such as the shared buffer pool, not just the work memory area. Consider the requirements of these additional memory areas before you increase work_mem.

For example, assume that your RDS for PostgreSQL instance class is db.r5.2xlarge. This class has 64 GiB of memory. By default, 25 percent of the memory is reserved for the shared buffer pool. After you subtract the amount allocated to the shared memory area, 16,384 MB remains. Don't allocate the remaining memory exclusively to the work memory area because the operating system and the engine also require memory.

The memory that you can allocate to work_mem depends on the instance class. If you use a larger instance class, more memory is available. However, in the preceding example, you can't use more than 16 GiB. Otherwise, your instance becomes unavailable when it runs out of memory. To recover the instance from the unavailable state, the RDS for PostgreSQL automation services automatically restart.

Manage the number of connections

Suppose that your database instance has 5,000 simultaneous connections. Each connection uses at least 4 MiB of work_mem. The high memory consumption of the connections is likely to degrade performance. In response, you have the following options:

- Upgrade to a larger instance class.
- Decrease the number of simultaneous database connections by using a connection proxy or pooler.

For proxies, consider Amazon RDS Proxy, pgBouncer, or a connection pooler based on your application. This solution alleviates the CPU load. It also reduces the risk when all connections require the work memory area. When fewer database connections exist, you can increase the value of work_mem. In this way, you reduce the occurrence of the IO:BufFileRead and IO:BufFileWrite wait events. Also, the queries waiting for the work memory area speed up significantly.

IO:DataFileRead

The IO:DataFileRead event occurs when a connection waits on a backend process to read a required page from storage because the page isn't available in shared memory.

Topics
- Supported engine versions (p. 2016)
- Context (p. 2016)
- Likely causes of increased waits (p. 2016)
- Actions (p. 2017)
Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

All queries and data manipulation (DML) operations access pages in the buffer pool. Statements that can induce reads include SELECT, UPDATE, and DELETE. For example, an UPDATE can read pages from tables or indexes. If the page being requested or updated isn't in the shared buffer pool, this read can lead to the IO:DataFileRead event.

Because the shared buffer pool is finite, it can fill up. In this case, requests for pages that aren't in memory force the database to read blocks from disk. If the IO:DataFileRead event occurs frequently, your shared buffer pool might be too small to accommodate your workload. This problem is acute for SELECT queries that read a large number of rows that don't fit in the buffer pool. For more information about the buffer pool, see Resource Consumption in the PostgreSQL documentation.

Likely causes of increased waits

Common causes for the IO:DataFileRead event include the following:

Connection spikes

You might find multiple connections generating the same number of IO:DataFileRead wait events. In this case, a spike (sudden and large increase) in IO:DataFileRead events can occur.

SELECT and DML statements performing sequential scans

Your application might be performing a new operation. Or an existing operation might change because of a new execution plan. In such cases, look for tables (particularly large tables) that have a greater seq_scan value. Find them by querying pg_stat_user_tables. To track queries that are generating more read operations, use the extension pg_stat_statements.

CTAS and CREATE INDEX for large data sets

A CTAS is a CREATE TABLE AS SELECT statement. If you run a CTAS using a large data set as a source, or create an index on a large table, the IO:DataFileRead event can occur. When you create an index, the database might need to read the entire object using a sequential scan. A CTAS generates IO:DataFile reads when pages aren't in memory.

Multiple vacuum workers running at the same time

Vacuum workers can be triggered manually or automatically. We recommend adopting an aggressive vacuum strategy. However, when a table has many updated or deleted rows, the IO:DataFileRead waits increase. After space is reclaimed, the vacuum time spent on IO:DataFileRead decreases.

Ingesting large amounts of data

When your application ingests large amounts of data, ANALYZE operations might occur more often. The ANALYZE process can be triggered by an autovacuum launcher or invoked manually.

The ANALYZE operation reads a subset of the table. The number of pages that must be scanned is calculated by multiplying 30 by the default_statistics_target value. For more information, see the PostgreSQL documentation. The default_statistics_target parameter accepts values between 1 and 10,000, where the default is 100.

Resource starvation

If instance network bandwidth or CPU are consumed, the IO:DataFileRead event might occur more frequently.
Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Check predicate filters for queries that generate waits (p. 2017)
- Minimize the effect of maintenance operations (p. 2017)
- Respond to high numbers of connections (p. 2021)

Check predicate filters for queries that generate waits

Assume that you identify specific queries that are generating IO:DataFileRead wait events. You might identify them using the following techniques:

- Performance Insights
- Catalog views such as the one provided by the extension pg_stat_statements
- The catalog view pg_stat_all_tables, if it periodically shows an increased number of physical reads
- The pg_statio_all_tables view, if it shows that _read counters are increasing

We recommend that you determine which filters are used in the predicate (WHERE clause) of these queries. Follow these guidelines:

- Run the EXPLAIN command. In the output, identify which types of scans are used. A sequential scan doesn't necessarily indicate a problem. Queries that use sequential scans naturally produce more IO:DataFileRead events when compared to queries that use filters.

  Find out whether the column listed in the WHERE clause is indexed. If not, consider creating an index for this column. This approach avoids the sequential scans and reduces the IO:DataFileRead events. If a query has restrictive filters and still produces sequential scans, evaluate whether the proper indexes are being used.

- Find out whether the query is accessing a very large table. In some cases, partitioning a table can improve performance, allowing the query to only read necessary partitions.

- Examine the cardinality (total number of rows) from your join operations. Note how restrictive the values are that you're passing in the filters for your WHERE clause. If possible, tune your query to reduce the number of rows that are passed in each step of the plan.

Minimize the effect of maintenance operations

Maintenance operations such as VACUUM and ANALYZE are important. We recommend that you don't turn them off because you find IO:DataFileRead wait events related to these maintenance operations. The following approaches can minimize the effect of these operations:

- Run maintenance operations manually during off-peak hours. This technique prevents the database from reaching the threshold for automatic operations.

- For very large tables, consider partitioning the table. This technique reduces the overhead of maintenance operations. The database only accesses the partitions that require maintenance.

- When you ingest large amounts of data, consider disabling the autoanalyze feature.

The autovacuum feature is automatically triggered for a table when the following formula is true.
The view `pg_stat_user_tables` and catalog `pg_class` have multiple rows. One row can correspond to one row in your table. This formula assumes that the `reltuples` are for a specific table. The parameters `autovacuum_vacuum_scale_factor` (0.20 by default) and `autovacuum_vacuum_threshold` (50 tuples by default) are usually set globally for the whole instance. However, you can set different values for a specific table.

### Topics
- Find tables consuming space unnecessarily (p. 2018)
- Find indexes consuming space unnecessarily (p. 2019)
- Find tables that are eligible to be autovacuumed (p. 2021)

### Find tables consuming space unnecessarily

To find tables consuming space unnecessarily, you can use functions from the PostgreSQL `pgstattuple` extension. This extension (module) is available by default on all RDS for PostgreSQL DB instances and can be instantiated on the instance with the following command.

```sql
CREATE EXTENSION pgstattuple;
```

For more information about this extension, see [pgstattuple](https://www.postgresql.org/docs/current/pgstattuple.html) in the PostgreSQL documentation.

The query shown in the listing returns results from tables for which your database user (role) has read permissions.

```sql
SELECT current_database(), schemaname, tblname, bs*tblpages AS real_size,
       (tblpages-est_tblpages)*bs AS extra_size,
       CASE WHEN tblpages - est_tblpages > 0
            THEN 100 * (tblpages - est_tblpages)/tblpages::float
            ELSE 0
       END AS extra_ratio,
       fillfactor, (tblpages-est_tblpages_ff)*bs AS bloat_size,
       CASE WHEN tblpages - est_tblpages_ff > 0
            THEN 100 * (tblpages - est_tblpages_ff)/tblpages::float
            ELSE 0
       END AS bloat_ratio,
       is_na
FROM (SELECT
       ceil( reltuples / ( (bs-page_hdr)/tpl_size ) ) + ceil( toasttuples / 4 )
       AS est_tblpages,
       ceil( reltuples / ( (bs-page_hdr)*fillfactor/(tpl_size*100) ) ) + ceil( toasttuples / 4 )
       AS est_tblpages_ff,
       tblpages, fillfactor, bs, tblid, schemaname, tblname, heappages, toastpages, is_na
FROM (SELECT
       ceil( ( 4 + tpl_hdr_size + tpl_data_size + (2*ma) - CASE WHEN tpl_hdr_size%ma = 0 THEN ma ELSE tpl_hdr_size%ma END - CASE WHEN ceil(tpl_data_size)::int%ma = 0 THEN ma ELSE ceil(tpl_data_size)::int%ma END ) AS tpl_size,
       bs - page_hdr AS size_per_block,
       heappages + toastpages AS tblpages,
       fillfactor, is_na
FROM (SELECT
       AS tple_size, bs - page_hdr AS size_per_block, (heappages + toastpages) AS tblpages,
       heappages,
       toastpages, reltuples, toasttuples, bs, page_hdr, tblid, schemaname, tblname,
       fillfactor, is_na
       FROM (SELECT
```
To find bloated indexes and estimate the amount of space consumed unnecessarily on the tables for which you have read privileges, you can run the following query.

```
-- WARNING: rows with is_na = 't' are known to have bad statistics ("name" type is not supported).
-- This query is compatible with PostgreSQL 8.2 and later.
SELECT current_database(), nspname AS schemaname, tblname, idxname, bs*(relpages)::bigint AS real_size,
       bs*(relpages-est_pages)::bigint AS extra_size,
       100 * (relpages-est_pages)::float / relpages AS extra_ratio,
       fillfactor, bs*(relpages-est_pages_ff)::bigint AS bloat_size,
       100 * (relpages-est_pages_ff)::float / relpages AS bloat_ratio,
       is_na
       -- , stattuple.pgstatindex(quote_ident(nspname)||'.'||quote_ident(idxname)) AS pst,
FROM (SELECT coalesce(1 +
       ceil(reltuples/floor((bs-pageopqdata-pagehdr)/(4+nulldatahdrwidth)::float)), 0
       -- ItemIdData size + computed avg size of a tuple (nulldatahdrwidth)
        ) AS est_pages,
       coalesce(1 +
       ceil(reltuples/floor((bs-pageopqdata-pagehdr)*fillfactor/(100*(4+nulldatahdrwidth)::float))), 0
       ) AS est_pages_ff,
       bs, nspname, table_oid, tblname, idxname, relpages, fillfactor, is_na
       -- , stattuple.pgstatindex(quote_ident(nspname)||'.'||quote_ident(idxname)) AS pst,

Find tables that are eligible to be autovacuumed

To find tables that are eligible to be autovacuumed, run the following query.

```sql
WITH vbt AS (SELECT setting AS autovacuum_vacuum_threshold
  FROM pg_settings WHERE name = 'autovacuum_vacuum_threshold')
, vsf AS (SELECT setting AS autovacuum_vacuum_scale_factor
  FROM pg_settings WHERE name = 'autovacuum_vacuum_scale_factor')
, fma AS (SELECT setting AS autovacuum_freeze_max_age
  FROM pg_settings WHERE name = 'autovacuum_freeze_max_age')
, sto AS (SELECT opt_oid, split_part(setting, '=', 1) as param,
  split_part(setting, '=', 2) as value
  FROM (SELECT oid opt_oid, unnest(reloptions) setting FROM pg_class) opt)
SELECT
  '"'||ns.nspname||'"."'||c.relname||'" as relation,
  pg_size_pretty(pg_table_size(c.oid)) as table_size,
  age(relfrozenxid) as xid_age,
  coalesce(cfma.value::float, autovacuum_freeze_max_age::float) as autovacuum_freeze_max_age,
  (coalesce(cvbt.value::float, autovacuum_vacuum_threshold::float) +
   coalesce(cvsf.value::float, autovacuum_vacuum_scale_factor::float) * c.reltuples) as autovacuum_vacuum_tuples,
  n_dead_tup as dead_tuples
FROM pg_class c
JOIN pg_namespace ns ON ns.oid = c.relnamespace
JOIN pg_stat_all_tables stat ON stat.relid = c.oid
JOIN vbt on (1=1)
JOIN vsf ON (1=1)
JOIN fma on (1=1)
LEFT JOIN sto cvbt ON cvbt.param = 'autovacuum_vacuum_threshold' AND c.oid = cvbt.opt_oid
LEFT JOIN sto cvsf ON cvsf.param = 'autovacuum_vacuum_scale_factor' AND c.oid = cvsf.opt_oid
LEFT JOIN sto cfma ON cfma.param = 'autovacuum_freeze_max_age' AND c.oid = cfma.opt_oid
WHERE c.relkind = 'r'
AND ns.nspname <> 'pg_catalog'
AND (
  age(relfrozenxid) >= coalesce(cfma.value::float, autovacuum_freeze_max_age::float)
  or
  coalesce(cvbt.value::float, autovacuum_vacuum_threshold::float) +
  coalesce(cvsf.value::float, autovacuum_vacuum_scale_factor::float) * c.reltuples <=
  n_dead_tup
  -- or 1 = 1
)
ORDER BY age(relfrozenxid) DESC;
```

Respond to high numbers of connections

When you monitor Amazon CloudWatch, you might find that the DatabaseConnections metric spikes. This increase indicates an increased number of connections to your database. We recommend the following approach:

- Limit the number of connections that the application can open with each instance. If your application has an embedded connection pool feature, set a reasonable number of connections. Base the number on what the vCPUs in your instance can parallelize effectively.
If your application doesn’t use a connection pool feature, considering using Amazon RDS Proxy or an alternative. This approach lets your application open multiple connections with the load balancer. The balancer can then open a restricted number of connections with the database. As fewer connections are running in parallel, your DB instance performs less context switching in the kernel. Queries should progress faster, leading to fewer wait events. For more information, see Using Amazon RDS Proxy (p. 961).

- Whenever possible, take advantage of read replicas for RDS for PostgreSQL. When your application runs a read-only operation, send these requests to the read replica(s). This technique reduces the I/O pressure on the primary (writer) node.
- Consider scaling up your DB instance. A higher-capacity instance class gives more memory, which gives RDS for PostgreSQL a larger shared buffer pool to hold pages. The larger size also gives the DB instance more vCPUs to handle connections. More vCPUs are particularly helpful when the operations that are generating IO:DataFileRead wait events are writes.

### IO:WALWrite

**Topics**

- Supported engine versions (p. 2022)
- Context (p. 2022)
- Likely causes of increased waits (p. 2022)
- Actions (p. 2023)

**Supported engine versions**

This wait event information is supported for all versions of RDS for PostgreSQL 10 and higher.

**Context**

Activity in the database that’s generating write-ahead log data fills up the WAL buffers first and then writes to disk, asynchronously. The wait event IO:WALWrite is generated when the SQL session is waiting for the WAL data to complete writing to disk so that it can release the transaction’s COMMIT call.

**Likely causes of increased waits**

If this wait event occurs often, you should review your workload and the type of updates that your workload performs and their frequency. In particular, look for the following types of activity.

**Heavy DML activity**

Changing data in database tables doesn’t happen instantaneously. An insert to one table might need to wait for an insert or an update to the same table from another client. The data manipulation language (DML) statements for changing data values (INSERT, UPDATE, DELETE, COMMIT, ROLLBACK TRANSACTION) can result in contention that causes the write-ahead logfile to be waiting for the buffers to be flushed. This situation is captured in the following Amazon RDS Performance Insights metrics that indicate heavy DML activity.

- tup_inserted
- tup_updated
- tup_deleted
For more information about these metrics, see Performance Insights counters for Amazon RDS for PostgreSQL (p. 661).

Frequent checkpoint activity

Frequent checkpoints contribute to larger WAL size. In RDS for PostgreSQL, full page writes are always "on." Full page writes help protect against data loss. However, when checkpointing occurs too frequently, the system can suffer overall performance issues. This is especially true on systems with heavy DML activity. In some cases, you might find error messages in your postgresql.log stating that "checkpoints are occurring too frequently."

We recommend that when tuning checkpoints, you carefully balance performance against expected time need to recover in the event of an abnormal shutdown.

Actions

We recommend the following actions to reduce the numbers of this wait event.

Topics

- Reduce the number of commits (p. 2023)
- Monitor your checkpoints (p. 2023)
- Scale up IO (p. 2024)

Reduce the number of commits

To reduce the number of commits, you can combine statements into transaction blocks. Use Amazon RDS Performance Insights to examine the type of queries being run. You can also move large maintenance operations to off-peak hours. For example, create indexes or use pg_repack operations during non-production hours.

Monitor your checkpoints

There are two parameters that you can monitor to see how frequently your RDS for PostgreSQL DB instance is writing to the WAL file for checkpoints.

- log_checkpoints – This parameter is set to "on" by default. It causes a message to get sent to the PostgreSQL log for each checkpoint. These log messages include the number of buffers written, the time spent writing them, and the number of WAL files added, removed, or recycled for the given checkpoint.
  
  For more information about this parameter, see Error Reporting and Logging in the PostgreSQL documentation.

- checkpoint_warning – This parameter sets a threshold value (in seconds) for checkpoint frequency above which a warning is generated. By default, this parameter isn't set. You can set a value for this parameter to get a warning when your RDS for PostgreSQL DB instance needs to write buffers to the WAL file more often than the specified value. For example, say you set this parameter to 30. If your RDS for PostgreSQL instance needs to write its buffers to the WAL file more often than every 30 seconds, the warning that "checkpoints are occurring too frequently" is sent to the PostgreSQL log.
  
  This can indicate that your max_wal_size value should be increased.

  For more information, see Write Ahead Log in the PostgreSQL documentation.
**Scale up IO**

This type of input/output (IO) wait event can remediated by scaling the input/output operations per second (IOPs) to provide faster IO. Scaling IO is preferable to scaling CPU, because scaling CPU can result in even more IO contention because the increased CPU can handle more work and thus make the IO bottleneck even worse. In general, we recommend that you consider tuning your workload before performing scaling operations.

**Lock:advisory**

The Lock:advisory event occurs when a PostgreSQL application uses a lock to coordinate activity across multiple sessions.

**Topics**

- Relevant engine versions (p. 2024)
- Context (p. 2024)
- Causes (p. 2024)
- Actions (p. 2025)

**Relevant engine versions**

This wait event information is relevant for RDS for PostgreSQL versions 9.6 and higher.

**Context**

PostgreSQL advisory locks are application-level, cooperative locks explicitly locked and unlocked by the user's application code. An application can use PostgreSQL advisory locks to coordinate activity across multiple sessions. Unlike regular, object- or row-level locks, the application has full control over the lifetime of the lock. For more information, see *Advisory Locks* in the PostgreSQL documentation.

Advisory locks can be released before a transaction ends or be held by a session across transactions. This isn't true for implicit, system-enforced locks, such as an access-exclusive lock on a table acquired by a CREATE INDEX statement.

For a description of the functions used to acquire (lock) and release (unlock) advisory locks, see *Advisory Lock Functions* in the PostgreSQL documentation.

Advisory locks are implemented on top of the regular PostgreSQL locking system and are visible in the pg_locks system view.

**Causes**

This lock type is exclusively controlled by an application explicitly using it. Advisory locks that are acquired for each row as part of a query can cause a spike in locks or a long-term buildup.

These effects happen when the query is run in a way that acquires locks on more rows than are returned by the query. The application must eventually release every lock, but if locks are acquired on rows that aren't returned, the application can't find all of the locks.

The following example is from *Advisory Locks* in the PostgreSQL documentation.

```
SELECT pg_advisory_lock(id) FROM foo WHERE id > 12345 LIMIT 100;
```
In this example, the LIMIT clause can only stop the query's output after the rows have already been internally selected and their ID values locked. This can happen suddenly when a growing data volume causes the planner to choose a different execution plan that wasn't tested during development. The buildup in this case happens because the application explicitly calls `pg_advisory_unlock` for every ID value that was locked. However, in this case it can't find the set of locks acquired on rows that weren't returned. Because the locks are acquired on the session level, they aren't released automatically at the end of the transaction.

Another possible cause for spikes in blocked lock attempts is unintended conflicts. In these conflicts, unrelated parts of the application share the same lock ID space by mistake.

**Actions**

Review application usage of advisory locks and detail where and when in the application flow each type of advisory lock is acquired and released.

Determine whether a session is acquiring too many locks or a long-running session isn't releasing locks early enough, leading to a slow buildup of locks. You can correct a slow buildup of session-level locks by ending the session using `pg_terminate_backend(pid)`.

A client waiting for an advisory lock appears in `pg_stat_activity` with `wait_event_type=Lock` and `wait_event=advisory`. You can obtain specific lock values by querying the `pg_locks` system view for the same `pid`, looking for `locktype=advisory` and `granted=f`.

You can then identify the blocking session by querying `pg_locks` for the same advisory lock having `granted=t`, as shown in the following example.

```sql
SELECT blocked_locks.pid AS blocked_pid,
       blocking_locks.pid AS blocking_pid,
       blocked_activity.usename AS blocked_user,
       blocking_activity.usename AS blocking_user,
       now() - blocked_activity.xact_start AS blocked_transaction_duration,
       now() - blocking_activity.xact_start AS blocking_transaction_duration,
       concat(blocked_activity.wait_event_type,':',blocked_activity.wait_event) AS blocked_wait_event,
       concat(blocking_activity.wait_event_type,':',blocking_activity.wait_event) AS blocking_wait_event,
       blocked_activity.state AS blocked_state,
       blocking_activity.state AS blocking_state,
       blocked_locks.locktype AS blocked_locktype,
       blocking_locks.locktype AS blocking_locktype,
       blocked_activity.query AS blocked_statement,
       blocking_activity.query AS blocking_statement
FROM pg_catalog.pg_locks blocked_locks
JOIN pg_catalog.pg_stat_activity blocked_activity ON blocked_activity.pid = blocked_locks.pid
JOIN pg_catalog.pg_locks blocking_locks ON blocked_locks.locktype = blocking_locks.locktype
AND blocking_locks.DATABASE IS NOT DISTINCT FROM blocked_locks.DATABASE
AND blocking_locks.relation IS NOT DISTINCT FROM blocked_locks.relation
AND blocking_locks.page IS NOT DISTINCT FROM blocked_locks.page
AND blocking_locks.tuple IS NOT DISTINCT FROM blocked_locks.tuple
AND blocking_locks.virtualxid IS NOT DISTINCT FROM blocked_locks.virtualxid
AND blocking_locks.transactionid IS NOT DISTINCT FROM blocked_locks.transactionid
AND blocking_locks.classid IS NOT DISTINCT FROM blocked_locks.classid
AND blocking_locks.objid IS NOT DISTINCT FROM blocked_locks.objid
AND blocking_locks.objsubid IS NOT DISTINCT FROM blocked_locks.objsubid
JOIN pg_catalog.pg_stat_activity blocking_activity ON blocking_activity.pid = blocking_activity.pid
WHERE NOT blocked_locks.GRANTED;
```
All of the advisory lock API functions have two sets of arguments, either one bigint argument or two integer arguments:

- For the API functions with one bigint argument, the upper 32 bits are in `pg_locks.classid` and the lower 32 bits are in `pg_locks.objid`.
- For the API functions with two integer arguments, the first argument is `pg_locks.classid` and the second argument is `pg_locks.objid`.

The `pg_locks.objsubid` value indicates which API form was used: 1 means one bigint argument; 2 means two integer arguments.

**Lock:extend**

The `Lock:extend` event occurs when a backend process is waiting to lock a relation to extend it while another process has a lock on that relation for the same purpose.

**Topics**
- Supported engine versions (p. 2026)
- Context (p. 2026)
- Likely causes of increased waits (p. 2026)
- Actions (p. 2026)

**Supported engine versions**

This wait event information is supported for all versions of RDS for PostgreSQL.

**Context**

The event `Lock:extend` indicates that a backend process is waiting to extend a relation that another backend process holds a lock on while it's extending that relation. Because only one process at a time can extend a relation, the system generates a `Lock:extend` wait event. INSERT, COPY, and UPDATE operations can generate this event.

**Likely causes of increased waits**

When the `Lock:extend` event appears more than normal, possibly indicating a performance problem, typical causes include the following:

**Surge in concurrent inserts or updates to the same table**

There might be an increase in the number of concurrent sessions with queries that insert into or update the same table.

**Insufficient network bandwidth**

The network bandwidth on the DB instance might be insufficient for the storage communication needs of the current workload. This can contribute to storage latency that causes an increase in `Lock:extend` events.

**Actions**

We recommend different actions depending on the causes of your wait event.
Reduce concurrent inserts and updates to the same relation

First, determine whether there's an increase in `tup_inserted` and `tup_updated` metrics and an accompanying increase in this wait event. If so, check which relations are in high contention for insert and update operations. To determine this, query the `pg_stat_all_tables` view for the values in `n_tup_ins` and `n_tup_upd` fields. For information about the `pg_stat_all_tables` view, see `pg_stat_all_tables` in the PostgreSQL documentation.

To get more information about blocking and blocked queries, query `pg_stat_activity` as in the following example:

```sql
SELECT blocked.pid, blocked.usename, blocked.query, blocking.pid AS blocking_id, blocking.query AS blocking_query, blocking.wait_event AS blocking_wait_event, blocking.wait_event_type AS blocking_wait_event_type
FROM pg_stat_activity AS blocked
JOIN pg_stat_activity AS blocking ON blocking.pid = ANY(pg_blocking_pids(blocked.pid))
WHERE blocked.wait_event = 'extend'
AND blocked.wait_event_type = 'Lock';
```

<table>
<thead>
<tr>
<th>pid</th>
<th>usename</th>
<th>query</th>
<th>blocking_id</th>
<th>blocking_query</th>
<th>blocking_wait_event</th>
<th>blocking_wait_event_type</th>
</tr>
</thead>
<tbody>
<tr>
<td>7143</td>
<td>myuser</td>
<td>insert into tab1 values (1);</td>
<td>4600</td>
<td>INSERT INTO tab1 (a)</td>
<td>DataFileExtend</td>
<td>IO</td>
</tr>
</tbody>
</table>

After you identify relations that contribute to increase `Lock:extend` events, use the following techniques to reduce the contention:

- Find out whether you can use partitioning to reduce contention for the same table. Separating inserted or updated tuples into different partitions can reduce contention. For information about partitioning, see `Managing PostgreSQL partitions with the pg_partman extension (p. 2048)`.

- If the wait event is mainly due to update activity, consider reducing the relation's fillfactor value. This can reduce requests for new blocks during the update. The fillfactor is a storage parameter for a table that determines the maximum amount of space for packing a table page. It's expressed as a percentage of the total space for a page. For more information about the fillfactor parameter, see `CREATE TABLE` in the PostgreSQL documentation.

Important

We highly recommend that you test your system if you change the fillfactor because changing this value can negatively impact performance, depending on your workload.

Increase network bandwidth

To see whether there's an increase in write latency, check the `WriteLatency` metric in CloudWatch. If there is, use the `WriteThroughput` and `ReadThroughput` Amazon CloudWatch metrics to monitor the
storage related traffic on the DB instance. These metrics can help you to determine if network bandwidth is sufficient for the storage activity of your workload.

If your network bandwidth isn't enough, increase it. If your DB instance is reaching the network bandwidth limits, the only way to increase the bandwidth is to increase your DB instance size.

For more information about CloudWatch metrics, see Amazon CloudWatch instance-level metrics for Amazon RDS (p. 644). For information about network performance for each DB instance class, see Amazon CloudWatch instance-level metrics for Amazon RDS (p. 644).

Lock:Relation

The Lock:Relation event occurs when a query is waiting to acquire a lock on a table or view (relation) that's currently locked by another transaction.

Topics

- Supported engine versions (p. 2028)
- Context (p. 2028)
- Likely causes of increased waits (p. 2029)
- Actions (p. 2029)

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

Most PostgreSQL commands implicitly use locks to control concurrent access to data in tables. You can also use these locks explicitly in your application code with the LOCK command. Many lock modes aren't compatible with each other, and they can block transactions when they're trying to access the same object. When this happens, RDS for PostgreSQL generates a Lock:Relation event. Some common examples are the following:

- Exclusive locks such as ACCESS EXCLUSIVE can block all concurrent access. Data definition language (DDL) operations such as DROP TABLE, TRUNCATE, VACUUM FULL, and CLUSTER acquire ACCESS EXCLUSIVE locks implicitly. ACCESS EXCLUSIVE is also the default lock mode for LOCK TABLE statements that don't specify a mode explicitly.
- Using CREATE INDEX (without CONCURRENT) on a table conflicts with data manipulation language (DML) statements UPDATE, DELETE, and INSERT, which acquire ROW EXCLUSIVE locks.

For more information about table-level locks and conflicting lock modes, see Explicit Locking in the PostgreSQL documentation.

Blocking queries and transactions typically unblock in one of the following ways:

- Blocking query – The application can cancel the query or the user can end the process. The engine can also force the query to end because of a session's statement-timeout or a deadlock detection mechanism.
- Blocking transaction – A transaction stops blocking when it runs a ROLLBACK or COMMIT statement. Rollbacks also happen automatically when sessions are disconnected by a client or by network issues, or are ended. Sessions can be ended when the database engine is shut down, when the system is out of memory, and so forth.
Likely causes of increased waits

When the Lock:Relation event occurs more frequently than normal, it can indicate a performance issue. Typical causes include the following:

**Increased concurrent sessions with conflicting table locks**

There might be an increase in the number of concurrent sessions with queries that lock the same table with conflicting locking modes.

**Maintenance operations**

Health maintenance operations such as VACUUM and ANALYZE can significantly increase the number of conflicting locks. VACUUM FULL acquires an ACCESS EXCLUSIVE lock, and ANALYZE acquires a SHARE UPDATE EXCLUSIVE lock. Both types of locks can cause a Lock:Relation wait event. Application data maintenance operations such as refreshing a materialized view can also increase blocked queries and transactions.

**Locks on reader instances**

There might be a conflict between the relation locks held by the writer and readers. Currently, only ACCESS EXCLUSIVE relation locks are replicated to reader instances. However, the ACCESS EXCLUSIVE relation lock will conflict with any ACCESS SHARE relation locks held by the reader. This can cause an increase in lock relation wait events on the reader.

**Actions**

We recommend different actions depending on the causes of your wait event.

**Topics**

- Reduce the impact of blocking SQL statements (p. 2029)
- Minimize the effect of maintenance operations (p. 2029)

**Reduce the impact of blocking SQL statements**

To reduce the impact of blocking SQL statements, modify your application code where possible. Following are two common techniques for reducing blocks:

- **Use the NOWAIT option** – Some SQL commands, such as SELECT and LOCK statements, support this option. The NOWAIT directive cancels the lock-requesting query if the lock can't be acquired immediately. This technique can help prevent a blocking session from causing a pile-up of blocked sessions behind it.

  For example: Assume that transaction A is waiting on a lock held by transaction B. Now, if B requests a lock on a table that's locked by transaction C, transaction A might be blocked until transaction C completes. But if transaction B uses a NOWAIT when it requests the lock on C, it can fail fast and ensure that transaction A doesn't have to wait indefinitely.

- **Use SET lock_timeout** – Set a lock_timeout value to limit the time a SQL statement waits to acquire a lock on a relation. If the lock isn't acquired within the timeout specified, the transaction requesting the lock is cancelled. Set this value at the session level.

**Minimize the effect of maintenance operations**

Maintenance operations such as VACUUM and ANALYZE are important. We recommend that you don't turn them off because you find Lock:Relation wait events related to these maintenance operations. The following approaches can minimize the effect of these operations:
• Run maintenance operations manually during off-peak hours.
• To reduce Lock:Relation waits caused by autovacuum tasks, perform any needed autovacuum tuning. For information about tuning autovacuum, see Working with PostgreSQL autovacuum on Amazon RDS in the Amazon RDS User Guide.

**Lock:transactionid**

The Lock:transactionid event occurs when a transaction is waiting for a row-level lock.

**Topics**
- Supported engine versions (p. 2030)
- Context (p. 2030)
- Likely causes of increased waits (p. 2030)
- Actions (p. 2031)

**Supported engine versions**

This wait event information is supported for all versions of RDS for PostgreSQL.

**Context**

The event Lock:transactionid occurs when a transaction is trying to acquire a row-level lock that has already been granted to a transaction that is running at the same time. The session that shows the Lock:transactionid wait event is blocked because of this lock. After the blocking transaction ends in either a COMMIT or ROLLBACK statement, the blocked transaction can proceed.

The multiversion concurrency control semantics of RDS for PostgreSQL guarantee that readers don't block writers and writers don't block readers. For row-level conflicts to occur, blocking and blocked transactions must issue conflicting statements of the following types:

- UPDATE
- SELECT ... FOR UPDATE
- SELECT ... FOR KEY SHARE

The statement SELECT ... FOR KEY SHARE is a special case. The database uses the clause FOR KEY SHARE to optimize the performance of referential integrity. A row-level lock on a row can block INSERT, UPDATE, and DELETE commands on other tables that reference the row.

**Likely causes of increased waits**

When this event appears more than normal, the cause is typically UPDATE, SELECT ... FOR UPDATE, or SELECT ... FOR KEY SHARE statements combined with the following conditions.

**Topics**
- High concurrency (p. 2030)
- Idle in transaction (p. 2031)
- Long-running transactions (p. 2031)

**High concurrency**

RDS for PostgreSQL can use granular row-level locking semantics. The probability of row-level conflicts increases when the following conditions are met:
A highly concurrent workload contends for the same rows.
Concurrency increases.

Idle in transaction

Sometimes the pg_stat_activity.state column shows the value idle in transaction. This value appears for sessions that have started a transaction, but haven’t yet issued a COMMIT or ROLLBACK. If the pg_stat_activity.state value isn’t active, the query shown in pg_stat_activity is the most recent one to finish running. The blocking session isn’t actively processing a query because an open transaction is holding a lock.

If an idle transaction acquired a row-level lock, it might be preventing other sessions from acquiring it. This condition leads to frequent occurrence of the wait event Lock:transactionid. To diagnose the issue, examine the output from pg_stat_activity and pg_locks.

Long-running transactions

Transactions that run for a long time get locks for a long time. These long-held locks can block other transactions from running.

Actions

Row-locking is a conflict among UPDATE, SELECT ... FOR UPDATE, or SELECT ... FOR KEY SHARE statements. Before attempting a solution, find out when these statements are running on the same row. Use this information to choose a strategy described in the following sections.

Topics

- Respond to high concurrency (p. 2031)
- Respond to idle transactions (p. 2031)
- Respond to long-running transactions (p. 2032)

Respond to high concurrency

If concurrency is the issue, try one of the following techniques:

- Lower the concurrency in the application. For example, decrease the number of active sessions.
- Implement a connection pool. To learn how to pool connections with RDS Proxy, see Using Amazon RDS Proxy (p. 961).
- Design the application or data model to avoid contending UPDATE and SELECT ... FOR UPDATE statements. You can also decrease the number of foreign keys accessed by SELECT ... FOR KEY SHARE statements.

Respond to idle transactions

If pg_stat_activity.state shows idle in transaction, use the following strategies:

- Turn on autocommit wherever possible. This approach prevents transactions from blocking other transactions while waiting for a COMMIT or ROLLBACK.
- Search for code paths that are missing COMMIT, ROLLBACK, or END.
- Make sure that the exception handling logic in your application always has a path to a valid end of transaction.
• Make sure that your application processes query results after ending the transaction with COMMIT or ROLLBACK.

**Respond to long-running transactions**

If long-running transactions are causing the frequent occurrence of Lock:transactionid, try the following strategies:

• Keep row locks out of long-running transactions.
• Limit the length of queries by implementing autocommit whenever possible.

**Lock:tuple**

The Lock:tuple event occurs when a backend process is waiting to acquire a lock on a tuple.

**Topics**

• Supported engine versions (p. 2032)
• Context (p. 2032)
• Likely causes of increased waits (p. 2033)
• Actions (p. 2033)

**Supported engine versions**

This wait event information is supported for all versions of RDS for PostgreSQL.

**Context**

The event Lock:tuple indicates that a backend is waiting to acquire a lock on a tuple while another backend holds a conflicting lock on the same tuple. The following table illustrates a scenario in which sessions generate the Lock:tuple event.

<table>
<thead>
<tr>
<th>Time</th>
<th>Session 1</th>
<th>Session 2</th>
<th>Session 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>t1</td>
<td>Starts a transaction.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>t2</td>
<td>Updates row 1.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>t3</td>
<td></td>
<td>Updates row 1. The session acquires an exclusive lock on the tuple and then waits for session 1 to release the lock by committing or rolling back.</td>
<td></td>
</tr>
<tr>
<td>t4</td>
<td></td>
<td></td>
<td>Updates row 1. The session waits for session 2 to release the exclusive lock on the tuple.</td>
</tr>
</tbody>
</table>

Or you can simulate this wait event by using the benchmarking tool pgbench. Configure a high number of concurrent sessions to update the same row in a table with a custom SQL file.

To learn more about conflicting lock modes, see *Explicit Locking* in the PostgreSQL documentation. To learn more about pgbench, see `pgbench` in the PostgreSQL documentation.
Likely causes of increased waits

When this event appears more than normal, possibly indicating a performance problem, typical causes include the following:

- A high number of concurrent sessions are trying to acquire a conflicting lock for the same tuple by running UPDATE or DELETE statements.
- Highly concurrent sessions are running a SELECT statement using the FOR UPDATE or FOR NO KEY UPDATE lock modes.
- Various factors drive application or connection pools to open more sessions to execute the same operations. As new sessions are trying to modify the same rows, DB load can spike, and Lock:tuple can appear.

For more information, see Row-Level Locks in the PostgreSQL documentation.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Investigate your application logic (p. 2033)
- Find the blocker session (p. 2033)
- Reduce concurrency when it is high (p. 2034)
- Troubleshoot bottlenecks (p. 2034)

Investigate your application logic

Find out whether a blocker session has been in the idle in transaction state for long time. If so, consider ending the blocker session as a short-term solution. You can use the pg_terminate_backend function. For more information about this function, see Server Signaling Functions in the PostgreSQL documentation.

For a long-term solution, do the following:

- Adjust the application logic.
- Use the idle_in_transaction_session_timeout parameter. This parameter ends any session with an open transaction that has been idle for longer than the specified amount of time. For more information, see Client Connection Defaults in the PostgreSQL documentation.
- Use autocommit as much as possible. For more information, see SET AUTOCOMMIT in the PostgreSQL documentation.

Find the blocker session

While the Lock:tuple wait event is occurring, identify the blocker and blocked session by finding out which locks depend on one another. For more information, see Lock dependency information in the PostgreSQL wiki.

The following example queries all sessions, filtering on tuple and ordering by wait_time.

```
SELECT blocked_locks.pid AS blocked_pid,
       blocking_locks.pid AS blocking_pid,
```
Reduce concurrency when it is high

The `Lock:tuple` event might occur constantly, especially in a busy workload time. In this situation, consider reducing the high concurrency for very busy rows. Often, just a few rows control a queue or the Boolean logic, which makes these rows very busy.

You can reduce concurrency by using different approaches based in the business requirement, application logic, and workload type. For example, you can do the following:

- Redesign your table and data logic to reduce high concurrency.
- Change the application logic to reduce high concurrency at the row level.
- Leverage and redesign queries with row-level locks.
- Use the `NOWAIT` clause with retry operations.
- Consider using optimistic and hybrid-locking logic concurrency control.
- Consider changing the database isolation level.

Troubleshoot bottlenecks

The `Lock:tuple` can occur with bottlenecks such as CPU starvation or maximum usage of Amazon EBS bandwidth. To reduce bottlenecks, consider the following approaches:

- Scale up your instance class type.
- Optimize resource-intensive queries.
- Change the application logic.
- Archive data that is rarely accessed.
LWLock:BufferMapping (LWLock:buffer_mapping)

This event occurs when a session is waiting to associate a data block with a buffer in the shared buffer pool.

**Note**
This event is named LWLock:BufferMapping for RDS for PostgreSQL version 13 and higher versions. For RDS for PostgreSQL version 12 and older versions, this event is named LWLock:buffer_mapping.

**Topics**
- Supported engine versions (p. 2035)
- Context (p. 2035)
- Causes (p. 2035)
- Actions (p. 2035)

**Supported engine versions**

This wait event information is relevant for RDS for PostgreSQL version 9.6 and higher.

**Context**

The *shared buffer pool* is a PostgreSQL memory area that holds all pages that are or were being used by processes. When a process needs a page, it reads the page into the shared buffer pool. The `shared_buffers` parameter sets the shared buffer size and reserves a memory area to store the table and index pages. If you change this parameter, make sure to restart the database.

The LWLock:buffer_mapping wait event occurs in the following scenarios:

- A process searches the buffer table for a page and acquires a shared buffer mapping lock.
- A process loads a page into the buffer pool and acquires an exclusive buffer mapping lock.
- A process removes a page from the pool and acquires an exclusive buffer mapping lock.

**Causes**

When this event appears more than normal, possibly indicating a performance problem, the database is paging in and out of the shared buffer pool. Typical causes include the following:

- Large queries
- Bloated indexes and tables
- Full table scans
- A shared pool size that is smaller than the working set

**Actions**

We recommend different actions depending on the causes of your wait event.

**Topics**
- Monitor buffer-related metrics (p. 2036)
- Assess your indexing strategy (p. 2036)
- Reduce the number of buffers that must be allocated quickly (p. 2036)
Monitor buffer-related metrics

When LWLock:buffer_mapping waits spike, investigate the buffer hit ratio. You can use these metrics to get a better understanding of what is happening in the buffer cache. Examine the following metrics:

BufferCacheHitRatio

This Amazon CloudWatch metric measures the percentage of requests that are served by the buffer cache of a DB instance in your DB instance. You might see this metric decrease in the lead-up to the LWLock:buffer_mapping wait event.

blks_hit

This Performance Insights counter metric indicates the number of blocks that were retrieved from the shared buffer pool. After the LWLock:buffer_mapping wait event appears, you might observe a spike in blks_hit.

blks_read

This Performance Insights counter metric indicates the number of blocks that required I/O to be read into the shared buffer pool. You might observe a spike in blks_read in the lead-up to the LWLock:buffer_mapping wait event.

Assess your indexing strategy

To confirm that your indexing strategy is not degrading performance, check the following:

Index bloat

Ensure that index and table bloat aren't leading to unnecessary pages being read into the shared buffer. If your tables contain unused rows, consider archiving the data and removing the rows from the tables. You can then rebuild the indexes for the resized tables.

Indexes for frequently used queries

To determine whether you have the optimal indexes, monitor DB engine metrics in Performance Insights. The tup_returned metric shows the number of rows read. The tup_fetched metric shows the number of rows returned to the client. If tup_returned is significantly larger than tup_fetched, the data might not be properly indexed. Also, your table statistics might not be current.

Reduce the number of buffers that must be allocated quickly

To reduce the LWLock:buffer_mapping wait events, try to reduce the number of buffers that must be allocated quickly. One strategy is to perform smaller batch operations. You might be able to achieve smaller batches by partitioning your tables.

LWLock:BufferIO

The LWLock:BufferIO event occurs when RDS for PostgreSQL is waiting for other processes to finish their input/output (I/O) operations when concurrently trying to access a page. Its purpose is for the same page to be read into the shared buffer.

Topics

- Relevant engine versions (p. 2037)
- Context (p. 2037)
- Causes (p. 2037)
- Actions (p. 2037)
**Relevant engine versions**

This wait event information is relevant for all RDS for PostgreSQL versions. For RDS for PostgreSQL versions earlier than PostgreSQL 14, this wait event type is `lwlock`. For PostgreSQL 14 and later releases, the wait_event type is `IPC`.

**Context**

Each shared buffer has an I/O lock that is associated with the `LWLock:BufferIO` wait event, each time a block (or a page) has to be retrieved outside the shared buffer pool.

This lock is used to handle multiple sessions that all require access to the same block. This block has to be read from outside the shared buffer pool, defined by the `shared_buffers` parameter.

As soon as the page is read inside the shared buffer pool, the `LWLock:BufferIO` lock is released.

**Note**

The `LWLock:BufferIO` wait event precedes the `IO:DataFileRead` wait event. The `IO:DataFileRead` wait event occurs while data is being read from storage.

For more information on lightweight locks, see [Locking Overview](#).

**Causes**

Common causes for the `LWLock:BufferIO` event to appear in top waits include the following:

- Multiple backends or connections trying to access the same page that's also pending an I/O operation
- The ratio between the size of the shared buffer pool (defined by the `shared_buffers` parameter) and the number of buffers needed by the current workload
- The size of the shared buffer pool not being well balanced with the number of pages being evicted by other operations
- Large or bloated indexes that require the engine to read more pages than necessary into the shared buffer pool
- Lack of indexes that forces the DB engine to read more pages from the tables than necessary
- Checkpoints occurring too frequently or needing to flush too many modified pages
- Sudden spikes for database connections trying to perform operations on the same page

**Actions**

We recommend different actions depending on the causes of your wait event:

- Observe Amazon CloudWatch metrics for correlation between sharp decreases in the `BufferCacheHitRatio` and `LWLock:BufferIO` wait events. This effect can mean that you have a small shared buffers setting. You might need to increase it or scale up your DB instance class. You can split your workload into more reader nodes.
- Tune `max_wal_size` and `checkpoint_timeout` based on your workload peak time if you see `LWLock:BufferIO` coinciding with `BufferCacheHitRatio` metric dips. Then identify which query might be causing it.
- Verify whether you have unused indexes, then remove them.
- Use partitioned tables (which also have partitioned indexes). Doing this helps to keep index reordering low and reduces its impact.
- Avoid indexing columns unnecessarily.
- Prevent sudden database connection spikes by using a connection pool.
- Restrict the maximum number of connections to the database as a best practice.
LWLock:buffer_content (BufferContent)

The LWLock:buffer_content event occurs when a session is waiting to read or write a data page in memory while another session has that page locked for writing. In RDS for PostgreSQL 13 and higher, this wait event is called BufferContent.

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

To read or manipulate data, PostgreSQL accesses it through shared memory buffers. To read from the buffer, a process gets a lightweight lock (LWLock) on the buffer content in shared mode. To write to the buffer, it gets that lock in exclusive mode. Shared locks allow other processes to concurrently acquire shared locks on that content. Exclusive locks prevent other processes from getting any type of lock on it.

The LWLock:buffer_content (BufferContent) event indicates that multiple processes are attempting to get a lock on contents of a specific buffer.

Likely causes of increased waits

When the LWLock:buffer_content (BufferContent) event appears more than normal, possibly indicating a performance problem, typical causes include the following:

Increased concurrent updates to the same data

There might be an increase in the number of concurrent sessions with queries that update the same buffer content. This contention can be more pronounced on tables with a lot of indexes.

Workload data is not in memory

When data that the active workload is processing is not in memory, these wait events can increase. This effect is because processes holding locks can keep them longer while they perform disk I/O operations.

Excessive use of foreign key constraints

Foreign key constraints can increase the amount of time a process holds onto a buffer content lock. This effect is because read operations require a shared buffer content lock on the referenced key while that key is being updated.

Actions

We recommend different actions depending on the causes of your wait event. You might identify LWLock:buffer_content (BufferContent) events by using Amazon RDS Performance Insights or by querying the view pg_stat_activity.

Topics

• Improve in-memory efficiency (p. 2039)
• Reduce usage of foreign key constraints (p. 2039)
• Remove unused indexes (p. 2039)
• Increase the cache size when using sequences (p. 2039)

**Improve in-memory efficiency**

To increase the chance that active workload data is in memory, partition tables or scale up your instance class. For information about DB instance classes, see DB instance classes (p. 10).

**Reduce usage of foreign key constraints**

Investigate workloads experiencing high numbers of LWLock:buffer_content (BufferContent) wait events for usage of foreign key constraints. Remove unnecessary foreign key constraints.

**Remove unused indexes**

For workloads experiencing high numbers of LWLock:buffer_content (BufferContent) wait events, identify unused indexes and remove them.

**Increase the cache size when using sequences**

If your tables uses sequences, increase the cache size to remove contention on sequence pages and index pages. Each sequence is a single page in shared memory. The pre-defined cache is per connection. This might not be enough to handle the workload when many concurrent sessions are getting a sequence value.

**LWLock:lock_manager (LWLock:lockmanager)**

This event occurs when the RDS for PostgreSQL engine maintains the shared lock's memory area to allocate, check, and deallocate a lock when a fast path lock isn't possible.

**Topics**

• Supported engine versions (p. 2039)
• Context (p. 2039)
• Likely causes of increased waits (p. 2041)
• Actions (p. 2041)

**Supported engine versions**

This wait event information is relevant for RDS for PostgreSQL version 9.6 and higher. For RDS for PostgreSQL releases older than version 13, the name of this wait event is LWLock:lock_manager. For RDS for PostgreSQL version 13 and higher, the name of this wait event is LWLock:lockmanager.

**Context**

When you issue a SQL statement, RDS for PostgreSQL records locks to protect the structure, data, and integrity of your database during concurrent operations. The engine can achieve this goal using a fast path lock or a path lock that isn't fast. A path lock that isn't fast is more expensive and creates more overhead than a fast path lock.

**Fast path locking**

To reduce the overhead of locks that are taken and released frequently, but that rarely conflict, backend processes can use fast path locking. The database uses this mechanism for locks that meet the following criteria:
• They use the DEFAULT lock method.
• They represent a lock on a database relation rather than a shared relation.
• They are weak locks that are unlikely to conflict.
• The engine can quickly verify that no conflicting locks can possibly exist.

The engine can't use fast path locking when either of the following conditions is true:
• The lock doesn't meet the preceding criteria.
• No more slots are available for the backend process.

To tune your queries for fast-path locking, you can use the following query.

```
SELECT count(*), pid, mode, fastpath
FROM pg_locks
WHERE fastpath IS NOT NULL
GROUP BY 4,3,2
ORDER BY pid, mode;
```

<table>
<thead>
<tr>
<th>count</th>
<th>pid</th>
<th>mode</th>
<th>fastpath</th>
</tr>
</thead>
<tbody>
<tr>
<td>16</td>
<td>9185</td>
<td>AccessShareLock</td>
<td>t</td>
</tr>
<tr>
<td>336</td>
<td>9185</td>
<td>AccessShareLock</td>
<td>f</td>
</tr>
<tr>
<td>1</td>
<td>9185</td>
<td>ExclusiveLock</td>
<td>t</td>
</tr>
</tbody>
</table>

The following query shows only the total across the database.

```
SELECT count(*), mode, fastpath
FROM pg_locks
WHERE fastpath IS NOT NULL
GROUP BY 3,2
ORDER BY mode,1;
```

<table>
<thead>
<tr>
<th>count</th>
<th>mode</th>
<th>fastpath</th>
</tr>
</thead>
<tbody>
<tr>
<td>16</td>
<td>AccessShareLock</td>
<td>t</td>
</tr>
<tr>
<td>337</td>
<td>AccessShareLock</td>
<td>f</td>
</tr>
<tr>
<td>1</td>
<td>ExclusiveLock</td>
<td>t</td>
</tr>
</tbody>
</table>

(3 rows)

For more information about fast path locking, see fast path in the PostgreSQL lock manager README and pg-locks in the PostgreSQL documentation.

**Example of a scaling problem for the lock manager**

In this example, a table named purchases stores five years of data, partitioned by day. Each partition has two indexes. The following sequence of events occurs:

1. You query many days worth of data, which requires the database to read many partitions.
2. The database creates a lock entry for each partition. If partition indexes are part of the optimizer access path, the database creates a lock entry for them, too.
3. When the number of requested locks entries for the same backend process is higher than 16, which is the value of FP_LOCK_SLOTS_PER_BACKEND, the lock manager uses the non–fast path lock method.

Modern applications might have hundreds of sessions. If concurrent sessions are querying the parent without proper partition pruning, the database might create hundreds or even thousands of non–fast path locks. Typically, when this concurrency is higher than the number of vCPUs, the LWLock:lock_manager wait event appears.
**Note**

The LWLock:lock_manager wait event isn't related to the number of partitions or indexes in a database schema. Instead, it's related to the number of non-fast path locks that the database must control.

**Likely causes of increased waits**

When the LWLock:lock_manager wait event occurs more than normal, possibly indicating a performance problem, the most likely causes of sudden spikes are as follows:

- Concurrent active sessions are running queries that don't use fast path locks. These sessions also exceed the maximum vCPU.
- A large number of concurrent active sessions are accessing a heavily partitioned table. Each partition has multiple indexes.
- The database is experiencing a connection storm. By default, some applications and connection pool software create more connections when the database is slow. This practice makes the problem worse. Tune your connection pool software so that connection storms don't occur.
- A large number of sessions query a parent table without pruning partitions.
- A data definition language (DDL), data manipulation language (DML), or a maintenance command exclusively locks either a busy relation or tuples that are frequently accessed or modified.

**Actions**

If the CPU wait event occurs, it doesn't necessarily indicate a performance problem. Respond to this event only when performance degrades and this wait event is dominating DB load.

**Topics**

- Use partition pruning (p. 2041)
- Remove unnecessary indexes (p. 2041)
- Tune your queries for fast path locking (p. 2042)
- Tune for other wait events (p. 2042)
- Reduce hardware bottlenecks (p. 2042)
- Use a connection pooler (p. 2042)
- Upgrade your RDS for PostgreSQL version (p. 2042)

**Use partition pruning**

*Partition pruning* is a query optimization strategy for declaratively partitioned tables that excludes unneeded partitions from table scans, thereby improving performance. Partition pruning is turned on by default. If it is turned off, turn it on as follows.

```
SET enable_partition_pruning = on;
```

Queries can take advantage of partition pruning when their WHERE clause contains the column used for the partitioning. For more information, see *Partition Pruning* in the PostgreSQL documentation.

**Remove unnecessary indexes**

Your database might contain unused or rarely used indexes. If so, consider deleting them. Do either of the following:

- Learn how to find unnecessary indexes by reading *Unused Indexes* in the PostgreSQL wiki.
Run PG Collector. This SQL script gathers database information and presents it in a consolidated HTML report. Check the "Unused indexes" section. For more information, see `pg-collector` in the AWS Labs GitHub repository.

**Tune your queries for fast path locking**

To find out whether your queries use fast path locking, query the `fastpath` column in the `pg_locks` table. If your queries aren't using fast path locking, try to reduce number of relations per query to fewer than 16.

**Tune for other wait events**

If `LWLock:lock_manager` is first or second in the list of top waits, check whether the following wait events also appear in the list:

- `Lock:Relation`
- `Lock:transactionid`
- `Lock:tuple`

If the preceding events appear high in the list, consider tuning these wait events first. These events can be a driver for `LWLock:lock_manager`.

**Reduce hardware bottlenecks**

You might have a hardware bottleneck, such as CPU starvation or maximum usage of your Amazon EBS bandwidth. In these cases, consider reducing the hardware bottlenecks. Consider the following actions:

- Scale up your instance class.
- Optimize queries that consume large amounts of CPU and memory.
- Change your application logic.
- Archive your data.

For more information about CPU, memory, and EBS network bandwidth, see Amazon RDS Instance Types.

**Use a connection pooler**

If your total number of active connections exceeds the maximum vCPU, more OS processes require CPU than your instance type can support. In this case, consider using or tuning a connection pool. For more information about the vCPUs for your instance type, see Amazon RDS Instance Types.

For more information about connection pooling, see the following resources:

- Using Amazon RDS Proxy (p. 961)
- `pgbouncer`
- Connection Pools and Data Sources in the PostgreSQL Documentation

**Upgrade your RDS for PostgreSQL version**

If your current version of RDS for PostgreSQL is lower than 12, upgrade to version 12 or higher. PostgreSQL versions 12 and later have an improved partition mechanism. For more information about version 12, see PostgreSQL 12.0 Release Notes. For more information about upgrading RDS for PostgreSQL, see Upgrading the PostgreSQL DB engine for Amazon RDS (p. 1891).
Timeout:PgSleep

The Timeout:PgSleep event occurs when a server process has called the pg_sleep function and is waiting for the sleep timeout to expire.

Topics
- Supported engine versions (p. 2043)
- Likely causes of increased waits (p. 2043)
- Actions (p. 2043)

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Likely causes of increased waits

This wait event occurs when an application, stored function, or user issues a SQL statement that calls one of the following functions:

- pg_sleep
- pg_sleep_for
- pg_sleep_until

The preceding functions delay execution until the specified number of seconds have elapsed. For example, SELECT pg_sleep(1) pauses for 1 second. For more information, see Delaying Execution in the PostgreSQL documentation.

Actions

Identify the statement that was running the pg_sleep function. Determine if the use of the function is appropriate.

Timeout:VacuumDelay

The Timeout:VacuumDelay event indicates that the cost limit for vacuum I/O has been exceeded and that the vacuum process has been put to sleep. Vacuum operations stop for the duration specified in the respective cost delay parameter and then it resumes its work. For the manual vacuum command, the delay is specified in the vacuum_cost_delay parameter. For the autovacuum daemon, the delay is specified in the autovacuum_vacuum_cost_delay parameter.

Topics
- Supported engine versions (p. 2043)
- Context (p. 2044)
- Likely causes of increased waits (p. 2044)
- Actions (p. 2045)

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.
Context

PostgreSQL has both an autovacuum daemon and a manual vacuum command. The autovacuum process is "on" by default for RDS for PostgreSQL DB instances. The manual vacuum command is used on an as-needed basis, for example, to purge tables of dead tuples or generate new statistics.

When vacuuming is underway, PostgreSQL uses an internal counter to keep track of estimated costs as the system performs various I/O operations. When the counter reaches the value specified by the cost limit parameter, the process performing the operation sleeps for the brief duration specified in the cost delay parameter. It then resets the counter and continues operations.

The vacuum process has parameters that can be used to regulate resource consumption. The autovacuum and the manual vacuum command have their own parameters for setting the cost limit value. They also have their own parameters to specify a cost delay, an amount of time to put the vacuum to sleep when the limit is reached. In this way, the cost delay parameter works as a throttling mechanism for resource consumption. In the following lists, you can find description of these parameters.

Parameters that affect throttling of the autovacuum daemon

- `autovacuum_vacuum_cost_limit` – Specifies the cost limit value to use in automatic vacuum operations. Increasing the setting for this parameter allows the vacuum process to use more resources and decreases the Timeout:VacuumDelay wait event.
- `autovacuum_vacuum_cost_delay` – Specifies the cost delay value to use in automatic vacuum operations. The default value is 2 milliseconds. Setting the delay parameter to 0 turns off the throttling mechanism and thus, the Timeout:VacuumDelay wait event won't appear.

For more information, see Automatic Vacuuming in the PostgreSQL documentation.

Parameters that affect throttling of the manual vacuum process

- `vacuum_cost_limit` – The threshold at which the vacuuming process is put to sleep. By default, the limit is 200. This number represents the accumulated cost estimates for extra I/O needed by various resources. Increasing this value reduces the number of the Timeout:VacuumDelay wait event.
- `vacuum_cost_delay` – The amount of time that the vacuum process sleeps when the vacuum cost limit has been reached. The default setting is 0, which means that this feature is off. You can set this to an integer value to specify the number of milliseconds to turn on this feature, but we recommend that you leave it at its default setting.

For more information about the `vacuum_cost_delay` parameter, see Resource Consumption in the PostgreSQL documentation.

To learn more about how to configure and use the autovacuum with RDS for PostgreSQL, see Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL (p. 1977).

Likely causes of increased waits

The Timeout:VacuumDelay is affected by the balance between the cost limit parameter settings (`vacuum_cost_limit`, `autovacuum_vacuum_cost_limit`) and the cost delay parameters (`vacuum_cost_delay`, `autovacuum_vacuum_cost_delay`) that control the vacuum's sleep duration. Raising a cost limit parameter value allows more resources to be used by the vacuum before being put to sleep. That results in fewer Timeout:VacuumDelay wait events. Increasing either of the delay parameters causes the Timeout:VacuumDelay wait event to occur more frequently and for longer periods of time.

The `autovacuum_max_worker` parameter setting can also increase numbers of the Timeout:VacuumDelay. Each additional autovacuum worker process contributes to the internal...
counter mechanism, and thus the limit can be reached more quickly than with a single autovacuum worker process. As the cost limit is reached more quickly, the cost delay is put to effect more frequently, resulting in more Timeout:VacuumDelay wait events. For more information, see autovacuum_max_worker in the PostgreSQL documentation.

Large objects, such as 500GB or larger, also raise this wait event because it can take some time for the vacuum to complete processing large objects.

Actions

If the vacuum operations complete as expected, no remediation is needed. In other words, this wait event doesn't necessarily indicate a problem. It indicates that the vacuum is being put to sleep for the period of time specified in the delay parameter so that resources can be applied to other processes that need to complete.

If you want vacuum operations to complete faster, you can lower the delay parameters. This shortens the time that the vacuum sleeps.
Using PostgreSQL extensions with Amazon RDS for PostgreSQL

You can extend the functionality of PostgreSQL by installing a variety of extensions and modules. For example, to work with spatial data you can install and use the PostGIS extension. For more information, see Managing spatial data with the PostGIS extension (p. 2081). As another example, if you want to improve data entry for very large tables, you can consider partitioning your data by using the `pg_partman` extension. To learn more, see Managing PostgreSQL partitions with the `pg_partman` extension (p. 2048).

**Note**

As of RDS for PostgreSQL 14.5, RDS for PostgreSQL supports Trusted Language Extensions for PostgreSQL. This feature is implemented as the extension `pg_tle`, which you can add to your RDS for PostgreSQL DB instance. By using this extension, developers can create their own PostgreSQL extensions in a safe environment that simplifies the setup and configuration requirements. For more information, see Working with Trusted Language Extensions for PostgreSQL (p. 2098).

In some cases, rather than installing an extension, you might add a specific module to the list of `shared_preload_libraries` in your RDS for PostgreSQL DB instance's custom DB parameter group. Typically, the default DB cluster parameter group loads only the `pg_stat_statements`, but several other modules are available to add to the list. For example, you can add scheduling capability by adding the `pg_cron` module, as detailed in Scheduling maintenance with the PostgreSQL `pg_cron` extension (p. 2061). As another example, you can log query execution plans by loading the `auto_explain` module. To learn more, see Logging execution plans of queries in the AWS knowledge center.

Depending on your version of RDS for PostgreSQL, installing an extension might require `rds_superuser` permissions, as follows:

- For RDS for PostgreSQL versions 12 and earlier versions, installing extensions requires `rds_superuser` privileges.
- For RDS for PostgreSQL version 13 and higher versions, users (roles) with create permissions on a given database instance can install and use any trusted extensions. For a list of trusted extensions, see PostgreSQL trusted extensions (p. 1860).

You can also specify precisely which extensions can be installed on your RDS for PostgreSQL DB instance, by listing them in the `rds_allowed_extensions` parameter. By default, this parameter isn't set, so any supported extension can be added if the user has permissions to do so. By adding a list of extensions to this parameter, you explicitly identify the extensions that your RDS for PostgreSQL DB instance can use. Any extensions not listed can't be installed. This capability is available for the following versions:

- RDS for PostgreSQL 14.1 and all higher versions
- RDS for PostgreSQL 13.3 and higher minor versions
- RDS for PostgreSQL 12.7 and higher minor versions

For more information, see Restricting installation of PostgreSQL extensions (p. 1859).

To learn more about the `rds_superuser` role, see Understanding PostgreSQL roles and permissions (p. 1967).

**Topics**

- Using functions from the orafce extension (p. 2047)
- Managing PostgreSQL partitions with the `pg_partman` extension (p. 2048)
Using functions from the orafce extension

The orafce extension provides functions and operators that emulate a subset of functions and packages from an Oracle database. The orafce extension makes it easier for you to port an Oracle application to PostgreSQL. RDS for PostgreSQL versions 9.6.6 and higher support this extension. For more information about orafce, see orafce on GitHub.

Note
RDS for PostgreSQL doesn't support the utl_file package that is part of the orafce extension. This is because the utl_file schema functions provide read and write operations on operating-system text files, which requires superuser access to the underlying host. As a managed service, RDS for PostgreSQL doesn't provide host access.

To use the orafce extension

1. Connect to the DB instance with the primary user name that you used to create the DB instance.

   If you want to turn on orafce for a different database in the same DB instance, use the /c dbname psql command. Using this command, you change from the primary database after initiating the connection.

2. Turn on the orafce extension with the CREATE EXTENSION statement.

    CREATE EXTENSION orafce;

3. Transfer ownership of the oracle schema to the rds_superuser role with the ALTER SCHEMA statement.

    ALTER SCHEMA oracle OWNER TO rds_superuser;

If you want to see the list of owners for the oracle schema, use the \dn psql command.
Managing PostgreSQL partitions with the `pg_partman` extension

PostgreSQL table partitioning provides a framework for high-performance handling of data input and reporting. Use partitioning for databases that require very fast input of large amounts of data. Partitioning also provides for faster queries of large tables. Partitioning helps maintain data without impacting the database instance because it requires less I/O resources.

By using partitioning, you can split data into custom-sized chunks for processing. For example, you can partition time-series data for ranges such as hourly, daily, weekly, monthly, quarterly, yearly, custom, or any combination of these. For a time-series data example, if you partition the table by hour, each partition contains one hour of data. If you partition the time-series table by day, the partitions hold one day's worth of data, and so on. The partition key controls the size of a partition.

When you use an `INSERT` or `UPDATE` SQL command on a partitioned table, the database engine routes the data to the appropriate partition. PostgreSQL table partitions that store the data are child tables of the main table.

During database query reads, the PostgreSQL optimizer examines the `WHERE` clause of the query and, if possible, directs the database scan to only the relevant partitions.

Starting with version 10, PostgreSQL uses declarative partitioning to implement table partitioning. This is also known as native PostgreSQL partitioning. Before PostgreSQL version 10, you used triggers to implement partitions.

PostgreSQL table partitioning provides the following features:

- Creation of new partitions at any time.
- Variable partition ranges.
- Detachable and reattachable partitions using data definition language (DDL) statements.

  For example, detachable partitions are useful for removing historical data from the main partition but keeping historical data for analysis.

- New partitions inherit the parent database table properties, including the following:
  - Indexes
  - Primary keys, which must include the partition key column
  - Foreign keys
  - Check constraints
  - References
- Creating indexes for the full table or each specific partition.

You can't alter the schema for an individual partition. However, you can alter the parent table (such as adding a new column), which propagates to partitions.

**Topics**

- **Overview of the PostgreSQL `pg_partman` extension (p. 2049)**
- **Enabling the `pg_partman` extension (p. 2049)**
- **Configuring partitions using the `create_parent` function (p. 2050)**
- **Configuring partition maintenance using the `run_maintenance_proc` function (p. 2051)**
Overview of the PostgreSQL pg_partman extension

You can use the PostgreSQL pg_partman extension to automate the creation and maintenance of table partitions. For more general information, see PG Partition Manager in the pg_partman documentation.

**Note**
The pg_partman extension is supported on RDS for PostgreSQL versions 12.5 and higher.

Instead of having to manually create each partition, you configure pg_partman with the following settings:

- Table to be partitioned
- Partition type
- Partition key
- Partition granularity
- Partition precreation and management options

After you create a PostgreSQL partitioned table, you register it with pg_partman by calling the create_parent function. Doing this creates the necessary partitions based on the parameters you pass to the function.

The pg_partman extension also provides the run_maintenance_proc function, which you can call on a scheduled basis to automatically manage partitions. To ensure that the proper partitions are created as needed, schedule this function to run periodically (such as hourly). You can also ensure that partitions are automatically dropped.

Enabling the pg_partman extension

If you have multiple databases inside the same PostgreSQL DB instance for which you want to manage partitions, enable the pg_partman extension separately for each database. To enable the pg_partman extension for a specific database, create the partition maintenance schema and then create the pg_partman extension as follows.

