To back up specific archived redo logs for an Amazon RDS Oracle DB instance by specifying a system change number (SCN) range, use the Amazon RDS procedure rdsadmin.rdsadmin_rman_util.backup_archivelog_scn. The SCN range specifies which archived redo logs to back up.

This procedure uses the following common parameters for RMAN tasks:

- p_owner
- p_directory_name
- p_label
- p_parallel
- p_compress
- p_rman_to_dbms_output
- p_tag

For more information, see Common parameters for RMAN procedures (p. 1914).

This procedure also uses the following additional parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_from_scn</td>
<td>number</td>
<td>An SCN of an archived redo log that exists on disk. The value must be less than or equal to the value specified for p_to_scn.</td>
<td>—</td>
<td>Yes</td>
<td>The starting SCN for the archived log backups.</td>
</tr>
<tr>
<td>p_to_scn</td>
<td>number</td>
<td>An SCN of an archived redo log that exists on disk. The value must be greater than or equal to the value specified for p_from_scn.</td>
<td>—</td>
<td>Yes</td>
<td>The ending SCN for the archived log backups.</td>
</tr>
</tbody>
</table>

The following example backs up archived redo logs in the SCN range for the DB instance.

```sql
BEGIN
rdsadmin.rdsadmin_rman_util.backup_archivelog_scn(
    p_owner => 'SYS',
    p_directory_name => 'MYDIRECTORY',
    p_from_scn => 1533835,
    p_to_scn => 1892447,
)
END
```
p_parallel => 4,
p_tag => 'MY_LOG_BACKUP',
p_rman_to_dbms_output => FALSE);
END;
/

Back up an archived redo log from a sequence number range

To back up specific archived redo logs for an Amazon RDS Oracle DB instance by specifying a sequence number range, use the Amazon RDS procedure rdsadmin.rdsadmin_rman_util.backup_archivelog_sequence. The sequence number range specifies which archived redo logs to back up.

This procedure uses the following common parameters for RMAN tasks:

- p_owner
- p_directory_name
- p_label
- p_parallel
- p_compress
- p_rman_to_dbms_output
- p_tag

For more information, see Common parameters for RMAN procedures (p. 1914).

This procedure also uses the following additional parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_from_sequence</td>
<td>number</td>
<td>A sequence number of an archived redo log that exists on disk. The value must be less than or equal to the value specified for p_to_sequence.</td>
<td>—</td>
<td>Yes</td>
<td>The starting sequence number for the archived log backups.</td>
</tr>
<tr>
<td>p_to_sequence</td>
<td>number</td>
<td>A sequence number of an archived redo log that exists on disk.</td>
<td>—</td>
<td>Yes</td>
<td>The ending sequence number for the archived log backups.</td>
</tr>
</tbody>
</table>
### RMAN tasks

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>The value must be greater than or equal to the value specified for <code>p_from_sequence</code>.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The following example backs up archived redo logs in the sequence number range for the DB instance.

```
BEGIN
  rdsadmin.rdsadmin_rman_util.backup_archivelog_sequence(
      p_owner => 'SYS',
      p_directory_name => 'MYDIRECTORY',
      p_from_sequence => 11160,
      p_to_sequence => 11160,
      p_parallel => 4,
      p_tag => 'MY_LOG_BACKUP',
      p_rman_to_dbms_output => FALSE);
END;
/
```

### Performing a full database backup

You can perform a backup of all blocks of data files included in the backup using Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_database_full`.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_section_size_mb`
- `p_include_archive_logs`
- `p_optimize`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see [Common parameters for RMAN procedures](p. 1914).

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2019-01.rur-2019-01.r1 or higher
• Oracle Database 12c Release 1 (12.1), using 12.1.0.2.v15 or higher

The following example performs a full backup of the DB instance using the specified values for the parameters.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_database_full(
        p_owner               => 'SYS',
        p_directory_name      => 'MYDIRECTORY',
        p_parallel            => 4,
        p_section_size_mb     => 10,
        p_tag                 => 'FULL_DB_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

### Performing an incremental database backup

You can perform an incremental backup of your DB instance using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_database_incremental`.

For more information about incremental backups, see Incremental backups in the Oracle documentation.

This procedure uses the following common parameters for RMAN tasks:

- p_owner
- p_directory_name
- p_label
- p_parallel
- p_section_size_mb
- p_include_archive_logs
- p_include_controlfile
- p_optimize
- p_compress
- p_rman_to_dbms_output
- p_tag

For more information, see Common parameters for RMAN procedures (p. 1914).

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2019-01.rur-2019-01.r1 or higher
- Oracle Database 12c Release 1 (12.1), using 12.1.0.2.v15 or higher

This procedure also uses the following additional parameter:

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_level</td>
<td>number</td>
<td>0, 1</td>
<td>0</td>
<td>No</td>
<td>Specify 0 to enable a full incremental backup.</td>
</tr>
</tbody>
</table>
The following example performs an incremental backup of the DB instance using the specified values for the parameters.

```sql
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_database_incremental(
        p_owner => 'SYS',
        p_directory_name => 'MYDIRECTORY',
        p_level => 1,
        p_parallel => 4,
        p_section_size_mb => 10,
        p_tag => 'MY_INCREMENTAL_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

### Backing up a tablespace

You can back up a tablespace using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_tablespace`.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_section_size_mb`
- `p_include_archive_logs`
- `p_include_controlfile`
- `p_optimize`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see [Common parameters for RMAN procedures (p. 1914)](#).

This procedure also uses the following additional parameter:

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_tablespace_name</td>
<td>varchar2</td>
<td>A valid tablespace name.</td>
<td>—</td>
<td>Yes</td>
<td>The name of the tablespace to back up.</td>
</tr>
</tbody>
</table>

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:
The following example performs a tablespace backup using the specified values for the parameters.

```
BEGIN
  rdsadmin.rdsadmin_rman_util.backup_tablespace(
    p_owner               => 'SYS',
    p_directory_name      => 'MYDIRECTORY',
    p_tablespace_name     => 'MYTABLESPACE',
    p_parallel            => 4,
    p_section_size_mb     => 10,
    p_tag                 => 'MYTABLESPACE_BACKUP',
    p_rman_to_dbms_output => FALSE);
END;
 /
```

### Backing up a control file

You can back up a control file using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_current_controlfile`. This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see [Common parameters for RMAN procedures (p. 1914)](p. 1914).

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2019-01.rur-2019-01.r1 or higher
- Oracle Database 12c Release 1 (12.1), using 12.1.0.2.v15 or higher

The following example backs up a control file using the specified values for the parameters.

```
BEGIN
  rdsadmin.rdsadmin_rman_util.backup_current_controlfile(
    p_owner               => 'SYS',
    p_directory_name      => 'MYDIRECTORY',
    p_tag                 => 'CONTROL_FILE_BACKUP',
    p_rman_to_dbms_output => FALSE);
END;
 /
```
Performing common scheduling tasks for Oracle DB instances

Some scheduler jobs owned by SYS can interfere with normal database operations. Oracle Support recommends you disable these jobs or modify the schedule. To perform tasks for Oracle Scheduler jobs owned by SYS, use the Amazon RDS package `rdsadmin.rdsadmin_dbms_scheduler`.

The `rdsadmin.rdsadmin_dbms_scheduler` procedures are supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c
- Oracle Database 12c Release 2 (12.2) on 12.2.0.2.ru-2019-07.rur-2019-07.r1 or higher 12.2 versions
- Oracle Database 12c Release 1 (12.1) on 12.1.0.2.v17 or higher 12.1 versions

Common parameters for Oracle Scheduler procedures

To perform tasks with Oracle Scheduler, use procedures in the Amazon RDS package `rdsadmin.rdsadmin_dbms_scheduler`. Several parameters are common to the procedures in the package. The package has the following common parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>varchar2</td>
<td>'SYS.BSLN_MAINTAIN_STATS_JOB', 'SYS.CLEANUP_ONLINE_IND_BUILD'</td>
<td></td>
<td>Yes</td>
<td>The name of the job to modify.</td>
</tr>
<tr>
<td>Note</td>
<td>Currently, you can only modify SYS.CLEANUP_ONLINE_IND_BUILD and SYS.BSLN_MAINTAIN_STATS_JOB jobs.</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>attribute</td>
<td>varchar2</td>
<td>'REPEAT_INTERVAL', 'SCHEDULE_NAME'</td>
<td></td>
<td>Yes</td>
<td>Attribute to modify.</td>
</tr>
<tr>
<td>value</td>
<td>varchar2</td>
<td>A valid schedule interval or schedule name, depending on</td>
<td>Yes</td>
<td>The new value of the attribute.</td>
<td></td>
</tr>
</tbody>
</table>

1930
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attribute</td>
<td>used</td>
<td></td>
<td></td>
<td></td>
<td>attribute</td>
</tr>
</tbody>
</table>

**Modifying DBMS_SCHEDULER jobs**

To modify certain components of Oracle Scheduler, use the Oracle procedure `dbms_scheduler.set_attribute`. For more information, see `DBMS_SCHEDULER` and `SET_ATTRIBUTE procedure` in the Oracle documentation.

When working with Amazon RDS DB instances, prepend the schema name SYS to the object name. The following example sets the resource plan attribute for the Monday window object.

```sql
BEGIN
    DBMS_SCHEDULER.SET_ATTRIBUTE(
        name => 'SYS.MONDAY_WINDOW',
        attribute => 'RESOURCE_PLAN',
        value => 'resource_plan_1');
END;
/
```

**Modifying AutoTask maintenance windows**

Amazon RDS for Oracle instances are created with default settings for maintenance windows. Automated maintenance tasks such as optimizer statistics collection run during these windows. By default, the maintenance windows turn on Oracle Database Resource Manager.

To modify the window, use the `DBMS_SCHEDULER` package. You might need to modify the maintenance window settings for the following reasons:

- You want maintenance jobs to run at a different time, with different settings, or not at all. For example, might want to modify the window duration, or change the repeat time and interval.
- You want to avoid the performance impact of enabling Resource Manager during maintenance. For example, if the default maintenance plan is specified, and if the maintenance window opens while the database is under load, you might see wait events such as resmgr:cpu quantum. This wait event is related to Database Resource Manager. You have the following options:
  - Ensure that maintenance windows are active during off-peak times for your DB instance.
  - Disable the default maintenance plan by setting the `resource_plan` attribute to an empty string.
  - Set the `resource_manager_plan` parameter to `FORCE` in your parameter group. If your instance uses Enterprise Edition, this setting prevents Database Resource Manager plans from activating.

**To modify your maintenance window settings**

1. Connect to your database using an Oracle SQL client.
2. Query the current configuration for a scheduler window.

   The following example queries the configuration for MONDAY_WINDOW.

   ```sql
   SELECT ENABLED, RESOURCE_PLAN, DURATION, REPEAT_INTERVAL
   FROM   DBA_SCHEDULER_WINDOWS
   WHERE  WINDOW_NAME='MONDAY_WINDOW';
   ```

   The following output shows that the window is using the default values.
### Oracle Scheduler tasks

<table>
<thead>
<tr>
<th>ENABLED</th>
<th>RESOURCE_PLAN</th>
<th>DURATION</th>
<th>REPEAT_INTERVAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRUE</td>
<td>DEFAULT_MAINTENANCE_PLAN</td>
<td>+000 04:00:00</td>
<td>freq=daily;byday=MON;byhour=22;byminute=0;bysecond=0</td>
</tr>
</tbody>
</table>

3. Modify the window using the `DBMS_SCHEDULER` package.

The following example sets the resource plan to null so that the Resource Manager won't run during the maintenance window.

```sql
BEGIN
    -- disable the window to make changes
    DBMS_SCHEDULER.DISABLE(name=>'"SYS"."MONDAY_WINDOW"', force=>TRUE);

    -- specify the empty string to use no plan
    DBMS_SCHEDULER.SET_ATTRIBUTE(name=>'"SYS"."MONDAY_WINDOW"', attribute=>'RESOURCE_PLAN', value=>'');

    -- re-enable the window
    DBMS_SCHEDULER.ENABLE(name=>'"SYS"."MONDAY_WINDOW"');
END;
/
```

The following example sets the maximum duration of the window to 2 hours.

```sql
BEGIN
    DBMS_SCHEDULER.DISABLE(name=>'"SYS"."MONDAY_WINDOW"', force=>TRUE);
    DBMS_SCHEDULER.SET_ATTRIBUTE(name=>'"SYS"."MONDAY_WINDOW"', attribute=>'DURATION', value=>'0 2:00:00');
    DBMS_SCHEDULER.ENABLE(name=>'"SYS"."MONDAY_WINDOW"');
END;
/
```

The following example sets the repeat interval to every Monday at 10 AM.

```sql
BEGIN
    DBMS_SCHEDULER.DISABLE(name=>'"SYS"."MONDAY_WINDOW"', force=>TRUE);
    DBMS_SCHEDULER.SET_ATTRIBUTE(name=>'"SYS"."MONDAY_WINDOW"', attribute=>'REPEAT_INTERVAL', value=>'freq=daily;byday=MON;byhour=10;byminute=0;bysecond=0');
    DBMS_SCHEDULER.ENABLE(name=>'"SYS"."MONDAY_WINDOW"');
END;
/
```

### Setting the time zone for Oracle Scheduler jobs

To modify the time zone for Oracle Scheduler, you can use the Oracle procedure `dbms_scheduler.set_scheduler_attribute`. For more information about the `dbms_scheduler` package, see `DBMS_SCHEDULER` and `SET_SCHEDULER_ATTRIBUTE` in the Oracle documentation.

**To modify the current time zone setting**

1. Connect to the database using a client such as SQL Developer. For more information, see [Connecting to your DB instance using Oracle SQL developer](p. 1824).
2. Set the default time zone as following, substituting your time zone for `time_zone_name`. 

---

1932
BEGIN
  DBMS_SCHEDULER.SET_SCHDEULER_ATTRIBUTE(
      attribute => 'default_timezone',
      value => 'time_zone_name'
  );
END;
/

In the following example, you change the time zone to Asia/Shanghai.

Start by querying the current time zone, as shown following.

SELECT VALUE FROM DBA_SCHEDULER_GLOBAL_ATTRIBUTE WHERE ATTRIBUTE_NAME='DEFAULT_TIMEZONE';

The output shows that the current time zone is ETC/UTC.

VALUE
-------
Etc/UTC

Then you set the time zone to Asia/Shanghai.

BEGIN
  DBMS_SCHEDULER.SET_SCHDEULER_ATTRIBUTE(
      attribute => 'default_timezone',
      value => 'Asia/Shanghai'
  );
END;
/

For more information about changing the system time zone, see Oracle time zone (p. 2103).

Turning off Oracle Scheduler jobs owned by SYS

To disable an Oracle Scheduler job owned by the SYS user, use the rdsadmin.rdsadmin_dbms_scheduler.disable procedure.

This procedure uses the name common parameter for Oracle Scheduler tasks. For more information, see Common parameters for Oracle Scheduler procedures (p. 1930).

The following example disables the SYS.CLEANUP_ONLINE_IND_BUILD Oracle Scheduler job.

BEGIN
  rdsadmin.rdsadmin_dbms_scheduler.disable('SYS.CLEANUP_ONLINE_IND_BUILD');
END;
/

Turning on Oracle Scheduler jobs owned by SYS

To turn on an Oracle Scheduler job owned by SYS, use the rdsadmin.rdsadmin_dbms_scheduler.enable procedure.

This procedure uses the name common parameter for Oracle Scheduler tasks. For more information, see Common parameters for Oracle Scheduler procedures (p. 1930).

The following example enables the SYS.CLEANUP_ONLINE_IND_BUILD Oracle Scheduler job.
BEGIN
  rdsadmin.rdsadmin_dbms_scheduler.enable('SYS.CLEANUP_ONLINE_IND_BUILD');
END;
/

Modifying the Oracle Scheduler repeat interval for jobs of CALENDAR type

To modify the repeat interval to modify a SYS-owned Oracle Scheduler job of CALENDAR type, use the rdsadmin.rdsadmin_dbms_scheduler.disable procedure.

This procedure uses the following common parameters for Oracle Scheduler tasks:

- name
- attribute
- value

For more information, see Common parameters for Oracle Scheduler procedures (p. 1930).

The following example modifies the repeat interval of the SYS.CLEANUP_ONLINE_IND_BUILD Oracle Scheduler job.

BEGIN
  rdsadmin.rdsadmin_dbms_scheduler.set_attribute(
    name => 'SYS.CLEANUP_ONLINE_IND_BUILD',
    attribute => 'repeat_interval',
    value => 'freq=daily;byday=FRI,SAT;byhour=20;byminute=0;bysecond=0');
END;
/

Modifying the Oracle Scheduler repeat interval for jobs of NAMED type

Some Oracle Scheduler jobs use a schedule name instead of an interval. For this type of jobs, you must create a new named schedule in the master user schema. Use the standard Oracle sys.dbms_scheduler.create_schedule procedure to do this. Also, use the rdsadmin.rdsadmin_dbms_scheduler.set_attribute procedure to assign the new named schedule to the job.

This procedure uses the following common parameter for Oracle Scheduler tasks:

- name
- attribute
- value

For more information, see Common parameters for Oracle Scheduler procedures (p. 1930).

The following example modifies the repeat interval of the SYS.BSLN_MAINTAIN_STATS_JOB Oracle Scheduler job.

BEGIN
  DBMS_SCHEDULER.CREATE_SCHEDULE(
    schedule_name => 'rds_master_user.new_schedule',
    start_date => SYSTIMESTAMP,
    ...);
END;
Turning off autocommit for Oracle Scheduler job creation

When DBMS_SCHEDULER.CREATE_JOB creates Oracle Scheduler jobs, it creates the jobs immediately and commits the changes. You might need to incorporate the creation of Oracle Scheduler jobs in the user transaction to do the following:

- Roll back the Oracle Scheduler job when the user transaction is rolled back.
- Create the Oracle Scheduler job when the main user transaction is committed.

You can use the procedure rdsadmin.rdsadmin_dbms_scheduler.set_no_commit_flag to turn on this behavior. This procedure takes no parameters. You can use this procedure in the following RDS for Oracle releases:

- 21.0.0.0.ru-2022-07.rur-2022-07.r1 and higher
- 19.0.0.0.ru-2022-07.rur-2022-07.r1 and higher

The following example turns off autocommit for Oracle Scheduler, creates an Oracle Scheduler job, and then rolls back the transaction. Because autocommit is turned off, the database also rolls back the creation of the Oracle Scheduler job.

```
BEGIN
    rdsadmin.rdsadmin_dbms_scheduler.set_no_commit_flag;
    DBMS_SCHEDULER.CREATE_JOB(job_name   => 'EMPTY_JOB',
                     job_type   => 'PLSQL_BLOCK',
                     job_action => 'begin null; end;',
                     auto_drop  => false);
    ROLLBACK;
END;
/
```

PL/SQL procedure successfully completed.

```
SELECT * FROM DBA_SCHEDULER_JOBS WHERE JOB_NAME='EMPTY_JOB';
```

no rows selected

Performing common diagnostic tasks for Oracle DB instances

Oracle Database includes a fault diagnosability infrastructure that you can use to investigate database problems. In Oracle terminology, a problem is a critical error such as a code bug or data corruption. An incident is the occurrence of a problem. If the same error occurs three times, then the infrastructure
shows three incidents of this problem. For more information, see Diagnosing and resolving problems in the Oracle Database documentation.

The Automatic Diagnostic Repository Command Interpreter (ADRCI) utility is an Oracle command-line tool that you use to manage diagnostic data. For example, you can use this tool to investigate problems and package diagnostic data. An incident package includes diagnostic data for an incident or all incidents that reference a specific problem. You can upload an incident package, which is implemented as a .zip file, to Oracle Support.

To deliver a managed service experience, Amazon RDS doesn't provide shell access to ADRCI. To perform diagnostic tasks for your Oracle instance, instead use the Amazon RDS package rdsadmin.rdsadmin_adrci_util.

By using the functions in rdsadmin_adrci_util, you can list and package problems and incidents, and also show trace files. All functions return a task ID. This ID forms part of the name of log file that contains the ADRCI output, as in dbtask-task_id.log. The log file resides in the BDUMP directory.

**Common parameters for diagnostic procedures**

To perform diagnostic tasks, use functions in the Amazon RDS package rdsadmin.rdsadmin_adrci_util. The package has the following common parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>incident_id</td>
<td>number</td>
<td>A valid incident ID or null</td>
<td>Null</td>
<td>No</td>
<td>If the value is null, the function shows all incidents. If the value isn't null and represents a valid incident ID, the function shows the specified incident.</td>
</tr>
<tr>
<td>problem_id</td>
<td>number</td>
<td>A valid problem ID or null</td>
<td>Null</td>
<td>No</td>
<td>If the value is null, the function shows all problems. If the value isn't null and represents a valid problem ID, the function shows the specified problem.</td>
</tr>
<tr>
<td>last</td>
<td>number</td>
<td>A valid integer greater than 0 or null</td>
<td>Null</td>
<td>No</td>
<td>If the value is null, then the function displays at most 50 items. If the value isn't null, the function displays the specified number.</td>
</tr>
</tbody>
</table>

**Listing incidents**

To list diagnostic incidents for Oracle, use the Amazon RDS function rdsadmin.rdsadmin_adrci_util.list_adrci_incidents. You can list incidents in either basic or detailed mode. By default, the function lists the 50 most recent incidents.

This function uses the following common parameters:

- incident_id
• problem_id
• last

If you specify incident_id and problem_id, then incident_id overrides problem_id. For more information, see Common parameters for diagnostic procedures (p. 1936).

This function uses the following additional parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>detail</td>
<td>boolean</td>
<td>TRUE or FALSE</td>
<td>FALSE</td>
<td>No</td>
<td>If TRUE, the function lists incidents in detail mode. If FALSE, the function lists incidents in basic mode.</td>
</tr>
</tbody>
</table>

To list all incidents, query the rdsadmin.rdsadmin_adrci_util.list_adrci_incidents function without any arguments. The query returns the task ID.

```
SQL> SELECT rdsadmin.rdsadmin_adrci_util.list_adrci_incidents AS task_id FROM DUAL;
```

<table>
<thead>
<tr>
<th>TASK_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1590786706158-3126</td>
</tr>
</tbody>
</table>

Or call the rdsadmin.rdsadmin_adrci_util.list_adrci_incidents function without any arguments and store the output in a SQL client variable. You can use the variable in other statements.

```
SQL> VAR task_id VARCHAR2(80);
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.list_adrci_incidents;
```

PL/SQL procedure successfully completed.

To read the log file, call the Amazon RDS procedure rdsadmin.rds_file_util.read_text_file. Supply the task ID as part of the file name. The following output shows three incidents: 53523, 53522, and 53521.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-':task_id':'.log'));
```

```

```

1937
To list a particular incident, specify its ID using the `incident_id` parameter. In the following example, you query the log file for incident 53523 only.

```sql
SQL> EXEC :task_id :=
    2 rdsadmin.rdsadmin_adrci_util.list_adrci_incidents(incident_id=>53523);
```

PL/SQL procedure successfully completed.

```sql
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
    2 'dbtask-'||:task_id||'.log'));
```

---

**Listing problems**

To list diagnostic problems for Oracle, use the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.list_adrci_problems`.

By default, the function lists the 50 most recent problems.

This function uses the common parameters `problem_id` and `last`. For more information, see Common parameters for diagnostic procedures (p. 1936).

To get the task ID for all problems, call the `rdsadmin.rdsadmin_adrci_util.list_adrci_problems` function without any arguments, and store the output in a SQL client variable.

```sql
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.list_adrci_problems;
```

PL/SQL procedure successfully completed.

To read the log file, call the `rdsadmin.rds_file_util.read_text_file` function, supplying the task ID as part of the file name. In the following output, the log file shows three problems: 1, 2, and 3.

```sql
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
    2 'dbtask-'||:task_id||'.log'));
```
Diagnostic tasks

2020-05-29 21:18:50.829 UTC [INFO ]
ADR Home = /rdsdbdata/log/diag/rdbms/orcl_a/ORCL:
*************************************************************************
PROBLEM_ID PROBLEM_KEY LAST_INCIDENT LASTINC_TIME

3 rows fetched

2020-05-29 21:18:50.829 UTC [INFO ] The ADRCI problems were successfully listed.
14 rows selected.

In the following example, you list problem 3 only.

SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.list_adrci_problems(problem_id=>3);
PL/SQL procedure successfully completed.

To read the log file for problem 3, call rdsadmin.rds_file_util.read_text_file. Supply the task ID as part of the file name.

SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
'dbtask-''||:task_id||''.log'));

Creating incident packages

You can create incident packages using the Amazon RDS function rdsadmin.rdsadmin_adrci_util.create_adrci_package. The output is a .zip file that you can supply to Oracle Support.
This function uses the following common parameters:

- `problem_id`
- `incident_id`

Make sure to specify one of the preceding parameters. If you specify both parameters, `incident_id` overrides `problem_id`. For more information, see Common parameters for diagnostic procedures (p. 1936).

To create a package for a specific incident, call the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.create_adrci_package` with the `incident_id` parameter. The following example creates a package for incident 53523.

```sql
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.create_adrci_package(incident_id=>53523);
PL/SQL procedure successfully completed.
```

To read the log file, call the `rdsadmin.rds_file_util.read_text_file`. You can supply the task ID as part of the file name. The output shows that you generated incident package `ORA700EVE_20200529212043_COM_1.zip`.

```sql
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-''||:task_id||''.log'));
TEXT
--------------------------------------------------------------------------------------------------------------------------------------
2020-05-29 21:20:43.031 UTC [INFO ] The ADRCI package is being created.
ORA700EVE_20200529212043_COM_1.zip, mode complete
2020-05-29 21:20:47.642 UTC [INFO ] The ADRCI package was successfully created.
```

To package diagnostic data for a particular problem, specify its ID using the `problem_id` parameter. In the following example, you package data for problem 3 only.

```sql
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.create_adrci_package(problem_id=>3);
PL/SQL procedure successfully completed.
```

To read the task output, call `rdsadmin.rds_file_util.read_text_file`, supplying the task ID as part of the file name. The output shows that you generated incident package `ORA700EVE_20200529212111_COM_1.zip`.

```sql
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-''||:task_id||''.log'));
TEXT
------------------------------------------------------------------------------------------------------------------------------------------------------------
ORA700EVE_20200529212143_COM_1.zip, mode complete
2020-05-29 21:21:15.646 UTC [INFO ] The ADRCI package was successfully created.
```
Showing trace files

You can use the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile` to list trace files under the trace directory and all incident directories under the current ADR home. You can also show the contents of trace files and incident trace files.

This function uses the following parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>filename</td>
<td>varchar2</td>
<td>A valid trace file name</td>
<td>Null</td>
<td>No</td>
<td>If the value is null, the function shows all trace files. If it isn't null, the function shows the specified file.</td>
</tr>
</tbody>
</table>

To show the trace file, call the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile`.

```
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile;
PL/SQL procedure successfully completed.
```

To list the trace file names, call the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`, supplying the task ID as part of the file name.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-':||:task_id||'.log')) WHERE TEXT LIKE '%/alert_%';
```

```
TEXT
-----------------------------------------------
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-28
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-27
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-26
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-25
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-24
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-23
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-22
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-21
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log
9 rows selected.
```

In the following example, you generate output for alert_ORCL.log.

```
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile('diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log');
PL/SQL procedure successfully completed.
```

To read the log file, call `rdsadmin.rds_file_util.read_text_file`. Supply the task ID as part of the file name. The output shows the first 10 lines of alert_ORCL.log.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-':||:task_id||'.log')) WHERE ROWNUM <= 10;
```

```
TEXT
1941
```
Performing miscellaneous tasks for Oracle DB instances

Following, you can find how to perform miscellaneous DBA tasks on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and restricts access to certain system procedures and tables that require advanced privileges.

Topics
- Creating and dropping directories in the main data storage space (p. 1942)
- Listing files in a DB instance directory (p. 1943)
- Reading files in a DB instance directory (p. 1943)
- Accessing Opatch files (p. 1944)
- Managing advisor tasks (p. 1946)
- Transporting tablespaces (p. 1948)

Creating and dropping directories in the main data storage space

To create directories, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.create_directory`. You can create up to 10,000 directories, all located in your main data storage space. To drop directories, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.drop_directory`.

The `create_directory` and `drop_directory` procedures have the following required parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_directory_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the directory.</td>
</tr>
</tbody>
</table>

The following example creates a new directory named PRODUCT_DESCRIPTIONS.

```sql
EXEC rdsadmin.rdsadmin_util.create_directory(p_directory_name => 'product_descriptions');
```

The data dictionary stores the directory name in uppercase. You can list the directories by querying `DBA_DIRECTORIES`. The system chooses the actual host pathname automatically. The following example gets the directory path for the directory named PRODUCT_DESCRIPTIONS:

```sql
SELECT DIRECTORY_PATH
```
The master user name for the DB instance has read and write privileges in the new directory, and can grant access to other users. EXECUTE privileges are not available for directories on a DB instance. Directories are created in your main data storage space and will consume space and I/O bandwidth.

The following example drops the directory named PRODUCT_DESCRIPTIONS.

```sql
EXEC rdsadmin.rdsadmin_util.drop_directory(p_directory_name => 'product_descriptions');
```

**Note**
You can also drop a directory by using the Oracle SQL command `DROP DIRECTORY`.

Dropping a directory doesn't remove its contents. Because the `rdsadmin.rdsadmin_util.create_directory` procedure can reuse pathnames, files in dropped directories can appear in a newly created directory. Before you drop a directory, we recommend that you use `UTL_FILE.FREMOVE` to remove files from the directory. For more information, see `FREMOVE procedure` in the Oracle documentation.

**Listing files in a DB instance directory**

To list the files in a directory, use the Amazon RDS procedure `rdsadmin.rds_file_util.listdir`. The `listdir` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_directory</code></td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the directory to list.</td>
</tr>
</tbody>
</table>

The following example grants read/write privileges on the directory PRODUCT_DESCRIPTIONS to user `rdsadmin`, and then lists the files in this directory.

```sql
GRANT READ,WRITE ON DIRECTORY PRODUCT_DESCRIPTIONS TO rdsadmin;
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory => 'PRODUCT_DESCRIPTIONS'));
```

**Reading files in a DB instance directory**

To read a text file, use the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`. The `read_text_file` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_directory</code></td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the directory that contains the file.</td>
</tr>
<tr>
<td><code>p_filename</code></td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the file to read.</td>
</tr>
</tbody>
</table>

The following example creates the file `rice.txt` in the directory PRODUCT_DESCRIPTIONS.
declare
    fh sys.utl_file.file_type;
begin
    fh := utl_file.fopen(location=>'PRODUCT_DESCRIPTIONS', filename=>'rice.txt',
            open_mode=>'w');
    utl_file.put(file=>fh, buffer=>'AnyCompany brown rice, 15 lbs');
    utl_file.fclose(file=>fh);
end;
/

The following example reads the file rice.txt from the directory PRODUCT_DESCRIPTIONS.

SELECT * FROM TABLE
  (rdsadmin.rds_file_util.read_text_file(
      p_directory  => 'PRODUCT_DESCRIPTIONS',
      p_filename   => 'rice.txt'));

Accessing Opatch files

Opatch is an Oracle utility that enables the application and rollback of patches to Oracle software.
The Oracle mechanism for determining which patches have been applied to a database is the o patch
lsinventory command. To open service requests for Bring Your Own Licence (BYOL) customers, Oracle
Support requests the lsinventory file and sometimes the lsinventory_detail file generated by
Opatch.

To deliver a managed service experience, Amazon RDS doesn't provide shell access to Opatch. Instead,
the lsinventory-dbv.txt in the BDUMP directory contains the patch information related to
your current engine version. When you perform a minor or major upgrade, Amazon RDS updates
lsinventory-dbv.txt within an hour of applying the patch. To verify the applied patches, read
lsinventory-dbv.txt. This action is similar to running the o patch lsinventory command.

Note

The examples in this section assume that the BDUMP directory is named BDUMP. On a read
replica, the BDUMP directory name is different. To learn how to get the BDUMP name by
querying V$DATABASE_DB_UNIQUE_NAME on a read replica, see Listing files (p. 925).

The inventory files use the Amazon RDS naming convention lsinventory-dbv.txt
and lsinventory_detail-dbv.txt, where dbv is the full name of your DB version.
The lsinventory-dbv.txt file is available on all DB versions. The corresponding
lsinventory_detail-dbv.txt is available on the following DB versions:

- 19.0.0.0, ru-2020-01.rur-2020-01.r1 or later
- 12.2.0.1, ru-2020-01.rur-2020-01.r1 or later
- 12.1.0.2, v19 or later

For example, if your DB version is 19.0.0.0.ru-2021-07.rur-2021-07.r1, then your inventory files have the
following names.

lsinventory-19.0.0.0.ru-2021-07.rur-2021-07.r1.txt
lsinventory_detail-19.0.0.0.ru-2021-07.rur-2021-07.r1.txt

Ensure that you download the files that match the current version of your DB engine.

Console

To download an inventory file using the console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the **Logs & events** tab.
5. Scroll down to the **Logs** section.
6. In the **Logs** section, search for `lsinventory`.
7. Select the file that you want to access, and then choose **Download**.

**SQL**

To read the `lsinventory-dbV.txt` in a SQL client, you can use a `SELECT` statement. For this technique, use either of the following `rdsadmin` functions: `rdsadmin.rds_file_util.read_text_file` or `rdsadmin.tracefile_listing`.

In the following sample query, replace `dbV` with your Oracle DB version. For example, your DB version might be `19.0.0.0.ru-2020-04.rur-2020-04.r1`.

```sql
SELECT text
FROM   TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'lsinventory-dbV.txt'))
```

**PL/SQL**

To read the `lsinventory-dbV.txt` in a SQL client, you can write a PL/SQL program. This program uses `utl_file` to read the file, and `dbms_output` to print it. These are Oracle-supplied packages.

In the following sample program, replace `dbV` with your Oracle DB version. For example, your DB version might be `19.0.0.0.ru-2020-04.rur-2020-04.r1`.

```plsql
SET SERVEROUTPUT ON
DECLARE
    v_file SYS.UTL_FILE.FILE_TYPE;
    v_line VARCHAR2(1000);
    v_oracle_home_type VARCHAR2(1000);
    c_directory VARCHAR2(30) := 'BDUMP';
    c_output_file VARCHAR2(30) := 'lsinventory-dbV.txt';
BEGIN
    v_file := SYS.UTL_FILE.FOPEN(c_directory, c_output_file, 'r');
    LOOP
        BEGIN
            SYS.UTL_FILE.GET_LINE(v_file, v_line,1000);
            DBMS_OUTPUT.PUT_LINE(v_line);
        EXCEPTION
            WHEN no_data_found THEN
                EXIT;
        END LOOP;
    END;
END;
```

Or query `rdsadmin.tracefile_listing`, and spool the output to a file. The following example spools the output to `/tmp/tracefile.txt`.

```sql
SPOOL /tmp/tracefile.txt
SELECT * 
FROM rdsadmin.tracefile_listing 
WHERE FILENAME LIKE 'lsinventory%';
SPOOL OFF;
```

1945
Managing advisor tasks

Oracle Database includes a number of advisors. Each advisor supports automated and manual tasks. You can use procedures in the rdsadmin.rdsadmin_util package to manage some advisor tasks.

The advisor task procedures are available in the following engine versions:

- Oracle Database 21c (21.0.0)
- Version 19.0.0.0.ru-2021-01.rur-2021-01.r1 and higher Oracle Database 19c versions
  
  For more information, see Version 19.0.0.0.ru-2021-01.rur-2021-01.r1 in the Amazon RDS for Oracle Release Notes.

- Version 12.2.0.1.ru-2021-01.rur-2021-01.r1 and higher Oracle Database 12c (Release 2) 12.2.0.1 versions
  
  For more information, see Version 12.2.0.1.ru-2021-01.rur-2021-01.r1 in the Amazon RDS for Oracle Release Notes.