```
CREATE SCHEMA partman;
CREATE EXTENSION pg_partman WITH SCHEMA partman;
```

**Note**
To create the pg_partman extension, make sure that you have rds_superuser privileges.

If you receive an error such as the following, grant the rds_superuser privileges to the account or use your superuser account.

```
ERROR: permission denied to create extension "pg_partman"
HINT: Must be superuser to create this extension.
```

To grant rds_superuser privileges, connect with your superuser account and run the following command.

```
GRANT rds_superuser TO user-or-role;
```

For the examples that show using the pg_partman extension, we use the following sample database table and partition. This database uses a partitioned table based on a timestamp. A schema data_mart contains a table named events with a column named created_at. The following settings are included in the events table:
• Primary keys event_id and created_at, which must have the column used to guide the partition.
• A check constraint ck_valid_operation to enforce values for an operation table column.
• Two foreign keys, where one (fk_orga_membership) points to the external table organization and the other (fk_parent_event_id) is a self-referenced foreign key.
• Two indexes, where one (idx_org_id) is for the foreign key and the other (idx_event_type) is for the event type.

The follow DDL statements create these objects, which are automatically included on each partition.

```sql
CREATE SCHEMA data_mart;
CREATE TABLE data_mart.organization ( org_id BIGSERIAL,
  org_name TEXT,
  CONSTRAINT pk_organization PRIMARY KEY (org_id) );
CREATE TABLE data_mart.events(
  event_id        BIGSERIAL,
  operation       CHAR(1),
  value           FLOAT(24),
  parent_event_id BIGINT,
  event_type      VARCHAR(25),
  org_id          BIGSERIAL,
  created_at      timestamp,
  CONSTRAINT pk_data_mart_event PRIMARY KEY (event_id, created_at),
  CONSTRAINT ck_valid_operation CHECK (operation = 'C' OR operation = 'D'),
  CONSTRAINT fk_orga_membership
    FOREIGN KEY(org_id)
    REFERENCES data_mart.organization (org_id),
  CONSTRAINT fk_parent_event_id
    FOREIGN KEY(parent_event_id, created_at)
    REFERENCES data_mart.events (event_id,created_at)
) PARTITION BY RANGE (created_at);
CREATE INDEX idx_org_id     ON  data_mart.events(org_id);
CREATE INDEX idx_event_type ON  data_mart.events(event_type);
```

Configuring partitions using the create_parent function

After you enable the pg_partman extension, use the create_parent function to configure partitions inside the partition maintenance schema. The following example uses the events table example created in Enabling the pg_partman extension (p. 2049). Call the create_parent function as follows.

```sql
SELECT partman.create_parent( p_parent_table => 'data_mart.events',
  p_control => 'created_at',
  p_type => 'native',
  p_interval=> 'daily',
  p_premake => 30);
```

The parameters are as follows:

• p_parent_table – The parent partitioned table. This table must already exist and be fully qualified, including the schema.
• p_control – The column on which the partitioning is to be based. The data type must be an integer or time-based.
• p_type – The type is either 'native' or 'partman'. You typically use the native type for its performance improvements and flexibility. The partman type relies on inheritance.
• **p_interval** – The time interval or integer range for each partition. Example values include daily, hourly, and so on.

• **p_premake** – The number of partitions to create in advance to support new inserts.

For a complete description of the `create_parent` function, see *Creation Functions* in the `pg_partman` documentation.

### Configuring partition maintenance using the `run_maintenance_proc` function

You can run partition maintenance operations to automatically create new partitions, detach partitions, or remove old partitions. Partition maintenance relies on the `run_maintenance_proc` function of the `pg_partman` extension and the `pg_cron` extension, which initiates an internal scheduler. The `pg_cron` scheduler automatically executes SQL statements, functions, and procedures defined in your databases.

The following example uses the `events` table example created in *Enabling the pg_partman extension* (p. 2049) to set partition maintenance operations to run automatically. As a prerequisite, add `pg_cron` to the `shared_preload_libraries` parameter in the DB instance's parameter group.

```sql
CREATE EXTENSION pg_cron;
UPDATE partman.part_config
SET infinite_time_partitions = true,
    retention = '3 months',
    retention_keep_table=true
WHERE parent_table = 'data_mart.events';
SELECT cron.schedule('@hourly', $$CALL partman.run_maintenance_proc()$$);
```

Following, you can find a step-by-step explanation of the preceding example:

1. Modify the parameter group associated with your DB instance and add `pg_cron` to the `shared_preload_libraries` parameter value. This change requires a DB instance restart for it to take effect. For more information, see *Modifying parameters in a DB parameter group* (p. 300).

2. Run the command `CREATE EXTENSION pg_cron;` using an account that has the `rds_superuser` permissions. Doing this enables the `pg_cron` extension. For more information, see *Scheduling maintenance with the PostgreSQL pg_cron extension* (p. 2061).

3. Run the command `UPDATE partman.part_config` to adjust the `pg_partman` settings for the `data_mart.events` table.

4. Run the command `SET ...` to configure the `data_mart.events` table, with these clauses:
   a. `infinite_time_partitions = true`, – Configures the table to be able to automatically create new partitions without any limit.
   b. `retention = '3 months'`, – Configures the table to have a maximum retention of three months.
   c. `retention_keep_table=true` – Configures the table so that when the retention period is due, the table isn’t deleted automatically. Instead, partitions that are older than the retention period are only detached from the parent table.

5. Run the command `SELECT cron.schedule ...` to make a `pg_cron` function call. This call defines how often the scheduler runs the `pg_partman` maintenance procedure, `partman.run_maintenance_proc`. For this example, the procedure runs every hour.

For a complete description of the `run_maintenance_proc` function, see *Maintenance Functions* in the `pg_partman` documentation.
Using pgAudit to log database activity

Financial institutions, government agencies, and many industries need to keep audit logs to meet regulatory requirements. By using the PostgreSQL Audit extension (pgAudit) with your RDS for PostgreSQL DB instance, you can capture the detailed records that are typically needed by auditors or to meet regulatory requirements. For example, you can set up the pgAudit extension to track changes made to specific databases and tables, to record the user who made the change, and many other details.

The pgAudit extension builds on the functionality of the native PostgreSQL logging infrastructure by extending the log messages with more detail. In other words, you use the same approach to view your audit log as you do to view any log messages. For more information about PostgreSQL logging, see RDS for PostgreSQL database log files (p. 752).

The pgAudit extension redacts sensitive data such as cleartext passwords from the logs. If your RDS for PostgreSQL DB instance is configured to log data manipulation language (DML) statements as detailed in Turning on query logging for your RDS for PostgreSQL DB instance (p. 754), you can avoid the cleartext password issue by using the PostgreSQL Audit extension.

You can configure auditing on your database instances with a great degree of specificity. You can audit all databases and all users. Or, you can choose to audit only certain databases, users, and other objects. You can also explicitly exclude certain users and databases from being audited. For more information, see Excluding users or databases from audit logging (p. 2057).

Given the amount of detail that can be captured, we recommend that if you do use pgAudit, you monitor your storage consumption.

The pgAudit extension is supported on all available RDS for PostgreSQL versions. For a list of pgAudit versions supported by available RDS for PostgreSQL versions, see Extension versions for Amazon RDS for PostgreSQL in the Amazon RDS for PostgreSQL Release Notes.

Topics

- Setting up the pgAudit extension (p. 2052)
- Auditing database objects (p. 2055)
- Excluding users or databases from audit logging (p. 2057)
- Reference for the pgAudit extension (p. 2059)

Setting up the pgAudit extension

To set up the pgAudit extension on your RDS for PostgreSQL DB instance, you first add pgAudit to the shared libraries on the custom DB parameter group for your RDS for PostgreSQL DB instance. For information about creating a custom DB parameter group, see Working with parameter groups (p. 295). Next, you install the pgAudit extension. Finally, you specify the databases and objects that you want to audit. The procedures in this section show you how. You can use the AWS Management Console or the AWS CLI.

You must have permissions as the rds_superuser role to perform all these tasks.

The steps following assume that your RDS for PostgreSQL DB instance is associated with a custom DB parameter group.

Console

To set up the pgAudit extension

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose your RDS for PostgreSQL DB instance.
3. Open the Configuration tab for your RDS for PostgreSQL DB instance. Among the Instance details, find the Parameter group link.
4. Choose the link to open the custom parameters associated with your RDS for PostgreSQL DB instance.
5. In the Parameters search field, type shared_pre to find the shared_preload_libraries parameter.
6. Choose Edit parameters to access the property values.
7. Add pgaudit to the list in the Values field. Use a comma to separate items in the list of values.

8. Reboot the RDS for PostgreSQL DB instance so that your change to the shared_preload_libraries parameter takes effect.
9. When the instance is available, verify that pgAudit has been initialized. Use psql to connect to the RDS for PostgreSQL DB instance, and then run the following command.

```
SHOW shared_preload_libraries;
shared_preload_libraries
--------------------------
rdsutils,pgaudit
(1 row)
```

10. With pgAudit initialized, you can now create the extension. You need to create the extension after initializing the library because the pgaudit extension installs event triggers for auditing data definition language (DDL) statements.

```
CREATE EXTENSION pgaudit;
```

11. Close the psql session.

```
labdb=> \q
```

12. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
13. Find the pgaudit.log parameter in the list and set to the appropriate value for your use case. For example, setting the pgaudit.log parameter to write as shown in the following image captures inserts, updates, deletes, and some other types changes to the log.
You can also choose one of the following values for the `pgaudit.log` parameter.

- **none** – This is the default. No database changes are logged.
- **all** – Logs everything (read, write, function, role, ddl, misc).
- **ddl** – Logs all data definition language (DDL) statements that aren’t included in the ROLE class.
- **function** – Logs function calls and DDL blocks.
- **misc** – Logs miscellaneous commands, such as DISCARD, FETCH, CHECKPOINT, VACUUM, and SET.
- **read** – Logs SELECT and COPY when the source is a relation (such as a table) or a query.
- **role** – Logs statements related to roles and privileges, such as GRANT, REVOKE, CREATE ROLE, ALTER ROLE, and DROP ROLE.
- **write** – Logs INSERT, UPDATE, DELETE, TRUNCATE, and COPY when the destination is a relation (table).

14. Choose **Save changes**.
15. Open the Amazon RDS console at **https://console.aws.amazon.com/rds/**.
16. Choose your RDS for PostgreSQL DB instance from the Databases list to select it, and then choose **Reboot** from the Actions menu.

**AWS CLI**

**To setup pgAudit**

To setup pgAudit using the AWS CLI, you call the `modify-db-parameter-group` operation to modify the audit log parameters in your custom parameter group, as shown in the following procedure.

1. Use the following AWS CLI command to add `pgaudit` to the `shared_preload_libraries` parameter.

   ```bash
   aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters "ParameterName=shared_preload_libraries,ParameterValue=pgaudit,ApplyMethod=pending-reboot" \
   --region aws-region
   ```

2. Use the following AWS CLI command to reboot the RDS for PostgreSQL DB instance so that the pgaudit library is initialized.

   ```bash
   aws rds reboot-db-instance \
   --db-instance-identifier your-instance \
   --region aws-region
   ```
3. When the instance is available, you can verify that pgAudit has been initialized. Use psql to connect to the RDS for PostgreSQL DB instance, and then run the following command.

```sql
SHOW shared_preload_libraries;
```

```
shared_preload_libraries
--------------------------
 rdsutils,pgaudit
(1 row)
```

With pgAudit initialized, you can now create the extension.

```sql
CREATE EXTENSION pgaudit;
```

4. Close the `psql` session so that you can use the AWS CLI.

```
labdb=> \q
```

5. Use the following AWS CLI command to specify the classes of statement that want logged by session audit logging. The example sets the `pgaudit.log` parameter to write, which captures inserts, updates, and deletes to the log.

```bash
aws rds modify-db-parameter-group \
  --db-parameter-group-name custom-param-group-name \
  --parameters "ParameterName=pgaudit.log,ParameterValue=write,ApplyMethod=pending-reboot" \
  --region aws-region
```

You can also choose one of the following values for the `pgaudit.log` parameter.

- none – This is the default. No database changes are logged.
- all – Logs everything (read, write, function, role, ddl, misc).
- ddl – Logs all data definition language (DDL) statements that aren't included in the ROLE class.
- function – Logs function calls and DO blocks.
- misc – Logs miscellaneous commands, such as DISCARD, FETCH, CHECKPOINT, VACUUM, and SET.
- read – Logs SELECT and COPY when the source is a relation (such as a table) or a query.
- role – Logs statements related to roles and privileges, such as GRANT, REVOKE, CREATE ROLE, ALTER ROLE, and DROP ROLE.
- write – Logs INSERT, UPDATE, DELETE, TRUNCATE, and COPY when the destination is a relation (table).

Reboot the RDS for PostgreSQL DB instance using the following AWS CLI command.

```bash
aws rds reboot-db-instance \
  --db-instance-identifier your-instance \
  --region aws-region
```

**Auditing database objects**

With pgAudit set up on your RDS for PostgreSQL DB instance and configured for your requirements, more detailed information is captured in the PostgreSQL log. For example, while the default PostgreSQL logging configuration identifies the date and time that a change was made in a database table, with the pgAudit extension the log entry can include the schema, user who made the change, and other details.
Using pgAudit to log database activity

depending on how the extension parameters are configured. You can set up auditing to track changes in the following ways.

- For each session, by user. For the session level, you can capture the fully qualified command text.
- For each object, by user and by database.

The object auditing capability is activated when you create the rds_pgaudit role on your system and then add this role to the pgaudit.role parameter in your custom parameter parameter group. By default, the pgaudit.role parameter is unset and the only allowable value is rds_pgaudit. The following steps assume that pgaudit has been initialized and that you have created the pgaudit extension by following the procedure in Setting up the pgAudit extension (p. 2052).

As shown in this example, the "LOG: AUDIT: SESSION" line provides information about the table and its schema, among other details.

To set up object auditing

1. Use psql to connect to the RDS for PostgreSQL DB instance.

   ```bash
   psql --host=your-instance-name.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
   ```

2. Create a database role named rds_pgaudit using the following command.

   ```bash
   labdb=> CREATE ROLE rds_pgaudit;
   CREATE ROLE
   ```

3. Close the psql session.

   ```bash
   labdb=> \q
   ```

In the next few steps, use the AWS CLI to modify the audit log parameters in your custom parameter group.

4. Use the following AWS CLI command to set the pgaudit.role parameter to rds_pgaudit. By default, this parameter is empty, and rds_pgaudit is the only allowable value.

   ```bash
   aws rds modify-db-parameter-group --db-parameter-group-name custom-param-group-name --parameters "ParameterName=pgaudit.role,ParameterValue=rds_pgaudit,ApplyMethod=pending-reboot" --region aws-region
   ```

5. Use the following AWS CLI command to reboot the RDS for PostgreSQL DB instance so that your changes to the parameters take effect.

   ```bash
   aws rds reboot-db-instance --db-instance-identifier your-instance --region aws-region
   ```
6. Run the following command to confirm that the pgaudit role is set to rds_pgaudit.

```sql
SHOW pgaudit.role;
pgaudit.role
------------------
rds_pgaudit
```

To test pgAudit logging, you can run several example commands that you want to audit. For example, you might run the following commands.

```sql
CREATE TABLE t1 (id int);
GRANT SELECT ON t1 TO rds_pgaudit;
SELECT * FROM t1;
```

id
----
(0 rows)

The database logs should contain an entry similar to the following.

```
2017-06-12 19:09:49 UTC:...:rds_test@postgres:[11701]:LOG: AUDIT:
OBJECT,1,1,READ,SELECT,TABLE,public.t1,select * from t1;
```

For information on viewing the logs, see Monitoring Amazon RDS log files (p. 716).

To learn more about the pgAudit extension, see pgAudit on GitHub.

**Excluding users or databases from audit logging**

As discussed in RDS for PostgreSQL database log files (p. 752), PostgreSQL logs consume storage space. Using the pgAudit extension adds to the volume of data gathered in your logs to varying degrees, depending on the changes that you track. You might not need to audit every user or database in your RDS for PostgreSQL DB instance.

To minimize impacts to your storage and to avoid needlessly capturing audit records, you can exclude users and databases from being audited. You can also change logging within a given session. The following examples show you how.

**Note**
Parameter settings at the session level take precedence over the settings in the custom DB parameter group for the RDS for PostgreSQL DB instance. If you don’t want database users to bypass your audit logging configuration settings, be sure to change their permissions.

Suppose that your RDS for PostgreSQL DB instance is configured to audit the same level of activity for all users and databases. You then decide that you don’t want to audit the user myuser. You can turn off auditing for myuser with the following SQL command.

```sql
ALTER USER myuser SET pgaudit.log TO 'NONE';
```

Then, you can use the following query to check the user_specific_settings column for pgaudit.log to confirm that the parameter is set to NONE.

```sql
SELECT
    usename AS user_name,
    useconfig AS user_specific_settings
```

2057
You see output such as the following.

<table>
<thead>
<tr>
<th>user_name</th>
<th>user_specific_settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>myuser</td>
<td>{pgaudit.log=NONE}</td>
</tr>
</tbody>
</table>

You can turn off logging for a given user in the midst of their session with the database with the following command.

```
ALTER USER myuser IN DATABASE mydatabase SET pgaudit.log TO 'none';
```

Use the following query to check the settings column for pgaudit.log for a specific user and database combination.

```sql
SELECT
    usename AS "user_name",
    datname AS "database_name",
    pg_catalog.array_to_string(setconfig, E'\n') AS "settings"
FROM
    pg_catalog.pg_db_role_setting s
    LEFT JOIN pg_catalog.pg_database d ON d.oid = setdatabase
    LEFT JOIN pg_catalog.pg_user r ON r.usesysid = setrole
WHERE
    usename = 'myuser'
    AND datname = 'mydatabase'
ORDER BY
    1,
    2;
```

You see output similar to the following.

<table>
<thead>
<tr>
<th>user_name</th>
<th>database_name</th>
<th>settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>myuser</td>
<td>mydatabase</td>
<td>pgaudit.log=none</td>
</tr>
</tbody>
</table>

After turning off auditing for myuser, you decide that you don’t want to track changes to mydatabase.

You turn off auditing for that specific database by using the following command.

```
ALTER DATABASE mydatabase SET pgaudit.log to 'NONE';
```

Then, use the following query to check the database_specific_settings column to confirm that pgaudit.log is set to NONE.

```sql
SELECT
    a.datname AS database_name,
    b.setconfig AS database_specific_settings
FROM
    pg_database a
    FULL JOIN pg_db_role_setting b ON a.oid = b.setdatabase
WHERE
```

2058
You see output such as the following.

<table>
<thead>
<tr>
<th>database_name</th>
<th>database_specific_settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>mydatabase</td>
<td>{pgaudit.log=None}</td>
</tr>
</tbody>
</table>

To return settings to the default setting for myuser, use the following command:

```
ALTER USER myuser RESET pgaudit.log;
```

To return settings to their default setting for a database, use the following command.

```
ALTER DATABASE mydatabase RESET pgaudit.log;
```

To reset user and database to the default setting, use the following command.

```
ALTER USER myuser IN DATABASE mydatabase RESET pgaudit.log;
```

You can also capture specific events to the log by setting the `pgaudit.log` to one of the other allowed values for the `pgaudit.log` parameter. For more information, see List of allowable settings for the `pgaudit.log` parameter (p. 2060).

```
ALTER USER myuser SET pgaudit.log TO 'read';
ALTER DATABASE mydatabase SET pgaudit.log TO 'function';
ALTER USER myuser IN DATABASE mydatabase SET pgaudit.log TO 'read,function'
```

### Reference for the pgAudit extension

You can specify the level of detail that you want for your audit log by changing one or more of the parameters listed in this section.

#### Controlling pgAudit behavior

You can control the audit logging by changing one or more of the parameters listed in the following table.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pgaudit.log</code></td>
<td>Specifies the statement classes that will be logged by session audit logging. Allowable values include: <code>ddl, function, misc, read, role, write, none, all</code>. For more information, see List of allowable settings for the <code>pgaudit.log</code> parameter (p. 2060).</td>
</tr>
<tr>
<td><code>pgaudit.log_catalog</code></td>
<td>When turned on (set to 1), adds statements to audit trail if all relations in a statement are in <code>pg_catalog</code>.</td>
</tr>
<tr>
<td><code>pgaudit.log_level</code></td>
<td>Specifies the log level to use for log entries. Allowed values: <code>debug5, debug4, debug3, debug2, debug1, info, notice, warning, log</code></td>
</tr>
<tr>
<td><code>pgaudit.log_parameter</code></td>
<td>When turned on (set to 1), parameters passed with the statement are captured in the audit log.</td>
</tr>
</tbody>
</table>
### Using pgAudit to log database activity

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pgaudit.log_relation</code></td>
<td>When turned on (set to 1), the audit log for the session creates a separate log entry for each relation (TABLE, VIEW, and so on) referenced in a SELECT or DML statement.</td>
</tr>
<tr>
<td><code>pgaudit.log_statement_once</code></td>
<td>Specifies whether logging will include the statement text and parameters with the first log entry for a statement/substatement combination or with every entry.</td>
</tr>
<tr>
<td><code>pgaudit.role</code></td>
<td>Specifies the master role to use for object audit logging. The only allowable entry is <code>rds_pgaudit</code>.</td>
</tr>
</tbody>
</table>

### List of allowable settings for the `pgaudit.log` parameter

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>This is the default. No database changes are logged.</td>
</tr>
<tr>
<td>all</td>
<td>Logs everything (read, write, function, role, ddl, misc).</td>
</tr>
<tr>
<td>ddl</td>
<td>Logs all data definition language (DDL) statements that aren't included in the ROLE class.</td>
</tr>
<tr>
<td>function</td>
<td>Logs function calls and DO blocks.</td>
</tr>
<tr>
<td>misc</td>
<td>Logs miscellaneous commands, such as DISCARD, FETCH, CHECKPOINT, VACUUM, and SET.</td>
</tr>
<tr>
<td>read</td>
<td>Logs SELECT and COPY when the source is a relation (such as a table) or a query.</td>
</tr>
<tr>
<td>role</td>
<td>Logs statements related to roles and privileges, such as GRANT, REVOKE, CREATE ROLE, ALTER ROLE, and DROP ROLE.</td>
</tr>
<tr>
<td>write</td>
<td>Logs INSERT, UPDATE, DELETE, TRUNCATE, and COPY when the destination is a relation (table).</td>
</tr>
</tbody>
</table>

To log multiple event types with session auditing, use a comma-separated list. To log all event types, set `pgaudit.log` to `ALL`. Reboot your DB instance to apply the changes.

With object auditing, you can refine audit logging to work with specific relations. For example, you can specify that you want audit logging for READ operations on one or more tables.
Scheduling maintenance with the PostgreSQL 
pg_cron extension

You can use the PostgreSQL pg_cron extension to schedule maintenance commands within a PostgreSQL database. For more information about the extension, see What is pg_cron? in the pg_cron documentation.

The pg_cron extension is supported on RDS for PostgreSQL engine versions 12.5 and higher.

To learn more about using pg_cron, see Schedule jobs with pg_cron on your RDS for PostgreSQL or your Aurora PostgreSQL-Compatible Edition databases

Topics
- Setting up the pg_cron extension (p. 2061)
- Granting database users permissions to use pg_cron (p. 2061)
- Scheduling pg_cron jobs (p. 2062)
- Reference for the pg_cron extension (p. 2064)

Setting up the pg_cron extension

Set up the pg_cron extension as follows:

1. Modify the custom parameter group associated with your PostgreSQL DB instance by adding pg_cron to the shared_preload_libraries parameter value.
   - If your RDS for PostgreSQL DB instance uses the rds.allowed_extensions parameter to explicitly list extensions that can be installed, you need to add the pg_cron extension to the list. Only certain versions of RDS for PostgreSQL support the rds.allowed_extensions parameter. By default, all available extensions are allowed. For more information, see Restricting installation of PostgreSQL extensions (p. 1859).

   Restart the PostgreSQL DB instance to have changes to the parameter group take effect. To learn more about working with parameter groups, see Modifying parameters in a DB parameter group (p. 300).

2. After the PostgreSQL DB instance has restarted, run the following command using an account that has rds_superuser permissions. For example, if you used the default settings when you created your RDS for PostgreSQL DB instance, connect as user postgres and create the extension.

   ```sql
   CREATE EXTENSION pg_cron;
   ```

   The pg_cron scheduler is set in the default PostgreSQL database named postgres. The pg_cron objects are created in this postgres database and all scheduling actions run in this database.

3. You can use the default settings, or you can schedule jobs to run in other databases within your PostgreSQL DB instance. To schedule jobs for other databases within your PostgreSQL DB instance, see the example in Scheduling a cron job for a database other than postgres (p. 2063).

Granting database users permissions to use pg_cron

Installing the pg_cron extension requires the rds_superuser privileges. However, permissions to use the pg_cron can be granted (by a member of the rds_superuser group/role) to other database users, so that they can schedule their own jobs. We recommend that you grant permissions to the cron schema only as needed if it improves operations in your production environment.
To grant a database user permission in the cron schema, run the following command:

```sql
postgres=> GRANT USAGE ON SCHEMA cron TO db-user;
```

This gives `db-user` permission to access the `cron` schema to schedule cron jobs for the objects that they have permissions to access. If the database user doesn't have permissions, the job fails after posting the error message to the `postgresql.log` file, as shown in the following:

```
2020-12-08 16:41:00 UTC::@:0:[30647]:ERROR: permission denied for table table-name
2020-12-08 16:41:00 UTC::@:0:[27071]:LOG: background worker "pg_cron" (PID 30647) exited with exit code 1
```

In other words, make sure that database users that are granted permissions on the `cron` schema also have permissions on the objects (tables, schemas, and so on) that they plan to schedule.

The details of the cron job and its success or failure are also captured in the `cron.job_run_details` table. For more information, see Tables for scheduling jobs and capturing status (p. 2066).

**Scheduling pg_cron jobs**

The following sections show how you can schedule various management tasks using `pg_cron` jobs.

**Note**

When you create `pg_cron` jobs, check that the `max_worker_processes` setting is larger than the number of `cron.max_running_jobs`. A `pg_cron` job fails if it runs out of background worker processes. The default number of `pg_cron` jobs is 5. For more information, see Parameters for managing the `pg_cron` extension (p. 2064).

**Topics**

- Vacuuming a table (p. 2062)
- Purging the `pg_cron` history table (p. 2063)
- Logging errors to the `postgresql.log` file only (p. 2063)
- Scheduling a cron job for a database other than `postgres` (p. 2063)

**Vacuuming a table**

Auto vacuum handles vacuum maintenance for most cases. However, you might want to schedule a vacuum of a specific table at a time of your choosing.

See also, Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL (p. 1977).

Following is an example of using the `cron.schedule` function to set up a job to use `VACUUM FREEZE` on a specific table every day at 22:00 (GMT).

```sql
SELECT cron.schedule('manual vacuum', '0 22 * * *', 'VACUUM FREEZE pgbench_accounts');
```

<table>
<thead>
<tr>
<th>schedule</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>

(1 row)

After the preceding example runs, you can check the history in the `cron.job_run_details` table as follows.

```sql
postgres=> SELECT * FROM cron.job_run_details;
```

```
jobid  | runid | job_pid | database | username | command                        | status
| return_message | start_time | end_time
| 0 22 * * * | VACUUM FREEZE pgbench_accounts | SUCCESS |
```

---

2062
Following is an querying the `cron.job_run_details` table to see failed jobs.

```sql
postgres=> SELECT * FROM cron.job_run_details WHERE status = 'failed';
jobid | runid | job_pid | database | username | command                       | status    | start_time                    | end_time
| return_message                                   |                                     |
------+-------+---------+----------+----------+-------------------------------+----------+-------------------------------+----------
| 5     | 4     | 30339   | postgres | adminuser| vacuum freeze pgbench_account | failed    | 2020-12-04 21:48:00.015145+00 | 2020-12-04 21:48:00.029567+00
(1 row)
```

For more information, see Tables for scheduling jobs and capturing status (p. 2066).

**Purging the pg_cron history table**

The `cron.job_run_details` table contains a history of cron jobs that can become very large over time. We recommend that you schedule a job that purges this table. For example, keeping a week's worth of entries might be sufficient for troubleshooting purposes.

The following example uses the `cron.schedule` function to schedule a job that runs every day at midnight to purge the `cron.job_run_details` table. The job keeps only the last seven days. Use your `rds_superuser` account to schedule the job such as the following.

```sql
SELECT cron.schedule('0 0 * * *', $$DELETE FROM cron.job_run_details WHERE end_time < now() - interval '7 days'$$);
```

For more information, see Tables for scheduling jobs and capturing status (p. 2066).

**Logging errors to the postgresql.log file only**

To prevent writing to the `cron.job_run_details` table, modify the parameter group associated with the PostgreSQL DB instance and set the `cron.log_run` parameter to off. The `pg_cron` extension no longer writes to the table and captures errors to the `postgresql.log` file only. For more information, see Modifying parameters in a DB parameter group (p. 300).

Use the following command to check the value of the `cron.log_run` parameter.

```sql
postgres=> SHOW cron.log_run;
```

For more information, see Parameters for managing the pg_cron extension (p. 2064).

**Scheduling a cron job for a database other than postgres**

The metadata for `pg_cron` is all held in the PostgreSQL default database named `postgres`. Because background workers are used for running the maintenance cron jobs, you can schedule a job in any of your databases within the PostgreSQL DB instance:

1. In the cron database, schedule the job as you normally do using the `cron.schedule` function.
postgres=> SELECT cron.schedule('database1 manual vacuum', '29 03 * * *', 'vacuum freeze test_table');

2. As a user with the rds_superuser role, update the database column for the job that you just created so that it runs in another database within your PostgreSQL DB instance.

postgres=> UPDATE cron.job SET database = 'database1' WHERE jobid = 106;

3. Verify by querying the cron.job table.

<table>
<thead>
<tr>
<th>jobid</th>
<th>schedule</th>
<th>command</th>
<th>nodename</th>
<th>nodeport</th>
<th>database</th>
</tr>
</thead>
<tbody>
<tr>
<td>106</td>
<td>29 03 * * *</td>
<td>vacuum freeze test_table</td>
<td>localhost</td>
<td>8192</td>
<td>database1</td>
</tr>
<tr>
<td></td>
<td>t</td>
<td>database1 manual vacuum</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>59 23 * * *</td>
<td>vacuum freeze pgbench_accounts</td>
<td>localhost</td>
<td>8192</td>
<td>postgres</td>
</tr>
<tr>
<td></td>
<td>t</td>
<td>manual vacuum</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Note

In some situations, you might add a cron job that you intend to run on a different database. In such cases, the job might try to run in the default database (postgres) before you update the correct database column. If the user name has permissions, the job successfully runs in the default database.

Reference for the pg_cron extension

You can use the following parameters, functions, and tables with the pg_cron extension. For more information, see What is pg_cron? in the pg_cron documentation.

Topics

- Parameters for managing the pg_cron extension (p. 2064)
- Function reference: cron.schedule (p. 2065)
- Function reference: cron.unschedule (p. 2066)
- Tables for scheduling jobs and capturing status (p. 2066)

Parameters for managing the pg_cron extension

Following is a list of parameters that control the pg_cron extension behavior.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cron.database_name</td>
<td>The database in which pg_cron metadata is kept.</td>
</tr>
<tr>
<td>cron.host</td>
<td>The hostname to connect to PostgreSQL. You can't modify this value.</td>
</tr>
<tr>
<td>cron.log_run</td>
<td>Log every job that runs in the job_run_details table. Values are on or off. For more information, see Tables for scheduling jobs and capturing status (p. 2066).</td>
</tr>
</tbody>
</table>
### Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cron.log_statement</code></td>
<td>Log all cron statements before running them. Values are on or off.</td>
</tr>
<tr>
<td><code>cron.max_running_jobs</code></td>
<td>The maximum number of jobs that can run concurrently.</td>
</tr>
<tr>
<td><code>cron.use_background_workers</code></td>
<td>Use background workers instead of client sessions. You can’t modify this value.</td>
</tr>
</tbody>
</table>

Use the following SQL command to display these parameters and their values.

```sql
postgres=> SELECT name, setting, short_desc FROM pg_settings WHERE name LIKE 'cron.%' ORDER BY name;
```

**Function reference: `cron.schedule`**

This function schedules a cron job. The job is initially scheduled in the default `postgres` database. The function returns a `bigint` value representing the job identifier. To schedule jobs to run in other databases within your PostgreSQL DB instance, see the example in [Scheduling a cron job for a database other than `postgres` (p. 2063)](#).

The function has two syntax formats.

**Syntax**

```sql
cron.schedule (job_name, schedule, command);
cron.schedule (schedule, command);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>job_name</code></td>
<td>The name of the cron job.</td>
</tr>
<tr>
<td><code>schedule</code></td>
<td>Text indicating the schedule for the cron job. The format is the standard cron format.</td>
</tr>
<tr>
<td><code>command</code></td>
<td>Text of the command to run.</td>
</tr>
</tbody>
</table>

**Examples**

```sql
postgres=> SELECT cron.schedule ('test','0 10 * * *', 'VACUUM pgbench_history');
```

```
<table>
<thead>
<tr>
<th>schedule</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>145</td>
<td>1 row</td>
</tr>
</tbody>
</table>
```

2065
Function reference: cron.unschedule

This function deletes a cron job. You can specify either the job_name or the job_id. A policy makes sure that you are the owner to remove the schedule for the job. The function returns a Boolean indicating success or failure.

The function has the following syntax formats.

**Syntax**

```
cron.unschedule (job_id);
cron.unschedule (job_name);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_id</td>
<td>A job identifier that was returned from the cron.schedule function when the cron job was scheduled.</td>
</tr>
<tr>
<td>job_name</td>
<td>The name of a cron job that was scheduled with the cron.schedule function.</td>
</tr>
</tbody>
</table>

**Examples**

```
postgres=> SELECT cron.unschedule(108);
unschedule
---------
t  (1 row)
```

```
postgres=> SELECT cron.unschedule('test');
unschedule
---------
t  (1 row)
```

**Tables for scheduling jobs and capturing status**

The following tables are used to schedule the cron jobs and record how the jobs completed.

<table>
<thead>
<tr>
<th>Table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cron.job</td>
<td>Contains the metadata about each scheduled job. Most interactions with this table should be done by using the cron.schedule and cron.unschedule functions.</td>
</tr>
</tbody>
</table>
### Table

<table>
<thead>
<tr>
<th>Table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Important</strong>&lt;br&gt;We recommend that you don't give update or insert privileges directly to this table. Doing so would allow the user to update the <code>username</code> column to run as <code>rds_superuser</code>.</td>
<td></td>
</tr>
<tr>
<td><strong>cron.job_run_details</strong>&lt;br&gt;Contains historic information about past scheduled jobs that ran. This is useful to investigate the status, return messages, and start and end time from the job that ran.</td>
<td></td>
</tr>
<tr>
<td><strong>Note</strong>&lt;br&gt;To prevent this table from growing indefinitely, purge it on a regular basis. For an example, see [Purging the pg_cron history table](p. 2063).</td>
<td></td>
</tr>
</tbody>
</table>
Using pglogical to synchronize data across instances

All currently available RDS for PostgreSQL versions support the pglogical extension. The pglogical extension predates the functionally similar logical replication feature that was introduced by PostgreSQL in version 10. For more information, see Performing logical replication for Amazon RDS for PostgreSQL (p. 1960).

The pglogical extension supports logical replication between two or more RDS for PostgreSQL DB instances. It also supports replication between different PostgreSQL versions, and between databases running on RDS for PostgreSQL DB instances and Aurora PostgreSQL DB clusters. The pglogical extension uses a publish-subscribe model to replicate changes to tables and other objects, such as sequences, from a publisher to a subscriber. It relies on a replication slot to ensure that changes are synchronized from a publisher node to a subscriber node, defined as follows.

- The **publisher node** is the RDS for PostgreSQL DB instance that's the source of data to be replicated to other nodes. The publisher node defines the tables to be replicated in a publication set.
- The **subscriber node** is the RDS for PostgreSQL DB instance that receives WAL updates from the publisher. The subscriber creates a subscription to connect to the publisher and get the decoded WAL data. When the subscriber creates the subscription, the replication slot is created on the publisher node.

Following, you can find information about setting up the pglogical extension.

**Topics**

- Requirements and limitations for the pglogical extension (p. 2068)
- Setting up the pglogical extension (p. 2068)
- Setting up logical replication for RDS for PostgreSQL DB instance (p. 2071)
- Reestablishing logical replication after a major upgrade (p. 2073)
- Managing logical replication slots for RDS for PostgreSQL (p. 2075)
- Parameter reference for the pglogical extension (p. 2076)

**Requirements and limitations for the pglogical extension**

All currently available releases of RDS for PostgreSQL support the pglogical extension.

Both the publisher node and the subscriber node must be set up for logical replication.

The tables that you want to replicate from subscriber to publisher must have the same names and the same schema. These tables must also contain the same columns, and the columns must use the same data types. Both publisher and subscriber tables must have the same primary keys. We recommend that you use only the PRIMARY KEY as the unique constraint.

The tables on the subscriber node can have more permissive constraints than those on the publisher node for CHECK constraints and NOT NULL constraints.

The pglogical extension provides features such as two-way replication that aren't supported by the logical replication feature built into PostgreSQL (version 10 and higher). For more information, see PostgreSQL bi-directional replication using pglogical.

**Setting up the pglogical extension**

To set up the pglogical extension on your RDS for PostgreSQL DB instance, you add pglogical to the shared libraries on the custom DB parameter group for your RDS for PostgreSQL DB instance.
You also need to set the value of the `rds.logical_replication` parameter to 1, to turn on logical decoding. Finally, you create the extension in the database. You can use the AWS Management Console or the AWS CLI for these tasks.

You must have permissions as the `rds_superuser` role to perform these tasks.

The steps following assume that your RDS for PostgreSQL DB instance is associated with a custom DB parameter group. For information about creating a custom DB parameter group, see Working with parameter groups (p. 295).

### Console

**To set up the pglogical extension**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose your RDS for PostgreSQL DB instance.
3. Open the `Configuration` tab for your RDS for PostgreSQL DB instance. Among the Instance details, find the `Parameter group` link.
4. Choose the link to open the custom parameters associated with your RDS for PostgreSQL DB instance.
5. In the `Parameters` search field, type `shared_pre` to find the `shared_preload_libraries` parameter.
6. Choose `Edit parameters` to access the property values.
7. Add `pglogical` to the list in the `Values` field. Use a comma to separate items in the list of values.

8. Find the `rds.logical_replication` parameter and set it to 1, to turn on logical replication.
9. Reboot the RDS for PostgreSQL DB instance so that your changes take effect.
10. When the instance is available, you can use `psql` (or pgAdmin) to connect to the RDS for PostgreSQL DB instance.

   ```
   psql --host=11112223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
   ```

11. To verify that pglogical is initialized, run the following command.

    ```
    SHOW shared_preload_libraries;
    shared_preload_libraries
    -----------------------------------
    rdsutils,pglogical
    ```
12. Verify the setting that enables logical decoding, as follows.

```
SHOW wal_level;
wal_level
----------
logical
(1 row)
```

13. Create the extension, as follows.

```
CREATE EXTENSION pglogical;
EXTENSION CREATED
```

14. Choose **Save changes**.

15. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).

16. Choose your RDS for PostgreSQL DB instance from the Databases list to select it, and then choose **Reboot** from the Actions menu.

### AWS CLI

**To setup the pglogical extension**

To setup pglogical using the AWS CLI, you call the `modify-db-parameter-group` operation to modify certain parameters in your custom parameter group as shown in the following procedure.

1. Use the following AWS CLI command to add `pglogical` to the `shared_preload_libraries` parameter.

   ```
   aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters "ParameterName=shared_preload_libraries,ParameterValue=pglogical,ApplyMethod=pending-reboot" \
   --region aws-region
   ```

2. Use the following AWS CLI command to set `rds.logical_replication` to `1` to turn on the logical decoding capability for the RDS for PostgreSQL DB instance.

   ```
   aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters "ParameterName=rds.logical_replication,ParameterValue=1,ApplyMethod=pending-reboot" \
   --region aws-region
   ```

3. Use the following AWS CLI command to reboot the RDS for PostgreSQL DB instance so that the pglogical library is initialized.

   ```
   aws rds reboot-db-instance \
   --db-instance-identifier your-instance \
   --region aws-region
   ```

4. When the instance is available, use `psql` to connect to the RDS for PostgreSQL DB instance.

   ```
   psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
   ```

5. Create the extension, as follows.
SETUP logical replication for RDS for PostgreSQL DB instance

The following procedure shows you how to start logical replication between two RDS for PostgreSQL DB instances. The steps assume that both the source (publisher) and the target (subscriber) have the `pglogical` extension set up as detailed in Setting up the pglogical extension (p. 2068).

**To create the publisher node and define the tables to replicate**

These steps assume that your RDS for PostgreSQL DB instance has a database that has one or more tables that you want to replicate to another node. You need to recreate the table structure from the publisher on the subscriber, so, first, get the table structure if necessary. You can do that by using the `psql` metacommand `\d tablename` and then creating the same table on the subscriber instance. The following procedure creates an example table on the publisher (source) for demonstration purposes.

1. Use `psql` to connect to the instance that has the table you want to use as a source for subscribers.

```
psql --host=source-instance.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
```

If you don't have an existing table that you want to replicate, you can create a sample table as follows.

a. Create an example table using the following SQL statement.

```
CREATE TABLE docs_lab_table (a int PRIMARY KEY);
```

b. Populate the table with generated data by using the following SQL statement.

```
INSERT INTO docs_lab_table VALUES (generate_series(1,5000));
```

c. Verify that data exists in the table by using the following SQL statement.

```
SELECT count(*) FROM docs_lab_table;
```

2. Identify this RDS for PostgreSQL DB instance as the publisher node, as follows.

```
SELECT pglogical.create_node(  
    node_name := 'docs_lab_provider',  
    dsn := 'host=source-instance.aws-region.rds.amazonaws.com port=5432 dbname=labdb');
```

---

6. Reboot the RDS for PostgreSQL DB instance using the following AWS CLI command.

```
aws rds reboot-db-instance \  
    --db-instance-identifier your-instance \  
    --region aws-region
```

3. Add the table that you want to replicate to the default replication set. For more information about replication sets, see Replication sets in the pglogical documentation.

```
SELECT pglogical.replication_set_add_table('default', 'docs_lab_table', 'true', NULL, NULL);
replication_set_add_table
---------------------------
t (1 row)
```

The publisher node setup is complete. You can now set up the subscriber node to receive the updates from the publisher.

**To set up the subscriber node and create a subscription to receive updates**

These steps assume that the RDS for PostgreSQL DB instance has been set up with the pglogical extension. For more information, see Setting up the pglogical extension (p. 2068).

1. Use `psql` to connect to the instance that you want to receive updates from the publisher.

   ```
   psql --host=target-instance.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
   ```

2. On the subscriber RDS for PostgreSQL DB instance, create the same table that exists on the publisher. For this example, the table is `docs_lab_table`. You can create the table as follows.

   ```
   CREATE TABLE docs_lab_table (a int PRIMARY KEY);
   ```

3. Verify that this table is empty.

   ```
   SELECT count(*) FROM docs_lab_table;
   count
   -------
   0
   (1 row)
   ```

4. Identify this RDS for PostgreSQL DB instance as the subscriber node, as follows.

   ```
   SELECT pglogical.create_node(  
     node_name := 'docs_lab_target',  
     dsn := 'host=target-instance.aws-region.rds.amazonaws.com port=5432 sslmode=require dbname=labdb user=postgres password=******');  
create_node
---------------------------
2182738256 (1 row)
   ```

5. Create the subscription.

   ```
   SELECT pglogical.create_subscription(  
     subscription_name := 'docs_lab_subscription',  
     provider_dsn := 'host=source-instance.aws-region.rds.amazonaws.com port=5432 sslmode=require dbname=labdb user=postgres password=******',  
     replication_sets := ARRAY['default'],  
     synchronize_data := true,  
     forward_origins := '{}');  
create_subscription
---------------------
1038357190
   ```
When you complete this step, the data from the table on the publisher is created in the table on the subscriber. You can verify that this has occurred by using the following SQL query.

```
SELECT count(*) FROM docs_lab_table;
```

```sql
<table>
<thead>
<tr>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>5000</td>
</tr>
</tbody>
</table>
```

From this point forward, changes made to the table on the publisher are replicated to the table on the subscriber.

## Reestablishing logical replication after a major upgrade

Before you can perform a major version upgrade of an RDS for PostgreSQL DB instance that's set up as a publisher node for logical replication, you must drop all replication slots, even those that aren't active. We recommend that you temporarily divert database transactions from the publisher node, drop the replication slots, upgrade the RDS for PostgreSQL DB instance, and then re-establish and restart replication.

The replication slots are hosted on the publisher node only. The RDS for PostgreSQL subscriber node in a logical replication scenario has no slots to drops, but it can't be upgraded to a major version while it's designated as a subscriber node with a subscription to the publisher. Before upgrading the RDS for PostgreSQL subscriber node, drop the subscription and the node. For more information, see Managing logical replication slots for RDS for PostgreSQL (p. 2075).

## Determining that logical replication has been disrupted

You can determine that the replication process has been disrupted by querying either the publisher node or the subscriber node, as follows.

### To check the publisher node

- Use `psql` to connect to the publisher node, and then query the `pg_replication_slots` function. Note the value in the active column. Normally, this will return `t` (true), showing that replication is active. If the query returns `f` (false), it's an indication that replication to the subscriber has stopped.

```
SELECT slot_name, plugin, slot_type, active FROM pg_replication_slots;
```

```sql
<table>
<thead>
<tr>
<th>slot_name</th>
<th>plugin</th>
<th>slot_type</th>
<th>active</th>
</tr>
</thead>
<tbody>
<tr>
<td>pgl_labdb_docs_labcb4fa94_docs_lab3de412c</td>
<td>pglogical_output</td>
<td>logical</td>
<td>f</td>
</tr>
</tbody>
</table>
```

### To check the subscriber node

On the subscriber node, you can check the status of replication in three different ways.

- Look through the PostgreSQL logs on the subscriber node to find failure messages. The log identifies failure with messages that include exit code 1, as shown following.

```
2022-07-06 16:17:03 UTC::@:
[7361]: log: background worker "pglogical apply 16404:2880255011" (PID 14610) exited with exit code 1
2022-07-06 16:19:44 UTC::@:
[7361]: log: background worker "pglogical apply 16404:2880255011" (PID 21783) exited with exit code 1
```
• Query the `pg_replication_origin` function. Connect to the database on the subscriber node using `psql` and query the `pg_replication_origin` function, as follows.

```sql
SELECT * FROM pg_replication_origin;
roident | roname
---------+--------
(0 rows)
```

The empty result set means that replication has been disrupted. Normally, you see output such as the following.

```sql
roident | roname
---------+-------------------------------------
 1 | pgl_labdb_docs_labcb4fa94_docs_lab3de412c
(1 row)
```

• Query the `pglogical.show_subscription_status` function as shown in the following example.

```sql
SELECT subscription_name, status, slot_name FROM pglogical.show_subscription_status();
subscription_name | status |              slot_name
---====----------------+--------+-------------------------------------
docs_lab_subscription | down   | pgl_labdb_docs_labcb4fa94_docs_lab3de412c
(1 row)
```

This output shows that replication has been disrupted. Its status is down. Normally, the output shows the status as replicating.

If your logical replication process has been disrupted, you can re-establish replication by following these steps.

**To reestablish logical replication between publisher and subscriber nodes**

To re-establish replication, you first disconnect the subscriber from the publisher node and then re-establish the subscription, as outlined in these steps.

1. Connect to the subscriber node using `psql` as follows.

```bash
psql --host=2222222222.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
```

2. Deactivate the subscription by using the `pglogical.alter_subscription_disable` function.

```sql
SELECT pglogical.alter_subscription_disable('docs_lab_subscription',true);
alter_subscription_disable
----------------------------
t
(1 row)
```

3. Get the publisher node's identifier by querying the `pg_replication_origin`, as follows.

```sql
SELECT * FROM pg_replication_origin;
roident | roname
---------+--------
 1 | pgl_labdb_docs_labcb4fa94_docs_lab3de412c
(1 row)
```

4. Use the response from the previous step with the `pg_replication_origin_create` command to assign the identifier that can be used by the subscription when re-established.
SELECT pg_replication_origin_create('pgl_labdb_docs_labcb4fa94_docs_lab3de412c');

```sql
pg_replication_origin_create
-----------------------------
1 (1 row)
```

5. Turn on the subscription by passing its name with a status of `true`, as shown in the following example.

```sql
SELECT pglogical.alter_subscription_enable('docs_lab_subscription',true);

alter_subscription_enable
---------------------------
t (1 row)
```

Check the status of the node. Its status should be replicating as shown in this example.

```sql
SELECT subscription_name,status,slot_name
FROM pglogical.show_subscription_status();

subscription_name |   status    |              slot_name
-------------------------------+-------------+-------------------------------------
docs_lab_subscription         | replicating | pgl_labdb_docs_lab98f517b_docs_lab3de412c
(1 row)
```

Check the status of the subscriber's replication slot on the publisher node. The slot's active column should return `t` (true), indicating that replication has been re-established.

```sql
SELECT slot_name,plugin,slot_type,active
FROM pg_replication_slots;

slot_name              |      plugin      | slot_type | active
-------------------------------------------+------------------+-----------+--------
pgl_labdb_docs_lab98f517b_docs_lab3de412c | pglogical_output | logical   | t      
(1 row)
```

### Managing logical replication slots for RDS for PostgreSQL

Before you can perform a major version upgrade on an RDS for PostgreSQL DB instance that's serving as a publisher node in a logical replication scenario, you must drop the replication slots on the instance. The major version upgrade pre-check process notifies you that the upgrade can't proceed until the slots are dropped.

To drop slots from your RDS for PostgreSQL DB instance, first drop the subscription and then drop the slot.

To identify replication slots that were created using the `pglogical` extension, log in to each database and get the name of the nodes. When you query the subscriber node, you get both the publisher and the subscriber nodes in the output, as shown in this example.

```sql
SELECT * FROM pglogical.node;

node_id |     node_name
------------+-------------------
2182738256 | docs_lab_target
3410995529 | docs_lab_provider
(2 rows)
```

You can get the details about the subscription with the following query.
You can now drop the subscription, as follows.

```sql
SELECT pglogical.drop_subscription(subscription_name := 'docs_lab_subscription');
```

<table>
<thead>
<tr>
<th>drop_subscription</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>

(1 row)

After dropping the subscription, you can delete the node.

```sql
SELECT pglogical.drop_node(node_name := 'docs-lab-subscriber');
```

<table>
<thead>
<tr>
<th>drop_node</th>
</tr>
</thead>
<tbody>
<tr>
<td>t</td>
</tr>
</tbody>
</table>

(1 row)

You can verify that the node no longer exists, as follows.

```sql
SELECT * FROM pglogical.node;
```

<table>
<thead>
<tr>
<th>node_id</th>
<th>node_name</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

(0 rows)

**Parameter reference for the pglogical extension**

In the table you can find parameters associated with the pglogical extension. Parameters such as `pglogical.conflict_log_level` and `pglogical.conflict_resolution` are used to handle update conflicts. Conflicts can emerge when changes are made locally to the same tables that are subscribed to changes from the publisher. Conflicts can also occur during various scenarios, such as two-way replication or when multiple subscribers are replicating from the same publisher. For more information, see [PostgreSQL bi-directional replication using pglogical](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/USER_PgLogical.html).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pglogical.batch_inserts</td>
<td>Batch inserts if possible. Not set by default. Change to '1' to turn on, '0' to turn off.</td>
</tr>
<tr>
<td>pglogical.conflict_log_level</td>
<td>Sets the log level to use for logging resolved conflicts. Supported string values are debug5, debug4, debug3, debug2, debug1, info, notice, warning, error, log, fatal, panic.</td>
</tr>
<tr>
<td>pglogical.conflict_resolution</td>
<td>Sets method to use to resolve conflicts when conflicts are resolvable. Supported string values are error, apply_remote, keep_local, last_update_wins, first_update_wins.</td>
</tr>
<tr>
<td>pglogical.extra_connection_options</td>
<td>Connection options to add to all peer node connections.</td>
</tr>
<tr>
<td>pglogical.synchronous_commit</td>
<td>pglogical specific synchronous commit value</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>pglogical.use_spi</td>
<td>Use SPI (server programming interface) instead of low-level API to apply changes. Set to '1' to turn on, '0' to turn off. For more information about SPI, see <a href="#">Server Programming Interface</a> in the PostgreSQL documentation.</td>
</tr>
</tbody>
</table>
Reducing bloat in tables and indexes with the pg_repack extension

You can use the pg_repack extension to remove bloat from tables and indexes. This extension is supported on RDS for PostgreSQL versions 9.6.3 and higher. For more information on the pg_repack extension, see the GitHub project documentation.

To use the pg_repack extension

1. Install the pg_repack extension on your RDS for PostgreSQL DB instance by running the following command.

   ```sql
   CREATE EXTENSION pg_repack;
   ```

2. Run the following commands to grant write access to repack temporary log tables created by pg_repack.

   ```sql
   ALTER DEFAULT PRIVILEGES IN SCHEMA repack GRANT INSERT ON TABLES TO PUBLIC;
   ALTER DEFAULT PRIVILEGES IN SCHEMA repack GRANT USAGE, SELECT ON SEQUENCES TO PUBLIC;
   ```

3. Connect to the database using the pg_repack client utility. Use an account that has rds_superuser privileges. As an example, assume that rds_test role has rds_superuser privileges. The command syntax is shown following.

   ```bash
   pg_repack -h db-instance-name.111122223333.aws-region.rds.amazonaws.com -U rds_test -k postgres
   ```

   Connect using the -k option. The -a option is not supported.

4. The response from the pg_repack client provides information on the tables on the DB instance that are repacked.

   ```text
   INFO: repacking table "pgbench_tellers"
   INFO: repacking table "pgbench_accounts"
   INFO: repacking table "pgbench_branches"
   ```
Upgrading and using the PLV8 extension

PLV8 is a trusted Javascript language extension for PostgreSQL. You can use it for stored procedures, triggers, and other procedural code that's callable from SQL. This language extension is supported by all current releases of PostgreSQL.

If you use PLV8 and upgrade PostgreSQL to a new PLV8 version, you immediately take advantage of the new extension. Take the following steps to synchronize your catalog metadata with the new version of PLV8. These steps are optional, but we highly recommend that you complete them to avoid metadata mismatch warnings.

The upgrade process drops all your existing PLV8 functions. Thus, we recommend that you create a snapshot of your RDS for PostgreSQL DB instance before upgrading. For more information, see Creating a DB snapshot (p. 483).

To synchronize your catalog metadata with a new version of PLV8

1. Verify that you need to update. To do this, run the following command while connected to your instance.

   ```sql
   SELECT * FROM pg_available_extensions WHERE name IN ('plv8','plls','plcoffee');
   ```

   If your results contain values for an installed version that is a lower number than the default version, continue with this procedure to update your extensions. For example, the following result set indicates that you should update.

   | name    | default_version | installed_version | comment |
   |---------+-----------------+-------------------|---------|
   | plls    | 2.1.0           | 1.5.3             | PL/LiveScript (v8) trusted procedural language |
   | plcoffee| 2.1.0           | 1.5.3             | PL/CoffeeScript (v8) trusted procedural language |
   | plv8    | 2.1.0           | 1.5.3             | PL/JavaScript (v8) trusted procedural language |
   (3 rows)

2. Create a snapshot of your RDS for PostgreSQL DB instance if you haven't done so yet. You can continue with the following steps while the snapshot is being created.

3. Get a count of the number of PLV8 functions in your DB instance so you can validate that they are all in place after the upgrade. For example, the following SQL query returns the number of functions written in plv8, plcoffee, and plls.

   ```sql
   SELECT proname, nspname, lanname
   FROM pg_proc p, pg_language l, pg_namespace n
   WHERE p.prolang = l.oid
   AND n.oid = p.pronamespace
   AND lanname IN ('plv8','plcoffee','plls');
   ```

4. Use pg_dump to create a schema-only dump file. For example, create a file on your client machine in the /tmp directory.

   ```bash
   ./pg_dump -Fc --schema-only -U master postgres >/tmp/test.dmp
   ```

   This example uses the following options:

   - `-Fc` – Custom format
• --schema-only – Dump only the commands necessary to create schema (functions in this case)
• -U – The RDS master user name
• database – The database name for our DB instance

For more information on pg_dump, see pg_dump in the PostgreSQL documentation.

5. Extract the "CREATE FUNCTION" DDL statement that is present in the dump file. The following example uses the grep command to extract the DDL statement that creates the functions and save them to a file. You use this in subsequent steps to recreate the functions.

```
./pg_restore -l /tmp/test.dmp | grep FUNCTION > /tmp/function_list/
```

For more information on pg_restore, see pg_restore in the PostgreSQL documentation.

6. Drop the functions and extensions. The following example drops any PLV8 based objects. The cascade option ensures that any dependent are dropped.

```
DROP EXTENSION pvl8 CASCADE;
```

If your PostgreSQL instance contains objects based on plcoffee or plls, repeat this step for those extensions.

7. Create the extensions. The following example creates the plv8, plcoffee, and plls extensions.

```
CREATE EXTENSION plv8;
CREATE EXTENSION plcoffee;
CREATE EXTENSION plls;
```

8. Create the functions using the dump file and "driver" file.

The following example recreates the functions that you extracted previously.

```
./pg_restore -U master -d postgres -Fc -L /tmp/function_list /tmp/test.dmp
```

9. Verify that all your functions have been recreated by using the following query.

```
SELECT * FROM pg_available_extensions WHERE name IN ('plv8','plls','plcoffee');
```

The PLV8 version 2 adds the following extra row to your result set:

```
proname | nspname | lanname
---------+----------+---------
plv8_version | pg_catalog | plv8
```
Managing spatial data with the PostGIS extension

PostGIS is an extension to PostgreSQL for storing and managing spatial information. To learn more about PostGIS, see PostGIS.net.

Starting with version 10.5, PostgreSQL supports the libprotobuf 1.3.0 library used by PostGIS for working with map box vector tile data.

Setting up the PostGIS extension requires rds_superuser privileges. We recommend that you create a user (role) to manage the PostGIS extension and your spatial data. The PostGIS extension and its related components add thousands of functions to PostgreSQL. Consider creating the PostGIS extension in its own schema if that makes sense for your use case. The following example shows how to install the extension in its own database, but this isn’t required.

Topics

• Step 1: Create a user (role) to manage the PostGIS extension (p. 2081)
• Step 2: Load the PostGIS extensions (p. 2082)
• Step 3: Transfer ownership of the extensions (p. 2082)
• Step 4: Transfer ownership of the PostGIS objects (p. 2083)
• Step 5: Test the extensions (p. 2083)
• Step 6: Upgrade the PostGIS extension (p. 2084)
• PostGIS extension versions (p. 2084)
• Upgrading PostGIS 2 to PostGIS 3 (p. 2085)

Step 1: Create a user (role) to manage the PostGIS extension

First, connect to your RDS for PostgreSQL DB instance as a user that has rds_superuser privileges. If you kept the default name when you set up your instance, you connect as postgres.

```sql
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
```

Create a separate role (user) to administer the PostGIS extension.

```sql
postgres=> CREATE ROLE gis_admin LOGIN PASSWORD 'change_me';
```

Grant this role rds_superuser privileges, to allow the role to install the extension.

```sql
postgres=> GRANT rds_superuser TO gis_admin;
```

Create a database to use for your PostGIS artifacts. This step is optional. Or you can create a schema in your user database for the PostGIS extensions, but this also isn’t required.

```sql
postgres=> CREATE DATABASE lab_gis;
```

Give the gis_admin all privileges on the lab_gis database.

```sql
postgres=> GRANT ALL PRIVILEGES ON DATABASE lab_gis TO gis_admin;
```
Exit the session and reconnect to your RDS for PostgreSQL DB instance as gis_admin.

postgres=> --host=11112223333.aws-region.rds.amazonaws.com --port=5432 --username=gis_admin --password --dbname=lab_gis
Password for user gis_admin:...
lab_gis=>

Continue setting up the extension as detailed in the next steps.

**Step 2: Load the PostGIS extensions**

The PostGIS extension includes several related extensions that work together to provide geospatial functionality. Depending on your use case, you might not need all the extensions created in this step.

Use `CREATE EXTENSION` statements to load the PostGIS extensions.

```
CREATE EXTENSION postgis;
CREATE EXTENSION postgis_raster;
CREATE EXTENSION postgis_tiger_geocoder;
CREATE EXTENSION postgis_topology;
CREATE EXTENSION fuzzystrmatch;
CREATE EXTENSION address_standardizer_data_us;
```

You can verify the results by running the SQL query shown in the following example, which lists the extensions and their owners.

```
SELECT n.nspname AS "Name",
       pg_catalog.pg_get_userbyid(n.nspowner) AS "Owner"
FROM pg_catalog.pg_namespace n
WHERE n.nspname !~ '^pg_' AND n.nspname <> 'information_schema'
ORDER BY 1;
```

<table>
<thead>
<tr>
<th>List of schemas</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>-------</td>
</tr>
<tr>
<td>public</td>
</tr>
<tr>
<td>tiger</td>
</tr>
<tr>
<td>tiger_data</td>
</tr>
<tr>
<td>topology</td>
</tr>
<tr>
<td>(4 rows)</td>
</tr>
</tbody>
</table>

**Step 3: Transfer ownership of the extensions**

Use the `ALTER SCHEMA` statements to transfer ownership of the schemas to the gis_admin role.

```
ALTER SCHEMA tiger OWNER TO gis_admin;
ALTER SCHEMA tiger_data OWNER TO gis_admin;
ALTER SCHEMA topology OWNER TO gis_admin;
```
You can confirm the ownership change by running the following SQL query. Or you can use the \dn
metacommand from the psql command line.

```
SELECT n.nspname AS "Name",
pg_catalog.pg_get_userbyid(n.nspowner) AS "Owner"
FROM pg_catalog.pg_namespace n
WHERE n.nspname !~ '^pg_' AND n.nspname <> 'information_schema'
ORDER BY 1;
```

<table>
<thead>
<tr>
<th>Name</th>
<th>Owner</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>postgres</td>
</tr>
<tr>
<td>tiger</td>
<td>gis_admin</td>
</tr>
<tr>
<td>tiger_data</td>
<td>gis_admin</td>
</tr>
<tr>
<td>topology</td>
<td>gis_admin</td>
</tr>
</tbody>
</table>

(4 rows)

Step 4: Transfer ownership of the PostGIS objects

Use the following function to transfer ownership of the PostGIS objects to the gis_admin role. Run the following statement from the psql prompt to create the function.

```
CREATE FUNCTION exec(text) returns text language plpgsql volatile AS $f$
BEGIN
EXECUTE $1;
RETURN $1;
END;
$f$
```

Next, run the following query to run the exec function that in turn runs the statements and alters the permissions.

```
SELECT exec('ALTER TABLE ' || quote_ident(s.nspname) || '.' || quote_ident(s.relname) || ' OWNER TO gis_admin;')
FROM (
    SELECT nspname, relname
    FROM pg_class c JOIN pg_namespace n ON (c.relnamespace = n.oid)
    WHERE nspname in ('tiger','topology') AND
    relkind IN ('r','S','v') ORDER BY relkind = 'S')
s;
```

Step 5: Test the extensions

To avoid needing to specify the schema name, add the tiger schema to your search path using the following command.

```
SET search_path=public,tiger;
```

Test the tiger schema by using the following SELECT statement.

```
SELECT address, streetname, streettypeabbrev, zip
FROM normalize_address('1 Devonshire Place, Boston, MA 02109') AS na;
```

<table>
<thead>
<tr>
<th>address</th>
<th>streetname</th>
<th>streettypeabbrev</th>
<th>zip</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Devonshire</td>
<td>Pl</td>
<td>02109</td>
</tr>
</tbody>
</table>

(1 row)

To learn more about this extension, see Tiger Geocoder in the PostGIS documentation.
Test access to the topology schema by using the following SELECT statement. This calls the `createtopology` function to register a new topology object (`my_new_topo`) with the specified spatial reference identifier (26986) and default tolerance (0.5). To learn more, see [CreateTopology](#) in the PostGIS documentation.

```
SELECT topology.createtopology('my_new_topo',26986,0.5);
```

### Step 6: Upgrade the PostGIS extension

Each new release of PostgreSQL supports one or more versions of the PostGIS extension compatible with that release. Upgrading the PostgreSQL engine to a new version doesn't automatically upgrade the PostGIS extension. Before upgrading the PostgreSQL engine, you typically upgrade PostGIS to the newest available version for the current PostgreSQL version. For details, see [PostGIS extension versions](#).

After the PostgreSQL engine upgrade, you then upgrade the PostGIS extension again, to the version supported for the newly upgraded PostgreSQL engine version. For more information about upgrading the PostgreSQL engine, see [How to perform a major version upgrade](#).

You can check for available PostGIS extension version updates on your RDS for PostgreSQL DB instance at any time. To do so, run the following command. This function is available with PostGIS 2.5.0 and higher versions.

```
SELECT postGIS_extensions_upgrade();
```

If your application doesn't support the latest PostGIS version, you can install an older version of PostGIS that's available in your major version as follows.

```
CREATE EXTENSION postgis VERSION "2.5.5";
```

If you want to upgrade to a specific PostGIS version from an older version, you can also use the following command.

```
ALTER EXTENSION postgis UPDATE TO "2.5.5";
```

Depending on the version that you're upgrading from, you might need to use this function again. The result of the first run of the function determines if an additional upgrade function is needed. For example, this is the case for upgrading from PostGIS 2 to PostGIS 3. For more information, see [Upgrading PostGIS 2 to PostGIS 3](#).

If you upgraded this extension to prepare for a major version upgrade of the PostgreSQL engine, you can continue with other preliminary tasks. For more information, see [How to perform a major version upgrade](#).

### PostGIS extension versions

We recommend that you install the versions of all extensions such as PostGIS as listed in [Extension versions for Amazon RDS for PostgreSQL](#) in the [Amazon RDS for PostgreSQL Release Notes](#). To get a list of versions that are available in your release, use the following command.

```
SELECT * FROM pg_available_extension_versions WHERE name='postgis';
```
You can find version information in the following sections in the Amazon RDS for PostgreSQL Release Notes:

- PostgreSQL version 14 extensions supported on Amazon RDS
- PostgreSQL version 13 extensions supported on Amazon RDS
- PostgreSQL version 12 extensions supported on Amazon RDS
- PostgreSQL version 11 extensions supported on Amazon RDS
- PostgreSQL version 10 extensions supported on Amazon RDS
- PostgreSQL version 9.6.x extensions supported on Amazon RDS

Upgrading PostGIS 2 to PostGIS 3

Starting with version 3.0, the PostGIS raster functionality is now a separate extension, postgis_raster. This extension has its own installation and upgrade path. This removes dozens of functions, data types, and other artifacts required for raster image processing from the core postgis extension. That means that if your use case doesn't require raster processing, you don't need to install the postgis_raster extension.

In the following upgrade example, the first upgrade command extracts raster functionality into the postgis_raster extension. A second upgrade command is then required to upgrade postgres_raster to the new version.

To upgrade from PostGIS 2 to PostGIS 3

1. Identify the default version of PostGIS that's available to the PostgreSQL version on your RDS for PostgreSQL DB instance. To do so, run the following query.

```
SELECT * FROM pg_available_extensions
    WHERE default_version > installed_version;
```

| name   | default_version | installed_version | comment                                                                 |
|--------+----------------+------------------|-------------------------------------------------------------------------|
| postgis| 3.1.4           | 2.3.7            | PostGIS geometry and geography spatial types and functions              |

(1 row)

2. Identify the versions of PostGIS installed in each database on your RDS for PostgreSQL DB instance. In other words, query each user database as follows.

```
SELECT e.extname AS "Name",
       e.extversion AS "Version",
       n.nspname AS "Schema",
       c.description AS "Description"
FROM pg_catalog.pg_extension e
    LEFT JOIN pg_catalog.pg_namespace n ON n.oid = e.extnamespace
    LEFT JOIN pg_catalog.pg_description c ON c.objoid = e.oid
    AND c.classoid = 'pg_catalog.pg_extension'::pg_catalog.regclass
WHERE e.extname LIKE '%postgis%'
ORDER BY 1;
```

<table>
<thead>
<tr>
<th>Name</th>
<th>Version</th>
<th>Schema</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>postgis</td>
<td>2.3.7</td>
<td>public</td>
<td>PostGIS geometry, geography, and raster spatial types and functions</td>
</tr>
</tbody>
</table>
This mismatch between the default version (PostGIS 3.1.4) and the installed version (PostGIS 2.3.7) means that you need to upgrade the PostGIS extension.

```
ALTER EXTENSION postgis UPDATE;
ALTER EXTENSION
WARNING: unpackaging raster
WARNING: PostGIS Raster functionality has been unpackaged
```

3. Run the following query to verify that the raster functionality is now in its own package.

```
SELECT
  probin,
  count(*)
FROM
  pg_proc
WHERE
  probin LIKE '%postgis%'
GROUP BY
  probin;
```

<table>
<thead>
<tr>
<th>probin</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>$libdir/rtpostgis-2.3</td>
<td>107</td>
</tr>
<tr>
<td>$libdir/postgis-3</td>
<td>487</td>
</tr>
</tbody>
</table>

The output shows that there's still a difference between versions. The PostGIS functions are version 3 (postgis-3), while the raster functions (rtpostgis) are version 2 (rtpostgis-2.3). To complete the upgrade, you run the upgrade command again, as follows.

```
postgres=> SELECT postgis_extensions_upgrade();
```

You can safely ignore the warning messages. Run the following query again to verify that the upgrade is complete. The upgrade is complete when PostGIS and all related extensions aren't marked as needing upgrade.

```
SELECT postgis_full_version();
```

4. Use the following query to see the completed upgrade process and the separately packaged extensions, and verify that their versions match.

```
SELECT
  e.extname AS "Name",
  e.extversion AS "Version",
  n.nspname AS "Schema",
  c.description AS "Description"
FROM
  pg_catalog.pg_extension e
LEFT JOIN pg_catalog.pg_namespace n ON n.oid = e.extnamespace
LEFT JOIN pg_catalog.pg_description c ON c.objoid = e.oid
  AND c.classoid = 'pg_catalog.pg_extension'::pg_catalog.regclass
WHERE
  e.extname LIKE '%postgis%'
ORDER BY
  1;
```

<table>
<thead>
<tr>
<th>Name</th>
<th>Version</th>
<th>Schema</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>+---------------------------------------------</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The output shows that the PostGIS 2 extension was upgraded to PostGIS 3, and both `postgis` and the now separate `postgis_raster` extension are version 3.1.5.

After this upgrade completes, if you don't plan to use the raster functionality, you can drop the extension as follows.

```
DROP EXTENSION postgis_raster;
```
A foreign data wrapper (FDW) is a specific type of extension that provides access to external data. For example, the oracle_fdw extension allows your RDS for PostgreSQL DB cluster to work with Oracle databases. As another example, by using the PostgreSQL native postgres_fdw extension you can access data stored in PostgreSQL DB instances external to your RDS for PostgreSQL DB instance.

Following, you can find information about several supported PostgreSQL foreign data wrappers.

**Topics**

- Using the log_fdw extension to access the DB log using SQL (p. 2088)
- Using the postgres_fdw extension to access external data (p. 2089)
- Working with MySQL databases by using the mysql_fdw extension (p. 2090)
- Working with Oracle databases by using the oracle_fdw extension (p. 2093)
- Working with SQL Server databases by using the tds_fdw extension (p. 2096)

**Using the log_fdw extension to access the DB log using SQL**

RDS for PostgreSQL supports the log_fdw extension, which you can use to access your database engine log using a SQL interface. The log_fdw extension provides two functions that make it easy to create foreign tables for database logs:

- list_postgres_log_files - Lists the files in the database log directory and the file size in bytes.
- create_foreign_table_for_log_file(table_name text, server_name text, log_file_name text) – Builds a foreign table for the specified file in the current database.

All functions created by log_fdw are owned by rds_superuser. Members of the rds_superuser role can grant access to these functions to other database users.

By default, the log files are generated by Amazon RDS in stderr (standard error) format, as specified in log_destination parameter. There are only two options for this parameter, stderr and csvlog (comma-separated values, CSV). If you add the csvlog option to the parameter, Amazon RDS generates both stderr and csvlog logs. This can affect the storage capacity on your instance, so you need to be aware of the other parameters that affect log handling. For more information, see Setting the log destination (stderr, csvlog) (p. 754).

One benefit of generating csvlog logs is that the log_fdw extension lets you build foreign tables with the data neatly split into several columns. To do this, your instance needs to be associated with a custom DB parameter group so that you can change the setting for log_destination. For more information about how to do so, see Working with parameters on your RDS for PostgreSQL DB instance (p. 1986).

The following example assumes that the log_destination parameter includes csvlog.

**To use the log_fdw extension**

1. Get the log_fdw extension.

   ```sql
   postgres=> CREATE EXTENSION log_fdw;
   CREATE EXTENSION
   ```
2. Create the log server as a foreign data wrapper.

```sql
postgres=> CREATE SERVER log_server FOREIGN DATA WRAPPER log_fdw;
```

3. Select all from a list of log files.

```sql
postgres=> SELECT * FROM list_postgres_log_files() ORDER BY 1;
```

A sample response is as follows.

<table>
<thead>
<tr>
<th>file_name</th>
<th>file_size_bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>postgresql.log.2016-08-09-22.csv</td>
<td>1111</td>
</tr>
<tr>
<td>postgresql.log.2016-08-09-23.csv</td>
<td>1172</td>
</tr>
<tr>
<td>postgresql.log.2016-08-10-00.csv</td>
<td>1744</td>
</tr>
<tr>
<td>postgresql.log.2016-08-10-01.csv</td>
<td>1102</td>
</tr>
</tbody>
</table>

(4 rows)

4. Create a table with a single 'log_entry' column for the selected file.

```sql
postgres=> SELECT create_foreign_table_for_log_file('my_postgres_error_log', 'log_server', 'postgresql.log.2016-08-09-22.csv');
```

The response provides no detail other than that the table now exists.

```
(1 row)
```

5. Select a sample of the log file. The following code retrieves the log time and error message description.

```sql
postgres=> SELECT log_time, message FROM my_postgres_error_log ORDER BY 1;
```

A sample response is as follows.

<table>
<thead>
<tr>
<th>log_time</th>
<th>message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tue Aug 09 15:45:18.172 2016 PDT</td>
<td>ending log output to stderr</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.175 2016 PDT</td>
<td>database system was interrupted; last known up at 2016-08-09 22:43:34 UTC</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.223 2016 PDT</td>
<td>checkpoint record is at 0/90002E0</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.223 2016 PDT</td>
<td>redo record is at 0/90002A8; shutdown FALSE</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.223 2016 PDT</td>
<td>next transaction ID: 0/1879; next OID: 24578</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.223 2016 PDT</td>
<td>next MultiXactId: 1; next MultiXactOffset: 0</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.223 2016 PDT</td>
<td>oldest unfrozen transaction ID: 1822, in database 1</td>
</tr>
</tbody>
</table>

(7 rows)

---

**Using the postgres_fdw extension to access external data**

You can access data in a table on a remote database server with the `postgres_fdw` extension. If you set up a remote connection from your PostgreSQL DB instance, access is also available to your read replica.
To use postgres_fdw to access a remote database server

1. Install the postgres_fdw extension.

   ```sql
   CREATE EXTENSION postgres_fdw;
   ```

2. Create a foreign data server using CREATE SERVER.

   ```sql
   CREATE SERVER foreign_server
   FOREIGN DATA WRAPPER postgres_fdw
   OPTIONS (host 'xxx.xx.xxx.xx', port '5432', dbname 'foreign_db');
   ```

3. Create a user mapping to identify the role to be used on the remote server.

   ```sql
   CREATE USER MAPPING FOR local_user
   SERVER foreign_server
   OPTIONS (user 'foreign_user', password 'password');
   ```

4. Create a table that maps to the table on the remote server.

   ```sql
   CREATE FOREIGN TABLE foreign_table (
       id integer NOT NULL,
       data text
   )
   SERVER foreign_server
   OPTIONS (schema_name 'some_schema', table_name 'some_table');
   ```

Working with MySQL databases by using the mysql_fdw extension

To access a MySQL-compatible database from your RDS for PostgreSQL DB instance, you can install and use the mysql_fdw extension. This foreign data wrapper lets you work with RDS for MySQL, Aurora MySQL, MariaDB, and other MySQL-compatible databases. The connection from RDS for PostgreSQL to the MySQL database is encrypted on a best-effort basis, depending on the client and server configurations. However, you can enforce encryption if you like. For more information, see Using encryption in transit with the extension (p. 2093).

The mysql_fdw extension is supported on Amazon RDS for PostgreSQL version 14.2, 13.6, and higher releases. It supports selects, inserts, updates, and deletes from an RDS for PostgreSQL DB to tables on a MySQL-compatible database instance.

Topics

- Setting up your RDS for PostgreSQL DB to use the mysql_fdw extension (p. 2090)
- Example: Working with an RDS for MySQL database from RDS for PostgreSQL (p. 2092)
- Using encryption in transit with the extension (p. 2093)

Setting up your RDS for PostgreSQL DB to use the mysql_fdw extension

Setting up the mysql_fdw extension on your RDS for PostgreSQL DB instance involves loading the extension in your DB instance and then creating the connection point to the MySQL DB instance. For that task, you need to have the following details about the MySQL DB instance:
• Hostname or endpoint. For an RDS for MySQL DB instance, you can find the endpoint by using the Console. Choose the Connectivity & security tab and look in the "Endpoint and port" section.
• Port number. The default port number for MySQL is 3306.
• Name of the database. The DB identifier.

You also need to provide access on the security group or the access control list (ACL) for the MySQL port, 3306. Both the RDS for PostgreSQL DB instance and the RDS for MySQL DB instance need access to port 3306. If access isn’t configured correctly, when you try to connect to MySQL-compatible table you see an error message similar to the following:

```
ERROR: failed to connect to MySQL: Can't connect to MySQL server on 'hostname.aws-region.rds.amazonaws.com:3306' (110)
```

In the following procedure, you (as the rds_superuser account) create the foreign server. You then grant access to the foreign server to specific users. These users then create their own mappings to the appropriate MySQL user accounts to work with the MySQL DB instance.

**To use mysql_fdw to access a MySQL database server**

1. Connect to your PostgreSQL DB instance using an account that has the rds_superuser role. If you accepted the defaults when you created your RDS for PostgreSQL DB instance, the user name is postgres, and you can connect using the psql command line tool as follows:

   ```
   psql --host=your-DB-instance.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   ```

2. Install the mysql_fdw extension as follows:

   ```
   postgres=> CREATE EXTENSION mysql_fdw;
   ```

   After the extension is installed on your RDS for PostgreSQL DB instance, you set up the foreign server that provides the connection to a MySQL database.

**To create the foreign server**

Perform these tasks on the RDS for PostgreSQL DB instance. The steps assume that you’re connected as a user with rds_superuser privileges, such as postgres.

1. Create a foreign server in the RDS for PostgreSQL DB instance:

   ```
   postgres=> CREATE SERVER mysql-db FOREIGN DATA WRAPPER mysql_fdw OPTIONS (host 'db-name.111122223333.aws-region.rds.amazonaws.com', port '3306');
   ```

2. Grant the appropriate users access to the foreign server. These should be non-administrator users, that is, users without the rds_superuser role.

   ```
   postgres=> GRANT USAGE ON FOREIGN SERVER mysql-db to user1;
   ```

   PostgreSQL users create and manage their own connections to the MySQL database through the foreign server.
Example: Working with an RDS for MySQL database from RDS for PostgreSQL

Suppose that you have a simple table on an RDS for MySQL DB instance. Your RDS for PostgreSQL users want to query (SELECT), INSERT, UPDATE, and DELETE items on that table. Assume that the mysql_fdw extension was created on your RDS for PostgreSQL DB instance, as detailed in the preceding procedure. After you connect to the RDS for PostgreSQL DB instance as a user that has rds_superuser privileges, you can proceed with the following steps.

1. On the RDS for PostgreSQL DB instance, create a foreign server:

   ```sql
   test=> CREATE SERVER mysqldb FOREIGN DATA WRAPPER mysql_fdw OPTIONS (host 'your-DB.aws-region.rds.amazonaws.com', port '3306');
   CREATE SERVER
   ```

2. Grant usage to a user who doesn't have rds_superuser permissions, for example, user1:

   ```sql
   test=> GRANT USAGE ON FOREIGN SERVER mysqldb TO user1;
   GRANT
   ```

3. Connect as user1, and then create a mapping to the MySQL user:

   ```sql
   test=> CREATE USER MAPPING FOR user1 SERVER mysqldb OPTIONS (username 'myuser', password 'mypassword');
   CREATE USER MAPPING
   ```

4. Create a foreign table linked to the MySQL table:

   ```sql
   test=> CREATE FOREIGN TABLE mytab (a int, b text) SERVER mysqldb OPTIONS (dbname 'test', table_name '');
   CREATE FOREIGN TABLE
   ```

5. Run a simple query against the foreign table:

   ```sql
   test=> SELECT * FROM mytab;
   a |   b
   ----+-------
   1 | apple
   (1 row)
   ```

6. You can add, change, and remove data from the MySQL table. For example:

   ```sql
   test=> INSERT INTO mytab values (2, 'mango');
   INSERT 0 1
   ```

   Run the SELECT query again to see the results:

   ```sql
   test=> SELECT * FROM mytab ORDER BY 1;
   a |   b
   ----+-------
   1 | apple
   2 | mango
   (2 rows)
   ```
Using encryption in transit with the extension

The connection to MySQL from RDS for PostgreSQL uses encryption in transit (TLS/SSL) by default. However, the connection falls back to non-encrypted when the client and server configuration differ. You can enforce encryption for all outgoing connections by specifying the REQUIRE SSL option on the RDS for MySQL user accounts. This same approach also works for MariaDB and Aurora MySQL user accounts.

For MySQL user accounts configured to REQUIRE SSL, the connection attempt fails if a secure connection can't be established.

To enforce encryption for existing MySQL database user accounts, you can use the ALTER USER command. The syntax varies, depending on the MySQL version, as shown in the following table. For more information, see ALTER USER in MySQL Reference Manual.

<table>
<thead>
<tr>
<th>MySQL 5.7, MySQL 8</th>
<th>MySQL 5.6</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTER USER 'user'@'%' REQUIRE SSL;</td>
<td>GRANT USAGE ON <em>.</em> to 'user'@'%'; REQUIRE SSL;</td>
</tr>
</tbody>
</table>

For more information about the mysql_fdw extension, see the mysql_fdw documentation.

Working with Oracle databases by using the oracle_fdw extension

To access an Oracle database from your RDS for PostgreSQL DB instance you can install and use the oracle_fdw extension. This extension is a foreign data wrapper for Oracle databases. To learn more about this extension, see the oracle_fdw documentation.

The oracle_fdw extension is supported on RDS for PostgreSQL 12.7, 13.3, and higher versions.

Topics
- Turning on the oracle_fdw extension (p. 2093)
- Example: Using a foreign server linked to an Amazon RDS for Oracle database (p. 2093)
- Working with encryption in transit (p. 2094)
- Understanding the pg_user_mappings view and permissions (p. 2094)

Turning on the oracle_fdw extension

To use the oracle_fdw extension, perform the following procedure.

To turn on the oracle_fdw extension

- Run the following command using an account that has rds_superuser permissions.

```
CREATE EXTENSION oracle_fdw;
```

Example: Using a foreign server linked to an Amazon RDS for Oracle database

The following example shows the use of a foreign server linked to an Amazon RDS for Oracle database.
To create a foreign server linked to an RDS for Oracle database

1. Note the following on the RDS for Oracle DB instance:
   - Endpoint
   - Port
   - Database name

2. Create a foreign server.
   ```
   test=> CREATE SERVER oradb FOREIGN DATA WRAPPER oracle_fdw OPTIONS (dbserver '//endpoint:port/DB_name');
   CREATE SERVER
   ```

3. Grant usage to a user who doesn't have rds_superuser privileges, for example user1.
   ```
   test=> GRANT USAGE ON FOREIGN SERVER oradb TO user1;
   GRANT
   ```

4. Connect as user1, and create a mapping to an Oracle user.
   ```
   test=> CREATE USER MAPPING FOR user1 SERVER oradb OPTIONS (user 'oracleuser', password 'mypassword');
   CREATE USER MAPPING
   ```

5. Create a foreign table linked to an Oracle table.
   ```
   test=> CREATE FOREIGN TABLE mytab (a int) SERVER oradb OPTIONS (table 'MYTABLE');
   CREATE FOREIGN TABLE
   ```

6. Query the foreign table.
   ```
   test=> SELECT * FROM mytab;
   a
   ---
   1
   (1 row)
   ```

If the query reports the following error, check your security group and access control list (ACL) to make sure that both instances can communicate.
```
ERROR: connection for foreign table "mytab" cannot be established
DETAIL: ORA-12170: TNS:Connect timeout occurred
```
pg_user_mappings view to see the mappings. In the following, you can find an example that shows how permissions apply with an example Oracle database, but this information applies more generally to any foreign data wrapper.

In the following output, you can find roles and permissions mapped to three different example users. Users `rdssu1` and `rdssu2` are members of the `rds_superuser` role, and `user1` isn’t. The example uses the `psql` metacommand `\du` to list existing roles.

<table>
<thead>
<tr>
<th>Users</th>
<th>Role name</th>
<th>Attributes</th>
<th>Member of</th>
</tr>
</thead>
<tbody>
<tr>
<td>rdssu1</td>
<td></td>
<td></td>
<td>{rds_superuser}</td>
</tr>
<tr>
<td>rdssu2</td>
<td></td>
<td></td>
<td>{rds_superuser}</td>
</tr>
<tr>
<td>user1</td>
<td></td>
<td></td>
<td>{}</td>
</tr>
</tbody>
</table>

All users, including users that have `rds_superuser` privileges, are allowed to view their own user mappings (`umoptions`) in the `pg_user_mappings` table. As shown in the following example, when `rdssu1` tries to obtain all user mappings, an error is raised even though `rdssu1` has `rds_superuser` privileges:

```
test=> SELECT * FROM pg_user_mapping;
ERROR: permission denied for table pg_user_mapping
```

Following are some examples.

<table>
<thead>
<tr>
<th>Command</th>
<th>Session Authorization</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>test=&gt;</td>
<td><code>\du</code></td>
<td>List of roles</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Role name</td>
</tr>
<tr>
<td></td>
<td></td>
<td>-----------------------------------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>rdssu1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>{rds_superuser}</td>
</tr>
<tr>
<td></td>
<td></td>
<td>rdssu2</td>
</tr>
<tr>
<td></td>
<td></td>
<td>{rds_superuser}</td>
</tr>
<tr>
<td></td>
<td></td>
<td>user1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>{}</td>
</tr>
</tbody>
</table>

Here are some examples:

```
test=> SELECT * FROM pg_user_mappings;
```

```
<table>
<thead>
<tr>
<th>umid</th>
<th>srvid</th>
<th>srvname</th>
<th>umuser</th>
<th>usename</th>
<th>umoptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>16414</td>
<td>16411</td>
<td>oradb</td>
<td>16412</td>
<td>user1</td>
<td></td>
</tr>
<tr>
<td>16423</td>
<td>16411</td>
<td>oradb</td>
<td>16421</td>
<td>rdssu1</td>
<td>{user=oracleuser,password=mypwd}</td>
</tr>
<tr>
<td>16424</td>
<td>16411</td>
<td>oradb</td>
<td>16422</td>
<td>rdssu2</td>
<td></td>
</tr>
</tbody>
</table>
```

```
test=> SELECT * FROM pg_user_mappings;
```

```
<table>
<thead>
<tr>
<th>umid</th>
<th>srvid</th>
<th>srvname</th>
<th>umuser</th>
<th>usename</th>
<th>umoptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>16414</td>
<td>16411</td>
<td>oradb</td>
<td>16412</td>
<td>user1</td>
<td></td>
</tr>
<tr>
<td>16423</td>
<td>16411</td>
<td>oradb</td>
<td>16421</td>
<td>rdssu1</td>
<td>{user=oracleuser,password=mypwd}</td>
</tr>
<tr>
<td>16424</td>
<td>16411</td>
<td>oradb</td>
<td>16422</td>
<td>rdssu2</td>
<td></td>
</tr>
</tbody>
</table>
```

```
test=> SELECT * FROM pg_user_mappings;
```

```
<table>
<thead>
<tr>
<th>umid</th>
<th>srvid</th>
<th>srvname</th>
<th>umuser</th>
<th>usename</th>
<th>umoptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>16414</td>
<td>16411</td>
<td>oradb</td>
<td>16412</td>
<td>user1</td>
<td>{user=oracleuser,password=mypwd}</td>
</tr>
<tr>
<td>16423</td>
<td>16411</td>
<td>oradb</td>
<td>16421</td>
<td>rdssu1</td>
<td></td>
</tr>
<tr>
<td>16424</td>
<td>16411</td>
<td>oradb</td>
<td>16422</td>
<td>rdssu2</td>
<td></td>
</tr>
</tbody>
</table>
```

2095
Because of implementation differences between information_schema._pg_user_mappings and pg_catalog.pg_user_mappings, a manually created rds_superuser requires additional permissions to view passwords in pg_catalog.pg_user_mappings.

No additional permissions are required for an rds_superuser to view passwords in information_schema._pg_user_mappings.

Users who don't have the rds_superuser role can view passwords in pg_user_mappings only under the following conditions:

- The current user is the user being mapped and owns the server or holds the USAGE privilege on it.
- The current user is the server owner and the mapping is for PUBLIC.

Working with SQL Server databases by using the tds_fdw extension

You can use the PostgreSQL tds_fdw extension to access databases that support the tabular data stream (TDS) protocol, such as Sybase and Microsoft SQL Server databases. This foreign data wrapper lets you connect from your RDS for PostgreSQL DB instance to databases that use the TDS protocol, including Amazon RDS for Microsoft SQL Server. For more information, see tds-fdw/tds_fdw documentation on GitHub.

The tds_fdw extension is supported on Amazon RDS for PostgreSQL version 14.2, 13.6, and higher releases.

Setting up your RDS for PostgreSQL DB to use the tds_fdw extension

In the following procedures, you can find an example of setting up and using the tds_fdw with an RDS for PostgreSQL DB instance. Before you can connect to a SQL Server database using tds_fdw, you need to get the following details for the instance:

- Hostname or endpoint. For an RDS for SQL Server DB instance, you can find the endpoint by using the Console. Choose the Connectivity & security tab and look in the "Endpoint and port" section.
- Port number. The default port number for Microsoft SQL Server is 1433.
- Name of the database. The DB identifier.

You also need to provide access on the security group or the access control list (ACL) for the SQL Server port, 1433. Both the RDS for PostgreSQL DB instance and the RDS for SQL Server DB instance need access to port 1433. If access isn't configured correctly, when you try to query the Microsoft SQL Server you see the following error message:

```
ERROR: DB-Library error: DB #: 20009, DB Msg: Unable to connect: Adaptive Server is unavailable or does not exist (mssql2019.aws-region.rds.amazonaws.com), OS #: 0, OS Msg: Success, Level: 9
```

To use tds_fdw to connect to a SQL Server database

1. Connect to your PostgreSQL DB instance using an account that has the rds_superuser role:

   ```bash
   psql --host=your-DB-instance.aws-region.rds.amazonaws.com --port=5432 --username=test --password
   ```
2. Install the `tds_fdw` extension:

```sql
CREATE EXTENSION tds_fdw;
```

After the extension is installed on your RDS for PostgreSQL DB instance, you set up the foreign server.

**To create the foreign server**

Perform these tasks on the RDS for PostgreSQL DB instance using an account that has `rds_superuser` privileges.

1. Create a foreign server in the RDS for PostgreSQL DB instance:

```sql
CREATE SERVER sqlserverdb FOREIGN DATA WRAPPER tds_fdw OPTIONS (servername 'mssql2019.aws-region.rds.amazonaws.com', port '1433', database 'tds_fdw_testing');
```

2. Grant permissions to a user who doesn't have `rds_superuser` role privileges, for example, `user1`:

```sql
GRANT USAGE ON FOREIGN SERVER sqlserverdb TO user1;
```

3. Connect as `user1` and create a mapping to a SQL Server user:

```sql
CREATE USER MAPPING FOR user1 SERVER sqlserverdb OPTIONS (username 'sqlserveruser', password 'password');
```

4. Create a foreign table linked to a SQL Server table:

```sql
CREATE FOREIGN TABLE mytab (a int) SERVER sqlserverdb OPTIONS (table 'MYTABLE');
```

5. Query the foreign table:

```sql
SELECT * FROM mytab;
a
---
1
(1 row)
```

**Using encryption in transit for the connection**

The connection from RDS for PostgreSQL to SQL Server uses encryption in transit (TLS/SSL) depending on the SQL Server database configuration. If the SQL Server isn't configured for encryption, the RDS for PostgreSQL client making the request to the SQL Server database falls back to unencrypted.

You can enforce encryption for the connection to RDS for SQL Server DB instances by setting the `rds.force_ssl` parameter. To learn how, see Forcing connections to your DB instance to use SSL. For more information about SSL/TLS configuration for RDS for SQL Server, see Using SSL with a Microsoft SQL Server DB instance.
Working with Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL is an open source development kit for building PostgreSQL extensions. It allows you to build high performance PostgreSQL extensions and safely run them on your RDS for PostgreSQL DB instance. By using Trusted Language Extensions (TLE) for PostgreSQL, you can create PostgreSQL extensions that follow the documented approach for extending PostgreSQL functionality. For more information, see Packaging Related Objects into an Extension in the PostgreSQL documentation.

One key benefit of TLE is that you can use it in environments that don't provide access to the file system underlying the PostgreSQL instance. Previously, installing a new extension required access to the file system. TLE removes this constraint. It provides a development environment for creating new extensions for any PostgreSQL database, including those running on your RDS for PostgreSQL DB instances.

TLE is designed to prevent access to unsafe resources for the extensions that you create using TLE. Its runtime environment limits the impact of any extension defect to a single database connection. TLE also gives database administrators fine-grained control over who can install extensions, and it provides a permissions model for running them.

TLE is supported on RDS for PostgreSQL version 14.5 and higher versions. The Trusted Language Extensions development environment and runtime are packaged as the pg_tle PostgreSQL extension, version 1.0.1. It supports creating extensions in JavaScript, Perl, PL/pgSQL, and SQL. You install the pg_tle extension in your RDS for PostgreSQL DB instance in the same way that you install other PostgreSQL extensions. After the pg_tle is set up, developers can use it to create new PostgreSQL extensions, known as TLE extensions.

In the following topics, you can find information about how to set up Trusted Language Extensions and how to get started creating your own TLE extensions.

Terminology

To help you better understand Trusted Language Extensions, view the following glossary for terms used in this topic.

Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL is the official name of the open source development kit that's packaged as the pg_tle extension. It's available for use on any PostgreSQL system. For more information, see aws/pg_tle on GitHub.
Trusted Language Extensions

*Trusted Language Extensions* is the short name for Trusted Language Extensions for PostgreSQL. This shortened name and its abbreviation (TLE) are also used in this documentation.

**trusted language**

A trusted language is a programming or scripting language that has specific security attributes. For example, trusted languages typically restrict access to the file system, and they limit use of specified networking properties. The TLE development kit is designed to support trusted languages. PostgreSQL supports several different languages that are used to create trusted or untrusted extensions. For an example, see Trusted and Untrusted PL/Perl in the PostgreSQL documentation. When you create an extension using Trusted Language Extensions, the extension inherently uses trusted language mechanisms.

**TLE extension**

A TLE extension is a PostgreSQL extension that's been created by using the Trusted Language Extensions (TLE) development kit.

Requirements for using Trusted Language Extensions for PostgreSQL

Use the following requirements for setting up and using the TLE development kit.

- **RDS for PostgreSQL 14.5 or higher version** – Trusted Language Extensions is supported on RDS for PostgreSQL version 14.5 and higher releases only.
  - If you need to upgrade your RDS for PostgreSQL instance, see Upgrading the PostgreSQL DB engine for Amazon RDS (p. 1891).
  - If you don't yet have an Amazon RDS DB instance running PostgreSQL, you can create one. For more information, see RDS for PostgreSQL DB instance and connecting to a database on a PostgreSQL DB instance (p. 193).
  - **Requires rds_superuser privileges** – To set up and configure the pg_tle extension, your database user role must have the permission of the rds_superuser role. By default, this role is granted to the postgres user that creates the RDS for PostgreSQL DB instance.
  - **Requires a custom DB parameter group** – Your RDS for PostgreSQL DB instance must be configured with a custom DB parameter group.
    - If your RDS for PostgreSQL DB instance isn't configured with a custom DB parameter group, you should create one and associate it with your RDS for PostgreSQL DB instance. For a short summary of steps, see Creating and applying a custom DB parameter group (p. 2099).
    - If your RDS for PostgreSQL DB instance is already configured using a custom DB parameter group, you can set up Trusted Language Extensions. For details, see Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance (p. 2101).

Creating and applying a custom DB parameter group

Use the following steps to create a custom DB parameter group and configure your RDS for PostgreSQL DB instance to use it.

**Console**

**To create a custom DB parameter group and use it with your RDS for PostgreSQL DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Parameter groups from the Amazon RDS menu.
3. Choose Create parameter group.
4. In the **Parameter group details** page, enter the following information.
   - For **Parameter group family**, choose postgres14.
   - For **Type**, choose DB Parameter Group.
   - For **Group name**, give your parameter group a meaningful name in the context of your operations.
   - For **Description**, enter a useful description so that others on your team can easily find it.
5. Choose Create. Your custom DB parameter group is created in your AWS Region. You can now modify your RDS for PostgreSQL DB instance to use it by following the next steps.
6. Choose Databases from the Amazon RDS menu.
7. Choose the RDS for PostgreSQL DB instance that you want to use with TLE from among those listed, and then choose Modify.
8. In the Modify DB instance settings page, find **Database options** in the Additional configuration section and choose your custom DB parameter group from the selector.
9. Choose Continue to save the change.
10. Choose **Apply immediately** so that you can continue setting up the RDS for PostgreSQL DB instance to use TLE.

To continue setting up your system for Trusted Language Extensions, see Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance (p. 2101).

For more information working with DB parameter groups, see Working with DB parameter groups (p. 297).

**AWS CLI**

You can avoid specifying the **--region** argument when you use CLI commands by configuring your AWS CLI with your default AWS Region. For more information, see Configuration basics in the *AWS Command Line Interface User Guide*.

**To create a custom DB parameter group and use it with your RDS for PostgreSQL DB instance**

1. Use the create-db-parameter-group **AWS CLI** command to create a custom DB parameter group based on postgres14 for your AWS Region.

   For Linux, macOS, or Unix:
   ```bash
   aws rds create-db-parameter-group \
   --region aws-region \n   --db-parameter-group-name custom-params-for-pg-tle \n   --db-parameter-group-family postgres14 \n   --description "My custom DB parameter group for Trusted Language Extensions"
   ```

   For Windows:
   ```bash
   aws rds create-db-parameter-group ^
   --region aws-region ^
   --db-parameter-group-name custom-params-for-pg-tle ^
   --db-parameter-group-family postgres14 ^
   --description "My custom DB parameter group for Trusted Language Extensions"
   ```

   Your custom DB parameter group is available in your AWS Region, so you can modify RDS for PostgreSQL DB instance to use it.
2. Use the `modify-db-instance` AWS CLI command to apply your custom DB parameter group to your RDS for PostgreSQL DB instance. This command immediately reboots the active instance.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance
  --region aws-region
  --db-instance-identifier your-instance-name
  --db-parameter-group-name custom-params-for-pg-tle
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --region aws-region ^
  --db-instance-identifier your-instance-name ^
  --db-parameter-group-name custom-params-for-pg-tle ^
  --apply-immediately
```

To continue setting up your system for Trusted Language Extensions, see Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance (p. 2101).

For more information, see Working with parameter groups (p. 295).

## Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance

The following steps assume that your RDS for PostgreSQL DB instance is associated with a custom DB parameter group. You can use the AWS Management Console or the AWS CLI for these steps.

When you set up Trusted Language Extensions in your RDS for PostgreSQL DB instance, you install it in a specific database for use by the database users who have permissions on that database.

### Console

**To set up Trusted Language Extensions**

Perform the following steps using an account that's a member of the `rds_superuser` group (role).

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose your RDS for PostgreSQL DB instance.
3. Open the `Configuration` tab for your RDS for PostgreSQL DB instance. Among the Instance details, find the `Parameter group` link.
4. Choose the link to open the custom parameters associated with your RDS for PostgreSQL DB instance.
5. In the `Parameters` search field, type `shared_pre` to find the `shared_preload_libraries` parameter.
6. Choose `Edit parameters` to access the property values.
7. Add `pg_tle` to the list in the `Values` field. Use a comma to separate items in the list of values.
8. Reboot the RDS for PostgreSQL DB instance so that your change to the shared_preload_libraries parameter takes effect.

9. When the instance is available, verify that pg_tle has been initialized. Use psql to connect to the RDS for PostgreSQL DB instance, and then run the following command.

```
SHOW shared_preload_libraries;
shared_preload_libraries
--------------------------
rdsutils,pg_tle
(1 row)
```

10. With the pg_tle extension initialized, you can now create the extension.

```
CREATE EXTENSION pg_tle;
```

You can verify that the extension is installed by using the following psql metacommand.

```
labdb=> \dx
List of installed extensions
    Name   | Version |   Schema   |                Description
---------+---------+------------+--------------------------------------------
       pg_tle  | 1.0.1   | pgtle      | Trusted-Language Extensions for PostgreSQL
   plpgsql | 1.0     | pg_catalog | PL/pgSQL procedural language
```

11. Grant the pgtle_admin role to the primary user name that you created for your RDS for PostgreSQL DB instance when you set it up. If you accepted the default, it’s postgres.

```
labdb=> GRANT pgtle_admin TO postgres;
GRANT ROLE
```

You can verify that the grant has occurred by using the psql metacommand as shown in the following example. Only the pgtle_admin and postgres roles are shown in the output. For more information, see Understanding the rds_superuser role (p. 1968).

```
labdb=> \du
List of roles
Role name    |           Attributes            |               Member of
-----------------+---------------------------------+-----------------------------------
     pgtle_admin     | Cannot login                     | {}                              
        postgres        | Create role, Create DB + | {rds_superuser,pgtle_admin}
          | Password valid until infinity |...
```

12. Close the psql session using the \q metacommand.
To get started creating TLE extensions, see Example: Creating a trusted language extension using SQL (p. 2105).

**AWS CLI**

You can avoid specifying the `--region` argument when you use CLI commands by configuring your AWS CLI with your default AWS Region. For more information, see Configuration basics in the AWS Command Line Interface User Guide.

**To set up Trusted Language Extensions**

1. Use the `modify-db-parameter-group` AWS CLI command to add `pg_tle` to the `shared_preload_libraries` parameter.

   ```bash
   aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters "ParameterName=shared_preload_libraries,ParameterValue=pg_tle,ApplyMethod=pending-reboot" \
   --region aws-region
   ```

2. Use the `reboot-db-instance` AWS CLI command to reboot the RDS for PostgreSQL DB instance and initialize the `pg_tle` library.

   ```bash
   aws rds reboot-db-instance \
   --db-instance-identifier your-instance \
   --region aws-region
   ```

3. When the instance is available, you can verify that `pg_tle` has been initialized. Use `psql` to connect to the RDS for PostgreSQL DB instance, and then run the following command.

   ```sql
   SHOW shared_preload_libraries;
   shared_preload_libraries
   --------------------------
   rdsutils,pg_tle
   (1 row)
   ```

   With `pg_tle` initialized, you can now create the extension.

   ```sql
   CREATE EXTENSION pg_tle;
   ```

4. Grant the `pgtle_admin` role to the primary user name that you created for your RDS for PostgreSQL DB instance when you set it up. If you accepted the default, it's `postgres`.

   ```sql
   GRANT pgtle_admin TO postgres;
   GRANT ROLE
   ```

5. Close the `psql` session as follows.

   ```sql
   labdb=> \q
   ```
To get started creating TLE extensions, see Example: Creating a trusted language extension using SQL (p. 2105).

Overview of Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL is a PostgreSQL extension that you install in your RDS for PostgreSQL DB instance in the same way that you set up other PostgreSQL extensions. In the following image of an example database in the pgAdmin client tool, you can view some of the components that comprise the pg_tle extension.

You can see the following details.

1. The Trusted Language Extensions (TLE) for PostgreSQL development kit is packaged as the pg_tle extension. As such, pg_tle is added to the available extensions for the database in which it's installed.

2. TLE has its own schema, pg_tle. This schema contains helper functions (3) for installing and managing the extensions that you create.

3. TLE provides over a dozen helper functions for installing, registering, and managing your extensions. To learn more about these functions, see Functions reference for Trusted Language Extensions for PostgreSQL (p. 2114).

Other components of the pg_tle extension include the following:
• **The `pgtle_admin` role** – The `pgtle_admin` role is created when the `pg_tle` extension is installed. This role is privileged and should be treated as such. We strongly recommend that you follow the principle of *least privilege* when granting the `pgtle_admin` role to database users. In other words, grant the `pgtle_admin` role only to database users that are allowed to create, install, and manage new TLE extensions, such as `postgres`.

• **The `pgtle.feature_info` table** – The `pgtle.feature_info` table is a protected table that contains information about your TLEs, hooks, and the custom stored procedures and functions that they use. If you have `pgtle_admin` privileges, you use the following Trusted Language Extensions functions to add and update that information in the table.
  
  • `pgtle.register_feature` (p. 2118)
  • `pgtle.register_feature_if_not_exists` (p. 2118)
  • `pgtle.unregister_feature` (p. 2123)
  • `pgtle.unregister_feature_if_exists` (p. 2123)

**Creating TLE extensions for RDS for PostgreSQL**

You can install any extensions that you create with TLE in any RDS for PostgreSQL DB instance that has the `pg_tle` extension installed. The `pg_tle` extension is scoped to the PostgreSQL database in which it's installed. The extensions that you create using TLE are scoped to the same database.

Use the various `pgtle` functions to install the code that makes up your TLE extension. The following Trusted Language Extensions functions all require the `pgtle_admin` role.

• `pgtle.install_extension` (p. 2116)
• `pgtle.install_update_path` (p. 2117)
• `pgtle.register_feature` (p. 2118)
• `pgtle.register_feature_if_not_exists` (p. 2118)
• `pgtle.set_default_version` (p. 2119)
• `pgtle.uninstall_extension(name)` (p. 2120)
• `pgtle.uninstall_extension(name, version)` (p. 2120)
• `pgtle.uninstall_extension_if_exists` (p. 2121)
• `pgtle.uninstall_update_path` (p. 2121)
• `pgtle.uninstall_update_path_if_exists` (p. 2122)
• `pgtle.unregister_feature` (p. 2123)
• `pgtle.unregister_feature_if_exists` (p. 2123)

**Example: Creating a trusted language extension using SQL**

The following example shows you how to create a TLE extension named `pg_distance` that contains a few SQL functions for calculating distances using different formulas. In the listing, you can find the function for calculating the Manhattan distance and the function for calculating the Euclidean distance. For more information about the difference between these formulas, see [Taxicab geometry](https://en.wikipedia.org/wiki/Taxicab_geometry) and [Euclidean geometry](https://en.wikipedia.org/wiki/Euclidean_geometry) in Wikipedia.

You can use this example in your own RDS for PostgreSQL DB instance if you have the `pg_tle` extension set up as detailed in Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance (p. 2101).

**Note**

You need to have the privileges of the `pgtle_admin` role to follow this procedure.
To create the example TLE extension

The following steps use an example database named labdb. This database is owned by the postgres primary user. The postgres role also has the permissions of the pgtle_admin role.

1. Use psql to connect to RDS for PostgreSQL DB instance.

   ```
   psql --host=db-instance-123456789012.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
   ```

2. Create a TLE extension named pg_distance by copying the following code and pasting it into your psql session console.

   ```
   SELECT pgtle.install_extension
   (  
   'pg_distance',  
   '0.1',  
   'Distance functions for two points',  
   $pg_tle_$_
   CREATE FUNCTION dist(x1 float8, y1 float8, x2 float8, y2 float8, norm int)
   RETURNS float8
   AS $$_
   SELECT (abs(x2 - x1) ^ norm + abs(y2 - y1) ^ norm) ^ (1::float8 / norm);
   $$ LANGUAGE SQL;
   CREATE FUNCTION manhattan_dist(x1 float8, y1 float8, x2 float8, y2 float8)
   RETURNS float8
   AS $$_
   SELECT dist(x1, y1, x2, y2, 1);
   $$ LANGUAGE SQL;
   CREATE FUNCTION euclidean_dist(x1 float8, y1 float8, x2 float8, y2 float8)
   RETURNS float8
   AS $$_
   SELECT dist(x1, y1, x2, y2, 2);
   $$ LANGUAGE SQL;
   $pg_tle_$_);
   ```

   You see the output, such as the following.

   ```
   install_extension
               -------
            t  
             (1 row)
   ```

   The artifacts that make up the pg_distance extension are now installed in your database. These artifacts include the control file and the code for the extension, which are items that need to be present so that the extension can be created using the CREATE EXTENSION command. In other words, you still need to create the extension to make its functions available to database users.

3. To create the extension, use the CREATE EXTENSION command as you do for any other extension. As with other extensions, the database user needs to have the CREATE permissions in the database.

   ```
   CREATE EXTENSION pg_distance;
   ```

4. To test the pg_distance TLE extension, you can use it to calculate the Manhattan distance between four points.

   ```
   labdb=> SELECT manhattan_dist(1, 1, 5, 5);
   ```
To calculate the **Euclidean distance** between the same set of points, you can use the following.

```
labdb=> SELECT euclidean_dist(1, 1, 5, 5);
5.656854249492381
```

The `pg_distance` extension loads the functions in the database and makes them available to any users with permissions on the database.

## Modifying your TLE extension

To improve query performance for the functions packaged in this TLE extension, add the following two PostgreSQL attributes to their specifications.

- **IMMUTABLE** – The IMMUTABLE attribute ensures that the query optimizer can use optimizations to improve query response times. For more information, see [Function Volatility Categories](https://www.postgresql.org/docs/current/volatility.html) in the PostgreSQL documentation.
- **PARALLEL SAFE** – The PARALLEL SAFE attribute is another attribute that allows PostgreSQL to run the function in parallel mode. For more information, see [CREATE FUNCTION](https://www.postgresql.org/docs/current/sql-createlanguage.html) in the PostgreSQL documentation.

In the following example, you can see how the `pgtle.install_update_path` function is used to add these attributes to each function to create a version 0.2 of the `pg_distance` TLE extension. For more information about this function, see `pgtle.install_update_path` (p. 2117). You need to have the `pgtle_admin` role to perform this task.

### To update an existing TLE extension and specify the default version

1. Connect to RDS for PostgreSQL DB instance using `psql` or another client tool, such as pgAdmin.

```
psql --host=db-instance-123456789012.aws-region.rds.amazonaws.com
--port=5432 --username=postgres --password --dbname=labdb
```

2. Modify the existing TLE extension by copying the following code and pasting it into your `psql` session console.

```
SELECT pgtle.install_update_path
('pg_distance',
 '0.1',
 '0.2',
$_pg_tle_$
CREATE OR REPLACE FUNCTION dist(x1 float8, y1 float8, x2 float8, y2 float8, norm int)
RETURNS float8
AS $$
SELECT (abs(x2 - x1) ^ norm + abs(y2 - y1) ^ norm) ^ (1::float8 / norm);
$$ LANGUAGE SQL IMMUTABLE PARALLEL SAFE;

CREATE OR REPLACE FUNCTION manhattan_dist(x1 float8, y1 float8, x2 float8, y2 float8)
RETURNS float8
AS $$
SELECT dist(x1, y1, x2, y2, 1);
$$ LANGUAGE SQL IMMUTABLE PARALLEL SAFE;
```

2107
Dropping your TLE extensions from a database

You can drop your TLE extensions by using the DROP EXTENSION command in the same way that you do for other PostgreSQL extensions. Dropping the extension doesn’t remove the installation files that make up the extension, which allows users to re-create the extension. To remove the extension and its installation files, do the following two-step process.

To drop the TLE extension and remove its installation files

1. Use psql or another client tool to connect to the RDS for PostgreSQL DB instance.

   ```
   psql --host=.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=dbname
   ```

2. Drop the extension as you would any PostgreSQL extension.

   ```
   DROP EXTENSION your-TLE-extension
   ```

   For example, if you create the pg_distance extension as detailed in Example: Creating a trusted language extension using SQL (p. 2105), you can drop the extension as follows.

   ```
   DROP EXTENSION pg_distance;
   ```

   You see output confirming that the extension has been dropped, as follows.
DROP EXTENSION

At this point, the extension is no longer active in the database. However, its installation files and control file are still available in the database, so database users can create the extension again if they like.

- If you want to leave the extension files intact so that database users can create your TLE extension, you can stop here.
- If you want to remove all files that make up the extension, continue to the next step.

3. To remove all installation files for your extension, use the `pgtle.uninstall_extension` function. This function removes all the code and control files for your extension.

```
SELECT pgtle.uninstall_extension('your-tle-extension-name');
```

For example, to remove all `pg_distance` installation files, use the following command.

```
SELECT pgtle.uninstall_extension('pg_distance');
```

Uninstalling Trusted Language Extensions for PostgreSQL

If you no longer want to create your own TLE extensions using TLE, you can drop the `pg_tle` extension and remove all artifacts. This action includes dropping any TLE extensions in the database and dropping the `pgtle` schema.

To drop the `pg_tle` extension and its schema from a database

1. Use `psql` or another client tool to connect to the RDS for PostgreSQL DB instance.

   ```
   psql --host=.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=dbname
   ```

2. Drop the `pg_tle` extension from the database. If the database has your own TLE extensions still running in the database, you need to also drop those extensions. To do so, you can use the `CASCADE` keyword, as shown in the following.

   ```
   DROP EXTENSION pg_tle CASCADE;
   ```

   If the `pg_tle` extension isn't still active in the database, you don't need to use the `CASCADE` keyword.

3. Drop the `pgtle` schema. This action removes all the management functions from the database.

   ```
   DROP SCHEMA pgtle CASCADE;
   ```

   The command returns the following when the process completes.
Drop Schema

The pg_tle extension, its schema and functions, and all artifacts are removed. To create new extensions using TLE, go through the setup process again. For more information, see Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance (p. 2101).

Using PostgreSQL hooks with your TLE extensions

A hook is a callback mechanism available in PostgreSQL that allows developers to call custom functions or other routines during regular database operations. The TLE development kit supports PostgreSQL hooks so that you can integrate custom functions with PostgreSQL behavior at runtime. For example, you can use a hook to associate the authentication process with your own custom code, or to modify the query planning and execution process for your specific needs.

Your TLE extensions can use hooks. If a hook is global in scope, it applies across all databases. Therefore, if your TLE extension uses a global hook, then you need to create your TLE extension in all databases that your users can access.

When you use the pg_tle extension to build your own Trusted Language Extensions, you can use the available hooks from a SQL API to build out the functions of your extension. You should register any hooks with pg_tle. For some hooks, you might also need to set various configuration parameters. For example, the passcode check hook can be set to on, off, or require. For more information about specific requirements for available pg_tle hooks, see Hooks reference for Trusted Language Extensions for PostgreSQL (p. 2124).

Example: Creating an extension that uses a PostgreSQL hook

The example discussed in this section uses a PostgreSQL hook to check the password provided during specific SQL operations and prevents database users from setting their passwords to any of those contained in the password_check.bad_passwords table. The table contains the top-ten most commonly used, but easily breakable choices for passwords.

To set up this example in your RDS for PostgreSQL DB instance, you must have already installed Trusted Language Extensions. For details, see Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance (p. 2101).

To set up the password-check hook example

1. Use psql to connect to RDS for PostgreSQL DB instance.

   ```bash
   psql --host=db-instance-123456789012.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
   ```

2. Copy the code from the Password-check hook code listing (p. 2113) and paste it into your database.

   ```sql
   SELECT pgtle.install_extension (  
   'my_password_check_rules',  
   '1.0',  
   'Do not let users use the 10 most commonly used passwords',  
   $pgtle$  
   CREATE SCHEMA password_check;  
   REVOKE ALL ON SCHEMA password_check FROM PUBLIC;  
   GRANT USAGE ON SCHEMA password_check TO PUBLIC;  
   CREATE TABLE password_check.bad_passwords (plaintext) AS
   ```
VALUES
('123456'),
('password'),
('12345678'),
('qwert'),
('123456789'),
('12345'),
('1234'),
('111111'),
('1234567'),
('dragon');
CREATE UNIQUE INDEX ON password_check.bad_passwords (plaintext);

CREATE FUNCTION password_check.passcheck_hook(username text, password text,
password_type pgtle.password_types, valid_until timestamptz, valid_null boolean)
RETURNS void AS $$
DECLARE
invalid bool := false;
BEGIN
IF password_type = 'PASSWORD_TYPE_MD5' THEN
SELECT EXISTS(
SELECT 1
FROM password_check.bad_passwords bp
WHERE ('md5' || md5(bp.plaintext || username)) = password
) INTO invalid;
IF invalid THEN
RAISE EXCEPTION 'Cannot use passwords from the common password dictionary';
END IF;
ELSIF password_type = 'PASSWORD_TYPE_PLAINTEXT' THEN
SELECT EXISTS(
SELECT 1
FROM password_check.bad_passwords bp
WHERE bp.plaintext = password
) INTO invalid;
IF invalid THEN
RAISE EXCEPTION 'Cannot use passwords from the common password dictionary';
END IF;
END IF;
END
$$ LANGUAGE plpgsql SECURITY DEFINER;

GRANT EXECUTE ON FUNCTION password_check.passcheck_hook TO PUBLIC;

SELECT pgtle.register_feature('password_check.passcheck_hook', 'passcheck');
$_pgtle_$

When the extension has been loaded into your database, you see the output such as the following.

<table>
<thead>
<tr>
<th>install_extension</th>
</tr>
</thead>
<tbody>
<tr>
<td>t</td>
</tr>
<tr>
<td>(1 row)</td>
</tr>
</tbody>
</table>

3. While still connected to the database, you can now create the extension.

CREATE EXTENSION my_password_check_rules;

4. You can confirm that the extension has been created in the database by using the following psql metacommand.

\dx
5. Open another terminal session to work with the AWS CLI. You need to modify your custom DB parameter group to turn on the password-check hook. To do so, use the `modify-db-parameter-group` CLI command as shown in the following example.