Topics

- Setting parameters for advisor tasks (p. 1946)
- Disabling AUTO_STATS_ADVISOR_TASK (p. 1947)
- Re-enabling AUTO_STATS_ADVISOR_TASK (p. 1948)

Setting parameters for advisor tasks

To set parameters for some advisor tasks, use the Amazon RDS procedure rdsadmin.rdsadmin_util.advisor_task_set_parameter. The advisor_task_set_parameter procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_task_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the advisor task whose parameters you want to change. The following values are valid:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• AUTO_STATS_ADVISOR_TASK</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• INDIVIDUAL_STATS_ADVISOR_TASK</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• SYS_AUTO_SPM_EVOLVE_TASK</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• SYS_AUTO_SQL_TUNING_TASK</td>
</tr>
<tr>
<td>p_parameter</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the task parameter. To find valid parameters for an advisor task, run the following query. Substitute p_task_name with a valid value for p_task_name:</td>
</tr>
</tbody>
</table>

| COL PARAMETER_NAME FORMAT a30 |
| COL PARAMETER_VALUE FORMAT a30 |
| SELECT PARAMETER_NAME, PARAMETER_VALUE FROM DBA_ADVISOR_PARAMETERS WHERE TASK_NAME='p_task_name' AND PARAMETER_VALUE != 'UNUSED' ORDER BY PARAMETER_NAME; |
The following PL/SQL program sets `ACCEPT_PLANS` to `FALSE` for `SYS_AUTO_SPM_EVOLVE_TASK`. The SQL Plan Management automated task verifies the plans and generates a report of its findings, but does not evolve the plans automatically. You can use a report to identify new SQL plan baselines and accept them manually.

```
BEGIN
    rdsadmin.rdsadmin_util.advisor_task_set_parameter(
        p_task_name => 'SYS_AUTO_SPM_EVOLVE_TASK',
        p_parameter => 'ACCEPT_PLANS',
        p_value     => 'FALSE');
END;
```

The following PL/SQL program sets `EXECUTION_DAYS_TO_EXPIRE` to `10` for `AUTO_STATS_ADVISOR_TASK`. The predefined task AUTO_STATS_ADVISOR_TASK runs automatically in the maintenance window once per day. The example sets the retention period for the task execution to 10 days.

```
BEGIN
    rdsadmin.rdsadmin_util.advisor_task_set_parameter(
        p_task_name => 'AUTO_STATS_ADVISOR_TASK',
        p_parameter => 'EXECUTION_DAYS_TO_EXPIRE',
        p_value     => '10');
END;
```

### Disabling AUTO_STATS_ADVISOR_TASK

To disable AUTO_STATS_ADVISOR_TASK, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.advisor_task_drop`. The `advisor_task_drop` procedure accepts the following parameter.

**Note**

This procedure is available in Oracle Database 12c Release 2 (12.2.0.1) and later.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_task_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the advisor task to be disabled. The only valid value is AUTO_STATS_ADVISOR_TASK.</td>
</tr>
</tbody>
</table>

The following command drops AUTO_STATS_ADVISOR_TASK.
To re-enable AUTO_STATS_ADVISOR_TASK, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.dbms_stats_init`. The `dbms_stats_init` procedure takes no parameters.

The following command re-enables AUTO_STATS_ADVISOR_TASK.

```
EXEC rdsadmin.rdsadmin_util.dbms_stats_init()
```

**Transporting tablespaces**

Use the Amazon RDS package `rdsadmin.rdsadmin_transport_util` to copy a set of tablespaces from an on-premises Oracle database to an RDS for Oracle DB instance. At the physical level, the transportable tablespace feature incrementally copies source data files and metadata files to your target instance. You can transfer the files using either Amazon EFS or Amazon S3. For more information, see Migrating using Oracle transportable tablespaces (p. 1978).

**Topics**

- Importing transported tablespaces to your DB instance (p. 1948)
- Importing transportable tablespace metadata into your DB instance (p. 1949)
- Listing orphaned files after a tablespace import (p. 1950)
- Deleting orphaned data files after a tablespace import (p. 1951)

**Importing transported tablespaces to your DB instance**

Use the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces` to restore tablespaces that you have previously exported from a source DB instance. In the transport phase, you back up your read-only tablespaces, export Data Pump metadata, transfer these files to your target DB instance, and then import the tablespaces. For more information, see Phase 4: Transport the tablespaces (p. 1983).

**Syntax**

```
FUNCTION import_xtts_tablespaces(
  p_tablespace_list IN CLOB,
  p_directory_name  IN VARCHAR2,
  p_platform_id     IN NUMBER DEFAULT 13,
  p_parallel        IN INTEGER DEFAULT 0) RETURN VARCHAR2;
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_tablespace_list</td>
<td>CLOB</td>
<td>—</td>
<td>Yes</td>
<td>The list of tablespaces to import.</td>
</tr>
<tr>
<td>p_directory_name</td>
<td>VARCHAR2</td>
<td>—</td>
<td>Yes</td>
<td>The directory that contains the tablespace backups.</td>
</tr>
</tbody>
</table>
Other tasks

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_platform_id</td>
<td>NUMBER</td>
<td>13</td>
<td>No</td>
<td>Provide a platform ID that matches the one specified during the backup phase. To find a list of platforms, query V $TRANSPORTABLE_PLATFORM. The default platform is Linux x86 64-bit, which is little endian.</td>
</tr>
<tr>
<td>p_parallel</td>
<td>INTEGER</td>
<td>0</td>
<td>No</td>
<td>The degree of parallelism. By default, parallelism is disabled.</td>
</tr>
</tbody>
</table>

Examples

The following example imports the tablespaces TBS1, TBS2, and TBS3 from the directory DATA_PUMP_DIR.

```sql
VAR task_id CLOB
BEGIN
    task_id:=rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces('TBS1,TBS2,TBS3', 'DATA_PUMP_DIR');
END;
/ 
PRINT task_id
```

Importing transportable tablespace metadata into your DB instance

Use the procedure rdsadmin.rdsadmin_transport_util.import_xtts_metadata to import transportable tablespace metadata into your RDS for Oracle DB instance. During the operation, the status of the metadata import is shown in the table rdsadmin.rds_xtts_operation_info. For more information, see Step 5: Import tablespace metadata on your target DB instance (p. 1985).

Syntax

```sql
PROCEDURE import_xtts_metadata(
    p_datapump_metadata_file IN SYS.DBA_DATA_FILES.FILE_NAME%TYPE,
    p_directory_name         IN VARCHAR2,
    p_exclude_stats          IN BOOLEAN DEFAULT FALSE,
    p_remap_tablespace_list  IN CLOB DEFAULT NULL,
    p_remap_user_list        IN CLOB DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_datapump_metadata</td>
<td>SYS.DBA_DATA_FILES.FILE_NAME%TYPE</td>
<td>Yes</td>
<td>The name of the Oracle Data Pump file that contains the metadata for your transportable tablespaces.</td>
<td></td>
</tr>
</tbody>
</table>
### Parameter names, data types, defaults, and descriptions

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_directory_name</td>
<td>VARCHAR2</td>
<td>—</td>
<td>Yes</td>
<td>The directory that contains the Data Pump file.</td>
</tr>
<tr>
<td>p_exclude_stats</td>
<td>BOOLEAN</td>
<td>FALSE</td>
<td>No</td>
<td>Flag that indicates whether to exclude statistics.</td>
</tr>
<tr>
<td>p_remap_tablespace_list</td>
<td>CLOB</td>
<td>NULL</td>
<td>No</td>
<td>A list of tablespaces to be remapped during the metadata import. Use the format from_tbs:to_tbs. For example, specify users:user_data.</td>
</tr>
<tr>
<td>p_remap_user_list</td>
<td>CLOB</td>
<td>NULL</td>
<td>No</td>
<td>A list of user schemas to be remapped during the metadata import. Use the format from_schema_name:to_schema_name. For example, specify hr:human_resources.</td>
</tr>
</tbody>
</table>

### Examples

The example imports the tablespace metadata from the file `xttdump.dmp`, which is located in directory `DATA_PUMP_DIR`.

```
BEGIN
  rdsadmin.rdsadmin_transport_util.import_xtts_metadata('xttdump.dmp','DATA_PUMP_DIR');
END;
/```  

Listing orphaned files after a tablespace import

Use the `rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files` procedure to list data files that were orphaned after a tablespace import. After you identify the data files, you can delete them by calling `rdsadmin.rdsadmin_transport_util.cleanup_incomplete_xtts_import`.

**Syntax**

```
FUNCTION list_xtts_orphan_files RETURN xtts_orphan_files_list_t PIPELINED;
```  

**Examples**

The following example runs the procedure `rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files`. The output shows two data files that are orphaned.

```
SQL> SELECT * FROM TABLE(rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files);
FILENAME  FILESIZE
---------------  ---------
1950
```
Deleting orphaned data files after a tablespace import

Use the rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files procedure to delete data files that were orphaned after a tablespace import. Running this command generates a log file that uses the name format rds-xtts-delete_xtts_orphaned_files-YYYY-MM-DD.HH24-MI-SS.FF.log in the BDUMP directory. Use the procedure rdsadmin.rdsadmin_transport_util.cleanup_incomplete_xtts_import to find the orphaned files. You can read the log file by calling the procedure rdsadmin.rds_file_util.read_text_file. For more information, see Phase 6: Clean up leftover files (p. 1986).

Syntax

PROCEDURE cleanup_incomplete_xtts_import(  
   p_directory_name IN VARCHAR2);

Parameters

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_directory_name</td>
<td>VARCHAR2</td>
<td>—</td>
<td>Yes</td>
<td>The directory that contains the orphaned data files.</td>
</tr>
</tbody>
</table>

Examples

The following example deletes the orphaned data files in DATA_PUMP_DIR.

BEGIN  
    rdsadmin.rdsadmin_transport_util.cleanup_incomplete_xtts_import('DATA_PUMP_DIR');  
END;  
/

The following example reads the log file generated by the previous command.

SELECT *  
FROM TABLE(rdsadmin.rds_file_util.read_text_file(  
   p_directory => 'BDUMP',  
   p_filename  => 'rds-xtts-delete_xtts_orphaned_files-2023-06-01-09-33-11.868894000.log'));  

TEXT  
--------------------------------------------------------------------------------  
orphan transported datafile datafile_7.dbf deleted.  
orphan transported datafile datafile_8.dbf deleted.  
--------------------------------------------------------------------------------
Configuring advanced RDS for Oracle features

RDS for Oracle supports various advanced features, including HugePages, an instance store, and extended data types.

Topics
- Storing temporary data in an RDS for Oracle instance store (p. 1952)
- Turning on HugePages for an RDS for Oracle instance (p. 1958)
- Turning on extended data types in RDS for Oracle (p. 1961)

Storing temporary data in an RDS for Oracle instance store

Use an instance store for the temporary tablespaces and the Database Smart Flash Cache (the flash cache) on supported RDS for Oracle DB instance classes.

Topics
- Overview of the RDS for Oracle instance store (p. 1952)
- Turning on an RDS for Oracle instance store (p. 1954)
- Configuring an RDS for Oracle instance store (p. 1954)
- Considerations when changing the DB instance type (p. 1956)
- Working with an instance store on an Oracle read replica (p. 1957)
- Configuring a temporary tablespace group on an instance store and Amazon EBS (p. 1957)
- Removing an RDS for Oracle instance store (p. 1958)

Overview of the RDS for Oracle instance store

An instance store provides temporary block-level storage for an RDS for Oracle DB instance. You can use an instance store for temporary storage of information that changes frequently.

An instance store is based on Non-Volatile Memory Express (NVMe) devices that are physically attached to the host computer. The storage is optimized for low latency, random I/O performance, and sequential read throughput.

The size of the instance store varies by DB instance type. For more information about the instance store, see Amazon EC2 instance store in the Amazon Elastic Compute Cloud User Guide for Linux Instances.

Topics
- Types of data in the RDS for Oracle instance store (p. 1952)
- Benefits of the RDS for Oracle instance store (p. 1953)
- Supported instance classes for the RDS for Oracle instance store (p. 1953)
- Supported engine versions for the RDS for Oracle instance store (p. 1954)
- Supported AWS Regions for the RDS for Oracle instance store (p. 1954)
- Cost of the RDS for Oracle instance store (p. 1954)

Types of data in the RDS for Oracle instance store

You can place the following types of RDS for Oracle temporary data in an instance store:
A temporary tablespace

Oracle Database uses temporary tablespaces to store intermediate query results that don't fit in memory. Larger queries can generate large amounts of intermediate data that needs to be cached temporarily, but doesn't need to persist. In particular, a temporary tablespace is useful for sorts, hash aggregations, and joins. If your RDS for Oracle DB instance uses the Enterprise Edition or Standard Edition 2, you can place a temporary tablespace in an instance store.

The flash cache

The flash cache improves the performance of single-block random reads in the conventional path. A best practice is to size the cache to accommodate most of your active data set. If your RDS for Oracle DB instance uses the Enterprise Edition, you can place the flash cache in an instance store.

By default, an instance store is configured for a temporary tablespace but not for the flash cache. You can't place Oracle data files and database log files in an instance store.

Benefits of the RDS for Oracle instance store

You might consider using an instance store to store temporary files and caches that you can afford to lose. If you want to improve DB performance, or if an increasing workload is causing performance problems for your Amazon EBS storage, consider scaling to an instance class that supports an instance store.

By placing your temporary tablespace and flash cache on an instance store, you get the following benefits:

• Lower read latencies
• Higher throughput
• Reduced load on your Amazon EBS volumes
• Lower storage and snapshot costs because of reduced Amazon EBS load
• Less need to provision high IOPS, possibly lowering your overall cost

By placing your temporary tablespace on the instance store, you deliver an immediate performance boost to queries that use temporary space. When you place the flash cache on the instance store, cached block reads typically have much lower latency than Amazon EBS reads. The flash cache needs to be "warmed up" before it delivers performance benefits. The cache warms up by itself because the database writes blocks to the flash cache as they age out of the database buffer cache.

**Note**

In some cases, the flash cache causes performance overhead because of cache management. Before you turn on the flash cache in a production environment, we recommend that you analyze your workload and test the cache in a test environment.

Supported instance classes for the RDS for Oracle instance store

Amazon RDS supports the instance store for the following DB instance classes:

• `db.m5d`
• `db.r5d`
• `db.x2idn`
• `db.x2iedn`

RDS for Oracle supports the preceding DB instance classes for the BYOL licensing model only. For more information, see [Supported RDS for Oracle instance classes](p. 1813) and [Bring Your Own License (BYOL)](p. 1809).
To see the total instance storage for the supported DB instance types, run the following command in the AWS CLI.

Example

```bash
aws ec2 describe-instance-types
  --filters "Name=instance-type,Values=*5d.*large*"
  --query "InstanceTypes[?contains(InstanceType,'m5d')||contains(InstanceType,'r5d')]
  [InstanceType, InstanceStorageInfo.TotalSizeInGB]"
  --output table
```

The preceding command returns the raw device size for the instance store. RDS for Oracle uses a small portion of this space for configuration. The space in the instance store that is available for temporary tablespaces or the flash cache is slightly smaller.

**Supported engine versions for the RDS for Oracle instance store**

The instance store is supported for the following RDS for Oracle engine versions:

- 21.0.0.0.ru-2022-01.rur-2022-01.r1 or higher Oracle Database 21c versions
- 19.0.0.0.ru-2021-10.rur-2021-10.r1 or higher Oracle Database 19c versions

**Supported AWS Regions for the RDS for Oracle instance store**

The instance store is available in all AWS Regions where one or more of these instance types are supported. For more information about the db.m5d and db.r5d instance classes, see [DB instance classes](p. 11). For more information on the instance classes supported by Amazon RDS for Oracle, see [RDS for Oracle instance classes](p. 1812).

**Cost of the RDS for Oracle instance store**

The cost of the instance store is built into the cost of the instance-store turned on instances. You don't incur additional costs by enabling an instance store on an RDS for Oracle DB instance. For more information about instance-store turned on instances, see [Supported instance classes for the RDS for Oracle instance store](p. 1953).

**Turning on an RDS for Oracle instance store**

To turn on the instance store for RDS for Oracle temporary data, do one of the following:

- Create an RDS for Oracle DB instance using a supported instance class. For more information, see [Creating an Amazon RDS DB instance](p. 300).
- Modify an existing RDS for Oracle DB instance to use a supported instance class. For more information, see [Modifying an Amazon RDS DB instance](p. 401).

**Configuring an RDS for Oracle instance store**

By default, 100% of instance store space is allocated to the temporary tablespace. To configure the instance store to allocate space to the flash cache and temporary tablespace, set the following parameters in the parameter group for your instance:

```sql
    db_flash_cache_size=(DBInstanceStore*{0,2,4,6,8,10}/10)
```

This parameter specifies the amount of storage space allocated for the flash cache. This parameter is valid only for Oracle Database Enterprise Edition. The default value is \(DBInstanceStore*0/10\). If you set a nonzero value for `db_flash_cache_size`, your RDS for Oracle instance enables the flash cache after you restart the instance.
### rds.instance_store_temp_size={DBInstanceStore*{0,2,4,6,8,10}/10}

This parameter specifies the amount of storage space allocated for the temporary tablespace. The default value is {DBInstanceStore*10/10}. This parameter is modifiable for Oracle Database Enterprise Edition and read-only for Standard Edition 2. If you set a nonzero value for rds.instance_store_temp_size, Amazon RDS allocates space in the instance store for the temporary tablespace.

You can set the db_flash_cache_size and rds.instance_store_temp_size parameters for DB instances that don't use an instance store. In this case, both settings evaluate to 0, which turns off the feature. In this case, you can use the same parameter group for different instance sizes and for instances that don't use an instance store. If you modify these parameters, make sure to reboot the associated instances so that the changes can take effect.

**Important**

If you allocate space for a temporary tablespace, Amazon RDS doesn't create the temporary tablespace automatically. To learn how to create the temporary tablespace on the instance store, see [Creating a temporary tablespace on the instance store](p. 1887).

The combined value of the preceding parameters must not exceed 10/10, or 100%. The following table illustrates valid and invalid parameter settings.

<table>
<thead>
<tr>
<th>db_flash_cache_size setting</th>
<th>rds.instance_store_temp_size setting</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>db_flash_cache_size={DBInstanceStore*0/10}</td>
<td>rds.instance_store_temp_size={DBInstanceStore*10/10}</td>
<td>This is a valid configuration for all editions of Oracle Database. Amazon RDS allocates 100% of instance store space to the temporary tablespace. This is the default.</td>
</tr>
<tr>
<td>db_flash_cache_size={DBInstanceStore*10/10}</td>
<td>rds.instance_store_temp_size={DBInstanceStore*0/10}</td>
<td>This is a valid configuration for Oracle Database Enterprise Edition only. Amazon RDS allocates 100% of instance store space to the flash cache.</td>
</tr>
<tr>
<td>db_flash_cache_size={DBInstanceStore*2/10}</td>
<td>rds.instance_store_temp_size={DBInstanceStore*8/10}</td>
<td>This is a valid configuration for Oracle Database Enterprise Edition only. Amazon RDS allocates 20% of instance store space to the flash cache, and 80% of instance store space to the temporary tablespace.</td>
</tr>
</tbody>
</table>
### Configuring the instance store

<table>
<thead>
<tr>
<th><code>db_flash_cache_size</code> setting</th>
<th><code>rds.instance_store_temp_size</code> setting</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db_flash_cache_size={DBInstanceStore*6/10}</code></td>
<td><code>instance_store_temp_size={DBInstanceStore*4/10}</code></td>
<td>This is a valid configuration for Oracle Database Enterprise Edition only. Amazon RDS allocates 60% of instance store space to the flash cache, and 40% of instance store space to the temporary tablespace.</td>
</tr>
<tr>
<td><code>db_flash_cache_size={DBInstanceStore*2/10}</code></td>
<td><code>instance_store_temp_size={DBInstanceStore*4/10}</code></td>
<td>This is a valid configuration for Oracle Database Enterprise Edition only. Amazon RDS allocates 20% of instance store space to the flash cache, and 40% of instance store space to the temporary tablespace.</td>
</tr>
<tr>
<td><code>db_flash_cache_size={DBInstanceStore*8/10}</code></td>
<td><code>instance_store_temp_size={DBInstanceStore*8/10}</code></td>
<td>This is an invalid configuration because the combined percentage of instance store space exceeds 100%. In such cases, Amazon RDS fails the attempt.</td>
</tr>
</tbody>
</table>

### Considerations when changing the DB instance type

If you change your DB instance type, it can affect the configuration of the flash cache or the temporary tablespace on the instance store. Consider the following modifications and their effects:

**You scale up or scale down the DB instance that supports the instance store.**

The following values increase or decrease proportionally to the new size of the instance store:
- The new size of the flash cache.
- The space allocated to the temporary tablespaces that reside in the instance store.

For example, the setting `db_flash_cache_size={DBInstanceStore*6/10}` on a `db.m5d.4xlarge` instance provides around 340 GB of flash cache space. If you scale up the instance type to `db.m5d.8xlarge`, the flash cache space increases to around 680 GB.
You modify a DB instance that doesn't use an instance store to an instance that does use an instance store.

If `db_flash_cache_size` is set to a value larger than 0, the flash cache is configured. If `rds.instance_store_temp_size` is set to a value larger than 0, the instance store space is allocated for use by a temporary tablespace. RDS for Oracle doesn't move tempfiles to the instance store automatically. For information about using the allocated space, see Configuring a temporary tablespace on the instance store (p. 1887) or Adding a tempfile to the instance store on a read replica (p. 1888).

You modify a DB instance that uses an instance store to an instance that doesn't use an instance store.

In this case, RDS for Oracle removes the flash cache. RDS re-creates the tempfile that is currently located on the instance store on an Amazon EBS volume. The maximum size of the new tempfile is the former size of the `rds.instance_store_temp_size` parameter.

## Working with an instance store on an Oracle read replica

Read replicas support the flash cache and temporary tablespaces on an instance store. While the flash cache works the same way as on the primary DB instance, note the following differences for temporary tablespaces:

- You can't create a temporary tablespace on a read replica. If you create a new temporary tablespace on the primary instance, RDS for Oracle replicates the tablespace information without tempfiles. To add a new tempfile, use either of the following techniques:
  - Use the Amazon RDS procedure `rdsadmin.rdsadmin_util.add_inst_store_tempfile`. RDS for Oracle creates a tempfile in the instance store on your read replica, and adds it to the specified temporary tablespace.
  - Run the `ALTER TABLESPACE ... ADD TEMPFILE` command. RDS for Oracle places the tempfile on Amazon EBS storage.

  **Note**
  The tempfile sizes and storage types can be different on the primary DB instance and the read replica.

- You can manage the default temporary tablespace setting only on the primary DB instance. RDS for Oracle replicates the setting to all read replicas.
- You can configure the temporary tablespace groups only on the primary DB instance. RDS for Oracle replicates the setting to all read replicas.

## Configuring a temporary tablespace group on an instance store and Amazon EBS

You can configure a temporary tablespace group to include temporary tablespaces on both an instance store and Amazon EBS. This technique is useful when you want more temporary storage than is allowed by the maximum setting of `rds.instance_store_temp_size`.

When you configure a temporary tablespace group on both an instance store and Amazon EBS, the two tablespaces have significantly different performance characteristics. Oracle Database chooses the tablespace to serve queries based on an internal algorithm. Therefore, similar queries can vary in performance.

Typically, you create a temporary tablespace in the instance store as follows:

1. Create a temporary tablespace in the instance store.
2. Set the new tablespace as the database default temporary tablespace.
If the tablespace size in the instance store is insufficient, you can create additional temporary storage as follows:

1. Assign the temporary tablespace in the instance store to a temporary tablespace group.
2. Create a new temporary tablespace in Amazon EBS if one doesn't exist.
3. Assign the temporary tablespace in Amazon EBS to the same tablespace group that includes the instance store tablespace.
4. Set the tablespace group as the default temporary tablespace.

The following example assumes that the size of the temporary tablespace in the instance store doesn't meet your application requirements. The example creates the temporary tablespace temp_in_inst_store in the instance store, assigns it to tablespace group temp_group, adds the existing Amazon EBS tablespace named temp_in_ebs to this group, and sets this group as the default temporary tablespace.

```
SQL> EXEC rdsadmin.rdsadmin_util.create_inst_store_tmp_tblspace('temp_in_inst_store');
PL/SQL procedure successfully completed.
SQL> ALTER TABLESPACE temp_in_inst_store TABLESPACE GROUP temp_group;
Tablespace altered.
SQL> ALTER TABLESPACE temp_in_ebs TABLESPACE GROUP temp_group;
Tablespace altered.
SQL> EXEC rdsadmin.rdsadmin_util.alter_default_temp_tablespace('temp_group');
PL/SQL procedure successfully completed.
SQL> SELECT * FROM DBA_TABLESPACE_GROUPS;
GROUP_NAME                     TABLESPACE_NAME
------------------------------ ------------------------------
TEMP_GROUP                     TEMP_IN_EBS
TEMP_GROUP                     TEMP_IN_INST_STORE
```

Removing an RDS for Oracle instance store

To remove the instance store, modify your RDS for Oracle DB instance to use an instance type that doesn't support instance store, such as db.m5 or db.r5.

Turning on HugePages for an RDS for Oracle instance

Amazon RDS for Oracle supports Linux kernel HugePages for increased database scalability. HugePages results in smaller page tables and less CPU time spent on memory management, increasing the performance of large database instances. For more information, see Overview of HugePages in the Oracle documentation.

You can use HugePages with all supported versions and editions of RDS for Oracle.
The `use_large_pages` parameter controls whether HugePages are turned on for a DB instance. The possible settings for this parameter are `ONLY`, `FALSE`, and `{DBInstanceClassHugePagesDefault}`. The `use_large_pages` parameter is set to `{DBInstanceClassHugePagesDefault}` in the default DB parameter group for Oracle.

To control whether HugePages are turned on for a DB instance automatically, you can use the `DBInstanceClassHugePagesDefault` formula variable in parameter groups. The value is determined as follows:

- For the DB instance classes mentioned in the table following, `DBInstanceClassHugePagesDefault` always evaluates to `FALSE` by default, and `use_large_pages` evaluates to `FALSE`. You can turn on HugePages manually for these DB instance classes if the DB instance class has at least 14 GiB of memory.
- For DB instance classes not mentioned in the table following, if the DB instance class has less than 14 GiB of memory, `DBInstanceClassHugePagesDefault` always evaluates to `FALSE`. Also, `use_large_pages` evaluates to `FALSE`.
- For DB instance classes not mentioned in the table following, if the instance class has at least 14 GiB of memory and less than 100 GiB of memory, `DBInstanceClassHugePagesDefault` evaluates to `TRUE` by default. Also, `use_large_pages` evaluates to `ONLY`. You can turn off HugePages manually by setting `use_large_pages` to `FALSE`.
- For DB instance classes not mentioned in the table following, if the instance class has at least 100 GiB of memory, `DBInstanceClassHugePagesDefault` always evaluates to `TRUE`. Also, `use_large_pages` evaluates to `ONLY` and HugePages can't be disabled.

HugePages are not turned on by default for the following DB instance classes.

<table>
<thead>
<tr>
<th>DB instance class family</th>
<th>DB instance classes with HugePages not turned on by default</th>
</tr>
</thead>
<tbody>
<tr>
<td>db.m5</td>
<td>db.m5.large</td>
</tr>
<tr>
<td>db.m4</td>
<td>db.m4.large, db.m4.xlarge, db.m4.2xlarge, db.m4.4xlarge, db.m4.10xlarge</td>
</tr>
<tr>
<td>db.t3</td>
<td>db.t3.micro, db.t3.small, db.t3.medium, db.t3.large</td>
</tr>
</tbody>
</table>

For more information about DB instance classes, see [Hardware specifications for DB instance classes](p. 87).

To turn on HugePages for new or existing DB instances manually, set the `use_large_pages` parameter to `ONLY`. You can't use HugePages with Oracle Automatic Memory Management (AMM). If you set the parameter `use_large_pages` to `ONLY`, then you must also set both `memory_target` and `memory_max_target` to 0. For more information about setting DB parameters for your DB instance, see [Working with parameter groups](p. 347).

You can also set the `sga_target`, `sga_max_size`, and `pga_aggregate_target` parameters. When you set system global area (SGA) and program global area (PGA) memory parameters, add the values together. Subtract this total from your available instance memory (`DBInstanceClassMemory`) to determine the free memory beyond the HugePages allocation. You must leave free memory of at least 2 GiB, or 10 percent of the total available instance memory, whichever is smaller.

After you configure your parameters, you must reboot your DB instance for the changes to take effect. For more information, see [Rebooting a DB instance](p. 436).

**Note**

The Oracle DB instance defers changes to SGA-related initialization parameters until you reboot the instance without failover. In the Amazon RDS console, choose **Reboot** but do not choose **Failover**.
Reboot with failover. In the AWS CLI, call the `reboot-db-instance` command with the `--no-force-failover` parameter. The DB instance does not process the SGA-related parameters during failover or during other maintenance operations that cause the instance to restart.

The following is a sample parameter configuration for HugePages that enables HugePages manually. You should set the values to meet your needs.

```
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>memory_target</td>
<td>0</td>
</tr>
<tr>
<td>memory_max_target</td>
<td>0</td>
</tr>
<tr>
<td>pga_aggregate_target</td>
<td>{DBInstanceClassMemory*1/8}</td>
</tr>
<tr>
<td>sga_target</td>
<td>{DBInstanceClassMemory*3/4}</td>
</tr>
<tr>
<td>sga_max_size</td>
<td>{DBInstanceClassMemory*5/4}</td>
</tr>
<tr>
<td>use_large_pages</td>
<td>ONLY</td>
</tr>
</tbody>
</table>
```

Assume the following parameters values are set in a parameter group.

```
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>memory_target</td>
<td>IF({DBInstanceClassHugePagesDefault}, 0, {DBInstanceClassMemory*3/4})</td>
</tr>
<tr>
<td>memory_max_target</td>
<td>IF({DBInstanceClassHugePagesDefault}, 0, {DBInstanceClassMemory*3/4})</td>
</tr>
<tr>
<td>pga_aggregate_target</td>
<td>IF({DBInstanceClassHugePagesDefault}, {DBInstanceClassMemory*1/8}, 0)</td>
</tr>
<tr>
<td>sga_target</td>
<td>IF({DBInstanceClassHugePagesDefault}, {DBInstanceClassMemory*3/4}, 0)</td>
</tr>
<tr>
<td>sga_max_size</td>
<td>IF({DBInstanceClassHugePagesDefault}, {DBInstanceClassMemory*5/4}, 0)</td>
</tr>
<tr>
<td>use_large_pages</td>
<td>{DBInstanceClassHugePagesDefault}</td>
</tr>
</tbody>
</table>
```

The parameter group is used by a db.r4 DB instance class with less than 100 GiB of memory. With these parameter settings and `use_large_pages` set to `{DBInstanceClassHugePagesDefault}`, HugePages are turned on for the db.r4 instance.

Consider another example with following parameters values set in a parameter group.

```
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>memory_target</td>
<td>IF({DBInstanceClassHugePagesDefault}, 0, {DBInstanceClassMemory*3/4})</td>
</tr>
<tr>
<td>memory_max_target</td>
<td>IF({DBInstanceClassHugePagesDefault}, 0, {DBInstanceClassMemory*3/4})</td>
</tr>
<tr>
<td>pga_aggregate_target</td>
<td>IF({DBInstanceClassHugePagesDefault}, {DBInstanceClassMemory*1/8}, 0)</td>
</tr>
<tr>
<td>sga_target</td>
<td>IF({DBInstanceClassHugePagesDefault}, {DBInstanceClassMemory*3/4}, 0)</td>
</tr>
<tr>
<td>sga_max_size</td>
<td>IF({DBInstanceClassHugePagesDefault}, {DBInstanceClassMemory*5/4}, 0)</td>
</tr>
<tr>
<td>use_large_pages</td>
<td>FALSE</td>
</tr>
</tbody>
</table>
```

The parameter group is used by a db.r4 DB instance class and a db.r5 DB instance class, both with less than 100 GiB of memory. With these parameter settings, HugePages are turned off on the db.r4 and db.r5 instance.

Note

If this parameter group is used by a db.r4 DB instance class or db.r5 DB instance class with at least 100 GiB of memory, the FALSE setting for `use_large_pages` is overridden and set to ONLY. In this case, a customer notification regarding the override is sent.

After HugePages are active on your DB instance, you can view HugePages information by enabling enhanced monitoring. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 797).
Turning on extended data types in RDS for Oracle

Amazon RDS for Oracle supports extended data types. With extended data types, the maximum size is 32,767 bytes for the VARCHAR2, NVARCHAR2, and RAW data types. To use extended data types, set the MAX_STRING_SIZE parameter to EXTENDED. For more information, see Extended data types in the Oracle documentation.

If you don’t want to use extended data types, keep the MAX_STRING_SIZE parameter set to STANDARD (the default). In this case, the size limits are 4,000 bytes for the VARCHAR2 and NVARCHAR2 data types, and 2,000 bytes for the RAW data type.

You can turn on extended data types on a new or existing DB instance. For new DB instances, DB instance creation time is typically longer when you turn on extended data types. For existing DB instances, the DB instance is unavailable during the conversion process.

Considerations for extended data types

Consider the following when you enable extended data types for your DB instance:

- When you turn on extended data types, you can't change the DB instance back to use the standard size for data types. After a DB instance is converted to use extended data types, if you set the MAX_STRING_SIZE parameter back to STANDARD it results in the incompatible-parameters status.
- When you restore a DB instance that uses extended data types, you must specify a parameter group with the MAX_STRING_SIZE parameter set to EXTENDED. During restore, if you specify the default parameter group or any other parameter group with MAX_STRING_SIZE set to STANDARD it results in the incompatible-parameters status.
- When the DB instance status is incompatible-parameters because of the MAX_STRING_SIZE setting, the DB instance remains unavailable until you set the MAX_STRING_SIZE parameter to EXTENDED and reboot the DB instance.
- We recommend that you don't turn on extended data types for Oracle DB instances running on the t2.micro DB instance class.

Turning on extended data types for a new DB instance

To turn on extended data types for a new DB instance

1. Set the MAX_STRING_SIZE parameter to EXTENDED in a parameter group.
   
   To set the parameter, you can either create a new parameter group or modify an existing parameter group.

   For more information, see Working with parameter groups (p. 347).

2. Create a new RDS for Oracle DB instance.

   For more information, see Creating an Amazon RDS DB instance (p. 300).

3. Associate the parameter group with MAX_STRING_SIZE set to EXTENDED with the DB instance.

   For more information, see Creating an Amazon RDS DB instance (p. 300).
Turning on extended data types for an existing DB instance

When you modify a DB instance to turn on extended data types, RDS converts the data in the database to use the extended sizes. The conversion and downtime occur when you next reboot the database after the parameter change. The DB instance is unavailable during the conversion.

The amount of time it takes to convert the data depends on the DB instance class, the database size, and the time of the last DB snapshot. To reduce downtime, consider taking a snapshot immediately before rebooting. This shortens the time of the backup that occurs during the conversion workflow.

**Note**
After you turn on extended data types, you can't perform a point-in-time restore to a time during the conversion. You can restore to the time immediately before the conversion or after the conversion.

**To turn on extended data types for an existing DB instance**

1. Take a snapshot of the database.

   If there are invalid objects in the database, Amazon RDS tries to recompile them. The conversion to extended data types can fail if Amazon RDS can't recompile an invalid object. The snapshot enables you to restore the database if there is a problem with the conversion. Always check for invalid objects before conversion and fix or drop those invalid objects. For production databases, we recommend testing the conversion process on a copy of your DB instance first.

   For more information, see [Creating a DB snapshot](p. 613).

2. Set the `MAX_STRING_SIZE` parameter to `EXTENDED` in a parameter group.

   To set the parameter, you can either create a new parameter group or modify an existing parameter group.

   For more information, see [Working with parameter groups](p. 347).

3. Modify the DB instance to associate it with the parameter group with `MAX_STRING_SIZE` set to `EXTENDED`.

   For more information, see [Modifying an Amazon RDS DB instance](p. 401).

4. Reboot the DB instance for the parameter change to take effect.

   For more information, see [Rebooting a DB instance](p. 436).
Importing data into Oracle on Amazon RDS

How you import data into an Amazon RDS for Oracle DB instance depends on the following:

- The amount of data you have
- The number of database objects in your database
- The variety of database objects in your database

For example, you can use the following tools, depending on your requirements:

- Oracle SQL Developer – Import a simple, 20 MB database.
- Oracle Data Pump – Import complex databases, or databases that are several hundred megabytes or several terabytes in size. For example, you can transport tablespaces from an on-premises database to your RDS for Oracle DB instance. You can use Amazon S3 or Amazon EFS to transfer the data files and metadata. For more information, see Migrating using Oracle transportable tablespaces (p. 1978), Amazon EFS integration (p. 2036), and Amazon S3 integration (p. 2008).
- AWS Database Migration Service (AWS DMS) – Migrate databases without downtime. For more information about AWS DMS, see What is AWS Database Migration Service and the blog post Migrating Oracle databases with near-zero downtime using AWS DMS.

**Important**
Before you use the preceding migration techniques, we recommend that you back up your database. After you import the data, you can back up your RDS for Oracle DB instances by creating snapshots. Later, you can restore the snapshots. For more information, see Backing up and restoring (p. 590).

For many database engines, ongoing replication can continue until you are ready to switch over to the target database. You can use AWS DMS to migrate to RDS for Oracle from either the same database engine or a different engine. If you migrate from a different database engine, you can use the AWS Schema Conversion Tool to migrate schema objects that AWS DMS doesn't migrate.

**Topics**

- Importing using Oracle SQL Developer (p. 1963)
- Importing using Oracle Data Pump (p. 1964)
- Importing using Oracle Export/Import (p. 1975)
- Importing using Oracle SQL*Loader (p. 1975)
- Migrating with Oracle materialized views (p. 1976)
- Migrating using Oracle transportable tablespaces (p. 1978)

**Importing using Oracle SQL Developer**

For small databases, you can use Oracle SQL Developer, a graphical Java tool distributed without cost by Oracle. You can install this tool on your desktop computer (Windows, Linux, or Mac) or on one of your servers. SQL Developer provides options for migrating data between two Oracle databases, or for migrating data from other databases, such as MySQL, to an Oracle database. SQL Developer is best suited for migrating small databases. We recommend that you read the Oracle SQL Developer product documentation before you begin migrating your data.

After you install SQL Developer, you can use it to connect to your source and target databases. Use the **Database Copy** command on the Tools menu to copy your data to your Amazon RDS instance.

Oracle also has documentation on how to migrate from other databases, including MySQL and SQL Server. For more information, see http://www.oracle.com/technetwork/database/migration in the Oracle documentation.

Importing using Oracle Data Pump

Oracle Data Pump is a utility that allows you to export Oracle data to a dump file and import it into another Oracle database. It is a long-term replacement for the Oracle Export/Import utilities. Oracle Data Pump is the recommended way to move large amounts of data from an Oracle database to an Amazon RDS DB instance.

The examples in this section show one way to import data into an Oracle database, but Oracle Data Pump supports other techniques. For more information, see the Oracle Database documentation.

The examples in this section use the DBMS_DATAPUMP package. You can accomplish the same tasks using the Oracle Data Pump command line utilities impdp and expdp. You can install these utilities on a remote host as part of an Oracle Client installation, including Oracle Instant Client. For more information, see How do I use Oracle Instant Client to run Data Pump Import or Export for my Amazon RDS for Oracle DB instance?

Topics
- Overview of Oracle Data Pump (p. 1964)
- Importing data with Oracle Data Pump and an Amazon S3 bucket (p. 1966)
- Importing data with Oracle Data Pump and a database link (p. 1970)

Overview of Oracle Data Pump

Oracle Data Pump is made up of the following components:

- Command-line clients expdp and impdp
- The DBMS_DATAPUMP PL/SQL package
- The DBMS_METADATA PL/SQL package

You can use Oracle Data Pump for the following scenarios:

- Import data from an Oracle database, either on-premises or on an Amazon EC2 instance, to an RDS for Oracle DB instance.
- Import data from an RDS for Oracle DB instance to an Oracle database, either on-premises or on an Amazon EC2 instance.
- Import data between RDS for Oracle DB instances, for example, to migrate data from EC2-Classic to VPC.

To download Oracle Data Pump utilities, see Oracle database software downloads on the Oracle Technology Network website. For compatibility considerations when migrating between versions of Oracle Database, see the Oracle Database documentation.

Oracle Data Pump workflow

Typically, you use Oracle Data Pump in the following stages:

1. Export your data into a dump file on the source database.
2. Upload your dump file to your destination RDS for Oracle DB instance. You can transfer using an Amazon S3 bucket or by using a database link between the two databases.

3. Import the data from your dump file into your RDS for Oracle DB instance.

**Oracle Data Pump best practices**

When you use Oracle Data Pump to import data into an RDS for Oracle instance, we recommend the following best practices:

- Perform imports in schema or table mode to import specific schemas and objects.
- Limit the schemas you import to those required by your application.
- Don't import in full mode or import schemas for system-maintained components.

Because RDS for Oracle doesn't allow access to SYS or SYSDBA administrative users, these actions might damage the Oracle data dictionary and affect the stability of your database.

- When loading large amounts of data, do the following:
  1. Transfer the dump file to the target RDS for Oracle DB instance.
  2. Take a DB snapshot of your instance.
  3. Test the import to verify that it succeeds.

  If database components are invalidated, you can delete the DB instance and re-create it from the DB snapshot. The restored DB instance includes any dump files staged on the DB instance when you took the DB snapshot.

- Don't import dump files that were created using the Oracle Data Pump export parameters TRANSFER_TABLESPACES, TRANSPORTABLE, or TRANSPORT_FULL_CHECK. RDS for Oracle DB instances don't support importing these dump files.

- Don't import dump files that contain Oracle Scheduler objects in SYS, SYSTEM, RDSADMIN, RDSSEC, and RDS_DATAGUARD, and belong to the following categories:
  - Jobs
  - Programs
  - Schedules
  - Chains
  - Rules
  - Evaluation contexts
  - Rule sets

RDS for Oracle DB instances don't support importing these dump files.

- To exclude unsupported Oracle Scheduler objects, use additional directives during the Data Pump export. If you use DBMS_DATAPUMP, you can add an additional METADATA_FILTER before the DBMS_METADATA.START_JOB:

```sql
DBMS_DATAPUMP.METADATA_FILTER(
  v_hdnl,
  'EXCLUDE_NAME_EXPR',
  q'IN (SELECT NAME FROM SYS.OBJ$
    WHERE TYPE# IN (66,67,74,79,59,62,46)
    AND OWNER# IN
      (SELECT USER# FROM SYS.USER$
        WHERE NAME IN ('RDSADMIN','SYS','SYSTEM','RDS_DATAGUARD','RDSSEC')
      )
  )',
  'PROCOBJ'
)
```
If you use expdp, create a parameter file that contains the exclude directive shown in the following example. Then use PARFILE=\texttt{parameter\_file} with your expdp command.

```
exclude=procobj:"IN
(SELECT NAME FROM sys.OBJ$
 WHERE TYPE# IN (66,67,74,79,59,62,46)
 AND OWNER# IN
 (SELECT USER# FROM SYS.USER$
   WHERE NAME IN ('RDSADMIN','SYS','SYSTEM','RDS_DATAGUARD','RDSSEC')
 )
)"
```

### Importing data with Oracle Data Pump and an Amazon S3 bucket

The following import process uses Oracle Data Pump and an Amazon S3 bucket. The steps are as follows:

1. Export data on the source database using the Oracle \texttt{DBMS\_DATAPUMP} package.
2. Place the dump file in an Amazon S3 bucket.
3. Download the dump file from the Amazon S3 bucket to the \texttt{DATA\_PUMP\_DIR} directory on the target RDS for Oracle DB instance.
4. Import the data from the copied dump file into the RDS for Oracle DB instance using the package \texttt{DBMS\_DATAPUMP}.

### Topics

- Requirements for Importing data with Oracle Data Pump and an Amazon S3 bucket (p. 1966)
- Step 1: Grant privileges to the database user on the RDS for Oracle target DB instance (p. 1967)
- Step 2: Export data into a dump file using \texttt{DBMS\_DATAPUMP} (p. 1967)
- Step 3: Upload the dump file to your Amazon S3 bucket (p. 1968)
- Step 4: Download the dump file from your Amazon S3 bucket to your target DB instance (p. 1969)
- Step 5: Import your dump file into your target DB instance using \texttt{DBMS\_DATAPUMP} (p. 1969)
- Step 6: Clean up (p. 1970)

### Requirements for Importing data with Oracle Data Pump and an Amazon S3 bucket

The process has the following requirements:

- Make sure that an Amazon S3 bucket is available for file transfers, and that the Amazon S3 bucket is in the same AWS Region as the DB instance. For instructions, see [Create a bucket](https://docs.aws.amazon.com/AmazonS3/latest/userguide/create-a-bucket.html) in the Amazon Simple Storage Service Getting Started Guide.

- The object that you upload into the Amazon S3 bucket must be 5 TB or less. For more information about working with objects in Amazon S3, see Amazon Simple Storage Service User Guide.

**Note**

If you dump file exceeds 5 TB, you can run the Oracle Data Pump export with the parallel option. This operation spreads the data into multiple dump files so that you do not exceed the 5 TB limit for individual files.
You must prepare the Amazon S3 bucket for Amazon RDS integration by following the instructions in Configuring IAM permissions for RDS for Oracle integration with Amazon S3 (p. 2008).

You must ensure that you have enough storage space to store the dump file on the source instance and the target DB instance.

**Note**
This process imports a dump file into the DATA_PUMP_DIR directory, a preconfigured directory on all Oracle DB instances. This directory is located on the same storage volume as your data files. When you import the dump file, the existing Oracle data files use more space. Thus, you should make sure that your DB instance can accommodate that additional use of space. The imported dump file is not automatically deleted or purged from the DATA_PUMP_DIR directory. To remove the imported dump file, use UTL_FILE.FREMOVE, found on the Oracle website.

**Step 1: Grant privileges to the database user on the RDS for Oracle target DB instance**

In this step, you create the schemas into which you plan to import data and grant the users necessary privileges.

**To create users and grant necessary privileges on the RDS for Oracle target instance**

1. Use SQL*Plus or Oracle SQL Developer to log in as the master user to the RDS for Oracle DB instance into which the data will be imported. For information about connecting to a DB instance, see Connecting to your RDS for Oracle DB instance (p. 1822).
2. Create the required tablespaces before you import the data. For more information, see Creating and sizing tablespaces (p. 1886).
3. Create the user account and grant the necessary permissions and roles if the user account into which the data is imported doesn’t exist. If you plan to import data into multiple user schemas, create each user account and grant the necessary privileges and roles to it.

For example, the following SQL statements create a new user and grant the necessary permissions and roles to import the data into the schema owned by this user. Replace `schema_1` with the name of your schema in this step and in the following steps.

```sql
CREATE USER schema_1 IDENTIFIED BY my_password;
GRANT CREATE SESSION, RESOURCE TO schema_1;
ALTER USER schema_1 QUOTA 100M ON users;
```

**Note**
Specify a password other than the prompt shown here as a security best practice.

The preceding statements grant the new user the CREATE SESSION privilege and the RESOURCE role. You might need additional privileges and roles depending on the database objects that you import.

**Step 2: Export data into a dump file using DBMS_DATAPUMP**

To create a dump file, use the DBMS_DATAPUMP package.

**To export Oracle data into a dump file**

1. Use SQL*Plus or Oracle SQL Developer to connect to the source RDS for Oracle DB instance with an administrative user. If the source database is an RDS for Oracle DB instance, connect with the Amazon RDS master user.
2. Export the data by calling DBMS_DATAPUMP procedures.
The following script exports the `SCHEMA_1` schema into a dump file named `sample.dmp` in the `DATA_PUMP_DIR` directory. Replace `SCHEMA_1` with the name of the schema that you want to export.

```sql
DECLARE
  v_hdnl NUMBER;
BEGIN
  v_hdnl := DBMS_DATAPUMP.OPEN(
    operation => 'EXPORT',
    job_mode  => 'SCHEMA',
    job_name  => null);
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'sample.dmp',
    directory => 'DATA_PUMP_DIR',
    filetype  => dbms_datapump.ku$_file_type_dump_file);
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'sample_exp.log',
    directory => 'DATA_PUMP_DIR',
    filetype  => dbms_datapump.ku$_file_type_log_file);
  DBMS_DATAPUMP.METADATA_FILTER(v_hdnl,'SCHEMA_EXPR','IN (''
    SCHEMA_1'')));
  DBMS_DATAPUMP.METADATA_FILTER(v_hdnl,'EXCLUDE_NAME_EXPR',
q'IN (SELECT NAME FROM SYS.OBJ$'
    WHERE TYPE# IN (66,67,74,79,59,62,46)
    AND OWNER# IN
    (SELECT USER# FROM SYS.USER$'
    WHERE NAME IN ('RDSADMIN','SYS','SYSTEM','RDS_DATAGUARD','RDSSEC')
    )
    ]',
    'PROCOBJ');
DBMS_DATAPUMP.START_JOB(v_hdnl);
END;
/
```

**Note**
Data Pump starts jobs asynchronously. For information about monitoring a Data Pump job, see [Monitoring job status](#) in the Oracle documentation.

3. (Optional) View the contents of the export log by calling the `rdsadmin.rds_file_util.read_text_file` procedure. For more information, see Reading files in a DB instance directory (p. 1943).

**Step 3: Upload the dump file to your Amazon S3 bucket**

Use the Amazon RDS procedure `rdsadmin.rdsadmin_s3_tasks.upload_to_s3` to copy the dump file to the Amazon S3 bucket. The following example uploads all of the files from the `DATA_PUMP_DIR` directory to an Amazon S3 bucket named `myS3bucket`.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
  p_bucket_name    =>  'myS3bucket',
  p_directory_name =>  'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```
Step 4: Download the dump file from your Amazon S3 bucket to your target DB instance

Perform this step using the Amazon RDS procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3`. When you download a file to a directory, the procedure `download_from_s3` skips the download if an identically named file already exists in the directory. To remove a file from the download directory, use `UTL_FILE.FREMOVE`, found on the Oracle website.

To download your dump file

1. Start SQL*Plus or Oracle SQL Developer and log in as the master on your Amazon RDS target Oracle DB instance
2. Download the dump file using the Amazon RDS procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3`. The following example downloads all files from an Amazon S3 bucket named `myS3bucket` to the directory `DATA_PUMP_DIR`.

   ```sql
   SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(     p_bucket_name    =>  'myS3bucket',     p_directory_name =>  'DATA_PUMP_DIR') AS TASK_ID FROM DUAL;
   ```

   The SELECT statement returns the ID of the task in a VARCHAR2 data type. For more information, see Downloading files from an Amazon S3 bucket to an Oracle DB instance (p. 2020).

Step 5: Import your dump file into your target DB instance using DBMS_DATAPUMP

Use DBMS_DATAPUMP to import the schema into your RDS for Oracle DB instance. Additional options such as METADATA_REMAP might be required.

To import data into your target DB instance

1. Start SQL*Plus or SQL Developer and log in as the master user to your RDS for Oracle DB instance.
2. Export the data by calling DBMS_DATAPUMP procedures.

The following example imports the `SCHEMA_1` data from `sample_copied.dmp` into your target DB instance.

   ```sql
   DECLARE
   v_hdnl NUMBER;
   BEGIN
   v_hdnl := DBMS_DATAPUMP.OPEN(     operation => 'IMPORT',     job_mode  => 'SCHEMA',     job_name  => null);
   DBMS_DATAPUMP.ADD_FILE(     handle    => v_hdnl,     filename  => 'sample_copied.dmp',     directory => 'DATA_PUMP_DIR',     filetype  => dbms_datapump.ku$_file_type_dump_file);
   DBMS_DATAPUMP.ADD_FILE(     handle    => v_hdnl,     filename  => 'sample_copied.dmp',     directory => 'DATA_PUMP_DIR',     filetype  => dbms_datapump.ku$_file_type_dump_file);
   ```

handle    => v_hdn1,
filename  => 'sample_imp.log',
directory => 'DATA_PUMP_DIR',
filetype  => dbms_datapump.ku$_file_type_log_file);
DBMS_DATAPUMP.METADATA_FILTER(v_hdn1,'SCHEMA_EXPR','IN (''
SCHEMA_1'')');
DBMS_DATAPUMP.START_JOB(v_hdn1);
END;
/

Note
Data Pump jobs are started asynchronously. For information about monitoring a Data Pump job, see Monitoring job status in the Oracle documentation. You can view the contents of the import log by using the rdsadmin.rds_file_util.read_text_file procedure. For more information, see Reading files in a DB instance directory (p. 1943).

3. Verify the data import by listing the schema tables on your target DB instance.

For example, the following query returns the number of tables for SCHEMA_1.

```sql
SELECT COUNT(*) FROM DBA_TABLES WHERE OWNER='SCHEMA_1';
```

### Step 6: Clean up

After the data has been imported, you can delete the files that you don't want to keep.

**To remove unneeded files**

1. Start SQL*Plus or SQL Developer and log in as the master user to your RDS for Oracle DB instance.
2. List the files in DATA_PUMP_DIR using the following command.

```sql
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir('DATA_PUMP_DIR')) ORDER BY MTIME;
```

3. Delete files in DATA_PUMP_DIR that you no longer require, use the following command.

```sql
EXEC UTL_FILE.FREMOVE('DATA_PUMP_DIR','filename');
```

For example, the following command deletes the file named sample_copied.dmp.

```sql
EXEC UTL_FILE.FREMOVE('DATA_PUMP_DIR','sample_copied.dmp');
```

### Importing data with Oracle Data Pump and a database link

The following import process uses Oracle Data Pump and the Oracle DBMS_FILE_TRANSFER package. The steps are as follows:

1. Connect to a source Oracle database, which can be an on-premises database, Amazon EC2 instance, or an RDS for Oracle DB instance.
2. Export data using the DBMS_DATAPUMP package.
3. Use DBMS_FILE_TRANSFER.PUT_FILE to copy the dump file from the Oracle database to the DATA_PUMP_DIR directory on the target RDS for Oracle DB instance that is connected using a database link.
4. Import the data from the copied dump file into the RDS for Oracle DB instance using the DBMS_DATAPUMP package.
The import process using Oracle Data Pump and the DBMS_FILE_TRANSFER package has the following steps.

**Topics**
- Requirements for importing data with Oracle Data Pump and a database link (p. 1971)
- Step 1: Grant privileges to the user on the RDS for Oracle target DB instance (p. 1971)
- Step 2: Grant privileges to the user on the source database (p. 1972)
- Step 3: Create a dump file using DBMS_DATAPUMP (p. 1972)
- Step 4: Create a database link to the target DB instance (p. 1973)
- Step 5: Copy the exported dump file to the target DB instance using DBMS_FILE_TRANSFER (p. 1973)
- Step 6: Import the data file to the target DB instance using DBMS_DATAPUMP (p. 1974)
- Step 7: Clean up (p. 1974)

**Requirements for importing data with Oracle Data Pump and a database link**

The process has the following requirements:

- You must have execute privileges on the DBMS_FILE_TRANSFER and DBMS_DATAPUMP packages.
- You must have write privileges to the DATA_PUMP_DIR directory on the source DB instance.
- You must ensure that you have enough storage space to store the dump file on the source instance and the target DB instance.

**Note**

This process imports a dump file into the DATA_PUMP_DIR directory, a preconfigured directory on all Oracle DB instances. This directory is located on the same storage volume as your data files. When you import the dump file, the existing Oracle data files use more space. Thus, you should make sure that your DB instance can accommodate that additional use of space. The imported dump file is not automatically deleted or purged from the DATA_PUMP_DIR directory. To remove the imported dump file, use UTL_FILE.FREMOVE, found on the Oracle website.

**Step 1: Grant privileges to the user on the RDS for Oracle target DB instance**

To grant privileges to the user on the RDS for Oracle target DB instance, take the following steps:

1. Use SQL Plus or Oracle SQL Developer to connect to the RDS for Oracle DB instance into which you intend to import the data. Connect as the Amazon RDS master user. For information about connecting to the DB instance, see [Connecting to your RDS for Oracle DB instance](p. 1822).
2. Create the required tablespaces before you import the data. For more information, see [Creating and sizing tablespaces](p. 1886).
3. If the user account into which the data is imported doesn't exist, create the user account and grant the necessary permissions and roles. If you plan to import data into multiple user schemas, create each user account and grant the necessary privileges and roles to it.

For example, the following commands create a new user named `schema_1` and grant the necessary permissions and roles to import the data into the schema for this user.

```sql
CREATE USER schema_1 IDENTIFIED BY my-password;
GRANT CREATE SESSION, RESOURCE TO schema_1;
ALTER USER schema_1 QUOTA 100M ON users;
```

**Note**

Specify a password other than the prompt shown here as a security best practice.
The preceding example grants the new user the CREATE SESSION privilege and the RESOURCE role. Additional privileges and roles might be required depending on the database objects that you import.

**Note**
Replace `schema_1` with the name of your schema in this step and in the following steps.

**Step 2: Grant privileges to the user on the source database**

Use SQL*Plus or Oracle SQL Developer to connect to the RDS for Oracle DB instance that contains the data to be imported. If necessary, create a user account and grant the necessary permissions.

**Note**
If the source database is an Amazon RDS instance, you can skip this step. You use your Amazon RDS master user account to perform the export.

The following commands create a new user and grant the necessary permissions.

```sql
CREATE USER export_user IDENTIFIED BY my-password;
GRANT CREATE SESSION, CREATE TABLE, CREATE DATABASE LINK TO export_user;
ALTER USER export_user QUOTA 100M ON users;
GRANT READ, WRITE ON DIRECTORY data_pump_dir TO export_user;
GRANT SELECT_CATALOG_ROLE TO export_user;
GRANT EXECUTE ON DBMS_DATAPUMP TO export_user;
GRANT EXECUTE ON DBMS_FILE_TRANSFER TO export_user;
```

**Note**
Specify a password other than the prompt shown here as a security best practice.

**Step 3: Create a dump file using DBMS_DATAPUMP**

To create a dump file, do the following:

1. Use SQL*Plus or Oracle SQL Developer to connect to the source Oracle instance with an administrative user or with the user you created in step 2. If the source database is an Amazon RDS for Oracle DB instance, connect with the Amazon RDS master user.
2. Create a dump file using the Oracle Data Pump utility.

The following script creates a dump file named `sample.dmp` in the `DATA_PUMP_DIR` directory.

```sql
DECLARE
  v_hdnl NUMBER;
BEGIN
  v_hdnl := DBMS_DATAPUMP.OPEN(
    operation => 'EXPORT',
    job_mode  => 'SCHEMA',
    job_name  => null
  );
  DBMS_DATAPUMP.ADD_FILE(
    handle     => v_hdnl,
    filename   => 'sample.dmp',
    directory  => 'DATA_PUMP_DIR',
    filetype   => dbms_datapump.ku$_file_type_dump_file
  );
  DBMS_DATAPUMP.ADD_FILE(
    handle     => v_hdnl,
    filename   => 'sample_exp.log',
    directory  => 'DATA_PUMP_DIR',
    filetype   => dbms_datapump.ku$_file_type_log_file
  );
```
Step 4: Create a database link to the target DB instance

Create a database link between your source DB instance and your target DB instance. Your local Oracle instance must have network connectivity to the DB instance in order to create a database link and to transfer your export dump file.

Perform this step connected with the same user account as the previous step.

If you are creating a database link between two DB instances inside the same VPC or peer VPCs, the two DB instances should have a valid route between them. The security group of each DB instance must allow ingress to and egress from the other DB instance. The security group inbound and outbound rules can refer to security groups from the same VPC or a peer VPC. For more information, see Adjusting database links for use with DB instances in a VPC (p. 1895).

The following command creates a database link named `to_rds` that connects to the Amazon RDS master user at the target DB instance.

```sql
CREATE DATABASE LINK to_rds
CONNECT TO <master_user_account> IDENTIFIED BY <password>
USING '(
  DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=<dns or ip address of remote db>)
  (PORT=<listener port>))(CONNECT_DATA=(SID=<remote SID>)))';
```

Step 5: Copy the exported dump file to the target DB instance using DBMS_FILE_TRANSFER

Use DBMS_FILE_TRANSFER to copy the dump file from the source database instance to the target DB instance. The following script copies a dump file named `sample.dmp` from the source instance to a target database link named `to_rds` (created in the previous step).

```sql
BEGIN
  DBMS_FILE_TRANSFER.PUT_FILE(
    v_hdl, 'DETAILED_LOG', 'on', 'ERROR_FILE', 'on', 'FILE_NAME', 'sample.dmp', 'TO_CHKSUM', 'off', 'TO_LANGUAGE', 'en', 'TO_OWNER', 'sys', 'TO_SCHEMA', 'example', 'TO_TABLESPACE', 'users', 'FROM_DSN', 'source_instance', 'TO_DSN', 'to_rds', 'BEGIN_TIMESTAMPS', 'off', 'END_TIMESTAMPS', 'off', 'DELETE_FROM_SOURCE', 'off', 'OVERWRITE', 'on');
END;
/
Step 6: Import the data file to the target DB instance using DBMS_DATAPUMP

Use Oracle Data Pump to import the schema in the DB instance. Additional options such as METADATA_REMAP might be required.

Connect to the DB instance with the Amazon RDS master user account to perform the import.

```sql
DECLARE
v_hdnl NUMBER;
BEGIN
v_hdnl := DBMS_DATAPUMP.OPEN(
    operation => 'IMPORT',
    job_mode  => 'SCHEMA',
    job_name  => null);
DBMS_DATAPUMP.ADD_FILE(
    handle => v_hdnl,
    filename => 'sample_copied.dmp',
    directory => 'DATA_PUMP_DIR',
    filetype  => dbms_datapump.ku$_file_type_dump_file);
DBMS_DATAPUMP.ADD_FILE(
    handle => v_hdnl,
    filename => 'sample_imp.log',
    directory => 'DATA_PUMP_DIR',
    filetype  => dbms_datapump.ku$_file_type_log_file);
DBMS_DATAPUMP.METADATA_FILTER(v_hdnl,'SCHEMA_EXPR','IN ('"SCHEMA_1"')');
DBMS_DATAPUMP.START_JOB(v_hdnl);
END;
/
```

Note

Data Pump jobs are started asynchronously. For information about monitoring a Data Pump job, see Monitoring job status in the Oracle documentation. You can view the contents of the import log by using the rdsadmin.rds_file_util.read_text_file procedure. For more information, see Reading files in a DB instance directory (p. 1943).

You can verify the data import by viewing the user's tables on the DB instance. For example, the following query returns the number of tables for `schema_1`.

```sql
SELECT COUNT(*) FROM DBA_TABLES WHERE OWNER='SCHEMA_1';
```

Step 7: Clean up

After the data has been imported, you can delete the files that you don't want to keep. You can list the files in `DATA_PUMP_DIR` using the following command.

```sql
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir('DATA_PUMP_DIR')) ORDER BY MTIME;
```

To delete files in `DATA_PUMP_DIR` that you no longer require, use the following command.

```sql
EXEC UTL_FILE.FREMOVE('DATA_PUMP_DIR','<file name>');
```
For example, the following command deletes the file named "sample_copied.dmp".

```
EXEC UTL_FILE.FREMOVE('DATA_PUMP_DIR','sample_copied.dmp');
```

## Importing using Oracle Export/Import

You might consider Oracle Export/Import utilities for migrations in the following conditions:

- Your data size is small.
- Data types such as binary float and double aren't required.

The import process creates the necessary schema objects. Thus, you don't need to run a script to create the objects beforehand.

The easiest way to install the Oracle the export and import utilities is to install the Oracle Instant Client. To download the software, go to [https://www.oracle.com/database/technologies/instant-client.html](https://www.oracle.com/database/technologies/instant-client.html). For documentation, see [Instant Client for SQL*Loader, Export, and Import](https://docs.oracle.com/en/database/oracle/oracle-database/18/utlref/index.html) in the Oracle Database Utilities manual.

### To export tables and then import them

1. Export the tables from the source database using the `exp` command.

   The following command exports the tables named `tab1`, `tab2`, and `tab3`. The dump file is `exp_file.dmp`.

   ```
   exp cust_dba@ORCL FILE=exp_file.dmp TABLES=(tab1,tab2,tab3) LOG=exp_file.log
   ```

   The export creates a binary dump file that contains both the schema and data for the specified tables.

2. Import the schema and data into a target database using the `imp` command.

   The following command imports the tables `tab1`, `tab2`, and `tab3` from dump file `exp_file.dmp`.

   ```
   imp cust_dba@targetdb FROMUSER=cust_schema TOUSER=cust_schema \\
   TABLES=(tab1,tab2,tab3) FILE=exp_file.dmp LOG=imp_file.log
   ```

Export and Import have other variations that might be better suited to your requirements. See the Oracle Database documentation for full details.

## Importing using Oracle SQL*Loader

You might consider Oracle SQL*Loader for large databases that contain a limited number of objects. Because the process of exporting from a source database and loading to a target database is specific to the schema, the following example creates the sample schema objects, exports from a source, and then loads the data into a target database.

### To import data using Oracle SQL*Loader

1. Create a sample source table using the following SQL statement.
Migrating with Oracle materialized views

To migrate large datasets efficiently, you can use Oracle materialized view replication. With replication, you can keep the target tables synchronized with the source tables. Thus, you can switch over to Amazon RDS later, if needed.
Before you can migrate using materialized views, make sure that you meet the following requirements:

- Configure access from the target database to the source database. In the following example, access rules were enabled on the source database to allow the RDS for Oracle target database to connect to the source over SQL*Net.
- Create a database link from the RDS for Oracle DB instance to the source database.

To migrate data using materialized views

1. Create a user account on both source and RDS for Oracle target instances that can authenticate with the same password. The following example creates a user named `dblink_user`.

```sql
CREATE USER dblink_user IDENTIFIED BY my-password
DEFAULT TABLESPACE users
TEMPORARY TABLESPACE temp;
GRANT CREATE SESSION TO dblink_user;
GRANT SELECT ANY TABLE TO dblink_user;
GRANT SELECT ANY DICTIONARY TO dblink_user;
```

**Note**
Specify a password other than the prompt shown here as a security best practice.

2. Create a database link from the RDS for Oracle target instance to the source instance using your newly created user.

```sql
CREATE DATABASE LINK remote_site
CONNECT TO dblink_user IDENTIFIED BY my-password
USING '(description=(address=(protocol=tcp) (host=my-host)
(port=my-listener-port)) (connect_data=(sid=my-source-db-sid)))';
```

**Note**
Specify a password other than the prompt shown here as a security best practice.

3. Test the link:

```sql
SELECT * FROM V$INSTANCE@remote_site;
```

4. Create a sample table with primary key and materialized view log on the source instance.

```sql
CREATE TABLE customer_0 TABLESPACE users
AS (SELECT ROWNUM id, o.*
FROM   ALL_OBJECTS o, ALL_OBJECTS x
WHERE  ROWNUM <= 1000000);
ALTER TABLE customer_0 ADD CONSTRAINT pk_customer_0 PRIMARY KEY (id) USING INDEX;
CREATE MATERIALIZED VIEW LOG ON customer_0;
```

5. On the target RDS for Oracle DB instance, create a materialized view.

```sql
CREATE MATERIALIZED VIEW customer_0
BUILD IMMEDIATE REFRESH FAST
AS (SELECT * FROM cust_dba.customer_0@remote_site);
```

6. On the target RDS for Oracle DB instance, refresh the materialized view.
EXEC DBMS_MV.REFRESH('CUSTOMER_0', 'f');

7. Drop the materialized view and include the PRESERVE TABLE clause to retain the materialized view container table and its contents.

DROP MATERIALIZED VIEW customer_0 PRESERVE TABLE;

The retained table has the same name as the dropped materialized view.

Migrating using Oracle transportable tablespaces

You can use the Oracle transportable tablespaces feature to copy a set of tablespaces from an on-premises Oracle database to an RDS for Oracle DB instance. At the physical level, this feature incrementally copies source data files and metadata files to your target instance. You can transfer the files using either Amazon EFS or Amazon S3.

Topics
- Overview of Oracle transportable tablespaces (p. 1978)
- Phase 1: Set up your source host (p. 1980)
- Phase 2: Prepare the full tablespace backup (p. 1981)
- Phase 3: Make and transfer incremental backups (p. 1983)
- Phase 4: Transport the tablespaces (p. 1983)
- Phase 5: Validate the transported tablespaces (p. 1986)
- Phase 6: Clean up leftover files (p. 1986)

Overview of Oracle transportable tablespaces

A transportable tablespace set consists of data files for the set of tablespaces being transported and an export dump file containing tablespace metadata. In a physical migration solution such as transportable tablespaces, you transfer physical files: data files, configuration files, and Data Pump dump files.

Topics
- Advantages and disadvantages of transportable tablespaces (p. 1978)
- Limitations for transportable tablespaces (p. 1979)
- Prerequisites for transportable tablespaces (p. 1979)

Advantages and disadvantages of transportable tablespaces

We recommend that you use transportable tablespaces when you need to migrate one or more large tablespaces to RDS with minimum downtime. Transportable tablespaces offer the following advantages over logical migration:

- Downtime is lower than most other Oracle migration solutions.
- Because the transportable tablespace feature copies only physical files, it avoids the data integrity errors and logical corruption that can occur in logical migration.
- No additional license is required.
- You can migrate a set of tablespaces across different platforms and endianness types, for example, from an Oracle Solaris platform to Linux. However, transporting tablespaces to and from Windows servers isn't supported.
Note
Linux is fully tested and supported. Not all UNIX variations have been tested.

If you use transportable tablespaces, you can transport data using either Amazon S3 or Amazon EFS:

- When you use S3, you download RMAN backups to EBS storage attached to your DB instance. The files remain in your EBS storage during the import. After the import, you can free up this space, which remains allocated to your DB instance.
- When you use EFS, your backups remain in the EFS file system for the duration of the import. You can remove the files afterward. In this technique, you don't need to provision EBS storage for your DB instance. For this reason, we recommend using Amazon EFS instead of S3. For more information, see Amazon EFS integration (p. 2036).

The primary disadvantage of transportable tablespaces is that you need relatively advanced knowledge of Oracle Database. For more information, see Transporting Tablespaces Between Databases in the Oracle Database Administrator's Guide.

Limitations for transportable tablespaces

Oracle Database limitations for transportable tablespaces apply when you use this feature in RDS for Oracle. For more information, see Limitations on Transportable Tablespaces and General Limitations on Transporting Data in the Oracle Database Administrator's Guide. Note the following additional limitations for transportable tablespaces in RDS for Oracle:

- Neither the source or target database can use Standard Edition 2 (SE2). Only Enterprise Edition is supported.
- You can't migrate data from an RDS for Oracle DB instance using transportable tablespaces. You can only use transportable tablespaces to migrate data to an RDS for Oracle DB instance.
- The Windows operating system isn't supported.
- You can't transport tablespaces into a database at a lower release level. The target database must be at the same or later release level as the source database. For example, you can't transport tablespaces from Oracle Database 21c into Oracle Database 19c.
- You can't transport administrative tablespaces such as SYSTEM and SYSAUX.
- You can't transport tablespaces that are encrypted or use encrypted columns.
- If you transfer files using Amazon S3, the maximum supported file size is 5 TiB.
- If the source database uses Oracle options such as Spatial, you can't transport tablespaces unless the same options are configured on the target database.
- You can't transport tablespaces into an RDS for Oracle DB instance in an Oracle replica configuration. As a workaround, you can delete all replicas, transport the tablespaces, and then recreate the replicas.

Prerequisites for transportable tablespaces

Before you begin, complete the following tasks:

- Review the requirements for transportable tablespaces described in the following documents in My Oracle Support:
  - Reduce Transportable Tablespace Downtime using Cross Platform Incremental Backup (Doc ID 2471245.1)
  - Transportable Tablespace (TTS) Restrictions and Limitations: Details, Reference, and Version Where Applicable (Doc ID 1454872.1)
  - Primary Note for Transportable Tablespaces (TTS) -- Common Questions and Issues (Doc ID 1166564.1)
• Make sure that the transportable tablespace feature is enabled on your target DB instance. The feature is enabled only if you don't get an ORA-20304 error when you run the following query:

```sql
SELECT * FROM TABLE(rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files);
```

If the transportable tablespace feature isn't enabled, reboot your DB instance. For more information, see Rebooting a DB instance (p. 436).

• If you plan to transfer files using Amazon S3, do the following:
  • Make sure that an Amazon S3 bucket is available for file transfers, and that the Amazon S3 bucket is in the same AWS Region as your DB instance. For instructions, see Create a bucket in the Amazon Simple Storage Service Getting Started Guide.
  • Prepare the Amazon S3 bucket for Amazon RDS integration by following the instructions in Configuring IAM permissions for RDS for Oracle integration with Amazon S3 (p. 2008).

• If you plan to transfer files using Amazon EFS, make sure that you have configured EFS according to the instructions in Amazon EFS integration (p. 2036).

• We strongly recommend that you turn on automatic backups in your target DB instance. Because the metadata import step (p. 1985) can potentially fail, it's important to be able to restore your DB instance to its state before the import, thereby avoiding the necessity to back up, transfer, and import your tablespaces again.

**Phase 1: Set up your source host**

In this step, you copy the transport tablespaces scripts provided by My Oracle Support and set up necessary configuration files. In the following steps, the source host is running the database that contains the tablespaces to be transported to your target instance.

**To set up your source host**

1. Log in to your source host as the owner of your Oracle home.
2. Make sure that your ORACLE_HOME and ORACLE_SID environment variables point to your source database.
3. Log in to your database as an administrator, and verify that the time zone version, DB character set, and national character set are the same as in your target database.

```sql
SELECT * FROM V$TIMEZONE_FILE;
SELECT * FROM NLS_DATABASE_PARAMETERS
  WHERE PARAMETER IN ('NLS_CHARACTERSET','NLS_NCHAR_CHARACTERSET');
```

4. Set up the transportable tablespace utility as described in Oracle Support note 2471245.1.

The setup includes editing the xtt.properties file on your source host. The following sample xtt.properties file specifies backups of three tablespaces in the /dsk1/backups directory. These are the tablespaces that you intend to transport to your target DB instance.

```properties
#linux system
platformid=13
#list of tablespaces to transport
tablespace=TBS1,TBS2,TBS3
#location where backup will be generated
src_scratch_location=/dsk1/backups
#RMAN command for performing backup
usermantransport=1
```

1980
Phase 2: Prepare the full tablespace backup

In this phase, you back up your tablespaces for the first time, transfer the backups to your target host, and then restore them using the procedure rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces. When this phase is complete, the initial tablespace backups reside on your target DB instance and can be updated with incremental backups.

Topics

- **Step 1: Back up the tablespaces on your source host** (p. 1981)
- **Step 2: Transfer the backup files to your target DB instance** (p. 1981)
- **Step 3: Import the tablespaces on your target DB instance** (p. 1982)

Step 1: Back up the tablespaces on your source host

In this step, you use the xttdriver.pl script to make a full backup of your tablespaces. The output of xttdriver.pl is stored in the TMPDIR environment variable.

**To back up your tablespaces**

1. If your tablespaces are in read-only mode, log in to your source database as a user with the ALTER TABLESPACE privilege, and place your tablespaces in read/write mode. Otherwise, skip to the next step.