```
aws rds modify-db-parameter-group \
  --region aws-region \
  --db-parameter-group-name your-custom-parameter-group \
  --parameters "ParameterName=pgtle.enable_password_check,ParameterValue=on,ApplyMethod=immediate"
```

When the parameter is successfully turned on, you see the output such as the following.

```
{
  "DBParameterGroupName": "docs-lab-parameters-for-tle"
}
```

It might take a few minutes for the change to the parameter group setting to take effect. This parameter is dynamic, however, so you don't need to restart the RDS for PostgreSQL DB instance for the setting to take effect.

6. Open the `psql` session and query the database to verify that the password_check hook has been turned on.

```
labdb=> SHOW pgtle.enable_password_check;
pgtle.enable_password_check
-----------------------------
on (1 row)
```

The password-check hook is now active. You can test it by creating a new role and using one of the bad passwords, as shown in the following example.

```
CREATE ROLE test_role PASSWORD 'password';
ERROR:  Cannot use passwords from the common password dictionary
CONTEXT:  PL/pgSQL function password_check.passcheck_hook(text,text,pgtle.password_types,timestamptz with time zone,boolean) line 21 at RAISE
SQL statement "SELECT password_check.passcheck_hook(  
  $1::pg_catalog.text,  
  $2::pg_catalog.text,  
  $3::pgtle.password_types,  
  $4::pg_catalog.timestamptz,  
  $5::pg_catalog.bool)
```

The output has been formatted for readability.

The following example shows that `psql` interactive metacommand `\password` behavior is also affected by the `password_check` hook.
postgres=> SET password_encryption TO 'md5';
SET
postgres=> \password
Enter new password for user "postgres":******
Enter it again:******
ERROR:  Cannot use passwords from the common password dictionary
CONTEXT:  PL/pgSQL function
password_check.passcheck_hook(text,text,pgtle.password_types,timestamptz,boolean)
SQL statement "SELECT password_check.passcheck_hook($1::pg_catalog.text, $2::pg_catalog.text, $3::pgtle.password_types, $4::pg_catalog.timestamptz, $5::pg_catalog.bool)"

You can drop this TLE extension and uninstall its source files if you want. For more information, see Dropping your TLE extensions from a database (p. 2108).

Password-check hook code listing

The example code shown here defines the specification for the my_password_check_rules TLE extension. When you copy this code and paste it into your database, the code for the my_password_check_rules extension is loaded into the database, and the password_check hook is registered for use by the extension.

```
SELECT pgtle.install_extension (  
   'my_password_check_rules',  
   '1.0',  
   'Do not let users use the 10 most commonly used passwords',  
   $pgtle$_
CREATE SCHEMA password_check;
REVOKE ALL ON SCHEMA password_check FROM PUBLIC;
GRANT USAGE ON SCHEMA password_check TO PUBLIC;

CREATE TABLE password_check.badPasswords (plaintext) AS

   IF password_type = 'PASSWORD_TYPE_MD5' THEN  
      SELECT EXISTS(  
         SELECT 1  
         FROM password_check.badPasswords bp  
         WHERE ('md5' || md5(bp.plaintext || username)) = password  
      ) INTO invalid;  
      IF invalid THEN  
         RAISE EXCEPTION 'Cannot use passwords from the common password dictionary';  
      END IF;  
   ELSEIF password_type = 'PASSWORD_TYPE_PLAINTEXT' THEN  
      SELECT EXISTS(  
```
SELECT 1
FROM password_check.bad_passwords bp
WHERE bp.plaintext = password
) INTO invalid;
IF invalid THEN
  RAISE EXCEPTION 'Cannot use passwords from the common password
dictionary';
  END IF;
END IF;
END
$$
LANGUAGE plpgsql SECURITY DEFINER;
GRANT EXECUTE ON FUNCTION password_check.passcheck_hook TO PUBLIC;
SELECT pgtle.register_feature('password_check.passcheck_hook', 'passcheck');
$_pgtle_$

Functions reference for Trusted Language Extensions for PostgreSQL

View the following reference documentation about functions available in Trusted Language Extensions for PostgreSQL. Use these functions to install, register, update, and manage your TLE extensions, that is, the PostgreSQL extensions that you develop using the Trusted Language Extensions development kit.

Topics

- pgtle.available_extensions (p. 2114)
- pgtle.available_extension_versions (p. 2115)
- pgtle.extension_update_paths (p. 2116)
- pgtle.install_extension (p. 2116)
- pgtle.install_update_path (p. 2117)
- pgtle.register_feature (p. 2118)
- pgtle.register_feature_if_not_exists (p. 2118)
- pgtle.set_default_version (p. 2119)
- pgtle.uninstall_extension(name) (p. 2120)
- pgtle.uninstall_extension(name, version) (p. 2120)
- pgtle.uninstall_extension_if_exists (p. 2121)
- pgtle.uninstall_update_path (p. 2121)
- pgtle.uninstall_update_path_if_exists (p. 2122)
- pgtle.unregister_feature (p. 2123)
- pgtle.unregister_feature_if_exists (p. 2123)

pgtle.available_extensions

The pgtle.available_extensions function is a set-returning function. It returns all available TLE extensions in the database. Each returned row contains information about a single TLE extension.

Function prototype

pgtle.available_extensions()
Role

None.

Arguments

None.

Output

- name – The name of the TLE extension.
- default_version – The version of the TLE extension to use when CREATE EXTENSION is called without a version specified.
- description – A more detailed description about the TLE extension.

Usage example

```sql
SELECT * FROM pgtle.available_extensions();
```

pgtle.available_extension_versions

The available_extension_versions function is a set-returning function. It returns a list of all available TLE extensions and their versions. Each row contains information about a specific version of the given TLE extension, including whether it requires a specific role.

Function prototype

```sql
pgtle.available_extension_versions()
```

Role

None.

Arguments

None.

Output

- name – The name of the TLE extension.
- version – The version of the TLE extension.
- superuser – This value is always false for your TLE extensions. The permissions needed to create the TLE extension or update it are the same as for creating other objects in the given database.
- trusted – This value is always false for a TLE extension.
- relocatable – This value is always false for a TLE extension.
- schema – Specifies the name of the schema in which the TLE extension is installed.
- requires – An array containing the names of other extensions needed by this TLE extension.
- description – A detailed description of the TLE extension.

For more information about output values, see Packaging Related Objects into an Extension > Extension Files in the PostgreSQL documentation.
Usage example

```
SELECT * FROM pgtle.available_extension_versions();
```

**pgtle.extension_update_paths**

The `extension_update_paths` function is a set-returning function. It returns a list of all the possible update paths for a TLE extension. Each row includes the available upgrades or downgrades for that TLE extension.

**Function prototype**

```
pgtle.extension_update_paths(name)
```

**Role**

None.

**Arguments**

- `name` – The name of the TLE extension from which to get upgrade paths.

**Output**

- `source` – The source version for an update.
- `target` – The target version for an update.
- `path` – The upgrade path used to update a TLE extension from source version to target version, for example, `0.1--0.2`.

**Usage example**

```
SELECT * FROM pgtle.extension_update_paths('your-TLE');
```

**pgtle.install_extension**

The `install_extension` function lets you install the artifacts that make up your TLE extension in the database, after which it can be created using the `CREATE EXTENSION` command.

**Function prototype**

```
pgtle.install_extension(name text, version text, description text, ext text, requires text[] DEFAULT NULL::text[])
```

**Role**

None.

**Arguments**

- `name` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`. 
• version – The version of the TLE extension.
• description – A detailed description about the TLE extension. This description is displayed in the comment field in `pgtle.available_extensions()`.
• ext – The contents of the TLE extension. This value contains objects such as functions.
• requires – An optional parameter that specifies dependencies for this TLE extension. The `pg_tle` extension is automatically added as a dependency.

Many of these arguments are the same as those that are included in an extension control file for installing a PostgreSQL extension on the file system of a PostgreSQL instance. For more information, see the Extension Files in Packaging Related Objects into an Extension in the PostgreSQL documentation.

Output

This function returns `OK` on success and `NULL` on error.

• OK – The TLE extension has been successfully installed in the database.
• NULL – The TLE extension hasn’t been successfully installed in the database.

Usage example

```sql
SELECT pgtle.install_extension(
    pg_tle_test,
    0.1,
    My first pg_tle extension,
    $pgtle$
    CREATE FUNCTION my_test()
    RETURNS INT
    AS $$
    SELECT 42;
    $$ LANGUAGE SQL IMMUTABLE;
    $pgtle$
);```

`pgtle.install_update_path`

The `install_update_path` function provides an update path between two different versions of a TLE extension. This function allows users of your TLE extension to update its version by using the `ALTER EXTENSION ... UPDATE` syntax.

Function prototype

```sql
pgtle.install_update_path(name text, fromvers text, tovers text, ext text)
```

Role

`pgtle_admin`

Arguments

• name – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
• fromvers – The source version of the TLE extension for the upgrade.
• tovers – The destination version of the TLE extension for the upgrade.
• ext – The contents of the update. This value contains objects such as functions.
Output

None.

Usage example

```
SELECT pgtle.install_update_path(pg_tle_test, 0.1, 0.2, $pgtle$,
  CREATE OR REPLACE FUNCTION my_test()
  RETURNS INT
  AS $$
    SELECT 21;
  $$ LANGUAGE SQL IMMUTABLE;
$pgtle$);
```

pgtle.register_feature

The `pgtle.register_feature` function adds the specified internal PostgreSQL feature to the `pgtle.feature_info` table. PostgreSQL hooks are an example of an internal PostgreSQL feature. The Trusted Language Extensions development kit supports the use of PostgreSQL hooks. Currently, this function supports the following feature.

- **passcheck** – Registers the password-check hook with your procedure or function that customizes PostgreSQL's password-check behavior.

**Function prototype**

```
pgtle.register_feature(proc regproc, feature pg_tle_feature)
```

**Role**

pgtle_admin

**Arguments**

- **proc** – The name of a stored procedure or function to use for the feature.
- **feature** – The name of the `pg_tle` feature (such as `passcheck`) to register with the function.

**Output**

None.

**Usage example**

```
SELECT pgtle.register_feature('pw_hook', 'passcheck');
```

pgtle.register_feature_if_not_exists

The `pgtle.register_feature_if_not_exists` function adds the specified PostgreSQL feature to the `pgtle.feature_info` table and identifies the TLE extension or other procedure or function that uses the feature. For more information about hooks and Trusted Language Extensions, see Using PostgreSQL hooks with your TLE extensions (p. 2110).
Function prototype

pgtle.register_feature_if_not_exists(proc regproc, feature pg_tle_feature)

Role
pgtle_admin

Arguments

- proc – The name of a stored procedure or function that contains the logic (code) to use as a feature for your TLE extension. For example, the pw_hook code.
- feature – The name of the PostgreSQL feature to register for the TLE function. Currently, the only available feature is the passcheck hook. For more information, see Password-check hook (passcheck) (p. 2124).

Output

Returns true after registering the feature for the specified extension. Returns false if the feature is already registered.

Usage example

SELECT pgtle.register_feature_if_not_exists('pw_hook', 'passcheck');

pgtle.set_default_version

The set_default_version function lets you specify a default_version for your TLE extension. You can use this function to define an upgrade path and designate the version as the default for your TLE extension. When database users specify your TLE extension in the CREATE EXTENSION and ALTER EXTENSION ... UPDATE commands, that version of your TLE extension is created in the database for that user.

This function returns true on success. If the TLE extension specified in the name argument doesn't exist, the function returns an error. Similarly, if the version of the TLE extension doesn't exist, it returns an error.

Function prototype

pgtle.set_default_version(name text, version text)

Role
pgtle_admin

Arguments

- name – The name of the TLE extension. This value is used when calling CREATE EXTENSION.
- version – The version of the TLE extension to set the default.

Output

- true – When setting default version succeeds, the function returns true.
• ERROR – Returns an error message if a TLE extension with the specified name or version doesn't exist.

Usage example

```sql
SELECT * FROM pgtle.set_default_version(my-extension, 1.1);
```

**pgtle.uninstall_extension(name)**

The `uninstall_extension` function removes all versions of a TLE extension from a database. This function prevents future calls of `CREATE EXTENSION` from installing the TLE extension. If the TLE extension doesn't exist in the database, an error is raised.

The `uninstall_extension` function won't drop a TLE extension that's currently active in the database. To remove a TLE extension that's currently active, you need to explicitly call `DROP EXTENSION` to remove it.

**Function prototype**

```sql
pgtle.uninstall_extension(extname text)
```

**Role**

`pgtle_admin`

**Arguments**

• `extname` – The name of the TLE extension to uninstall. This name is the same as the one used with `CREATE EXTENSION` to load the TLE extension for use in a given database.

**Output**

None.

**Usage example**

```sql
SELECT * FROM pgtle.uninstall_extension(pg_tle_test);
```

**pgtle.uninstall_extension(name, version)**

The `uninstall_extension(name, version)` function removes the specified version of the TLE extension from the database. This function prevents `CREATE EXTENSION` and `ALTER EXTENSION` from installing or updating a TLE extension to the specified version. This function also removes all update paths for the specified version of the TLE extension. This function won't uninstall the TLE extension if it's currently active in the database. You must explicitly call `DROP EXTENSION` to remove the TLE extension. To uninstall all versions of a TLE extension, see `pgtle.uninstall_extension(name)` (p. 2120).

**Function prototype**

```sql
pgtle.uninstall_extension(extname text, version text)
```

**Role**

`pgtle_admin`
Arguments

- extname – The name of the TLE extension. This value is used when calling CREATE EXTENSION.
- version – The version of the TLE extension to uninstall from the database.

Output

None.

Usage example

```sql
SELECT * FROM pgtle.uninstall_extension(pg_tle_test, 0.2);
```

`pgtle.uninstall_extension_if_exists`

The `uninstall_extension_if_exists` function removes all versions of a TLE extension from a given database. If the TLE extension doesn't exist, the function returns silently (no error message is raised). If the specified extension is currently active within a database, this function doesn't drop it. You must explicitly call DROP EXTENSION to remove the TLE extension before using this function to uninstall its artifacts.

Function prototype

```sql
pgtle.uninstall_extension_if_exists(extname text)
```

Role

`pgtle_admin`

Arguments

- extname – The name of the TLE extension. This value is used when calling CREATE EXTENSION.

Output

The `uninstall_extension_if_exists` function returns true after uninstalling the specified extension. If the specified extension doesn't exist, the function returns false.

- true – Returns true after uninstalling the TLE extension.
- false – Returns false when the TLE extension doesn't exist in the database.

Usage example

```sql
SELECT * FROM pgtle.uninstall_extension_if_exists(pg_tle_test);
```

`pgtle.uninstall_update_path`

The `uninstall_update_path` function removes the specific update path from a TLE extension. This prevents ALTER EXTENSION ... UPDATE TO from using this as an update path.

If the TLE extension is currently being used by one of the versions on this update path, it remains in the database.
If the update path specified doesn't exist, this function raises an error.

**Function prototype**

```
pgtle.uninstall_update_path(extname text, fromvers text, tovers text)
```

**Role**

`pgtle_admin`

**Arguments**

- `extname` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- `fromvers` – The source version of the TLE extension used on the update path.
- `tovers` – The destination version of the TLE extension used on the update path.

**Output**

None.

**Usage example**

```
SELECT * FROM pgtle.uninstall_update_path(pg_tle_test, 0.1, 0.2);
```

---

**pgtle.uninstall_update_path_if_exists**

The `uninstall_update_path_if_exists` function is similar to `uninstall_update_path` in that it removes the specified update path from a TLE extension. However, if the update path doesn't exist, this function doesn't raise an error message. Instead, the function returns `false`.

**Function prototype**

```
pgtle.uninstall_update_path_if_exists(extname text, fromvers text, tovers text)
```

**Role**

`pgtle_admin`

**Arguments**

- `extname` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- `fromvers` – The source version of the TLE extension used on the update path.
- `tovers` – The destination version of the TLE extension used on the update path.

**Output**

- `true` – The function has successfully updated the path for the TLE extension.
- `false` – The function wasn't able to update the path for the TLE extension.

**Usage example**

```
SELECT * FROM pgtle.uninstall_update_path_if_exists(pg_tle_test, 0.1, 0.2);
```
pgtle.unregister_feature

The unregister_feature function provides a way to remove functions that were registered to use pg_tle features, such as hooks. For information about registering a feature, see pgtle.register_feature (p. 2118).

Function prototype

```
pgtle.unregister_feature(proc regproc, feature pg_tle_features)
```

Role

pgtle_admin

Arguments

- proc – The name of a stored function to register with a pg_tle feature.
- feature – The name of the pg_tle feature to register with the function. For example, passcheck is a feature that can be registered for use by the trusted language extensions that you develop. For more information, see Password-check hook (passcheck) (p. 2124).

Output

None.

Usage example

```
SELECT * FROM pgtle.unregister_feature(pw_hook, passcheck);
```

pgtle.unregister_feature_if_exists

The unregister_feature function provides a way to remove functions that were registered to use pg_tle features, such as hooks. For more information, see Using PostgreSQL hooks with your TLE extensions (p. 2110). Returns true after successfully unregistering the feature. Returns false if the feature wasn't registered.

For information about registering pg_tle features for your TLE extensions, see pgtle.register_feature (p. 2118).

Function prototype

```
pgtle.unregister_feature_if_exists(proc regproc, feature pg_tle_features)
```

Role

pgtle_admin

Arguments

- proc – The name of the stored function that was registered to include a pg_tle feature.
- feature – The name of the pg_tle feature that was registered with the trusted language extension.
Output

Returns true or false, as follows.

- true – The function has successfully unregistered the feature from extension.
- false – The function wasn't able to unregister the feature from the TLE extension.

Usage example

```sql
SELECT * FROM pgtle.unregister_feature_if_exists(pw_hook, passcheck);
```

Hooks reference for Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL supports PostgreSQL hooks. A hook is an internal callback mechanism available to developers for extending PostgreSQL's core functionality. By using hooks, developers can implement their own functions or procedures for use during various database operations, thereby modifying PostgreSQL's behavior in some way. For example, you can use a passcheck hook to customize how PostgreSQL handles the passwords supplied when creating or changing passwords for users (roles).

View the following documentation to learn about the hooks available for your TLE extensions.

Topics

- Password-check hook (passcheck) (p. 2124)

Password-check hook (passcheck)

The passcheck hook is used to customize PostgreSQL behavior during the password-checking process for the following SQL commands and psql metacommand.

- CREATE ROLE `username` ... PASSWORD – For more information, see CREATE ROLE in the PostgreSQL documentation.
- ALTER ROLE `username` ... PASSWORD – For more information, see ALTER ROLE in the PostgreSQL documentation.
- `\password` `username` – This interactive psql metacommand securely changes the password for the specified user by hashing the password before transparently using the ALTER ROLE ... PASSWORD syntax. The metacommand is a secure wrapper for the ALTER ROLE ... PASSWORD command, thus the hook applies to the behavior of the psql metacommand.

For an example, see Password-check hook code listing (p. 2113).

Function prototype

```sql
passcheck_hook(username text, password text, password_type pgtle.password_types, valid_until timestamptz, valid_null boolean)
```

Arguments

A passcheck hook function takes the following arguments.
• **username** – The name (as text) of the role (username) that's setting a password.
• **password** – The plaintext or hashed password. The password entered should match the type specified in **password_type**.
• **password_type** – Specify the `pgtle.password_type` format of the password. This format can be one of the following options.
  • **PASSWORD_TYPE_PLAINTEXT** – A plaintext password.
  • **PASSWORD_TYPE_MD5** – A password that's been hashed using MD5 (message digest 5) algorithm.
  • **PASSWORD_TYPE_SCRAM_SHA_256** – A password that's been hashed using SCRAM-SHA-256 algorithm.
• **valid_until** – Specify the time when the password becomes invalid. This argument is optional. If you use this argument, specify the time as a `timestamptz` value.
• **valid_null** – If this Boolean is set to true, the valid_until option is set to NULL.

**Configuration**

The function `pgtle.enable_password_check` controls whether the passcheck hook is active. The passcheck hook has three possible settings.

• **off** – Turns off the passcheck password-check hook. This is the default value.
• **on** – Turns on the passcode password-check hook so that passwords are checked against the table.
• **require** – Requires a password check hook to be defined.

**Usage notes**

To turn the passcheck hook on or off, you need to modify the custom DB parameter group for your RDS for PostgreSQL DB instance.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group \
  --region aws-region \
  --db-parameter-group-name your-custom-parameter-group \
  --parameters \
  "ParameterName=pgtle.enable_password_check,ParameterValue=on,ApplyMethod=immediate"
```

For Windows:

```bash
aws rds modify-db-parameter-group ^
  --region aws-region ^
  --db-parameter-group-name your-custom-parameter-group ^
  --parameters 
  "ParameterName=pgtle.enable_password_check,ParameterValue=on,ApplyMethod=immediate"
```
Security in Amazon RDS

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS compliance programs. To learn about the compliance programs that apply to Amazon RDS, see AWS services in scope by compliance program.
- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your organization’s requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Amazon RDS. The following topics show you how to configure Amazon RDS to meet your security and compliance objectives. You also learn how to use other AWS services that help you monitor and secure your Amazon RDS resources.

You can manage access to your Amazon RDS resources and your databases on a DB instance. The method you use to manage access depends on what type of task the user needs to perform with Amazon RDS:

- Run your DB instance in a virtual private cloud (VPC) based on the Amazon VPC service for the greatest possible network access control. For more information about creating a DB instance in a VPC, see Amazon VPC VPCs and Amazon RDS (p. 2251).
- Use AWS Identity and Access Management (IAM) policies to assign permissions that determine who is allowed to manage Amazon RDS resources. For example, you can use IAM to determine who is allowed to create, describe, modify, and delete DB instances, tag resources, or modify security groups.
- Use security groups to control what IP addresses or Amazon EC2 instances can connect to your databases on a DB instance. When you first create a DB instance, its firewall prevents any database access except through rules specified by an associated security group.
- Use Secure Socket Layer (SSL) or Transport Layer Security (TLS) connections with DB instances running the MySQL, MariaDB, PostgreSQL, Oracle, or Microsoft SQL Server database engines. For more information on using SSL/TLS with a DB instance, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152).
- Use Amazon RDS encryption to secure your DB instances and snapshots at rest. Amazon RDS encryption uses the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your DB instance. For more information, see Encrypting Amazon RDS resources (p. 2147).
- Use network encryption and transparent data encryption with Oracle DB instances; for more information, see Oracle native network encryption (p. 1763) and Oracle Transparent Data Encryption (p. 1803)
- Use the security features of your DB engine to control who can log in to the databases on a DB instance. These features work just as if the database was on your local network.

**Note**
You have to configure security only for your use cases. You don't have to configure security access for processes that Amazon RDS manages. These include creating backups, replicating data between a primary DB instance and a read replica, and other processes.
Database authentication with Amazon RDS

Amazon RDS supports several ways to authenticate database users.

Password, Kerberos, and IAM database authentication use different methods of authenticating to the database. Therefore, a specific user can log in to a database using only one authentication method.

For PostgreSQL, use only one of the following role settings for a user of a specific database:

- To use IAM database authentication, assign the rds_iam role to the user.
- To use Kerberos authentication, assign the rds_ad role to the user.
- To use password authentication, don’t assign either the rds_iam or rds_ad roles to the user.

Don't assign both the rds_iam and rds_ad roles to a user of a PostgreSQL database either directly or indirectly by nested grant access. If the rds_iam role is added to the master user, IAM authentication takes precedence over password authentication so the master user has to log in as an IAM user.

**Important**

We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

**Topics**

- **Password authentication** (p. 2127)
- **IAM database authentication** (p. 2128)
- **Kerberos authentication** (p. 2128)

Password authentication

With *password authentication*, your database performs all administration of user accounts. You create users with SQL statements such as `CREATE USER`, with the appropriate clause required by the DB engine.
for specifying passwords. For example, in MySQL the statement is `CREATE USER name IDENTIFIED BY password`, while in PostgreSQL, the statement is `CREATE USER name WITH PASSWORD password`.

With password authentication, your database controls and authenticates user accounts. If a DB engine has strong password management features, they can enhance security. Database authentication might be easier to administer using password authentication when you have small user communities. Because clear text passwords are generated in this case, integrating with AWS Secrets Manager can enhance security.

For information about using Secrets Manager with Amazon RDS, see Creating a basic secret and Rotating secrets for supported Amazon RDS databases in the AWS Secrets Manager User Guide. For information about programmatically retrieving your secrets in your custom applications, see Retrieving the secret value in the AWS Secrets Manager User Guide.

IAM database authentication

You can authenticate to your DB instance using AWS Identity and Access Management (IAM) database authentication. IAM database authentication works with MySQL and PostgreSQL. With this authentication method, you don't need to use a password when you connect to a DB instance. Instead, you use an authentication token.

For more information about IAM database authentication, including information about availability for specific DB engines, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 2195).

Kerberos authentication

Amazon RDS supports external authentication of database users using Kerberos and Microsoft Active Directory. Kerberos is a network authentication protocol that uses tickets and symmetric-key cryptography to eliminate the need to transmit passwords over the network. Kerberos has been built into Active Directory and is designed to authenticate users to network resources, such as databases.

Amazon RDS support for Kerberos and Active Directory provides the benefits of single sign-on and centralized authentication of database users. You can keep your user credentials in Active Directory. Active Directory provides a centralized place for storing and managing credentials for multiple DB instances.

You can make it possible for your database users to authenticate against DB instances in two ways. They can use credentials stored either in AWS Directory Service for Microsoft Active Directory or in your on-premises Active Directory.

Microsoft SQL Server, MySQL, and PostgreSQL DB instances support one- and two-way forest trust relationships. Oracle DB instances support one- and two-way external and forest trust relationships. For more information, see When to create a trust relationship in the AWS Directory Service Administration Guide.

For information about Kerberos authentication with a specific DB engine, see the following:

- Using Windows Authentication with an Amazon RDS for SQL Server DB instance (p. 1184)
- Using Kerberos authentication for MySQL (p. 1374)
- Configuring Kerberos authentication for Amazon RDS for Oracle (p. 1553)
- Using Kerberos authentication with Amazon RDS for PostgreSQL (p. 1875)

Note
Currently, Kerberos authentication isn't supported for MariaDB DB instances.
Password management with Amazon RDS and AWS Secrets Manager

Amazon RDS integrates with Secrets Manager to manage master user passwords for your DB instances and Multi-AZ DB clusters.

**Topics**
- Overview of managing master user passwords with AWS Secrets Manager (p. 2129)
- Benefits of managing master user passwords with Secrets Manager (p. 2130)
- Permissions required for Secrets Manager integration (p. 2130)
- Enforcing RDS management of the master user password in AWS Secrets Manager (p. 2131)
- Managing the master user password for a DB instance with Secrets Manager (p. 2131)
- Managing the master user password for a Multi-AZ DB cluster with Secrets Manager (p. 2134)
- Rotating the master user password secret for a DB instance (p. 2137)
- Rotating the master user password secret for a Multi-AZ DB cluster (p. 2138)
- Viewing the details about a secret for a DB instance (p. 2140)
- Viewing the details about a secret for a Multi-AZ DB cluster (p. 2143)
- Region and version availability (p. 2146)
- Limitations for Secrets Manager integration with Amazon RDS (p. 2146)

**Overview of managing master user passwords with AWS Secrets Manager**

With AWS Secrets Manager, you can replace hard-coded credentials in your code, including database passwords, with an API call to Secrets Manager to retrieve the secret programmatically. For more information about Secrets Manager, see AWS Secrets Manager User Guide.

You can specify that RDS manages the master user password in Secrets Manager for an Amazon RDS DB instance or Multi-AZ DB cluster when you perform one of the following operations:

- Create the DB instance
- Create the Multi-AZ DB cluster
- Modify the DB instance
- Modify the Multi-AZ DB cluster
- Restore the DB instance from Amazon S3

When you specify that RDS manages the master user password in Secrets Manager, RDS generates the password and stores it in Secrets Manager. You can interact directly with the secret to retrieve the credentials for the master user. You can also specify a customer managed key to encrypt the secret, or use the KMS key that is provided by Secrets Manager.

RDS manages the settings for the secret and rotates the secret every seven days by default. You can modify some of the settings, such as the rotation schedule. If you delete a DB instance that manages a secret in Secrets Manager, the secret and its associated metadata are also deleted.

To connect to a DB instance or Multi-AZ DB cluster with the credentials in a secret, you can retrieve the secret from Secrets Manager. For more information, see Retrieve secrets from AWS Secrets Manager.
Benefits of managing master user passwords with Secrets Manager

Managing RDS master user passwords with Secrets Manager provides the following benefits:

- RDS automatically generates database credentials.
- RDS automatically stores and manages database credentials in AWS Secrets Manager.
- RDS rotates database credentials regularly, without requiring application changes.
- Secrets Manager secures database credentials from human access and plain text view.
- Secrets Manager allows retrieval of database credentials in secrets for database connections.
- Secrets Manager allows fine-grained control of access to database credentials in secrets using IAM.
- You can optionally separate database encryption from credentials encryption with different KMS keys.
- You can eliminate manual management and rotation of database credentials.
- You can monitor database credentials easily with AWS CloudTrail and Amazon CloudWatch.

For more information about the benefits of Secrets Manager, see AWS Secrets Manager User Guide.

Permissions required for Secrets Manager integration

Users must have the required permissions to perform operations related to Secrets Manager integration. You can create IAM policies that grant permissions to perform specific API operations on the specified resources they need. You can then attach those policies to the IAM permission sets or roles that require those permissions. For more information, see Identity and access management for Amazon RDS (p. 2162).

For create, modify, or restore operations, the user who specifies that Amazon RDS manages the master user password in Secrets Manager must have permissions to perform the following operations:

- kms:DescribeKey
- secretsmanager:CreateSecret
- secretsmanager:TagResource

For create, modify, or restore operations, the user who specifies the customer managed key to encrypt the secret in Secrets Manager must have permissions to perform the following operations:

- kms:Decrypt
- kms:GenerateDataKey
- kms:CreateGrant

For modify operations, the user who rotates the master user password in Secrets Manager must have permissions to perform the following operation:

- secretsmanager:RotateSecret
Enforcing RDS management of the master user password in AWS Secrets Manager

You can use IAM condition keys to enforce RDS management of the master user password in AWS Secrets Manager. The following policy doesn't allow users to create or restore DB instances or DB clusters unless the master user password is managed by RDS in Secrets Manager.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": ["rds:CreateDBInstance, rds:CreateDBCluster, rds:RestoreDBInstanceFromS3, rds:RestoreDBClusterFromS3"],
      "Resource": "*",
      "Condition": {
        "Bool": {
          "rds:ManageMasterUserPassword": false
        }
      }
    }
  ]
}
```

For more information about using condition keys in IAM policies, see Policy condition keys for Amazon RDS (p. 2169) and Example policies: Using condition keys (p. 2177).

Managing the master user password for a DB instance with Secrets Manager

You can configure RDS management of the master user password in Secrets Manager when you perform the following actions:

- Creating an Amazon RDS DB instance (p. 236)
- Modifying an Amazon RDS DB instance (p. 333)
- Restoring a backup into a MySQL DB instance (p. 1408)

You can use the RDS console, the AWS CLI, or the RDS API to perform these actions.

Console

Follow the instructions for creating or modifying a DB instance with the RDS console:

- Creating a DB instance (p. 239)
- Modifying an Amazon RDS DB instance (p. 333)
- Importing data from Amazon S3 to a new MySQL DB instance (p. 1413)

When you use the RDS console to perform one of these operations, you can specify that the master user password is managed by RDS in Secrets Manager. To do so when you are creating or restoring a DB instance, select Manage master credentials in AWS Secrets Manager in Credential settings. When you are modifying a DB instance, select Manage master credentials in AWS Secrets Manager in Settings.

The following image is an example of the Manage master credentials in AWS Secrets Manager setting when you are creating or restoring a DB instance.
When you select this option, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

You can choose to encrypt the secret with a KMS key that Secrets Manager provides or with a customer managed key that you create. After RDS is managing the database credentials for a DB instance, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements. For more information about the available settings when you are creating a DB instance, see Settings for DB instances (p. 243). For more information about the available settings when you are modifying a DB instance, see Settings for DB instances (p. 334).
AWS CLI

To manage the master user password with RDS in Secrets Manager, specify the `--manage-master-user-password` option in one of the following AWS CLI commands:

- `create-db-instance`
- `modify-db-instance`
- `restore-db-instance-from-s3`

When you specify the `--manage-master-user-password` option in these commands, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `--master-user-secret-kms-key-id` option to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN. After RDS is managing the database credentials for a DB instance, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements. For more information about the available settings when you are creating a DB instance, see [Settings for DB instances](p. 243). For more information about the available settings when you are modifying a DB instance, see [Settings for DB instances](p. 334).

This example creates a DB instance and specifies that RDS manages the master user password in Secrets Manager. The secret is encrypted using the KMS key that is provided by Secrets Manager.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance
   --db-instance-identifier mydbinstance
   --engine mysql
   --engine-version 8.0.30
   --db-instance-class db.r5b.large
   --allocated-storage 200
   --manage-master-user-password
```

For Windows:

```bash
aws rds create-db-instance ^
   --db-instance-identifier mydbinstance ^
   --engine mysql ^
   --engine-version 8.0.30 ^
   --db-instance-class db.r5b.large ^
   --allocated-storage 200 ^
   --manage-master-user-password
```

RDS API

To specify that RDS manages the master user password in Secrets Manager, set the `ManageMasterUserPassword` parameter to `true` in one of the following RDS API operations:

- `CreateDBInstance`
- `ModifyDBInstance`
• RestoreDBInstanceFromS3

When you set the ManageMasterUserPassword parameter to true in one of these operations, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the MasterUserSecretKmsKeyId parameter to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN. After RDS is managing the database credentials for a DB instance, you can't change the KMS key that is used to encrypt the secret.

Managing the master user password for a Multi-AZ DB cluster with Secrets Manager

You can configure RDS management of the master user password in Secrets Manager when you perform the following actions:

• Creating a Multi-AZ DB cluster (p. 258)
• Modifying a Multi-AZ DB cluster (p. 348)

You can use the RDS console, the AWS CLI, or the RDS API to perform these actions.

Console

Follow the instructions for creating or modifying a Multi-AZ DB cluster with the RDS console:

• Creating a DB cluster (p. 261)
• Modifying a Multi-AZ DB cluster (p. 348)

When you use the RDS console to perform one of these operations, you can specify that the master user password is managed by RDS in Secrets Manager. To do so when you are creating a DB cluster, select Manage master credentials in AWS Secrets Manager in Credential settings. When you are modifying a DB cluster, select Manage master credentials in AWS Secrets Manager in Settings.

The following image is an example of the Manage master credentials in AWS Secrets Manager setting when you are creating a DB cluster.
When you select this option, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

You can choose to encrypt the secret with a KMS key that Secrets Manager provides or with a customer managed key that you create. After RDS is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements.

For more information about the available settings when you are creating a Multi-AZ DB cluster, see Settings for creating Multi-AZ DB clusters (p. 264). For more information about the available settings when you are modifying a Multi-AZ DB cluster, see Settings for modifying Multi-AZ DB clusters (p. 349).
AWS CLI

To specify that RDS manages the master user password in Secrets Manager, specify the `--manage-master-user-password` option in one of the following commands:

- `create-db-cluster`
- `modify-db-cluster`

When you specify the `--manage-master-user-password` option in these commands, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `--master-user-secret-kms-key-id` option to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN. After RDS is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements.

For more information about the available settings when you are creating a Multi-AZ DB cluster, see Settings for creating Multi-AZ DB clusters (p. 264). For more information about the available settings when you are modifying a Multi-AZ DB cluster, see Settings for modifying Multi-AZ DB clusters (p. 349).

This example creates a Multi-AZ DB cluster and specifies that RDS manages the password in Secrets Manager. The secret is encrypted using the KMS key that is provided by Secrets Manager.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster \
  --db-cluster-identifier mysql-multi-az-db-cluster \
  --engine mysql \
  --engine-version 8.0.28 \
  --backup-retention-period 1 \
  --allocated-storage 4000 \
  --storage-type io1 \
  --iops 10000 \
  --db-cluster-instance-class db.r6gd.xlarge \
  --manage-master-user-password
```

For Windows:

```bash
aws rds create-db-cluster ^
  --db-cluster-identifier mysql-multi-az-db-cluster ^
  --engine mysql ^
  --engine-version 8.0.28 ^
  --backup-retention-period 1 ^
  --allocated-storage 4000 ^
  --storage-type io1 ^
  --iops 10000 ^
  --db-cluster-instance-class db.r6gd.xlarge ^
  --manage-master-user-password
```

**RDS API**

To specify that RDS manages the master user password in Secrets Manager, set the `ManageMasterUserPassword` parameter to true in one of the following operations:
Rotating the master user password secret for a DB instance

When you set the `ManageMasterUserPassword` parameter to `true` in one of these operations, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `MasterUserSecretKmsKeyId` parameter to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN. After RDS is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

**Rotating the master user password secret for a DB instance**

When RDS rotates a master user password secret, Secrets Manager generates a new secret version for the existing secret. The new version of the secret contains the new master user password. Amazon RDS changes the master user password for the DB instance to match the password for the new secret version.

You can rotate a secret immediately instead of waiting for a scheduled rotation. To rotate a master user password secret in Secrets Manager, modify the DB instance. For information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](p. 333).

You can rotate a master user password secret immediately with the RDS console, the AWS CLI, or the RDS API.

**Console**

To rotate a master user password secret using the RDS console, modify the DB instance and select **Rotate secret immediately in Settings**.

![Settings](image)

Follow the instructions for modifying a DB instance with the RDS console in [Modifying an Amazon RDS DB instance](p. 333). You must choose **Apply immediately** on the confirmation page.
AWS CLI

To rotate a master user password secret using the AWS CLI, use the `modify-db-instance` command and specify the `--rotate-master-user-password` option. You must specify the `--apply-immediately` option when you rotate the master password.

This example rotates a master user password secret.

**Example**

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \ 
    --rotate-master-user-password \ 
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^ \
    --db-instance-identifier mydbinstance ^ 
    --rotate-master-user-password ^ 
    --apply-immediately
```

RDS API

You can rotate a master user password secret using the `ModifyDBInstance` operation and setting the `RotateMasterUserPassword` parameter to `true`. You must set the `ApplyImmediately` parameter to `true` when you rotate the master password.

**Rotating the master user password secret for a Multi-AZ DB cluster**

When RDS rotates a master user password secret, Secrets Manager generates a new secret version for the existing secret. The new version of the secret contains the new master user password. Amazon RDS changes the master user password for the Multi-AZ DB cluster to match the password for the new secret version.

You can rotate a secret immediately instead of waiting for a scheduled rotation. To rotate a master user password secret in Secrets Manager, modify the Multi-AZ DB cluster. For information about modifying a Multi-AZ DB cluster, see Modifying a Multi-AZ DB cluster (p. 348).

You can rotate a master user password secret immediately with the RDS console, the AWS CLI, or the RDS API.

**Console**

To rotate a master user password secret using the RDS console, modify the Multi-AZ DB cluster and select **Rotate secret immediately** in **Settings**.
Follow the instructions for modifying a Multi-AZ DB cluster with the RDS console in Modifying a Multi-AZ DB cluster (p. 348). You must choose Apply immediately on the confirmation page.

**AWS CLI**

To rotate a master user password secret using the AWS CLI, use the `modify-db-cluster` command and specify the `--rotate-master-user-password` option. You must specify the `--apply-immediately` option when you rotate the master password.

This example rotates a master user password secret.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster \
  --db-cluster-identifier mydbcluster \
  --rotate-master-user-password \
  --apply-immediately
```

For Windows:

```bash
aws rds modify-db-cluster ^
  --db-cluster-identifier mydbcluster ^
  --rotate-master-user-password ^
  --apply-immediately
```
RDS API

You can rotate a master user password secret using the ModifyDBCluster operation and setting the RotateMasterUserPassword parameter to true. You must set the ApplyImmediately parameter to true when you rotate the master password.

Viewing the details about a secret for a DB instance

You can retrieve your secrets using the console (https://console.aws.amazon.com/secretsmanager/) or the AWS CLI (get-secret-value Secrets Manager command).

You can find the Amazon Resource Name (ARN) of a secret managed by RDS in Secrets Manager with the RDS console, the AWS CLI, or the RDS API.

Console

To view the details about a secret managed by RDS in Secrets Manager

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the name of the DB instance to show its details.
4. Choose the Configuration tab.

   In Master Credentials ARN, you can view the secret ARN.
You can follow the Manage in Secrets Manager link to view and manage the secret in the Secrets Manager console.

**AWS CLI**

You can use the `describe-db-instances` RDS CLI command to find the following information about a secret managed by RDS in Secrets Manager:

- **SecretArn** – The ARN of the secret
- **SecretStatus** – The status of the secret

The possible status values include the following:

- **creating** – The secret is being created.
- **active** – The secret is available for normal use and rotation.
- **rotating** – The secret is being rotated.
Viewing the details about a secret for a DB instance

- **impaired** – The secret can be used to access database credentials, but it can't be rotated. A secret might have this status if, for example, permissions are changed so that RDS can no longer access the secret or the KMS key for the secret.

When a secret has this status, you can correct the condition that caused the status. If you correct the condition that caused status, the status remains impaired until the next rotation. Alternatively, you can modify the DB instance to turn off automatic management of database credentials, and then modify the DB instance again to turn on automatic management of database credentials. To modify the DB instance, use the `--manage-master-user-password` option in the `modify-db-instance` command.

- **KmsKeyId** – The ARN of the KMS key that is used to encrypt the secret

Specify the `--db-instance-identifier` option to show output for a specific DB instance. This example shows the output for a secret that is used by a DB instance.

**Example**

```
aws rds describe-db-instances --db-instance-identifier mydbinstance
```

Following is sample output for a secret:

```
"MasterUserSecret": {
  "SecretArn": "arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!db-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx",
  "SecretStatus": "active",
  "KmsKeyId": "arn:aws:kms:eu-west-1:123456789012:key/0987dcba-09fe-87dc-65ba-ab0987654321"
}
```

When you have the secret ARN, you can view details about the secret using the `get-secret-value` Secrets Manager CLI command.

This example shows the details for the secret in the previous sample output.

**Example**

For Linux, macOS, or Unix:

```
aws secretsmanager get-secret-value \
  --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!db-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

For Windows:

```
aws secretsmanager get-secret-value ^
  --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!db-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

**RDS API**

You can view the ARN, status, and KMS key for a secret managed by RDS in Secrets Manager by using the `DescribeDBInstances` operation and setting the `DBInstanceIdentifier` parameter to a DB instance identifier. Details about the secret are included in the output.

When you have the secret ARN, you can view details about the secret using the `GetSecretValue` Secrets Manager operation.
Viewing the details about a secret for a Multi-AZ DB cluster

You can retrieve your secrets using the console (https://console.aws.amazon.com/secretsmanager/) or the AWS CLI (`get-secret-value` Secrets Manager command).

You can find the Amazon Resource Name (ARN) of a secret managed by RDS in Secrets Manager with the RDS console, the AWS CLI, or the RDS API.

Console

To view the details about a secret managed by RDS in Secrets Manager

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the name of the Multi-AZ DB cluster to show its details.
4. Choose the Configuration tab.

   In Master Credentials ARN, you can view the secret ARN.
You can follow the **Manage in Secrets Manager** link to view and manage the secret in the Secrets Manager console.

**AWS CLI**

You can use the RDS AWS CLI `describe-db-clusters` command to find the following information about a secret managed by RDS in Secrets Manager:

- **SecretArn** – The ARN of the secret
- **SecretStatus** – The status of the secret

The possible status values include the following:
- **creating** – The secret is being created.
- **active** – The secret is available for normal use and rotation.
- **rotating** – The secret is being rotated.
Viewing the details about a secret for a Multi-AZ DB cluster

- **impaired** – The secret can be used to access database credentials, but it can’t be rotated. A secret might have this status if, for example, permissions are changed so that RDS can no longer access the secret or the KMS key for the secret.

  When a secret has this status, you can correct the condition that caused the status. If you correct the condition that caused status, the status remains impaired until the next rotation. Alternatively, you can modify the DB cluster to turn off automatic management of database credentials, and then modify the DB cluster again to turn on automatic management of database credentials. To modify the DB cluster, use the **--manage-master-user-password** option in the `modify-db-cluster` command.

- **KmsKeyId** – The ARN of the KMS key that is used to encrypt the secret

Specify the **--db-cluster-identifier** option to show output for a specific DB cluster. This example shows the output for a secret that is used by a DB cluster.

**Example**

```
aws rds describe-db-clusters --db-cluster-identifier mydbcluster
```

The following sample shows the output for a secret:

```
"MasterUserSecret": {
cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRdx",
  "SecretStatus": "active",
  "KmsKeyId": "arn:aws:kms:eu-west-1:123456789012:key/0987dcba-09fe-87dc-65ba-ab0987654321"
}
```

When you have the secret ARN, you can view details about the secret using the `get-secret-value` Secrets Manager CLI command.

This example shows the details for the secret in the previous sample output.

**Example**

For Linux, macOS, or Unix:

```
aws secretsmanager get-secret-value \
  --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!
cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRdx'
```

For Windows:

```
aws secretsmanager get-secret-value ^
  --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!
cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRdx'
```

**RDS API**

You can view the ARN, status, and KMS key for a secret managed by RDS in Secrets Manager using the `DescribeDBClusters` RDS operation and setting the `DBClusterIdentifier` parameter to a DB cluster identifier. Details about the secret are included in the output.

When you have the secret ARN, you can view details about the secret using the `GetSecretValue` Secrets Manager operation.
Region and version availability

Feature availability and support varies across specific versions of each database engine and across AWS Regions. For more information about version and Region availability with Secrets Manager integration with Amazon RDS, see Secrets Manager integration (p. 123).

Limitations for Secrets Manager integration with Amazon RDS

Managing master user passwords with Secrets Manager isn't supported for the following features:

- DB instances with read replicas, except for RDS for SQL Server DB instances
- Read replicas
- Amazon RDS Blue/Green Deployments
- Amazon RDS Custom
- Oracle Data Guard switchover
- Oracle Multitenant
- AWS CloudFormation

Data protection in Amazon RDS

The AWS shared responsibility model applies to data protection in Amazon Relational Database Service. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. This content includes the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see the AWS Shared Responsibility Model and GDPR blog post on the AWS Security Blog.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual user accounts with AWS Identity and Access Management (IAM). That way each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We recommend TLS 1.2 or later.
- Set up API and user activity logging with AWS CloudTrail.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form fields such as a Name field. This includes when you work with Amazon RDS or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.
Protecting data using encryption

You can enable encryption for database resources. You can also encrypt connections to DB instances.

Topics

- Encrypting Amazon RDS resources (p. 2147)
- AWS KMS key management (p. 2151)
- Using SSL/TLS to encrypt a connection to a DB instance (p. 2152)
- Rotating your SSL/TLS certificate (p. 2154)

Encrypting Amazon RDS resources

Amazon RDS can encrypt your Amazon RDS DB instances. Data that is encrypted at rest includes the underlying storage for DB instances, its automated backups, read replicas, and snapshots.

Amazon RDS encrypted DB instances use the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your Amazon RDS DB instances. After your data is encrypted, Amazon RDS handles authentication of access and decryption of your data transparently with a minimal impact on performance. You don’t need to modify your database client applications to use encryption.

Note
For encrypted and unencrypted DB instances, data that is in transit between the source and the read replicas is encrypted, even when replicating across AWS Regions.

Topics

- Overview of encrypting Amazon RDS resources (p. 2147)
- Encrypting a DB instance (p. 2148)
- Determining whether encryption is turned on for a DB instance (p. 2148)
- Availability of Amazon RDS encryption (p. 2150)
- Limitations of Amazon RDS encrypted DB instances (p. 2150)

Overview of encrypting Amazon RDS resources

Amazon RDS encrypted DB instances provide an additional layer of data protection by securing your data from unauthorized access to the underlying storage. You can use Amazon RDS encryption to increase data protection of your applications deployed in the cloud, and to fulfill compliance requirements for encryption at rest.

Amazon RDS also supports encrypting an Oracle or SQL Server DB instance with Transparent Data Encryption (TDE). TDE can be used with RDS encryption at rest, although using TDE and RDS encryption at rest simultaneously might slightly affect the performance of your database. You must manage different keys for each encryption method. For more information on TDE, see Oracle Transparent Data Encryption (p. 1803) or Support for Transparent Data Encryption in SQL Server (p. 1258).

For an Amazon RDS encrypted DB instance, all logs, backups, and snapshots are encrypted. Amazon RDS uses an AWS KMS key to encrypt these resources. For more information about KMS keys, see AWS KMS keys in the AWS Key Management Service Developer Guide. If you copy an encrypted snapshot, you can...
use a different KMS key to encrypt the target snapshot than the one that was used to encrypt the source snapshot.

A read replica of an Amazon RDS encrypted instance must be encrypted using the same KMS key as the primary DB instance when both are in the same AWS Region. If the primary DB instance and read replica are in different AWS Regions, you encrypt the read replica using the KMS key for that AWS Region.

You can use an AWS managed key, or you can create customer managed keys. To manage the customer managed keys used for encrypting and decrypting your Amazon RDS resources, you use the AWS Key Management Service (AWS KMS). AWS KMS combines secure, highly available hardware and software to provide a key management system scaled for the cloud. Using AWS KMS, you can create customer managed keys and define the policies that control how these customer managed keys can be used. AWS KMS supports CloudTrail, so you can audit KMS key usage to verify that customer managed keys are being used appropriately. You can use your customer managed keys with Amazon Aurora and supported AWS services such as Amazon S3, Amazon EBS, and Amazon Redshift. For a list of services that are integrated with AWS KMS, see AWS Service Integration.

Encrypting a DB instance

To encrypt a new DB instance, choose Enable encryption on the Amazon RDS console. For information on creating a DB instance, see Creating an Amazon RDS DB instance (p. 236).

If you use the create-db-instance AWS CLI command to create an encrypted DB instance, set the --storage-encrypted parameter. If you use the CreateDBInstance API operation, set the StorageEncrypted parameter to true.

When you create an encrypted DB instance, you can choose a customer managed key or the AWS managed key for Amazon RDS to encrypt your DB instance. If you don't specify the key identifier for a customer managed key, Amazon RDS uses the AWS managed key for your new DB instance. Amazon RDS creates an AWS managed key for Amazon RDS for your AWS account. Your AWS account has a different AWS managed key for Amazon RDS for each AWS Region.

Once you have created an encrypted DB instance, you can't change the KMS key used by that DB instance. Therefore, be sure to determine your KMS key requirements before you create your encrypted DB instance.

If you use the AWS CLI create-db-instance command to create an encrypted DB instance with a customer managed key, set the --kms-key-id parameter to any key identifier for the KMS key. If you use the Amazon RDS API CreateDBInstance operation, set the KmsKeyId parameter to any key identifier for the KMS key. To use a customer managed key in a different AWS account, specify the key ARN or alias ARN.

Important
Amazon RDS can lose access to the KMS key for a DB instance. For example, RDS loses access when the KMS key isn't enabled, or when RDS access to a KMS key is revoked. In these cases, the encrypted DB instance goes into inaccessible-encryption-credentials-recoverable state. The DB instance remains in this state for seven days. When you start the DB instance during that time, it checks if the KMS key is active and recovers the DB instance if it is. Restart the DB instance using the AWS CLI command start-db-instance. Currently, you can't start a DB instance in this state using the AWS Management Console.

If the DB instance isn't recovered, then it goes into the terminal inaccessible-encryption-credentials state. In this case, you can only restore the DB instance from a backup. We strongly recommend that you always turn on backups for encrypted DB instances to guard against the loss of encrypted data in your databases.

Determining whether encryption is turned on for a DB instance

You can use the AWS Management Console, AWS CLI, or RDS API to determine whether encryption at rest is turned on for a DB instance.
Console

To determine whether encryption at rest is turned on for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the name of the DB instance that you want to check to view its details.
4. Choose the Configuration tab, and check the Encryption value under Storage.

It shows either Enabled or Not enabled.

AWS CLI

To determine whether encryption at rest is turned on for a DB instance by using the AWS CLI, call the describe-db-instances command with the following option:

- --db-instance-identifier – The name of the DB instance.

The following example uses a query to return either TRUE or FALSE regarding encryption at rest for the mydb DB instance.

Example

```
aws rds describe-db-instances --db-instance-identifier mydb --query "[*].{StorageEncrypted:StorageEncrypted}" --output text
```

RDS API

To determine whether encryption at rest is turned on for a DB instance by using the Amazon RDS API, call the DescribeDBInstances operation with the following parameter:

- DBInstanceIdentifier – The name of the DB instance.
Availability of Amazon RDS encryption

Amazon RDS encryption is currently available for all database engines and storage types, except for SQL Server Express Edition.

Amazon RDS encryption is available for most DB instance classes. The following table lists DB instance classes that don't support Amazon RDS encryption:

<table>
<thead>
<tr>
<th>Instance type</th>
<th>Instance class</th>
</tr>
</thead>
<tbody>
<tr>
<td>General purpose (M1)</td>
<td>db.m1.small</td>
</tr>
<tr>
<td></td>
<td>db.m1.medium</td>
</tr>
<tr>
<td></td>
<td>db.m1.large</td>
</tr>
<tr>
<td></td>
<td>db.m1.xlarge</td>
</tr>
<tr>
<td>Memory optimized (M2)</td>
<td>db.m2.xlarge</td>
</tr>
<tr>
<td></td>
<td>db.m2.2xlarge</td>
</tr>
<tr>
<td></td>
<td>db.m2.4xlarge</td>
</tr>
<tr>
<td>Burstable (T2)</td>
<td>db.t2.micro</td>
</tr>
</tbody>
</table>

Limitations of Amazon RDS encrypted DB instances

The following limitations exist for Amazon RDS encrypted DB instances:

- You can only encrypt an Amazon RDS DB instance when you create it, not after the DB instance is created.
  
  However, because you can encrypt a copy of an unencrypted snapshot, you can effectively add encryption to an unencrypted DB instance. That is, you can create a snapshot of your DB instance, and then create an encrypted copy of that snapshot. You can then restore a DB instance from the encrypted snapshot, and thus you have an encrypted copy of your original DB instance. For more information, see Copying a DB snapshot (p. 493).

- You can't turn off encryption on an encrypted DB instance.

- You can't create an encrypted snapshot of an unencrypted DB instance.

- A snapshot of an encrypted DB instance must be encrypted using the same KMS key as the DB instance.

- You can't have an encrypted read replica of an unencrypted DB instance or an unencrypted read replica of an encrypted DB instance.

- Encrypted read replicas must be encrypted with the same KMS key as the source DB instance when both are in the same AWS Region.

- You can't restore an unencrypted backup or snapshot to an encrypted DB instance.

- To copy an encrypted snapshot from one AWS Region to another, you must specify the KMS key in the destination AWS Region. This is because KMS keys are specific to the AWS Region that they are created in.

  The source snapshot remains encrypted throughout the copy process. Amazon RDS uses envelope encryption to protect data during the copy process. For more information about envelope encryption, see Envelope encryption in the AWS Key Management Service Developer Guide.
• You can't unencrypt an encrypted DB instance. However, you can export data from an encrypted DB instance and import the data into an unencrypted DB instance.

**AWS KMS key management**

Amazon RDS automatically integrates with AWS Key Management Service (AWS KMS) for key management. Amazon RDS uses envelope encryption. For more information about envelope encryption, see [Envelope encryption](https://docs.aws.amazon.com/key-management-service/latest/devguide/envelope-encryption.html) in the *AWS Key Management Service Developer Guide*.

An AWS KMS key is a logical representation of a key. The KMS key includes metadata, such as the key ID, creation date, description, and key state. The KMS key also contains the key material used to encrypt and decrypt data. For more information about KMS keys, see [AWS KMS keys](https://docs.aws.amazon.com/kms/latest/APIReference/Welcome.html) in the *AWS Key Management Service Developer Guide*.

You can manage KMS keys used for Amazon RDS encrypted DB instances using the AWS Key Management Service (AWS KMS) in the AWS KMS console, the AWS CLI, or the AWS KMS API. If you want full control over a KMS key, then you must create a customer managed key. For more information about customer managed keys, see [Customer managed keys](https://docs.aws.amazon.com/kms/latest/developerguide/key-managed-by-customer.html) in the *AWS Key Management Service Developer Guide*.

AWS managed keys are KMS keys in your account that are created, managed, and used on your behalf by an AWS service that is integrated with AWS KMS. You can't delete, edit, or rotate AWS managed keys. For more information about AWS managed keys, see [AWS managed keys](https://docs.aws.amazon.com/kms/latest/developerguide/key-managed-by-aws.html) in the *AWS Key Management Service Developer Guide*.

You can't share a snapshot that has been encrypted using the AWS managed key of the AWS account that shared the snapshot.

You can view audit logs of every action taken with an AWS managed or customer managed key by using AWS CloudTrail.

**Important**

If you turn off or revoke permissions to a KMS key used by an RDS database, RDS puts your database into a terminal state when access to the KMS key is required. This change could be immediate, or deferred, depending on the use case that required access to the KMS key. In this state, the DB instance is no longer available, and the current state of the database can't be recovered. To restore the DB instance, you must re-enable access to the KMS key for RDS, and then restore the DB instance from the latest available backup.

**Authorizing use of a customer managed key**

When RDS uses a customer managed key in cryptographic operations, it acts on behalf of the user who is creating or changing the RDS resource.

To create an RDS resource using a customer managed key, a user must have permissions to call the following operations on the customer managed key:

- `kms:CreateGrant`
- `kms:DescribeKey`

You can specify these required permissions in a key policy, or in an IAM policy if the key policy allows it.

You can make the IAM policy stricter in various ways. For example, to allow the customer managed key to be used only for requests that originate in RDS, you can use the `kms:ViaService condition key` with the `rds.<region>.amazonaws.com` value.

You can also use the keys or values in the encryption context as a condition for using the customer managed key for cryptographic operations.
For more information, see Allowing users in other accounts to use a KMS key in the AWS Key Management Service Developer Guide.

Using SSL/TLS to encrypt a connection to a DB instance

You can use Secure Socket Layer (SSL) or Transport Layer Security (TLS) from your application to encrypt a connection to a DB instance running MariaDB, Microsoft SQL Server, MySQL, Oracle, or PostgreSQL.

SSL/TLS connections provide one layer of security by encrypting data that moves between your client and a DB instance. Using a server certificate provides an extra layer of security by validating that the connection is being made to an Amazon RDS DB instance. It does so by checking the server certificate that is automatically installed on all DB instances that you provision.

Each DB engine has its own process for implementing SSL/TLS. To learn how to implement SSL/TLS for your DB instance, use the link following that corresponds to your DB engine:

- Using SSL/TLS with a MariaDB DB instance (p. 1033)
- Using SSL with a Microsoft SQL Server DB instance (p. 1176)
- Using SSL/TLS with a MySQL DB instance (p. 1368)
- Using SSL with an RDS for Oracle DB instance (p. 1550)
- Using SSL with a PostgreSQL DB instance (p. 1868)

Note
All certificates are only available for download using SSL/TLS connections.