   The following example places tbs1, tbs2, and tbs3 in read/write mode.

   ```sql
   ALTER TABLESPACE tbs1 READ WRITE;
   ALTER TABLESPACE tbs2 READ WRITE;
   ALTER TABLESPACE tbs3 READ WRITE;
   ```

2. Back up your tablespaces using the xttdriver.pl script. Optionally, you can specify `--debug` to run the script in debug mode.

   ```bash
   export TMPDIR=location_of_log_files
   cd location_of_xttdriver.pl
   $ORACLE_HOME/perl/bin/perl xttdriver.pl --backup
   ```

Step 2: Transfer the backup files to your target DB instance

In this step, copy the backup and configuration files from your scratch location to your target DB instance. Choose one of the following options:

- If the source and target hosts share an Amazon EFS file system, use an operating system utility such as cp to copy your backup files and the res.txt file from your scratch location to a shared directory. Then skip to **Step 3: Import the tablespaces on your target DB instance** (p. 1982).

- If you need to stage your backups to an Amazon S3 bucket, complete the following steps.
Step 2.2: Upload the backups to your Amazon S3 bucket

Upload your backups and the `res.txt` file from your scratch directory to your Amazon S3 bucket. For more information, see Uploading objects in the Amazon Simple Storage Service User Guide.

Step 2.3: Download the backups from your Amazon S3 bucket to your target DB instance

In this step, you use the procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3` to download your backups to your RDS for Oracle DB instance.

To download your backups from your Amazon S3 bucket

1. Start SQL*Plus or Oracle SQL Developer and log in to your RDS for Oracle DB instance.
2. Download the backups from the Amazon S3 bucket to your target DB instance by using the Amazon RDS procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3` to `d`. The following example downloads all of the files from an Amazon S3 bucket named `mys3bucket` to the `DATA_PUMP_DIR` directory.

   ```sql
   EXEC UTL_FILE.FREMOVE ('DATA_PUMP_DIR', 'res.txt');
   SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3( 
     p_bucket_name => 'mys3bucket',
     p_directory_name => 'DATA_PUMP_DIR')
   AS TASK_ID FROM DUAL;
   
   The SELECT statement returns the ID of the task in a VARCHAR2 data type. For more information, see Downloading files from an Amazon S3 bucket to an Oracle DB instance (p. 2020).
   
Step 3: Import the tablespaces on your target DB instance

Use the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces` to restore your tablespaces to your target DB instance. This procedure automatically converts the data files to the correct endian format.

Import the tablespaces on your target DB instance

1. Start an Oracle SQL client and log in to your target RDS for Oracle DB instance as the master user.
2. Run the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces`, specifying the tablespaces to import and the directory containing the backups.

   The following example imports the tablespaces `TBS1`, `TBS2`, and `TBS3` from the directory `DATA_PUMP_DIR`.

   ```sql
   VAR task_id CLOB
   ```
BEGIN
:task_id:=rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces('TBS1,TBS2,TBS3','DATA_PUMP_DIR');
END;
/
PRINT task_id

3. (Optional) Monitor progress by querying the table rdsadmin.rds_xtts_operation_info. The xtts_operation_state column shows the value EXECUTING, COMPLETED, or FAILED.

```
SELECT * FROM rdsadmin.rds_xtts_operation_info;
```

**Note**
For long-running operations, you can also query V$SESSION_LONGOPS, V$RMAN_STATUS, and V$RMAN_OUTPUT.

4. View the log of the completed import by using the task ID from the previous step.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-''&task_id'':''&task_id'':''.log'));
```

Make sure that the import succeeded before continuing to the next step.

### Phase 3: Make and transfer incremental backups

In this phase, you make and transfer incremental backups periodically while the source database is active. This technique reduces the size of your final tablespace backup. If you take multiple incremental backups, you must copy the res.txt file after the last incremental backup before you can apply it on the target instance.

The steps are the same as in **Phase 2: Prepare the full tablespace backup (p. 1981)**, except that the import step is optional.

### Phase 4: Transport the tablespaces

In this phase, you back up your read-only tablespaces and export Data Pump metadata, transfer these files to your target host, and import both the tablespaces and the metadata.

**Topics**
- Step 1: Back up your read-only tablespaces (p. 1983)
- Step 2: Export tablespace metadata on your source host (p. 1984)
- Step 3: (Amazon S3 only) Transfer the backup and export files to your target DB instance (p. 1984)
- Step 4: Import the tablespaces on your target DB instance (p. 1984)
- Step 5: Import tablespace metadata on your target DB instance (p. 1985)

### Step 1: Back up your read-only tablespaces

This step is identical to **Step 1: Back up the tablespaces on your source host (p. 1981)**, with one key difference: you place your tablespaces in read-only mode before backing up your tablespaces for the last time.

The following example places tbs1, tbs2, and tbs3 in read-only mode.

```
ALTER TABLESPACE tbs1 READ ONLY;
ALTER TABLESPACE tbs2 READ ONLY;
```
ALTER TABLESPACE tbs3 READ ONLY;

**Step 2: Export tablespace metadata on your source host**

Export your tablespace metadata by running the expdb utilty on your source host. The following example exports tablespaces **TBS1**, **TBS2**, and **TBS3** to dump file `xttdump.dmp` in directory `DATA_PUMP_DIR`.

```
expdp username/pwd \
    dumpfile=xttdump.dmp \
    directory=DATA_PUMP_DIR \
    statistics=NONE \
    transport_tablespaces=TBS1,TBS2,TBS3 \
    transport_full_check=y \
    logfile=tts_export.log
```

If `DATA_PUMP_DIR` is a shared directory in Amazon EFS, skip to **Step 4: Import the tablespaces on your target DB instance** (p. 1984).

**Step 3: (Amazon S3 only) Transfer the backup and export files to your target DB instance**

If you are using Amazon S3 to stage your tablespace backups and Data Pump export file, complete the following steps.

**Step 3.1: Upload the backups and dump file from your source host to your Amazon S3 bucket**

Upload your backup and dump files from your source host to your Amazon S3 bucket. For more information, see **Uploading objects** in the *Amazon Simple Storage Service User Guide*.

**Step 3.2: Download the backups and dump file from your Amazon S3 bucket to your target DB instance**

In this step, you use the procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3` to download your backups and dump file to your RDS for Oracle DB instance. Follow the steps in **Step 2.3: Download the backups from your Amazon S3 bucket to your target DB instance** (p. 1982).

**Step 4: Import the tablespaces on your target DB instance**

Use the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces` to restore the tablespaces. For syntax and semantics of this procedure, see **Importing transported tablespaces to your DB instance** (p. 1948)

**Important**

After you complete your final tablespace import, the next step is **importing the Oracle Data Pump metadata** (p. 1984). If the import fails, it's important to return your DB instance to its state before the failure. Thus, we recommend that you create a DB snapshot of your DB instance by following the instructions in **Creating a DB snapshot** (p. 613). The snapshot will contain all imported tablespaces, so if the import fails, you don't need to repeat the backup and import process.

If your target DB instance has automatic backups turned on, and Amazon RDS doesn't detect that a valid snapshot was initiated before you import the metadata, RDS attempts to create a snapshot. Depending on your instance activity, this snapshot might or might not succeed. If a valid snapshot isn't detected or a snapshot can't be initiated, the metadata import exits with errors.

**Import the tablespaces on your target DB instance**

1. Start an Oracle SQL client and log in to your target RDS for Oracle DB instance as the master user.
2. Run the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces`, specifying the tablespaces to import and the directory containing the backups.

   The following example imports the tablespaces `TBS1`, `TBS2`, and `TBS3` from the directory `DATA_PUMP_DIR`.

   ```sql
   BEGIN
   :task_id:=rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces('TBS1,TBS2,TBS3','DATA_PUMP_DIR');
   END;
   /
   PRINT task_id
   ```

3. (Optional) Monitor progress by querying the table `rdsadmin.rds_xtts_operation_info`. The `xtts_operation_state` column shows the value EXECUTING, COMPLETED, or FAILED.

   ```sql
   SELECT * FROM rdsadmin.rds_xtts_operation_info;
   ```

   **Note**
   For long-running operations, you can also query `V$SESSION_LONGOPS`, `V$RMAN_STATUS`, and `V$RMAN_OUTPUT`.

4. View the log of the completed import by using the task ID from the previous step.

   ```sql
   SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-''&task_id''&''.log'));
   ```

   Make sure that the import succeeded before continuing to the next step.

5. Take a manual DB snapshot by following the instructions in Creating a DB snapshot (p. 613).

**Step 5: Import tablespace metadata on your target DB instance**

In this step, you import the transportable tablespace metadata into your RDS for Oracle DB instance using the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_metadata`. For syntax and semantics of this procedure, see Importing transportable tablespace metadata into your DB instance (p. 1949). During the operation, the status of the import is shown in the table `rdsadmin.rds_xtts_operation_info`.

**Important**
Before you import metadata, we strongly recommend that you confirm that a DB snapshot was successfully created after you imported your tablespaces. If the import step fails, restore your DB instance, address the import errors, and then attempt the import again.

**Import the Data Pump metadata into your RDS for Oracle DB instance**

1. Start your Oracle SQL client and log in to your target DB instance as the master user.

2. Create the users that own schemas in your transported tablespaces, if these users don't already exist.

   ```sql
   CREATE USER tbs_owner IDENTIFIED BY password;
   ```

3. Import the metadata, specifying the name of the dump file and its directory location.

   ```sql
   BEGIN
   rdsadmin.rdsadmin_transport_util.import_xtts_metadata('xttdump.dmp','DATA_PUMP_DIR');
   END;
   /
4. (Optional) Query the transportable tablespace history table to see the status of the metadata import.

```
SELECT * FROM rdsadmin.rds_xtts_operation_info;
```

When the operation completes, your tablespaces are in read-only mode.

5. (Optional) View the log file.

The following example lists the contents of the BDUMP directory and then queries the import log.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory => 'BDUMP'));
SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file(p_directory => 'BDUMP',
  p_filename => 'rds-xtts-import_xtts_metadata-2023-05-22.01-52-35.560858000.log'));
```

**Phase 5: Validate the transported tablespaces**

In this optional step, you validate your transported tablespaces using the procedure `rdsadmin.rdsadmin_rman_util.validate_tablespace`, and then place your tablespaces in read/write mode.

**To validate the transported data**

1. Start SQL*Plus or SQL Developer and log in to your target DB instance as the master user.
2. Validate the tablespaces using the procedure `rdsadmin.rdsadmin_rman_util.validate_tablespace`.

```
SET SERVEROUTPUT ON
BEGIN
  rdsadmin.rdsadmin_rman_util.validate_tablespace(p_tablespace_name => 'TBS1',
    p_validation_type => 'PHYSICAL+LOGICAL',
    p_rman_to_dbms_output => TRUE);
  rdsadmin.rdsadmin_rman_util.validate_tablespace(p_tablespace_name => 'TBS2',
    p_validation_type => 'PHYSICAL+LOGICAL',
    p_rman_to_dbms_output => TRUE);
  rdsadmin.rdsadmin_rman_util.validate_tablespace(p_tablespace_name => 'TBS3',
    p_validation_type => 'PHYSICAL+LOGICAL',
    p_rman_to_dbms_output => TRUE);
END;
/
```

3. Place your tablespaces in read/write mode.

```
ALTER TABLESPACE TBS1 READ WRITE;
ALTER TABLESPACE TBS2 READ WRITE;
ALTER TABLESPACE TBS3 READ WRITE;
```

**Phase 6: Clean up leftover files**

In this optional step, you remove any unneeded files. Use the `rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files` procedure.
to list data files that were orphaned after a tablespace import, and then use `rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files` procedure to delete them. For syntax and semantics of these procedures, see Listing orphaned files after a tablespace import (p. 1950) and Deleting orphaned data files after a tablespace import (p. 1951).

**To clean up leftover files**

1. Remove old backups in `DATA_PUMP_DIR` as follows:
   a. List the backup files by running `rdsadmin.rdsadmin_file_util.listdir`.
      
      ```sql
      SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory => 'DATA_PUMP_DIR'));
      ```
   b. Remove the backups one by one by calling `UTL_FILE.FREMOVE`.
      
      ```sql
      EXEC UTL_FILE.FREMOVE ('DATA_PUMP_DIR', 'backup_filename');
      ```

2. If you imported tablespaces but didn't import metadata for these tablespaces, you can delete the orphaned data files as follows:
   a. List the orphaned data files that you need to delete. The following example runs the procedure `rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files`.
      
      ```sql
      SQL> SELECT * FROM TABLE(rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files);
      FILENAME       FILESIZE
      -------------- ---------
datafile_7.dbf   104865792
datafile_8.dbf   104865792
      ```
   b. Delete the orphaned files by running the procedure `rdsadmin.rdsadmin_transport_util.cleanup_incomplete_xtts_import`.
      
      ```sql
      BEGIN
      rdsadmin.rdsadmin_transport_util.cleanup_incomplete_xtts_import('DATA_PUMP_DIR');
      END;
      ```

      The cleanup operation generates a log file that uses the name format `rds-xtts-delete_xtts_orphaned_files-YYYY-MM-DD.HH24-MI-SS.FF.log` in the `BDUMP` directory.
   c. Read the log file generated in the previous step. The following example reads log `rds-xtts-delete_xtts_orphaned_files-2023-06-01.09-33-11.868894000.log`.
      
      ```sql
      SELECT *
      FROM TABLE(rdsadmin.rds_file_util.read_text_file(  
          p_directory => 'BDUMP',  
          p_filename  => 'rds-xtts-delete_xtts_orphaned_files-2023-06-01.09-33-11.868894000.log' ));
      TEXT
      -----------------------------------------------  
orphan transported datafile datafile_7.dbf deleted.
orphan transported datafile datafile_8.dbf deleted.
      ```

3. If you imported tablespaces and imported metadata for these tablespaces, but you encountered compatibility errors or other Oracle Data Pump issues, clean up the partially transported data files as follows:
a. List the tablespaces that contain partially transported data files by querying DBA_TABLESPACES.

```sql
SQL> SELECT TABLESPACE_NAME FROM DBA_TABLESPACES WHERE PLUGGED_IN='YES';
TABLESPACE_NAME
---------------------------------------------------------------
TBS_3
```

b. Drop the tablespaces and the partially transported data files.

```sql
DROP TABLESPACE TBS_3 INCLUDING CONTENTS AND DATAFILES;
```
Working with read replicas for Amazon RDS for Oracle

To configure replication between Oracle DB instances, you can create replica databases. For an overview of Amazon RDS read replicas, see Overview of Amazon RDS read replicas (p. 439). For a summary of the differences between Oracle replicas and other DB engines, see Differences among read replicas for DB engines (p. 441).

Topics

- Overview of RDS for Oracle replicas (p. 1989)
- Requirements and considerations for RDS for Oracle replicas (p. 1990)
- Preparing to create an Oracle replica (p. 1993)
- Creating an RDS for Oracle replica in mounted mode (p. 1994)
- Modifying the RDS for Oracle replica mode (p. 1995)
- Working with RDS for Oracle replica backups (p. 1996)
- Performing an Oracle Data Guard switchover (p. 1998)
- Troubleshooting RDS for Oracle replicas (p. 2004)

Overview of RDS for Oracle replicas

An Oracle replica database is a physical copy of your primary database. An Oracle replica in read-only mode is called a read replica. An Oracle replica in mounted mode is called a mounted replica. Oracle Database doesn't permit writes in a replica, but you can promote a replica to make it writable. The promoted read replica has the replicated data to the point when the request was made to promote it.

The following video provides a helpful overview of RDS for Oracle disaster recovery.

For more information, see the blog post Managed disaster recovery with Amazon RDS for Oracle cross-Region automated backups - Part 1 and Managed disaster recovery with Amazon RDS for Oracle cross-Region automated backups - Part 2.

Topics

- Read-only and mounted replicas (p. 1989)
- Multitenant read replicas (p. 1990)
- Archived redo log retention (p. 1990)
- Outages during replication (p. 1990)

Read-only and mounted replicas

When creating or modifying an Oracle replica, you can place it in either of the following modes:

Read-only

This is the default. Active Data Guard transmits and applies changes from the source database to all read replica databases.

You can create up to five read replicas from one source DB instance. For general information about read replicas that applies to all DB engines, see Working with DB instance read replicas (p. 438). For information about Oracle Data Guard, see Oracle Data Guard concepts and administration in the Oracle documentation.
Mounted

In this case, replication uses Oracle Data Guard, but the replica database doesn't accept user connections. The primary use for mounted replicas is cross-Region disaster recovery.

A mounted replica can't serve a read-only workload. The mounted replica deletes archived redo log files after it applies them, regardless of the archived log retention policy.

You can create a combination of mounted and read-only DB replicas for the same source DB instance. You can change a read-only replica to mounted mode, or change a mounted replica to read-only mode. In either case, the Oracle database preserves the archived log retention setting.

Multitenant read replicas

RDS for Oracle supports Data Guard read replicas for Oracle Database 19c and 21c CDBs. You can create, manage, and promote read replicas in a CDB, just as you can in a non-CDB. Mounted replicas are supported for the single-tenant configuration. You get the following benefits:

- Managed disaster recovery, high availability, and read-only access to your replicas
- The ability to create read replicas in a different AWS Region.
- Integration with the existing RDS read replica APIs: CreateDBInstanceReadReplica, PromoteReadReplica, and SwitchoverReadReplica

To use this feature, you need an Active Data Guard license and an Oracle Database Enterprise Edition license for both the replica and primary DB instances. There are no additional costs related to using CDB architecture. You pay only for your DB instances.

 Archived redo log retention

If a primary DB instance has no cross-Region read replicas, Amazon RDS for Oracle keeps a minimum of two hours of archived redo logs on the source DB instance. This is true regardless of the setting for archivelog retention hours in rdsadmin.rdsadmin_util.set_configuration.

RDS purges logs from the source DB instance after two hours or after the archive log retention hours setting has passed, whichever is longer. RDS purges logs from the read replica after the archive log retention hours setting has passed only if they have been successfully applied to the database.

In some cases, a primary DB instance might have one or more cross-Region read replicas. If so, Amazon RDS for Oracle keeps the transaction logs on the source DB instance until they have been transmitted and applied to all cross-Region read replicas. For information about rdsadmin.rdsadmin_util.set_configuration, see Retaining archived redo logs (p. 1909).

Outages during replication

When you create an Oracle replica, no outage occurs for the source DB instance. Amazon RDS takes a snapshot of the source DB instance. This snapshot becomes the replica. Amazon RDS sets the necessary parameters and permissions for the source DB and replica without service interruption. Similarly, if you delete a replica, no outage occurs.

Requirements and considerations for RDS for Oracle replicas

Before creating an Oracle replica, familiarize yourself with the following requirements and considerations.
Version and licensing requirements for RDS for Oracle replicas

Before you create an RDS for Oracle replica, consider the following:

- If the replica is in read-only mode, make sure that you have an Active Data Guard license. If you place the replica in mounted mode, you don't need an Active Data Guard license. Only the Oracle DB engine supports mounted replicas.
- Oracle replicas are supported for the Oracle Enterprise Edition (EE) engine only.
- Oracle replicas of non-CDBs are supported only for DB instances created using version Oracle Database 12c Release 1 (12.1.0.2.v10) and higher 12c releases, and for non-CDB instances of Oracle Database 19c.
- Oracle replicas of CDBs are supported only for CDB instances created using version Oracle Database 19c and higher.
- Oracle replicas are available for DB instances running only on DB instance classes with two or more vCPUs. A source DB instance can't use the db.t3.micro or db.t3.small instance classes.
- The Oracle DB engine version of the source DB instance and all of its replicas must be the same. Amazon RDS upgrades the replicas immediately after upgrading the source DB instance, regardless of a replica's maintenance window. For major version upgrades of cross-Region replicas, Amazon RDS automatically does the following:
  - Generates an option group for the target version.
  - Copies all options and option settings from the original option group to the new option group.
  - Associates the upgraded cross-Region replica with the new option group.

For more information about upgrading the DB engine version, see Upgrading the RDS for Oracle DB engine (p. 2119).

Option group considerations for RDS for Oracle replicas

Before you create an RDS for Oracle replica, consider the following:

- If your Oracle replica is in the same AWS Region as its source DB instance, make sure that it belongs to the same option group as the source DB instance. Modifications to the source option group or source option group membership propagate to replicas. These changes are applied to the replicas immediately after they are applied to the source DB instance, regardless of the replica's maintenance window.

For more information about option groups, see Working with option groups (p. 331).
- When you create an RDS for Oracle cross-Region replica, Amazon RDS creates a dedicated option group for it.

You can't remove an RDS for Oracle cross-Region replica from its dedicated option group. No other DB instances can use the dedicated option group for an RDS for Oracle cross-Region replica.

You can only add or remove the following nonreplicated options from a dedicated option group:
• NATIVE_NETWORK_ENCRYPTION
• OEM
• OEM_AGENT
• SSL

To add other options to an RDS for Oracle cross-Region replica, add them to the source DB instance's option group. The option is also installed on all of the source DB instance's replicas. For licensed options, make sure that there are sufficient licenses for the replicas.

When you promote an RDS for Oracle cross-Region replica, the promoted replica behaves the same as other Oracle DB instances, including the management of its options. You can promote a replica explicitly or implicitly by deleting its source DB instance.

For more information about option groups, see Working with option groups (p. 331).

Backup and restore considerations for RDS for Oracle replicas

Before you create an RDS for Oracle replica, consider the following:

• To create snapshots of RDS for Oracle replicas or turn on automatic backups, make sure to set the backup retention period manually. Automatic backups aren't turned on by default.
• When you restore a replica backup, you restore to the database time, not the time that the backup was taken. The database time refers to the latest applied transaction time of the data in the backup. The difference is significant because a replica can lag behind the primary for minutes or hours.

To find the difference, use the describe-db-snapshots command. Compare the snapshotDatabaseTime, which is the database time of the replica backup, and the OriginalSnapshotCreateTime field, which is the latest applied transaction on the primary database.

Oracle Data Guard requirements and limitations for RDS for Oracle replicas

Before you create an RDS for Oracle replica, note the following requirements and limitations:

• If your primary DB instance uses the single-tenant configuration of the multitenant architecture, consider the following:
  • You must use Oracle Database 19c or higher with the Enterprise Edition.
  • Your primary CDB instance must be in an ACTIVE lifecycle.
  • You can’t convert a non-CDB primary instance to a CDB instance and convert its replicas in the same operation. Instead, delete the non-CDB replicas, convert the primary DB instance to a CDB, and then create new replicas
• Make sure that a logon trigger on a primary DB instance permits access to the RDS_DATAGUARD user and to any user whose AUTHENTICATED_IDENTITY value is RDS_DATAGUARD or rdsdb. Also, the trigger must not set the current schema for the RDS_DATAGUARD user.
• To avoid blocking connections from the Data Guard broker process, don't enable restricted sessions. For more information about restricted sessions, see Enabling and disabling restricted sessions (p. 1874).

Miscellaneous considerations for RDS for Oracle replicas

Before you create an RDS for Oracle replica, consider the following:
Preparing to create an Oracle replica

Before you can begin using your replica, perform the following tasks.

Topics
- Enabling automatic backups (p. 1993)
- Enabling force logging mode (p. 1993)
- Changing your logging configuration (p. 1993)
- Setting the MAX_STRING_SIZE parameter (p. 1994)
- Planning compute and storage resources (p. 1994)

Enabling automatic backups

Before a DB instance can serve as a source DB instance, make sure to enable automatic backups on the source DB instance. To learn how to perform this procedure, see Enabling automated backups (p. 593).

Enabling force logging mode

We recommend that you enable force logging mode. In force logging mode, the Oracle database writes redo records even when NOLOGGING is used with data definition language (DDL) statements.

To enable force logging mode

1. Log in to your Oracle database using a client tool such as SQL Developer.
2. Enable force logging mode by running the following procedure.

```sql
exec rdsadmin.rdsadmin_util.force_logging(p_enable => true);
```

For more information about this procedure, see Setting force logging (p. 1905).

Changing your logging configuration

If you want to change your logging configuration, we recommend that you complete the changes before making a DB instance the source for replicas. Also, we recommend that you not modify the logging...
configurations after you create the replicas. Modifications can cause the online redo logging configuration
to get out of sync with the standby logging configuration.

Modify the logging configuration for a DB instance by using the Amazon RDS procedures
rdsadmin.rdsadmin_util.add_logfile and rdsadmin.rdsadmin_util.drop_logfile. For
more information, see Adding online redo logs (p. 1906) and Dropping online redo logs (p. 1907).

**Setting the MAX_STRING_SIZE parameter**

Before you create an Oracle replica, ensure that the setting of the MAX_STRING_SIZE parameter is
the same on the source DB instance and the replica. You can do this by associating them with the same
parameter group. If you have different parameter groups for the source and the replica, you can set
MAX_STRING_SIZE to the same value. For more information about setting this parameter, see Turning
on extended data types for a new DB instance (p. 1961).

**Planning compute and storage resources**

Ensure that the source DB instance and its replicas are sized properly, in terms of compute and storage,
to suit their operational load. If a replica reaches compute, network, or storage resource capacity, the
replica stops receiving or applying changes from its source. Amazon RDS for Oracle doesn't intervene to
mitigate high replica lag between a source DB instance and its replicas. You can modify the storage and
CPU resources of a replica independently from its source and other replicas.

**Creating an RDS for Oracle replica in mounted mode**

By default, Oracle replicas are read-only. To create a replica in mounted mode, use the console, the AWS
CLI, or the RDS API.

**Console**

To create a mounted replica from a source Oracle DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://
   console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the Oracle DB instance that you want to use as the source for a mounted replica.
4. For Actions, choose Create replica.
5. For Replica mode, choose Mounted.
6. Choose the settings that you want to use. For DB instance identifier, enter a name for the read
   replica. Adjust other settings as needed.
7. For Regions, choose the Region where the mounted replica will be launched.
8. Choose your instance size and storage type. We recommend that you use the same DB instance class
   and storage type as the source DB instance for the read replica.
9. For Multi-AZ deployment, choose Create a standby instance to create a standby of your replica
    in another Availability Zone for failover support for the mounted replica. Creating your mounted
    replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB
    instance.
10. Choose the other settings that you want to use.
11. Choose Create replica.

In the Databases page, the mounted replica has the role Replica.
AWS CLI

To create an Oracle replica in mounted mode, set --replica-mode to mounted in the AWS CLI command create-db-instance-read-replica.

Example

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance-read-replica \
--db-instance-identifier myreadreplica \
--source-db-instance-identifier mydbinstance \
--replica-mode mounted
```

For Windows:

```bash
aws rds create-db-instance-read-replica ^
   --db-instance-identifier myreadreplica ^
   --source-db-instance-identifier mydbinstance ^
   --replica-mode mounted
```

To change a read-only replica to a mounted state, set --replica-mode to mounted in the AWS CLI command modify-db-instance. To place a mounted replica in read-only mode, set --replica-mode to open-read-only.

RDS API

To create an Oracle replica in mounted mode, specify ReplicaMode=mounted in the RDS API operation CreateDBInstanceReadReplica.

Modifying the RDS for Oracle replica mode

To change the replica mode of an existing replica, use the console, AWS CLI, or RDS API. When you change to mounted mode, the replica disconnects all active connections. When you change to read-only mode, Amazon RDS initializes Active Data Guard.

The change operation can take a few minutes. During the operation, the DB instance status changes to modifying. For more information about status changes, see Viewing Amazon RDS DB instance status (p. 684).

Console

To change the replica mode of an Oracle replica from mounted to read-only

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the mounted replica database.
4. Choose Modify.
5. For Replica mode, choose Read-only.
6. Choose the other settings that you want to change.
7. Choose Continue.
8. For **Scheduling of modifications**, choose **Apply immediately**.
9. Choose **Modify DB instance**.

### AWS CLI

To change a read replica to mounted mode, set `--replica-mode` to `mounted` in the AWS CLI command `modify-db-instance`. To change a mounted replica to read-only mode, set `--replica-mode` to `read-only`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance
   --db-instance-identifier myreadreplica
   --replica-mode mode
```

For Windows:

```bash
aws rds modify-db-instance ^
   --db-instance-identifier myreadreplica ^
   --replica-mode mode
```

### RDS API

To change a read-only replica to mounted mode, set `ReplicaMode=mounted` in `ModifyDBInstance`. To change a mounted replica to read-only mode, set `ReplicaMode=read-only`.

### Working with RDS for Oracle replica backups

You can create and restore backups of an RDS for Oracle replica. Both automatic backups and manual snapshots are supported. For more information, see [Backing up and restoring](p. 590). The following sections describe the key differences between managing backups of a primary and an RDS for Oracle replica.

### Turning on RDS for Oracle replica backups

An Oracle replica doesn't have automated backups turned on by default. You turn on automated backups by setting the backup retention period to a positive nonzero value.

#### Console

**To enable automated backups immediately**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**, and then choose the DB instance or Multi-AZ DB cluster that you want to modify.
3. Choose **Modify**.
4. For **Backup retention period**, choose a positive nonzero value, for example 3 days.
5. Choose **Continue**.
6. Choose **Apply immediately**.
7. Choose **Modify DB instance** or **Modify cluster** to save your changes and enable automated backups.

**AWS CLI**

To enable automated backups, use the AWS CLI `modify-db-instance` or `modify-db-cluster` command.

Include the following parameters:

- `--db-instance-identifier` (or `--db-cluster-identifier` for a Multi-AZ DB cluster)
- `--backup-retention-period`
- `--apply-immediately` or `--no-apply-immediately`

In the following example, we enable automated backups by setting the backup retention period to three days. The changes are applied immediately.

**Example**

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --backup-retention-period 3 \
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --backup-retention-period 3 ^
  --apply-immediately
```

**RDS API**

To enable automated backups, use the RDS API `ModifyDBInstance` or `ModifyDBCluster` operation with the following required parameters:

- `DBInstanceIdentifier` or `DBClusterIdentifier`
- `BackupRetentionPeriod`

**Restoring an RDS for Oracle replica backup**

You can restore an Oracle replica backup just as you can restore a backup of the primary instance. For more information, see the following:

- [Restoring from a DB snapshot](#)
- [Restoring a DB instance to a specified time](#)

The main consideration when you restore a replica backup is determining the point in time to which you are restoring. The *database time* refers to the latest applied transaction time of the data in the backup. When you restore a replica backup, you restore to the database time, not the time when the backup
completed. The difference is significant because an RDS for Oracle replica can lag behind the primary by minutes or hours. Thus, the database time of a replica backup, and thus the point in time to which you restore it, might be much earlier than the backup creation time.

To find the difference between database time and creation time, use the `describe-db-snapshots` command. Compare the `SnapshotDatabaseTime`, which is the database time of the replica backup, and the `OriginalSnapshotCreateTime` field, which is the latest applied transaction on the primary database. The following example shows the difference between the two times:

```bash
aws rds describe-db-snapshots
  --db-instance-identifier my-oracle-replica
  --db-snapshot-identifier my-replica-snapshot
{
  "DBSnapshots": [
    {
      "DBSnapshotIdentifier": "my-replica-snapshot",
      "DBInstanceIdentifier": "my-oracle-replica",
      "SnapshotDatabaseTime": "2022-07-26T17:49:44Z",
      ... 
      "OriginalSnapshotCreateTime": "2021-07-26T19:49:44Z"
    }
  ]
}
```

**Performing an Oracle Data Guard switchover**

In an Oracle Data Guard environment, a primary database supports one or more standby databases. You can perform a managed, switchover-based role transition from a primary database to a standby database.

**Topics**

- [Overview of Oracle Data Guard switchover](#) (p. 1998)
- [Preparing for the Oracle Data Guard switchover](#) (p. 2002)
- [Initiating the Oracle Data Guard switchover](#) (p. 2002)
- [Monitoring the Oracle Data Guard switchover](#) (p. 2004)

**Overview of Oracle Data Guard switchover**

A *switchover* is a role reversal between a primary database and a standby database. During a switchover, the original primary database transitions to a standby role, while the original standby database transitions to the primary role.
Amazon RDS supports a fully managed, switchover-based role transition for Oracle Database replicas. The replicas can reside in separate AWS Regions or in different Availability Zones (AZs) of a single Region. You can only initiate a switchover to a standby database that is mounted or open read-only.

**Topics**
- Benefits of Oracle Data Guard switchover (p. 2000)
- Supported Oracle Database versions (p. 2000)
- AWS Region support (p. 2000)
- Cost of Oracle Data Guard switchover (p. 2000)
- How Oracle Data Guard switchover works (p. 2001)
Benefits of Oracle Data Guard switchover

Just as for RDS for Oracle read replicas, a managed switchover relies on Oracle Data Guard. The operation is designed to have zero data loss. Amazon RDS automates the following aspects of the switchover:

- Reverses the roles of your primary database and specified standby database, putting the new standby database in the same state (mounted or read-only) as the original standby
- Ensures data consistency
- Maintains your replication configuration after the transition
- Supports repeated reversals, allowing your new standby database to return to its original primary role

Supported Oracle Database versions

Oracle Data Guard switchover is supported for the following releases:

- Oracle Database 19c
- Oracle Database 12c Release 2 (12.2)
- Oracle Database 12c Release 1 (12.1) using PSU 12.1.0.2.v10 or higher

AWS Region support

Oracle Data Guard switchover is available in the following AWS Regions:

- Asia Pacific (Mumbai)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (London)
- Europe (Paris)
- Europe (Stockholm)
- South America (São Paulo)
- US East (N. Virginia)
- US East (Ohio)
- US West (N. California)
- US West (Oregon)
- AWS GovCloud (US-East)
- AWS GovCloud (US-West)

Cost of Oracle Data Guard switchover

The Oracle Data Guard switchover feature doesn't incur additional costs. Oracle Database Enterprise Edition includes support for standby databases in mounted mode. To open standby databases in read-only mode, you need the Oracle Active Data Guard option.
How Oracle Data Guard switchover works

Oracle Data Guard switchover is a fully managed operation. You initiate the switchover for a standby database by issuing the CLI command `switchover-read-replica`. Then Amazon RDS modifies the primary and standby roles in your replication configuration.

The original standby and original primary are the roles that exist before the switchover. The new standby and new primary are the roles that exist after the switchover. A bystander replica is a replica database that serves as a standby database in the Oracle Data Guard environment but is not switching roles.

**Topics**
- [Stages of the Oracle Data Guard switchover (p. 2001)](#)
- [After the Oracle Data Guard switchover (p. 2001)](#)

Stages of the Oracle Data Guard switchover

To perform the switchover, Amazon RDS must take the following steps:

1. Block new transactions on the original primary database. During the switchover, Amazon RDS interrupts replication for all databases in your Oracle Data Guard configuration. During the switchover, the original primary database can't process write requests.
2. Ship unapplied transactions to the original standby database, and apply them.
3. Restart the new standby database in read-only or mounted mode. The mode depends on the open state of the original standby database before the switchover.
4. Open the new primary database in read/write mode.

After the Oracle Data Guard switchover

Amazon RDS switches the roles of the primary and standby database. You are responsible for reconnecting your application and performing any other desired configuration.

**Topics**
- [Success criteria (p. 2001)](#)
- [Connection to the new primary database (p. 2001)](#)
- [Configuration of the new primary database (p. 2002)](#)

Success criteria

The Oracle Data Guard switchover is successful when the original standby database does the following:

- Transitions to its role as new primary database
- Completes its reconfiguration

To limit downtime, your new primary database becomes active as soon as possible. Because Amazon RDS configures bystander replicas asynchronously, these replicas might become active after the original primary database.

Connection to the new primary database

Amazon RDS won't propagate your current database connections to the new primary database after the switchover. After the Oracle Data Guard switchover completes, reconnect your application to the new primary database.
**Configuration of the new primary database**

To perform a switchover to the new primary database, Amazon RDS changes the mode of the original standby database to open. The change in role is the only change to the database. Amazon RDS doesn't set up features such as Multi-AZ replication.

If you perform a switchover to a cross-Region replica with different options, the new primary database keeps its own options. Amazon RDS won't migrate the options on the original primary database. If the original primary database had options such as SSL, NNE, OEM, and OEM_AGENT, Amazon RDS doesn't propagate them to the new primary database.

**Preparing for the Oracle Data Guard switchover**

Before initiating the Oracle Data Guard switchover, make sure that your replication environment meets the following requirements:

- The original standby database is mounted or open read-only.
- Automatic backups are enabled on the original standby database.
- The original primary database and the original standby database are in an available state.
- The original primary database and the original standby database have no pending maintenance actions.
- The original standby database is in the replicating state.
- You aren't attempting to initiate a switchover when either the primary database or standby database is currently in a switchover lifecycle. If a replica database is reconfiguring after a switchover, Amazon RDS prevents you from initiating another switchover.

**Note**

A **bystander replica** is a replica in the Oracle Data Guard configuration that isn't the target of the switchover. Bystander replicas can be in any state during the switchover.

- The original standby database has a configuration that is as close as desired to the original primary database. Assume a scenario where the original primary and original standby databases have different options. After the switchover completes, Amazon RDS doesn't automatically reconfigure the new primary database to have the same options as the original primary database.
- You configure your desired Multi-AZ deployment before initiating a switchover. Amazon RDS doesn't manage Multi-AZ as part of the switchover. The Multi-AZ deployment remains as it is.

Assume that db_maz is the primary database in a Multi-AZ deployment, and db_saz is a Single-AZ replica. You initiate a switchover from db_maz to db_saz. Afterward, db_maz is a Multi-AZ replica database, and db_saz is a Single-AZ primary database. The new primary database is now unprotected by a Multi-AZ deployment.

- In preparation for a cross-Region switchover, the primary database doesn't use the same option group as a DB instance outside of the replication configuration. For a cross-Region switchover to succeed, the current primary database and its read replicas must be the only DB instances to use the option group of the current primary database. Otherwise, Amazon RDS prevents the switchover.

**Initiating the Oracle Data Guard switchover**

You can switch over an RDS for Oracle read replica to the primary role, and the former primary DB instance to a replica role.

**Console**

**To switch over an Oracle read replica to the primary DB role**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the Amazon RDS console, choose **Databases**.

   The **Databases** pane appears. Each read replica shows **Replica** in the **Role** column.

3. Choose the read replica that you want to switch over to the primary role.

4. For **Actions**, choose **Switch over replica**.

5. Choose **I acknowledge**. Then choose **Switch over replica**.

6. On the **Databases** page, monitor the progress of the switchover.

   When the switchover completes, the role of the switchover target changes from **Replica** to **Source**.

**AWS CLI**

To switch over an Oracle replica to the primary DB role, use the AWS CLI `switchover-read-replica` command. The following examples make the Oracle replica named `replica-to-be-made-primary` into the new primary database.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds switchover-read-replica --db-instance-identifier replica-to-be-made-primary
```

For Windows:

```powershell
aws rds switchover-read-replica --db-instance-identifier replica-to-be-made-primary
```

**RDS API**

To switch over an Oracle replica to the primary DB role, call the Amazon RDS API `SwitchoverRead Replica` operation with the required parameter `DBInstanceIdentifier`. This parameter specifies the name of the Oracle replica that you want to assume the primary DB role.
Monitoring the Oracle Data Guard switchover

To check the status of your instances, use the AWS CLI command `describe-db-instances`. The following command checks the status of the DB instance `orcl2`. This database was a standby database before the switchover, but is the new primary database after the switchover.

```
aws rds describe-db-instances \
  --db-instance-identifier orcl2
```

To confirm that the switchover completed successfully, query `V$DATABASE.OPEN_MODE`. Check that the value for the new primary database is `READ WRITE`.

```
SELECT OPEN_MODE FROM V$DATABASE;
```

To look for switchover-related events, use the AWS CLI command `describe-events`. The following example looks for events on the `orcl2` instance.

```
aws rds describe-events \
  --source-identifier orcl2 \
  --source-type db-instance
```

Troubleshooting RDS for Oracle replicas

This section describes possible replication problems and solutions.

Topics

- Monitoring Oracle replication lag (p. 2004)
- Troubleshooting Oracle replication failure after adding or modifying triggers (p. 2005)

Monitoring Oracle replication lag

To monitor replication lag in Amazon CloudWatch, view the Amazon RDS ReplicaLag metric. For more information about replication lag time, see Monitoring read replication (p. 449) and Amazon CloudWatch metrics for Amazon RDS (p. 806).

For a read replica, if the lag time is too long, query the following views:

- `V$ARCHIVED_LOG` – Shows which commits have been applied to the read replica.
- `V$DATAGUARD_STATS` – Shows a detailed breakdown of the components that make up the ReplicaLag metric.
- `V$DATAGUARD_STATUS` – Shows the log output from Oracle's internal replication processes.

For a mounted replica, if the lag time is too long, you can't query the V$ views. Instead, do the following:

- Check the ReplicaLag metric in CloudWatch.
- Check the alert log file for the replica in the console. Look for errors in the recovery messages. The messages include the log sequence number, which you can compare to the primary sequence number. For more information, see Oracle database log files (p. 924).
Troubleshooting Oracle replication failure after adding or modifying triggers

If you add or modify any triggers, and if replication fails afterward, the problem may be the triggers. Ensure that the trigger excludes the following user accounts, which are required by RDS for replication:

- User accounts with administrator privileges
- SYS
- SYSTEM
- RDS_DATAGUARD
- rdsdb

For more information, see Miscellaneous considerations for RDS for Oracle replicas (p. 1992).
Adding options to Oracle DB instances

In Amazon RDS, an option is an additional feature. Following, you can find a description of options that you can add to Amazon RDS instances running the Oracle DB engine.

Topics

- Overview of Oracle DB options (p. 2006)
- Amazon S3 integration (p. 2008)
- Oracle Application Express (APEX) (p. 2025)
- Amazon EFS integration (p. 2036)
- Oracle Java virtual machine (p. 2047)
- Oracle Enterprise Manager (p. 2050)
- Oracle Label Security (p. 2065)
- Oracle Locator (p. 2068)
- Oracle Multimedia (p. 2071)
- Oracle native network encryption (p. 2073)
- Oracle OLAP (p. 2081)
- Oracle Secure Sockets Layer (p. 2084)
- Oracle Spatial (p. 2091)
- Oracle SQLT (p. 2094)
- Oracle Statspack (p. 2100)
- Oracle time zone (p. 2103)
- Oracle time zone file autoupgrade (p. 2107)
- Oracle Transparent Data Encryption (p. 2113)
- Oracle UTL_MAIL (p. 2115)
- Oracle XML DB (p. 2118)

Overview of Oracle DB options

To enable options for your Oracle database, add them to an option group, and then associate the option group with your DB instance. For more information, see Working with option groups (p. 331).

Topics

- Summary of Oracle Database options (p. 2006)
- Options supported for different editions (p. 2007)
- Memory requirements for specific options (p. 2007)

Summary of Oracle Database options

You can add the following options for Oracle DB instances.

<table>
<thead>
<tr>
<th>Option</th>
<th>Option ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon S3 integration (p. 2008)</td>
<td>S3_INTEGRATION</td>
</tr>
<tr>
<td>Oracle Application Express (APEX) (p. 2025)</td>
<td>APEX</td>
</tr>
<tr>
<td></td>
<td>APEX-DEV</td>
</tr>
</tbody>
</table>
### Options supported for different editions

RDS for Oracle prevents you from adding options to an edition if they aren’t supported. To find out which RDS options are supported in different Oracle Database editions, use the command `aws rds describe-option-group-options`. The following example lists supported options for Oracle Database 19c Enterprise Edition.

```bash
aws rds describe-option-group-options \
  --engine-name oracle-ee \
  --major-engine-version 19
```

For more information, see `describe-option-group-options` in the [AWS CLI Command Reference](https://docs.aws.amazon.com/cli/latest/reference/rds/describe-option-group-options.html).

### Memory requirements for specific options

Some options require additional memory to run on your DB instance. For example, Oracle Enterprise Manager Database Control uses about 300 MB of RAM. If you enable this option for a small DB instance, you might encounter performance problems due to memory constraints. You can adjust the Oracle parameters so that the database requires less RAM. Alternatively, you can scale up to a larger DB instance.
Amazon S3 integration

You can transfer files between your RDS for Oracle DB instance and an Amazon S3 bucket. You can use Amazon S3 integration with Oracle Database features such as Oracle Data Pump. For example, you can download Data Pump files from Amazon S3 to your RDS for Oracle DB instance. For more information, see Importing data into Oracle on Amazon RDS (p. 1963).

Note
Your DB instance and your Amazon S3 bucket must be in the same AWS Region.

Topics
• Configuring IAM permissions for RDS for Oracle integration with Amazon S3 (p. 2008)
• Adding the Amazon S3 integration option (p. 2016)
• Transferring files between Amazon RDS for Oracle and an Amazon S3 bucket (p. 2017)
• Troubleshooting Amazon S3 integration (p. 2023)
• Removing the Amazon S3 integration option (p. 2024)

Configuring IAM permissions for RDS for Oracle integration with Amazon S3

For RDS for Oracle to integrate with Amazon S3, your DB instance must have access to an Amazon S3 bucket. The Amazon VPC used by your DB instance doesn't need to provide access to the Amazon S3 endpoints.

RDS for Oracle supports uploading files from a DB instance in one account to an Amazon S3 bucket in a different account. Where additional steps are required, they are noted in the following sections.

Topics
• Step 1: Create an IAM policy for your Amazon RDS role (p. 2008)
• Step 2: (Optional) Create an IAM policy for your Amazon S3 bucket (p. 2012)
• Step 3: Create an IAM role for your DB instance and attach your policy (p. 2013)
• Step 4: Associate your IAM role with your RDS for Oracle DB instance (p. 2015)

Step 1: Create an IAM policy for your Amazon RDS role

In this step, you create an AWS Identity and Access Management (IAM) policy with the permissions required to transfer files from your Amazon S3 bucket to your RDS DB instance. This step assumes that you have already created an S3 bucket.

Before you create the policy, note the following pieces of information:

• The Amazon Resource Name (ARN) for your bucket
• The ARN for your AWS KMS key, if your bucket uses SSE-KMS or SSE-S3 encryption

Note
An RDS for Oracle DB instance can't access Amazon S3 buckets encrypted with SSE-C.

For more information, see Protecting data using server-side encryption in the Amazon Simple Storage Service User Guide.
Console

To create an IAM policy to allow Amazon RDS to access your Amazon S3 bucket

1. Open the IAM Management Console.
3. Choose Create Policy.
4. On the Visual editor tab, choose Choose a service, and then choose S3.
5. For Actions, choose Expand all, and then choose the bucket permissions and object permissions required to transfer files from an Amazon S3 bucket to Amazon RDS. For example, do the following:
   - Expand List, and then select ListBucket.
   - Expand Read, and then select GetObject.
   - Expand Write, and then select PutObject and DeleteObject.
   - Expand Permissions management, and then select PutObjectAcl. This permission is necessary if you plan to upload files to a bucket owned by a different account, and this account needs full control of the bucket contents.

Object permissions are permissions for object operations in Amazon S3. You must grant them for objects in a bucket, not the bucket itself. For more information, see Permissions for object operations.

6. Choose Resources, and then do the following:
   a. Choose Specific.
   b. For bucket, choose Add ARN. Enter your bucket ARN. The bucket name is filled in automatically. Then choose Add.
   c. If the object resource is shown, either choose Add ARN to add resources manually or choose Any.

   Note
   You can set Amazon Resource Name (ARN) to a more specific ARN value to allow Amazon RDS to access only specific files or folders in an Amazon S3 bucket. For more information about how to define an access policy for Amazon S3, see Managing access permissions to your Amazon S3 resources.

7. (Optional) Choose Add additional permissions to add resources to the policy. For example, do the following:
   a. If your bucket is encrypted with a custom KMS key, select KMS for the service.
   b. For Manual actions, select the following:
      - Encrypt
      - ReEncrypt from and ReEncrypt to
      - Decrypt
      - DescribeKey
      - GenerateDataKey
   c. For Resources, choose Specific.
   d. For key, choose Add ARN. Enter the ARN of your custom key as the resource, and then choose Add.

   For more information, see Protecting Data Using Server-Side Encryption with KMS keys Stored in AWS Key Management Service (SSE-KMS) in the Amazon Simple Storage Service User Guide.

   e. If you want Amazon RDS to access to access other buckets, add the ARNs for these buckets. Optionally, you can also grant access to all buckets and objects in Amazon S3.
8. Choose **Next: Tags** and then **Next: Review**.

9. For **Name**, enter a name for your IAM policy, for example `rds-s3-integration-policy`. You use this name when you create an IAM role to associate with your DB instance. You can also add an optional **Description** value.

10. Choose **Create policy**.

**AWS CLI**

Create an AWS Identity and Access Management (IAM) policy that grants Amazon RDS access to an Amazon S3 bucket. After you create the policy, note the ARN of the policy. You need the ARN for a subsequent step.

Include the appropriate actions in the policy based on the type of access required:

- **GetObject** – Required to transfer files from an Amazon S3 bucket to Amazon RDS.
- **ListBucket** – Required to transfer files from an Amazon S3 bucket to Amazon RDS.
- **PutObject** – Required to transfer files from Amazon RDS to an Amazon S3 bucket.

The following AWS CLI command creates an IAM policy named `rds-s3-integration-policy` with these options. It grants access to a bucket named `your-s3-bucket-arn`.

**Example**

For Linux, macOS, or Unix:

```bash
aws iam create-policy \
--policy-name rds-s3-integration-policy \
--policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "s3integration",
      "Action": [
        "s3:GetObject",
        "s3:ListBucket",
        "s3:PutObject"
      ],
      "Effect": "Allow",
      "Resource": [
        "arn:aws:s3:::your-s3-bucket-arn",
        "arn:aws:s3:::your-s3-bucket-arn/*"
      ]
    }
  ]
}';
```

The following example includes permissions for custom KMS keys.

```bash
aws iam create-policy \
--policy-name rds-s3-integration-policy \
--policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "s3integration",
      "Action": [
        "s3:GetObject",
        "s3:ListBucket",
        "s3:PutObject",
```
For Windows:

```
aws iam create-policy
  --policy-name rds-s3-integration-policy
  --policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Sid": "s3integration",
        "Action": [
          "s3:GetObject",
          "s3:ListBucket",
          "s3:PutObject"
        ],
        "Effect": "Allow",
        "Resource": [
          "arn:aws:s3:::your-s3-bucket-arn",
          "arn:aws:s3:::your-s3-bucket-arn/*"
        ]
      }
    ]
  }
}
```

The following example includes permissions for custom KMS keys.

```
aws iam create-policy
  --policy-name rds-s3-integration-policy
  --policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Sid": "s3integration",
        "Action": [
          "s3:GetObject",
          "s3:ListBucket",
          "s3:PutObject",
          "kms:Decrypt",
          "kms:Encrypt",
          "kms:ReEncrypt",
          "kms:GenerateDataKey",
          "kms:DescribeKey",
        ],
        "Effect": "Allow",
        "Resource": [
          "arn:aws:kms:::your-kms-arn"
        ]
      }
    ]
  }
}
```
Step 2: (Optional) Create an IAM policy for your Amazon S3 bucket

This step is necessary only in the following conditions:

- You plan to upload files to an Amazon S3 bucket from one account (account A) and access them from a different account (account B).
- Account B owns the bucket.
- Account B needs full control of objects loaded into the bucket.

If the preceding conditions don’t apply to you, skip to Step 3: Create an IAM role for your DB instance and attach your policy (p. 2013).

To create your bucket policy, make sure you have the following:

- The account ID for account A
- The user name for account A
- The ARN value for the Amazon S3 bucket in account B

Console

To create or edit a bucket policy

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the Buckets list, choose the name of the bucket that you want to create a bucket policy for or whose bucket policy you want to edit.
3. Choose Permissions.
4. Under Bucket policy, choose Edit. This opens the Edit bucket policy page.
5. On the Edit bucket policy page, explore Policy examples in the Amazon S3 User Guide, choose Policy generator to generate a policy automatically, or edit the JSON in the Policy section.

If you choose Policy generator, the AWS Policy Generator opens in a new window:

a. On the AWS Policy Generator page, in Select Type of Policy, choose S3 Bucket Policy.

b. Add a statement by entering the information in the provided fields, and then choose Add Statement. Repeat for as many statements as you would like to add. For more information about these fields, see the IAM JSON policy elements reference in the IAM User Guide.

Note
For convenience, the Edit bucket policy page displays the Bucket ARN (Amazon Resource Name) of the current bucket above the Policy text field. You can copy this ARN for use in the statements on the AWS Policy Generator page.

c. After you finish adding statements, choose Generate Policy.

d. Copy the generated policy text, choose Close, and return to the Edit bucket policy page in the Amazon S3 console.

6. In the Policy box, edit the existing policy or paste the bucket policy from the Policy generator. Make sure to resolve security warnings, errors, general warnings, and suggestions before you save your policy.
Amazon Relational Database Service User Guide
Amazon S3 integration

"Version": "2012-10-17",
"Statement": [
    {
        "Sid": "Example permissions",
        "Effect": "Allow",
        "Principal": {
        },
        "Action": [
            "s3:PutObject",
            "s3:PutObjectAcl"
        ],
        "Resource": [
            "arn:aws:s3:::account-B-bucket-arn",
            "arn:aws:s3:::account-B-bucket-arn/*"
        ]
    }
]

7. Choose Save changes, which returns you to the Bucket Permissions page.

Step 3: Create an IAM role for your DB instance and attach your policy

This step assumes that you have created the IAM policy in Step 1: Create an IAM policy for your Amazon RDS role (p. 2008). In this step, you create a role for your RDS for Oracle DB instance and then attach your policy to the role.

Console

To create an IAM role to allow Amazon RDS to access an Amazon S3 bucket

1. Open the IAM Management Console.
2. In the navigation pane, choose Roles.
3. Choose Create role.
4. Choose AWS service.
5. For Use cases for other AWS services; choose RDS and then RDS – Add Role to Database. Then choose Next.
6. For Search under Permissions policies, enter the name of the IAM policy you created in Step 1: Create an IAM policy for your Amazon RDS role (p. 2008), and select the policy when it appears in the list. Then choose Next.
7. For Role name, enter a name for your IAM role, for example, rds-s3-integration-role. You can also add an optional Description value.
8. Choose Create role.

AWS CLI

To create a role and attach your policy to it

1. Create an IAM role that Amazon RDS can assume on your behalf to access your Amazon S3 buckets.

We recommend using the aws:SourceArn and aws:SourceAccount global condition context keys in resource-based trust relationships to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

You might use both global condition context keys and have the aws:SourceArn value contain the account ID. In this case, the aws:SourceAccount value and the account in the aws:SourceArn value must use the same account ID when used in the same statement.
• Use `aws:SourceArn` if you want cross-service access for a single resource.

• Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role.

The following AWS CLI command creates the role named `rds-s3-integration-role` for this purpose.

**Example**

For Linux, macOS, or Unix:

```bash
aws iam create-role
--role-name rds-s3-integration-role
--assume-role-policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": my_account_ID,
          "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:dbname"
        }
      }
    }
  ]
}
''
```

For Windows:

```bash
aws iam create-role ^
--role-name rds-s3-integration-role ^
--assume-role-policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": my_account_ID,
          "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:dbname"
        }
      }
    }
  ]
}
''
```

2014
For more information, see [Creating a role to delegate permissions to an IAM user](https://docs.aws.amazon.com/IAM/latest/userguide/idp-delegation-step-5.html) in the [IAM User Guide](https://docs.aws.amazon.com/IAM/latest/userguide/). 

2. After the role is created, note the ARN of the role. You need the ARN for a subsequent step.

3. Attach the policy you created to the role you created.

The following AWS CLI command attaches the policy to the role named `rds-s3-integration-role`.

**Example**

For Linux, macOS, or Unix:

```bash
aws iam attach-role-policy
  --policy-arn your-policy-arn
  --role-name rds-s3-integration-role
```

For Windows:

```bash
aws iam attach-role-policy ^
  --policy-arn your-policy-arn ^
  --role-name rds-s3-integration-role
```

Replace `your-policy-arn` with the policy ARN that you noted in a previous step.

**Step 4: Associate your IAM role with your RDS for Oracle DB instance**

The last step in configuring permissions for Amazon S3 integration is associating your IAM role with your DB instance. Note the following requirements:

- You must have access to an IAM role with the required Amazon S3 permissions policy attached to it.
- You can only associate one IAM role with your RDS for Oracle DB instance at a time.
- Your DB instance must be in the Available state.

**Console**

**To associate your IAM role with your RDS for Oracle DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Choose Databases from the navigation pane.
3. Choose the RDS for Oracle DB instance name to display its details.
4. On the Connectivity & security tab, scroll down to the Manage IAM roles section at the bottom of the page.
5. For Add IAM roles to this instance, choose the role that you created in [Step 3: Create an IAM role for your DB instance and attach your policy (p. 2013)](#). 
6. For Feature, choose S3_INTEGRATION.
7. Choose Add role.

AWS CLI

The following AWS CLI command adds the role to an Oracle DB instance named mydbinstance.

Example

For Linux, macOS, or Unix:

```
aws rds add-role-to-db-instance
   --db-instance-identifier mydbinstance
   --feature-name S3_INTEGRATION
   --role-arn your-role-arn
```

For Windows:

```
aws rds add-role-to-db-instance
   --db-instance-identifier mydbinstance
   --feature-name S3_INTEGRATION
   --role-arn your-role-arn
```

Replace your-role-arn with the role ARN that you noted in a previous step. S3_INTEGRATION must be specified for the --feature-name option.

Adding the Amazon S3 integration option

To integrate Amazon RDS for Oracle with Amazon S3, your DB instance must be associated with an option group that includes the S3_INTEGRATION option.

Console

To configure an option group for Amazon S3 integration

1. Create a new option group or identify an existing option group to which you can add the S3_INTEGRATION option.

   For information about creating an option group, see Creating an option group (p. 332).

2. Add the S3_INTEGRATION option to the option group.

   For information about adding an option to an option group, see Adding an option to an option group (p. 335).
3. Create a new RDS for Oracle DB instance and associate the option group with it, or modify an RDS for Oracle DB instance to associate the option group with it.

For information about creating a DB instance, see Creating an Amazon RDS DB instance (p. 300).

For information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 401).

AWS CLI

To configure an option group for Amazon S3 integration

1. Create a new option group or identify an existing option group to which you can add the S3_INTEGRATION option.

For information about creating an option group, see Creating an option group (p. 332).

2. Add the S3_INTEGRATION option to the option group.

For example, the following AWS CLI command adds the S3_INTEGRATION option to an option group named myoptiongroup.

Example

For Linux, macOS, or Unix:

```bash
aws rds add-option-to-option-group
  --option-group-name myoptiongroup
  --options OptionName=S3_INTEGRATION,OptionVersion=1.0
```

For Windows:

```bash
aws rds add-option-to-option-group ^
  --option-group-name myoptiongroup ^
  --options OptionName=S3_INTEGRATION,OptionVersion=1.0
```

3. Create a new RDS for Oracle DB instance and associate the option group with it, or modify an RDS for Oracle DB instance to associate the option group with it.

For information about creating a DB instance, see Creating an Amazon RDS DB instance (p. 300).

For information about modifying an RDS for Oracle DB instance, see Modifying an Amazon RDS DB instance (p. 401).

Transferring files between Amazon RDS for Oracle and an Amazon S3 bucket

To transfer files between an RDS for Oracle DB instance and an Amazon S3 bucket, you can use the Amazon RDS package rdsadmin_s3_tasks. You can compress files with GZIP when uploading them, and decompress them when downloading.

**Note**

The procedures in rdsadmin_s3_tasks upload or download the files in a single directory. You can't include subdirectories in these operations.

**Topics**

- [Uploading files from your RDS for Oracle DB instance to an Amazon S3 bucket](p. 2018)
- [Downloading files from an Amazon S3 bucket to an Oracle DB instance](p. 2020)
- Monitoring the status of a file transfer (p. 2023)

### Uploading files from your RDS for Oracle DB instance to an Amazon S3 bucket

To upload files from your DB instance to an Amazon S3 bucket, use the procedure `rdsadmin.rdsadmin_s3_tasks.upload_to_s3`. For example, you can upload Oracle Recovery Manager (RMAN) backup files or Oracle Data Pump files. The maximum object size in an Amazon S3 bucket is 5 TB. For more information about working with objects, see Amazon Simple Storage Service User Guide. For more information about performing RMAN backups, see Performing common RMAN tasks for Oracle DB instances (p. 1913).

The `rdsadmin.rdsadmin_s3_tasks.upload_to_s3` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_bucket_name</td>
<td>VARCHAR2</td>
<td>–</td>
<td>required</td>
<td>The name of the Amazon S3 bucket to upload files to.</td>
</tr>
<tr>
<td>p_directory_name</td>
<td>VARCHAR2</td>
<td>–</td>
<td>required</td>
<td>The name of the Oracle directory object to upload files from. The directory can be any user-created directory object or the Data Pump directory, such as DATA_PUMP_DIR. Note You can only upload files from the specified directory. You can't upload files in subdirectories in the specified directory.</td>
</tr>
<tr>
<td>p_s3_prefix</td>
<td>VARCHAR2</td>
<td>–</td>
<td>required</td>
<td>An Amazon S3 file name prefix that files are uploaded to. An empty prefix uploads all files to the top level in the specified Amazon S3 bucket and doesn't add a prefix to the file names. For example, if the prefix is folder_1/oradb, files are uploaded to folder_1. In this case, the oradb prefix is added to each file.</td>
</tr>
<tr>
<td>p_prefix</td>
<td>VARCHAR2</td>
<td>–</td>
<td>required</td>
<td>A file name prefix that file names must match to be uploaded. An empty prefix uploads all files in the specified directory.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Data type</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>-----------</td>
<td>---------</td>
<td>----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>p_compression_level</td>
<td>NUMBER</td>
<td>0</td>
<td>optional</td>
<td>The level of GZIP compression. Valid values range from 0 to 9:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• 0 – No compression</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• 1 – Fastest compression</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• 9 – Highest compression</td>
</tr>
<tr>
<td>p_bucket_owner_full_control</td>
<td>VARCHAR2</td>
<td>-</td>
<td>optional</td>
<td>The access control setting for the bucket. The only valid values are null or</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>FULL_CONTROL. This setting is required only if you upload files from one</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>account (account A) into a bucket owned by a different account (account B),</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>and account B needs full control of the files.</td>
</tr>
</tbody>
</table>

The return value for the `rdsadmin.rdsadmin_s3_tasks.upload_to_s3` procedure is a task ID.

The following example uploads all of the files in the `DATA_PUMP_DIR` directory to the Amazon S3 bucket named `mys3bucket`. The files aren't compressed.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
    p_bucket_name    =>  'mys3bucket',
    p_prefix         =>  '',
    p_s3_prefix      =>  '',
    p_directory_name =>  'DATA_PUMP_DIR'
) AS TASK_ID FROM DUAL;
```

The following example uploads all of the files with the prefix `db` in the `DATA_PUMP_DIR` directory to the Amazon S3 bucket named `mys3bucket`. Amazon RDS applies the highest level of GZIP compression to the files.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
    p_bucket_name       =>  'mys3bucket',
    p_prefix            =>  'db',
    p_s3_prefix         =>  '',
    p_directory_name    =>  'DATA_PUMP_DIR',
    p_compression_level =>  9
) AS TASK_ID FROM DUAL;
```

The following example uploads all of the files in the `DATA_PUMP_DIR` directory to the Amazon S3 bucket named `mys3bucket`. The files are uploaded to a `dbfiles` folder. In this example, the GZIP compression level is 1, which is the fastest level of compression.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
    p_bucket_name       =>  'mys3bucket',
    p_prefix            =>  '',
    p_s3_prefix         =>  'dbfiles/',
    p_directory_name    =>  'DATA_PUMP_DIR',
    p_compression_level =>  1
) AS TASK_ID FROM DUAL;
```
AS TASK_ID FROM DUAL;

The following example uploads all of the files in the `DATA_PUMP_DIR` directory to the Amazon S3 bucket named `mys3bucket`. The files are uploaded to a `dbfiles` folder and `ora` is added to the beginning of each file name. No compression is applied.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
    p_bucket_name    =>  'mys3bucket',
    p_prefix         =>  '',
    p_s3_prefix      =>  'dbfiles/ora',
    p_directory_name =>  'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

The following example assumes that the command is run in account A, but account B requires full control of the bucket contents. The command `rdsadmin_s3_tasks.upload_to_s3` transfers all files in the `DATA_PUMP_DIR` directory to the bucket named `s3bucketOwnedByAccountB`. Access control is set to `FULL_CONTROL` so that account B can access the files in the bucket. The GZIP compression level is 6, which balances speed and file size.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
    p_bucket_name               =>  's3bucketOwnedByAccountB',
    p_prefix                    =>  '',
    p_s3_prefix                 =>  '',
    p_directory_name            =>  'DATA_PUMP_DIR',
    p_bucket_owner_full_control =>  'FULL_CONTROL',
    p_compression_level         =>  6)
AS TASK_ID FROM DUAL;
```

In each example, the SELECT statement returns the ID of the task in a VARCHAR2 data type.

You can view the result by displaying the task's output file.

```sql
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-task-id.log'));
```

Replace `task-id` with the task ID returned by the procedure.

**Note**

Tasks are executed asynchronously.

**Downloading files from an Amazon S3 bucket to an Oracle DB instance**

To download files from an Amazon S3 bucket to an RDS for Oracle instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3`.

When you download files using the procedure `download_from_s3`, consider the following:

- The download limit is 2000 files per procedure call. If you need to download more than 2000 files from Amazon S3, split your download into separate actions, with no more than 2000 files per procedure call.

- If a file exists in your download folder, and you attempt to download a file with the same name, `download_from_s3` skips the download. To remove a file from the download directory, use `UTL_FILE.FREMOVE`, found on the Oracle website.

The `download_from_s3` procedure has the following parameters.
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_bucket_name</td>
<td>VARCHAR2</td>
<td>–</td>
<td>Required</td>
<td>The name of the Amazon S3 bucket to download files from.</td>
</tr>
<tr>
<td>p_directory_name</td>
<td>VARCHAR2</td>
<td>–</td>
<td>Required</td>
<td>The name of the Oracle directory object to download files to. The directory can be any user-created directory object or the Data Pump directory, such as DATA_PUMP_DIR.</td>
</tr>
<tr>
<td>p_error_on_zero_downloads</td>
<td>VARCHAR2</td>
<td>FALSE</td>
<td>Optional</td>
<td>A flag that determines whether the task raises an error when no objects in the Amazon S3 bucket match the prefix. If this parameter is not set or set to FALSE (default), the task prints a message that no objects were found, but doesn't raise an exception or fail. If this parameter is TRUE, the task raises an exception and fails. Examples of prefix specifications that can fail match tests are spaces in prefixes, as in 'import/test9.log', and case mismatches, as in test9.log and test9.LOG.</td>
</tr>
<tr>
<td>p_s3_prefix</td>
<td>VARCHAR2</td>
<td>–</td>
<td>Required</td>
<td>A file name prefix that file names must match to be downloaded. An empty prefix downloads all of the top level files in the specified Amazon S3 bucket, but not the files in folders in the bucket. The procedure downloads Amazon S3 objects only from the first level folder that matches the prefix. Nested directory structures matching the specified prefix are not downloaded. For example, suppose that an Amazon S3 bucket has the folder structure folder_1/folder_2/folder_3. You specify the 'folder_1/folder_2/' prefix. In this case, only the files in folder_2 are downloaded, not the files in folder_1 or folder_3. If, instead, you specify the 'folder_1/folder_2' prefix, all files in folder_1 that match the 'folder_2' prefix are downloaded, and no files in folder_2 are downloaded.</td>
</tr>
<tr>
<td>p_decompression_format</td>
<td>VARCHAR2</td>
<td>–</td>
<td>Optional</td>
<td>The decompression format. Valid values are NONE for no decompression and GZIP for decompression.</td>
</tr>
</tbody>
</table>
The return value for the rdsadmin.rdsadmin_s3_tasks.download_from_s3 procedure is a task ID.

The following example downloads all files in the Amazon S3 bucket named `mys3bucket` to the `DATA_PUMP_DIR` directory. The files aren't compressed, so no decompression is applied.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
    p_bucket_name    =>  'mys3bucket',
    p_directory_name =>  'DATA_PUMP_DIR'
) AS TASK_ID FROM DUAL;
```

The following example downloads all of the files with the prefix `db` in the Amazon S3 bucket named `mys3bucket` to the `DATA_PUMP_DIR` directory. The files are compressed with GZIP, so decompression is applied. The parameter `p_error_on_zero_downloads` turns on prefix error checking, so if the prefix doesn't match any files in the bucket, the task raises and exception and fails.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
    p_bucket_name               =>  'mys3bucket',
    p_s3_prefix                 =>  'db',
    p_directory_name            =>  'DATA_PUMP_DIR',
    p_decompression_format      =>  'GZIP',
    p_error_on_zero_downloads   =>  'TRUE'
) AS TASK_ID FROM DUAL;
```

The following example downloads all of the files in the folder `myfolder/` in the Amazon S3 bucket named `mys3bucket` to the `DATA_PUMP_DIR` directory. Use the `p_s3_prefix` parameter to specify the Amazon S3 folder. The uploaded files are compressed with GZIP, but aren't decompressed during the download.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
    p_bucket_name          =>  'mys3bucket',
    p_s3_prefix            =>  'myfolder/',
    p_directory_name       =>  'DATA_PUMP_DIR',
    p_decompression_format =>  'NONE'
) AS TASK_ID FROM DUAL;
```

The following example downloads the file `mydumpfile.dmp` in the Amazon S3 bucket named `mys3bucket` to the `DATA_PUMP_DIR` directory. No decompression is applied.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
    p_bucket_name    =>  'mys3bucket',
    p_s3_prefix      =>  'mydumpfile.dmp',
    p_directory_name =>  'DATA_PUMP_DIR'
) AS TASK_ID FROM DUAL;
```

In each example, the SELECT statement returns the ID of the task in a VARCHAR2 data type.

You can view the result by displaying the task's output file.

```sql
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-task-id.log'));
```

Replace `task-id` with the task ID returned by the procedure.

**Note**

Tasks are executed asynchronously. You can use the UTL_FILE.FREMOVE Oracle procedure to remove files from a directory. For more information, see [FREMOVE procedure](https://docs.oracle.com/en/database/oracle/oracle-database/19/utlfnl/FREMOVE.html) in the Oracle documentation.
Monitoring the status of a file transfer

File transfer tasks publish Amazon RDS events when they start and when they complete. The event message contains the task ID for the file transfer. For information about viewing events, see Viewing Amazon RDS events (p. 852).

You can view the status of an ongoing task in a bdump file. The bdump files are located in the /rdsdbdata/log/trace directory. Each bdump file name is in the following format:

dbtask-task-id.log

Replace task-id with the ID of the task that you want to monitor.

Note
Tasks are executed asynchronously.

You can use the rdsadmin.rds_file_util.read_text_file stored procedure to view the contents of bdump files. For example, the following query returns the contents of the dbtask-1234567890123-1234.log bdump file.

```sql
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-1234567890123-1234.log'));
```

The following sample shows the log file for a failed transfer.

<table>
<thead>
<tr>
<th>TASK_ID</th>
<th>TEXT</th>
</tr>
</thead>
<tbody>
<tr>
<td>1234567890123-1234</td>
<td>2023-04-17 18:21:33.993 UTC [INFO ] File #1: Uploading the file /rdsdbdata/datapump/A123B4CDEF567890G1234567890H1234/sample.dmp to Amazon S3 with bucket name mys3bucket and key sample.dmp.</td>
</tr>
<tr>
<td></td>
<td>2023-04-17 18:21:34.188 UTC [ERROR] RDS doesn't have permission to write to Amazon S3 bucket name mys3bucket and key sample.dmp.</td>
</tr>
</tbody>
</table>

Troubleshooting Amazon S3 integration

For troubleshooting tips, see the AWS re:Post article How do I troubleshoot issues when I integrate Amazon RDS for Oracle with Amazon S3?
Removing the Amazon S3 integration option

You can remove Amazon S3 integration option from a DB instance.

To remove the Amazon S3 integration option from a DB instance, do one of the following:

- To remove the Amazon S3 integration option from multiple DB instances, remove the S3_INTEGRATION option from the option group to which the DB instances belong. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 343).

- To remove the Amazon S3 integration option from a single DB instance, modify the instance and specify a different option group that doesn't include the S3_INTEGRATION option. You can specify the default (empty) option group or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 401).
Oracle Application Express (APEX)

Amazon RDS supports Oracle Application Express (APEX) through the use of the APEX and APEX-DEV options. You can deploy Oracle APEX as a run-time environment or as a full development environment for web-based applications. Using Oracle APEX, you can build applications entirely within the web browser. For more information, see Oracle application Express in the Oracle documentation.

Topics

- APEX components (p. 2025)
- APEX version requirements (p. 2025)
- Oracle APEX and ORDS requirements and limitations (p. 2027)
- Adding the APEX and APEX-DEV options (p. 2027)
- Unlocking the public user account (p. 2028)
- Configuring RESTful services for Oracle APEX (p. 2028)
- Setting up ORDS for Oracle APEX (p. 2028)
- Setting up Oracle APEX listener (p. 2032)
- Upgrading the APEX version (p. 2034)
- Removing the APEX option (p. 2035)

APEX components

Oracle APEX consists of the following main components:

- A repository that stores the metadata for APEX applications and components. The repository consists of tables, indexes, and other objects that are installed in your Amazon RDS DB instance.
- A listener that manages HTTP communications with Oracle APEX clients. The listener resides on a separate host such as an Amazon EC2 instance, an on-premises server at your company, or your desktop computer. The listener accepts incoming connections from web browsers, forwards them to the Amazon RDS DB instance for processing, and then sends results from the repository back to the browsers. RDS for Oracle supports the following types of listeners:
  - For APEX version 5.0 and later, use Oracle Rest Data Services (ORDS) version 19.1 and higher. We recommend that you use the latest supported version of Oracle APEX and ORDS. This documentation describes older versions for backwards compatibility only.
  - For APEX version 4.1.1, you can use Oracle APEX Listener version 1.1.4.
  - You can use Oracle HTTP Server and mod_plsql listeners.