To get a certificate bundle that contains both the intermediate and root certificates for all AWS Regions, download from https://truststore.pki.rds.amazonaws.com/global/global-bundle.pem.

If your application is on Microsoft Windows and requires a PKCS7 file, you can download the PKCS7 certificate bundle. This bundle contains both the intermediate and root certificates at https://truststore.pki.rds.amazonaws.com/global/global-bundle.p7b.

Note
Amazon RDS Proxy uses certificates from the AWS Certificate Manager (ACM). If you are using RDS Proxy, you don’t need to download Amazon RDS certificates or update applications that use RDS Proxy connections. For more information about using TLS/SSL with RDS Proxy, see Using TLS/SSL with RDS Proxy (p. 967).

Certificate bundles for AWS Regions

To get a certificate bundle that contains both the intermediate and root certificates for an AWS Region, download from the link for the AWS Region in the following table.

<table>
<thead>
<tr>
<th>AWS Region</th>
<th>Certificate bundle (PEM)</th>
<th>Certificate bundle (PKCS7)</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1-bundle.pem</td>
<td>us-east-1-bundle.p7b</td>
</tr>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2-bundle.pem</td>
<td>us-east-2-bundle.p7b</td>
</tr>
<tr>
<td>US West (N. California)</td>
<td>us-west-1-bundle.pem</td>
<td>us-west-1-bundle.p7b</td>
</tr>
<tr>
<td>US West (Oregon)</td>
<td>us-west-2-bundle.pem</td>
<td>us-west-2-bundle.p7b</td>
</tr>
<tr>
<td>Africa (Cape Town)</td>
<td>af-south-1-bundle.pem</td>
<td>af-south-1-bundle.p7b</td>
</tr>
<tr>
<td>Asia Pacific (Hong Kong)</td>
<td>ap-east-1-bundle.pem</td>
<td>ap-east-1-bundle.p7b</td>
</tr>
</tbody>
</table>
Data encryption

AWS GovCloud (US) certificates

If your application is on Microsoft Windows and requires a PKCS7 file, you can download the PKCS7 certificate bundle. This bundle contains both the intermediate and root certificates at https://truststore.pki.us-gov-west-1.rds.amazonaws.com/global/global-bundle.p7b.

To get a certificate bundle that contains both the intermediate and root certificates for an AWS GovCloud (US) Region, download from the link for the AWS GovCloud (US) Region in the following table.

<table>
<thead>
<tr>
<th>AWS GovCloud (US) Region</th>
<th>Certificate bundle (PEM)</th>
<th>Certificate bundle (PKCS7)</th>
</tr>
</thead>
</table>
Rotating your SSL/TLS certificate

As of March 5, 2020, Amazon RDS CA-2015 certificates have expired. If you use or plan to use Secure Sockets Layer (SSL) or Transport Layer Security (TLS) with certificate verification to connect to your RDS DB instances, you require Amazon RDS CA-2019 certificates, which are enabled by default for new DB instances. If you currently do not use SSL/TLS with certificate verification, you might still have expired CA-2015 certificates and must update them to CA-2019 certificates if you plan to use SSL/TLS with certificate verification to connect to your RDS databases.

Follow these instructions to complete your updates. Before you update your DB instances to use the new CA certificate, make sure that you update your clients or applications connecting to your RDS databases.

Amazon RDS provides new CA certificates as an AWS security best practice. For information about the new certificates and the supported AWS Regions, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152).

**Note**
Amazon RDS Proxy uses certificates from the AWS Certificate Manager (ACM). If you are using RDS Proxy, when you rotate your SSL/TLS certificate, you don't need to update applications that use RDS Proxy connections. For more information about using TLS/SSL with RDS Proxy, see Using TLS/SSL with RDS Proxy (p. 967).

**Note**
If you are using a Go version 1.15 application with a DB instance that was created or updated to the rds-ca-2019 certificate prior to July 28, 2020, you must update the certificate again. Run the `modify-db-instance` command shown in the AWS CLI section using `rds-ca-2019` as the CA certificate identifier. In this case, it isn't possible to update the certificate using the AWS Management Console. If you created your DB instance or updated its certificate after July 28, 2020, no action is required. For more information, see Go GitHub issue #39568.

**Topics**
- Updating your CA certificate by modifying your DB instance (p. 2154)
- Updating your CA certificate by applying DB instance maintenance (p. 2157)
- Sample script for importing certificates into your trust store (p. 2160)

**Updating your CA certificate by modifying your DB instance**

Complete the following steps to update your CA certificate.

**To update your CA certificate by modifying your DB instance**

1. Download the new SSL/TLS certificate as described in Using SSL/TLS to encrypt a connection to a DB instance (p. 2152).
2. Update your applications to use the new SSL/TLS certificate.

The methods for updating applications for new SSL/TLS certificates depend on your specific applications. Work with your application developers to update the SSL/TLS certificates for your applications.

For information about checking for SSL/TLS connections and updating applications for each DB engine, see the following topics:

- Using new SSL/TLS certificates for MariaDB DB instances (p. 1035)
- Updating applications to connect to Microsoft SQL Server DB instances using new SSL/TLS certificates (p. 1132)
- Using new SSL/TLS certificates for MySQL DB instances (p. 1371)
• Updating applications to use new SSL/TLS certificates (p. 1550)
• Updating applications to use new SSL/TLS certificates (p. 1871)

For a sample script that updates a trust store for a Linux operating system, see Sample script for importing certificates into your trust store (p. 2160).

**Note**
The certificate bundle contains certificates for both the old and new CA, so you can upgrade your application safely and maintain connectivity during the transition period. If you are using the AWS Database Migration Service to migrate a database to a DB instance, we recommend using the certificate bundle to ensure connectivity during the migration.

3. Modify the DB instance to change the CA from **rds-ca-2015** to **rds-ca-2019**.

**Important**
By default, this operation restarts your DB instance. If you don't want to restart your DB instance during this operation, you can use the `modify-db-instance` CLI command and specify the `--no-certificate-rotation-restart` option. This option will not rotate the certificate until the next time the database restarts, either for planned or unplanned maintenance. This option is only recommended if you don't use SSL/TLS.

If you are experiencing connectivity issues after certificate expiry, use the apply immediately option by specifying **Apply immediately** in the console or by specifying the `--apply-immediately` option using the AWS CLI. By default, this operation is scheduled to run during your next maintenance window.

You can use the AWS Management Console or the AWS CLI to change the CA certificate from **rds-ca-2015** to **rds-ca-2019** for a DB instance.

**Console**

**To change the CA from rds-ca-2015 to rds-ca-2019 for a DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**.

The **Modify DB Instance** page appears.

4. In the **Connectivity** section, choose **rds-ca-2019**.
5. Choose Continue and check the summary of modifications.
6. To apply the changes immediately, choose Apply immediately.
   Important
   Choosing this option restarts your database immediately.
7. On the confirmation page, review your changes. If they are correct, choose Modify DB Instance to save your changes.
   Important
   When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

Or choose Back to edit your changes or Cancel to cancel your changes.

AWS CLI

To use the AWS CLI to change the CA from rds-ca-2015 to rds-ca-2019 for a DB instance, call the modify-db-instance command. Specify the DB instance identifier and the --ca-certificate-identifier option.

Important
When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

Example

The following code modifies mydbinstance by setting the CA certificate to rds-ca-2019. The changes are applied during the next maintenance window by using --no-apply-immediately. Use --apply-immediately to apply the changes immediately.

Important
By default, this operation reboots your DB instance. If you don't want to reboot your DB instance during this operation, you can use the modify-db-instance CLI command and specify the --no-certificate-rotation-restart option.

This option will not rotate the certificate until the next time the database restarts, either for planned or unplanned maintenance. This option is only recommended if you do not use SSL/TLS.

Use --apply-immediately to apply the update immediately. By default, this operation is scheduled to run during your next maintenance window.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance
   --db-instance-identifier mydbinstance
   --ca-certificate-identifier rds-ca-2019
   --no-apply-immediately
```
For Windows:

```
aws rds modify-db-instance ^
   --db-instance-identifier mydbinstance ^
   --ca-certificate-identifier rds-ca-2019 ^
   --no-apply-immediately
```

### Updating your CA certificate by applying DB instance maintenance

Complete the following steps to update your CA certificate by applying DB instance maintenance.

#### To update your CA certificate by applying DB instance maintenance

1. Download the new SSL/TLS certificate as described in Using SSL/TLS to encrypt a connection to a DB instance (p. 2152).
2. Update your database applications to use the new SSL/TLS certificate.
   
   The methods for updating applications for new SSL/TLS certificates depend on your specific applications. Work with your application developers to update the SSL/TLS certificates for your applications.
   
   For information about checking for SSL/TLS connections and updating applications for each DB engine, see the following topics:
   
   - Using new SSL/TLS certificates for MariaDB DB instances (p. 1035)
   - Updating applications to connect to Microsoft SQL Server DB instances using new SSL/TLS certificates (p. 1132)
   - Using new SSL/TLS certificates for MySQL DB instances (p. 1371)
   - Updating applications to use new SSL/TLS certificates (p. 1550)
   - Updating applications to use new SSL/TLS certificates (p. 1871)
   
   For a sample script that updates a trust store for a Linux operating system, see Sample script for importing certificates into your trust store (p. 2160).

   **Note**
   
   The certificate bundle contains certificates for both the old and new CA, so you can upgrade your application safely and maintain connectivity during the transition period.
3. Apply DB instance maintenance to change the CA from `rds-ca-2015` to `rds-ca-2019`.

   **Important**
   
   You can choose to apply the change immediately. By default, this operation is scheduled to run during your next maintenance window.

You can use the AWS Management Console to apply DB instance maintenance to change the CA certificate from `rds-ca-2015` to `rds-ca-2019` for multiple DB instances.

### Updating your CA certificate by applying maintenance to multiple DB instances

Use the AWS Management Console to change the CA certificate for multiple DB instances.

**To change the CA from rds-ca-2015 to rds-ca-2019 for multiple DB instances**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
In the navigation pane, there is a **Certificate update** option that shows the total number of affected DB instances.

Choose **Certificate update** in the navigation pane.

The **Update your Amazon RDS SSL/TLS certificates** page appears.
3. Choose the DB instance you want to update.

You can schedule the certificate rotation for your next maintenance window by choosing **Update at the next maintenance window**. Apply the rotation immediately by choosing **Update now**.

**Important**
When your CA certificate is rotated, the operation restarts your DB instance.
If you experience connectivity issues after certificate expiry, use the **Update now** option.

4. If you choose **Update at the next maintenance window** or **Update now**, you are prompted to confirm the CA certificate rotation.

**Important**
Before scheduling the CA certificate rotation on your database, update any client applications that use SSL/TLS and the server certificate to connect. These updates are specific to your DB engine. To determine whether your applications use SSL/TLS and the server certificate to connect, see [Step 2: Update Your Database Applications to Use the New SSL/TLS Certificate](p. 2157). After you have updated these client applications, you can confirm the CA certificate rotation.

To continue, choose the check box, and then choose **Confirm**.

5. Repeat steps 3 and 4 for each DB instance that you want to update.
Sample script for importing certificates into your trust store

The following are sample shell scripts that import the certificate bundle into a trust store.

Each sample shell script uses keytool, which is part of the Java Development Kit (JDK). For information about installing the JDK, see JDK Installation Guide.

Topics

• Sample script for importing certificates on Linux (p. 2160)
• Sample script for importing certificates on macOS (p. 2160)

Sample script for importing certificates on Linux

The following is a sample shell script that imports the certificate bundle into a trust store on a Linux operating system.

```bash
mydir=tmp/certs
if [ ! -e "${mydir}" ]
then
    mkdir -p "${mydir}"
fi

truststore=${mydir}/rds-truststore.jks
storepassword=changeit

global-bundle.pem

awk 'split_after == 1 {n++;split_after=0} /-----END CERTIFICATE-----/ {split_after=1}{print
> "rds-ca-" n "pem"}' < ${mydir}/global-bundle.pem

for CERT in rds-ca-*; do
    alias=$(openssl x509 -noout -text -in $CERT | perl -ne 'next unless /Subject:/; s/.*(CN=|
CN = )//; print')
    echo "Importing $alias"
    keytool -import -file ${CERT} -alias "${alias}" -storepass ${storepassword} -keystore
    ${truststore} -noprompt
    rm $CERT
done

rm ${mydir}/global-bundle.pem

echo "Trust store content is: "

keytool -list -v -keystore "$truststore" -storepass ${storepassword} | grep Alias | cut -d
" " -f3- | while read alias
do
    expiry=`keytool -list -v -keystore "$truststore" -storepass ${storepassword} -alias
    "$alias" | grep Valid | perl -ne 'if(/until: (.*?)\n/) { print "$1\n"; }'`
    echo " Certificate $alias expires in $expiry"
done
```

Sample script for importing certificates on macOS

The following is a sample shell script that imports the certificate bundle into a trust store on macOS.

```bash
mydir=tmp/certs
if [ ! -e "$mydir" ]
then
```

2160
Internetwork traffic privacy

Connections are protected both between Amazon RDS and on-premises applications and between Amazon RDS and other AWS resources within the same AWS Region.

Traffic between service and on-premises clients and applications

You have two connectivity options between your private network and AWS:

- An AWS Site-to-Site VPN connection. For more information, see What is AWS Site-to-Site VPN?
- An AWS Direct Connect connection. For more information, see What is AWS Direct Connect?

You get access to Amazon RDS through the network by using AWS-published API operations. Clients must support Transport Layer Security (TLS) 1.0. We recommend TLS 1.2. Clients must also support cipher suites with Perfect Forward Secrecy (PFS), such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Diffie-Hellman Ephemeral (ECDHE). Most modern systems such as Java 7 and later support these modes. Additionally, you must sign requests using an access key identifier and a secret access key that are associated with an IAM principal. Or you can use the AWS security token service (STS) to generate temporary security credentials to sign requests.
Identity and access management for Amazon RDS

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use Amazon RDS resources. IAM is an AWS service that you can use with no additional charge.

**Topics**
- Audience (p. 2162)
- Authenticating with identities (p. 2162)
- Managing access using policies (p. 2164)
- How Amazon RDS works with IAM (p. 2166)
- Identity-based policy examples for Amazon RDS (p. 2171)
- AWS managed policies for Amazon RDS (p. 2182)
- Amazon RDS updates to AWS managed policies (p. 2189)
- Preventing cross-service confused deputy problems (p. 2193)
- IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 2195)
- Troubleshooting Amazon RDS identity and access (p. 2222)

**Audience**

How you use AWS Identity and Access Management (IAM) differs, depending on the work you do in Amazon RDS.

**Service user** – If you use the Amazon RDS service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more Amazon RDS features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in Amazon RDS, see Troubleshooting Amazon RDS identity and access (p. 2222).

**Service administrator** – If you’re in charge of Amazon RDS resources at your company, you probably have full access to Amazon RDS. It’s your job to determine which Amazon RDS features and resources your employees should access. You must then submit requests to your IAM administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with Amazon RDS, see How Amazon RDS works with IAM (p. 2166).

**IAM administrator** – If you’re an IAM administrator, you might want to learn details about how you can write policies to manage access to Amazon RDS. To view example Amazon RDS identity-based policies that you can use in IAM, see Identity-based policy examples for Amazon RDS (p. 2171).

**Authenticating with identities**

Authentication is how you sign in to AWS using your identity credentials. For more information about signing in using the AWS Management Console, see The IAM console and sign-in page in the IAM User Guide.

You must be *authenticated* (signed in to AWS) as the AWS account root user, an IAM user, or by assuming an IAM role. You can also use your company's single sign-on authentication, or even sign in using Google or Facebook. In these cases, your administrator previously set up identity federation using IAM roles. When you access AWS using credentials from another company, you are assuming a role indirectly.
To sign in directly to the AWS Management Console, use your password with your root user email or your IAM user name. You can access AWS programmatically using your root user or IAM user access keys. AWS provides SDK and command line tools to cryptographically sign your request using your credentials. If you don’t use AWS tools, you must sign the request yourself. Do this using Signature Version 4, a protocol for authenticating inbound API requests. For more information about authenticating requests, see Signature Version 4 signing process in the AWS General Reference.

Regardless of the authentication method that you use, you might also be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see Using multi-factor authentication (MFA) in AWS in the IAM User Guide.

AWS account root user

When you create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account root user and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you don’t use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see Tasks that require root user credentials in the AWS Account Management Reference Guide.

IAM users and groups

An IAM user is an identity within your AWS account that has specific permissions for a single person or application. An IAM user can have long-term credentials such as a user name and password or a set of access keys. To learn how to generate access keys, see Managing access keys for IAM users in the IAM User Guide. When you generate access keys for an IAM user, make sure you view and securely save the key pair. You cannot recover the secret access key in the future. Instead, you must generate a new access key pair.

An IAM group is an identity that specifies a collection of IAM users. You can't sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named IAMAdmins and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see When to create an IAM user (instead of a role) in the IAM User Guide.

You can authenticate to your DB instance using IAM database authentication.

IAM database authentication works with the following DB engines:

- RDS for MariaDB
- RDS for MySQL
- RDS for PostgreSQL

For more information about authenticating to your DB instance using IAM, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 2195).

IAM roles

An IAM role is an identity within your AWS account that has specific permissions. It is similar to an IAM user, but is not associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by switching roles. You can assume a role by calling an AWS CLI or AWS API
operation or by using a custom URL. For more information about methods for using roles, see Using IAM roles in the IAM User Guide.

IAM roles with temporary credentials are useful in the following situations:

- **Temporary IAM user permissions** – An IAM user can assume an IAM role to temporarily take on different permissions for a specific task.

- **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see Creating a role for a third-party Identity Provider in the IAM User Guide. If you use IAM Identity Center, you configure a permission set. To control what your identities can access after they authenticate, IAM Identity Center correlates the permission set to a role in IAM. For information about permissions sets, see Permission sets in the AWS IAM Identity Center (successor to AWS Single Sign-On) User Guide.

- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.

- **Cross-service access** – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.

- **Principal permissions** – When you use an IAM user or role to perform actions in AWS, you are considered a principal. Policies grant permissions to a principal. When you use some services, you might perform an action that then triggers another action in a different service. In this case, you must have permissions to perform both actions. To see whether an action requires additional dependent actions in a policy, see Actions, Resources, and Condition Keys for Amazon RDS in the Service Authorization Reference.

- **Service role** – A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

- **Service-linked role** – A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your IAM account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

- **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see Using an IAM role to grant permissions to applications running on Amazon EC2 instances in the IAM User Guide.

To learn whether to use IAM roles, see When to create an IAM role (instead of a user) in the IAM User Guide.

### Managing access using policies

You control access in AWS by creating policies and attaching them to IAM identities or AWS resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. AWS evaluates these policies when an entity (root user, IAM user, or IAM role) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored...
An IAM administrator can use policies to specify who has access to AWS resources, and what actions they can perform on those resources. Every IAM entity (user or role) starts with no permissions. In other words, by default, users can do nothing, not even change their own password. To give a user permission to do something, an administrator must attach a permissions policy to a user. Or the administrator can add the user to a group that has the intended permissions. When an administrator gives permissions to a group, all users in that group are granted those permissions.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the `iam:GetRole` action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

**Identity-based policies**

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, role, or group. These policies control what actions that identity can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see [Creating IAM policies](#) in the [IAM User Guide](#).

Identity-based policies can be further categorized as *inline policies* or *managed policies*. Inline policies are embedded directly into a single user, group, or role. Managed policies are standalone policies that you can attach to multiple users, groups, and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see [Choosing between managed policies and inline policies](#) in the [IAM User Guide](#).

For information about AWS managed policies that are specific to Amazon RDS, see [AWS managed policies for Amazon RDS](#) (p. 2182).

**Other policy types**

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (IAM user or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the user or role in the `Principal` field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see [Permissions boundaries for IAM entities](#) in the [IAM User Guide](#).

- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for grouping and centrally managing multiple AWS accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each AWS account root user. For more information about Organizations and SCPs, see [How SCPs work](#) in the [AWS Organizations User Guide](#).

- **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's permissions are the intersection of the user or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see [Session policies](#) in the [IAM User Guide](#).
Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see Policy evaluation logic in the IAM User Guide.

How Amazon RDS works with IAM

Before you use IAM to manage access to Amazon RDS, you should understand what IAM features are available to use with Amazon RDS.

IAM features you can use with Amazon RDS

<table>
<thead>
<tr>
<th>IAM feature</th>

Amazon RDS identity-based policies

<table>
<thead>
<tr>
<th>Supports identity-based policies</th>
<th>Yes</th>
</tr>
</thead>
</table>

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Creating IAM policies in the IAM User Guide.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. You can’t specify the principal in an identity-based policy because it applies to the user or role to which it is attached. To learn about all of the elements that you can use in a JSON policy, see IAM JSON policy elements reference in the IAM User Guide.

Identity-based policy examples for Amazon RDS

To view examples of Amazon RDS identity-based policies, see Identity-based policy examples for Amazon RDS (p. 2171).

Resource-based policies within Amazon RDS

<table>
<thead>
<tr>
<th>Supports resource-based policies</th>
<th>No</th>
</tr>
</thead>
</table>

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM role trust policies and Amazon S3 bucket policies. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. Adding a cross-account principal to a resource-based policy is only half of establishing the trust relationship. When the principal and the resource are in different AWS accounts, an IAM administrator in the trusted account must also grant the principal entity (user or role) permission to access the resource. They grant permission by attaching an identity-based policy to the entity. However, if a resource-based policy grants access to a principal in the same account, no additional identity-based policy is required. For more information, see How IAM roles differ from resource-based policies in the IAM User Guide.

Policy actions for Amazon RDS

<table>
<thead>
<tr>
<th>Supports policy actions</th>
<th>Yes</th>
</tr>
</thead>
</table>

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Action element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated AWS API operation. There are some exceptions, such as permission-only actions that don’t have a matching API operation. There are also
some operations that require multiple actions in a policy. These additional actions are called dependent actions.

Include actions in a policy to grant permissions to perform the associated operation.

Policy actions in Amazon RDS use the following prefix before the action: rds:. For example, to grant someone permission to describe DB instances with the Amazon RDS DescribeDBInstances API operation, you include the rds:DescribeDBInstances action in their policy. Policy statements must include either an Action or NotAction element. Amazon RDS defines its own set of actions that describe tasks that you can perform with this service.

To specify multiple actions in a single statement, separate them with commas as follows.

```
"Action": [
    "rds:action1",
    "rds:action2"
]
```

You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word Describe, include the following action.

```
"Action": "rds:Describe*"
```

To see a list of Amazon RDS actions, see Actions Defined by Amazon RDS in the Service Authorization Reference.

### Policy resources for Amazon RDS

<table>
<thead>
<tr>
<th>Supports policy resources</th>
<th>Yes</th>
</tr>
</thead>
</table>

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Resource JSON policy element specifies the object or objects to which the action applies. Statements must include either a Resource or a NotResource element. As a best practice, specify a resource using its Amazon Resource Name (ARN). You can do this for actions that support a specific resource type, known as resource-level permissions.

For actions that don't support resource-level permissions, such as listing operations, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*
```

The DB instance resource has the following Amazon Resource Name (ARN).

```
arn:${Partition}:rds:${Region}:${Account}:${ResourceType}/${Resource}
```

For more information about the format of ARNs, see Amazon Resource Names (ARNs) and AWS service namespaces.

For example, to specify the dbtest DB instance in your statement, use the following ARN.

```
```
To specify all DB instances that belong to a specific account, use the wildcard (*).

`"Resource": "arn:aws:rds:us-east-1:123456789012:db:*"`

Some RDS API operations, such as those for creating resources, can't be performed on a specific resource. In those cases, use the wildcard (*).

`"Resource": "*"`

Many Amazon RDS API operations involve multiple resources. For example, `CreateDBInstance` creates a DB instance. You can specify that an IAM user must use a specific security group and parameter group when creating a DB instance. To specify multiple resources in a single statement, separate the ARNs with commas.

`"Resource": ["resource1", "resource2"]`

To see a list of Amazon RDS resource types and their ARNs, see Resources Defined by Amazon RDS in the Service Authorization Reference. To learn with which actions you can specify the ARN of each resource, see Actions Defined by Amazon RDS.

### Policy condition keys for Amazon RDS

| Supports service-specific policy condition keys | Yes |

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The **Condition** element (or **Condition block**) lets you specify conditions in which a statement is in effect. The **Condition** element is optional. You can create conditional expressions that use **condition operators**, such as equals or less than, to match the condition in the policy with values in the request.

If you specify multiple **Condition** elements in a statement, or multiple keys in a single **Condition** element, AWS evaluates them using a logical **AND** operation. If you specify multiple values for a single condition key, AWS evaluates the condition using a logical **OR** operation. All of the conditions must be met before the statement's permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see IAM policy elements: variables and tags in the IAM User Guide.

AWS supports global condition keys and service-specific condition keys. To see all AWS global condition keys, see AWS global condition context keys in the IAM User Guide.

Amazon RDS defines its own set of condition keys and also supports using some global condition keys. To see all AWS global condition keys, see AWS global condition context keys in the IAM User Guide.

All RDS API operations support the `aws:RequestedRegion` condition key.

To see a list of Amazon RDS condition keys, see Condition Keys for Amazon RDS in the Service Authorization Reference. To learn with which actions and resources you can use a condition key, see Actions Defined by Amazon RDS.
Access control lists (ACLs) in Amazon RDS

| Supports access control lists (ACLs) | No |

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Attribute-based access control (ABAC) in policies with Amazon RDS tags

| Supports attribute-based access control (ABAC) tags in policies | Yes |

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes. In AWS, these attributes are called tags. You can attach tags to IAM entities (users or roles) and to many AWS resources. Tagging entities and resources is the first step of ABAC. Then you design ABAC policies to allow operations when the principal's tag matches the tag on the resource that they are trying to access.

ABAC is helpful in environments that are growing rapidly and helps with situations where policy management becomes cumbersome.

To control access based on tags, you provide tag information in the condition element of a policy using the aws:ResourceTag/key-name, aws:RequestTag/key-name, or aws:TagKeys condition keys.

If a service supports all three condition keys for every resource type, then the value is Yes for the service. If a service supports all three condition keys for only some resource types, then the value is Partial.

For more information about ABAC, see What is ABAC? in the IAM User Guide. To view a tutorial with steps for setting up ABAC, see Use attribute-based access control (ABAC) in the IAM User Guide.

For more information about tagging Amazon RDS resources, see Specifying conditions: Using custom tags (p. 2178). To view an example identity-based policy for limiting access to a resource based on the tags on that resource, see Grant permission for actions on a resource with a specific tag with two different values (p. 2176).

Using temporary credentials with Amazon RDS

| Supports temporary credentials | Yes |

Some AWS services don't work when you sign in using temporary credentials. For additional information, including which AWS services work with temporary credentials, see AWS services that work with IAM in the IAM User Guide.

You are using temporary credentials if you sign in to the AWS Management Console using any method except a user name and password. For example, when you access AWS using your company's single sign-on (SSO) link, that process automatically creates temporary credentials. You also automatically create temporary credentials when you sign in to the console as a user and then switch roles. For more information about switching roles, see Switching to a role (console) in the IAM User Guide.

You can manually create temporary credentials using the AWS CLI or AWS API. You can then use those temporary credentials to access AWS. AWS recommends that you dynamically generate temporary
credentials instead of using long-term access keys. For more information, see Temporary security credentials in IAM.

Cross-service principal permissions for Amazon RDS

<table>
<thead>
<tr>
<th>Supports principal permissions</th>
<th>Yes</th>
</tr>
</thead>
</table>

When you use an IAM user or role to perform actions in AWS, you are considered a principal. Policies grant permissions to a principal. When you use some services, you might perform an action that then triggers another action in a different service. In this case, you must have permissions to perform both actions. To see whether an action requires additional dependent actions in a policy, see Actions, Resources, and Condition Keys for Amazon RDS in the Service Authorization Reference.

Service roles for Amazon RDS

<table>
<thead>
<tr>
<th>Supports service roles</th>
<th>Yes</th>
</tr>
</thead>
</table>

A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

**Warning**
Changing the permissions for a service role might break Amazon RDS functionality. Edit service roles only when Amazon RDS provides guidance to do so.

Service-linked roles for Amazon RDS

<table>
<thead>
<tr>
<th>Supports service-linked roles</th>
<th>Yes</th>
</tr>
</thead>
</table>

A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your IAM account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

For details about using Amazon RDS service-linked roles, see Using service-linked roles for Amazon RDS (p. 2236).

Identity-based policy examples for Amazon RDS

By default, IAM users and roles don't have permission to create or modify Amazon RDS resources. They also can't perform tasks using the AWS Management Console, AWS CLI, or AWS API. An IAM administrator must create IAM policies that grant users and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the IAM users or groups that require those permissions.

To learn how to create an IAM identity-based policy using these example JSON policy documents, see Creating policies on the JSON tab in the IAM User Guide.

**Topics**
- Policy best practices (p. 2172)
- Using the Amazon RDS console (p. 2172)
- Allow users to view their own permissions (p. 2173)
• Allow a user to create DB instances in an AWS account (p. 2173)
• Permissions required to use the console (p. 2175)
• Allow a user to perform any describe action on any RDS resource (p. 2175)
• Allow a user to create a DB instance that uses the specified DB parameter group and subnet group (p. 2175)
• Grant permission for actions on a resource with a specific tag with two different values (p. 2176)
• Prevent a user from deleting a DB instance (p. 2176)
• Deny all access to a resource (p. 2176)
• Example policies: Using condition keys (p. 2177)
• Specifying conditions: Using custom tags (p. 2178)

Policy best practices

Identity-based policies determine whether someone can create, access, or delete Amazon RDS resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

• Get started with AWS managed policies and move toward least-privilege permissions – To get started granting permissions to your users and workloads, use the AWS managed policies that grant permissions for many common use cases. They are available in your AWS account. We recommend that you reduce permissions further by defining AWS customer managed policies that are specific to your use cases. For more information, see AWS managed policies or AWS managed policies for job functions in the IAM User Guide.

• Apply least-privilege permissions – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as least-privilege permissions. For more information about using IAM to apply permissions, see Policies and permissions in IAM in the IAM User Guide.

• Use conditions in IAM policies to further restrict access – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific AWS service, such as AWS CloudFormation. For more information, see IAM JSON policy elements: Condition in the IAM User Guide.

• Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see IAM Access Analyzer policy validation in the IAM User Guide.

• Require multi-factor authentication (MFA) – If you have a scenario that requires IAM users or root users in your account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see Configuring MFA-protected API access in the IAM User Guide.

For more information about best practices in IAM, see Security best practices in IAM in the IAM User Guide.

Using the Amazon RDS console

To access the Amazon RDS console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the Amazon RDS resources in your AWS account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won’t function as intended for entities (IAM users or roles) with that policy.
You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that you're trying to perform.

To ensure that those entities can still use the Amazon RDS console, also attach the following AWS managed policy to the entities.

```yaml
AmazonRDSReadOnlyAccess
```

For more information, see Adding permissions to a user in the IAM User Guide.

### Allow users to view their own permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ViewOwnUserInfo",
            "Effect": "Allow",
            "Action": [
                "iam:GetUserPolicy",
                "iam:ListGroupsForUser",
                "iam:ListAttachedUserPolicies",
                "iam:ListUserPolicies",
                "iam:GetUser"
            ],
            "Resource": ["arn:aws:iam::*:user/${aws:username}"],
        },
        {
            "Sid": "NavigateInConsole",
            "Effect": "Allow",
            "Action": [
                "iam:GetGroupPolicy",
                "iam:GetPolicyVersion",
                "iam:GetPolicy",
                "iam:ListAttachedGroupPolicies",
                "iam:ListGroupPolicies",
                "iam:ListPolicy Versions",
                "iam:ListPolicies",
                "iam:ListUsers"
            ],
            "Resource": "*"
        }
    ]
}
```

### Allow a user to create DB instances in an AWS account

The following is an example policy that allows the user with the ID 123456789012 to create DB instances for your AWS account. The policy requires that the name of the new DB instance begin with `test`. The new DB instance must also use the MySQL database engine and the `db.t2.micro` DB instance class. In addition, the new DB instance must use an option group and a DB parameter group that starts with `default`, and it must use the default subnet group.

```json
{
```

2173
The policy includes a single statement that specifies the following permissions for the IAM user:

- The policy allows the IAM user to create a DB instance using the `CreateDBInstance` API operation (this also applies to the `create-db-instance` AWS CLI command and the AWS Management Console).
- The `Resource` element specifies that the user can perform actions on or with resources. You specify resources using an Amazon Resources Name (ARN). This ARN includes the name of the service that the resource belongs to (rds), the AWS Region (indicates any region in this example), the user account number (123456789012 is the user ID in this example), and the type of resource. For more information about creating ARNs, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 414).
- The `Condition` element specifies that the DB engine must be MySQL and the DB instance class must be `db.t2.micro`. The `Condition` element specifies the conditions when a policy should take effect. You can add additional permissions or restrictions by using the `Condition` element. For more information about specifying conditions, see Policy condition keys for Amazon RDS (p. 2169). This example specifies the `rds:DatabaseEngine` and `rds:DatabaseClass` conditions. For information about the valid condition values for `rds:DatabaseEngine`, see the list under the Engine parameter in `CreateDBInstance`. For information about the valid condition values for `rds:DatabaseClass`, see Supported DB engines for DB instance classes (p. 12).

The policy doesn't specify the `Principal` element because in an identity-based policy you don't specify the principal who gets the permission. When you attach policy to a user, the user is the implicit principal. When you attach a permission policy to an IAM role, the principal identified in the role's trust policy gets the permissions.

To see a list of Amazon RDS actions, see Actions Defined by Amazon RDS in the Service Authorization Reference.
Permissions required to use the console

For a user to work with the console, that user must have a minimum set of permissions. These permissions allow the user to describe the Amazon RDS resources for their AWS account and to provide other related information, including Amazon EC2 security and network information.

If you create an IAM policy that is more restrictive than the minimum required permissions, the console doesn't function as intended for users with that IAM policy. To ensure that those users can still use the console, also attach the AmazonRDSReadOnlyAccess managed policy to the user, as described in Managing access using policies (p. 2164).

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the Amazon RDS API.

The following policy grants full access to all Amazon RDS resources for the root AWS account:

```json
AmazonRDSFullAccess
```

Allow a user to perform any describe action on any RDS resource

The following permissions policy grants permissions to a user to run all of the actions that begin with Describe. These actions show information about an RDS resource, such as a DB instance. The wildcard character (*) in the Resource element indicates that the actions are allowed for all Amazon RDS resources owned by the account.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "AllowRDSDescribe",
         "Effect": "Allow",
         "Action": "rds:Describe*",
         "Resource": "*"
      }
   ]
}
```

Allow a user to create a DB instance that uses the specified DB parameter group and subnet group

The following permissions policy grants permissions to allow a user to only create a DB instance that must use the mydbpg DB parameter group and the mydbsubnetgroup DB subnet group.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "VisualEditor0",
         "Effect": "Allow",
         "Action": "rds:CreateDBInstance",
         "Resource": [
            "arn:aws:rds:*:*:pg:mydbpg",
            "arn:aws:rds:*:*:subgrp:mydbsubnetgroup"
         ]
      }
   ]
}
```
Grant permission for actions on a resource with a specific tag with two different values

You can use conditions in your identity-based policy to control access to Amazon RDS resources based on tags. The following policy allows permission to perform the ModifyDBInstance and CreateDBSnapshot API operations on DB instances with either the stage tag set to development or test.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowDevTestCreate",
      "Effect": "Allow",
      "Action": [
        "rds:ModifyDBInstance",
        "rds:CreateDBSnapshot"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "rds:db-tag/stage": ["development", "test"
        ]
      }
    }
  ]
}
```

Prevent a user from deleting a DB instance

The following permissions policy grants permissions to prevent a user from deleting a specific DB instance. For example, you might want to deny the ability to delete your production DB instances to any user that is not an administrator.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyDelete1",
      "Effect": "Deny",
      "Action": "rds:DeleteDBInstance",
    }
  ]
}
```

Deny all access to a resource

You can explicitly deny access to a resource. Deny policies take precedence over allow policies. The following policy explicitly denies a user the ability to manage a resource:
Example policies: Using condition keys

Following are examples of how you can use condition keys in Amazon RDS IAM permissions policies.

Example 1: Grant permission to create a DB instance that uses a specific DB engine and isn't MultiAZ

The following policy uses an RDS condition key and allows a user to create only DB instances that use the MySQL database engine and don't use MultiAZ. The Condition element indicates the requirement that the database engine is MySQL.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
        "Sid": "AllowMySQLCreate",
        "Effect": "Allow",
        "Action": "rds:CreateDBInstance",
        "Resource": "*",
        "Condition": {
          "StringEquals": {
            "rds:DatabaseEngine": "mysql"
          },
          "Bool": {
            "rds:MultiAz": false
          }
        }
      }
    ]
}
```

Example 2: Explicitly deny permission to create DB instances for certain DB instance classes and create DB instances that use Provisioned IOPS

The following policy explicitly denies permission to create DB instances that use the DB instance classes r3.8xlarge and m4.10xlarge, which are the largest and most expensive DB instance classes. This policy also prevents users from creating DB instances that use Provisioned IOPS, which incurs an additional cost.

Explicitly denying permission supersedes any other permissions granted. This ensures that identities to not accidentally get permission that you never want to grant.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
        "Sid": "DenyLargeCreate",
        "Effect": "Deny",
        "Action": "*",
        "Resource": "*",
        "Condition": {
          "StringNotEquals": {
            "rds:InstanceClass": ["r3.8xlarge", "m4.10xlarge"]
          },
          "Bool": {
            "rds: provisionedIops": false
          }
        }
      }
    ]
}
```
Example 3: Limit the set of tag keys and values that can be used to tag a resource

The following policy uses an RDS condition key and allows the addition of a tag with the key stage to be added to a resource with the values test, qa, and production.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds:AddTagsToResource",
        "rds:RemoveTagsFromResource"
      ],
      "Resource": "*",
      "Condition": {
        "streq": {
          "rds:req-tag/stage": [
            "test",
            "qa",
            "production"
          ]
        }
      }
    }
  ]
}
```

Specifying conditions: Using custom tags

Amazon RDS supports specifying conditions in an IAM policy using custom tags.

For example, suppose that you add a tag named environment to your DB instances with values such as beta, staging, production, and so on. If you do, you can create a policy that restricts certain users to DB instances based on the environment tag value.
Note
Custom tag identifiers are case-sensitive.

The following table lists the RDS tag identifiers that you can use in a Condition element.

<table>
<thead>
<tr>
<th>RDS tag identifier</th>
<th>Applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>db-tag</td>
<td>DB instances, including read replicas</td>
</tr>
<tr>
<td>snapshot-tag</td>
<td>DB snapshots</td>
</tr>
<tr>
<td>ri-tag</td>
<td>Reserved DB instances</td>
</tr>
<tr>
<td>og-tag</td>
<td>DB option groups</td>
</tr>
<tr>
<td>pg-tag</td>
<td>DB parameter groups</td>
</tr>
<tr>
<td>subgrp-tag</td>
<td>DB subnet groups</td>
</tr>
<tr>
<td>es-tag</td>
<td>Event subscriptions</td>
</tr>
<tr>
<td>cluster-tag</td>
<td>DB clusters</td>
</tr>
<tr>
<td>cluster-pg-tag</td>
<td>DB cluster parameter groups</td>
</tr>
<tr>
<td>cluster-snapshot-tag</td>
<td>DB cluster snapshots</td>
</tr>
</tbody>
</table>

The syntax for a custom tag condition is as follows:

"Condition":{"StringEquals":{"rds:rds-tag-identifier/tag-name": ["value"]} }

For example, the following Condition element applies to DB instances with a tag named environment and a tag value of production.

"Condition":{"StringEquals":{"rds:db-tag/environment": ["production"]} }

For information about creating tags, see Tagging Amazon RDS resources (p. 404).

Important
If you manage access to your RDS resources using tagging, we recommend that you secure access to the tags for your RDS resources. You can manage access to tags by creating policies for the AddTagsToResource and RemoveTagsFromResource actions. For example, the following policy denies users the ability to add or remove tags for all resources. You can then create policies to allow specific users to add or remove tags.

```json
{
  "Version":"2012-10-17",
  "Statement": [  
    {  
      "Sid":"DenyTagUpdates",
      "Effect":"Deny",
      "Action": [  
        "rds:AddTagsToResource",
        "rds:RemoveTagsFromResource"
      ],
      "Resource": "*"
    }
  ]
}
```
To see a list of Amazon RDS actions, see Actions Defined by Amazon RDS in the Service Authorization Reference.

**Example policies: Using custom tags**

Following are examples of how you can use custom tags in Amazon RDS IAM permissions policies. For more information about adding tags to an Amazon RDS resource, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 414).

**Note**

All examples use the us-west-2 region and contain fictitious account IDs.

**Example 1: Grant permission for actions on a resource with a specific tag with two different values**

The following policy allows permission to perform the ModifyDBInstance and CreateDBSnapshot API operations on DB instances with either the stage tag set to development or test.

```json
{
    "Version":"2012-10-17",
    "Statement":[
        {
            "Sid":"AllowDevTestCreate",
            "Effect":"Allow",
            "Action": [
                "rds:ModifyDBInstance",
                "rds:CreateDBSnapshot"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "rds:db-tag/stage": [
                        "development",
                        "test"
                    ]
                }
            }
        }
    ]
}
```

**Example 2: Explicitly deny permission to create a DB instance that uses specified DB parameter groups**

The following policy explicitly denies permission to create a DB instance that uses DB parameter groups with specific tag values. You might apply this policy if you require that a specific customer-created DB parameter group always be used when creating DB instances. Policies that use Deny are most often used to restrict access that was granted by a broader policy.

Explicitly denying permission supersedes any other permissions granted. This ensures that identities to not accidentally get permission that you never want to grant.

```json
{
    "Version":"2012-10-17",
    "Statement":[
        {
            "Sid":"DenyProductionCreate",
            "Effect":"Deny",
            "Action": "rds:CreateDBInstance",
            "Resource": "*",
            "Condition": {
            }
        }
    ]
}
```
Identity-based policy examples

Example 3: Grant permission for actions on a DB instance with an instance name that is prefixed with a user name

The following policy allows permission to call any API (except to AddTagsToResource or RemoveTagsFromResource) on a DB instance that has a DB instance name that is prefixed with the user's name and that has a tag called stage equal to devo or that has no tag called stage.

The Resource line in the policy identifies a resource by its Amazon Resource Name (ARN). For more information about using ARNs with Amazon RDS resources, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 414).

```json
{
  "Version":"2012-10-17",
  "Statement":[
    {
      "Sid":"AllowFullDevAccessNoTags",
      "Effect":"Allow",
      "NotAction":[
        "rds:AddTagsToResource",
        "rds:RemoveTagsFromResource"
      ],
      "Resource":"arn:aws:rds:*:123456789012:db:${aws:username}*",
      "Condition":{
        "StringEqualsIfExists":{
          "rds:db-tag/stage":"devo"
        }
      }
    }
  ]
}
```
AWS managed policies for Amazon RDS

To add permissions to users, groups, and roles, it's easier to use AWS managed policies than to write policies yourself. It takes time and expertise to create IAM customer managed policies that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see AWS managed policies in the IAM User Guide.

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (users, groups, and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services don't remove permissions from an AWS managed policy, so policy updates don't break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the ReadOnlyAccess AWS managed policy provides read-only access to all AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see AWS managed policies for job functions in the IAM User Guide.

Topics

- AWS managed policy: AmazonRDSReadOnlyAccess (p. 2182)
- AWS managed policy: AmazonRDSFullAccess (p. 2183)
- AWS managed policy: AmazonRDSDataFullAccess (p. 2185)
- AWS managed policy: AmazonRDSEnhancedMonitoringRole (p. 2186)
- AWS managed policy: AmazonRDSPerformanceInsightsReadOnly (p. 2186)
- AWS managed policy: AmazonRDSDirectoryServiceAccess (p. 2187)
- AWS managed policy: AmazonRDSServiceRolePolicy (p. 2188)
- AWS managed policy: AmazonRDSCustomServiceRolePolicy (p. 2188)

AWS managed policy: AmazonRDSReadOnlyAccess

This policy allows read-only access to Amazon RDS through the AWS Management Console.

Permissions details

This policy includes the following permissions:

- rds – Allows principals to describe Amazon RDS resources and list the tags for Amazon RDS resources.
- cloudwatch – Allows principals to get Amazon CloudWatch metric statistics.
- ec2 – Allows principals to describe Availability Zones and networking resources.
- logs – Allows principals to describe CloudWatch Logs log streams of log groups, and get CloudWatch Logs log events.
- devops-guru – Allows principals to describe resources that have Amazon DevOps Guru coverage, which is specified either by CloudFormation stack names or resource tags.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Action": [
            "rds:Describe*",
            "rds:ListTagsForResource",
```

2182
AWS managed policy: AmazonRDSFullAccess

This policy provides full access to Amazon RDS through the AWS Management Console.

Permissions details

This policy includes the following permissions:

- **rds** – Allows principals full access to Amazon RDS.
- **application-autoscaling** – Allows principals describe and manage Application Auto Scaling scaling targets and policies.
- **cloudwatch** – Allows principals get CloudWatch metric statics and manage CloudWatch alarms.
- **ec2** – Allows principals to describe Availability Zones and networking resources.
- **logs** – Allows principals to describe CloudWatch Logs log streams of log groups, and get CloudWatch Logs log events.
- **outposts** – Allows principals to get AWS Outposts instance types.
- **pi** – Allows principals to get Performance Insights metrics.
- **sns** – Allows principals to Amazon Simple Notification Service (Amazon SNS) subscriptions and topics, and to publish Amazon SNS messages.
- **devops-guru** – Allows principals to describe resources that have Amazon DevOps Guru coverage, which is specified either by CloudFormation stack names or resource tags.

```json
{
    "Version": "2012-10-17",

AWS managed policy: AmazonRDSDataFullAccess

This policy allows full access to use the Data API and the query editor on Aurora Serverless clusters in a specific AWS account. This policy allows the AWS account to get the value of a secret from AWS Secrets Manager.

You can attach the AmazonRDSDataFullAccess policy to your IAM identities.

Permissions details

This policy includes the following permissions:

- dbqms – Allows principals to access, create, delete, describe, and update queries. The Database Query Metadata Service (dbqms) is an internal-only service. It provides your recent and saved queries for the query editor on the AWS Management Console for multiple AWS services, including Amazon RDS.
- rds-data – Allows principals to run SQL statements on Aurora Serverless databases.
- secretsmanager – Allows principals to get the value of a secret from AWS Secrets Manager.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "SecretsManagerDbCredentialsAccess",
      "Effect": "Allow",
      "Action": [
        "secretsmanager:GetSecretValue",
        "secretsmanager:PutResourcePolicy",
        "secretsmanager:PutSecretValue",
        "secretsmanager:DeleteSecret",
        "secretsmanager:DescribeSecret",
        "secretsmanager:TagResource"
      ],
      "Resource": "arn:aws:secretsmanager:*:*:secret:rds-db-credentials/*"
    },
    {
      "Sid": "RDSDataServiceAccess",

AWS managed policy: AmazonRDSEnhancedMonitoringRole

This policy provides access to Amazon CloudWatch Logs for Amazon RDS Enhanced Monitoring.

Permissions details

This policy includes the following permissions:

- logs – Allows principals to create CloudWatch Logs log groups and retention policies, and to create and describe CloudWatch Logs log streams of log groups. It also allows principals to put and get CloudWatch Logs log events.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "EnableCreationAndManagementOfRDSCloudwatchLogGroups",
            "Effect": "Allow",
            "Action": [
                "logs:CreateLogGroup",
                "logs:PutRetentionPolicy"
            ],
            "Resource": [
                "arn:aws:logs:*:*:log-group:RDS*"
            ]
        },
        {
            "Sid": "EnableCreationAndManagementOfRDSCloudwatchLogStreams",
            "Effect": "Allow",
            "Action": [
                "logs:CreateLogStream",
                "logs:PutLogEvents",
                "logs:DescribeLogStreams",
                "logs:GetLogEvents"
            ],
            "Resource": [
                "arn:aws:logs:*:*:log-group:RDS*:log-stream:*"
            ]
        }
    ]
}
```

AWS managed policy: AmazonRDSPerformanceInsightsReadOnly

This policy provides read-only access to Amazon RDS Performance Insights for Amazon RDS DB instances and Amazon Aurora DB clusters.

Permissions details

This policy includes the following permissions:

- rds – Allows principals to describe Amazon RDS DB instances and Amazon Aurora DB clusters.
- pi – Allows principals make calls to the Amazon RDS Performance Insights API and access Performance Insights metrics.
AWS managed policy: AmazonRDSDirectoryServiceAccess

This policy allows Amazon RDS to make calls to the AWS Directory Service.

Permissions details

This policy includes the following permissions:

- ds – Allows principals to describe AWS Directory Service directories and control authorization to AWS Directory Service directories.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": "rds:DescribeDBInstances",
         "Resource": "*"
      },
      {
         "Effect": "Allow",
         "Action": "rds:DescribeDBClusters",
         "Resource": "*"
      },
      {
         "Effect": "Allow",

      },
      {
         "Effect": "Allow",
         "Action": "pi:GetDimensionKeyDetails",
         "Resource": "arn:aws:pi:*:*:metrics/rds/*"
      },
      {
         "Effect": "Allow",
         "Action": "pi:GetResourceMetadata",
         "Resource": "arn:aws:pi:*:*:metrics/rds/*"
      },
      {
         "Effect": "Allow",
         "Action": "pi:GetResourceMetrics",
         "Resource": "arn:aws:pi:*:*:metrics/rds/*"
      },
      {
         "Effect": "Allow",
         "Action": "pi:ListAvailableResourceDimensions",
         "Resource": "arn:aws:pi:*:*:metrics/rds/*"
      },
      {
         "Effect": "Allow",
         "Action": "pi:ListAvailableResourceMetrics",
         "Resource": "arn:aws:pi:*:*:metrics/rds/*"
      }
   ]
}
```
AWS managed policy: AmazonRDSServiceRolePolicy

You can’t attach the AmazonRDSServiceRolePolicy policy to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to perform actions on your behalf. For more information, see Service-linked role permissions for Amazon RDS (p. 2236).

AWS managed policy: AmazonRDSCustomServiceRolePolicy

You can’t attach the AmazonRDSCustomServiceRolePolicy policy to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to perform actions on your behalf. For more information, see Service-linked role permissions for Amazon RDS Custom (p. 2241).
## Amazon RDS updates to AWS managed policies

View details about updates to AWS managed policies for Amazon RDS since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the Amazon RDS Document history page.

Preventing cross-service confused deputy problems

The confused deputy problem is a security issue where an entity that doesn’t have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem.

Cross-service impersonation can occur when one service (the calling service) calls another service (the called service). The calling service can be manipulated to use its permissions to act on another customer’s resources in a way that it shouldn’t have permission to access. To prevent this, AWS provides tools that can help you protect your data for all services with service principals that have been given access to resources in your account. For more information, see The confused deputy problem in the IAM User Guide.

To limit the permissions that Amazon RDS gives another service for a specific resource, we recommend using the aws:SourceArn and aws:SourceAccount global condition context keys in resource policies.

In some cases, the aws:SourceArn value doesn’t contain the account ID, for example when you use the Amazon Resource Name (ARN) for an Amazon S3 bucket. In these cases, make sure to use both global condition context keys to limit permissions. In some cases, you use both global condition context keys and the aws:SourceArn value contains the account ID. In these cases, make sure that the aws:SourceAccount value and the account in the aws:SourceArn use the same account ID when they’re used in the same policy statement. If you want only one resource to be associated with the cross-service access, use aws:SourceArn. If you want to allow any resource in the specified AWS account to be associated with the cross-service use, use aws:SourceAccount.

Make sure that the value of aws:SourceArn is an ARN for an Amazon RDS resource type. For more information, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 414).

The most effective way to protect against the confused deputy problem is to use the aws:SourceArn global condition context key with the full ARN of the resource. In some cases, you might not know the full ARN of the resource or you might be specifying multiple resources. In these cases, use the aws:SourceArn global context condition key with wildcards (*) for the unknown portions of the ARN. An example is arn:aws:rds:*:123456789012:*

The following example shows how you can use the aws:SourceArn and aws:SourceAccount global condition context keys in Amazon RDS to prevent the confused deputy problem.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Sid": "ConfusedDeputyPreventionExamplePolicy",
    "Effect": "Allow",
    "Principal": {
      "Service": "rds.amazonaws.com"
    },
    "Action": "sts:AssumeRole",
    "Condition": {
      "ArnLike": {
        "aws:SourceArn": "arn:aws:rds:us-east-1:123456789012:db:mydbinstance"
      },
      "StringEquals": {
        "aws:SourceAccount": "123456789012"
      }
    }
  }
}
```

For more examples of policies that use the aws:SourceArn and aws:SourceAccount global condition context keys, see the following sections:

2193
• Granting permissions to publish notifications to an Amazon SNS topic (p. 689)
• Manually creating an IAM role for native backup and restore (p. 1143)
• Setting up Windows Authentication for SQL Server DB instances (p. 1185)
• Prerequisites for integrating RDS for SQL Server with S3 (p. 1195)
• Manually creating an IAM role for SQL Server Audit (p. 1270)
• Configuring IAM permissions for RDS for Oracle integration with Amazon S3 (p. 1700)
• Setting up access to an Amazon S3 bucket (p. 1918) (PostgreSQL import)
• Setting up access to an Amazon S3 bucket (p. 1938) (PostgreSQL export)
IAM database authentication for MariaDB, MySQL, and PostgreSQL

You can authenticate to your DB instance using AWS Identity and Access Management (IAM) database authentication. IAM database authentication works with MariaDB, MySQL, and PostgreSQL. With this authentication method, you don't need to use a password when you connect to a DB instance. Instead, you use an authentication token.

An authentication token is a unique string of characters that Amazon RDS generates on request. Authentication tokens are generated using AWS Signature Version 4. Each token has a lifetime of 15 minutes. You don't need to store user credentials in the database, because authentication is managed externally using IAM. You can also still use standard database authentication. The token is only used for authentication and doesn't affect the session after it is established.

IAM database authentication provides the following benefits:

- Network traffic to and from the database is encrypted using Secure Socket Layer (SSL) or Transport Layer Security (TLS). For more information about using SSL/TLS with Amazon RDS, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152).
- You can use IAM to centrally manage access to your database resources, instead of managing access individually on each DB instance.
- For applications running on Amazon EC2, you can use profile credentials specific to your EC2 instance to access your database instead of a password, for greater security.

In general, consider using IAM database authentication when your applications create fewer than 200 connections per second, and you don't want to manage usernames and passwords directly in your application code.

The AWS JDBC Driver for MySQL supports IAM database authentication. For more information, see AWS IAM Database Authentication in the AWS JDBC Driver for MySQL GitHub repository.

Topics

- Region and version availability (p. 2195)
- CLI and SDK support (p. 2195)
- Limitations for IAM database authentication (p. 2196)
- Recommendations for IAM database authentication (p. 2196)
- Enabling and disabling IAM database authentication (p. 2196)
- Creating and using an IAM policy for IAM database access (p. 2198)
- Creating a database account using IAM authentication (p. 2201)
- Connecting to your DB instance using IAM authentication (p. 2202)

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability with Amazon RDS and IAM database authentication, see IAM database authentication (p. 103).

CLI and SDK support

IAM database authentication is available for the AWS CLI and for the following language-specific AWS SDKs:
Limitations for IAM database authentication

When using IAM database authentication, the following limitations apply:

- The maximum number of connections per second for your DB instance might be limited depending on its DB instance class and your workload.
- Currently, IAM database authentication doesn't support all global condition context keys.

For more information about global condition context keys, see AWS global condition context keys in the IAM User Guide.
- For PostgreSQL, if the IAM role (rds_i.am) is added to a user (including the RDS master user), IAM authentication takes precedence over password authentication, so the user must log in as an IAM user.

Recommendations for IAM database authentication

We recommend the following when using IAM database authentication:

- Use IAM database authentication as a mechanism for temporary, personal access to databases.
- Use IAM database authentication when your application requires fewer than 200 new IAM database authentication connections per second.

The database engines that work with Amazon RDS don't impose any limits on authentication attempts per second. However, when you use IAM database authentication, your application must generate an authentication token. Your application then uses that token to connect to the DB instance. If you exceed the limit of maximum new connections per second, then the extra overhead of IAM database authentication can cause connection throttling.

Enabling and disabling IAM database authentication

By default, IAM database authentication is disabled on DB instances. You can enable or disable IAM database authentication using the AWS Management Console, AWS CLI, or the API.

You can enable IAM database authentication when you perform one of the following actions:

- To create a new DB instance with IAM database authentication enabled, see Creating an Amazon RDS DB instance (p. 236).
- To modify a DB instance to enable IAM database authentication, see Modifying an Amazon RDS DB instance (p. 333).
- To restore a DB instance from a snapshot with IAM database authentication enabled, see Restoring from a DB snapshot (p. 487).
- To restore a DB instance to a point in time with IAM database authentication enabled, see Restoring a DB instance to a specified time (p. 534).
IAM authentication for PostgreSQL DB instances requires that the SSL value be 1. You can't enable IAM authentication for a PostgreSQL DB instance if the SSL value is 0. You can't change the SSL value to 0 if IAM authentication is enabled for a PostgreSQL DB instance.

**Console**

Each creation or modification workflow has a **Database authentication** section, where you can enable or disable IAM database authentication. In that section, choose **Password and IAM database authentication** to enable IAM database authentication.

**To enable or disable IAM database authentication for an existing DB instance**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify.
   
   **Note**
   Make sure that the DB instance is compatible with IAM authentication. Check the compatibility requirements in Region and version availability (p. 2195).

4. Choose **Modify**.
5. In the **Database authentication** section, choose **Password and IAM database authentication** to enable IAM database authentication.
6. Choose **Continue**.
7. To apply the changes immediately, choose **Immediately** in the **Scheduling of modifications** section.
8. Choose **Modify DB instance**.

**AWS CLI**

To create a new DB instance with IAM authentication by using the AWS CLI, use the `create-db-instance` command. Specify the `--enable-iam-database-authentication` option, as shown in the following example.

```bash
aws rds create-db-instance --db-instance-identifier mydbinstance --db-instance-class db.m3.medium --engine MySQL --allocated-storage 20 --master-username masterawsuser --master-user-password masteruserpassword --enable-iam-database-authentication
```

To update an existing DB instance to have or not have IAM authentication, use the AWS CLI command `modify-db-instance`. Specify either the `--enable-iam-database-authentication` or `--no-enable-iam-database-authentication` option, as appropriate.

**Note**
Make sure that the DB instance is compatible with IAM authentication. Check the compatibility requirements in Region and version availability (p. 2195).

By default, Amazon RDS performs the modification during the next maintenance window. If you want to override this and enable IAM DB authentication as soon as possible, use the `--apply-immediately` parameter.

The following example shows how to immediately enable IAM authentication for an existing DB instance.

```bash
aws rds modify-db-instance
```
If you are restoring a DB instance, use one of the following AWS CLI commands:

- `restore-db-instance-to-point-in-time`
- `restore-db-instance-from-db-snapshot`

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the `--enable-iam-database-authentication` or `--no-enable-iam-database-authentication` option, as appropriate.

**RDS API**

To create a new DB instance with IAM authentication by using the API, use the API operation `CreateDBInstance`. Set the `Enable IAM Database Authentication` parameter to `true`.

To update an existing DB instance to have IAM authentication, use the API operation `ModifyDBInstance`. Set the `Enable IAM Database Authentication` parameter to `true` to enable IAM authentication, or `false` to disable it.

**Note**

Make sure that the DB instance is compatible with IAM authentication. Check the compatibility requirements in Region and version availability (p. 2195).

If you are restoring a DB instance, use one of the following API operations:

- `RestoreDBInstanceFromDBSnapshot`
- `RestoreDBInstanceToPointInTime`

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the `Enable IAM Database Authentication` parameter to `true` to enable IAM authentication, or `false` to disable it.

### Creating and using an IAM policy for IAM database access

To allow an IAM user or role to connect to your DB instance, you must create an IAM policy. After that, you attach the policy to an IAM user or role.

**Note**

To learn more about IAM policies, see Identity and access management for Amazon RDS (p. 2162).

The following example policy allows an IAM user to connect to a DB instance using IAM database authentication.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["rds-db:connect"],
            "Resource": [
```
Important
A user with administrator permissions can access DB instances without explicit permissions in an IAM policy. If you want to restrict administrator access to DB instances, you can create an IAM role with the appropriate, lesser privileged permissions and assign it to the administrator.

Note
Don't confuse the `rds-db:` prefix with other RDS API operation prefixes that begin with `rds:`. You use the `rds-db:` prefix and the `rds-db:connect` action only for IAM database authentication. They aren't valid in any other context.

The example policy includes a single statement with the following elements:

- **Effect** – Specify `Allow` to grant access to the DB instance. If you don't explicitly allow access, then access is denied by default.
- **Action** – Specify `rds-db:connect` to allow connections to the DB instance.
- **Resource** – Specify an Amazon Resource Name (ARN) that describes one database account in one DB instance. The ARN format is as follows.

```
arn:aws:rds-db:region:account-id:dbuser:DbiResourceId/db-user-name
```

In this format, replace the following:

- **`region`** is the AWS Region for the DB instance. In the example policy, the AWS Region is `us-east-2`.
- **`account-id`** is the AWS account number for the DB instance. In the example policy, the account number is `1234567890`.
- **`DbiResourceId`** is the identifier for the DB instance. This identifier is unique to an AWS Region and never changes. In the example policy, the identifier is `db-ABCDEFGHIJKL01234`.