  Note
  Amazon RDS doesn't support the Oracle XML DB HTTP server with the embedded PL/SQL gateway; you can't use this as a listener for APEX. In general, Oracle recommends against using the embedded PL/SQL gateway for applications that run on the internet.

  For more information about these listener types, see About choosing a web listener in the Oracle documentation.

When you add the Amazon RDS APEX options to your RDS for Oracle DB instance, Amazon RDS installs the Oracle APEX repository only. Install your listener on a separate host.

APEX version requirements

The APEX option uses storage on the DB instance class for your DB instance. Following are the supported versions and approximate storage requirements for Oracle APEX.
<table>
<thead>
<tr>
<th>APEX version</th>
<th>Storage requirements</th>
<th>Supported Oracle Database versions</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle APEX version 23.1.v1</td>
<td>106 MiB</td>
<td>19c and higher</td>
<td>This version includes patch 35283657: PSE BUNDLE FOR APEX 23.1 (PSES ON TOP OF 23.1.0), PATCH_VERSION 2.</td>
</tr>
<tr>
<td>Oracle APEX version 22.2.v1</td>
<td>106 MiB</td>
<td>All</td>
<td>This version includes patch 34628174: PSE BUNDLE FOR APEX 22.2 (PSES ON TOP OF 22.2.0), PATCH_VERSION 4.</td>
</tr>
<tr>
<td>Oracle APEX version 22.1.v1</td>
<td>124 MiB</td>
<td>All</td>
<td>This version includes patch 34020981: PSE BUNDLE FOR APEX 22.1 (PSES ON TOP OF 22.1.0), PATCH_VERSION 6.</td>
</tr>
<tr>
<td>Oracle APEX version 21.2.v1</td>
<td>125 MiB</td>
<td>All</td>
<td>This version includes patch 33420059: PSE BUNDLE FOR APEX 21.2 (PSES ON TOP OF 21.2.0), PATCH_VERSION 8.</td>
</tr>
<tr>
<td>Oracle APEX version 21.1.v1</td>
<td>125 MiB</td>
<td>All</td>
<td>This version includes patch 32598392: PSE BUNDLE FOR APEX 21.1, PATCH_VERSION 3.</td>
</tr>
<tr>
<td>Oracle APEX version 20.2.v1</td>
<td>148 MiB</td>
<td>All except 21c</td>
<td>This version includes patch 32006852: PSE BUNDLE FOR APEX 20.2, PATCH_VERSION 2020.11.12. You can see the patch number and date by running the following query:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td><code>SELECT PATCH_VERSION, PATCH_NUMBER FROM APEX_PATCHES;</code></td>
</tr>
<tr>
<td>Oracle APEX version 20.1.v1</td>
<td>173 MiB</td>
<td>All except 21c</td>
<td>This version includes patch 30990551: PSE BUNDLE FOR APEX 20.1, PATCH_VERSION 2020.07.15.</td>
</tr>
<tr>
<td>Oracle APEX version 19.2.v1</td>
<td>149 MiB</td>
<td>All except 21c</td>
<td></td>
</tr>
<tr>
<td>Oracle APEX version 19.1.v1</td>
<td>148 MiB</td>
<td>All except 21c</td>
<td></td>
</tr>
<tr>
<td>Oracle APEX version 18.2.v1</td>
<td>146 MiB</td>
<td>12.1 and 12.2 only</td>
<td></td>
</tr>
<tr>
<td>Oracle APEX version 18.1.v1</td>
<td>145 MiB</td>
<td>12.1 and 12.2 only</td>
<td></td>
</tr>
<tr>
<td>Oracle APEX version 5.1.4.v1</td>
<td>220 MiB</td>
<td>12.1 and 12.2 only</td>
<td></td>
</tr>
<tr>
<td>Oracle APEX version 5.1.2.v1</td>
<td>150 MiB</td>
<td>12.1 and 12.2 only</td>
<td></td>
</tr>
<tr>
<td>Oracle APEX version 5.0.4.v1</td>
<td>140 MiB</td>
<td>12.1 and 12.2 only</td>
<td></td>
</tr>
<tr>
<td>Oracle APEX version 4.2.6.v1</td>
<td>160 MiB</td>
<td>12.1 only</td>
<td></td>
</tr>
</tbody>
</table>
For downloadable APEX .zip files, see Oracle APEX Prior Release Archives on the Oracle website.

Oracle APEX and ORDS requirements and limitations

Note the following requirements for APEX and ORDS:

• You must use the Java Runtime Environment (JRE).
• Your Oracle client installation must include the following:
  • SQL*Plus or SQL Developer for administration tasks
  • Oracle Net Services for configuring connections to your RDS for Oracle DB instance

You can’t use an RDS for Oracle CDB with ORDS v22 and higher. As a workaround, you can either use a lower version of ORDS or use an Oracle Database 19c non-CDB.

Adding the APEX and APEX-DEV options

To add the APEX and APEX-DEV options to a DB instance, do the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the APEX and APEX-DEV options to the option group.
3. Associate the option group with the DB instance.

When you add the Amazon RDS APEX options, a brief outage occurs while your DB instance is automatically restarted.

**Note**
APEX_MAIL is available when the APEX option is installed. The execute privilege for the APEX_MAIL package is granted to PUBLIC so you don’t need the APEX administrative account to use it.

To add the APEX options to a DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine**, choose the Oracle edition that you want to use. The APEX options are supported on all editions.
   b. For **Major engine version**, choose the version of your DB instance.

For more information, see Creating an option group (p. 332).

2. Add the options to the option group. If you want to deploy only the Oracle APEX run-time environment, add only the APEX option. If you want to deploy the full development environment, add both the APEX and APEX-DEV options. For Oracle Database 12c, add the APEX and APEX-DEV options.

   For **Version**, choose the version of APEX that you want to use. If you don’t choose a version, version 4.2.6.v1 is the default for Oracle Database 12c.

   **Important**
   If you add the APEX options to an existing option group that is already attached to one or more DB instances, a brief outage occurs. During this outage, all the DB instances are automatically restarted.

   For more information about adding options, see Adding an option to an option group (p. 335).
3. Apply the option group to a new or existing DB instance:

   • For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 300).

   • For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. When you add the APEX options to an existing DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see Modifying an Amazon RDS DB instance (p. 401).

Unlocking the public user account

After the Amazon RDS APEX options are installed, make sure to do the following:

1. Change the password for the APEX public user account.
2. Unlock the account.

You can do this by using the Oracle SQL*Plus command line utility. Connect to your DB instance as the master user, and issue the following commands. Replace new_password with a password of your choice.

```
ALTER USER APEX_PUBLIC_USER IDENTIFIED BY new_password;
ALTER USER APEX_PUBLIC_USER ACCOUNT UNLOCK;
```

Configuring RESTful services for Oracle APEX

To configure RESTful services in APEX (not needed for APEX 4.1.1.V1), use SQL*Plus to connect to your DB instance as the master user. After you do this, run the rdsadmin.rdsadmin_run_apex_rest_config stored procedure. When you run the stored procedure, you provide passwords for the following users:

• APEX_LISTENER

• APEX_REST_PUBLIC_USER

The stored procedure runs the apex_rest_config.sql script, which creates new database accounts for these users.

**Note**
Configuration isn't required for Oracle APEX version 4.1.1.v1. For this Oracle APEX version only, you don't need to run the stored procedure.

The following command runs the stored procedure.

```
EXEC rdsadmin.rdsadmin_run_apex_rest_config('apex_listener_password',
'apex_rest_public_user_password');
```

Setting up ORDS for Oracle APEX

You are now ready to install and configure Oracle Rest Data Services (ORDS) for use with Oracle APEX. For APEX version 5.0 and later, use Oracle Rest Data Services (ORDS) version 19.1 and higher.

Install the listener on a separate host such as an Amazon EC2 instance, an on-premises server at your company, or your desktop computer. For the examples in this section, we assume that the name of your host is myapexhost.example.com, and that your host is running Linux.
Preparing to install ORDS

Before you can install ORDS, you need to create a nonprivileged OS user, and then download and unzip the APEX installation file.

**To prepare for ORDS installation**

1. Log in to `myapexhost.example.com` as `root`.
2. Create a nonprivileged OS user to own the listener installation. The following command creates a new user named `apexuser`.
   
   ```
   useradd -d /home/apexuser apexuser
   ```

   The following command assigns a password to the new user.

   ```
   passwd apexuser;
   ```

3. Log in to `myapexhost.example.com` as `apexuser`, and download the APEX installation file from Oracle to your `/home/apexuser` directory:

4. Unzip the file in the `/home/apexuser` directory.

   ```
   unzip apex_<version>.zip
   ```

   After you unzip the file, there is an `apex` directory in the `/home/apexuser` directory.

Installing and configuring ORDS

Before you can use APEX, you need to download the ords.war file, use Java to install ORDS, and then start the listener.

**To install and configure ORDS for use with Oracle APEX**

1. Create a new directory based on ORDS, and then unzip the listener file.

   ```
   mkdir /home/apexuser/ORDS
   cd /home/apexuser/ORDS
   ```

2. Download the file `ords.version.number.zip` from Oracle REST data services.

3. Unzip the file into the `/home/apexuser/ORDS` directory.

4. If you're installing ORDS in a multitenant database, add the following line to the file `/home/apexuser/ORDS/params/ords_params.properties`:

   ```
   pdb.disable.lockdown=false
   ```

5. Grant the master user the required privileges to install ORDS.

   After the Amazon RDS APEX option is installed, give the master user the required privileges to install the ORDS schema. You can do this by connecting to the database and running the following commands. Replace `MASTER_USER` with the uppercase name of your master user.
Important
When you enter the user name, use uppercase unless you created the user with a case-sensitive identifier. For example, if you run `CREATE USER myuser` or `CREATE USER MYUSER`, the data dictionary stores MYUSER. However, if you use double quotes in `CREATE USER "MyUser"`, the data dictionary stores MyUser. For more information, see Granting SELECT or EXECUTE privileges to SYS objects (p. 1875).

```
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_OBJECTS', 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_ROLE_PRIVS', 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_TAB_COLUMNS', 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_CONS_COLUMNS', 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_CONSTRAINTS', 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_OBJECTS', 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_PROCEDURES', 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_TAB_COLUMNS', 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_TABLES', 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_VIEWS', 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('WPIUTL', 'MASTER_USER', 'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_SESSION', 'MASTER_USER', 'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_UTILITY', 'MASTER_USER', 'EXECUTE', true);
```

Note
These commands apply to ORDS version 19.1 and later.

6. Install the ORDS schema using the downloaded ords.war file.

```
java -jar ords.war install advanced
```

The program prompts you for the following information. The default values are in brackets. For more information, see Introduction to Oracle REST data services in the Oracle documentation.

- Enter the location to store configuration data:
  - Enter `/home/apexuser/ORDS`. This is the location of the ORDS configuration files.
  - Choose the desired connection type.
- Enter the name of the database server [localhost]: *DB_instance_endpoint*
  - Choose the default or enter the correct value.
- Enter the database listener port [1521]: *DB_instance_port*
  - Choose the default or enter the correct value.
- Enter 1 to specify the database service name, or 2 to specify the database SID [1]:
  - Choose 2 to specify the database SID.
• Database SID [xe]
  Choose the default or enter the correct value.
• Enter 1 if you want to verify/install Oracle REST Data Services schema or 2 to skip this step [1]:
  Choose 1. This step creates the Oracle REST Data Services proxy user named ORDS_PUBLIC_USER.
• Enter the database password for ORDS_PUBLIC_USER:
  Enter the password, and then confirm it.
• Requires to login with administrator privileges to verify Oracle REST Data Services schema.
  Enter the administrator user name: master_user
  Enter the database password for master_user: master_user_password
  Confirm the password: master_user_password

  **Note**
  Specify a password other than the prompt shown here as a security best practice.
• Enter the default tablespace for ORDS_METADATA [SYSAUX].
  Enter the temporary tablespace for ORDS_METADATA [TEMP].
  Enter the default tablespace for ORDS_PUBLIC_USER [USERS].
  Enter the temporary tablespace for ORDS_PUBLIC_USER [TEMP].
• Enter 1 if you want to use PL/SQL Gateway or 2 to skip this step. If you're using Oracle Application Express or migrating from mod_plsql, you must enter 1 [1].
  Choose the default.
• Enter the PL/SQL Gateway database user name [APEX_PUBLIC_USER]
  Choose the default.
• Enter the database password for APEX_PUBLIC_USER:
  Enter the password, and then confirm it.
• Enter 1 to specify passwords for Application Express RESTful Services database users (APEX_LISTENER, APEX_REST_PUBLIC_USER) or 2 to skip this step [1]:
  Choose 2 for APEX 4.1.1.V1; choose 1 for all other APEX versions.
• [Not needed for APEX 4.1.1.v1] Database password for APEX_LISTENER
  Enter the password (if required), and then confirm it.
• [Not needed for APEX 4.1.1.v1] Database password for APEX_REST_PUBLIC_USER
  Enter the password (if required), and then confirm it.
• Enter a number to select a feature to enable:
  Enter 1 to enable all features: SQL Developer Web, REST Enabled SQL, and Database API.
• Enter 1 if you wish to start in standalone mode or 2 to exit [1]:
  Enter 1.
• Enter the APEX static resources location:
  If you unzipped APEX installation files into /home/apexuser, enter /home/apexuser/apex/images. Otherwise, enter unzip_path/apex/images, where unzip_path is the directory where you unzipped the file.
• Enter 1 if using HTTP or 2 if using HTTPS [1]:
  If you enter 1, specify the HTTP port. If you enter 2, specify the HTTPS port and the SSL host name. The HTTPS option prompts you to specify how you will provide the certificate:
  • Enter 1 to use the self-signed certificate.
  • Enter 2 to provide your own certificate. If you enter 2, specify the path for the SSL certificate and the path for the SSL certificate private key.
7. Set a password for the APEX admin user. To do this, use SQL*Plus to connect to your DB instance as the master user, and then run the following commands.

```
EXEC rdsadmin.rdsadmin_util.grant_apex_admin_role;
grant APEX_ADMINISTRATOR_ROLE to master;
@/home/apexuser/apex/apxchpwd.sql
```

Replace `master` with your master user name. When the `apxchpwd.sql` script prompts you, enter a new admin password.

8. Start the ORDS listener. Run the following code.

```
java -jar ords.war
```

The first time you start ORDS, you are prompted to provide the location of the APEX Static resources. This images folder is located in the `/apex/images` directory in the installation directory for APEX.

9. Return to the APEX administration window in your browser and choose Administration. Next, choose Application Express Internal Administration. When you are prompted for credentials, enter the following information:

  • User name – admin
  • Password – the password you set using the `apxchpwd.sql` script

Choose Login, and then set a new password for the admin user.

Your listener is now ready for use.

### Setting up Oracle APEX listener

**Note**

Oracle APEX Listener is deprecated.

Amazon RDS for Oracle continues to support APEX version 4.1.1 and Oracle APEX Listener version 1.1.4. We recommend that you use the latest supported versions of Oracle APEX and ORDS.

Install Oracle APEX Listener on a separate host such as an Amazon EC2 instance, an on-premises server at your company, or your desktop computer. We assume that the name of your host is `myapexhost.example.com`, and that your host is running Linux.

### Preparing to install Oracle APEX listener

Before you can install Oracle APEX Listener, you need to create a nonprivileged OS user, and then download and unzip the APEX installation file.

**To prepare for Oracle APEX listener installation**

1. Log in to `myapexhost.example.com` as root.
2. Create a nonprivileged OS user to own the listener installation. The following command creates a new user named `apexuser`.

```
useradd -d /home/apexuser apexuser
```

The following command assigns a password to the new user.

```
pwd apexuser;
```

3. Log in to `myapexhost.example.com` as `apexuser`, and download the APEX installation file from Oracle to your `/home/apexuser` directory:

4. Unzip the file in the `/home/apexuser` directory.

```
unzip apex_<version>.zip
```

After you unzip the file, there is an `apex` directory in the `/home/apexuser` directory.

5. While you are still logged into `myapexhost.example.com` as `apexuser`, download the Oracle APEX Listener file from Oracle to your `/home/apexuser` directory.

### Installing and configuring Oracle APEX listener

Before you can use APEX, you need to download the `apex.war` file, use Java to install Oracle APEX Listener, and then start the listener.

**To install and configure Oracle APEX listener**

1. Create a new directory based on Oracle APEX Listener and open the listener file.

   Run the following code:

   ```
   mkdir /home/apexuser/apexlistener
cd /home/apexuser/apexlistener
   unzip ../apex_listener.<version>.zip
   ```

2. Run the following code.

   ```
   java -Dapex.home=./apex -Dapex.images=/home/apexuser/apex/images -Dapex.erase -jar ./apex.war
   ```

3. Enter information for the program prompts following:

   - The APEX Listener Administrator user name. The default is `adminlistener`.
   - A password for the APEX Listener Administrator.
   - The APEX Listener Manager user name. The default is `managerlistener`.
   - A password for the APEX Listener Administrator.

   The program prints a URL that you need to complete the configuration, as follows.

   ```
   INFO: Please complete configuration at: http://localhost:8080/apex/listenerConfigure
   Database is not yet configured
   ```
4. Leave Oracle APEX Listener running so that you can use Oracle Application Express. When you have finished this configuration procedure, you can run the listener in the background.

5. From your web browser, go to the URL provided by the APEX Listener program. The Oracle Application Express Listener administration window appears. Enter the following information:
   - **Username** – `APEX_PUBLIC_USER`
   - **Password** – the password for `APEX_PUBLIC_USER`. This password is the one that you specified earlier when you configured the APEX repository. For more information, see Unlocking the public user account (p. 2028).
   - **Connection type** – Basic
   - **Hostname** – the endpoint of your Amazon RDS DB instance, such as `mydb.f9rbfa893tft.us-east-1.rds.amazonaws.com`
   - **Port** – 1521
   - **SID** – the name of the database on your Amazon RDS DB instance, such as `mydb`.

6. Choose **Apply**. The APEX administration window appears.

7. Set a password for the APEX admin user. To do this, use SQL*Plus to connect to your DB instance as the master user, and then run the following commands.

   ```sql
   EXEC rdsadmin.rdsadmin_util.grant_apex_admin_role;
   grant APEX_ADMINISTRATOR_ROLE to master;
   @/home/apexuser/apex/apxchpwd.sql
   ```

   Replace `master` with your master user name. When the `apxchpwd.sql` script prompts you, enter a new admin password.

8. Return to the APEX administration window in your browser and choose **Administration**. Next, choose **Application Express Internal Administration**. When you are prompted for credentials, enter the following information:
   - **User name** – `admin`
   - **Password** – the password you set using the `apxchpwd.sql` script

   Choose **Login**, and then set a new password for the admin user.

Your listener is now ready for use.

**Upgrading the APEX version**

**Important**
Back up your DB instance before you upgrade APEX. For more information, see Creating a DB snapshot (p. 613) and Testing an Oracle DB upgrade (p. 2127).

To upgrade APEX with your DB instance, do the following:

- Create a new option group for the upgraded version of your DB instance.
- Add the upgraded versions of APEX and APEX-DEV to the new option group. Be sure to include any other options that your DB instance uses. For more information, see Option group considerations (p. 2126).
- When you upgrade your DB instance, specify the new option group for your upgraded DB instance.

After you upgrade your version of APEX, the APEX schema for the previous version might still exist in your database. If you don't need it anymore, you can drop the old APEX schema from your database after you upgrade.
If you upgrade the APEX version and RESTful services were not configured in the previous APEX version, we recommend that you configure RESTful services. For more information, see Configuring RESTful services for Oracle APEX (p. 2028).

In some cases when you plan to do a major version upgrade of your DB instance, you might find that you're using an APEX version that isn't compatible with your target database version. In these cases, you can upgrade your version of APEX before you upgrade your DB instance. Upgrading APEX first can reduce the amount of time that it takes to upgrade your DB instance.

Note
After upgrading APEX, install and configure a listener for use with the upgraded version. For instructions, see Setting up Oracle APEX listener (p. 2032).

Removing the APEX option

You can remove the Amazon RDS APEX options from a DB instance. To remove the APEX options from a DB instance, do one of the following:

- To remove the APEX options from multiple DB instances, remove the APEX options from the option group they belong to. This change affects all DB instances that use the option group. When you remove the APEX options from an option group that is attached to multiple DB instances, a brief outage occurs while all the DB instances are restarted.

  For more information, see Removing an option from an option group (p. 343).

- To remove the APEX options from a single DB instance, modify the DB instance and specify a different option group that doesn't include the APEX options. You can specify the default (empty) option group, or a different custom option group. When you remove the APEX options, a brief outage occurs while your DB instance is automatically restarted.

  For more information, see Modifying an Amazon RDS DB instance (p. 401).

When you remove the APEX options from a DB instance, the APEX schema is removed from your database.
Amazon EFS integration

Amazon Elastic File System (Amazon EFS) provides serverless, fully elastic file storage so that you can share file data without provisioning or managing storage capacity and performance. With Amazon EFS, you can create a file system and then mount it in your VPC through the NFS versions 4.0 and 4.1 (NFSv4) protocol. Then you can use the EFS file system like any other POSIX-compliant file system. For general information, see What is Amazon Elastic File System? and the AWS blog Integrate Amazon RDS for Oracle with Amazon EFS.

Topics

• Overview of Amazon EFS integration (p. 2036)
• Configuring network permissions for RDS for Oracle integration with Amazon EFS (p. 2037)
• Configuring IAM permissions for RDS for Oracle integration with Amazon EFS (p. 2038)
• Adding the EFS_INTEGRATION option (p. 2041)
• Configuring Amazon EFS file system permissions (p. 2042)
• Transferring files between RDS for Oracle and an Amazon EFS file system (p. 2043)
• Removing the EFS_INTEGRATION option (p. 2044)
• Troubleshooting Amazon EFS integration (p. 2044)

Overview of Amazon EFS integration

With Amazon EFS, you can transfer files between your RDS for Oracle DB instance and an EFS file system. For example, you can use EFS to support the following use cases:

• Share a file system between applications and multiple database servers.
• Create a shared directory for migration-related files, including transportable tablespace data files. For more information, see Migrating using Oracle transportable tablespaces (p. 1978).
• Store and share archived redo log files without allocating additional storage space on the server.
• Use Oracle Database utilities such as UTL_FILE to read and write files.

Advantages to Amazon EFS integration

When you choose an EFS file system over alternative data transfer solutions, you get the following benefits:

• You can transfer Oracle Data Pump files between Amazon EFS and your RDS for Oracle DB instance. You don't need to copy these files locally because Data Pump imports directly from the EFS file system. For more information, see Importing data into Oracle on Amazon RDS (p. 1963).
• Data migration is faster than using a database link.
• You avoid allocating storage space on your RDS for Oracle DB instance to hold the files.
• An EFS file systems can automatically scale storage without requiring you to provision it.
• Amazon EFS integration has no minimum fees or setup costs. You pay only for what you use.

Requirements for Amazon EFS integration

Make sure that you meet the following requirements:

• Your database runs database version 19.0.0.0.ru-2022-07.ru-2022-07.r1 or later.
• Your DB instance and your EFS file system are in the same AWS Region and the same VPC.
Your VPC has the enableDnsSupport attribute enabled. For more information, see DNS attributes in your VPC in the Amazon Virtual Private Cloud User Guide.

Your EFS file system uses the Standard or Standard-IA storage class.

To be able to use a DNS name in the mount command, the following must be true:

- The connecting DB instance is inside a VPC and is configured to use the DNS server provided by Amazon. Custom DNS servers aren't supported.
- The VPC of the connecting instance must have both DNS Resolution and DNS Hostnames enabled.
- The connecting instance must be inside the same VPC as the EFS file system.
- You use non-RDS solutions to back up your EFS file system. RDS for Oracle doesn't support automated backups or manual DB snapshots of an EFS file system. For more information, see Backing up your Amazon EFS file systems.

Configuring network permissions for RDS for Oracle integration with Amazon EFS

For RDS for Oracle to integrate with Amazon EFS, make sure that your DB instance has network access to an EFS file system. For more information, see Controlling network access to Amazon EFS file systems for NFS clients in the Amazon Elastic File System User Guide.

Topics
- Controlling network access with security groups (p. 2037)
- Controlling network access with file system policies (p. 2037)

Controlling network access with security groups

You can control your DB instance access to EFS file systems using network layer security mechanisms such as VPC security groups. To allow access to an EFS file system for your DB instance, make sure that your EFS file system meets the following requirements:

- An EFS mount target exists in every Availability Zone used by an RDS for Oracle DB instance.

  An EFS mount target provides an IP address for an NFSv4 endpoint at which you can mount an EFS file system. You mount your file system using its DNS name, which resolves to the IP address of the EFS mount target in the used by the Availability Zone of your DB instance.

  You can configure DB instances in different AZs to use the same EFS file system. For Multi-AZ, you need a mount point for each AZ in your deployment. You might need to move a DB instance to a different AZ. For these reasons, we recommend that you create an EFS mount point in each AZ in your VPC. By default, when you create a new EFS file system using the console, RDS creates mount targets for all AZs.

- A security group is attached to the mount target.
- The security group has an inbound rule to allow the network subnet or security group of the RDS for Oracle DB instance on TCP/2049 (Type NFS).

For more information, see Creating Amazon EFS file systems and Creating and managing EFS mount targets and security groups in the Amazon Elastic File System User Guide.

Controlling network access with file system policies

Amazon EFS integration with RDS for Oracle works with the default (empty) EFS file system policy. The default policy doesn't use IAM to authenticate. Instead, it grants full access to any anonymous client.
that can connect to the file system using a mount target. The default policy is in effect whenever a user-configured file system policy isn't in effect, including at file system creation. For more information, see Default EFS file system policy in the Amazon Elastic File System User Guide.

To strengthen access to your EFS file system for all clients, including RDS for Oracle, you can configure IAM permissions. In this approach, you create a file system policy. For more information, see Creating file system policies in the Amazon Elastic File System User Guide.

Configuring IAM permissions for RDS for Oracle integration with Amazon EFS

For RDS for Oracle to integrate with Amazon EFS, your DB instance must have IAM permissions to access an Amazon EFS file system.

Topics
- Step 1: Create an IAM role for your DB instance and attach your policy (p. 2038)
- Step 2: Create a file system policy for your Amazon EFS file system (p. 2039)
- Step 3: Associate your IAM role with your RDS for Oracle DB instance (p. 2040)

Step 1: Create an IAM role for your DB instance and attach your policy

In this step, you create a role for your RDS for Oracle DB instance to allow Amazon RDS to access your EFS file system.

Console

To create an IAM role to allow Amazon RDS access to an EFS file system

1. Open the IAM Management Console.
2. In the navigation pane, choose Roles.
3. Choose Create role.
4. For AWS service, choose RDS.
5. For Select your use case, choose RDS – Add Role to Database.
6. Choose Next.
7. Don't add any permissions policies. Choose Next.
8. Set Role name to a name for your IAM role, for example rds-efs-integration-role. You can also add an optional Description value.
9. Choose Create role.

AWS CLI

To limit the service's permissions to a specific resource, we recommend using the aws:SourceArn and aws:SourceAccount global condition context keys in resource-based trust relationships. This is the most effective way to protect against the confused deputy problem.

You might use both global condition context keys and have the aws:SourceArn value contain the account ID. In this case, the aws:SourceAccount value and the account in the aws:SourceArn value must use the same account ID when used in the same statement.

- Use aws:SourceArn if you want cross-service access for a single resource.
• Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role.

The following AWS CLI command creates the role named `rds-efs-integration-role` for this purpose.

**Example**

For Linux, macOS, or Unix:

```bash
aws iam create-role \
  --role-name rds-efs-integration-role \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
          "StringEquals": {
            "aws:SourceAccount": my_account_ID,
            "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:dbname"
          }
        }
      }
    ]
  }
}
```

For Windows:

```bash
aws iam create-role ^
  --role-name rds-efs-integration-role ^
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
          "StringEquals": {
            "aws:SourceAccount": my_account_ID,
            "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:dbname"
          }
        }
      }
    ]
  }
}
```

For more information, see [Creating a role to delegate permissions to an IAM user](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles_create_for')+` in the IAM User Guide.

**Step 2: Create a file system policy for your Amazon EFS file system**

In this step, you create a file system policy for your EFS file system.
To create or edit an EFS file system policy

1. Open the EFS Management Console.
3. On the File systems page, choose the file system that you want to edit or create a file system policy for. The details page for that file system is displayed.
4. Choose the File system policy tab.

If the policy is empty, then the default EFS file system policy is in use. For more information, see Default EFS file system policy in the Amazon Elastic File System User Guide.

5. Choose Edit. The File system policy page appears.
6. In Policy editor, enter a policy such as the following, and then choose Save.

```
{
    "Version": "2012-10-17",
    "Id": "ExamplePolicy01",
    "Statement": [
        {
            "Sid": "ExampleStatement01",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:role/rds-efs-integration-role"
            },
            "Action": ["elasticfilesystem:ClientMount",
                        "elasticfilesystem:ClientWrite",
                        "elasticfilesystem:ClientRootAccess"
                    ],
            "Resource": "arn:aws:elasticfilesystem:us-east-1:123456789012:file-system/fs-1234567890abcdef0"
        }
    ]
}
```

Step 3: Associate your IAM role with your RDS for Oracle DB instance

In this step, you associate your IAM role with your DB instance. Be aware of the following requirements:

- You must have access to an IAM role with the required Amazon EFS permissions policy attached to it.
- You can associate only one IAM role with your RDS for Oracle DB instance at a time.
- The status of your instance must be Available.

For more information, see Identity and access management for Amazon EFS in the Amazon Elastic File System User Guide.

Console

To associate your IAM role with your RDS for Oracle DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Databases.
3. If your database instance is unavailable, choose Actions and then Start. When the instance status shows Started, go to the next step.
4. Choose the Oracle DB instance name to display its details.
5. On the Connectivity & security tab, scroll down to the Manage IAM roles section at the bottom of the page.
6. Choose the role to add in the Add IAM roles to this instance section.
7. For Feature, choose EFS_INTEGRATION.
8. Choose Add role.

**AWS CLI**

The following AWS CLI command adds the role to an Oracle DB instance named mydbinstance.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds add-role-to-db-instance
  --db-instance-identifier mydbinstance
  --feature-name EFS_INTEGRATION
  --role-arn your-role-arn
```

For Windows:

```bash
aws rds add-role-to-db-instance
  --db-instance-identifier mydbinstance
  --feature-name EFS_INTEGRATION
  --role-arn your-role-arn
```

Replace your-role-arn with the role ARN that you noted in a previous step. EFS_INTEGRATION must be specified for the --feature-name option.

**Adding the EFS_INTEGRATION option**

To integrate Amazon RDS for Oracle with Amazon EFS, your DB instance must be associated with an option group that includes the EFS_INTEGRATION option.

Multiple Oracle DB instances that belong to the same option group share the same EFS file system. Different DB instances can access the same data, but access can be divided by using different Oracle directories. For more information see Transferring files between RDS for Oracle and an Amazon EFS file system (p. 2043).

**Console**

**To configure an option group for Amazon EFS integration**

1. Create a new option group or identify an existing option group to which you can add the EFS_INTEGRATION option.
   
   For information about creating an option group, see Creating an option group (p. 332).
2. Add the EFS_INTEGRATION option to the option group. You need to specify the EFS_ID file system ID and set the USE_IAM_ROLE flag.
   
   For more information, see Adding an option to an option group (p. 335).
3. Associate the option group with your DB instance in either of the following ways:
   
   - Create a new Oracle DB instance and associate the option group with it. For information about creating a DB instance, see Creating an Amazon RDS DB instance (p. 300).
• Modify an Oracle DB instance to associate the option group with it. For information about modifying an Oracle DB instance, see Modifying an Amazon RDS DB instance (p. 401).

AWS CLI

To configure an option group for EFS integration

1. Create a new option group or identify an existing option group to which you can add the EFS_INTEGRATION option.
   For information about creating an option group, see Creating an option group (p. 332).
2. Add the EFS_INTEGRATION option to the option group.
   For example, the following AWS CLI command adds the EFS_INTEGRATION option to an option group named myoptiongroup.

   Example
   For Linux, macOS, or Unix:
   ```
   aws rds add-option-to-option-group \
   --option-group-name myoptiongroup \
   --options "OptionName=EFS_INTEGRATION,OptionSettings=\n   [{Name=EFS_ID,Value=fs-1234567890abcdef0},{Name=USE_IAM_ROLE,Value=TRUE}]"
   ```
   For Windows:
   ```
   aws rds add-option-to-option-group ^
   --option-group-name myoptiongroup ^
   --options "OptionName=EFS_INTEGRATION,OptionSettings=^\n   [{Name=EFS_ID,Value=fs-1234567890abcdef0},{Name=USE_IAM_ROLE,Value=TRUE}]"
   ```
3. Associate the option group with your DB instance in either of the following ways:
   • Create a new Oracle DB instance and associate the option group with it. For information about creating a DB instance, see Creating an Amazon RDS DB instance (p. 300).
   • Modify an Oracle DB instance to associate the option group with it. For information about modifying an Oracle DB instance, see Modifying an Amazon RDS DB instance (p. 401).

Configuring Amazon EFS file system permissions

By default, only the root user (UID 0) has read, write, and execute permissions for a newly created EFS file system. For other users to modify the file system, the root user must explicitly grant them access. The user for the RDS for Oracle DB instance is in the others category. For more information, see Working with users, groups, and permissions at the Network File System (NFS) Level in the Amazon Elastic File System User Guide.

To allow your RDS for Oracle DB instance to read and write files on an EFS file system, do the following:

• Mount an EFS file system locally on your Amazon EC2 or on-premises instance.
• Configure fine grain permissions.

For example, to grant other users permissions to write to the EFS file system root, run chmod 777 on this directory. For more information, see Example Amazon EFS file system use cases and permissions in the Amazon Elastic File System User Guide.
Transferring files between RDS for Oracle and an Amazon EFS file system

To transfer files between an RDS for Oracle instance and an Amazon EFS file system, create at least one Oracle directory and configure EFS file system permissions to control DB instance access.

Topics

• Creating an Oracle directory (p. 2043)
• Transferring data to and from an EFS file system: examples (p. 2043)

Creating an Oracle directory

To create an Oracle directory, use the procedure `rdsadmin.rdsadmin_util.create_directory_efs`. The procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_directory_name</td>
<td>VARCHAR2</td>
<td>–</td>
<td>Yes</td>
<td>The name of the Oracle directory.</td>
</tr>
<tr>
<td>p_path_on_efs</td>
<td>VARCHAR2</td>
<td>–</td>
<td>Yes</td>
<td>The path on the EFS file system. The prefix of the path name uses the pattern <code>/rdsefs-fsid/</code>, where <code>fsid</code> is a placeholder for your EFS file system ID. For example, if your EFS file system is named <code>fs-1234567890abcdef0</code>, and you create a subdirectory on this file system named <code>mydir</code>, you could specify the following value: <code>/rdsefs-fs-1234567890abcdef0/mydir</code></td>
</tr>
</tbody>
</table>

Assume that you create a subdirectory named `/datapump1` on the EFS file system `fs-1234567890abcdef0`. The following example creates an Oracle directory `DATA_PUMP_DIR_EFS` that points to the `/datapump1` directory on the EFS file system. The file system path value for the `p_path_on_efs` parameter is prefixed with the string `/rdsefs-`.

```sql
BEGIN
  rdsadmin.rdsadmin_util.create_directory_efs(    
    p_directory_name => 'DATA_PUMP_DIR_EFS', 
    p_path_on_efs    => '/rdsefs-fs-1234567890abcdef0/datapump1');
END;
```

Transferring data to and from an EFS file system: examples

The following example uses Oracle Data Pump to export the table named `MY_TABLE` to file `datapump.dmp`. This file resides on an EFS file system.

```sql
DECLARE
  v_hdnl NUMBER;
BEGIN
  v_hdnl := DBMS_DATAPUMP.OPEN(operation => 'EXPORT', job_mode => 'TABLE', job_name=>null);
  DBMS_DATAPUMP.ADD_FILE(
    handle => v_hdnl,
```
The following example uses Oracle Data Pump to import the table named MY_TABLE from file datapump.dmp. This file resides on an EFS file system.

```sql
DECLARE
  v_hdnl NUMBER;
BEGIN
  v_hdnl := DBMS_DATAPUMP.OPEN(
    operation => 'IMPORT',
    job_mode  => 'TABLE',
    job_name  => null);
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'datapump.dmp',
    directory => 'DATA_PUMP_DIR_EFS',
    filetype  => dbms_datapump.ku$_file_type_dump_file );
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'datapump-exp.log',
    directory => 'DATA_PUMP_DIR_EFS',
    filetype  => dbms_datapump.ku$_file_type_log_file);
  DBMS_DATAPUMP.METADATA_FILTER(v_hdnl,'NAME_EXPR','IN (''MY_TABLE'')');
  DBMS_DATAPUMP.START_JOB(v_hdnl);
END;
/
```

For more information, see Importing data into Oracle on Amazon RDS (p. 1963).

### Removing the EFS_INTEGRATION option

To remove the EFS_INTEGRATION option from an RDS for Oracle DB instance, do one of the following:

- To remove the EFS_INTEGRATION option from multiple DB instances, remove the EFS_INTEGRATION option from the option group to which the DB instances belong. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 343).

- To remove the EFS_INTEGRATION option from a single DB instance, modify the instance and specify a different option group that doesn't include the EFS_INTEGRATION option. You can specify the default (empty) option group or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 401).

### Troubleshooting Amazon EFS integration

Your RDS for Oracle DB instance monitors the connectivity to an Amazon EFS file system. When monitoring detects an issue, it might try to correct the issue and publish an event in the RDS console. For more information, see Viewing Amazon RDS events.
Use the information in this section to help you diagnose and fix common issues when you work with Amazon EFS integration.

<table>
<thead>
<tr>
<th>Notification</th>
<th>Description</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>The EFS for RDS Oracle instance <code>instance_name</code> isn't available on the primary host. NFS port 2049 of your EFS isn't reachable.</td>
<td>The DB instance can't communicate with the EFS file system.</td>
<td>Make sure of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• The EFS file system exists.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• The security group that is attached to the EFS mount target has an inbound rule to allow the security group or network subnet of the RDS for Oracle DB instance on TCP/2049 (Type NFS).</td>

<tr>
<td></td>
<td></td>
<td>• The connecting DB instance is inside a VPC and is configured to use the DNS server provided by Amazon. Custom DNS servers aren't supported.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• The VPC of the connecting instance must have both DNS Resolution and DNS Hostnames enabled.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• The connecting instance must be inside the same VPC as the EFS file system.</td>
</tr>
</tbody>
</table>

simplest technique is to run the `chmod 777` command on the top directory of the EFS file system.
Oracle Java virtual machine

Amazon RDS supports Oracle Java Virtual Machine (JVM) through the use of the JVM option. Oracle Java provides a SQL schema and functions that facilitate Oracle Java features in an Oracle database. For more information, see Introduction to Java in Oracle database in the Oracle documentation.

You can use Oracle JVM with the following Oracle Database versions:

- Oracle Database 21c (21.0.0), all versions
- Oracle Database 19c (19.0.0), all versions
- Oracle Database 12c Release 2 (12.2), all versions
- Oracle Database 12c Release 1 (12.1), version 12.1.0.2.v13 and higher

Java implementation in Amazon RDS has a limited set of permissions. The master user is granted the RDS_JAVA_ADMIN role, which grants a subset of the privileges granted by the JAVA_ADMIN role. To list the privileges granted to the RDS_JAVA_ADMIN role, run the following query on your DB instance:

```
SELECT * FROM dba_java_policy
WHERE grantee IN ('RDS_JAVA_ADMIN', 'PUBLIC')
AND enabled = 'ENABLED'
ORDER BY type_name, name, grantee;
```

Prerequisites for Oracle JVM

The following are prerequisites for using Oracle Java:

- Your DB instance must be of a large enough class. Oracle Java isn't supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see DB instance classes (p. 11).
- Your DB instance must have Auto Minor Version Upgrade enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available. Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance (p. 401).

Best practices for Oracle JVM

The following are best practices for using Oracle Java:

- For maximum security, use the JVM option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer (p. 2084).
- Configure your DB instance to restrict network access. For more information, see Scenarios for accessing a DB instance in a VPC (p. 2718) and Working with a DB instance in a VPC (p. 2705).
- Update the configuration of your HTTPS endpoints to support TLSv1.2 if you meet the following conditions:
  - You use Oracle Java Virtual Machine (JVM) to connect an HTTPS endpoint over TLSv1 or TLSv1.1 protocols.
  - Your endpoint doesn't support the TLSv1.2 protocol.
  - You haven't applied the April 2021 release update to your Oracle DB.

By updating your endpoint configuration, you ensure that the connectivity of the JVM to the HTTPS endpoint will continue to work. For more information about TLS changes in the Oracle JRE and JDK, see Oracle JRE and JDK Cryptographic Roadmap.
Adding the Oracle JVM option

The following is the general process for adding the JVM option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

There is a brief outage while the JVM option is added. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle Java is available.

**Note**
During this outage, password verification functions are disabled briefly. You can also expect to see events related to password verification functions during the outage. Password verification functions are enabled again before the Oracle DB instance is available.

**To add the JVM option to a DB instance**

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   - For **Engine**, choose the DB engine used by the DB instance (*oracle-ee*, *oracle-se*, *oracle-se1*, or *oracle-se2*).
   - For **Major engine version**, choose the version of your DB instance.

   For more information, see [Creating an option group](p. 332).

2. Add the **JVM** option to the option group. For more information about adding options, see [Adding an option to an option group](p. 335).

3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](p. 300).
   - For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. For more information, see [Modifying an Amazon RDS DB instance](p. 401).

4. Grant the required permissions to users.

   The Amazon RDS master user has the permissions to use the JVM option by default. If other users require these permissions, connect to the DB instance as the master user in a SQL client and grant the permissions to the users.

   The following example grants the permissions to use the JVM option to the test_proc user.

   ```sql
   create user test_proc identified by password;
   CALL dbms_java.grant_permission('TEST_PROC', 'oracle.aurora.security.JServerPermission', 'LoadClassInPackage.*', '');
   ```

   **Note**
   Specify a password other than the prompt shown here as a security best practice.

   After the user is granted the permissions, the following query should return output.

   ```sql
   select * from dba_java_policy where grantee='TEST_PROC';
   ```
Note
The Oracle user name is case-sensitive, and it usually has all uppercase characters.

Removing the Oracle JVM option

You can remove the JVM option from a DB instance. There is a brief outage while the option is removed. After you remove the JVM option, you don't need to restart your DB instance.

Warning
Removing the JVM option can result in data loss if the DB instance is using data types that were enabled as part of the option. Back up your data before proceeding. For more information, see Backing up and restoring (p. 590).

To remove the JVM option from a DB instance, do one of the following:

- Remove the JVM option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 343).
- Modify the DB instance and specify a different option group that doesn't include the JVM option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 401).
Oracle Enterprise Manager

Amazon RDS supports Oracle Enterprise Manager (OEM). OEM is the Oracle product line for integrated management of enterprise information technology.

Amazon RDS supports OEM through the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Option ID</th>
<th>Supported OEM releases</th>
<th>Supported Oracle Database releases</th>
</tr>
</thead>
<tbody>
<tr>
<td>OEM Database</td>
<td>OEM</td>
<td>OEM Database Express 12c</td>
<td>Oracle Database 19c (non-CDB only)</td>
</tr>
<tr>
<td>Express (p. 2051)</td>
<td></td>
<td></td>
<td>Oracle Database 12c</td>
</tr>
<tr>
<td>OEM Management</td>
<td>OEM_AGENT</td>
<td>OEM Cloud Control for 13c</td>
<td>Oracle Database 19c (non-CDB only)</td>
</tr>
<tr>
<td>Agent (p. 2055)</td>
<td></td>
<td>OEM Cloud Control for 12c</td>
<td>Oracle Database 12c</td>
</tr>
</tbody>
</table>

**Note**
You can use OEM Database or OEM Management Agent, but not both.

**Note**
These options aren't supported for the Oracle multitenant architecture.
Oracle Enterprise Manager Database Express

Amazon RDS supports Oracle Enterprise Manager (OEM) Database Express through the use of the OEM option. Amazon RDS supports Oracle Enterprise Manager Database Express for the following releases:

- Oracle Database 19c (non-CDB only)
- Oracle Database 12c

OEM Database Express and Database Control are similar tools that have a web-based interface for Oracle database administration. For more information about these tools, see Accessing Enterprise Manager database Express 18c and Accessing Enterprise Manager Database Express 12c in the Oracle documentation.

The following is a limitation for OEM Database Express:

- OEM Database Express isn't supported on the db.t3.micro or db.t3.small DB instance classes.

For more information about DB instance classes, see RDS for Oracle instance classes (p. 1812).

OEM Database option settings

Amazon RDS supports the following settings for the OEM option.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>An integer value</td>
<td>The port on the DB instance that listens for OEM Database. The default for OEM Database Express is 5500.</td>
</tr>
<tr>
<td>Security Groups</td>
<td>—</td>
<td>A security group that has access to Port.</td>
</tr>
</tbody>
</table>

Adding the OEM Database option

The general process for adding the OEM option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

When you add the OEM option for an Oracle Database 12c or later DB instance, a brief outage occurs while your DB instance is automatically restarted.

To add the OEM option to a DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For Engine choose the oracle edition for your DB instance.
   b. For Major engine version choose the version of your DB instance.
2. Add the OEM option to the option group, and configure the option settings. For more information about adding options, see Adding an option to an option group (p. 335). For more information about each setting, see OEM Database option settings (p. 2051).

**Note**
If you add the OEM option to an existing option group that is already attached to one or more Oracle Database 19c (non-CDB only) or Oracle Database 12c DB instances, a brief outage occurs while all the DB instances are automatically restarted.

3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating a new Amazon RDS DB instance (p. 300).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. When you add the OEM option for an Oracle Database 19c (non-CDB only) or Oracle Database 12c DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see Modifying an Amazon RDS DB instance (p. 401).

**Note**
You can also use the AWS CLI to add the OEM option. For examples, see Adding an option to an option group (p. 335).

### Accessing OEM through your browser

After you enable the OEM option, you can begin using the OEM Database tool from your web browser.

You can access either OEM Database Control or OEM Database Express from your web browser. For example, if the endpoint for your Amazon RDS DB instance is mydb.f9rbfa893tft.us-east-1.rds.amazonaws.com, and your OEM port is 1158, then the URL to access the OEM Database Control is the following.

```plaintext
https://mydb.f9rbfa893tft.us-east-1.rds.amazonaws.com:1158/em
```

When you access either tool from your web browser, a login window appears that prompts you for a user name and password. Type the master user name and master password for your DB instance. You are now ready to manage your Oracle databases.

### Modifying OEM Database settings

After you enable OEM Database, you can modify the Security Groups setting for the option.

You can't modify the OEM port number after you have associated the option group with a DB instance. To change the OEM port number for a DB instance, do the following:

1. Create a new option group.
2. Add the OEM option with the new port number to the new option group.
3. Remove the existing option group from the DB instance.
4. Add the new option group to the DB instance.

For more information about how to modify option settings, see Modifying an option setting (p. 340). For more information about each setting, see OEM Database option settings (p. 2051).
Running OEM Database Express tasks

You can use Amazon RDS procedures to run certain OEM Database Express tasks. By running these procedures, you can do the tasks listed following.

**Note**

OEM Database Express tasks run asynchronously.

**Tasks**

- Switching the website front end for OEM Database Express to Adobe Flash (p. 2053)
- Switching the website front end for OEM Database Express to Oracle JET (p. 2054)

Switching the website front end for OEM Database Express to Adobe Flash

**Note**

This task is available only for Oracle Database 19c non-CDBs.

Starting with Oracle Database 19c, Oracle has deprecated the former OEM Database Express user interface, which was based on Adobe Flash. Instead, OEM Database Express now uses an interface built with Oracle JET. If you experience difficulties with the new interface, you can switch back to the deprecated Flash-based interface. Difficulties you might experience with the new interface include being stuck on a Loading screen after logging in to OEM Database Express. You might also miss certain features that were present in the Flash-based version of OEM Database Express.

To switch the OEM Database Express website front end to Adobe Flash, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_flash`. This procedure is equivalent to the `execemx emx` SQL command.

Security best practices discourage the use of Adobe Flash. Although you can revert to the Flash-based OEM Database Express, we recommend the use of the JET-based OEM Database Express websites if possible. If you revert to using Adobe Flash and want to switch back to using Oracle JET, use the `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet` procedure. After an Oracle database upgrade, a newer version of Oracle JET might resolve JET-related issues in OEM Database Express. For more information about switching to Oracle JET, see Switching the website front end for OEM Database Express to Oracle JET (p. 2054).

**Note**

Running this task from the source DB instance for a read replica also causes the read replica to switch its OEM Database Express website front ends to Adobe Flash.

The following procedure invocation creates a task to switch the OEM Database Express website to Adobe Flash and returns the ID of the task.

```sql
SELECT rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_flash() as TASK_ID FROM DUAL;
```

You can view the result by displaying the task's output file.

```sql
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-task-id.log'));
```

Replace `task-id` with the task ID returned by the procedure. For more information about the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`, see Reading files in a DB instance directory (p. 1943)

You can also view the contents of the task's output file in the AWS Management Console by searching the log entries in the Logs & events section for the task-id.
Switching the website front end for OEM Database Express to Oracle JET

Note
This task is available only for Oracle Database 19c non-CDBs.

To switch the OEM Database Express website front end to Oracle JET, run the Amazon RDS procedure rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet. This procedure is equivalent to the execemx omx SQL command.

By default, the OEM Database Express websites for Oracle DB instances running 19c or later use Oracle JET. If you used the rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_flash procedure to switch the OEM Database Express website front end to Adobe Flash, you can switch back to Oracle JET. To do this, use the rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet procedure. For more information about switching to Adobe Flash, see Switching the website front end for OEM Database Express to Adobe Flash (p. 2053).

Note
Running this task from the source DB instance for a read replica also causes the read replica to switch its OEM Database Express website front ends to Oracle JET.

The following procedure invocation creates a task to switch the OEM Database Express website to Oracle JET and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet() as TASK_ID from DUAL;
```

You can view the result by displaying the task's output file.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-task-id.log'));
```

Replace task-id with the task ID returned by the procedure. For more information about the Amazon RDS procedure rdsadmin.rds_file_util.read_text_file, see Reading files in a DB instance directory (p. 1943)

You can also view the contents of the task's output file in the AWS Management Console by searching the log entries in the Logs & events section for the task-id.

Removing the OEM Database option

You can remove the OEM option from a DB instance. When you remove the OEM option for an Oracle Database 12c or later DB instance, a brief outage occurs while your instance is automatically restarted. Therefore, after you remove the OEM option, you don't need to restart your DB instance.

To remove the OEM option from a DB instance, do one of the following:

- Remove the OEM option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 343).
- Modify the DB instance and specify a different option group that doesn't include the OEM option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 401).
Oracle Management Agent for Enterprise Manager Cloud Control

Oracle Enterprise Manager (OEM) Management Agent is a software component that monitors targets running on hosts and communicates that information to the middle-tier Oracle Management Service (OMS). For more information, see Overview of Oracle Enterprise Manager cloud control 12c and Overview of Oracle Enterprise Manager cloud control 13c in the Oracle documentation.

Amazon RDS supports Management Agent through the use of the OEM_AGENT option. Management Agent requires an Amazon RDS DB instance running any of the following releases:

- Oracle Database 19c (19.0.0.0) using the non-CDB architecture
- Oracle Database 12c Release 2 (12.2.0.1)
- Oracle Database 12c Release 1 (12.1.0.2)

Amazon RDS supports Management Agent for the following versions of OEM:

- Oracle Enterprise Manager Cloud Control for 13c
- Oracle Enterprise Manager Cloud Control for 12c

Topics

- Prerequisites for Management Agent (p. 2055)
- Limitations for Management Agent (p. 2057)
- Option settings for Management Agent (p. 2057)
- Adding the Management Agent option (p. 2059)
- Using the Management Agent (p. 2060)
- Modifying Management Agent settings (p. 2061)
- Performing database tasks with the Management Agent (p. 2061)
- Removing the Management Agent option (p. 2064)

Prerequisites for Management Agent

To use Management Agent, ensure that you meet the following prerequisites.

General prerequisites

Following are general prerequisites for using Management Agent:

- You need an Oracle Management Service (OMS) that is configured to connect to your Amazon RDS DB instance.
- In most cases, you must configure your VPC to allow connections from OMS to your DB instance. If you aren't familiar with Amazon Virtual Private Cloud (Amazon VPC), we recommend that you complete the steps in Tutorial: Create a VPC for use with a DB instance (IPv4 only) (p. 2723) before continuing.
- Management Agent version 13.5.0.0.v1 requires OMS version 13.5.0.0 or later.
- Management Agent version 13.4.0.9.v1 requires OMS version 13.4.0.9 or later and patch 32198287.
- Ensure that you have sufficient storage space for your OEM release:
  - At least 8.5 GiB for OEM 13c Release 5
  - At least 8.5 GiB for OEM 13c Release 4
  - At least 8.5 GiB for OEM 13c Release 3
  - At least 5.5 GiB for OEM 13c Release 2
• At least 4.5 GiB OEM 13c Release 1
• At least 2.5 GiB for OEM 12c

• If you are using Management Agent versions OEM_AGENT 13.2.0.0.v3 and 13.3.0.0.v2, and if you want to use TCPS connectivity, follow the instructions in Configuring third party CA certificates for communication with target databases in the Oracle documentation. Also, update the JDK on your OMS by following the instructions in the Oracle document with the Oracle Doc ID 2241358.1. This step ensures that OMS supports all the cipher suites that the database supports.

Note

TCPS connectivity between the Management Agent and the DB instance is supported for Management Agent OEM_AGENT 13.2.0.0.v3, 13.3.0.0.v2, 13.4.0.9.v1, and higher versions.

Oracle Database release prerequisites

Following are the supported Oracle Database versions for each Management Agent version.

<table>
<thead>
<tr>
<th>Management Agent version</th>
<th>Oracle Database 19c using the non-CDB architecture</th>
<th>Oracle Database 12c Release 2 (12.2)</th>
<th>Oracle Database 12c Release 1 (12.1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>13.5.0.0.v1</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.4.0.9.v1</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.3.0.0.v2</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.3.0.0.v1</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.2.0.0.v3</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.2.0.0.v2</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.2.0.0.v1</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.1.0.0.v1</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>12.1.0.5.v1</td>
<td>Not supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>12.1.0.4.v1</td>
<td>Not supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
</tbody>
</table>

Following are prerequisites for different database versions:

• For an Amazon RDS DB instance running Oracle Database 19c (19.0.0.0), the minimum AGENT_VERSION is 13.1.0.0.v1.
• For an Amazon RDS DB instance running Oracle Database Release 2 (12.2.0.1) or lower, meet the following requirements:
  • For OMS 13c Release 2 with Oracle patch 25163555 applied, use OEM Agent 13.2.0.0.v2 or later.
  Use OMSUpdater to apply the patch.
  • For unpatched OMS 13c Release 2, use OEM Agent 13.2.0.0.v1.
  Use OMSUpdater to apply patches.
OMS host communication prerequisites

Make sure that your OMS host and your Amazon RDS DB instance can communicate. Do the following:

- To connect from the Management Agent to your OMS, if your OMS is behind a firewall, add the IP addresses of your DB instances to your OMS.

  Make sure the firewall for the OMS allows traffic from both the DB listener port (default 1521) and the OEM Agent port (default 3872), originating from the IP address of the DB instance.

- To connect from your OMS to the Management Agent, if your OMS has a publicly resolvable host name, add the OMS address to a security group. Your security group must have inbound rules that allow access to the DB listener port and the Management Agent port. For an example of creating a security and adding inbound rules, see Tutorial: Create a VPC for use with a DB instance (IPv4 only) (p. 2723).

- To connect from your OMS to the Management Agent, if your OMS doesn't have a publicly resolvable host name, use one of the following:

  - If your OMS is hosted on an Amazon Elastic Compute Cloud (Amazon EC2) instance in a private VPC, you can set up VPC peering to connect from OMS to Management Agent. For more information, see A DB instance in a VPC accessed by an EC2 instance in a different VPC (p. 2720).

  - If your OMS is hosted on-premises, you can set up a VPN connection to allow access from OMS to Management Agent. For more information, see A DB instance in a VPC accessed by a client application through the internet (p. 2721) or VPN connections.

Limitations for Management Agent

Following are some limitations to using Management Agent:

- Administrative tasks such as job execution and database patching, that require host credentials, aren't supported.

- Host metrics and the process list aren't guaranteed to reflect the actual system state. Thus, you shouldn't use OEM to monitor the root file system or mount point file system. For more information about monitoring the operating system, see Monitoring OS metrics with Enhanced Monitoring (p. 797).

- Autodiscovery isn't supported. You must manually add database targets.

- OMS module availability depends on your database edition. For example, the database performance diagnosis and tuning module is only available for Oracle Database Enterprise Edition.

- Management Agent consumes additional memory and computing resources. If you experience performance problems after enabling the OEM_AGENT option, we recommend that you scale up to a larger DB instance class. For more information, see DB instance classes (p. 11) and Modifying an Amazon RDS DB instance (p. 401).

- The user running the OEM_AGENT on the Amazon RDS host doesn't have operating system access to the alert log. Thus, you can't collect metrics for DB Alert Log and DB Alert Log Error Status in OEM.

Option settings for Management Agent

Amazon RDS supports the following settings for the Management Agent option.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Required</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (AGENT_VERSION)</td>
<td>Yes</td>
<td>13.5.0.0.v1</td>
<td>The version of the Management Agent software.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>13.4.0.9.v1</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>13.3.0.0.v2</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>The AWS CLI option name is OptionVersion.</td>
<td></td>
</tr>
<tr>
<td>Option setting</td>
<td>Required</td>
<td>Valid values</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------------</td>
<td>----------</td>
<td>-------------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>13.3.0.0.v1 13.2.0.0.v3 13.2.0.0.v2 13.1.0.0.v1 12.1.0.5.v1 12.1.0.4.v1</td>
<td><strong>Note</strong> In the AWS GovCloud (US) Regions, 12.1 and 13.1 versions aren't available.</td>
</tr>
<tr>
<td>Port (AGENT_PORT)</td>
<td>Yes</td>
<td>An integer value</td>
<td>The port on the DB instance that listens for the OMS host. The default is 3872. Your OMS host must belong to a security group that has access to this port. The AWS CLI option name is Port.</td>
</tr>
<tr>
<td>Security Groups</td>
<td>Yes</td>
<td>Existing security groups</td>
<td>A security group that has access to Port. Your OMS host must belong to this security group. The AWS CLI option name is VpcSecurityGroupMemberships or DBSecurityGroupMemberships.</td>
</tr>
<tr>
<td>OMS_HOST</td>
<td>Yes</td>
<td>A string value, for example my.example.oms</td>
<td>The publicly accessible host name or IP address of the OMS. The AWS CLI option name is OMS_HOST.</td>
</tr>
<tr>
<td>OMS_PORT</td>
<td>Yes</td>
<td>An integer value</td>
<td>The HTTPS upload port on the OMS Host that listens for the Management Agent. To determine the HTTPS upload port, connect to the OMS host, and run the following command (which requires the SYSMAN password): emctl status oms -details The AWS CLI option name is OMS_PORT.</td>
</tr>
<tr>
<td>AGENT_REGISTRATION_PASSWORD</td>
<td>Yes</td>
<td>A string value</td>
<td>The password that the Management Agent uses to authenticate itself with the OMS. We recommend that you create a persistent password in your OMS before enabling the OEM_AGENT option. With a persistent password you can share a single Management Agent option group among multiple Amazon RDS databases. The AWS CLI option name is AGENT_REGISTRATION_PASSWORD.</td>
</tr>
<tr>
<td>Option setting</td>
<td>Required</td>
<td>Valid values</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>----------</td>
<td>--------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ALLOW_TLS_ONLY</td>
<td>No</td>
<td>true, false</td>
<td>A value that configures the OEM Agent to support only the TLSv1 protocol while the agent listens as a server. This setting is only supported for 12.1 agent versions. Later agent versions only support Transport Layer Security (TLS) by default.</td>
</tr>
<tr>
<td>MINIMUM_TLS_VERSION</td>
<td>No</td>
<td>TLSv1 (default), TLSv1.2</td>
<td>A value that specifies the minimum TLS version supported by the OEM Agent while the agent listens as a server. This setting is only supported for agent versions 13.1.0.0.v1 and higher. Earlier agent versions only support the TLSv1 setting.</td>
</tr>
<tr>
<td>TLS_CIPHER_SUITE</td>
<td>No</td>
<td>See TLS settings for the Management Agent option (p. 2059)</td>
<td>A value that specifies the TLS cipher suite used by the OEM Agent while the agent listens as a server.</td>
</tr>
</tbody>
</table>

The following table lists the TLS cipher suites that the Management Agent option supports.

**TLS settings for the Management Agent option**

<table>
<thead>
<tr>
<th>Cipher suite</th>
<th>Agent version supported</th>
<th>FedRAMP compliant</th>
</tr>
</thead>
<tbody>
<tr>
<td>TLS_RSA_WITH_AES_128_CBC_SHA</td>
<td>All</td>
<td>No</td>
</tr>
<tr>
<td>TLS_RSA_WITH_AES_128_CBC_SHA256</td>
<td>13.1.0.0.v1 or higher</td>
<td>No</td>
</tr>
<tr>
<td>TLS_RSA_WITH_AES_256_CBC_SHA</td>
<td>13.2.0.0.v3 or higher</td>
<td>No</td>
</tr>
<tr>
<td>TLS_RSA_WITH_AES_256_CBC_SHA256</td>
<td>13.2.0.0.v3 or higher</td>
<td>No</td>
</tr>
<tr>
<td>TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA13.2.0.0.v3 or higher</td>
<td>Yes</td>
<td></td>
</tr>
<tr>
<td>TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA13.2.0.0.v3 or higher</td>
<td>Yes</td>
<td></td>
</tr>
<tr>
<td>TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256</td>
<td></td>
<td>Yes</td>
</tr>
<tr>
<td>TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384.0.0.v3 or higher</td>
<td>Yes</td>
<td></td>
</tr>
</tbody>
</table>

**Adding the Management Agent option**

The general process for adding the Management Agent option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If you encounter errors, check [My Oracle Support](https://support.oracle.com) documents for information about resolving specific problems.

After you add the Management Agent option, you don’t need to restart your DB instance. As soon as the option group is active, the OEM Agent is active.
If your OMS host is using an untrusted third-party certificate, Amazon RDS returns the following error.

| You successfully installed the OEM_AGENT option. Your OMS host is using an untrusted third party certificate. |
| Configure your OMS host with the trusted certificates from your third party. |

If this error is returned, the Management Agent option isn't enabled until the problem is corrected. For information about correcting the problem, see the My Oracle Support document 2202569.1.

**Console**

**To add the Management Agent option to a DB instance**

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine** choose the oracle edition for your DB instance.
   b. For **Major engine version** choose the version of your DB instance.

   For more information, see [Creating an option group](p. 332).

2. Add the **OEM_AGENT** option to the option group, and configure the option settings. For more information about adding options, see [Adding an option to an option group](p. 335). For more information about each setting, see [Option settings for Management Agent](p. 2057).

3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](p. 300).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see [Modifying an Amazon RDS DB instance](p. 401).

**AWS CLI**

The following example uses the AWS CLI `add-option-to-option-group` command to add the OEM_AGENT option to an option group called `myoptiongroup`.

For Linux, macOS, or Unix:

```bash
aws rds add-option-to-option-group \
  --option-group-name "myoptiongroup" \
  --options
  OptionName=OEM_AGENT,OptionVersion=13.1.0.0.v1,Port=3872,VpcSecurityGroupMemberships=sg-1234567890,OptionSettings=[
  \{Name=OMS_HOST,Value=my.example.oms\},\{Name=OMS_PORT,Value=4903\},\{Name=AGENT_REGISTRATION_PASSWORD,Value=password\}]
  --apply-immediately
```

For Windows:

```bash
aws rds add-option-to-option-group ^
  --option-group-name "myoptiongroup" ^
  --options
  OptionName=OEM_AGENT,OptionVersion=13.1.0.0.v1,Port=3872,VpcSecurityGroupMemberships=sg-1234567890,OptionSettings=[
  \{Name=OMS_HOST,Value=my.example.oms\},\{Name=OMS_PORT,Value=4903\},\{Name=AGENT_REGISTRATION_PASSWORD,Value=password\}]
  --apply-immediately
```

**Using the Management Agent**

After you enable the Management Agent option, take the following steps to begin using it.
To use the Management Agent

1. Unlock and reset the DBSNMP account credential. Do this by running the following code on your target database on your DB instance and using your master user account.

   ```sql
   ALTER USER dbsnmp IDENTIFIED BY new_password ACCOUNT UNLOCK;
   ```

2. Add your targets to the OMS console manually:
   
   a. In your OMS console, choose Setup, Add Target, Add Targets Manually.
   b. Choose Add Targets Declaratively by Specifying Target Monitoring Properties.
   c. For Target Type, choose Database Instance.
   d. For Monitoring Agent, choose the agent with the identifier that is the same as your RDS DB instance identifier.
   e. Choose Add Manually.
   f. Enter the endpoint for the Amazon RDS DB instance, or choose it from the host name list. Make sure that the specified host name matches the endpoint of the Amazon RDS DB instance.
      
      For information about finding the endpoint for your Amazon RDS DB instance, see Finding the endpoint of your RDS for Oracle DB instance (p. 1822).
   g. Specify the following database properties:
      
      • For Target name, enter a name.
      • For Database system name, enter a name.
      • For Monitor username, enter dbsnmp.
      • For Monitor password, enter the password from step 1.
      • For Role, enter normal.
      • For Oracle home path, enter /oracle.
      • For Listener Machine name, the agent identifier already appears.
      • For Port, enter the database port. The RDS default port is 1521.
      • For Database name, enter the name of your database.
   h. Choose Test Connection.
   i. Choose Next. The target database appears in your list of monitored resources.

Modifying Management Agent settings

After you enable the Management Agent, you can modify settings for the option. For more information about how to modify option settings, see Modifying an option setting (p. 340). For more information about each setting, see Option settings for Management Agent (p. 2057).

Performing database tasks with the Management Agent

You can use Amazon RDS procedures to run certain EMCTL commands on the Management Agent. By running these procedures, you can do the tasks listed following.

Note
Tasks are executed asynchronously.

Tasks

• Getting the status of the Management Agent (p. 2062)
• Restarting the Management Agent (p. 2062)
• Listing the targets monitored by the Management Agent (p. 2062)
• Listing the collection threads monitored by the Management Agent (p. 2062)
• **Clearing the Management Agent state (p. 2063)**
• **Making the Management Agent upload its OMS (p. 2063)**
• **Pinging the OMS (p. 2063)**
• **Viewing the status of an ongoing task (p. 2063)**

**Getting the status of the Management Agent**

To get the status of the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.get_status_oem_agent`. This procedure is equivalent to the `emctl status agent` command.

The following procedure creates a task to get the Management Agent's status and returns the ID of the task.

```sql
SELECT rdsadmin.rdsadmin_oem_agent_tasks.get_status_oem_agent() as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see [Viewing the status of an ongoing task (p. 2063)](#).

**Restarting the Management Agent**

To restart the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.restart_oem_agent`. This procedure is equivalent to running the `emctl stop agent` and `emctl start agent` commands.

The following procedure creates a task to restart the Management Agent and returns the ID of the task.

```sql
SELECT rdsadmin.rdsadmin_oem_agent_tasks.restart_oem_agent as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see [Viewing the status of an ongoing task (p. 2063)](#).

**Listing the targets monitored by the Management Agent**

To list the targets monitored by the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.list_targets_oem_agent`. This procedure is equivalent to running the `emctl config agent listtargets` command.

The following procedure creates a task to list the targets monitored by the Management Agent and returns the ID of the task.

```sql
SELECT rdsadmin.rdsadmin_oem_agent_tasks.list_targets_oem_agent as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see [Viewing the status of an ongoing task (p. 2063)](#).

**Listing the collection threads monitored by the Management Agent**

To list all the running, ready, and scheduled collection threads monitored by the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.list_clxn_threads_oem_agent`. This procedure is equivalent to the `emctl status agent scheduler` command.

The following procedure creates a task to list the collection threads and returns the ID of the task.

```sql
SELECT rdsadmin.rdsadmin_oem_agent_tasks.list_clxn_threads_oem_agent as TASK_ID from DUAL;
```
### Clearing the Management Agent state

To clear the Management Agent's state, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.clearstate_oem_agent()`. This procedure is equivalent to running the `emctl clearstate` command.

The following procedure creates a task that clears the Management Agent's state and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.clearstate_oem_agent() as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see [Viewing the status of an ongoing task](#) (p. 2063).

### Making the Management Agent upload its OMS

To make the Management Agent upload the Oracle Management Server (OMS) associated with it, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.upload_oem_agent()`. This procedure is equivalent to running the `emctl upload` command.

The following procedure creates a task that makes the Management Agent upload its associated OMS and return the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.upload_oem_agent() as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see [Viewing the status of an ongoing task](#) (p. 2063).

### Pinging the OMS

To ping the Management Agent's OMS, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.ping_oms_oem_agent()`. This procedure is equivalent to running the `emctl pingOMS` command.

The following procedure creates a task that pings the Management Agent's OMS and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.ping_oms_oem_agent() as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see [Viewing the status of an ongoing task](#) (p. 2063).

### Viewing the status of an ongoing task

You can view the status of an ongoing task in a bdump file. The bdump files are located in the `/rdsdbdata/log/trace` directory. Each bdump file name is in the following format.

```
dbtask-<task-id>.log
```

When you want to monitor a task, replace `<task-id>` with the ID of the task that you want to monitor.
To view the contents of bdump files, run the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`. The following query returns the contents of the `dbtask-154698886389-2444.log` bdump file.

```sql
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-154698886389-2444.log'));
```

For more information about the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`, see [Reading files in a DB instance directory](#).

### Removing the Management Agent option

You can remove the OEM Agent from a DB instance. After you remove the OEM Agent, you don't need to restart your DB instance.

To remove the OEM Agent from a DB instance, do one of the following:

- Remove the OEM Agent option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see [Removing an option from an option group](#).
- Modify the DB instance and specify a different option group that doesn't include the OEM Agent option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see [Modifying an Amazon RDS DB instance](#).
Oracle Label Security

Amazon RDS supports Oracle Label Security for the Enterprise Edition of Oracle Database through the use of the OLS option.

Most database security controls access at the object level. Oracle Label Security provides fine-grained control of access to individual table rows. For example, you can use Label Security to enforce regulatory compliance with a policy-based administration model. You can use Label Security policies to control access to sensitive data, and restrict access to only users with the appropriate clearance level. For more information, see Introduction to Oracle Label Security in the Oracle documentation.

Topics

- Prerequisites for Oracle Label Security (p. 2065)
- Adding the Oracle Label Security option (p. 2065)
- Using Oracle Label Security (p. 2066)
- Removing the Oracle Label Security option (not supported) (p. 2066)
- Troubleshooting (p. 2066)

Prerequisites for Oracle Label Security

Familiarize yourself with the following prerequisites for Oracle Label Security:

- Your DB instance must use the Bring Your Own License model. For more information, see RDS for Oracle licensing options (p. 1809).
- You must have a valid license for Oracle Enterprise Edition with Software Update License and Support.
- Your Oracle license must include the Label Security option.
- You must be using the non-multitenant (non-CDB) database architecture. For more information, see Overview of RDS for Oracle CDBs (p. 1856).

Adding the Oracle Label Security option

The general process for adding the Oracle Label Security option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
   
   **Important**
   
   Oracle Label Security is a permanent and persistent option.

3. Associate the option group with the DB instance.

After you add the Label Security option, as soon as the option group is active, Label Security is active.

To add the label security option to a DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   
   a. For **Engine**, choose oracle-ee.
   
   b. For **Major engine version**, choose the version of your DB instance.
For more information, see Creating an option group (p. 332).

2. Add the OLS option to the option group. For more information about adding options, see Adding an option to an option group (p. 335).

**Important**
If you add Label Security to an existing option group that is already attached to one or more DB instances, all the DB instances are restarted.

3. Apply the option group to a new or existing DB instance:

   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 300).

   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. When you add the Label Security option to an existing DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see Modifying an Amazon RDS DB instance (p. 401).

**Using Oracle Label Security**

To use Oracle Label Security, you create policies that control access to specific rows in your tables. For more information, see Creating an Oracle Label Security policy in the Oracle documentation.

When you work with Label Security, you perform all actions as the LBAC_DBA role. The master user for your DB instance is granted the LBAC_DBA role. You can grant the LBAC_DBA role to other users so that they can administer Label Security policies.

For the following releases, make sure to grant access to the OLS_ENFORCEMENT package to any new users who require access to Oracle Label Security:

- Oracle Database 19c using the non-CDB architecture
- Oracle Database 12c Release 2 (12.2)

To grant access to the OLS_ENFORCEMENT package, connect to the DB instance as the master user and run the following SQL statement:

```
GRANT ALL ON LBACSYS.OLS_ENFORCEMENT TO username;
```

You can configure Label Security through the Oracle Enterprise Manager (OEM) Cloud Control. Amazon RDS supports the OEM Cloud Control through the Management Agent option. For more information, see Oracle Management Agent for Enterprise Manager Cloud Control (p. 2055).

**Removing the Oracle Label Security option (not supported)**

Starting with Oracle Database 12c Release 2 (12.2), Oracle Label Security is a permanent and persistent option. Because the option is permanent, you can't remove it from an option group. If you add Oracle Label Security to an option group and associate it with your DB instance, you can later associate a different option group with your DB instance, but this group must also contain the Oracle Label Security option.