To find a DB instance resource ID in the AWS Management Console for Amazon RDS, choose the DB instance to see its details. Then choose the **Configuration** tab. The **Resource ID** is shown in the **Configuration** section.

Alternatively, you can use the AWS CLI command to list the identifiers and resource IDs for all of your DB instance in the current AWS Region, as shown following.

```
aws rds describe-db-instances --query "DBInstances[*].[DBInstanceIdentifier,DbiResourceId]"
```

If you are using Amazon Aurora, specify a `DbClusterResourceId` instead of a `DbiResourceId`. For more information, see **Creating and using an IAM policy for IAM database access** in the **Amazon Aurora User Guide**.

Note
If you are connecting to a database through RDS Proxy, specify the proxy resource ID, such as `prx-ABCDEFGHIJKL01234`. For information about using IAM database authentication with RDS Proxy, see **Connecting to a proxy using IAM authentication** (p. 980).
- **db-user-name** is the name of the database account to associate with IAM authentication. In the example policy, the database account is `db_user`.

You can construct other ARNs to support various access patterns. The following policy allows access to two different database accounts in a DB instance.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds-db:connect"
      ],
      "Resource": [
      ]
    }
  ]
}
```

The following policy uses the `*` character to match all DB instances and database accounts for a particular AWS account and AWS Region.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds-db:connect"
      ],
      "Resource": [
      ]
    }
  ]
}
```

The following policy matches all of the DB instances for a particular AWS account and AWS Region. However, the policy only grants access to DB instances that have a `jane_doe` database account.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds-db:connect"
      ],
      "Resource": [
        "arn:aws:rds-db:us-east-2:123456789012:dbuser:*/jane_doe"
      ]
    }
  ]
}
```
The IAM user or role has access to only those databases that the database user does. For example, suppose that your DB instance has a database named dev, and another database named test. If the database user jane_doe has access only to dev, any IAM users or roles that access that DB instance with the jane_doe user also have access only to dev. This access restriction is also true for other database objects, such as tables, views, and so on.

An IAM administrator must create IAM policies that grant users and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the IAM users or groups that require those permissions. For examples of policies, see Identity-based policy examples for Amazon RDS (p. 2171).

Attaching an IAM policy to an IAM user or role

After you create an IAM policy to allow database authentication, you need to attach the policy to an IAM user or role. For a tutorial on this topic, see Create and attach your first customer managed policy in the IAM User Guide.

As you work through the tutorial, you can use one of the policy examples shown in this section as a starting point and tailor it to your needs. At the end of the tutorial, you have an IAM user with an attached policy that can make use of the rds-db:connect action.

Note
You can map multiple IAM users or roles to the same database user account. For example, suppose that your IAM policy specified the following resource ARN:

```
arn:aws:rds-db:us-east-2:123456789012:dbuser:db-12ABC34DEFG5HIJ6KL8MN0P78QR/jane_doe
```

If you attach the policy to IAM users Jane, Bob, and Diego, then each of those users can connect to the specified DB instance using the jane_doe database account.

Creating a database account using IAM authentication

With IAM database authentication, you don't need to assign database passwords to the user accounts you create. If you remove an IAM user that is mapped to a database account, you should also remove the database account with the DROP USER statement.

Note
The user name used for IAM authentication must match the case of the user name in the database.

Topics
• Using IAM authentication with MariaDB and MySQL (p. 2201)
• Using IAM authentication with PostgreSQL (p. 2202)

Using IAM authentication with MariaDB and MySQL

With MariaDB and MySQL, authentication is handled by AWSAuthenticationPlugin—an AWS-provided plugin that works seamlessly with IAM to authenticate your IAM users. Connect to the DB instance as the master user or a different user who can create users and grant privileges. After connecting, issue the CREATE USER statement, as shown in the following example.

```
CREATE USER jane_doe IDENTIFIED WITH AWSAuthenticationPlugin AS 'RDS';
```
The IDENTIFIED WITH clause allows MariaDB and MySQL to use the AWSAuthenticationPlugin to authenticate the database account (jane_doe). The AS `RDS` clause refers to the authentication method. Make sure the specified database user name is the same as a resource in the IAM policy for IAM database access. For more information, see Creating and using an IAM policy for IAM database access (p. 2198).

Note

If you see the following message, it means that the AWS-provided plugin is not available for the current DB instance.

ERROR 1524 (HY000): Plugin 'AWSAuthenticationPlugin' is not loaded

To troubleshoot this error, verify that you are using a supported configuration and that you have enabled IAM database authentication on your DB instance. For more information, see Region and version availability (p. 2195) and Enabling and disabling IAM database authentication (p. 2196).

After you create an account using AWSAuthenticationPlugin, you manage it in the same way as other database accounts. For example, you can modify account privileges with GRANT and REVOKE statements, or modify various account attributes with the ALTER USER statement.

Using IAM authentication with PostgreSQL

To use IAM authentication with PostgreSQL, connect to the DB instance as the master user or a different user who can create users and grant privileges. After connecting, create database users and then grant them the rds_iam role as shown in the following example.

```
CREATE USER db_userx;
GRANT rds_iam TO db_userx;
```

Make sure the specified database user name is the same as a resource in the IAM policy for IAM database access. For more information, see Creating and using an IAM policy for IAM database access (p. 2198).

Connecting to your DB instance using IAM authentication

With IAM database authentication, you use an authentication token when you connect to your DB instance. An authentication token is a string of characters that you use instead of a password. After you generate an authentication token, it's valid for 15 minutes before it expires. If you try to connect using an expired token, the connection request is denied.

Every authentication token must be accompanied by a valid signature, using AWS signature version 4. (For more information, see Signature Version 4 signing process in the AWS General Reference.) The AWS CLI and an AWS SDK, such as the AWS SDK for Java or AWS SDK for Python (Boto3), can automatically sign each token you create.

You can use an authentication token when you connect to Amazon RDS from another AWS service, such as AWS Lambda. By using a token, you can avoid placing a password in your code. Alternatively, you can use an AWS SDK to programmatically create and programmatically sign an authentication token.

After you have a signed IAM authentication token, you can connect to an Amazon RDS DB instance. Following, you can find out how to do this using either a command line tool or an AWS SDK, such as the AWS SDK for Java or AWS SDK for Python (Boto3).

For more information, see the following blog posts:

- Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL
- Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL
Prerequisites
The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication (p. 2196)
- Creating and using an IAM policy for IAM database access (p. 2198)
- Creating a database account using IAM authentication (p. 2201)

- Connecting to your DB instance using IAM authentication and the AWS SDK for Python (Boto3) (p. 2220)

Connecting to your DB instance using IAM authentication from the command line: AWS CLI and mysql client

You can connect from the command line to an Amazon RDS DB instance with the AWS CLI and mysql command line tool as described following.

Prerequisites
The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication (p. 2196)
- Creating and using an IAM policy for IAM database access (p. 2198)
- Creating a database account using IAM authentication (p. 2201)

Note
For information about connecting to your database using SQL Workbench/J with IAM authentication, see the blog post Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL.

Topics

- Generating an IAM authentication token (p. 2203)
- Connecting to a DB instance (p. 2204)

Generating an IAM authentication token

The following example shows how to get a signed authentication token using the AWS CLI.

```
aws rds generate-db-auth-token \
   --hostname rdsmysql.123456789012.us-west-2.rds.amazonaws.com \
   --port 3306 \
   --region us-west-2 \
   --username jane_doe
```
In the example, the parameters are as follows:

- **--hostname** – The host name of the DB instance that you want to access
- **--port** – The port number used for connecting to your DB instance
- **--region** – The AWS Region where the DB instance is running
- **--username** – The database account that you want to access

The first several characters of the token look like the following.

```
rdsmysql.123456789012.us-west-2.rds.amazonaws.com:3306/?Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```

**Connecting to a DB instance**

The general format for connecting is shown following.

```
mysql --host=hostName --port=portNumber --ssl-ca=full_path_to_ssl_certificate --enable-cleartext-plugin --user=userName --password=authToken
```

The parameters are as follows:

- **--host** – The host name of the DB instance that you want to access
- **--port** – The port number used for connecting to your DB instance
- **--ssl-ca** – The full path to the SSL certificate file that contains the public key

For more information about SSL/TLS support for MariaDB, see Using SSL/TLS with a MariaDB DB instance (p. 1033).

For more information about SSL/TLS support for MySQL, see Using SSL/TLS with a MySQL DB instance (p. 1368).

To download an SSL certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152).

- **--enable-cleartext-plugin** – A value that specifies that AWSAuthenticationPlugin must be used for this connection

  If you are using a MariaDB client, the **--enable-cleartext-plugin** option isn't required.

- **--user** – The database account that you want to access
- **--password** – A signed IAM authentication token

The authentication token consists of several hundred characters. It can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows one way to perform this workaround. In the example, `/sample_dir/` is the full path to the SSL certificate file that contains the public key.

```
RDSHOST="mysqldb.123456789012.us-east-1.rds.amazonaws.com"
TOKEN="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 3306 --region us-west-2 --username jane_doe )"

mysql --host=$RDSHOST --port=3306 --ssl-ca=/sample_dir/global-bundle.pem --enable-cleartext-plugin --user=jane_doe --password=$TOKEN
```

When you connect using AWSAuthenticationPlugin, the connection is secured using SSL. To verify this, type the following at the mysql> command prompt.
Connecting to your DB instance using IAM authentication from the command line: AWS CLI and psql client

You can connect from the command line to an Amazon RDS for PostgreSQL DB instance with the AWS CLI and psql command line tool as described following.

Prerequisites
The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication (p. 2196)
- Creating and using an IAM policy for IAM database access (p. 2198)
- Creating a database account using IAM authentication (p. 2201)

Note
For information about connecting to your database using pgAdmin with IAM authentication, see the blog post Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL.

Topics
- Generating an IAM authentication token (p. 2205)
- Connecting to an Amazon RDS PostgreSQL instance (p. 2206)

Generating an IAM authentication token

The authentication token consists of several hundred characters so it can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows how to use the AWS CLI to get a signed authentication token using the generate-db-auth-token command, and store it in a PGPASSWORD environment variable.

```bash
export RDSHOST="rdspostgres.123456789012.us-west-2.rds.amazonaws.com"
export PGPASSWORD="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --region us-west-2 --username jane_doe )"
```
In the example, the parameters to the `generate-db-auth-token` command are as follows:

- `--hostname` – The host name of the DB instance that you want to access
- `--port` – The port number used for connecting to your DB instance
- `--region` – The AWS Region where the DB instance is running
- `--username` – The database account that you want to access

The first several characters of the generated token look like the following.

```plaintext
rdspostgres.123456789012.us-west-2.rds.amazonaws.com:5432/?
Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```

**Connecting to an Amazon RDS PostgreSQL instance**

The general format for using `psql` to connect is shown following.

```plaintext
codeblock
psql "host=hostname port=portNumber sslmode=verify-full sslrootcert=full_path_to_ssl_certificate dbname=DBName user=userName password=authToken"
```

The parameters are as follows:

- `host` – The host name of the DB instance that you want to access
- `port` – The port number used for connecting to your DB instance
- `sslmode` – The SSL mode to use

  When you use `sslmode=verify-full`, the SSL connection verifies the DB instance endpoint against the endpoint in the SSL certificate.

- `sslrootcert` – The full path to the SSL certificate file that contains the public key

  For more information, see Using SSL with a PostgreSQL DB instance (p. 1868).

  To download an SSL certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152).

- `dbname` – The database that you want to access
- `user` – The database account that you want to access
- `password` – A signed IAM authentication token

The following example shows using `psql` to connect. In the example, `psql` uses the environment variable `RDSHOST` for the host and the environment variable `PGPASSWORD` for the generated token. Also, `/sample_dir/` is the full path to the SSL certificate file that contains the public key.

```plaintext
codeblock
export RDSHOST="rdspostgres.123456789012.us-west-2.rds.amazonaws.com"
export PGPASSWORD="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --region us-west-2 --username jane_doe )"
psql "host=$RDSHOST port=5432 sslmode=verify-full sslrootcert=/sample_dir/global-bundle.pem dbname=DBName user=jane_doe password=$PGPASSWORD"
```

**Connecting to your DB instance using IAM authentication and the AWS SDK for .NET**

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for .NET as described following.
Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication (p. 2196)
- Creating and using an IAM policy for IAM database access (p. 2198)
- Creating a database account using IAM authentication (p. 2201)

Examples

The following code examples show how to generate an authentication token, and then use it to connect to a DB instance.

To run this code example, you need the AWS SDK for .NET, found on the AWS site. The AWSSDK.Core and the AWSSDK.RDS packages are required. To connect to a DB instance, use the .NET database connector for the DB engine, such as MySqlConnector for MariaDB or MySQL, or Npgsql for PostgreSQL.

This code connects to a MariaDB or MySQL DB instance.

Modify the values of the following variables as needed:

- server – The endpoint of the DB instance that you want to access
- user – The database account that you want to access
- database – The database that you want to access
- port – The port number used for connecting to your DB instance
- SslMode – The SSL mode to use

When you use SslMode=Required, the SSL connection verifies the DB instance endpoint against the endpoint in the SSL certificate.

- SslCa – The full path to the SSL certificate for Amazon RDS

To download a certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152).

```csharp
using System;
using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;
using Amazon;

namespace ubuntu
{
    class Program
    {
        static void Main(string[] args)
        {
            var pwd = Amazon.RDS.Util.RDSAuthTokenGenerator.GenerateAuthToken(RegionEndpoint.USEast1, "mysqldb.123456789012.us-east-1.rds.amazonaws.com", 3306, "jane_doe");
            // for debug only Console.Write("\n", pwd); //this verifies the token is generated

            MySqlConnection conn = new MySqlConnection($"server=mysqldb.123456789012.us-east-1.rds.amazonaws.com;user=jane_doe;database=myDB;port=3306;password={pwd};SslMode=Required;SslCa=full_path_to_ssl_certificate");
            conn.Open();

            // Define a query
            MySqlCommand sampleCommand = new MySqlCommand("SHOW DATABASES;", conn);
```
This code connects to a PostgreSQL DB instance.

Modify the values of the following variables as needed:

- **Server** – The endpoint of the DB instance that you want to access
- **User ID** – The database account that you want to access
- **Database** – The database that you want to access
- **Port** – The port number used for connecting to your DB instance
- **SSL Mode** – The SSL mode to use

When you use SSL Mode=Required, the SSL connection verifies the DB instance endpoint against the endpoint in the SSL certificate.

- **Root Certificate** – The full path to the SSL certificate for Amazon RDS

To download a certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152).
Connecting to your DB instance using IAM authentication and the AWS SDK for Go

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for Go as described following.

Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication (p. 2196)
- Creating and using an IAM policy for IAM database access (p. 2198)
- Creating a database account using IAM authentication (p. 2201)

Examples

To run these code examples, you need the AWS SDK for Go, found on the AWS site.

Modify the values of the following variables as needed:

- dbName – The database that you want to access
- dbUser – The database account that you want to access
- dbHost – The endpoint of the DB instance that you want to access
- dbPort – The port number used for connecting to your DB instance
- region – The AWS Region where the DB instance is running

In addition, make sure the imported libraries in the sample code exist on your system.

Important

The examples in this section use the following code to provide credentials that access a database from a local environment:

```go
creds := credentials.NewEnvCredentials()
```

If you are accessing a database from an AWS service, such as Amazon EC2 or Amazon ECS, you can replace the code with the following code:

```go
sess := session.Must(session.NewSession())
creds := sess.Config.Credentials
```

If you make this change, make sure you add the following import:

`"github.com/aws/aws-sdk-go/aws/session"

Topics

- Connecting using IAM authentication and the AWS SDK for Go V1. (p. 2211)

Connecting using IAM authentication and the AWS SDK for Go V2

You can connect to a DB instance using IAM authentication and the AWS SDK for Go V2.
The following code examples show how to generate an authentication token, and then use it to connect to a DB instance.

This code connects to a MariaDB or MySQL DB instance.

```go
package main

import {
    "context"
    "database/sql"
    "fmt"
    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/feature/rds/auth"
    // "github.com/go-sql-driver/mysql"
}

func main() {
    var dbName string = "DatabaseName"
    var dbUser string = "DatabaseUser"
    var dbHost string = "mysql.db.123456789012.us-east-1.rds.amazonaws.com"
    var dbPort int = 3306
    var dbEndpoint string = fmt.Sprintf("%s:%d", dbHost, dbPort)
    var region string = "us-east-1"

    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        panic("configuration error: " + err.Error())
    }

    authToken, err := auth.BuildAuthToken(
        context.TODO(), dbEndpoint, region, dbUser, cfg.Credentials)
    if err != nil {
        panic("failed to create authentication token: " + err.Error())
    }

    dsn := fmt.Sprintf("%s:%s@tcp(%s)/%s?tls=true&allowCleartextPasswords=true",
        dbUser, authToken, dbEndpoint, dbName,
    )

    db, err := sql.Open("mysql", dsn)
    if err != nil {
        panic(err)
    }

    err = db.Ping()
    if err != nil {
        panic(err)
    }
}
```

This code connects to a PostgreSQL DB instance.

```go
package main

import {
    "context"
    "database/sql"
    "fmt"
    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/feature/rds/auth"
    // "github.com/lib/pq"
}

func main() {
    var dbName string = "DatabaseName"
    var dbUser string = "DatabaseUser"
    var dbHost string = "mysql.db.123456789012.us-east-1.rds.amazonaws.com"
    var dbPort int = 3306
    var dbEndpoint string = fmt.Sprintf("%s:%d", dbHost, dbPort)
    var region string = "us-east-1"

    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        panic("configuration error: " + err.Error())
    }

    authToken, err := auth.BuildAuthToken(
        context.TODO(), dbEndpoint, region, dbUser, cfg.Credentials)
    if err != nil {
        panic("failed to create authentication token: " + err.Error())
    }

    dsn := fmt.Sprintf("%s:%s@tcp(%s)/%s?tls=true&allowCleartextPasswords=true",
        dbUser, authToken, dbEndpoint, dbName,
    )

    db, err := sql.Open("mysql", dsn)
    if err != nil {
        panic(err)
    }

    err = db.Ping()
    if err != nil {
        panic(err)
    }
}
```
Connecting using IAM authentication and the AWS SDK for Go V1.

You can connect to a DB instance using IAM authentication and the AWS SDK for Go V1.

The following code examples show how to generate an authentication token, and then use it to connect to a DB instance.

This code connects to a MariaDB or MySQL DB instance.
region := "us-east-1"
creds := credentials.NewEnvCredentials()
authToken, err := rdsutils.BuildAuthToken(dbEndpoint, region, dbUser, creds)
if err != nil {
    panic(err)
}
dsn := fmt.Sprintf("%s:%s@tcp(%s)/%s?tls=true&allowCleartextPasswords=true",
    dbUser, authToken, dbEndpoint, dbName,
)
db, err := sql.Open("mysql", dsn)
if err != nil {
    panic(err)
}
err = db.Ping()
if err != nil {
    panic(err)
}

This code connects to a PostgreSQL DB instance.

func main() {
    dbName := "app"
dbUser := "jane_doe"
dbHost := "postgresmydb.123456789012.us-east-1.rds.amazonaws.com"
dbPort := 5432
dbEndpoint := fmt.Sprintf("%s:%d", dbHost, dbPort)
region := "us-east-1"
creds := credentials.NewEnvCredentials()
authToken, err := rdsutils.BuildAuthToken(dbEndpoint, region, dbUser, creds)
if err != nil {
    panic(err)
}
dsn := fmt.Sprintf("host=%s port=%d user=%s password=%s dbname=%s",
    dbHost, dbPort, dbUser, authToken, dbName,
)
db, err := sql.Open("postgres", dsn)
if err != nil {
    panic(err)
}
err = db.Ping()
if err != nil {
    panic(err)
}
Connecting to your DB instance using IAM authentication and the AWS SDK for Java

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for Java as described following.

Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication (p. 2196)
- Creating and using an IAM policy for IAM database access (p. 2198)
- Creating a database account using IAM authentication (p. 2201)
- Set up the AWS SDK for Java

Topics

- Generating an IAM authentication token (p. 2213)
- Manually constructing an IAM authentication token (p. 2214)
- Connecting to a DB instance (p. 2217)

Generating an IAM authentication token

If you are writing programs using the AWS SDK for Java, you can get a signed authentication token using the RdsIamAuthTokenGenerator class. Using this class requires that you provide AWS credentials. To do this, you create an instance of the DefaultAWSCredentialsProviderChain class. DefaultAWSCredentialsProviderChain uses the first AWS access key and secret key that it finds in the default credential provider chain. For more information about AWS access keys, see Managing access keys for IAM users.

After you create an instance of RdsIamAuthTokenGenerator, you can call the getAuthToken method to obtain a signed token. Provide the AWS Region, host name, port number, and user name. The following code example illustrates how to do this.

```java
package com.amazonaws.codesamples;
import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.services.rds.auth.GetIamAuthTokenRequest;
import com.amazonaws.services.rds.auth.RdsIamAuthTokenGenerator;

public class GenerateRDSAuthToken {
    public static void main(String[] args) {
        String region = "us-west-2";
        String hostname = "rdsmysql.123456789012.us-west-2.rds.amazonaws.com";
        String port = "3306";
        String username = "jane_doe";

        System.out.println(generateAuthToken(region, hostname, port, username));
    }

    static String generateAuthToken(String region, String hostName, String port, String username) {
        RdsIamAuthTokenGenerator generator = RdsIamAuthTokenGenerator.builder()
            .credentials(new DefaultAWSCredentialsProviderChain())
            .region(region)
            .build();

        GetIamAuthTokenRequest request = new GetIamAuthTokenRequest()
            .withRegion(region)
            .withHost(hostName)
            .withPort(Integer.parseInt(port))
            .withUsername(username);

        GetIamAuthTokenResult result = generator.getAuthToken(request);
        System.out.println(result.getAuthTokenValue());
    }
}
```
Manually constructing an IAM authentication token

In Java, the easiest way to generate an authentication token is to use RdsIamAuthTokenGenerator. This class creates an authentication token for you, and then signs it using AWS signature version 4. For more information, see Signature version 4 signing process in the AWS General Reference.

However, you can also construct and sign an authentication token manually, as shown in the following code example.

```java
package com.amazonaws.codesamples;

import com.amazonaws.SdkClientException;
import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.auth.SigningAlgorithm;
import com.amazonaws.util.BinaryUtils;
import org.apache.commons.lang3.StringUtils;
import javax.crypto.Mac;
import javax.crypto.spec.SecretKeySpec;
import java.nio.charset.Charset;
import java.security.MessageDigest;
import java.text.SimpleDateFormat;
import java.util.Date;
import java.util.SortedMap;
import java.util.TreeMap;
import static com.amazonaws.auth.internal.SignerConstants.AWS4_TERMINATOR;
import static com.amazonaws.util.StringUtils.UTF8;

public class CreateRDSAuthTokenManually {
    public static String httpMethod = "GET";
    public static String action = "connect";
    public static String canonicalURIParameter = "/";
    public static String algorithm = "AWS4-HMAC-SHA256";
    public static String serviceName = "rds-db";
    public static String requestWithoutSignature;

    public static void main(String[] args) throws Exception {
        String region = "us-west-2";
        String instanceName = "rdsmysql.123456789012.us-west-2.rds.amazonaws.com";
        String port = "3306";
        String username = "jane_doe";

        Date now = new Date();
        String date = new SimpleDateFormat("yyyyMMdd").format(now);
        String dateTimeStamp = new SimpleDateFormat("yyyyMMdd'T'HHmmss'Z'").format(now);
```

    } catch (Exception e) {
Connecting to a DB instance

The following code example shows how to generate an authentication token, and then use it to connect to an instance running MariaDB or MySQL.

To run this code example, you need the AWS SDK for Java, found on the AWS site. In addition, you need the following:

- MySQL Connector/J. This code example was tested with mysql-connector-java-5.1.33-bin.jar.
- An intermediate certificate for Amazon RDS that is specific to an AWS Region. (For more information, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152).) At runtime, the class loader looks for the certificate in the same directory as this Java code example, so that the class loader can find it.
- Modify the values of the following variables as needed:
  - RDS_INSTANCE_HOSTNAME – The host name of the DB instance that you want to access.
  - RDS_INSTANCE_PORT – The port number used for connecting to your PostgreSQL DB instance.
  - REGION_NAME – The AWS Region where the DB instance is running.
  - DB_USER – The database account that you want to access.
  - SSL_CERTIFICATE – An SSL certificate for Amazon RDS that is specific to an AWS Region.

To download a certificate for your AWS Region, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152). Place the SSL certificate in the same directory as this Java program file, so that the class loader can find the certificate at runtime.

This code example obtains AWS credentials from the default credential provider chain.

```java
package com.amazonaws.samples;
import com.amazonaws.services.rds.auth.RdsIamAuthTokenGenerator;
import com.amazonaws.services.rds.auth.GetIamAuthTokenRequest;
import com.amazonaws.auth.BasicAWSCredentials;
import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.auth.AWSStaticCredentialsProvider;
import java.io.File;
import java.io.FileOutputStream;
import java.io.InputStream;
import java.security.KeyStore;
import java.security.cert.CertificateFactory;
import java.security.cert.X509Certificate;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.ResultSet;
import java.sql.Statement;
import java.util.Properties;
import java.net.URL;
public class IAMDatabaseAuthenticationTester {
    ```

}

Connecting to your DB instance using IAM authentication and the AWS SDK for Python (Boto3)

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for
Python (Boto3) as described following.

Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication (p. 2196)
- Creating and using an IAM policy for IAM database access (p. 2198)
- Creating a database account using IAM authentication (p. 2201)

In addition, make sure the imported libraries in the sample code exist on your system.

Examples

The code examples use profiles for shared credentials. For information about the specifying credentials,
see Credentials in the AWS SDK for Python (Boto3) documentation.

The following code examples show how to generate an authentication token, and then use it to connect
to a DB instance.

To run this code example, you need the AWS SDK for Python (Boto3), found on the AWS site.

Modify the values of the following variables as needed:

- ENDPOINT – The endpoint of the DB instance that you want to access
- PORT – The port number used for connecting to your DB instance
IAM database authentication

- USER – The database account that you want to access
- REGION – The AWS Region where the DB instance is running
- DBNAME – The database that you want to access
- SSLCERTIFICATE – The full path to the SSL certificate for Amazon RDS

For ssl_ca, specify an SSL certificate. To download an SSL certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2152).

This code connects to a MariaDB or MySQL DB instance.

Before running this code, install Connector/Python version 8.0 by following the instructions in Connector/Python Installation in the MySQL documentation.

```python
import mysql.connector
import sys
import boto3
import os

ENDPOINT="mysqldb.123456789012.us-east-1.rds.amazonaws.com"
PORT="3306"
USER="jane_doe"
REGION="us-east-1"
DBNAME="mydb"
os.environ[‘LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN’] = ’1’

#gets the credentials from .aws/credentials
session = boto3.Session(profile_name='default')
client = session.client(‘rds’)  
token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USER, Region=REGION)

try:
    conn = mysql.connector.connect(host=ENDPOINT, user=USER, passwd=token, port=PORT, database=DBNAME, ssl_ca='SSLCERTIFICATE')
    cur = conn.cursor()
    cur.execute("""SELECT now()""")
    query_results = cur.fetchall()
    print(query_results)
except Exception as e:
    print("Database connection failed due to {}".format(e))
```

This code connects to a PostgreSQL DB instance.

Before running this code, install psycopg2 by following the instructions in Psycopg documentation.

```python
import psycopg2
import sys
import boto3
import os

ENDPOINT="postgresmydb.123456789012.us-east-1.rds.amazonaws.com"
PORT="5432"
USER="jane_doe"
REGION="us-east-1"
DBNAME="mydb"

#gets the credentials from .aws/credentials
session = boto3.Session(profile_name='RDSCreds')
```
client = session.client('rds')

token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USER, Region=REGION)

try:
    conn = psycopg2.connect(host=ENDPOINT, port=PORT, database=DBNAME, user=USER,
                            password=token, sslrootcert="SSLCERTIFICATE")
    cur = conn.cursor()
    cur.execute("""SELECT now()""")
    query_results = cur.fetchall()
    print(query_results)
except Exception as e:
    print("Database connection failed due to {}").format(e))

Troubleshooting Amazon RDS identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with Amazon RDS and IAM.

Topics
- I'm not authorized to perform an action in Amazon RDS (p. 2222)
- I'm not authorized to perform iam:PassRole (p. 2222)
- I want to view my access keys (p. 2223)
- I'm an administrator and want to allow others to access Amazon RDS (p. 2223)
- I want to allow people outside of my AWS account to access my Amazon RDS resources (p. 2223)

I'm not authorized to perform an action in Amazon RDS

If the AWS Management Console tells you that you're not authorized to perform an action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your user name and password.

The following example error occurs when the mateojackson IAM user tries to use the console to view details about a widget but does not have rds:GetWidget permissions.

User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform: rds:GetWidget on resource: my-example-widget

In this case, Mateo asks his administrator to update his policies to allow him to access the my-example-widget resource using the rds:GetWidget action.

I'm not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the iam:PassRole action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your user name and password. Ask that person to update your policies to allow you to pass a role to Amazon RDS.

Some AWS services allow you to pass an existing role to that service, instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named marymajor tries to use the console to perform an action in Amazon RDS. However, the action requires the service to have permissions granted by a service role. Mary does not have permissions to pass the role to the service.
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform: iam:PassRole

In this case, Mary asks her administrator to update her policies to allow her to perform the iam:PassRole action.

I want to view my access keys

After you create your IAM user access keys, you can view your access key ID at any time. However, you can't view your secret access key again. If you lose your secret key, you must create a new access key pair.

Access keys consist of two parts: an access key ID (for example, AKIAIOSFODNN7EXAMPLE) and a secret access key (for example, wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY). Like a user name and password, you must use both the access key ID and secret access key together to authenticate your requests. Manage your access keys as securely as you do your user name and password.

**Important**
Do not provide your access keys to a third party, even to help find your canonical user ID. By doing this, you might give someone permanent access to your account.

When you create an access key pair, you are prompted to save the access key ID and secret access key in a secure location. The secret access key is available only at the time you create it. If you lose your secret access key, you must add new access keys to your IAM user. You can have a maximum of two access keys. If you already have two, you must delete one key pair before creating a new one. To view instructions, see Managing access keys in the IAM User Guide.

I'm an administrator and want to allow others to access Amazon RDS

To enable others to access Amazon RDS, you must create an IAM entity (user or role) for the person or application that needs access. They use the credentials for that entity to access AWS. You must then attach a policy to the entity that grants them the correct permissions in Amazon RDS.

To get started right away, see Creating your first IAM delegated user and group in the IAM User Guide.

I want to allow people outside of my AWS account to access my Amazon RDS resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Amazon RDS supports these features, see How Amazon RDS works with IAM (p. 2166).
- To learn how to provide access to your resources across AWS accounts that you own, see Providing access to an IAM user in another AWS account that you own in the IAM User Guide.
- To learn how to provide access to your resources to third-party AWS accounts, see Providing access to AWS accounts owned by third parties in the IAM User Guide.
- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the IAM User Guide.
- To learn the difference between using roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.
Logging and monitoring in Amazon RDS

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon RDS and your AWS solutions. You should collect monitoring data from all of the parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. AWS provides several tools for monitoring your Amazon RDS resources and responding to potential incidents:

**Amazon CloudWatch Alarms**

Using Amazon CloudWatch alarms, you watch a single metric over a time period that you specify. If the metric exceeds a given threshold, a notification is sent to an Amazon SNS topic or AWS Auto Scaling policy. CloudWatch alarms do not invoke actions because they are in a particular state. Rather the state must have changed and been maintained for a specified number of periods.

**AWS CloudTrail Logs**

CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon RDS. CloudTrail captures all API calls for Amazon RDS as events, including calls from the console and from code calls to Amazon RDS API operations. Using the information collected by CloudTrail, you can determine the request that was made to Amazon RDS, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see [Monitoring Amazon RDS API calls in AWS CloudTrail](p. 761).

**Enhanced Monitoring**

Amazon RDS provides metrics in real time for the operating system (OS) that your DB instance runs on. You can view the metrics for your DB instance using the console, or consume the Enhanced Monitoring JSON output from Amazon CloudWatch Logs in a monitoring system of your choice. For more information, see [Monitoring OS metrics with Enhanced Monitoring](p. 635).

**Amazon RDS Performance Insights**

Performance Insights expands on existing Amazon RDS monitoring features to illustrate your database's performance and help you analyze any issues that affect it. With the Performance Insights dashboard, you can visualize the database load and filter the load by waits, SQL statements, hosts, or users. For more information, see [Monitoring DB load with Performance Insights on Amazon RDS](p. 578).

**Database Logs**

You can view, download, and watch database logs using the AWS Management Console, AWS CLI, or RDS API. For more information, see [Monitoring Amazon RDS log files](p. 716).

**Amazon RDS Recommendations**

Amazon RDS provides automated recommendations for database resources. These recommendations provide best practice guidance by analyzing DB instance configuration, usage, and performance data. For more information, see [Viewing Amazon RDS recommendations](p. 555).

**Amazon RDS Event Notification**

Amazon RDS uses the Amazon Simple Notification Service (Amazon SNS) to provide notification when an Amazon RDS event occurs. These notifications can be in any notification form supported by Amazon SNS for an AWS Region, such as an email, a text message, or a call to an HTTP endpoint. For more information, see [Working with Amazon RDS event notification](p. 685).

**AWS Trusted Advisor**

Trusted Advisor draws upon best practices learned from serving hundreds of thousands of AWS customers. Trusted Advisor inspects your AWS environment and then makes recommendations when opportunities exist to save money, improve system availability and performance, or help close security gaps. All AWS customers have access to five Trusted Advisor checks. Customers with a Business or Enterprise support plan can view all Trusted Advisor checks.
Trusted Advisor has the following Amazon RDS-related checks:
- Amazon RDS Idle DB Instances
- Amazon RDS Security Group Access Risk
- Amazon RDS Backups
- Amazon RDS Multi-AZ

For more information on these checks, see Trusted Advisor best practices (checks).

For more information about monitoring Amazon RDS, see Monitoring metrics in an Amazon RDS instance (p. 545).
Compliance validation for Amazon RDS

Third-party auditors assess the security and compliance of Amazon RDS as part of multiple AWS compliance programs. These include SOC, PCI, FedRAMP, HIPAA, and others.

For a list of AWS services in scope of specific compliance programs, see AWS services in scope by compliance program. For general information, see AWS compliance programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading reports in AWS Artifact.

Your compliance responsibility when using Amazon RDS is determined by the sensitivity of your data, your organization's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- **Security and compliance quick start guides** – These deployment guides discuss architectural considerations and provide steps for deploying security- and compliance-focused baseline environments on AWS.
- **Architecting for HIPAA security and compliance whitepaper** – This whitepaper describes how companies can use AWS to create HIPAA-compliant applications.
- **AWS compliance resources** – This collection of workbooks and guides that might apply to your industry and location.
- **AWS Config** – This AWS service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- **AWS Security Hub** – This AWS service provides a comprehensive view of your security state within AWS that helps you check your compliance with security industry standards and best practices.
Resilience in Amazon RDS

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see AWS global infrastructure.

In addition to the AWS global infrastructure, Amazon RDS offers features to help support your data resiliency and backup needs.

Backup and restore

Amazon RDS creates and saves automated backups of your DB instance. Amazon RDS creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases.

Amazon RDS creates automated backups of your DB instance during the backup window of your DB instance. Amazon RDS saves the automated backups of your DB instance according to the backup retention period that you specify. If necessary, you can recover your database to any point in time during the backup retention period. You can also back up your DB instance manually, by manually creating a DB snapshot.

You can create a DB instance by restoring from this DB snapshot as a disaster recovery solution if the source DB instance fails.

For more information, see Backing up and restoring an Amazon RDS DB instance (p. 461).

Replication

Amazon RDS uses the MariaDB, MySQL, Oracle, and PostgreSQL DB engines' built-in replication functionality to create a special type of DB instance called a read replica from a source DB instance. Updates made to the source DB instance are asynchronously copied to the read replica. You can reduce the load on your source DB instance by routing read queries from your applications to the read replica. Using read replicas, you can elastically scale out beyond the capacity constraints of a single DB instance for read-heavy database workloads. You can promote a read replica to a standalone instance as a disaster recovery solution if the source DB instance fails. For some DB engines, Amazon RDS also supports other replication options.

For more information, see Working with read replicas (p. 382).

Failover

Amazon RDS provides high availability and failover support for DB instances using Multi-AZ deployments. Amazon RDS uses several different technologies to provide failover support. Multi-AZ deployments for Oracle, PostgreSQL, MySQL, and MariaDB DB instances use Amazon's failover technology. SQL Server DB instances use SQL Server Database Mirroring (DBM).

For more information, see Multi-AZ deployments for high availability (p. 125).
Infrastructure security in Amazon RDS

As a managed service, Amazon RDS is protected by the AWS global network security procedures that are described in the Best Practices for Security, Identity, and Compliance.

You use AWS published API calls to access Amazon RDS through the network. Clients must support Transport Layer Security (TLS) 1.0. We recommend TLS 1.2 or later. Clients must also support cipher suites with perfect forward secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Ephemeral Diffie-Hellman (ECDHE). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

In addition, Amazon RDS offers features to help support infrastructure security.

Security groups

Security groups control the access that traffic has in and out of a DB instance. By default, network access is turned off to a DB instance. You can specify rules in a security group that allow access from an IP address range, port, or security group. After ingress rules are configured, the same rules apply to all DB instances that are associated with that security group.

For more information, see Controlling access with security groups (p. 2232).

Public accessibility

When you launch a DB instance inside a virtual private cloud (VPC) based on the Amazon VPC service, you can turn on or off public accessibility for that DB instance. To designate whether the DB instance that you create has a DNS name that resolves to a public IP address, you use the Public accessibility parameter. By using this parameter, you can designate whether there is public access to the DB instance. You can modify a DB instance to turn on or off public accessibility by modifying the Public accessibility parameter.

For more information, see Hiding a DB instance in a VPC from the internet (p. 2257).

Note

If your DB instance is in a VPC but isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy (p. 2161).
Amazon RDS API and interface VPC endpoints (AWS PrivateLink)

You can establish a private connection between your VPC and Amazon RDS API endpoints by creating an *interface VPC endpoint*. Interface endpoints are powered by AWS PrivateLink.

AWS PrivateLink enables you to privately access Amazon RDS API operations without an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. DB instances in your VPC don't need public IP addresses to communicate with Amazon RDS API endpoints to launch, modify, or terminate DB instances. Your DB instances also don't need public IP addresses to use any of the available RDS API operations. Traffic between your VPC and Amazon RDS doesn't leave the Amazon network.

Each interface endpoint is represented by one or more elastic network interfaces in your subnets. For more information on elastic network interfaces, see [Elastic network interfaces in the Amazon EC2 User Guide](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/vpc-configuring.html).

For more information about VPC endpoints, see [Interface VPC endpoints (AWS PrivateLink)](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/vpc-configuring.html) in the *Amazon VPC User Guide*. For more information about RDS API operations, see [Amazon RDS API Reference](https://docs.aws.amazon.com/AmazonRDS/latest/APIReference/)

You don't need an interface VPC endpoint to connect to a DB instance. For more information, see [Scenarios for accessing a DB instance in a VPC](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/DBConsole.html#介紹dbinstances).

**Considerations for VPC endpoints**

Before you set up an interface VPC endpoint for Amazon RDS API endpoints, ensure that you review [Interface endpoint properties and limitations](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/vpc-configuring.html) in the *Amazon VPC User Guide*.

All RDS API operations relevant to managing Amazon RDS resources are available from your VPC using AWS PrivateLink.

VPC endpoint policies are supported for RDS API endpoints. By default, full access to RDS API operations is allowed through the endpoint. For more information, see [Controlling access to services with VPC endpoints](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/vpc-controlling-access.html) in the *Amazon VPC User Guide*.

**Availability**

Amazon RDS API currently supports VPC endpoints in the following AWS Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
Creating an interface VPC endpoint for Amazon RDS API

You can create a VPC endpoint for the Amazon RDS API using either the Amazon VPC console or the AWS Command Line Interface (AWS CLI). For more information, see Creating an interface endpoint in the Amazon VPC User Guide.

Create a VPC endpoint for Amazon RDS API using the service name com.amazonaws.region.rds.

Excluding AWS Regions in China, if you enable private DNS for the endpoint, you can make API requests to Amazon RDS with the VPC endpoint using its default DNS name for the AWS Region, for example rds.us-east-1.amazonaws.com. For the China (Beijing) and China (Ningxia) AWS Regions, you can make API requests with the VPC endpoint using rds-api.cn-north-1.amazonaws.com.cn and rds-api.cn-northwest-1.amazonaws.com.cn, respectively.

For more information, see Accessing a service through an interface endpoint in the Amazon VPC User Guide.

Creating a VPC endpoint policy for Amazon RDS API

You can attach an endpoint policy to your VPC endpoint that controls access to Amazon RDS API. The policy specifies the following information:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

For more information, see Controlling access to services with VPC endpoints in the Amazon VPC User Guide.

Example: VPC endpoint policy for Amazon RDS API actions

The following is an example of an endpoint policy for Amazon RDS API. When attached to an endpoint, this policy grants access to the listed Amazon RDS API actions for all principals on all resources.

```json
{
   "Statement": [
      {
         "Principal": "*",
```
Security best practices for Amazon RDS

Use AWS Identity and Access Management (IAM) accounts to control access to Amazon RDS API operations, especially operations that create, modify, or delete Amazon RDS resources. Such resources include DB instances, security groups, and parameter groups. Also use IAM to control actions that perform common administrative actions such as backing up and restoring DB instances.

- Create an individual IAM user for each person who manages Amazon RDS resources, including yourself. Don't use AWS root credentials to manage Amazon RDS resources.
- Grant each user the minimum set of permissions required to perform his or her duties.
- Use IAM groups to effectively manage permissions for multiple users.
- Rotate your IAM credentials regularly.
- Configure AWS Secrets Manager to automatically rotate the secrets for Amazon RDS. For more information, see Rotating your AWS Secrets Manager secrets in the AWS Secrets Manager User Guide. You can also retrieve the credential from AWS Secrets Manager programmatically. For more information, see Retrieving the secret value in the AWS Secrets Manager User Guide.

For more information about Amazon RDS security, see Security in Amazon RDS (p. 2126). For more information about IAM, see AWS Identity and Access Management. For information on IAM best practices, see IAM best practices.
Use the AWS Management Console, the AWS CLI, or the RDS API to change the password for your master user. If you use another tool, such as a SQL client, to change the master user password, it might result in privileges being revoked for the user unintentionally.

Controlling access with security groups

VPC security groups control the access that traffic has in and out of a DB instance. By default, network access is turned off for a DB instance. You can specify rules in a security group that allow access from an IP address range, port, or security group. After ingress rules are configured, the same rules apply to all DB instances that are associated with that security group. You can specify up to 20 rules in a security group.

Overview of VPC security groups

Each VPC security group rule makes it possible for a specific source to access a DB instance in a VPC that is associated with that VPC security group. The source can be a range of addresses (for example, 203.0.113.0/24), or another VPC security group. By specifying a VPC security group as the source, you allow incoming traffic from all instances (typically application servers) that use the source VPC security group. VPC security groups can have rules that govern both inbound and outbound traffic. However, the outbound traffic rules typically don't apply to DB instances. Outbound traffic rules apply only if the DB instance acts as a client. For example, outbound traffic rules apply to an Oracle DB instance with outbound database links. You must use the Amazon EC2 API or the Security Group option on the VPC console to create VPC security groups.

When you create rules for your VPC security group that allow access to the instances in your VPC, you must specify a port for each range of addresses that the rule allows access for. For example, if you want to turn on Secure Shell (SSH) access for instances in the VPC, create a rule allowing access to TCP port 22 for the specified range of addresses.

You can configure multiple VPC security groups that allow access to different ports for different instances in your VPC. For example, you can create a VPC security group that allows access to TCP port 80 for web servers in your VPC. You can then create another VPC security group that allows access to TCP port 3306 for RDS for MySQL DB instances in your VPC.

For more information on VPC security groups, see Security groups in the Amazon Virtual Private Cloud User Guide.

Note
If your DB instance is in a VPC but isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy (p. 2161).

Security group scenario

A common use of a DB instance in a VPC is to share data with an application server running in an Amazon EC2 instance in the same VPC, which is accessed by a client application outside the VPC. For this scenario, you use the RDS and VPC pages on the AWS Management Console or the RDS and EC2 API operations to create the necessary instances and security groups:

1. Create a VPC security group (for example, sg-0123ec2example) and define inbound rules that use the IP addresses of the client application as the source. This security group allows your client application to connect to EC2 instances in a VPC that uses this security group.
2. Create an EC2 instance for the application and add the EC2 instance to the VPC security group (sg-0123ec2example) that you created in the previous step.
3. Create a second VPC security group (for example, sg-6789rdsexample) and create a new rule by specifying the VPC security group that you created in step 1 (sg-0123ec2example) as the source.
4. Create a new DB instance and add the DB instance to the VPC security group (sg-6789rdsexample) that you created in the previous step. When you create the DB instance, use the same port number as the one specified for the VPC security group (sg-6789rdsexample) rule that you created in step 3.

The following diagram shows this scenario.

For detailed instructions about configuring a VPC for this scenario, see Tutorial: Create a VPC for use with a DB instance (IPv4 only) (p. 2268). For more information about using a VPC, see Amazon VPC VPCs and Amazon RDS (p. 2251).

Creating a VPC security group

You can create a VPC security group for a DB instance by using the VPC console. For information about creating a security group, see Provide access to your DB instance in your VPC by creating a security group (p. 156) and Security groups in the Amazon Virtual Private Cloud User Guide.
# Associating a security group with a DB instance

You can associate a security group with a DB instance by using **Modify** on the RDS console, the ModifyDBInstance Amazon RDS API, or the modify-db-instance AWS CLI command.

For information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](#) (p. 333). For security group considerations when you restore a DB instance from a DB snapshot, see [Security group considerations](#) (p. 487).

## Master user account privileges

When you create a new DB instance, the default master user that you use gets certain privileges for that DB instance. You can't change the master user name after the DB instance is created.

**Important**

We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

**Note**

If you accidentally delete the permissions for the master user, you can restore them by modifying the DB instance and setting a new master user password. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](#) (p. 333).

The following table shows the privileges and database roles the master user gets for each of the database engines.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>System privilege</th>
<th>Database role</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL and MariaDB</td>
<td>SELECT, INSERT, UPDATE, DELETE, CREATE, DROP, RELOAD, PROCESS, REFERENCES, INDEX, ALTER, SHOW DATABASES, CREATE TEMPORARY TABLES, LOCK TABLES, EXECUTE, REPLICATION CLIENT, CREATE VIEW, SHOW VIEW, CREATE ROUTINE, ALTER ROUTINE, CREATE USER, EVENT, TRIGGER ON <em>.</em> WITH GRANT OPTION, REPLICATION SLAVE</td>
<td>—</td>
</tr>
<tr>
<td>PostgreSQL</td>
<td>CREATE ROLE, CREATE DB, PASSWORD VALID UNTIL INFINITY, CREATE EXTENSION, ALTER EXTENSION, DROP EXTENSION, CREATE TABLESPACE, ALTER &lt;OBJECT&gt; OWNER, CHECKPOINT, PG_CANCEL_BACKEND(), PG_TERMINATE_BACKEND(), SELECT PG_STAT_REPLICATION, EXECUTE PG_STAT_STATEMENTS_RESET(), OWN POSTGRES_FDW_HANDLER(), OWN POSTGRES_FDW_VALIDATOR(), OWN POSTGRES_FDW, EXECUTE PG_BUFFERCACHE_PAGES(), SELECT PG_BUFFERCACHE</td>
<td>RDS_SUPERUSER For more information about RDS_SUPERUSER, see <a href="#">Understanding PostgreSQL roles and permissions</a> (p. 1967).</td>
</tr>
<tr>
<td>Oracle</td>
<td>ALTER DATABASE LINK, ALTER PUBLIC DATABASE LINK, DROP ANY DIRECTORY, EXEMPT ACCESS POLICY, EXEMPT IDENTITY POLICY, GRANT ANY OBJECT PRIVILEGE, RESTRICTED SESSION, EXEMPT REDACTION POLICY</td>

<td>DB_OWNER (database-level role), PROCESSADMIN (server-level role), SETUPADMIN (server-level role), SQLAgentUserRole (database-level role)</td>
</tr>
</tbody>
</table>
Using service-linked roles for Amazon RDS

Amazon RDS uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Amazon RDS. Service-linked roles are predefined by Amazon RDS and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes using Amazon RDS easier because you don't have to manually add the necessary permissions. Amazon RDS defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon RDS can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete the roles only after first deleting their related resources. This protects your Amazon RDS resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS services that work with IAM and look for the services that have Yes in the Service-Linked Role column. Choose a Yes with a link to view the service-linked role documentation for that service.

Service-linked role permissions for Amazon RDS

Amazon RDS uses the service-linked role named AWSServiceRoleForRDS to allow Amazon RDS to call AWS services on behalf of your DB instances.

The AWSServiceRoleForRDS service-linked role trusts the following services to assume the role:

- rds.amazonaws.com

This service-linked role has a permissions policy attached to it called AmazonRDSServiceRolePolicy that grants it permissions to operate in your account. The role permissions policy allows Amazon RDS to complete the following actions on the specified resources:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "rds:CrossRegionCommunication"
         ],
         "Resource": "*"
      },
      {
         "Effect": "Allow",
         "Action": [
            "ec2:AllocateAddress",
            "ec2:AssociateAddress",
            "ec2:AuthorizeSecurityGroupIngress",
            "ec2:CreateCoipPoolPermission",
            "ec2:CreateLocalGatewayRouteTablePermission",
            "ec2:CreateNetworkInterface",
            "ec2:CreateSecurityGroup",
            "ec2:DeleteCoipPoolPermission",
            "ec2:DeleteLocalGatewayRouteTablePermission",
            "ec2:DeleteNetworkInterface",
            "ec2:DeleteSecurityGroup",
            "ec2:DescribeAddresses",
            "ec2:DescribeAvailiabilityZones"
         ]
      }
   ]
}
```

],
"Resource": "*"
],
"Effect": "Allow",
"Action": [ "secretsmanager:DeleteSecret",
  "secretsmanager:DescribeSecret",
  "secretsmanager:PutSecretValue",
  "secretsmanager:RotateSecret",
  "secretsmanager:UpdateSecret",
  "secretsmanager:UpdateSecretVersionStage",
  "secretsmanager:ListSecretVersionIds"
],
"Resource": [
  "arn:aws:secretsmanager:*:*:secret:rds!*
],
"Condition": {
  "StringLike": {
    "secretsmanager:ResourceTag/aws:secretsmanager:owningService": "rds"
  }
}
],
"Effect": "Allow",
"Action": "secretsmanager:TagResource",
"Resource": "arn:aws:secretsmanager:*:*:secret:rds!*",
"Condition": {
  "ForAllValues:StringEquals": {

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message:

Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.

Make sure you have the following permissions enabled:

```
{
    "Action": "iam:CreateServiceLinkedRole",
    "Effect": "Allow",
    "Resource": "arn:aws:iam::*:role/aws-service-role/rds.amazonaws.com/AWSServiceRoleForRDS",
    "Condition": {
        "StringLike": {
            "iam:AWSServiceName": "rds.amazonaws.com"
        }
    }
}
```

For more information, see Service-linked role permissions in the IAM User Guide.

## Creating a service-linked role for Amazon RDS

You don't need to manually create a service-linked role. When you create a DB instance, Amazon RDS creates the service-linked role for you.

**Important**

If you were using the Amazon RDS service before December 1, 2017, when it began supporting service-linked roles, then Amazon RDS created the AWSServiceRoleForRDS role in your account. To learn more, see A new role appeared in my AWS account.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a DB instance, Amazon RDS creates the service-linked role for you again.

## Editing a service-linked role for Amazon RDS

Amazon RDS does not allow you to edit the AWSServiceRoleForRDS service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the IAM User Guide.

## Deleting a service-linked role for Amazon RDS

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or
maintained. However, you must delete all of your DB instances before you can delete the service-linked role.

**Cleaning up a service-linked role**

Before you can use IAM to delete a service-linked role, you must first confirm that the role has no active sessions and remove any resources used by the role.

**To check whether the service-linked role has an active session in the IAM console**

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane of the IAM console, choose **Roles**. Then choose the name (not the check box) of the AWSServiceRoleForRDS role.
3. On the **Summary** page for the chosen role, choose the **Access Advisor** tab.
4. On the **Access Advisor** tab, review recent activity for the service-linked role.

**Note**

If you are unsure whether Amazon RDS is using the AWSServiceRoleForRDS role, you can try to delete the role. If the service is using the role, then the deletion fails and you can view the AWS Regions where the role is being used. If the role is being used, then you must wait for the session to end before you can delete the role. You cannot revoke the session for a service-linked role.

If you want to remove the AWSServiceRoleForRDS role, you must first delete all of your DB instances.

**Deleting all of your instances**

Use one of these procedures to delete each of your instances.

**To delete an instance (console)**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the instance that you want to delete.
4. For **Actions**, choose **Delete**.
5. If you are prompted for **Create final Snapshot?**, choose Yes or No.
6. If you chose Yes in the previous step, for **Final snapshot name** enter the name of your final snapshot.
7. Choose **Delete**.

**To delete an instance (CLI)**

See delete-db-instance in the AWS CLI Command Reference.

**To delete an instance (API)**

See DeleteDBInstance in the Amazon RDS API Reference.

You can use the IAM console, the IAM CLI, or the IAM API to delete the AWSServiceRoleForRDS service-linked role. For more information, see Deleting a service-linked role in the IAM User Guide.
Service-linked role permissions for Amazon RDS Custom

Amazon RDS Custom uses the service-linked role named AWSServiceRoleForRDSCustom to allow RDS Custom to call AWS services on behalf of your DB instances and DB clusters.

The AWSServiceRoleForRDSCustom service-linked role trusts the following services to assume the role:

- custom.rds.amazonaws.com

This service-linked role has a permissions policy attached to it called AmazonRDSCustomServiceRolePolicy that grants it permissions to operate in your account. The role permissions policy allows RDS Custom to complete the following actions on the specified resources:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ecc1",
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeInstances",
        "ec2:DescribeInstanceAttribute",
        "ec2:DescribeRegions",
        "ec2:DescribeSnapshots",
        "ec2:DescribeNetworkInterfaces",
        "ec2:DescribeVolumes",
        "ec2:DescribeInstanceStatus",
        "ec2:DescribeIamInstanceProfileAssociations",
        "ec2:DescribeImages",
        "ec2:DescribeVpcs",
        "ec2:RegisterImage",
        "ec2:DeregisterImage",
        "ec2:DescribeTags",
        "ec2:DescribeSecurityGroups",
        "ec2:DescribeVolumesModifications",
        "ec2:DescribeSubnets",
        "ec2:DescribeVpcAttribute",
        "ec2:SearchTransitGatewayMulticastGroups",
        "ec2:GetTransitGatewayMulticastDomainAssociations",
        "ec2:DescribeTransitGatewayMulticastDomains",
        "ec2:DescribeTransitGateways",
        "ec2:DescribeTransitGatewayVpcAttachments",
        "ec2:DescribePlacementGroups",
        "ec2:DescribeRouteTables"
      ],
      "Resource": ["*"]
    },
    {
      "Sid": "ecc2",
      "Effect": "Allow",
      "Action": [

Creating, editing, or deleting the service-linked role for RDS Custom works the same as for Amazon RDS. For more information, see Service-linked role permissions for Amazon RDS (p. 2236).

**Note**
You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message:

*Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.*

Make sure you have the following permissions enabled:

```json
{
  "Action": "iam:CreateServiceLinkedRole",
  "Effect": "Allow",
  "Resource": "arn:aws:iam::*:role/aws-service-role/custom.rds.amazonaws.com/AmazonRDSCustomServiceRolePolicy",
  "Condition": {
    "StringLike": {
      "iam:AWSServiceName": "custom.rds.amazonaws.com"
    }
  }
}
```

For more information, see Service-linked role permissions in the IAM User Guide.
Amazon VPC VPCs and Amazon RDS

Amazon Virtual Private Cloud (Amazon VPC) makes it possible for you to launch AWS resources, such as Amazon RDS DB instances, into a virtual private cloud (VPC).

When you use a VPC, you have control over your virtual networking environment. You can choose your own IP address range, create subnets, and configure routing and access control lists. There is no additional cost to run your DB instance in a VPC.

Accounts have a default VPC. All new DB instances are created in the default VPC unless you specify otherwise.

Topics
- Working with a DB instance in a VPC (p. 2251)
- Updating the VPC for a DB instance (p. 2262)
- Scenarios for accessing a DB instance in a VPC (p. 2263)
- Tutorial: Create a VPC for use with a DB instance (IPv4 only) (p. 2268)
- Tutorial: Create a VPC for use with a DB instance (dual-stack mode) (p. 2274)
- Moving a DB instance not in a VPC into a VPC (p. 2281)

Following, you can find a discussion about VPC functionality relevant to Amazon RDS DB instances. For more information about Amazon VPC, see Amazon VPC Getting Started Guide and Amazon VPC User Guide.

Working with a DB instance in a VPC

Your DB instance is in a virtual private cloud (VPC). A VPC is a virtual network that is logically isolated from other virtual networks in the AWS Cloud. Amazon VPC makes it possible for you to launch AWS resources, such as an Amazon RDS DB instance or Amazon EC2 instance, into a VPC. The VPC can either be a default VPC that comes with your account or one that you create. All VPCs are associated with your AWS account.

Your default VPC has three subnets that you can use to isolate resources inside the VPC. The default VPC also has an internet gateway that can be used to provide access to resources inside the VPC from outside the VPC.

For a list of scenarios involving Amazon RDS DB instances in a VPC and outside of a VPC, see Scenarios for accessing a DB instance in a VPC (p. 2263).

Topics
- Working with a DB instance in a VPC (p. 2252)
- Working with DB subnet groups (p. 2252)
- Amazon RDS IP addressing (p. 2253)
- Hiding a DB instance in a VPC from the internet (p. 2257)
- Creating a DB instance in a VPC (p. 2259)

In the following tutorials, you can learn to create a VPC that you can use for a common Amazon RDS scenario:
- Tutorial: Create a VPC for use with a DB instance (IPv4 only) (p. 2268)
- Tutorial: Create a VPC for use with a DB instance (dual-stack mode) (p. 2274)
Working with a DB instance in a VPC

Here are some tips on working with a DB instance in a VPC:

• Your VPC must have at least two subnets. These subnets must be in two different Availability Zones in the AWS Region where you want to deploy your DB instance. A subnet is a segment of a VPC's IP address range that you can specify and that you can use to group DB instances based on your security and operational needs.

For Multi-AZ deployments, defining a subnet for two or more Availability Zones in an AWS Region allows Amazon RDS to create a new standby in another Availability Zone as needed. Make sure to do this even for Single-AZ deployments, just in case you want to convert them to Multi-AZ deployments at some point.

**Note**
The DB subnet group for a Local Zone can have only one subnet.

• If you want your DB instance in the VPC to be publicly accessible, make sure to turn on the VPC attributes DNS hostnames and DNS resolution.

• Your VPC must have a DB subnet group that you create. You create a DB subnet group by specifying the subnets you created. Amazon RDS chooses a subnet and an IP address within that subnet to associate with your DB instance. The DB instance uses the Availability Zone that contains the subnet.

• Your VPC must have a VPC security group that allows access to the DB instance.

For more information, see Scenarios for accessing a DB instance in a VPC (p. 2263).

• The CIDR blocks in each of your subnets must be large enough to accommodate spare IP addresses for Amazon RDS to use during maintenance activities, including failover and compute scaling. For example, a range such as 10.0.0.0/24 and 10.0.1.0/24 is typically large enough.

• A VPC can have an instance tenancy attribute of either default or dedicated. All default VPCs have the instance tenancy attribute set to default, and a default VPC can support any DB instance class.

If you choose to have your DB instance in a dedicated VPC where the instance tenancy attribute is set to dedicated, the DB instance class of your DB instance must be one of the approved Amazon EC2 dedicated instance types. For example, the r5.large EC2 dedicated instance corresponds to the db.r5.large DB instance class. For information about instance tenancy in a VPC, see Dedicated instances in the Amazon Elastic Compute Cloud User Guide.

For more information about the instance types that can be in a dedicated instance, see Amazon EC2 dedicated instances on the EC2 pricing page.

**Note**
When you set the instance tenancy attribute to dedicated for a DB instance, it doesn’t guarantee that the DB instance will run on a dedicated host.

• When an option group is assigned to a DB instance, it's associated with the DB instance's VPC. This linkage means that you can't use the option group assigned to a DB instance if you attempt to restore the DB instance into a different VPC.

• If you restore a DB instance into a different VPC, make sure to either assign the default option group to the DB instance, assign an option group that is linked to that VPC, or create a new option group and assign it to the DB instance. With persistent or permanent options, such as Oracle TDE, you must create a new option group that includes the persistent or permanent option when restoring a DB instance into a different VPC.

Working with DB subnet groups

Subnets are segments of a VPC's IP address range that you designate to group your resources based on security and operational needs. A DB subnet group is a collection of subnets (typically private) that you
create in a VPC and that you then designate for your DB instances. By using a DB subnet group, you can specify a particular VPC when creating DB instances using the AWS CLI or RDS API. If you use the console, you can choose the VPC and subnet groups you want to use.

Each DB subnet group should have subnets in at least two Availability Zones in a given AWS Region. When creating a DB instance in a VPC, you choose a DB subnet group for it. From the DB subnet group, Amazon RDS chooses a subnet and an IP address within that subnet to associate with the DB instance. The DB uses the Availability Zone that contains the subnet.

If the primary DB instance of a Multi-AZ deployment fails, Amazon RDS can promote the corresponding standby and later create a new standby using an IP address of the subnet in one of the other Availability Zones.

The subnets in a DB subnet group are either public or private. The subnets are public or private, depending on the configuration that you set for their network access control lists (network ACLs) and routing tables. For a DB instance to be publicly accessible, all of the subnets in its DB subnet group must be public. If a subnet that's associated with a publicly accessible DB instance changes from public to private, it can affect DB instance availability.

To create a DB subnet group that supports dual-stack mode, make sure that each subnet that you add to the DB subnet group has an Internet Protocol version 6 (IPv6) CIDR block associated with it. For more information, see Amazon RDS IP addressing (p. 2253) and Migrating to IPv6 in the Amazon VPC User Guide.

Note
The DB subnet group for a Local Zone can have only one subnet.

When Amazon RDS creates a DB instance in a VPC, it assigns a network interface to your DB instance by using an IP address from your DB subnet group. However, we strongly recommend that you use the Domain Name System (DNS) name to connect to your DB instance. We recommend this because the underlying IP address changes during failover.

Note
For each DB instance that you run in a VPC, make sure to reserve at least one address in each subnet in the DB subnet group for use by Amazon RDS for recovery actions.

Amazon RDS IP addressing

IP addresses enable resources in your VPC to communicate with each other, and with resources over the internet. Amazon RDS support both the Internet Protocol version 4 (IPv4) and IPv6 addressing protocols. By default, Amazon RDS and Amazon VPC use the IPv4 addressing protocol. You can’t turn off this behavior. When you create a VPC, make sure to specify an IPv4 CIDR block (a range of private IPv4 addresses). You can optionally assign an IPv6 CIDR block to your VPC and subnets, and assign IPv6 addresses from that block to DB instances in your subnet.

Support for the IPv6 protocol expands the number of supported IP addresses. By using the IPv6 protocol, you ensure that you have sufficient available addresses for the future growth of the internet. New and existing RDS resources can use IPv4 and IPv6 addresses within your Amazon VPC. Configuring, securing, and translating network traffic between the two protocols used in different parts of an application can cause operational overhead. You can standardize on the IPv6 protocol for Amazon RDS resources to simplify your network configuration.

Topics
- IPv4 addresses (p. 2254)
- IPv6 addresses (p. 2254)
- Dual-stack mode (p. 2254)
IPv4 addresses

When you create a VPC, you must specify a range of IPv4 addresses for the VPC in the form of a CIDR block, such as 10.0.0.0/16. A DB subnet group defines the range of IP addresses in this CIDR block that a DB instance can use. These IP addresses can be private or public.

A private IPv4 address is an IP address that's not reachable over the internet. You can use private IPv4 addresses for communication between your DB instance and other resources, such as Amazon EC2 instances, in the same VPC. Each DB instance has a private IP address for communication in the VPC.

A public IP address is an IPv4 address that's reachable from the internet. You can use public addresses for communication between your DB instance and resources on the internet, such as a SQL client. You control whether your DB instance receives a public IP address.

For a tutorial that shows you how to create a VPC with only private IPv4 addresses that you can use for a common Amazon RDS scenario, see Tutorial: Create a VPC for use with a DB instance (IPv4 only) (p. 2268).

IPv6 addresses

You can optionally associate an IPv6 CIDR block with your VPC and subnets, and assign IPv6 addresses from that block to the resources in your VPC. Each IPv6 addresses is globally unique.

The IPv6 CIDR block for your VPC is automatically assigned from Amazon's pool of IPv6 addresses. You can't choose the range yourself.

When connecting to an IPv6 address, make sure that the following conditions are met:

• The client is configured so that client to database traffic over IPv6 is allowed.
• RDS security groups used by the DB instance are configured correctly so that client to database traffic over IPv6 is allowed.
• The client operating system stack allows traffic on the IPv6 address, and operating system drivers and libraries are configured to choose the correct default DB instance endpoint (either IPv4 or IPv6).

For more information about IPv6, see IP Addressing in the Amazon VPC User Guide.

Dual-stack mode

When a DB instance can communicate over both the IPv4 and IPv6 addressing protocols, it's running in dual-stack mode. So, resources can communicate with the DB instance over IPv4, IPv6, or both. RDS disables Internet Gateway access for IPv6 endpoints of private dual-stack mode DB instances. RDS does this to ensure that your IPv6 endpoints are private and can only be accessed from within your VPC.

Topics

• Dual-stack mode and DB subnet groups (p. 2255)
• Working with dual-stack mode DB instances (p. 2255)
• Modifying IPv4-only DB instances to use dual-stack mode (p. 2255)
• Region and version availability (p. 2257)
• Limitations for dual-stack network DB instances (p. 2257)

For a tutorial that shows you how to create a VPC with both IPv4 and IPv6 addresses that you can use for a common Amazon RDS scenario, see Tutorial: Create a VPC for use with a DB instance (dual-stack mode) (p. 2274).
Dual-stack mode and DB subnet groups

To use dual-stack mode, make sure that each subnet in the DB subnet group that you associate with the DB instance has an IPv6 CIDR block associated with it. You can create a new DB subnet group or modify an existing DB subnet group to meet this requirement. After a DB instance is in dual-stack mode, clients can connect to it normally. Make sure that client security firewalls and RDS DB instance security groups are accurately configured to allow traffic over IPv6. To connect, clients use the DB instance's endpoint. Client applications can specify which protocol is preferred when connecting to a database. In dual-stack mode, the DB instance detects the client's preferred network protocol, either IPv4 or IPv6, and uses that protocol for the connection.

If a DB subnet group stops supporting dual-stack mode because of subnet deletion or CIDR disassociation, there's a risk of an incompatible network state for DB instances that are associated with the DB subnet group. Also, you can't use the DB subnet group when you create new dual-stack mode DB instance.

To determine whether a DB subnet group supports dual-stack mode by using the AWS Management Console, view the Network type on the details page of the DB subnet group. To determine whether a DB subnet group supports dual-stack mode by using the AWS CLI, call the describe-db-subnet-groups command and view SupportedNetworkTypes in the output.

Read replicas are treated as independent DB instances and can have a network type that's different from the primary DB instance. If you change the network type of a read replica's primary DB instance, the read replica isn't affected. When you are restoring a DB instance, you can restore it to any network type that's supported.

Working with dual-stack mode DB instances

When you create or modify a DB instance, you can specify dual-stack mode to allow your resources to communicate with your DB instance over IPv4, IPv6, or both.

When you use the AWS Management Console to create or modify a DB instance, you can specify dual-stack mode in the Network type section. The following image shows the Network type section in the console.

![Network type section](image)

When you use the AWS CLI to create or modify a DB instance, set the --network-type option to DUAL to use dual-stack mode. When you use the RDS API to create or modify a DB instance, set the NetworkType parameter to DUAL to use dual-stack mode. When you are modifying the network type of a DB instance, downtime is possible. If dual-stack mode isn't supported by the specified DB engine version or DB subnet group, the NetworkTypeNotSupported error is returned.

For more information about creating a DB instance, see Creating an Amazon RDS DB instance (p. 236). For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 333).

To determine whether a DB instance is in dual-stack mode by using the console, view the Network type on the Connectivity & security tab for the DB instance.

Modifying IPv4-only DB instances to use dual-stack mode

You can modify an IPv4-only DB instance to use dual-stack mode. To do so, change the network type of the DB instance. The modification might result in downtime.
Before modifying a DB instance to use dual-stack mode, make sure that its DB subnet group supports dual-stack mode. If the DB subnet group associated with the DB instance doesn't support dual-stack mode, specify a different DB subnet group that supports it when you modify the DB instance. If you modify the DB subnet group of a DB instance before you change the DB instance to use dual-stack mode, make sure that the DB subnet group is valid for the DB instance before and after the change.

If you can't connect to the DB instance after the change, make sure that the client and database security firewalls and route tables are accurately configured to allow cross traffic to the database on the selected network (either IPv4 or IPv6). You might also need to modify operating system parameter, libraries, or drivers to connect using an IPv6 address.

The following limitations apply to modifying a DB instance to use dual-stack mode:

- Dual-stack mode DB instances can't be publicly accessible.
- DB instances can't have an IPv6-only endpoint.
- There can't be a pending change from a Single-AZ deployment to a Multi-AZ deployment, or from a Multi-AZ deployment to a Single-AZ deployment.

**To modify an IPv4-only DB instance to use dual-stack mode**

1. Modify a DB subnet group to support dual-stack mode, or create a DB subnet group that supports dual-stack mode:
   - a. Associate an IPv6 CIDR block with your VPC.
      
      For instructions, see *Associate an IPv6 CIDR block with your VPC* in the *Amazon VPC User Guide*.
   - b. Attach the IPv6 CIDR block to all of the subnets in your the DB subnet group.
      
      For instructions, see *Associate an IPv6 CIDR block with your subnet* in the *Amazon VPC User Guide*.
   - c. Confirm that the DB subnet group supports dual-stack mode.
      
      If you are using the AWS Management Console, select the DB subnet group, and make sure that the **Supported network types** value is Dual, IPv4.
      
      If you are using the AWS CLI, call the `describe-db-subnet-groups` command, and make sure that the `SupportedNetworkType` value for the DB instance is Dual, IPv4.

2. Modify the security group associated with the DB instance to allow IPv6 connections to the database, or create a new security group that allows IPv6 connections.
   
   For instructions, see *Security group rules* in the *Amazon VPC User Guide*.

3. Modify the DB instance to support dual-stack mode. To do so, set the **Network type** to **Dual-stack mode**.

   If you are using the console, make sure that the following settings are correct:

   - **Network type** – Dual-stack mode
     
     ![Network type Info](image)
     
     **Dual-stack mode**
     
     Your resources can communicate over IPv4, IPv6, or both.

   - **DB subnet group** – The DB subnet group that you configured in a previous step
• **Security group** – The security that you configured in a previous step

If you are using the AWS CLI, make sure that the following settings are correct:

- `--network-type=dual`
- `--db-subnet-group-name` – The DB subnet group that you configured in a previous step
- `--vpc-security-group-ids` – The VPC security group that you configured in a previous step

4. Confirm that the DB instance supports dual-stack mode.

If you are using the console, choose the **Connectivity & security** tab for the DB instance. On that tab, make sure that the **Network type** value is **Dual-stack mode**.

If you are using the AWS CLI, call the `describe-db-instances` command, and make sure that the **NetworkType** value for the DB instance is **dual**.

Run the `dig` command on the DB instance endpoint to identify the IPv6 address associated with it.

```
dig db-instance-endpoint AAAA
```

Use the DB instance endpoint, not the IPv6 address, to connect to the DB instance.

**Region and version availability**

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability with dual stack mode, see [Dual-stack mode](p. 92).

**Limitations for dual-stack network DB instances**

The following limitations apply to dual-stack network DB instances:

- DB instances can't use the IPv6 protocol exclusively. They can use IPv4 exclusively, or they can use the IPv4 and IPv6 protocol (dual-stack mode).
- Amazon RDS doesn't support native IPv6 subnets.
- DB instances that use dual-stack mode must be private. They can't be publicly accessible.
- Dual-stack mode doesn't support the db.m3 and db.r3 DB instance classes.
- For RDS for SQL Server, dual-stack mode DB instances that use Always On AGs availability group listener endpoints only present IPv4 addresses.
- You can't use RDS Proxy with dual-stack mode DB instances.
- You can't use dual-stack mode with RDS on AWS Outposts DB instances.
- You can't use dual-stack mode with DB instances in a Local Zone.

**Hiding a DB instance in a VPC from the internet**

One common Amazon RDS scenario is to have a VPC in which you have an EC2 instance with a public-facing web application and a DB instance with a database that isn't publicly accessible. For example, you can create a VPC that has a public subnet and a private subnet. Amazon EC2 instances that function as web servers can be deployed in the public subnet. The DB instances are deployed in the private subnet. In such a deployment, only the web servers have access to the DB instances. For an illustration of this scenario, see [A DB instance in a VPC accessed by an EC2 instance in the same VPC](p. 2263).

When you launch a DB instance inside a VPC, the DB instance has a private IP address for traffic inside the VPC. This private IP address isn't publicly accessible. You can use the **Public access** option to
designate whether the DB instance also has a public IP address in addition to the private IP address. If the DB instance is designated as publicly accessible, its DNS endpoint resolves to the private IP address from within the VPC. It resolves to the public IP address from outside of the VPC. Access to the DB instance is ultimately controlled by the security group it uses. That public access is not permitted if the security group assigned to the DB instance doesn't include inbound rules that permit it. In addition, for a DB instance to be publicly accessible, the subnets in its DB subnet group must have an internet gateway. For more information, see Can't connect to Amazon RDS DB instance (p. 2289)

You can modify a DB instance to turn on or off public accessibility by modifying the Public access option. The following illustration shows the Public access option in the Additional connectivity configuration section. To set the option, open the Additional connectivity configuration section in the Connectivity section.

---

For information about modifying a DB instance to set the Public access option, see Modifying an Amazon RDS DB instance (p. 333).
Creating a DB instance in a VPC

The following procedures help you create a DB instance in a VPC. To use the default VPC, you can begin with step 2, and use the VPC and DB subnet group have already been created for you. If you want to create an additional VPC, you can create a new VPC.

Note
If you want your DB instance in the VPC to be publicly accessible, you must update the DNS information for the VPC by enabling the VPC attributes DNS hostnames and DNS resolution. For information about updating the DNS information for a VPC instance, see Updating DNS support for your VPC.

Follow these steps to create a DB instance in a VPC:

• Step 1: Create a VPC (p. 2259)
• Step 2: Create a DB subnet group (p. 2259)
• Step 3: Create a VPC security group (p. 2262)
• Step 4: Create a DB instance in the VPC (p. 2262)

Step 1: Create a VPC

Create a VPC with subnets in at least two Availability Zones. You use these subnets when you create a DB subnet group. If you have a default VPC, a subnet is automatically created for you in each Availability Zone in the AWS Region.

For more information, see Create a VPC with private and public subnets (p. 2269), or see Create a VPC in the Amazon VPC User Guide.

Step 2: Create a DB subnet group

A DB subnet group is a collection of subnets (typically private) that you create for a VPC and that you then designate for your DB instances. A DB subnet group allows you to specify a particular VPC when you create DB instances using the AWS CLI or RDS API. If you use the console, you can just choose the VPC and subnets you want to use. Each DB subnet group must have at least one subnet in at least two Availability Zones in the AWS Region. As a best practice, each DB subnet group should have at least one subnet for every Availability Zone in the AWS Region.

For Multi-AZ deployments, defining a subnet for all Availability Zones in an AWS Region enables Amazon RDS to create a new standby replica in another Availability Zone if necessary. You can follow this best practice even for Single-AZ deployments, because you might convert them to Multi-AZ deployments in the future.

For a DB instance to be publicly accessible, the subnets in the DB subnet group must have an internet gateway. For more information about internet gateways for subnets, see Connect to the internet using an internet gateway in the Amazon VPC User Guide.

Note
The DB subnet group for a Local Zone can have only one subnet.

When you create a DB instance in a VPC, you can choose a DB subnet group. Amazon RDS chooses a subnet and an IP address within that subnet to associate with your DB instance. If no DB subnet groups exist, Amazon RDS creates a default subnet group when you create a DB instance. Amazon RDS creates and associates an Elastic Network Interface to your DB instance with that IP address. The DB instance uses the Availability Zone that contains the subnet.

For Multi-AZ deployments, defining a subnet for two or more Availability Zones in an AWS Region allows Amazon RDS to create a new standby in another Availability Zone should the need arise. You need to do
In this step, you create a DB subnet group and add the subnets that you created for your VPC.

To create a DB subnet group

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Subnet groups.
3. Choose Create DB Subnet Group.
4. For Name, type the name of your DB subnet group.
5. For Description, type a description for your DB subnet group.
6. For VPC, choose the default VPC or the VPC that you created.
7. In the Add subnets section, choose the Availability Zones that include the subnets from Availability Zones, and then choose the subnets from Subnets.
Create DB Subnet Group

To create a new subnet group, give it a name and a description, and choose an existing VPC. You will then be able to add subnets related to that VPC.

**Subnet group details**

**Name**
You won’t be able to modify the name after your subnet group has been created.

```
mydbsubnetgroup
```

Must contain from 1 to 255 characters. Alphanumeric characters, spaces, hyphens, underscores, and periods are allowed.

**Description**

```
My DB Subnet Group
```

**VPC**
Choose a VPC identifier that corresponds to the subnets you want to use for your DB subnet group. You won’t be able to choose a different VPC identifier after your subnet group has been created.

```
tutorial-vpc (vpc-068fe38b85af0c014)
```

**Add subnets**

**Availability Zones**
Choose the Availability Zones that include the subnets you want to add.

```
Choose an availability zone
```

- us-east-1a ✗
- us-east-1c ✗

**Subnets**
Choose the subnets that you want to add. The list includes the subnets in the selected Availability Zones.

```
Select subnets
```

- subnet-079bd4b89539e16dd (10.0.0.0/24) ✗
- subnet-057e85b72c46fdd9a (10.0.1.0/24) ✗

**Subnets selected (2)**

<table>
<thead>
<tr>
<th>Availability zone</th>
<th>Subnet ID</th>
<th>CIDR block</th>
</tr>
</thead>
<tbody>
<tr>
<td>us-east-1a</td>
<td>subnet-079bd4b89539e16dd</td>
<td>10.0.0.0/24</td>
</tr>
<tr>
<td>us-east-1c</td>
<td>subnet-057e85b72c46fdd9a</td>
<td>10.0.1.0/24</td>
</tr>
</tbody>
</table>
8. Choose Create.

Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see details, including all of the subnets associated with the group, in the details pane at the bottom of the window.

**Step 3: Create a VPC security group**

Before you create your DB instance, you can create a VPC security group to associate with your DB instance. If you don't create a VPC security group, you can use the default security group when you create a DB instance. For instructions on how to create a security group for your DB instance, see Create a VPC security group for a private DB instance (p. 2270), or see Control traffic to resources using security groups in the Amazon VPC User Guide.

**Step 4: Create a DB instance in the VPC**

In this step, you create a DB instance and use the VPC name, the DB subnet group, and the VPC security group you created in the previous steps.

**Note**

If you want your DB instance in the VPC to be publicly accessible, you must enable the VPC attributes DNS hostnames and DNS resolution. For more information, see DNS attributes for your VPC in the Amazon VPC User Guide.

For details on how to create a DB instance, see Creating an Amazon RDS DB instance (p. 236).

When prompted in the Connectivity section, enter the VPC name, the DB subnet group, and the VPC security group.

**Updating the VPC for a DB instance**

You can use the AWS Management Console to move your DB instance to a different VPC.

For information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 333). In the Connectivity section of the modify page, shown following, enter the new DB subnet group for DB subnet group. The new subnet group must be a subnet group in a new VPC.

**Connectivity**

<table>
<thead>
<tr>
<th>Subnet group</th>
<th>default-vpc-665e7a1f</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Security group</th>
</tr>
</thead>
<tbody>
<tr>
<td>List of DB security groups to associate with this DB instance.</td>
</tr>
</tbody>
</table>

You can't change the VPC for a DB instance if the following conditions apply:
Scenarios for accessing a DB instance in a VPC

Amazon RDS supports the following scenarios for accessing a DB instance in a VPC:

• An EC2 instance in the same VPC (p. 2263)
• An EC2 instance in a different VPC (p. 2265)
• A client application through the internet (p. 2266)
• A private network (p. 2267)

A DB instance in a VPC accessed by an EC2 instance in the same VPC

A common use of a DB instance in a VPC is to share data with an application server that is running in an EC2 instance in the same VPC.

The following diagram shows this scenario.
The simplest way to manage access between EC2 instances and DB instances in the same VPC is to do the following:

- Create a VPC security group for your DB instances to be in. This security group can be used to restrict access to the DB instances. For example, you can create a custom rule for this security group. This might allow TCP access using the port that you assigned to the DB instance when you created it and an IP address you use to access the DB instance for development or other purposes.
- Create a VPC security group for your EC2 instances (web servers and clients) to be in. This security group can, if needed, allow access to the EC2 instance from the internet by using the VPC's routing table. For example, you can set rules on this security group to allow TCP access to the EC2 instance over port 22.
- Create custom rules in the security group for your DB instances that allow connections from the security group you created for your EC2 instances. These rules might allow any member of the security group to access the DB instances.

There is an additional public and private subnet in a separate Availability Zone. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easy to switch to a Multi-AZ DB instance deployment in the future.

For a tutorial that shows you how to create a VPC with both public and private subnets for this scenario, see Tutorial: Create a VPC for use with a DB instance (IPv4 only) (p. 2268).

Tip
You can set up network connectivity between an Amazon EC2 instance and a DB instance automatically when you create the DB instance. For more information, see .
To create a rule in a VPC security group that allows connections from another security group, do the following:

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc.
2. In the navigation pane, choose Security groups.
3. Choose or create a security group for which you want to allow access to members of another security group. In the preceding scenario, this is the security group that you use for your DB instances. Choose the Inbound rules tab, and then choose Edit inbound rules.
5. For Type, choose the entry that corresponds to the port you used when you created your DB instance, such as MYSQL/Aurora.
6. In the Source box, start typing the ID of the security group, which lists the matching security groups. Choose the security group with members that you want to have access to the resources protected by this security group. In the scenario preceding, this is the security group that you use for your EC2 instance.
7. If required, repeat the steps for the TCP protocol by creating a rule with All TCP as the Type and your security group in the Source box. If you intend to use the UDP protocol, create a rule with All UDP as the Type and your security group in Source.
8. Choose Save rules.

The following screen shows an inbound rule with a security group for its source.

A DB instance in a VPC accessed by an EC2 instance in a different VPC

When your DB instances is in a different VPC from the EC2 instance you are using to access it, you can use VPC peering to access the DB instance.

The following diagram shows this scenario.
A VPC peering connection is a networking connection between two VPCs that enables you to route traffic between them using private IP addresses. Resources in either VPC can communicate with each other as if they are within the same network. You can create a VPC peering connection between your own VPCs, with a VPC in another AWS account, or with a VPC in a different AWS Region. To learn more about VPC peering, see VPC peering in the Amazon Virtual Private Cloud User Guide.

**A DB instance in a VPC accessed by a client application through the internet**

To access a DB instances in a VPC from a client application through the internet, you configure a VPC with a single public subnet, and an internet gateway to enable communication over the internet.

The following diagram shows this scenario.

We recommend the following configuration:

- A VPC of size /16 (for example CIDR: 10.0.0.0/16). This size provides 65,536 private IP addresses.
- A subnet of size /24 (for example CIDR: 10.0.0.0/24). This size provides 256 private IP addresses.
- An Amazon RDS DB instance that is associated with the VPC and the subnet. Amazon RDS assigns an IP address within the subnet to your DB instance.
- An internet gateway which connects the VPC to the internet and to other AWS products.
• A security group associated with the DB instance. The security group's inbound rules allow your client application to access to your DB instance.

For information about creating a DB instances in a VPC, see Creating a DB instance in a VPC (p. 2259).

**A DB instance in a VPC accessed by a private network**

If your DB instance isn't publicly accessible, you have the following options for accessing it from a private network:

• An AWS Site-to-Site VPN connection. For more information, see What is AWS Site-to-Site VPN?
• An AWS Direct Connect connection. For more information, see What is AWS Direct Connect?

The following diagram shows a scenario with an AWS Site-to-Site VPN connection.

For more information, see Internetwork traffic privacy (p. 2161).
Tutorial: Create a VPC for use with a DB instance (IPv4 only)

A common scenario includes a DB instance in a virtual private cloud (VPC) based on the Amazon VPC service. This VPC shares data with a web server that is running in the same VPC. In this tutorial, you create the VPC for this scenario.

The following diagram shows this scenario. For information about other scenarios, see Scenarios for accessing a DB instance in a VPC (p. 2263).

Your DB instance needs to be available only to your web server, and not to the public internet. Thus, you create a VPC with both public and private subnets. The web server is hosted in the public subnet, so that it can reach the public internet. The DB instance is hosted in a private subnet. The web server can connect to the DB instance because it is hosted within the same VPC. But the DB instance isn’t available to the public internet, providing greater security.

This tutorial configures an additional public and private subnet in a separate Availability Zone. These subnets aren’t used by the tutorial. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easier to switch to a Multi-AZ DB instance deployment in the future.

This tutorial describes configuring a VPC for Amazon RDS DB instances. For a tutorial that shows you how to create a web server for this VPC scenario, see Tutorial: Create a web server and an Amazon RDS DB instance (p. 204). For more information about Amazon VPC, see Amazon VPC Getting Started Guide and Amazon VPC User Guide.
Tip
You can set up network connectivity between an Amazon EC2 instance and a DB instance automatically when you create the DB instance. The network configuration is similar to the one described in this tutorial. For more information, see Configure automatic network connectivity with an EC2 instance (p. 236).

Create a VPC with private and public subnets

Use the following procedure to create a VPC with both public and private subnets.

To create a VPC and subnets

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the top-right corner of the AWS Management Console, choose the Region to create your VPC in. This example uses the US West (Oregon) Region.
3. In the upper-left corner, choose VPC dashboard. To begin creating a VPC, choose Create VPC.
4. For Resources to create under VPC settings, choose VPC and more.
5. For the VPC settings, set these values:
   - Name tag auto-generation – tutorial
   - IPv4 CIDR block – 10.0.0.0/16
   - IPv6 CIDR block – No IPv6 CIDR block
   - Tenancy – Default
   - Number of Availability Zones (AZs) – 2
   - Customize AZs – Keep the default values.
   - Number of public subnet – 2
   - Number of private subnets – 2
   - Customize subnets CIDR blocks – Keep the default values.
   - NAT gateways ($) – None
   - VPC endpoints – None
   - DNS options – Keep the default values.

Note
Amazon RDS requires at least two subnets in two different Availability Zones to support Multi-AZ DB instance deployments. This tutorial creates a Single-AZ deployment, but the requirement makes it easier to convert to a Multi-AZ DB instance deployment in the future.

6. Choose Create VPC.

Create a VPC security group for a public web server

Next, you create a security group for public access. To connect to public EC2 instances in your VPC, you add inbound rules to your VPC security group. These allow traffic to connect from the internet.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose VPC Dashboard, choose Security Groups, and then choose Create security group.
3. On the Create security group page, set these values:
   - Security group name: tutorial-securitygroup
• Description: Tutorial Security Group
• VPC: Choose the VPC that you created earlier, for example: vpc-identifier (tutorial-vpc)
4. Add inbound rules to the security group.
   a. Determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH). To determine your public IP address, in a different browser window or tab, you can use the service at https://checkip.amazonaws.com. An example of an IP address is 203.0.113.25/32.
   In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, find the range of IP addresses used by client computers.
   Warning
   If you use 0.0.0.0/0 for SSH access, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances using SSH.
   b. In the Inbound rules section, choose Add rule.
   c. Set the following values for your new inbound rule to allow SSH access to your Amazon EC2 instance. If you do this, you can connect to your Amazon EC2 instance to install the web server and other utilities. You also connect to your EC2 instance to upload content for your web server.
      • Type: SSH
      • Source: The IP address or range from Step a, for example: 203.0.113.25/32.
   d. Choose Add rule.
   e. Set the following values for your new inbound rule to allow HTTP access to your web server:
      • Type: HTTP
      • Source: 0.0.0.0/0
5. Choose Create security group to create the security group.
   Note the security group ID because you need it later in this tutorial.

Create a VPC security group for a private DB instance

To keep your DB instance private, create a second security group for private access. To connect to private DB instances in your VPC, you add inbound rules to your VPC security group that allow traffic from your web server only.

To create a VPC security group
1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose VPC Dashboard, choose Security Groups, and then choose Create security group.
3. On the Create security group page, set these values:
   • Security group name: tutorial-db-securitygroup
   • Description: Tutorial DB Instance Security Group
   • VPC: Choose the VPC that you created earlier, for example: vpc-identifier (tutorial-vpc)
4. Add inbound rules to the security group.
   a. In the Inbound rules section, choose Add rule.
   b. Set the following values for your new inbound rule to allow MySQL traffic on port 3306 from your Amazon EC2 instance. If you do this, you can connect from your web server to your DB
instance. By doing so, you can store and retrieve data from your web application to your database.

- **Type:** MySQL/Aurora
- **Source:** The identifier of the `tutorial-securitygroup` security group that you created previously in this tutorial, for example: `sg-9edd5cfb`.

5. Choose **Create security group** to create the security group.

### Create a DB subnet group

A **DB subnet group** is a collection of subnets that you create in a VPC and that you then designate for your DB instances. A DB subnet group makes it possible for you to specify a particular VPC when creating DB instances.

**To create a DB subnet group**

1. Identify the private subnets for your database in the VPC.
   - a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   - b. Choose **VPC Dashboard**, and then choose **Subnets**.
   - c. Note the subnet IDs of the subnets named `tutorial-subnet-private1-us-west-2a` and `tutorial-subnet-private2-us-west-2b`.

      You need the subnet IDs when you create your DB subnet group.

2. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.

   Make sure that you connect to the Amazon RDS console, not to the Amazon VPC console.

3. In the navigation pane, choose **Subnet groups**.

4. Choose **Create DB subnet group**.

5. On the **Create DB subnet group** page, set these values in **Subnet group details**:
   - **Name:** `tutorial-db-subnet-group`
   - **Description:** Tutorial DB Subnet Group
   - **VPC:** `tutorial-vpc (vpc-identifier)`

6. In the **Add subnets** section, choose the **Availability Zones** and **Subnets**.

   For this tutorial, choose `us-west-2a` and `us-west-2b` for the **Availability Zones**. For **Subnets**, choose the private subnets you identified in the previous step.

7. Choose **Create**.

   Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see details in the details pane at the bottom of the window. These details include all of the subnets associated with the group.

**Note**

If you created this VPC to complete Tutorial: Create a web server and an Amazon RDS DB instance (p. 204), create the DB instance by following the instructions in **Create a DB instance** (p. 209).

### Deleting the VPC

After you create the VPC and other resources for this tutorial, you can delete them if they are no longer needed.
To delete a VPC and related resources

1. Delete the DB subnet group.
   a. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   b. In the navigation pane, choose Subnet groups.
   c. Select the DB subnet group you want to delete, such as tutorial-db-subnet-group.
   d. Choose Delete, and then choose Delete in the confirmation window.

2. Note the VPC ID.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose VPC Dashboard, and then choose VPCs.
   c. In the list, identify the VPC that you created, such as tutorial-vpc.
   d. Note the VPC ID of the VPC that you created. You need the VPC ID in later steps.

3. Delete the security groups.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose VPC Dashboard, and then choose Security Groups.
   c. Select the security group for the Amazon RDS DB instance, such as tutorial-db-securitygroup.
   d. For Actions, choose Delete security groups, and then choose Delete on the confirmation page.
   e. On the Security Groups page, select the security group for the Amazon EC2 instance, such as tutorial-securitygroup.
   f. For Actions, choose Delete security groups, and then choose Delete on the confirmation page.

4. Delete the NAT gateway.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose VPC Dashboard, and then choose NAT Gateways.
   c. Select the NAT gateway of the VPC that you created. Use the VPC ID to identify the correct NAT gateway.
   d. For Actions, choose Delete NAT gateway.
   e. On the confirmation page, enter delete, and then choose Delete.

5. Delete the VPC.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose VPC Dashboard, and then choose VPCs.
   c. Select the VPC you want to delete, such as tutorial-vpc.
   d. For Actions, choose Delete VPC.
      The confirmation page shows other resources that are associated with the VPC that will also be deleted, including the subnets associated with it.
   e. On the confirmation page, enter delete, and then choose Delete.

6. Release the Elastic IP addresses:
   a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
   b. Choose Amazon EC2 Dashboard, and then choose Elastic IPs.
   c. Select the Elastic IP address you want to release.
d. For Actions, choose Release Elastic IP addresses.

e. On the confirmation page, choose Release.
Tutorial: Create a VPC for use with a DB instance (dual-stack mode)

A common scenario includes a DB instance in a virtual private cloud (VPC) based on the Amazon VPC service. This VPC shares data with a public Amazon EC2 instance that is running in the same VPC. In this tutorial, you create the VPC for this scenario that works with a database running in dual-stack mode.

The following diagram shows this scenario.

For information about other scenarios, see Scenarios for accessing a DB instance in a VPC (p. 2263).

Your DB instance needs to be available only to your Amazon EC2 instance, and not to the public internet. Thus, you create a VPC with both public and private subnets. The Amazon EC2 instance is hosted in the public subnet, so that it can reach the public internet. The DB instance is hosted in a private subnet. The Amazon EC2 instance can connect to the DB instance because it’s hosted within the same VPC. However, the DB instance is not available to the public internet, providing greater security.

This tutorial configures an additional public and private subnet in a separate Availability Zone. These subnets aren’t used by the tutorial. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easy to switch to a Multi-AZ DB instance deployment in the future.

To create a DB instance that uses dual-stack mode, specify Dual-stack mode for the Network type setting. You can also modify a DB instance with the same setting. For more information, see Creating an Amazon RDS DB instance (p. 236) and Modifying an Amazon RDS DB instance (p. 333).
Create a VPC with private and public subnets

Use the following procedure to create a VPC with both public and private subnets.

To create a VPC and subnets

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the upper-right corner of the AWS Management Console, choose the Region to create your VPC in. This example uses the US East (Ohio) Region.
3. In the upper-left corner, choose VPC dashboard. To begin creating a VPC, choose Create VPC.
4. For Resources to create under VPC settings, choose VPC and more.
5. For the remaining VPC settings, set these values:
   - Name tag auto-generation – tutorial-dual-stack
   - IPv4 CIDR block – 10.0.0.0/16
   - IPv6 CIDR block – Amazon-provided IPv6 CIDR block
   - Tenancy – Default
   - Number of Availability Zones (AZs) – 2
   - Customize AZs – Keep the default values.
   - Number of public subnet – 2
   - Number of private subnets – 2
   - Customize subnets CIDR blocks – Keep the default values.
   - NAT gateways ($) – None
   - Egress only internet gateway – No
   - VPC endpoints – None
   - DNS options – Keep the default values.

Note
Amazon RDS requires at least two subnets in two different Availability Zones to support Multi-AZ DB instance deployments. This tutorial creates a Single-AZ deployment, but the requirement makes it easy to convert to a Multi-AZ DB instance deployment in the future.

6. Choose Create VPC.

Create a VPC security group for a public Amazon EC2 instance

Next, you create a security group for public access. To connect to public EC2 instances in your VPC, add inbound rules to your VPC security group that allow traffic to connect from the internet.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose VPC Dashboard, choose Security Groups, and then choose Create security group.
3. On the Create security group page, set these values:
   - Security group name: tutorial-dual-stack-securitygroup
   - Description: Tutorial Dual-Stack Security Group
• VPC: Choose the VPC that you created earlier, for example: vpc-identifier (tutorial-dual-stack-vpc)

4. Add inbound rules to the security group.

a. Determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH).

To determine your public IP address, in a different browser window or tab use the service at https://checkip.amazonaws.com. An example of an Internet Protocol version 4 (IPv4) address is 203.0.113.25/32. An example of an Internet Protocol version 6 (IPv6) address is 2001:DB8::/32.

In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, find the range of IP addresses used by client computers.

Warning
If you use 0.0.0.0/0 for IPv4 or ::0 for IPv6, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances.

b. In the Inbound rules section, choose Add rule.

c. Set the following values for your new inbound rule to allow Secure Shell (SSH) access to your Amazon EC2 instance. If you do this, you can connect to your EC2 instance to install SQL clients and other applications. Specify an IP address so you can access your EC2 instance:

• Type: SSH
• Source: The IP address or range from step a. An example of an IPv4 IP address is 203.0.113.25/32. An example of an IPv6 IP address is 2001:DB8::/32.

5. Choose Create security group to create the security group.

Note the security group ID because you need it later in this tutorial.

Create a VPC security group for a private DB instance

To keep your DB instance private, create a second security group for private access. To connect to private DB instances in your VPC, add inbound rules to your VPC security group. These allow traffic from your Amazon EC2 instance only.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose VPC Dashboard, choose Security Groups, and then choose Create security group.
3. On the Create security group page, set these values:

• Security group name: tutorial-dual-stack-db-securitygroup
• Description: Tutorial Dual-Stack DB Instance Security Group
• VPC: Choose the VPC that you created earlier, for example: vpc-identifier (tutorial-dual-stack-vpc)

4. Add inbound rules to the security group:

a. In the Inbound rules section, choose Add rule.

b. Set the following values for your new inbound rule to allow MySQL traffic on port 3306 from your Amazon EC2 instance. If you do, you can connect from your EC2 instance to your DB
instance. Doing this means that you can store and retrieve data from your EC2 instance to your database.

- **Type:** MySQL/Aurora
- **Source:** The identifier of the tutorial-dual-stack-securitygroup security group that you created previously in this tutorial, for example sg-9edd5cfb.

5. To create the security group, choose Create security group.

### Create a DB subnet group

A **DB subnet group** is a collection of subnets that you create in a VPC and that you then designate for your DB instances. By using a DB subnet group, you can specify a particular VPC when creating DB instances. To create a DB subnet group that is DUAL compatible, all subnets must be DUAL compatible. To be DUAL compatible, a subnet must have an IPv6 CIDR associated with it.

**To create a DB subnet group**

1. Identify the private subnets for your database in the VPC.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose VPC Dashboard, and then choose Subnets.
   c. Note the subnet IDs of the subnets named tutorial-dual-stack-subnet-private1-us-west-2a and tutorial-dual-stack-subnet-private2-us-west-2b.

   You will need the subnet IDs when you create your DB subnet group.

2. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.

   Make sure that you connect to the Amazon RDS console, not to the Amazon VPC console.

3. In the navigation pane, choose Subnet groups.

4. Choose Create DB subnet group.

5. On the Create DB subnet group page, set these values in Subnet group details:
   - **Name:** tutorial-dual-stack-db-subnet-group
   - **Description:** Tutorial Dual-Stack DB Subnet Group
   - **VPC:** tutorial-dual-stack-vpc (vpc-identifier)

6. In the Add subnets section, choose values for the Availability Zones and Subnets options.

   For this tutorial, choose us-east-2a and us-east-2b for the Availability Zones. For Subnets, choose the private subnets you identified in the previous step.

7. Choose Create.

Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see its details. These include the supported addressing protocols and all of the subnets associated with the group and the network type supported by the DB subnet group.

### Create an Amazon EC2 instance in dual-stack mode

To create an Amazon EC2 instance, follow the instructions in Launch an instance using the new launch instance wizard in the Amazon EC2 User Guide for Linux Instances.

On the **Configure Instance Details** page, set these values and keep the other values as their defaults:
Create a VPC for use with a DB instance (dual-stack mode)

- **Network** – Choose the VPC with both public and private subnets that you chose for the DB instance, such as `vpc-identifier | tutorial-dual-stack-vpc` created in Create a VPC with private and public subnets (p. 2275).
- **Subnet** – Choose an existing public subnet, such as `subnet-identifier | tutorial-dual-stack-subnet-public1-us-east-2a | us-east-2a` created in Create a VPC security group for a public Amazon EC2 instance (p. 2275).
- **Auto-assign Public IP** – Choose Enable.
- **Auto-assign IPv6 IP** – Choose Enable.
- **Firewall (security groups)** – Choose Select an existing security group.
- **Common security groups** – Choose an existing security group, such as the `tutorial-securitygroup` created in Create a VPC security group for a public Amazon EC2 instance (p. 2275).

Create a DB instance in dual-stack mode

In this step, you create a DB instance that runs in dual-stack mode.

**To create a DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at `https://console.aws.amazon.com/rds/`.
2. In the upper-right corner of the console, choose the AWS Region where you want to create the DB instance. This example uses the US East (Ohio) Region.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.
5. On the **Create database** page, make sure that the **Standard create** option is chosen, and then choose the MySQL DB engine type.
6. In the **Connectivity** section, set these values:

   - **Network type** – Choose **Dual-stack mode**.
   - **Virtual private cloud (VPC)** – Choose an existing VPC with both public and private subnets, such as `tutorial-dual-stack-vpc (vpc-identifier)` created in Create a VPC with private and public subnets (p. 2275).

   The VPC must have subnets in different Availability Zones.

   - **DB subnet group** – Choose a DB subnet group for the VPC, such as `tutorial-dual-stack-db-subnet-group` created in Create a DB subnet group (p. 2277).
   - **Public access** – Choose **No**.
   - **VPC security group (firewall)** – Select **Choose existing**.
   - **Existing VPC security groups** – Choose an existing VPC security group that is configured for private access, such as `tutorial-dual-stack-db-securitygroup` created in Create a VPC security group for a private DB instance (p. 2276).
Remove other security groups, such as the default security group, by choosing the X associated with each.

- **Availability Zone** – Choose `us-west-2a`.

To avoid cross-AZ traffic, make sure the DB instance and the EC2 instance are in the same Availability Zone.

7. For the remaining sections, specify your DB instance settings. For information about each setting, see [Settings for DB instances](p. 243).

## Connect to your Amazon EC2 instance and DB instance

After you create your Amazon EC2 instance and DB instance in dual-stack mode, you can connect to each one using the IPv6 protocol. To connect to an Amazon EC2 instance using the IPv6 protocol, follow the instructions in [Connect to your Linux instance](in the Amazon EC2 User Guide for Linux Instances).

To connect to your DB instance, follow the instructions in [Connecting to an Amazon RDS DB instance](p. 273).

## Deleting the VPC

After you create the VPC and other resources for this tutorial, you can delete them if they are no longer needed.

If you added resources in the VPC that you created for this tutorial, you might need to delete these before you can delete the VPC. Examples of resources are Amazon EC2 instances or DB instances. For more information, see [Delete your VPC](in the Amazon VPC User Guide).

**To delete a VPC and related resources**

1. Delete the DB subnet group:
   a. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
   b. In the navigation pane, choose **Subnet groups**.
   c. Select the DB subnet group to delete, such as `tutorial-db-subnet-group`.
   d. Choose **Delete**, and then choose **Delete** in the confirmation window.

2. Note the VPC ID:
   a. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
   b. Choose **VPC Dashboard**, and then choose **VPCs**.
   c. In the list, identify the VPC you created, such as `tutorial-dual-stack-vpc`.
   d. Note the **VPC ID** value of the VPC that you created. You need this VPC ID in subsequent steps.

3. Delete the security groups:
   a. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
   b. Choose **VPC Dashboard**, and then choose **Security Groups**.
   c. Select the security group for the Amazon RDS DB instance, such as `tutorial-dual-stack-db-securitygroup`.
   d. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.
   e. On the **Security Groups** page, select the security group for the Amazon EC2 instance, such as `tutorial-dual-stack-securitygroup`.
   f. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.

4. Delete the NAT gateway:
a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
b. Choose VPC Dashboard, and then choose NAT Gateways.
c. Select the NAT gateway of the VPC that you created. Use the VPC ID to identify the correct NAT gateway.
d. For Actions, choose Delete NAT gateway.
e. On the confirmation page, enter delete, and then choose Delete.

5. Delete the VPC:
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose VPC Dashboard, and then choose VPCs.
   c. Select the VPC that you want to delete, such as tutorial-dual-stack-vpc.
   d. For Actions, choose Delete VPC.
      The confirmation page shows other resources that are associated with the VPC that will also be deleted, including the subnets associated with it.
   e. On the confirmation page, enter delete, and then choose Delete.

6. Release the Elastic IP addresses:
   a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
   b. Choose EC2 Dashboard, and then choose Elastic IPs.
   c. Select the Elastic IP address that you want to release.
   d. For Actions, choose Release Elastic IP addresses.
   e. On the confirmation page, choose Release.
Moving a DB instance not in a VPC into a VPC

Some legacy DB instances on the EC2-Classic platform are not in a VPC. If your DB instance is not in a VPC, you can use the AWS Management Console to easily move your DB instance into a VPC. Before you can move a DB instance not in a VPC, into a VPC, you must create the VPC.

<table>
<thead>
<tr>
<th>Important</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you are a new Amazon RDS customer, if you have never created a DB instance before, or if you are creating a DB instance in an AWS Region you have not used before, in almost all cases you are on the EC2-VPC platform and have a default VPC. For information about working with DB instances in a VPC, see Working with a DB instance in a VPC (p. 2251).</td>
</tr>
</tbody>
</table>

Follow these steps to create a VPC for your DB instance.

- **Step 1:** Create a VPC (p. 2259)
- **Step 2:** Create a DB subnet group (p. 2259)
- **Step 3:** Create a VPC security group (p. 2262)

After you create the VPC, follow these steps to move your DB instance into the VPC.

- **Updating the VPC for a DB instance** (p. 2262)

We highly recommend that you create a backup of your DB instance immediately before the migration. Doing so ensures that you can restore the data if the migration fails. For more information, see **Backing up and restoring an Amazon RDS DB instance** (p. 461).

The following are some limitations to moving your DB instance into the VPC.

- **Previous generation DB instance classes** – Previous generation DB instance classes might not be supported on the VPC platform. When moving a DB instance to a VPC, choose a db.m3 or db.r3 DB instance class. After you move the DB instance to a VPC, you can scale the DB instance to use a later DB instance class. For a full list of VPC supported instance classes, see **Amazon RDS instance types**.

- **Multi-AZ** – Moving a Multi-AZ DB instance not in a VPC into a VPC is not currently supported. To move your DB instance to a VPC, first modify the DB instance so that it is a single-AZ deployment. Change the Multi-AZ deployment setting to No. After you move the DB instance to a VPC, modify it again to make it a Multi-AZ deployment. For more information, see **Modifying an Amazon RDS DB instance** (p. 333).

- **Read replicas** – Moving a DB instance with read replicas not in a VPC into a VPC is not currently supported. To move your DB instance to a VPC, first delete all of its read replicas. After you move the DB instance to a VPC, recreate the read replicas. For more information, see **Working with read replicas** (p. 382).

- **Option groups** – If you move your DB instance to a VPC, and the DB instance is using a custom option group, change the option group that is associated with your DB instance. Option groups are platform-specific, and moving to a VPC is a change in platform. To use a custom option group in this case, assign the default VPC option group to the DB instance, assign an option group that is used by other DB instances in the VPC you are moving to, or create a new option group and assign it to the DB instance. For more information, see **Working with option groups** (p. 279).
Alternatives for moving a DB instance not in a VPC into a VPC with minimal downtime

Using the following alternatives, you can move a DB instance not in a VPC into a VPC with minimal downtime. These alternatives cause minimum disruption to the source DB instance and allow it to serve user traffic during the migration. However, the time required to migrate to a VPC will vary based on the database size and the live workload characteristics.

- **AWS Database Migration Service (AWS DMS)** – AWS DMS enables the live migration of data while keeping the source DB instance fully operational, but it replicates only a limited set of DDL statements. AWS DMS doesn’t propagate items such as indexes, users, privileges, stored procedures, and other database changes not directly related to table data. In addition, AWS DMS doesn’t automatically use RDS snapshots for the initial DB instance creation, which can increase migration time. For more information, see [AWS Database Migration Service](https://docs.aws.amazon.com/AmazonRDS/latest/AWSDatabaseMigrationServiceUserGuide/index.html).

- **DB snapshot restore or point-in-time recovery** – You can move a DB instance to a VPC by restoring a snapshot of the DB instance or by restoring a DB instance to a point in time. For more information, see [Restoring from a DB snapshot](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/CHAP_MonitoringMonitoringTools.html) and [Restoring a DB instance to a specified time](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/CHAP_MonitoringMonitoringTools.html).
Quotas and constraints for Amazon RDS

Following, you can find a description of the resource quotas and naming constraints for Amazon RDS.

Topics
- Quotas in Amazon RDS (p. 2283)
- Naming constraints in Amazon RDS (p. 2286)
- Maximum number of database connections (p. 2287)
- File size limits in Amazon RDS (p. 2288)

Quotas in Amazon RDS

Each AWS account has quotas, for each AWS Region, on the number of Amazon RDS resources that can be created. After a quota for a resource has been reached, additional calls to create that resource fail with an exception.

The following table lists the resources and their quotas per AWS Region.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Adjust</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Authorizations per DB security group</td>
<td>Each supported Region: 20</td>
<td>No</td>
<td>Number of security group authorizations per DB security group</td>
</tr>
<tr>
<td>Custom engine versions</td>
<td>Each supported Region: 40</td>
<td>Yes</td>
<td>The maximum number of custom engine versions allowed in this account in the current Region</td>
</tr>
<tr>
<td>DB cluster parameter groups</td>
<td>Each supported Region: 50</td>
<td>No</td>
<td>The maximum number of DB cluster parameter groups</td>
</tr>
<tr>
<td>DB clusters</td>
<td>Each supported Region: 40</td>
<td>Yes</td>
<td>The maximum number of Aurora clusters allowed in this account in the current Region</td>
</tr>
<tr>
<td>DB instances</td>
<td>Each supported Region: 40</td>
<td>Yes</td>
<td>The maximum number of DB instances allowed in this account in the current Region</td>
</tr>
<tr>
<td>DB subnet groups</td>
<td>Each supported Region: 50</td>
<td>Yes</td>
<td>The maximum number of DB subnet groups</td>
</tr>
<tr>
<td>Data API HTTP request body size</td>
<td>Each supported Region: 4 Megabytes</td>
<td>No</td>
<td>The maximum size allowed for the HTTP request body.</td>
</tr>
<tr>
<td>Name</td>
<td>Default</td>
<td>Adjust</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------------------------</td>
<td>--------------------------</td>
<td>--------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Data API maximum concurrent cluster-secret pairs</td>
<td>Each supported Region: 30</td>
<td>No</td>
<td>The maximum number of unique pairs of Aurora Serverless DB clusters and secrets in concurrent Data API requests for the current account and AWS Region.</td>
</tr>
<tr>
<td>Data API maximum concurrent requests</td>
<td>Each supported Region: 500</td>
<td>No</td>
<td>The maximum number of Data API requests to an Aurora Serverless DB cluster that use the same secret and can be processed at the same time. Additional requests are queued and processed as in-process requests complete.</td>
</tr>
<tr>
<td>Data API maximum result set size</td>
<td>Each supported Region: 1 Megabytes</td>
<td>No</td>
<td>The maximum size of the database result set that can be returned by the Data API.</td>
</tr>
<tr>
<td>Data API maximum size of JSON response string</td>
<td>Each supported Region: 10 Megabytes</td>
<td>No</td>
<td>The maximum size of the simplified JSON response string returned by the RDS Data API.</td>
</tr>
<tr>
<td>Data API requests per second</td>
<td>Each supported Region: 1,000 per second</td>
<td>No</td>
<td>The maximum number of requests to the Data API per second allowed in this account in the current AWS Region.</td>
</tr>
<tr>
<td>Event subscriptions</td>
<td>Each supported Region: 20</td>
<td>Yes</td>
<td>The maximum number of event subscriptions</td>
</tr>
<tr>
<td>IAM roles per DB cluster</td>
<td>Each supported Region: 5</td>
<td>Yes</td>
<td>The maximum number of IAM roles associated with a DB cluster</td>
</tr>
<tr>
<td>IAM roles per DB instance</td>
<td>Each supported Region: 5</td>
<td>Yes</td>
<td>The maximum number of IAM roles associated with a DB instance</td>
</tr>
<tr>
<td>Manual DB cluster snapshots</td>
<td>Each supported Region: 100</td>
<td>Yes</td>
<td>The maximum number of manual DB cluster snapshots</td>
</tr>
<tr>
<td>Manual DB instance snapshots</td>
<td>Each supported Region: 100</td>
<td>Yes</td>
<td>The maximum number of manual DB instance snapshots</td>
</tr>
<tr>
<td>Option groups</td>
<td>Each supported Region: 20</td>
<td>Yes</td>
<td>The maximum number of option groups</td>
</tr>
</tbody>
</table>
### Quotas in Amazon RDS

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Adjust</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter groups</td>
<td>Each supported Region: 50</td>
<td>Yes</td>
<td>The maximum number of parameter groups</td>
</tr>
<tr>
<td>Proxies</td>
<td>Each supported Region: 20</td>
<td>Yes</td>
<td>The maximum number of proxies allowed in this account in the current AWS Region</td>
</tr>
<tr>
<td>Read replicas per master</td>
<td>Each supported Region: 15</td>
<td>Yes</td>
<td>The maximum number of read replicas per master</td>
</tr>
<tr>
<td>Reserved DB instances</td>
<td>Each supported Region: 40</td>
<td>Yes</td>
<td>The maximum number of reserved DB instances allowed in this account in the current AWS Region</td>
</tr>
<tr>
<td>Rules per security group</td>
<td>Each supported Region: 20</td>
<td>No</td>
<td>The maximum number of rules per DB security group</td>
</tr>
<tr>
<td>Security groups</td>
<td>Each supported Region: 25</td>
<td>Yes</td>
<td>The maximum number of DB security groups</td>
</tr>
<tr>
<td>Security groups (VPC)</td>
<td>Each supported Region: 5</td>
<td>No</td>
<td>The maximum number of DB security groups per Amazon VPC</td>
</tr>
<tr>
<td>Subnets per DB subnet group</td>
<td>Each supported Region: 20</td>
<td>No</td>
<td>The maximum number of subnets per DB subnet group</td>
</tr>
<tr>
<td>Tags per resource</td>
<td>Each supported Region: 50</td>
<td>No</td>
<td>The maximum number of tags per Amazon RDS resource</td>
</tr>
<tr>
<td>Total storage for all DB instances</td>
<td>Each supported Region: 100,000 Gigabytes</td>
<td>Yes</td>
<td>The maximum total storage (in GB) for all DB instances added together</td>
</tr>
</tbody>
</table>

**Note**
By default, you can have up to a total of 40 DB instances. RDS DB instances, Aurora DB instances, Amazon Neptune instances, and Amazon DocumentDB instances apply to this quota. The following limitations apply to the Amazon RDS DB instances:

- 10 for each SQL Server edition (Enterprise, Standard, Web, and Express) under the "license-included" model
- 10 for Oracle under the "license-included" model
- 40 for MySQL, MariaDB, or PostgreSQL
- 40 for Oracle under the "bring-your-own-license" (BYOL) licensing model

If your application requires more DB instances, you can request additional DB instances by opening the Service Quotas console. In the navigation pane, choose AWS Services. Choose Amazon Relational Database Service (Amazon RDS), choose a quota, and follow the directions to request a quota increase. For more information, see Requesting a quota increase in the Service Quotas User Guide.
For RDS for Oracle and RDS for SQL Server, the read replica limit is 5 per source database for each Region.

Backups managed by AWS Backup are considered manual DB snapshots, but don’t count toward the manual snapshot quota. For information about AWS Backup, see the AWS Backup Developer Guide.

If you use any RDS API operations and exceed the default quota for the number of calls per second, the Amazon RDS API issues an error like the following one.

ClientError: An error occurred (ThrottlingException) when calling the API_name operation: Rate exceeded.

Here, reduce the number of calls per second. The quota is meant to cover most use cases. If higher limits are needed, request a quota increase by contacting AWS Support. Open the AWS Support Center page, sign in if necessary, and choose Create case. Choose Service limit increase. Complete and submit the form.

Note
This quota can’t be changed in the Amazon RDS Service Quotas console.

Naming constraints in Amazon RDS

The following table describes naming constraints in Amazon RDS.

<table>
<thead>
<tr>
<th>Resource or item</th>
<th>Constraints</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB instance identifier</td>
<td>Identifiers have these naming constraints:</td>
</tr>
<tr>
<td></td>
<td>• Must contain 1–63 alphanumeric characters or hyphens.</td>
</tr>
<tr>
<td></td>
<td>• First character must be a letter.</td>
</tr>
<tr>
<td></td>
<td>• Can’t end with a hyphen or contain two consecutive hyphens.</td>
</tr>
<tr>
<td></td>

Maximum number of database connections

The maximum number of simultaneous database connections varies by the DB engine type and the memory allocation for the DB instance class. The maximum number of connections is generally set in the parameter group associated with the DB instance. The exception is Microsoft SQL Server, where it is set in the server properties for the DB instance in SQL Server Management Studio (SSMS).

`DBInstanceClassMemory` is in bytes. For details about how this value is calculated, see Specifying DB parameters (p. 316). Because of memory reserved for the operating system and RDS management processes, this memory size is smaller than the value in gibibytes (GiB) shown in Hardware specifications for DB instance classes (p. 62).

If your applications frequently open and close connections, or keep a large number of long-lived connections open, we recommend that you use Amazon RDS Proxy. RDS Proxy is a fully managed, highly available database proxy that uses connection pooling to share database connections securely and efficiently. To learn more about RDS Proxy, see Using Amazon RDS Proxy (p. 961).

**Note**
For Oracle, you set the maximum number of user processes and user and system sessions.

### Maximum database connections

**Note**
If the default value calculation results in a value greater than 16,000, Amazon RDS sets
## File size limits in Amazon RDS

In some instances, the total RAM is 16 GiB, or 17,179,869,184 bytes. In these instances, the variable `DBInstanceClassMemory` automatically subtracts the amounts reserved to the operating system and the RDS processes that manage the instance. The remainder of the subtraction is then divided by 12,582,880. This results in the maximum connections number being around 1,300, depending on instance type, instance size, and DB engine.

Database connections consume memory. Setting one of these parameters too high can cause a low memory condition that might cause a DB instance to be placed in the **incompatible-parameters** status. For more information, see Diagnosing and resolving incompatible parameters status for a memory limit (p. 2296).

**Note**

You might see fewer than the maximum number of DB connections. This is to avoid potential out-of-memory issues.

### File size limits in Amazon RDS

File size limits apply to certain Amazon RDS DB instances. For more information, see the following engine-specific limits:

- MariaDB file size limits in Amazon RDS (p. 1097)
- MySQL file size limits in Amazon RDS (p. 1484)
- Oracle file size limits in Amazon RDS (p. 1538)

### Parameter Limits for DB Engines

In some instances, the total RAM is 16 GiB, or 17,179,869,184 bytes. In these instances, the variable `DBInstanceClassMemory` automatically subtracts the amounts reserved to the operating system and the RDS processes that manage the instance. The remainder of the subtraction is then divided by 12,582,880. This results in the maximum connections number being around 1,300, depending on instance type, instance size, and DB engine.
Can't connect to Amazon RDS DB instance

When you can't connect to a DB instance, the following are common causes:

- **Inbound rules** – The access rules enforced by your local firewall and the IP addresses authorized to access your DB instance might not match. The problem is most likely the inbound rules in your security group.

  By default, DB instances don't allow access. Access is granted through a security group associated with the VPC that allows traffic into and out of the DB instance. If necessary, add inbound and outbound rules for your particular situation to the security group. You can specify an IP address, a range of IP addresses, or another VPC security group.

  **Note**
  When adding a new inbound rule, you can choose **My IP** for **Source** to allow access to the DB instance from the IP address detected in your browser.

  For more information about setting up security groups, see **Provide access to your DB instance in your VPC by creating a security group** (p. 156).

  **Note**
  Client connections from IP addresses within the range 169.254.0.0/16 aren't permitted. This is the Automatic Private IP Addressing Range (APIPA), which is used for local-link addressing.

- **Public accessibility** – To connect to your DB instance from outside of the VPC, such as by using a client application, the instance must have a public IP address assigned to it.

  To make the instance publicly accessible, modify it and choose **Yes** under **Public accessibility**. For more information, see **Hiding a DB instance in a VPC from the internet** (p. 2257).

- **Port** – The port that you specified when you created the DB instance can't be used to send or receive communications due to your local firewall restrictions. To determine if your network allows the specified port to be used for inbound and outbound communication, check with your network administrator.
• **Availability** – For a newly created DB instance, the DB instance has a status of **creating** until the DB instance is ready to use. When the state changes to **available**, you can connect to the DB instance. Depending on the size of your DB instance, it can take up to 20 minutes before an instance is available.

• **Internet gateway** – For a DB instance to be publicly accessible, the subnets in its DB subnet group must have an internet gateway.

**To configure an internet gateway for a subnet**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**, and then choose the name of the DB instance.
3. In the **Connectivity & security** tab, write down the values of the VPC ID under **VPC** and the subnet ID under **Subnets**.
4. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
5. In the navigation pane, choose **Internet Gateways**. Verify that there is an internet gateway attached to your VPC. Otherwise, choose **Create Internet Gateway** to create an internet gateway. Select the internet gateway, and then choose **Attach to VPC** and follow the directions to attach it to your VPC.
6. In the navigation pane, choose **Subnets**, and then select your subnet.
7. On the **Route Table** tab, verify that there is a route with 0.0.0.0/0 as the destination and the internet gateway for your VPC as the target.

   If you’re connecting to your instance using its IPv6 address, verify that there is a route for all IPv6 traffic (::/0) that points to the internet gateway. Otherwise, do the following:

   a. Choose the ID of the route table (rtb-xxxxxxx) to navigate to the route table.
   b. On the **Routes** tab, choose **Edit routes**. Choose **Add route**, use 0.0.0.0/0 as the destination and the internet gateway as the target.
   c. Choose **Save routes**.

   Also, if you are trying to connect to IPv6 endpoint, make sure that client IPv6 address range is authorized to connect to the DB instance.

   For more information, see **Working with a DB instance in a VPC** (p. 2251).

For engine-specific connection issues, see the following topics:

- Troubleshooting connections to your SQL Server DB instance (p. 1130)
- Troubleshooting connections to your Oracle DB instance (p. 1545)
- Troubleshooting connections to your RDS for PostgreSQL instance (p. 1866)
- Maximum MySQL and MariaDB connections (p. 2295)

**Testing a connection to a DB instance**

You can test your connection to a DB instance using common Linux or Microsoft Windows tools.

From a Linux or Unix terminal, you can test the connection by entering the following. Replace **DB-instance-endpoint** with the endpoint and **port** with the port of your DB instance.
nc -zv DB-instance-endpoint port

For example, the following shows a sample command and the return value.

```
nc -zv postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 8299
Connection to postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 8299 port [tcp/v4/vr-data] succeeded!
```

Windows users can use Telnet to test the connection to a DB instance. Telnet actions aren't supported other than for testing the connection. If a connection is successful, the action returns no message. If a connection isn't successful, you receive an error message such as the following.

```
C:\>telnet sg-postgresql1.c6c8mntfake0.us-west-2.rds.amazonaws.com 819
Connecting To sg-postgresql1.c6c8mntfake0.us-west-2.rds.amazonaws.com...Could not open connection to the host, on port 819: Connect failed
```

If Telnet actions return success, your security group is properly configured.

**Note**

Amazon RDS doesn't accept internet control message protocol (ICMP) traffic, including ping.

**Troubleshooting connection authentication**

In some cases, you can connect to your DB instance but you get authentication errors. In these cases, you might want to reset the master user password for the DB instance. You can do this by modifying the RDS instance.

For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](#).

**Amazon RDS security issues**

To avoid security issues, never use your master AWS user name and password for a user account. Best practice is to use your master AWS account to create users and assign those to DB user accounts. You can also use your master account to create other user accounts, if necessary.

For information about creating IAM users, see [Creating an IAM user in your AWS account](#). For information about creating users in AWS IAM Identity Center (successor to AWS Single Sign-On), see [Manage identities in IAM Identity Center](#).

**Error message "failed to retrieve account attributes, certain console functions may be impaired."**

You can get this error for several reasons. It might be because your account is missing permissions, or your account hasn’t been properly set up. If your account is new, you might not have waited for the account to be ready. If this is an existing account, you might lack permissions in your access policies to perform certain actions such as creating a DB instance. To fix the issue, your administrator needs to provide the necessary roles to your account. For more information, see [the IAM documentation](#).
Resetting the DB instance owner password

If you get locked out of your DB instance, you can log in as the master user. Then you can reset the credentials for other administrative users or roles. If you can't log in as the master user, the AWS account owner can reset the master user password. For details of which administrative accounts or roles you might need to reset, see Master user account privileges (p. 2234).

You can change the DB instance password by using the Amazon RDS console, the AWS CLI command modify-db-instance, or by using the ModifyDBInstance API operation. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 333).

Amazon RDS DB instance outage or reboot

A DB instance outage can occur when a DB instance is rebooted. It can also occur when the DB instance is put into a state that prevents access to it, and when the database is restarted. A reboot can occur when you manually reboot your DB instance. A reboot can also occur when you change a DB instance setting that requires a reboot before it can take effect.

A DB instance reboot occurs when you change a setting that requires a reboot, or when you manually cause a reboot. A reboot can occur immediately if you change a setting and request that the change take effect immediately. Or it can occur during the DB instance's maintenance window.

A DB instance reboot occurs immediately when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0. You then set Apply Immediately to true.
- You change the DB instance class, and Apply Immediately is set to true.
- You change the storage type from Magnetic (Standard) to General Purpose (SSD) or Provisioned IOPS (SSD), or from Provisioned IOPS (SSD) or General Purpose (SSD) to Magnetic (Standard).

A DB instance reboot occurs during the maintenance window when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0, and Apply Immediately is set to false.
- You change the DB instance class, and Apply Immediately is set to false.

When you change a static parameter in a DB parameter group, the change doesn't take effect until the DB instance associated with the parameter group is rebooted. The change requires a manual reboot. The DB instance isn't automatically rebooted during the maintenance window.

To see a table that shows DB instance actions and the effect that setting the Apply Immediately value has, see Modifying an Amazon RDS DB instance (p. 333).

Amazon RDS DB parameter changes not taking effect

In some cases, you might change a parameter in a DB parameter group but don't see the changes take effect. If so, you likely need to reboot the DB instance associated with the DB parameter group.
When you change a dynamic parameter, the change takes effect immediately. When you change a static parameter, the change doesn't take effect until you reboot the DB instance associated with the parameter group.

You can reboot a DB instance using the RDS console. Or you can explicitly call the RebootDBInstance API operation. You can reboot without failover if the DB instance is in a Multi-AZ deployment. The requirement to reboot the associated DB instance after a static parameter change helps mitigate the risk of a parameter misconfiguration affecting an API call. An example of this is calling ModifyDBInstance to change the DB instance class. For more information, see Modifying parameters in a DB parameter group (p. 300).

Amazon RDS DB instance running out of storage

If your DB instance runs out of storage space, it might no longer be available. We highly recommend that you constantly monitor the FreeStorageSpace metric published in CloudWatch to make sure that your DB instance has enough free storage space.

If your database instance runs out of storage, its status changes to storage-full. For example, a call to the DescribeDBInstances API operation for a DB instance that has used up its storage outputs the following.

```
aws rds describe-db-instances --db-instance-identifier mydbinstance

DBINSTANCE  mydbinstance  2009-12-22T23:06:11.915Z  db.m5.large  mysql8.0  50  sa
storage-full  mydbinstance.clla4j4jgyph.us-east-1.rds.amazonaws.com  3306
us-east-1b  3
SECGROUP  default  active
PARAMGRP  default.mysql8.0  in-sync
```

To recover from this scenario, add more storage space to your instance using the ModifyDBInstance API operation or the following AWS CLI command.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance --db-instance-identifier mydbinstance --allocated-storage 60 --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --allocated-storage 60 ^
  --apply-immediately
```

```
DBINSTANCE  mydbinstance  2009-12-22T23:06:11.915Z  db.m5.large  mysql8.0  50  sa
storage-full  mydbinstance.clla4j4jgyph.us-east-1.rds.amazonaws.com  3306
us-east-1b  3  60
SECGROUP  default  active
PARAMGRP  default.mysql8.0  in-sync
```

Now, when you describe your DB instance, you see that your DB instance has modifying status, which indicates the storage is being scaled.
After storage scaling is complete, your DB instance status changes to available.

You can receive notifications when your storage space is exhausted using the DescribeEvents operation. For example, in this scenario, if you make a DescribeEvents call after these operations you see the following output.

You can receive notifications when your storage space is exhausted using the DescribeEvents operation. For example, in this scenario, if you make a DescribeEvents call after these operations you see the following output.

The InsufficientDBInstanceCapacity error can be returned when you try to create, start, or modify a DB instance. It can also be returned when you try to restore a DB instance from a DB snapshot. When this error is returned, a common cause is that the specific DB instance class isn't available in the requested Availability Zone. You can try one of the following to solve the problem:

- Retry the request with a different DB instance class.
- Retry the request with a different Availability Zone.
- Retry the request without specifying an explicit Availability Zone.

For information about troubleshooting instance capacity issues for Amazon EC2, see Insufficient instance capacity in the Amazon EC2 User Guide.

For information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 333).

Freeable memory issues in Amazon RDS

Freeable memory is the total random access memory (RAM) on a DB instance that can be made available to the database engine. It's the sum of the free operating-system (OS) memory and the available buffer
and page cache memory. The database engine uses most of the memory on the host, but OS processes also use some RAM. Memory currently allocated to the database engine or used by OS processes isn't included in freeable memory. When the database engine is running out of memory, the DB instance can use the temporary space that is normally used for buffering and caching. As previously mentioned, this temporary space is included in freeable memory.

You use the `FreeableMemory` metric in Amazon CloudWatch to monitor the freeable memory. For more information, see Overview of monitoring metrics in Amazon RDS (p. 546).

If your DB instance consistently runs low on freeable memory or uses swap space, consider scaling up to a larger DB instance class. For more information, see DB instance classes (p. 10).

You can also change the memory settings. For example, on RDS for MySQL, you might adjust the size of the `innodb_buffer_pool_size` parameter. This parameter is set by default to 75 percent of physical memory. For more MySQL troubleshooting tips, see How can I troubleshoot low freeable memory in an Amazon RDS for MySQL database?

### MySQL and MariaDB issues

You can diagnose and correct issues with MySQL and MariaDB DB instances.

#### Topics
- Maximum MySQL and MariaDB connections (p. 2295)
- Diagnosing and resolving incompatible parameters status for a memory limit (p. 2296)
- Diagnosing and resolving lag between read replicas (p. 2297)
- Diagnosing and resolving a MySQL or MariaDB read replication failure (p. 2298)
- Creating triggers with binary logging enabled requires SUPER privilege (p. 2299)
- Diagnosing and resolving point-in-time restore failures (p. 2300)
- Replication stopped error (p. 2301)
- Read replica create fails or replication breaks with fatal error 1236 (p. 2301)

### Maximum MySQL and MariaDB connections

The maximum number of connections allowed to an RDS for MySQL or RDS for MariaDB DB instance is based on the amount of memory available for its DB instance class. A DB instance class with more memory available results in a larger number of connections available. For more information on DB instance classes, see DB instance classes (p. 10).

The connection limit for a DB instance is set by default to the maximum for the DB instance class. You can limit the number of concurrent connections to any value up to the maximum number of connections allowed. Use the `max_connections` parameter in the parameter group for the DB instance. For more information, see Maximum number of database connections (p. 2287) and Working with parameter groups (p. 295).

You can retrieve the maximum number of connections allowed for a MySQL or MariaDB DB instance by running the following query.

```sql
SELECT @@max_connections;
```

You can retrieve the number of active connections to a MySQL or MariaDB DB instance by running the following query.
Diagnosing and resolving incompatible parameters status for a memory limit

A MariaDB or MySQL DB instance can be placed in incompatible-parameters status for a memory limit when both of the following conditions are met:

- The DB instance is either restarted at least three times in one hour or at least five times in one day, or an attempt to restart the DB instance fails.
- The potential memory usage of the DB instance exceeds 1.2 times the memory allocated to its DB instance class.

When a DB instance is restarted for the third time in one hour or for the fifth time in one day, Amazon RDS for MySQL performs a check for memory usage. The check makes a calculation of the potential memory usage of the DB instance. The value returned by the calculation is the sum of the following values:

- **Value 1** – The sum of the following parameters:
  - innodb_additional_mem_pool_size
  - innodb_buffer_pool_size
  - innodb_log_buffer_size
  - key_buffer_size
  - query_cache_size (MySQL version 5.7 only)
  - tmp_table_size

- **Value 2** – The max_connections parameter multiplied by the sum of the following parameters:
  - binlog_cache_size
  - join_buffer_size
  - read_buffer_size
  - read_rnd_buffer_size
  - sort_buffer_size
  - thread_stack

- **Value 3** – If the performance_schema parameter is enabled, then multiply the max_connections parameter by 257700.
  - If the performance_schema parameter is disabled, then this value is zero.

So, the value returned by the calculation is the following:

Value 1 + Value 2 + Value 3

When this value exceeds 1.2 times the memory allocated to the DB instance class used by the DB instance, the DB instance is placed in incompatible-parameters status. For information about the memory allocated to DB instance classes, see Hardware specifications for DB instance classes (p. 62).

The calculation multiplies the value of the max_connections parameter by the sum of several parameters. If the max_connections parameter is set to a large value, it might cause the check to return an inordinately high value for the potential memory usage of the DB instance. In this case, consider lowering the value of the max_connections parameter.

To resolve the problem, complete the following steps:
1. Adjust the memory parameters in the DB parameter group associated with the DB instance. Do so such that the potential memory usage is lower than 1.2 times the memory allocated to its DB instance class.

   For information about setting parameters, see Modifying parameters in a DB parameter group (p. 300).

2. Restart the DB instance.

   For information about setting parameters, see Starting an Amazon RDS DB instance that was previously stopped (p. 326).

Diagnosing and resolving lag between read replicas

After you create a MySQL or MariaDB read replica and the replica is available, Amazon RDS first replicates the changes made to the source DB instance from the time the read replica create operation started. During this phase, the replication lag time for the read replica is greater than 0. You can monitor this lag time in Amazon CloudWatch by viewing the Amazon RDS ReplicaLag metric.

The ReplicaLag metric reports the value of the Seconds_Behind_Master field of the MariaDB or MySQL SHOW REPLICA STATUS command. For more information, see SHOW REPLICA STATUS. When the ReplicaLag metric reaches 0, the replica has caught up to the source DB instance. If the ReplicaLag metric returns -1, replication might not be active. To troubleshoot a replication error, see Diagnosing and resolving a MySQL or MariaDB read replication failure (p. 2298). A ReplicaLag value of -1 can also mean that the Seconds_Behind_Master value can't be determined or is NULL.

   Note

   Previous versions of MariaDB and MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MariaDB version before 10.5 or a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

The ReplicaLag metric returns -1 during a network outage or when a patch is applied during the maintenance window. In this case, wait for network connectivity to be restored or for the maintenance window to end before you check the ReplicaLag metric again.

The MySQL and MariaDB read replication technology is asynchronous. Thus, you can expect occasional increases for the BinLogDiskUsage metric on the source DB instance and for the ReplicaLag metric on the read replica. For example, consider a situation where a high volume of write operations to the source DB instance occur in parallel. At the same time, write operations to the read replica are serialized using a single I/O thread. Such a situation can lead to a lag between the source instance and read replica.

For more information about read replicas and MySQL, see Replication implementation details in the MySQL documentation. For more information about read replicas and MariaDB, see Replication overview in the MariaDB documentation.

You can reduce the lag between updates to a source DB instance and the subsequent updates to the read replica by doing the following:

- Set the DB instance class of the read replica to have a storage size comparable to that of the source DB instance.
- Make sure that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the max_allowed_packet parameter in the next section.
- Disable the query cache. For tables that are modified often, using the query cache can increase replica lag because the cache is locked and refreshed often. If this is the case, you might see less replica lag if you disable the query cache. You can disable the query cache by setting the query_cache_type parameter to 0 in the DB parameter group for the DB instance. For more information on the query cache, see Query cache configuration.
• Warm the buffer pool on the read replica for InnoDB for MySQL or MariaDB. For example, suppose that you have a small set of tables that are being updated often and you're using the InnoDB or XtraDB table schema. In this case, dump those tables on the read replica. Doing this causes the database engine to scan through the rows of those tables from the disk and then cache them in the buffer pool. This approach can reduce replica lag. The following shows an example.

For Linux, macOS, or Unix:

```
PROMPT> mysqldump \
   -h <endpoint> \
   --port=<port> \
   -u=<username> \
   -p <password> \
   database_name table1 table2 > /dev/null
```

For Windows:

```
PROMPT> mysqldump ^
   -h <endpoint> ^
   --port=<port> ^
   -u=<username> ^
   -p <password> ^
   database_name table1 table2 > /dev/null
```

**Diagnosing and resolving a MySQL or MariaDB read replication failure**

Amazon RDS monitors the replication status of your read replicas. RDS updates the Replication State field of the read replica instance to Error if replication stops for any reason. You can review the details of the associated error thrown by the MySQL or MariaDB engines by viewing the Replication Error field. Events that indicate the status of the read replica are also generated, including RDS-EVENT-0045 (p. 710), RDS-EVENT-0046 (p. 710), and RDS-EVENT-0047 (p. 707). For more information about events and subscribing to events, see Working with Amazon RDS event notification (p. 685). If a MySQL error message is returned, check the error in the MySQL error message documentation. If a MariaDB error message is returned, check the error in the MariaDB error message documentation.

Common situations that can cause replication errors include the following:

• The value for the max_allowed_packet parameter for a read replica is less than the max_allowed_packet parameter for the source DB instance.

The max_allowed_packet parameter is a custom parameter that you can set in a DB parameter group. The max_allowed_packet parameter is used to specify the maximum size of data manipulation language (DML) that can be run on the database. In some cases, the max_allowed_packet value for the source DB instance might be larger than the max_allowed_packet value for the read replica. If so, the replication process can throw an error and stop replication. The most common error is packet bigger than 'max_allowed_packet' bytes. You can fix the error by having the source and read replica use DB parameter groups with the same max_allowed_packet parameter values.

• Writing to tables on a read replica. If you're creating indexes on a read replica, you need to have the read_only parameter set to 0 to create the indexes. If you're writing to tables on the read replica, it can break replication.

• Using a nontransactional storage engine such as MyISAM. Read replicas require a transactional storage engine. Replication is only supported for the following storage engines: InnoDB for MySQL or MariaDB.
Creating triggers with binary logging enabled requires SUPER privilege

When trying to create triggers in an RDS for MySQL or RDS for MariaDB DB instance, you might receive the following error.

"You do not have the SUPER privilege and binary logging is enabled"

To use triggers when binary logging is enabled requires the SUPER privilege, which is restricted for RDS for MySQL and RDS for MariaDB DB instances. You can create triggers when binary logging is enabled without the SUPER privilege by setting the log_bin_trust_function_creators parameter to true. To set the log_bin_trust_function_creators to true, create a new DB parameter group or modify an existing DB parameter group.

You can create a new DB parameter group so you can create triggers in your RDS for MySQL or RDS for MariaDB DB instance with binary logging enabled. To do so, use the following CLI commands. To modify an existing parameter group, start with step 2.

To create a new parameter group to allow triggers with binary logging enabled using the CLI

1. Create a new parameter group.

   For Linux, macOS, or Unix:

   ```bash
   aws rds create-db-parameter-group
       --db-parameter-group-name allow-triggers
       --db-parameter-group-family mysql8.0
   ```
2. Modify the DB parameter group to allow triggers.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group
  --db-parameter-group-name allow-triggers
  --parameters "ParameterName=log_bin_trust_functionCreators, ParameterValue=true, ApplyMethod=pending-reboot"
```

For Windows:

```
aws rds modify-db-parameter-group
  --db-parameter-group-name allow-triggers
  --parameters "ParameterName=log_bin_trust_functionCreators, ParameterValue=true, ApplyMethod=pending-reboot"
```

3. Modify your DB instance to use the new DB parameter group.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance
  --db-instance-identifier mydbinstance
  --db-parameter-group-name allow-triggers
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance
  --db-instance-identifier mydbinstance
  --db-parameter-group-name allow-triggers
  --apply-immediately
```

4. For the changes to take effect, manually reboot the DB instance.

```
aws rds reboot-db-instance --db-instance-identifier mydbinstance
```

Diagnosing and resolving point-in-time restore failures

Restoring a DB Instance That Includes Temporary Tables

When attempting a point-in-time restore (PITR) of your MySQL or MariaDB DB instance, you might encounter the following error.

```
Database instance could not be restored because there has been incompatible database activity for restore
```
Common examples of incompatible activity include using temporary tables, in-memory tables, or using MyISAM tables. In this case, use of Temporary table was detected.

PITR relies on both backup snapshots and binary logs (binlogs) from MySQL or MariaDB to restore your DB instance to a particular time. Temporary table information can be unreliable in binlogs and can cause a PITR failure. If you use temporary tables in your MySQL or MariaDB DB instance, you can lower the possibility of a PITR failure. To do so, perform more frequent backups. A PITR failure is most probable in the time between a temporary table's creation and the next backup snapshot.

Restoring a DB Instance That Includes In-Memory Tables

You might encounter a problem when restoring a database that has in-memory tables. In-memory tables are purged during a restart. As a result, your in-memory tables might be empty after a reboot. We recommend that when you use in-memory tables, you architect your solution to handle empty tables in the event of a restart. If you're using in-memory tables with replicated DB instances, you might need to recreate the read replicas after a restart. This might be necessary if a read replica reboots and can't restore data from an empty in-memory table.

For more information about backups and PITR, see Working with backups (p. 462) and Restoring a DB instance to a specified time (p. 534).

Replication stopped error

When you call the `mysql.rds_skip_repl_error` command, you might receive an error message stating that replication is down or disabled.

This error message appears because replication is stopped and can't be restarted.

If you need to skip a large number of errors, the replication lag can increase beyond the default retention period for binary log files. In this case, you might encounter a fatal error due to binary log files being purged before they have been replayed on the replica. This purge causes replication to stop, and you can no longer call the `mysql.rds_skip_repl_error` command to skip replication errors.

You can mitigate this issue by increasing the number of hours that binary log files are retained on your replication source. After you have increased the binlog retention time, you can restart replication and call the `mysql.rds_skip_repl_error` command as needed.

To set the binlog retention time, use the `mysql.rds_set_configuration` procedure. Specify a configuration parameter of 'binlog retention hours' along with the number of hours to retain binlog files on the DB cluster, up to 720 (30 days). The following example sets the retention period for binlog files to 48 hours.

```sql
CALL mysql.rds_set_configuration('binlog retention hours', 48);
```

Read replica create fails or replication breaks with fatal error 1236

After changing default parameter values for a MySQL or MariaDB DB instance, you might encounter one of the following problems:

- You can't create a read replica for the DB instance.
- Replication fails with fatal error 1236.

Some default parameter values for MySQL and MariaDB DB instances help to make sure that the database is ACID compliant and read replicas are crash-safe. They do this by making sure that each
commit is fully synchronized by writing the transaction to the binary log before it's committed. Changing these parameters from their default values to improve performance can cause replication to fail when a transaction hasn't been written to the binary log.

To resolve this issue, set the following parameter values:

- `sync_binlog = 1`
- `innodb_support_xa = 1`
- `innodb_flush_log_at_trx_commit = 1`

## Can't set backup retention period to 0

There are several reasons why you might need to set the backup retention period to 0. For example, you can disable automatic backups immediately by setting the retention period to 0.

In some cases, you might set the value to 0 and receive a message saying that the retention period must be between 1 and 35. In these cases, check to make sure that you haven't set up a read replica for the instance. Read replicas require backups for managing read replica logs, and therefore you can't set a retention period of 0.
Amazon RDS API reference

In addition to the AWS Management Console and the AWS Command Line Interface (AWS CLI), Amazon RDS also provides an API. You can use the API to automate tasks for managing your DB instances and other objects in Amazon RDS.

- For an alphabetical list of API operations, see Actions.
- For an alphabetical list of data types, see Data types.
- For a list of common query parameters, see Common parameters.
- For descriptions of the error codes, see Common errors.

For more information about the AWS CLI, see AWS Command Line Interface reference for Amazon RDS.

Topics
- Using the Query API (p. 2303)
- Troubleshooting applications on Amazon RDS (p. 2303)

Using the Query API

The following sections briefly discuss the parameters and request authentication used with the Query API.

For general information about how the Query API works, see Query requests in the Amazon EC2 API Reference.

Query parameters

HTTP Query-based requests are HTTP requests that use the HTTP verb GET or POST and a Query parameter named Action.

Each Query request must include some common parameters to handle authentication and selection of an action.

Some operations take lists of parameters. These lists are specified using the \texttt{param} \texttt{n} notation. Values of \texttt{n} are integers starting from 1.

For information about Amazon RDS Regions and endpoints, go to Amazon Relational Database Service (RDS) in the Regions and Endpoints section of the Amazon Web Services General Reference.

Query request authentication

You can only send Query requests over HTTPS, and you must include a signature in every Query request. You must use either AWS signature version 4 or signature version 2. For more information, see Signature Version 4 signing process and Signature version 2 signing process.

Troubleshooting applications on Amazon RDS

Amazon RDS provides specific and descriptive errors to help you troubleshoot problems while interacting with the Amazon RDS API.
Retrieving errors

Typically, you want your application to check whether a request generated an error before you spend any time processing results. The easiest way to find out if an error occurred is to look for an Error node in the response from the Amazon RDS API.

XPath syntax provides a simple way to search for the presence of an Error node. It also provides a relatively easy way to retrieve the error code and message. The following code snippet uses Perl and the XML::XPath module to determine if an error occurred during a request. If an error occurred, the code prints the first error code and message in the response.

```perl
use XML::XPath;
my $xp = XML::XPath->new(xml =>$response);
if ( $xp->find("//Error") ) {
    print "There was an error processing your request:
    Error code: ",
    $xp->findvalue("//Error[1]/Code"), "\n", "",
    $xp->findvalue("//Error[1]/Message"), "\n\n"; }
```

Troubleshooting tips

We recommend the following processes to diagnose and resolve problems with the Amazon RDS API:

- Verify that Amazon RDS is operating normally in the AWS Region that you're targeting by checking [http://status.aws.amazon.com](http://status.aws.amazon.com).
- Check the structure of your request.

  Each Amazon RDS operation has a reference page in the *Amazon RDS API Reference*. Double-check that you are using parameters correctly. For ideas about what might be wrong, look at the sample requests or user scenarios to see if those examples do similar operations.

- Check AWS re:Post.

  Amazon RDS has a development community where you can search for solutions to problems others have experienced along the way. To view the topics, go to [AWS re:Post](http://aws.amazon.com/repost).
Document history

Current API version: 2014-10-31

The following table describes important changes in each release of the Amazon RDS User Guide after May 2018. For notification about updates to this documentation, you can subscribe to an RSS feed.

**Note**
You can filter new Amazon RDS features on the What's New with Database? page. For Products, choose Amazon RDS. Then search using keywords such as RDS Proxy or Oracle 2022.

<td>January 17, 2018</td>
</tr>
<tr>
<td>Multi-AZ support for read replicas</td>
<td>You can now create a read replica as a Multi-AZ DB instance. Amazon RDS creates a standby of your replica in another Availability Zone for failover support for the replica. Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance. For more information, see Working with read replicas (p. 382).</td>
<td>January 11, 2018</td>
</tr>
<tr>
<td>Amazon RDS for MariaDB supports a new major version</td>
<td>You can now create Amazon RDS DB instances running MariaDB version 10.2. For more information, see MariaDB 10.2 support on Amazon RDS (p. 1019).</td>
<td>January 3, 2018</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>--------------</td>
</tr>
<tr>
<td>Amazon Aurora PostgreSQL-Compatible Edition available in new AWS Region</td>
<td>Aurora PostgreSQL is now available in the EU (Paris) region. For the complete list of AWS Regions for Aurora PostgreSQL, see <a href="#">Availability for Amazon Aurora PostgreSQL</a>.</td>
<td>December 22, 2017</td>
</tr>
<tr>
<td>Aurora PostgreSQL supports new instance types</td>
<td>Aurora PostgreSQL now supports new instance types. For the complete list of instance types, see <a href="#">Choosing the DB instance class</a>.</td>
<td>December 20, 2017</td>
</tr>
<tr>
<td>Amazon Aurora MySQL-Compatible Edition available in new AWS Region</td>
<td>Aurora MySQL is now available in the EU (Paris) region. For the complete list of AWS Regions for Aurora MySQL, see <a href="#">Availability for Amazon Aurora MySQL</a>.</td>
<td>December 18, 2017</td>
</tr>
<tr>
<td>Aurora MySQL supports hash joins</td>
<td>This feature can improve query performance when you need to join a large amount of data by using an equijoin. For more information, see <a href="#">Working with hash joins in Aurora MySQL</a>.</td>
<td>December 11, 2017</td>
</tr>
<tr>
<td>Aurora MySQL supports native functions to invoke AWS Lambda functions</td>
<td>You can call the native functions <code>lambda_sync</code> and <code>lambda_async</code> when you use Aurora MySQL. For more information, see <a href="#">Invoking a Lambda function from an Amazon Aurora MySQL DB cluster</a>.</td>
<td>December 11, 2017</td>
</tr>
<tr>
<td>Added Aurora PostgreSQL HIPAA eligibility</td>
<td>Aurora PostgreSQL now supports building HIPAA compliant applications. For more information, see <a href="#">Working with Amazon Aurora PostgreSQL</a>.</td>
<td>December 6, 2017</td>
</tr>
<tr>
<td>Additional AWS Regions available for Amazon Aurora with PostgreSQL compatibility</td>
<td>Amazon Aurora with PostgreSQL compatibility is now available in four new AWS Regions. For more information, see <a href="#">Availability for Amazon Aurora PostgreSQL</a>.</td>
<td>November 22, 2017</td>
</tr>
<tr>
<td>Modify storage for Amazon RDS DB instances running Microsoft SQL Server</td>
<td>You can now modify the storage of your Amazon RDS DB instances running SQL Server. For more information, see <a href="#">Modifying an Amazon RDS DB instance</a> (p. 333).</td>
<td>November 21, 2017</td>
</tr>
<tr>
<td>Amazon RDS supports 16 TiB storage for Linux-based engines</td>
<td>You can now create MySQL, MariaDB, PostgreSQL, and Oracle RDS DB instances with up to 16 TiB of storage. For more information, see <a href="#">Amazon RDS DB instance storage</a> (p. 71).</td>
<td>November 21, 2017</td>
</tr>
<tr>
<td>Amazon RDS supports fast scale up of storage</td>
<td>You can now add storage to MySQL, MariaDB, PostgreSQL, and Oracle RDS DB instances in a few minutes. For more information, see <a href="#">Amazon RDS DB instance storage</a> (p. 71).</td>
<td>November 21, 2017</td>
</tr>
<tr>
<td>Amazon RDS supports MariaDB versions 10.1.26 and 10.0.32</td>
<td>You can now create Amazon RDS DB instances running MariaDB versions 10.1.26 and 10.0.32. For more information, see <a href="#">MariaDB on Amazon RDS versions</a> (p. 1023).</td>
<td>November 20, 2017</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>--------------</td>
</tr>
<tr>
<td>Amazon RDS for Microsoft SQL Server now supports new DB instance classes</td>
<td>You can now create Amazon RDS DB instances running SQL Server that use the db.r4 and db.m4.16xlarge DB instance classes. For more information, see [DB instance class support for Microsoft SQL Server](p. 1103).</td>
<td>November 20, 2017</td>
</tr>
<tr>
<td>Amazon RDS for MySQL and MariaDB now supports new DB instance classes</td>
<td>You can now create Amazon RDS DB instances running MySQL and MariaDB that use the db.r4, db.m4.16xlarge, db.t2.xlarge, and db.t2.2xlarge DB instance classes. For more information, see [DB instance classes](p. 10).</td>
<td>November 20, 2017</td>
</tr>
<tr>
<td>SQL Server 2017</td>
<td>You can now create Amazon RDS DB instances running Microsoft SQL Server 2017. You can also create DB instances running SQL Server 2016 SP1 CU5. For more information, see [Amazon RDS for Microsoft SQL Server](p. 1099).</td>
<td>November 17, 2017</td>
</tr>
<tr>
<td>Restore MySQL backups from Amazon S3</td>
<td>You can now create a backup of your on-premises database, store it on Amazon S3, and then restore the backup file onto a new Amazon RDS DB instance running MySQL. For more information, see [Restoring a backup into a MySQL DB instance](p. 1408).</td>
<td>November 17, 2017</td>
</tr>
<tr>
<td>Auto Scaling with Aurora Replicas</td>
<td>Amazon Aurora MySQL now supports Aurora Auto Scaling. Aurora Auto Scaling dynamically adjusts the number of Aurora Replicas based on increases or decreases in connectivity or workload. For more information, see [Using Amazon Aurora Auto Scaling with Aurora replicas](p. 17).</td>
<td>November 17, 2017</td>
</tr>
<tr>
<td>Oracle default edition support</td>
<td>Amazon RDS for Oracle DB instances now supports setting the default edition for the DB instance. For more information, see [Setting the default edition for a DB instance](p. 1605).</td>
<td>November 3, 2017</td>
</tr>
<tr>
<td>Oracle DB instance file validation</td>
<td>Amazon RDS for Oracle DB instances now supports validating DB instance files with the Oracle Recovery Manager (RMAN) logical validation utility. For more information, see [Validating DB instance files](p. 1623).</td>
<td>November 3, 2017</td>
</tr>
<tr>
<td>Management Agent for OEM 13c</td>
<td>Amazon RDS for Oracle DB instances now support the Management Agent for Oracle Enterprise Manager (OEM) Cloud Control 13c. For more information, see [Oracle Management Agent for Enterprise Manager Cloud Control](p. 1745).</td>
<td>November 1, 2017</td>
</tr>
<tr>
<td>Storage reconfiguration for Microsoft SQL Server snapshots</td>
<td>You can now reconfigure the storage when you restore a snapshot to an Amazon RDS DB instance running Microsoft SQL Server. For more information, see [Restoring from a DB snapshot](p. 487).</td>
<td>October 26, 2017</td>
</tr>
<tr>
<td>Asynchronous key prefetch for Aurora MySQL-Compatible Edition</td>
<td>Asynchronous key prefetch (AKP) improves the performance of noncached index joins, by prefetching keys in memory ahead of when they are needed. For more information, see [Working with asynchronous key prefetch in Amazon Aurora](p. 17).</td>
<td>October 26, 2017</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>--------------</td>
</tr>
<tr>
<td>MySQL 5.7.19, 5.6.37, and 5.5.57</td>
<td>You can now create Amazon RDS DB instances running MySQL versions 5.7.19, 5.6.37, and 5.5.57. For more information, see MySQL on Amazon RDS versions (p. 1356).</td>
<td>October 25, 2017</td>
</tr>
<tr>
<td>General availability of Amazon Aurora with PostgreSQL compatibility</td>
<td>Amazon Aurora with PostgreSQL compatibility makes it simple and cost-effective to set up, operate, and scale your new and existing PostgreSQL deployments, thus freeing you to focus on your business and applications. For more information, see Working with Amazon Aurora PostgreSQL.</td>
<td>October 24, 2017</td>
</tr>
<tr>
<td>Amazon RDS for Oracle DB instances support new DB instance classes</td>
<td>Amazon RDS for Oracle DB instances now support memory optimized next generation (db.r4) instance classes. Amazon RDS for Oracle DB instances also now support the following new current generation instance classes: db.m4.16xlarge, db.t2.xlarge, and db.t2.2xlarge. For more information, see DB instance classes (p. 10) and RDS for Oracle instance classes (p. 1529).</td>
<td>October 23, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Your new and existing ReservedInstances can now cover multiple sizes in the same DB instance class. Size-flexible reserved instances are available for DB instances with the same AWS Region, database engine, and instance family, and across AZ configuration. Size-flexible reserved instances are available for the following database engines: Amazon Aurora, MariaDB, MySQL, Oracle (Bring Your Own License), PostgreSQL. For more information, see Size-flexible reserved DB instances (p. 146).</td>
<td>October 11, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use the Oracle SQLT option to tune a SQL statement for optimal performance. For more information, see Oracle SQLT (p. 1785).</td>
<td>September 22, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>If you have existing manual DB snapshots of your Amazon RDS for Oracle DB instances, you can now upgrade them to a later version of the Oracle database engine. For more information, see Upgrading an Oracle DB snapshot (p. 1816).</td>
<td>September 20, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use Oracle Spatial to store, retrieve, update, and query spatial data in your Amazon RDS DB instances running Oracle. For more information, see Oracle Spatial (p. 1782).</td>
<td>September 15, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use Oracle Locator to support internet and wireless service-based applications and partner-based GIS solutions with your Amazon RDS DB instances running Oracle. For more information, see Oracle Locator (p. 1758).</td>
<td>September 15, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use Oracle Multimedia to store, manage, and retrieve images, audio, video, and other heterogeneous media data in your Amazon RDS DB instances running Oracle. For more information, see Oracle Multimedia (p. 1761).</td>
<td>September 15, 2017</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now export audit logs from your Amazon Aurora MySQL DB clusters to Amazon CloudWatch Logs. For more information, see Publishing Aurora MySQL logs to Amazon CloudWatch Logs.</td>
<td>September 14, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports multiple versions of Oracle Application Express (APEX) for your DB instances running Oracle. For more information, see Oracle Application Express (APEX) (p. 1716).</td>
<td>September 13, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use Amazon Aurora to migrate an unencrypted or encrypted DB snapshot or MySQL DB instance to an encrypted Aurora MySQL DB cluster. For more information, see Migrating an RDS for MySQL snapshot to Aurora and Migrating data from a MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica.</td>
<td>September 5, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can use Amazon RDS for Microsoft SQL Server databases to build HIPAA-compliant applications. For more information, see Compliance program support for Microsoft SQL Server DB instances (p. 1106).</td>
<td>August 31, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use Amazon RDS for MariaDB databases to build HIPAA-compliant applications. For more information, see Amazon RDS for MariaDB (p. 1015).</td>
<td>August 31, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now create Amazon RDS DB instances running Microsoft SQL Server with allocated storage up to 16 TiB, and Provisioned IOPS to storage ranges of 1:1–50:1. For more information, see Amazon RDS DB instance storage (p. 71).</td>
<td>August 22, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use Multi-AZ deployments for DB instances running Microsoft SQL Server in the EU (Frankfurt) region. For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server (p. 1170).</td>
<td>August 3, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now create Amazon RDS DB instances running MariaDB versions 10.1.23 and 10.0.31. For more information, see MariaDB on Amazon RDS versions (p. 1023).</td>
<td>July 17, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports Microsoft SQL Server Enterprise Edition with the License Included model in all AWS Regions. For more information, see Licensing Microsoft SQL Server on Amazon RDS (p. 1124).</td>
<td>July 13, 2017</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>----------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS for Oracle now supports Linux kernel huge pages for increased database scalability. The use of huge pages results in smaller page tables and less CPU time spent on memory management, increasing the performance of large database instances. You can use huge pages with your Amazon RDS DB instances running all editions of Oracle versions 12.1.0.2 and 11.2.0.4. For more information, see Turning on HugePages for an RDS for Oracle instance (p. 1662).</td>
<td>July 7, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support encryption at rest (EAR) for db.t2.small and db.t2.medium DB instance classes for all non-Aurora DB engines. For more information, see Availability of Amazon RDS encryption (p. 2150).</td>
<td>June 27, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Amazon Aurora in the Europe (Frankfurt) region. For more information, see Availability for Amazon Aurora MySQL.</td>
<td>June 16, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now specify an option group when you copy a DB snapshot across AWS regions. For more information, see Option group considerations (p. 498).</td>
<td>June 12, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now copy DB snapshots created from specialized DB instances across AWS regions. You can copy snapshots from DB instances that use Oracle TDE, Microsoft SQL Server TDE, and Microsoft SQL Server Multi-AZ with Mirroring. For more information, see Copying a DB snapshot (p. 499).</td>
<td>June 12, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon Aurora now allows you to quickly and cost-effectively copy all of your databases in an Amazon Aurora DB cluster. For more information, see Cloning databases in an Aurora DB cluster.</td>
<td>June 12, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports Microsoft SQL Server 2016 SP1 CU2. For more information, see Amazon RDS for Microsoft SQL Server (p. 1099).</td>
<td>June 7, 2017</td>
</tr>
<tr>
<td>Preview</td>
<td>Public preview of Amazon Aurora with PostgreSQL Compatibility. For more information, see Working with Amazon Aurora PostgreSQL.</td>
<td>April 19, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon Aurora now allows you to run an ALTER TABLE tbl_name ADD COLUMN col_name column_definition operation nearly instantaneously. The operation completes without requiring the table to be copied and without materially impacting other DML statements. For more information, see Altering tables in Amazon Aurora using fast DDL.</td>
<td>April 5, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>We have added a new monitoring command, SHOW VOLUME STATUS, to display the number of nodes and disks in a volume. For more information, see Displaying volume status for an Aurora DB cluster.</td>
<td>April 5, 2017</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------------</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use your own custom logic in your custom password verification functions for Oracle on Amazon RDS. For more information, see [Creating custom functions to verify passwords](p. 1588).</td>
<td>March 21, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now access your online and archived redo log files on your Oracle DB instances on Amazon RDS. For more information, see [Accessing online and archived redo logs](p. 1618).</td>
<td>March 21, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now copy both encrypted and unencrypted DB cluster snapshots between accounts in the same region. For more information, see [Copying a DB cluster snapshot across accounts](p. 1618).</td>
<td>March 7, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now share encrypted DB cluster snapshots between accounts in the same region. For more information, see [Sharing a DB cluster snapshot](p. 1618).</td>
<td>March 7, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now replicate encrypted Amazon Aurora MySQL DB clusters to create cross-region Aurora Replicas. For more information, see [Replicating Aurora MySQL DB clusters across AWS Regions](p. 1618).</td>
<td>March 7, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now require that all connections to your DB instance running Microsoft SQL Server use Secure Sockets Layer (SSL). For more information, see [Using SSL with a Microsoft SQL Server DB instance](p. 1176).</td>
<td>February 27, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now set your local time zone to one of 15 additional time zones. For more information, see [Supported time zones](p. 1116).</td>
<td>February 27, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use the Amazon RDS procedure <code>msdb.dbo.rds_shrink_tempdbfile</code> to shrink the tempdb database on your DB instances running Microsoft SQL Server. For more information, see [Shrinking the tempdb database](p. 1333).</td>
<td>February 17, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now compress your backup file when you export your Enterprise and Standard Edition Microsoft SQL Server database from an Amazon RDS DB instance to Amazon S3. For more information, see [Compressing backup files](p. 1156).</td>
<td>February 17, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports custom DNS servers to resolve DNS names used in outbound network access on your DB instances running Oracle. For more information, see [Setting up a custom DNS server](p. 1591).</td>
<td>January 26, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports creating an encrypted read replica in another region. For more information, see [Creating a read replica in a different AWS Region](p. 395) and [CreateDBInstanceReadReplica](p. 395).</td>
<td>January 23, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports upgrading a MySQL DB snapshot from MySQL 5.1 to MySQL 5.5.</td>
<td>January 20, 2017</td>
</tr>
</tbody>
</table>
### Earlier updates

<table>
<thead>
<tr>
<th>Change</th>
<th>Description</th>
<th>Date changed</th>
</tr>
</thead>
<tbody>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports copying an encrypted DB snapshot to another region for the MariaDB, MySQL, Oracle, PostgreSQL, and Microsoft SQL Server database engines. For more information, see Copying a DB snapshot (p. 499) and CopyDBSnapshot.</td>
<td>December 20, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon Aurora MySQL now supports spatial indexing. Spatial indexing improves query performance on large datasets for queries that use spatial data. For more information, see Amazon Aurora MySQL and spatial data.</td>
<td>December 14, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports outbound network access on your DB instances running Oracle. You can use utl_http, utl_tcp, and utl_smtp to connect from your DB instance to the network. For more information, see Configuring UTL_HTTP access using certificates and an Oracle wallet (p. 1565).</td>
<td>December 5, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS has retired support for MySQL version 5.1. However, you can restore existing MySQL 5.1 snapshots to a MySQL 5.5 instance. For more information, see Supported storage engines for RDS for MySQL (p. 1353).</td>
<td>November 15, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports Microsoft SQL Server 2016 RTM CU2. For more information, see Amazon RDS for Microsoft SQL Server (p. 1099).</td>
<td>November 4, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports major version upgrades for DB instances running Oracle. You can now upgrade your Oracle DB instances from 11g to 12c. For more information, see Upgrading the RDS for Oracle DB engine (p. 1809).</td>
<td>November 2, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now create DB instances running Microsoft SQL Server 2014 Enterprise Edition. Amazon RDS now supports SQL Server 2014 SP2 for all editions and all regions. For more information, see Amazon RDS for Microsoft SQL Server (p. 1099).</td>
<td>October 25, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon Aurora MySQL now integrates with other AWS services: You can load text or XML data into a table from an Amazon S3 bucket, or invoke an AWS Lambda function from database code. For more information, see Integrating Aurora MySQL with other AWS services.</td>
<td>October 18, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now access the tempdb database on your Amazon RDS DB instances running Microsoft SQL Server. You can access the tempdb database by using Transact-SQL through Microsoft SQL Server Management Studio (SSMS), or any other standard SQL client application. For more information, see Accessing the tempdb database on Microsoft SQL Server DB instances on Amazon RDS (p. 1333).</td>
<td>September 29, 2016</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use the UTL_MAIL package with your Amazon RDS DB instances running Oracle. For more information, see Oracle UTL_MAIL (p. 1805).</td>
<td>September 20, 2016</td>
</tr>
<tr>
<td>New features</td>
<td>You can now set the time zone of your new Microsoft SQL Server DB instances to a local time zone, to match the time zone of your applications. For more information, see Local time zone for Microsoft SQL Server DB instances (p. 1115).</td>
<td>September 19, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use the Oracle Label Security option to control access to individual table rows in your Amazon RDS DB instances running Oracle Database 12c. With Oracle Label Security, you can enforce regulatory compliance with a policy-based administration model, and ensure that an access to sensitive data is restricted to only users with the appropriate clearance level. For more information, see Oracle Label Security (p. 1755).</td>
<td>September 8, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now connect to an Amazon Aurora DB cluster using the reader endpoint, which load-balances connections across the Aurora Replicas that are available in the DB cluster. As clients request new connections to the reader endpoint, Aurora distributes the connection requests among the Aurora Replicas in the DB cluster. This functionality can help balance your read workload across multiple Aurora Replicas in your DB cluster. For more information, see Amazon Aurora endpoints.</td>
<td>September 8, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now support the Oracle Enterprise Manager Cloud Control on your Amazon RDS DB instances running Oracle. You can enable the Management Agent on your DB instances, and share data with your Oracle Management Service (OMS). For more information, see Oracle Management Agent for Enterprise Manager Cloud Control (p. 1745).</td>
<td>September 1, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>This release adds support to get an ARN for a resource. For more information, see Getting an existing ARN (p. 418).</td>
<td>August 23, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now assign up to 50 tags for each Amazon RDS resource, for managing your resources and tracking costs. For more information, see Tagging Amazon RDS resources (p. 404).</td>
<td>August 19, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports the License Included model for Oracle Standard Edition Two. For more information, see Creating an Amazon RDS DB instance (p. 236).</td>
<td>August 5, 2016</td>
</tr>
<tr>
<td></td>
<td>You can now change the license model of your Amazon RDS DB instances running Microsoft SQL Server and Oracle. For more information, see Licensing Microsoft SQL Server on Amazon RDS (p. 1124) and RDS for Oracle licensing options (p. 1526).</td>
<td></td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports native backup and restore for Microsoft SQL Server databases using full backup files (.bak files). You can now easily migrate SQL Server databases to Amazon RDS, and import and export databases in a single, easily-portable file, using Amazon S3 for storage, and AWS KMS for encryption. For more information, see Importing and exporting SQL Server databases using native backup and restore (p. 1140).</td>
<td>July 27, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now copy the source files from a MySQL database to an Amazon Simple Storage Service (Amazon S3) bucket, and then restore an Amazon Aurora DB cluster from those files. This option can be considerably faster than migrating data using mysqldump. For more information, see Migrating data from an external MySQL database to an Aurora MySQL DB cluster.</td>
<td>July 20, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now restore an unencrypted Amazon Aurora DB cluster snapshot to create an encrypted Amazon Aurora DB cluster by including an AWS Key Management Service (AWS KMS) encryption key during the restore operation. For more information, see Encrypting Amazon RDS resources.</td>
<td>June 30, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use the Oracle Repository Creation Utility (RCU) to create a repository on Amazon RDS for Oracle. For more information, see Using the Oracle Repository Creation Utility on RDS for Oracle (p. 1838).</td>
<td>June 17, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Adds support for PostgreSQL cross-region read replicas. For more information, see Creating a read replica in a different AWS Region (p. 395).</td>
<td>June 16, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use the AWS Management Console to easily add Multi-AZ with Mirroring to a Microsoft SQL Server DB instance. For more information, see Adding Multi-AZ to a Microsoft SQL Server DB instance (p. 1171).</td>
<td>June 9, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use Multi-AZ Deployments Using SQL Server Mirroring in the following additional regions: Asia Pacific (Sydney), Asia Pacific (Tokyo), and South America (São Paulo). For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server (p. 1170).</td>
<td>June 9, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support MariaDB version 10.1. For more information, see Amazon RDS for MariaDB (p. 1015).</td>
<td>June 1, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Amazon Aurora cross-region DB clusters that are read replicas. For more information, see Replicating Aurora MySQL DB clusters across AWS Regions.</td>
<td>June 1, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Enhanced Monitoring is now available for Oracle DB instances. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 635) and Modifying an Amazon RDS DB instance (p. 333).</td>
<td>May 27, 2016</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>

<tr>
<td>New feature</td>
<td>Updated to support manual snapshot sharing for Amazon Aurora DB cluster snapshots. For more information, see <a href="#">Sharing a DB cluster snapshot</a>.</td>
<td>May 18, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use the MariaDB Audit Plugin to log database activity on MariaDB and MySQL database instances. For more information, see <a href="#">Options for MariaDB database engine</a> and <a href="#">Options for MySQL DB instances</a>.</td>
<td>April 27, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>In-place, major version upgrades are now available for upgrading from MySQL version 5.6 to version 5.7. For more information, see <a href="#">Upgrading the MySQL DB engine</a>.</td>
<td>April 26, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Enhanced Monitoring is now available for Microsoft SQL Server DB instances. For more information, see <a href="#">Monitoring OS metrics with Enhanced Monitoring</a>.</td>
<td>April 22, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to provide an Amazon Aurora Clusters view in the Amazon RDS console. For more information, see <a href="#">Viewing an Aurora DB cluster</a>.</td>
<td>April 1, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support SQL Server Multi-AZ with mirroring in the Asia Pacific (Seoul) region. For more information, see <a href="#">Multi-AZ deployments for Amazon RDS for Microsoft SQL Server</a>.</td>
<td>March 31, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Amazon Aurora Multi-AZ with mirroring in the Asia Pacific (Seoul) region. For more information, see <a href="#">Availability for Amazon Aurora MySQL</a>.</td>
<td>March 31, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>PostgreSQL DB instances have the ability to require connections to use SSL. For more information, see <a href="#">Using SSL with a PostgreSQL DB instance</a>.</td>
<td>March 25, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Enhanced Monitoring is now available for PostgreSQL DB instances. For more information, see <a href="#">Monitoring OS metrics with Enhanced Monitoring</a>.</td>
<td>March 25, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Microsoft SQL Server DB instances can now use Windows Authentication for user authentication. For more information, see <a href="#">Using Windows Authentication with an Amazon RDS for SQL Server DB instance</a>.</td>
<td>March 23, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Enhanced Monitoring is now available in the Asia Pacific (Seoul) region. For more information, see <a href="#">Monitoring OS metrics with Enhanced Monitoring</a>.</td>
<td>March 16, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now customize the order in which Aurora Replicas are promoted to primary instance during a failover. For more information, see <a href="#">Fault tolerance for an Aurora DB cluster</a>.</td>
<td>March 14, 2016</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support encryption when migrating to an Aurora DB cluster. For more information, see <a href="#">Migrating data to an Aurora DB cluster</a>.</td>
<td>March 2, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support local time zone for Aurora DB clusters. For more information, see <a href="#">Local time zone for Aurora DB clusters</a>.</td>
<td>March 1, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to add support for MySQL version 5.7 for current generation Amazon RDS DB instance classes.</td>
<td>February 22, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support <code>db.r3</code> and <code>db.t2</code> DB instance classes in the AWS GovCloud (US-West) region.</td>
<td>February 11, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support encrypting copies of DB snapshots and sharing encrypted DB snapshots. For more information, see <a href="#">Copying a DB snapshot</a> and <a href="#">Sharing a DB snapshot</a>.</td>
<td>February 11, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Amazon Aurora in the Asia Pacific (Sydney) region. For more information, see <a href="#">Availability for Amazon Aurora MySQL</a>.</td>
<td>February 11, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support SSL for Oracle DB Instances. For more information, see <a href="#">Using SSL with an RDS for Oracle DB instance</a>.</td>
<td>February 9, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support local time zone for MySQL and MariaDB DB instances. For more information, see <a href="#">Local time zone for MySQL DB instances</a> and <a href="#">Local time zone for MariaDB DB instances</a>.</td>
<td>December 21, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Enhanced Monitoring of OS metrics for MySQL and MariaDB instances and Aurora DB clusters. For more information, see <a href="#">Viewing metrics in the Amazon RDS console</a>.</td>
<td>December 18, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support <code>db.t2</code>, <code>db.r3</code>, and <code>db.m4</code> DB instance classes for MySQL version 5.5. For more information, see <a href="#">DB instance classes</a>.</td>
<td>December 4, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support modifying the database port for an existing DB instance.</td>
<td>December 3, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support major version upgrades of the database engine for PostgreSQL instances. For more information, see <a href="#">Upgrading the PostgreSQL DB engine for Amazon RDS</a>.</td>
<td>November 19, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support modifying the public accessibility of an existing DB instance. Updated to support <code>db.m4</code> standard DB instance classes.</td>
<td>November 11, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support manual DB snapshot sharing. For more information, see <a href="#">Sharing a DB snapshot</a>.</td>
<td>October 28, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Microsoft SQL Server 2014 for the Web, Express, and Standard editions.</td>
<td>October 26, 2015</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support the MySQL-based MariaDB database engine. For more information, see <a href="#">Amazon RDS for MariaDB</a> (p. 1015).</td>
<td>October 7, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Amazon Aurora in the Asia Pacific (Tokyo) region. For more information, see <a href="#">Availability for Amazon Aurora MySQL</a>.</td>
<td>October 7, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support db.t2 burst-capable DB instance classes for all DB engines and the addition of the db.t2.large DB instance class. For more information, see <a href="#">DB instance classes</a> (p. 10).</td>
<td>September 25, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Oracle DB instances on R3 and T2 DB instance classes. For more information, see <a href="#">DB instance classes</a> (p. 10).</td>
<td>August 5, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Microsoft SQL Server Enterprise Edition is now available with the License Included service model. For more information, see <a href="#">Licensing Microsoft SQL Server on Amazon RDS</a> (p. 1124).</td>
<td>July 29, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon Aurora has officially released. The Amazon Aurora DB engine supports multiple DB instances in a DB cluster. For detailed information, see <a href="#">What is Amazon Aurora?</a>.</td>
<td>July 27, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support copying tags to DB snapshots.</td>
<td>July 20, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support increases in storage size for all DB engines and an increase in Provisioned IOPS for SQL Server.</td>
<td>June 18, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated options for reserved DB instances.</td>
<td>June 15, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support using Amazon CloudHSM with Oracle DB instances using TDE.</td>
<td>January 8, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to include the new Amazon DB engine: Aurora. The Amazon Aurora DB engine supports multiple DB instances in a DB cluster. Amazon Aurora is currently in preview release and is subject to change. For detailed information, see <a href="#">What is Amazon Aurora?</a>.</td>
<td>November 12, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support PostgreSQL read replicas.</td>
<td>November 10, 2014</td>
</tr>
<tr>
<td>New API and features</td>
<td>Updated to support the GP2 storage type and new API version 2014-09-01. Updated to support the ability to copy an existing option or parameter group to create a new option or parameter group.</td>
<td>October 7, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support InnoDB Cache Warming for DB instances running MySQL version 5.6.19 and later.</td>
<td>September 3, 2014</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support SSL certificate verification when connecting to MySQL version 5.6, SQL Server, and PostgreSQL database engines.</td>
<td>August 5, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support the db.t2 burstable DB instance classes.</td>
<td>August 4, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support the db.r3 memory optimized DB instance classes for use with the MySQL (version 5.6), SQL Server, and PostgreSQL database engines.</td>
<td>May 28, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support SQL Server Multi-AZ deployments using SQL Server Mirroring.</td>
<td>May 19, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support upgrades from MySQL version 5.5 to version 5.6.</td>
<td>April 23, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Oracle GoldenGate.</td>
<td>April 3, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support the M3 DB instance classes.</td>
<td>February 20, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support the Oracle Timezone option.</td>
<td>January 13, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support replication between MySQL DB instances in different regions.</td>
<td>November 26, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support the PostgreSQL DB engine.</td>
<td>November 14, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support SQL Server transparent data encryption (TDE).</td>
<td>November 7, 2013</td>
</tr>
<tr>
<td>New API and new feature</td>
<td>Updated to support cross region DB snapshot copies; new API version, 2013-09-09.</td>
<td>October 31, 2013</td>
</tr>
<tr>
<td>New features</td>
<td>Updated to support Oracle Statspack.</td>
<td>September 26, 2013</td>
</tr>
<tr>
<td>New features</td>
<td>Updated to support using replication to import or export data between instances of MySQL running in Amazon RDS and instances of MySQL running on-premises or on Amazon EC2.</td>
<td>September 5, 2013</td>
</tr>
<tr>
<td>New features</td>
<td>Updated to support the db.cr1.8xlarge DB instance class for MySQL 5.6.</td>
<td>September 4, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support replication of read replicas.</td>
<td>August 28, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support parallel read replica creation.</td>
<td>July 22, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support fine-grained permissions and tagging for all Amazon RDS resources.</td>
<td>July 8, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support MySQL 5.6 for new instances, including support for the MySQL 5.6 memcached interface and binary log access.</td>
<td>July 1, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support major version upgrades from MySQL 5.1 to MySQL 5.5.</td>
<td>June 20, 2013</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated DB parameter groups to allow expressions for parameter values.</td>
<td>June 20, 2013</td>
</tr>
<tr>
<td>New features</td>
<td>Updated to support Oracle Advanced Security features for native network encryption and Oracle Transparent Data Encryption.</td>
<td>April 18, 2013</td>
</tr>
<tr>
<td>New features</td>
<td>Updated to support major version upgrades for SQL Server and additional functionality for Provisioned IOPS.</td>
<td>March 13, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support VPC By Default for RDS.</td>
<td>March 11, 2013</td>
</tr>
<tr>
<td>New API and feature</td>
<td>Updated to support log access; new API version 2013-02-12</td>
<td>March 4, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support RDS event notification subscriptions.</td>
<td>February 4, 2013</td>
</tr>
<tr>
<td>New API and feature</td>
<td>Updated to support DB instance renaming and the migration of DB security group members in a VPC to a VPC security group.</td>
<td>January 14, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated for AWS GovCloud (US-West) support.</td>
<td>December 17, 2012</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support m1.medium and m1.xlarge DB Instance classes.</td>
<td>November 6, 2012</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support read replica promotion.</td>
<td>October 11, 2012</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support SSL in Microsoft SQL Server DB Instances.</td>
<td>October 10, 2012</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Oracle micro DB Instances.</td>
<td>September 27, 2012</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support SQL Server 2012.</td>
<td>September 26, 2012</td>
</tr>
<tr>
<td>New API and feature</td>
<td>Updated to support provisioned IOPS. API version 2012-09-17.</td>
<td>September 25, 2012</td>
</tr>
<tr>
<td>New features</td>
<td>Updated for SQL Server support for DB Instances in VPC and Oracle support for Data Pump.</td>
<td>September 13, 2012</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated for support for SQL Server Agent.</td>
<td>August 22, 2012</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated for support for tagging of DB Instances.</td>
<td>August 21, 2012</td>
</tr>
<tr>
<td>New features</td>
<td>Updated for support for Oracle APEX and XML DB, Oracle time zones, and Oracle DB Instances in a VPC.</td>
<td>August 16, 2012</td>
</tr>
<tr>
<td>New features</td>
<td>Updated for support for SQL Server Database Engine Tuning Advisor and Oracle DB Instances in VPC.</td>
<td>July 18, 2012</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated for support for option groups and first option, Oracle Enterprise Manager Database Control.</td>
<td>May 29, 2012</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated for support for read replicas in Amazon Virtual Private Cloud.</td>
<td>May 17, 2012</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>-------------</td>
<td>------------------------------------------------------------------------------</td>
<td>--------------</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated for Microsoft SQL Server support.</td>
<td>May 8, 2012</td>
</tr>
<tr>
<td>New features</td>
<td>Updated for support for forced failover, Multi-AZ deployment of Oracle DB Instances, and nondefault character sets for Oracle DB Instances.</td>
<td>May 2, 2012</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated for Amazon Virtual Private Cloud (VPC) Support.</td>
<td>February 13, 2012</td>
</tr>
<tr>
<td>Updated content</td>
<td>Updated for new Reserved Instance types.</td>
<td>December 19, 2011</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated for Oracle engine support.</td>
<td>May 23, 2011</td>
</tr>
<tr>
<td>Updated content</td>
<td>Console updates.</td>
<td>May 13, 2011</td>
</tr>
<tr>
<td>Updated content</td>
<td>Edited content for shortened backup and maintenance windows.</td>
<td>February 28, 2011</td>
</tr>
<tr>
<td>New feature</td>
<td>Added support for MySQL 5.5.</td>
<td>January 31, 2011</td>
</tr>
<tr>
<td>New feature</td>
<td>Added support for read replicas.</td>
<td>October 4, 2010</td>
</tr>
<tr>
<td>New feature</td>
<td>Added support for AWS Identity and Access Management (IAM).</td>
<td>September 2, 2010</td>
</tr>
<tr>
<td>New feature</td>
<td>Added Reserved DB Instances.</td>
<td>August 16, 2010</td>
</tr>
<tr>
<td>New Feature</td>
<td>Amazon RDS now supports SSL connections to your DB Instances.</td>
<td>June 28, 2010</td>
</tr>
<tr>
<td>New Guide</td>
<td>This is the first release of the Amazon RDS User Guide.</td>
<td>June 7, 2010</td>
</tr>