**Troubleshooting**

The following are issues you might encounter when you use Oracle Label Security.
<table>
<thead>
<tr>
<th>Issue</th>
<th>Troubleshooting suggestions</th>
</tr>
</thead>
<tbody>
<tr>
<td>When you try to create a policy, you see an error message similar to the following: insufficient authorization for the SYSDBA package.</td>
<td>A known issue with Oracle's Label Security feature prevents users with usernames of 16 or 24 characters from running Label Security commands. You can create a new user with a different number of characters, grant LBAC_DBA to the new user, log in as the new user, and run the OLS commands as the new user. For additional information, please contact Oracle support.</td>
</tr>
</tbody>
</table>
Oracle Locator

Amazon RDS supports Oracle Locator through the use of the LOCATOR option. Oracle Locator provides capabilities that are typically required to support internet and wireless service-based applications and partner-based GIS solutions. Oracle Locator is a limited subset of Oracle Spatial. For more information, see Oracle Locator in the Oracle documentation.

Important
If you use Oracle Locator, Amazon RDS automatically updates your DB instance to the latest Oracle PSU if there are security vulnerabilities with a Common Vulnerability Scoring System (CVSS) score of 9+ or other announced security vulnerabilities.

Amazon RDS supports Oracle Locator for the following releases of Oracle Database:

- Oracle Database 19c (19.0.0.0)
- Oracle Database 12c Release 2 (12.2.0.1)
- Oracle Database 12c Release 1 (12.1), version 12.1.0.2.v13 or later

Oracle Locator isn’t supported for Oracle Database 21c, but its functionality is available in the Oracle Spatial option. Formerly, the Spatial option required additional licenses. Oracle Locator represented a subset of Oracle Spatial features and didn’t require additional licenses. In 2019, Oracle announced that all Oracle Spatial features were included in the Enterprise Edition and Standard Edition Two licenses without additional cost. Consequently, the Oracle Spatial option no longer required additional licensing.

Starting with Oracle Database 21c, the Oracle Locator option is no longer supported. To use the Oracle Locator features in Oracle Database 21c, install the Oracle Spatial option instead. For more information, see Machine Learning, Spatial and Graph - No License Required! in the Oracle Database Insider blog.

Prerequisites for Oracle Locator

The following are prerequisites for using Oracle Locator:

- Your DB instance must be of sufficient class. Oracle Locator is not supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see RDS for Oracle instance classes (p. 1812).
- Your DB instance must have Auto Minor Version Upgrade enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available and is required for any options that install the Oracle Java Virtual Machine (JVM). Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance (p. 401).

Best practices for Oracle Locator

The following are best practices for using Oracle Locator:

- For maximum security, use the LOCATOR option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer (p. 2084).
- Configure your DB instance to restrict access to your DB instance. For more information, see Scenarios for accessing a DB instance in a VPC (p. 2718) and Working with a DB instance in a VPC (p. 2705).

Adding the Oracle Locator option

The following is the general process for adding the LOCATOR option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the LOCATOR option is added. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle Locator is available.

**Note**
During this outage, password verification functions are disabled briefly. You can also expect to see events related to password verification functions during the outage. Password verification functions are enabled again before the Oracle DB instance is available.

**To add the LOCATOR option to a DB instance**

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine**, choose the oracle edition for your DB instance.
   b. For **Major engine version**, choose the version of your DB instance.

   For more information, see [Creating an option group](p. 332).

2. Add the **LOCATOR** option to the option group. For more information about adding options, see [Adding an option to an option group](p. 335).

3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](p. 300).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see [Modifying an Amazon RDS DB instance](p. 401).

**Using Oracle Locator**

After you enable the Oracle Locator option, you can begin using it. You should only use Oracle Locator features. Don't use any Oracle Spatial features unless you have a license for Oracle Spatial.

For a list of features that are supported for Oracle Locator, see [Features Included with Locator](p. 332) in the Oracle documentation.

For a list of features that are not supported for Oracle Locator, see [Features Not Included with Locator](p. 332) in the Oracle documentation.

**Removing the Oracle Locator option**

After you drop all objects that use data types provided by the LOCATOR option, you can remove the option from a DB instance. If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the LOCATOR option is removed. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you remove the LOCATOR option, you don't need to restart your DB instance.

**To drop the LOCATOR option**

1. Back up your data.
Warning
If the instance uses data types that were enabled as part of the option, and if you remove the LOCATOR option, you can lose data. For more information, see Backing up and restoring (p. 590).

2. Check whether any existing objects reference data types or features of the LOCATOR option.

If LOCATOR options exist, the instance can get stuck when applying the new option group that doesn't have the LOCATOR option. You can identify the objects by using the following queries:

```sql
SELECT OWNER, SEGMENT_NAME, TABLESPACE_NAME, BYTES/1024/1024 mbytes
FROM   DBA_SEGMENTS
WHERE  SEGMENT_TYPE LIKE '%TABLE%
AND    (OWNER, SEGMENT_NAME) IN
       (SELECT DISTINCT OWNER, TABLE_NAME
        FROM   DBA_TAB_COLUMNS
        WHERE  DATA_TYPE='SDO_GEOMETRY'
        AND    OWNER <> 'MDSYS')
ORDER BY 1,2,3,4;

SELECT OWNER, TABLE_NAME, COLUMN_NAME
FROM   DBA_TAB_COLUMNS
WHERE  DATA_TYPE = 'SDO_GEOMETRY'
AND    OWNER <> 'MDSYS'
ORDER BY 1,2,3;
```

3. Drop any objects that reference data types or features of the LOCATOR option.
4. Do one of the following:

   • Remove the LOCATOR option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 343).

   • Modify the DB instance and specify a different option group that doesn't include the LOCATOR option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 401).
Oracle Multimedia

Amazon RDS supports Oracle Multimedia through the use of the MULTIMEDIA option. You can use Oracle Multimedia to store, manage, and retrieve images, audio, video, and other heterogeneous media data. For more information, see Oracle Multimedia in the Oracle documentation.

Important
If you use Oracle Multimedia, Amazon RDS automatically updates your DB instance to the latest Oracle PSU if there are security vulnerabilities with a Common Vulnerability Scoring System (CVSS) score of 9+ or other announced security vulnerabilities.

Amazon RDS supports Oracle Multimedia for all editions of the following versions:

- Oracle Database 12c Release 2 (12.2)
- Oracle Database 12c Release 1 (12.1), version 12.1.0.2.v13 or higher

Note
Oracle desupported Oracle Multimedia in Oracle Database 19c. So, Oracle Multimedia isn't supported for Oracle Database 19c DB instances. For more information, see Desupport of Oracle Multimedia in the Oracle documentation.

Prerequisites for Oracle Multimedia

The following are prerequisites for using Oracle Multimedia:

- Your DB instance must be of sufficient class. Oracle Multimedia is not supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see RDS for Oracle instance classes (p. 1812).
- Your DB instance must have Auto Minor Version Upgrade enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available and is required for any options that install the Oracle Java Virtual Machine (JVM). Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance (p. 401).

Best practices for Oracle Multimedia

The following are best practices for using Oracle Multimedia:

- For maximum security, use the MULTIMEDIA option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer (p. 2084).
- Configure your DB instance to restrict access to your DB instance. For more information, see Scenarios for accessing a DB instance in a VPC (p. 2718) and Working with a DB instance in a VPC (p. 2705).

Adding the Oracle Multimedia option

The following is the general process for adding the MULTIMEDIA option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the MULTIMEDIA option is added. There is no outage if Oracle Java Virtual Machine (JVM) is already installed.
on the DB instance. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle Multimedia is available.

**Note**
During this outage, password verification functions are disabled briefly. You can also expect to see events related to password verification functions during the outage. Password verification functions are enabled again before the Oracle DB instance is available.

**To add the MULTIMEDIA option to a DB instance**

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine**, choose the edition for your Oracle DB instance.
   b. For **Major engine version**, choose the version of your DB instance.

   For more information, see Creating an option group (p. 332).
2. Add the MULTIMEDIA option to the option group. For more information about adding options, see Adding an option to an option group (p. 335).
3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 300).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 401).

**Removing the Oracle Multimedia option**

After you drop all objects that use data types provided by the MULTIMEDIA option, you can remove the option from a DB instance. If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the MULTIMEDIA option is removed. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you remove the MULTIMEDIA option, you don’t need to restart your DB instance.

**To drop the MULTIMEDIA option**

1. Back up your data.

   **Warning**
   If the instance uses data types that were enabled as part of the option, and if you remove the MULTIMEDIA option, you can lose data. For more information, see Backing up and restoring (p. 590).
2. Check whether any existing objects reference data types or features of the MULTIMEDIA option.
3. Drop any objects that reference data types or features of the MULTIMEDIA option.
4. Do one of the following:
   - Remove the MULTIMEDIA option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 343).
   - Modify the DB instance and specify a different option group that doesn't include the MULTIMEDIA option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 401).
Oracle native network encryption

Amazon RDS supports Oracle native network encryption (NNE). With native network encryption, you can encrypt data as it moves to and from a DB instance. Amazon RDS supports NNE for all editions of Oracle Database.

A detailed discussion of Oracle native network encryption is beyond the scope of this guide, but you should understand the strengths and weaknesses of each algorithm and key before you decide on a solution for your deployment. For information about the algorithms and keys that are available through Oracle native network encryption, see Configuring network data encryption in the Oracle documentation. For more information about AWS security, see the AWS security center.

**Note**

You can use Native Network Encryption or Secure Sockets Layer, but not both. For more information, see Oracle Secure Sockets Layer (p. 2084).

NNE option settings

You can specify encryption requirements on both the server and the client. The DB instance can act as a client when, for example, it uses a database link to connect to another database. You might want to avoid forcing encryption on the server side. For example, you might not want to force all client communications to use encryption because the server requires it. In this case, you can force encryption on the client side using the SQLNET.*CLIENT options.

Amazon RDS supports the following settings for the NNE option.

**Note**

When you use commas to separate values for an option setting, don't put a space after the comma.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Default values</th>
<th>Description</th>
</tr>
</thead>
</table>
| SQLNET.ALLOW_WEAK_CRYPTO_CLIENT       | TRUE, FALSE                       | TRUE           | The behavior of the server when a client using a non-secure cipher attempts to connect to the database. If TRUE, clients can connect even if they aren't patched with the July 2021 PSU. If the setting is FALSE, clients can connect to the database only when they are patched with the July 2021 PSU. Before you set SQLNET.ALLOW_WEAK_CRYPTO_CLIENT to FALSE, make sure that the following conditions are met:
  - SQLNET.ENCRIPTION_TYPES_SERVER and SQLNET.ENCRIPTION_TYPES_CLIENT have one matching encryption method that is not DES, 3DES, or RC4 (all key lengths).
  - SQLNET.CHECKSUM_TYPES_SERVER and SQLNET.CHECKSUM_TYPES_CLIENT have one matching secure checksumming method that is not MD5.
  - The client is patched with the July 2021 PSU. If the client isn't patched, the client loses the connection and receives the ORA-12269 error. |

<td>A list of encryption algorithms used by the client. The client attempts to decrypt the server input by trying each algorithm in order, proceeding until an algorithm succeeds or the end of the list is reached. Amazon RDS uses the following default list from Oracle. RDS starts with RC4_256 and proceeds down the list in order. You can change the order or limit the algorithms that the DB instance will accept.</td>
</tr>
</tbody>
</table>

1. RC4_256: RSA RC4 (256-bit key size)  
2. AES256: AES (256-bit key size)  
3. AES192: AES (192-bit key size)  
4. 3DES168: 3-key Triple-DES (112-bit effective key size)  
5. RC4_128: RSA RC4 (128-bit key size)  
6. AES128: AES (128-bit key size)  
7. 3DES112: 2-key Triple-DES (80-bit effective key size)  
8. RC4_56: RSA RC4 (56-bit key size)  
9. DES: Standard DES (56-bit key size)  
10. RC4_40: RSA RC4 (40-bit key size)  
11. DES40: DES40 (40-bit key size)  

You can specify either one value or a comma-separated list of values. If you a comma, don't insert a space after the comma; otherwise, you receive an InvalidParameterValue error.  
This parameter and SQLNET.SQLNET.ENCRYPTION_TYPES_SERVER must have a common cipher.
### Native network encryption (NNE)

**Option setting**

<table>
<thead>
<tr>
<th>Valid values</th>
<th>Default values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLNET.ENCRYPTION_TYPES_SERVER</td>
<td>RC4_256, AES256, AES192, 3DES168, RC4_128, AES128, 3DES112, RC4_56, DES, RC4_40, DES40</td>
<td>A list of encryption algorithms used by the DB instance. The DB instance uses each algorithm, in order, to attempt to decrypt the client input until an algorithm succeeds or until the end of the list is reached. Amazon RDS uses the following default list from Oracle. You can change the order or limit the algorithms that the client will accept. 1. RC4_256: RSA RC4 (256-bit key size) 2. AES256: AES (256-bit key size) 3. AES192: AES (192-bit key size) 4. 3DES168: 3-key Triple-DES (112-bit effective key size) 5. RC4_128: RSA RC4 (128-bit key size) 6. AES128: AES (128-bit key size) 7. 3DES112: 2-key Triple-DES (80-bit effective key size) 8. RC4_56: RSA RC4 (56-bit key size) 9. DES: Standard DES (56-bit key size) 10. RC4_40: RSA RC4 (40-bit key size) 11. DES40: DES40 (40-bit key size)</td>
</tr>
</tbody>
</table>

You can specify either one value or a comma-separated list of values. If you comma, don't insert a space after the comma; otherwise, you receive an InvalidParameterValue error.

This parameter and SQLNET.SQLNET.ENCRYPTION_TYPES_SERVER must have a common cipher.

---

### Adding the NNE option

The general process for adding the NNE option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

When the option group is active, NNE is active.

**To add the NNE option to a DB instance using the AWS Management Console**

1. For *Engine*, choose the Oracle edition that you want to use. NNE is supported on all editions.
2. For *Major engine version*, choose the version of your DB instance.

   For more information, see [Creating an option group (p. 332)](creating-an-option-group-p-332).
3. Add the **NNE** option to the option group. For more information about adding options, see *Adding an option to an option group (p. 335)*.

    **Note**
    After you add the NNE option, you don't need to restart your DB instances. As soon as the option group is active, NNE is active.

4. Apply the option group to a new or existing DB instance:

    • For a new DB instance, you apply the option group when you launch the instance. For more information, see *Creating an Amazon RDS DB instance (p. 300)*.
    • For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. After you add the NNE option, you don't need to restart your DB instance. As soon as the option group is active, NNE is active. For more information, see *Modifying an Amazon RDS DB instance (p. 401)*.

### Setting NNE values in the sqlnet.ora

With Oracle native network encryption, you can set network encryption on the server side and client side. The client is the computer used to connect to the DB instance. You can specify the following client settings in the sqlnet.ora:

- SQLNET.ALLOW_WEAK_CRYPTO
- SQLNET.ALLOW_WEAK_CRYPTO_CLIENTS
- SQLNET.CRYPTO_CHECKSUM_CLIENT
- SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT
- SQLNET.ENCRYPTION_CLIENT
- SQLNET.ENCRYPTION_TYPES_CLIENT

For information, see *Configuring network data encryption and integrity for Oracle servers and clients* in the Oracle documentation.

Sometimes, the DB instance rejects a connection request from an application. For example, a rejection can occur when the encryption algorithms on the client and on the server don't match. To test Oracle native network encryption, add the following lines to the sqlnet.ora file on the client:

```python
DIAG_ADR_ENABLED=off
TRACE_DIRECTORY_CLIENT=/tmp
TRACE_FILE_CLIENT=nettrace
TRACE_LEVEL_CLIENT=16
```

When a connection is attempted, the preceding lines generate a trace file on the client called /tmp/nettrace*. The trace file contains information about the connection. For more information about connection-related issues when you are using Oracle Native Network Encryption, see *About negotiating encryption and integrity* in the Oracle Database documentation.

### Modifying NNE option settings

After you enable NNE, you can modify its settings. Currently, you can modify NNE option settings only with the AWS CLI or RDS API. You can't use the console. To learn how to modify option settings using the CLI, see *AWS CLI (p. 341)*. For more information about each setting, see *NNE option settings (p. 2073)*.

**Topics**

- *Modifying CRYPTO_CHECKSUM_* values (p. 2079)
- *Modifying ALLOW_WEAK_CRYPTO* settings (p. 2079)
Modifying CRYPTO_CHECKSUM_* values

If you modify NNE option settings, make sure that the following option settings have at least one common cipher:

- SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER
- SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT

The following example shows a scenario in which you modify SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER. The configuration is valid because the CRYPTO_CHECKSUM_TYPES_CLIENT and CRYPTO_CHECKSUM_TYPES_SERVER both use SHA256.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Values before modification</th>
<th>Values after modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT</td>
<td>SHA256, SHA384, SHA512</td>
<td>SHA1, MD5, SHA256</td>
</tr>
<tr>
<td>SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER</td>
<td>SHA256, SHA384, SHA512, SHA1, MD5</td>
<td>SHA1, MD5, SHA256</td>
</tr>
</tbody>
</table>

For another example, assume that you want to modify SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER from its default setting to SHA1, MD5. In this case, make sure you set SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT to SHA1 or MD5. These algorithms aren't included in the default values for SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT.

Modifying ALLOW_WEAK_CRYPTO* settings

To set the SQLNET.ALLOW_WEAK_CRYPTO* options from the default value to FALSE, make sure that the following conditions are met:

- SQLNET.ENCRIPTION_TYPES_SERVER and SQLNET.ENCRIPTION_TYPES_CLIENT have one matching secure encryption method. A method is considered secure if it's not DES, 3DES, or RC4 (all key lengths).
- SQLNET.CHECKSUM_TYPES_SERVER and SQLNET.CHECKSUM_TYPES_CLIENT have one matching secure checksumming method. A method is considered secure if it's not MD5.
- The client is patched with the July 2021 PSU. If the client isn't patched, the client loses the connection and receives the ORA-12269 error.

The following example shows sample NNE settings. Assume that you want to set SQLNET.ENCRIPTION_TYPES_SERVER and SQLNET.ENCRIPTION_TYPES_CLIENT to FALSE, thereby blocking non-secure connections. The checksum option settings meet the prerequisites because they both have SHA256. However, SQLNET.ENCRIPTION_TYPES_CLIENT and SQLNET.ENCRIPTION_TYPES_SERVER use the DES, 3DES, and RC4 encryption methods, which are non-secure. Therefore, to set the SQLNET. ALLOW_WEAK_CRYPTO* options to FALSE, first set SQLNET.ENCRIPTION_TYPES_SERVER and SQLNET.ENCRIPTION_TYPES_CLIENT to a secure encryption method such as AES256.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT</td>
<td>SHA256, SHA384, SHA512</td>
</tr>
<tr>
<td>SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER</td>
<td>SHA1, MD5, SHA256</td>
</tr>
<tr>
<td>SQLNET.ENCRIPTION_TYPES_CLIENT</td>
<td>RC4_256, 3DES168, DES40</td>
</tr>
</tbody>
</table>
### Native network encryption (NNE)

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLNET.ENCRYPTION_TYPES_SERVER</td>
<td>RC4_256, 3DES168, DES40</td>
</tr>
</tbody>
</table>

### Removing the NNE option

You can remove NNE from a DB instance.

To remove NNE from a DB instance, do one of the following:

- To remove NNE from multiple DB instances, remove the NNE option from the option group they belong to. This change affects all DB instances that use the option group. After you remove the NNE option, you don't need to restart your DB instances. For more information, see [Removing an option from an option group](p. 343).

- To remove NNE from a single DB instance, modify the DB instance and specify a different option group that doesn't include the NNE option. You can specify the default (empty) option group, or a different custom option group. After you remove the NNE option, you don't need to restart your DB instance. For more information, see [Modifying an Amazon RDS DB instance](p. 401).
Oracle OLAP

Amazon RDS supports Oracle OLAP through the use of the OLAP option. This option provides On-line Analytical Processing (OLAP) for Oracle DB instances. You can use Oracle OLAP to analyze large amounts of data by creating dimensional objects and cubes in accordance with the OLAP standard. For more information, see the Oracle documentation.

**Important**

If you use Oracle OLAP, Amazon RDS automatically updates your DB instance to the latest Oracle PSU if there are security vulnerabilities with a Common Vulnerability Scoring System (CVSS) score of 9+ or other announced security vulnerabilities.

Amazon RDS supports Oracle OLAP for the following editions and versions of Oracle:

- Oracle Database 21c Enterprise Edition, all versions
- Oracle Database 19c Enterprise Edition, all versions
- Oracle Database 12c Release 2 (12.2.0.1) Enterprise Edition, all versions
- Oracle Database 12c Release 1 (12.1.0.2) Enterprise Edition, version 12.1.0.2.v13 or later

**Prerequisites for Oracle OLAP**

The following are prerequisites for using Oracle OLAP:

- You must have an Oracle OLAP license from Oracle. For more information, see Licensing Information in the Oracle documentation.

- Your DB instance must be of a sufficient instance class. Oracle OLAP isn’t supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see RDS for Oracle instance classes (p. 1812).

- Your DB instance must have Auto Minor Version Upgrade enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available and is required for any options that install the Oracle Java Virtual Machine (JVM). Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance (p. 401).

- Your DB instance must not have a user named OLAPSYS. If it does, the OLAP option installation fails.

**Best practices for Oracle OLAP**

The following are best practices for using Oracle OLAP:

- For maximum security, use the OLAP option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer (p. 2084).

- Configure your DB instance to restrict access to your DB instance. For more information, see Scenarios for accessing a DB instance in a VPC (p. 2718) and Working with a DB instance in a VPC (p. 2705).

**Adding the Oracle OLAP option**

The following is the general process for adding the OLAP option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.
If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the OLAP option is added. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle OLAP is available.

To add the OLAP option to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   - For Engine, choose the Oracle edition for your DB instance.
   - For Major engine version, choose the version of your DB instance.

   For more information, see Creating an option group (p. 332).

2. Add the OLAP option to the option group. For more information about adding options, see Adding an option to an option group (p. 335).

3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 300).
   - For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 401).

Using Oracle OLAP

After you enable the Oracle OLAP option, you can begin using it. For a list of features that are supported for Oracle OLAP, see the Oracle documentation.

Removing the Oracle OLAP option

After you drop all objects that use data types provided by the OLAP option, you can remove the option from a DB instance. If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the OLAP option is removed. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you remove the OLAP option, you don't need to restart your DB instance.

To drop the OLAP option

1. Back up your data.

   Warning
   If the instance uses data types that were enabled as part of the option, and if you remove the OLAP option, you can lose data. For more information, see Backing up and restoring (p. 590).

2. Check whether any existing objects reference data types or features of the OLAP option.

3. Drop any objects that reference data types or features of the OLAP option.

4. Do one of the following:
   - Remove the OLAP option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 343).
   - Modify the DB instance and specify a different option group that doesn't include the OLAP option. This change affects a single DB instance. You can specify the default (empty) option group,
or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 401).
Oracle Secure Sockets Layer

You enable SSL encryption for an RDS for Oracle DB instance by adding the Oracle SSL option to the option group associated with the DB instance. Amazon RDS uses a second port, as required by Oracle, for SSL connections. This approach allows both clear text and SSL-encrypted communication to occur at the same time between a DB instance and SQL*Plus. For example, you can use the port with clear text communication to communicate with other resources inside a VPC while using the port with SSL-encrypted communication to communicate with resources outside the VPC.

**Note**

You can use either SSL or Native Network Encryption (NNE) on the same RDS for Oracle DB instance, but not both. If you use SSL encryption, make sure to turn off any other connection encryption. For more information, see Oracle native network encryption (p. 2073).

SSL/TLS and NNE are no longer part of Oracle Advanced Security. In RDS for Oracle, you can use SSL encryption with all licensed editions of the following database versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2) – this release is no longer supported
- Oracle Database 12c Release 1 (12.1) – this release is no longer supported

### TLS versions for the Oracle SSL option

Amazon RDS for Oracle supports Transport Layer Security (TLS) versions 1.0 and 1.2. When you add a new Oracle SSL option, set `SQLNET.SSL_VERSION` explicitly to a valid value. The following values are allowed for this option setting:

- "1.0" – Clients can connect to the DB instance using TLS version 1.0 only. For existing Oracle SSL options, `SQLNET.SSL_VERSION` is set to "1.0" automatically. You can change the setting if necessary.
- "1.2" – Clients can connect to the DB instance using TLS 1.2 only.
- "1.2 or 1.0" – Clients can connect to the DB instance using either TLS 1.2 or 1.0.

### Cipher suites for the Oracle SSL option

Amazon RDS for Oracle supports multiple SSL cipher suites. By default, the Oracle SSL option is configured to use the `SSL_RSA_WITH_AES_256_CBC_SHA` cipher suite. To specify a different cipher suite to use over SSL connections, use the `SQLNET.CIPHER_SUITE` option setting.

The following table summarizes SSL support for RDS for Oracle. The specified Oracle Database releases support all editions.

<table>
<thead>
<tr>
<th>Cipher suite (SQLNET.CIPHER_SUITE)</th>
<th>TLS version support (SQLNET.SSL_VERSION)</th>
<th>Supported Oracle Database releases</th>
<th>FIPS support</th>
<th>FedRAMP compliant</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSL_RSA_WITH_AES_256_CBC_SHA (default)</td>
<td>1.0 and 1.2</td>
<td>12c, 19c, 21c</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>SSL_RSA_WITH_AES_256_CBC_SHA256</td>
<td>1.2</td>
<td>12c, 19c, 21c</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>SSL_RSA_WITH_AES_256_GCM_SHA384</td>
<td>1.2</td>
<td>12c, 19c, 21c</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>
FIPS support

RDS for Oracle allows you to use the Federal Information Processing Standard (FIPS) standard for 140-2. FIPS 140-2 is a United States government standard that defines cryptographic module security requirements. You turn on the FIPS standard by setting `FIPS.SSLFIPS_140` to TRUE for the Oracle SSL option. When FIPS 140-2 is configured for SSL, the cryptographic libraries encrypt data between the client and the RDS for Oracle DB instance.

Clients must use the cipher suite that is FIPS-compliant. When establishing a connection, the client and RDS for Oracle DB instance negotiate which cipher suite to use when transmitting messages back and forth. The table in Cipher suites for the Oracle SSL option (p. 2084) shows the FIPS-compliant SSL cipher suites for each TLS version. For more information, see Oracle database FIPS 140-2 settings in the Oracle Database documentation.

Adding the SSL option

To use SSL, your RDS for Oracle DB instance must be associated with an option group that includes the SSL option.

**Console**

**To add the SSL option to an option group**

1. Create a new option group or identify an existing option group to which you can add the SSL option.
   
   For information about creating an option group, see Creating an option group (p. 332).

2. Add the SSL option to the option group.

   If you want to use only FIPS-verified cipher suites for SSL connections, set the option `FIPS.SSLFIPS_140` to TRUE. For information about the FIPS standard, see FIPS support (p. 2085).

   For information about adding an option to an option group, see Adding an option to an option group (p. 335).

3. Create a new RDS for Oracle DB instance and associate the option group with it, or modify an RDS for Oracle DB instance to associate the option group with it.

   For information about creating an DB instance, see Creating an Amazon RDS DB instance (p. 300).

   For information about modifying an DB instance, see Modifying an Amazon RDS DB instance (p. 401).
AWS CLI

To add the SSL option to an option group

1. Create a new option group or identify an existing option group to which you can add the SSL option.
   For information about creating an option group, see Creating an option group (p. 332).

2. Add the SSL option to the option group.
   Specify the following option settings:
   - Port – The SSL port number
   - VpcSecurityGroupMemberships – The VPC security group for which the option is enabled
   - SQLNET.SSL_VERSION – The TLS version that client can use to connect to the DB instance

   For example, the following AWS CLI command adds the SSL option to an option group named ora-option-group.

   Example

   For Linux, macOS, or Unix:
   ```bash
   aws rds add-option-to-option-group --option-group-name ora-option-group --options "OptionName=SSL,Port=2484,VpcSecurityGroupMemberships="sg-68184619",OptionSettings=[{Name=SQLNET.SSL_VERSION,Value=1.0}]
   ```

   For Windows:
   ```bash
   aws rds add-option-to-option-group --option-group-name ora-option-group --options "OptionName=SSL,Port=2484,VpcSecurityGroupMemberships="sg-68184619",OptionSettings=[{Name=SQLNET.SSL_VERSION,Value=1.0}]
   ```

3. Create a new RDS for Oracle DB instance and associate the option group with it, or modify an RDS for Oracle DB instance to associate the option group with it.
   For information about creating an DB instance, see Creating an Amazon RDS DB instance (p. 300).
   For information about modifying an DB instance, see Modifying an Amazon RDS DB instance (p. 401).

Configuring SQL*Plus to use SSL with an RDS for Oracle DB instance

Before you can connect to an RDS for Oracle DB instance that uses the Oracle SSL option, you must configure SQL*Plus before connecting.

**Note**
To allow access to the DB instance from the appropriate clients, ensure that your security groups are configured correctly. For more information, see Controlling access with security groups (p. 2697). Also, these instructions are for SQL*Plus and other clients that directly use an Oracle home. For JDBC connections, see Setting up an SSL connection over JDBC (p. 2088).
To configure SQL*Plus to use SSL to connect to an RDS for Oracle DB instance

1. Set the ORACLE_HOME environment variable to the location of your Oracle home directory.

The path to your Oracle home directory depends on your installation. The following example sets
the ORACLE_HOME environment variable.

```
prompt>export ORACLE_HOME=/home/user/app/user/product/12.1.0/dbhome_1
```

For information about setting Oracle environment variables, see SQL*Plus environment variables
in the Oracle documentation, and also see the Oracle installation guide for your operating system.

2. Append $ORACLE_HOME/lib to the LD_LIBRARY_PATH environment variable.

The following is an example that sets the LD_LIBRARY_PATH environment variable.

```
prompt>export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:$ORACLE_HOME/lib
```

3. Create a directory for the Oracle wallet at $ORACLE_HOME/ssl_wallet.

The following is an example that creates the Oracle wallet directory.

```
prompt>mkdir $ORACLE_HOME/ssl_wallet
```

4. Download the root certificate that works for all AWS Regions and put the file in the ssl_wallet
directory.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection
to a DB instance (p. 2608).

5. In the $ORACLE_HOME/network/admin directory, modify or create the tnsnames.ora file and
include the following entry.

```
net_service_name =
  (DESCRIPTION =
   (ADDRESS_LIST =
    (ADDRESS =
     (PROTOCOL = TCPS)
     (HOST = endpoint)
     (PORT = ssl_port_number)
    )
   )
   (CONNECT_DATA =
    (SID = database_name)
   )
   (SECURITY =
    (SSL_SERVER_CERT_DN =
     "C=US,ST=Washington,L=Seattle,O=Amazon.com,OU=RDS,CN=endpoint")
   )
  )
```

6. In the same directory, modify or create the sqlnet.ora file and include the following parameters.

**Note**
To communicate with entities over a TLS secured connection, Oracle requires a wallet with
the necessary certificates for authentication. You can use Oracle's ORAPKI utility to create
and maintain Oracle wallets, as shown in step 7. For more information, see Setting up
Oracle wallet using ORAPKI in the Oracle documentation.

```
WALLET_LOCATION = (SOURCE = (METHOD = FILE) (METHOD_DATA = (DIRECTORY = $ORACLE_HOME/ssl_wallet)))
```
SSL_CLIENT.AUTHENTICATION = FALSE
SSL_VERSION = 1.0
SSL_CIPHER_SUITES = (SSL_RSA_WITH_AES_256_CBC_SHA)
SSL_SERVER_DN_MATCH = ON

**Note**
You can set SSL_VERSION to a higher value if your DB instance supports it.

7. Run the following commands to create the Oracle wallet.

```bash
prompt> orapki wallet create -wallet $ORACLE_HOME/ssl_wallet -auto_login_only
prompt> orapki wallet add -wallet $ORACLE_HOME/ssl_wallet -trusted_cert -cert $ORACLE_HOME/ssl_wallet/rds-ca-2019-root.pem -auto_login_only
```

Replace the file name with the one you downloaded.

### Connecting to an RDS for Oracle DB instance using SSL

After you configure SQL*Plus to use SSL as described previously, you can connect to the RDS for Oracle DB instance with the SSL option. Optionally, you can first export the TNS_ADMIN value that points to the directory that contains the tnsnames.ora and sqlnet.ora files. Doing so ensures that SQL*Plus can find these files consistently. The following example exports the TNS_ADMIN value.

```bash
export TNS_ADMIN = ${ORACLE_HOME}/network/admin
```

Connect to the DB instance. For example, you can connect using SQL*Plus and a `<net_service_name>` in a tnsnames.ora file.

```bash
sqlplus mydbuser@net_service_name
```

You can also connect to the DB instance using SQL*Plus without using a tnsnames.ora file by using the following command.

```bash
sqlplus 'mydbuser@(DESCRIPTION = (ADDRESS = (PROTOCOL = TCP)(HOST = endpoint)(PORT = ssl_port_number))(CONNECT_DATA = (SID = database_name)))'
```

You can also connect to the RDS for Oracle DB instance without using SSL. For example, the following command connects to the DB instance through the clear text port without SSL encryption.

```bash
sqlplus 'mydbuser@(DESCRIPTION = (ADDRESS = (PROTOCOL = TCP)(HOST = endpoint)(PORT = port_number))(CONNECT_DATA = (SID = database_name)))'
```

If you want to close Transmission Control Protocol (TCP) port access, create a security group with no IP address ingresses and add it to the instance. This addition closes connections over the TCP port, while still allowing connections over the SSL port that are specified from IP addresses within the range permitted by the SSL option security group.

### Setting up an SSL connection over JDBC

To use an SSL connection over JDBC, you must create a keystore, trust the Amazon RDS root CA certificate, and use the code snippet specified following.

To create the keystore in JKS format, use the following command. For more information about creating the keystore, see the Oracle documentation.

2088
Next, take the following steps to trust the Amazon RDS root CA certificate.

**To trust the Amazon RDS root CA certificate**

1. **Download the root certificate that works for all AWS Regions and put the file in the ssl_wallet directory.**

   For information about downloading the root certificate, see [Using SSL/TLS to encrypt a connection to a DB instance](p. 2608).

2. **Convert the certificate to .der format using the following command.**

   ```bash
   ```

   Replace the file name with the one you downloaded.

3. **Import the certificate into the keystore using the following command.**

   ```bash
   ```

4. **Confirm that the key store was created successfully.**

   ```bash
   keytool -list -v -keystore clientkeystore.jks
   ```

   Enter the keystore password when you are prompted for it.

The following code example shows how to set up the SSL connection using JDBC.

```java
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;
import java.util.Properties;

public class OracleSslConnectionTest {
    private static final String DB_SERVER_NAME = "dns-name-provided-by-amazon-rds";
    private static final Integer SSL_PORT = "ssl-option-port-configured-in-option-group";
    private static final String DB_SID = "oracle-sid";
    private static final String DB_USER = "user-name";
    private static final String DB_PASSWORD = "password";
    // This key store has only the prod root ca.
    private static final String KEY_STORE_FILE_PATH = "file-path-to-keystore";
    private static final String KEY_STORE_PASS = "keystore-password";

    public static void main(String[] args) throws SQLException {
        final Properties properties = new Properties();
        final String connectionString = String.format("jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=%s)(PORT=%d))(CONNECT_DATA=(SID=%s)))", DB_SERVER_NAME, SSL_PORT, DB_SID);
        properties.put("user", DB_USER);
        properties.put("password", DB_PASSWORD);
        properties.put("oracle.jdbc:2EE13Compliant", "true");
        properties.put("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
        properties.put("javax.net.ssl.trustStoreType", "JKS");
        properties.put("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);
    }
}
```
final Connection connection = DriverManager.getConnection(connectionString, properties);

// If no exception, that means handshake has passed, and an SSL connection can be opened
}

Note
Specify a password other than the prompt shown here as a security best practice.

Enforcing a DN match with an SSL connection

You can use the Oracle parameter SSL_SERVER_DN_MATCH to enforce that the distinguished name (DN) for the database server matches its service name. If you enforce the match verifications, then SSL ensures that the certificate is from the server. If you don't enforce the match verification, then SSL performs the check but allows the connection, regardless if there is a match. If you do not enforce the match, you allow the server to potentially fake its identify.

To enforce DN matching, add the DN match property and use the connection string specified below.

Add the property to the client connection to enforce DN matching.

properties.put("oracle.net.ssl_server_dn_match", "TRUE");

Use the following connection string to enforce DN matching when using SSL.

final String connectionString = String.format(
    "jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCPS)(HOST=%s)(PORT=%d))" +
    "(CONNECT_DATA=(SID=%s))" +
    "(SECURITY = (SSL_SERVER_CERT_DN = "C=US,ST=Washington,L=Seattle,O=Amazon.com,OU=RDS,CN=%s")))",
    DB_SERVER_NAME, SSL_PORT, DB_SID, DB_SERVER_NAME);

Troubleshooting SSL connections

You might query your database and receive the ORA-28860 error.

ORA-28860: Fatal SSL error
28860. 00000 - "Fatal SSL error"
*Cause: An error occurred during the SSL connection to the peer. It is likely that this side sent data which the peer rejected.
*Action: Enable tracing to determine the exact cause of this error.

This error occurs when the client attempts to connect using a version of TLS that the server doesn't support. To avoid this error, edit the sqlnet.ora and set SSL_VERSION to the correct TLS version. For more information, see Oracle Support Document 2748438.1 in My Oracle Support.
Oracle Spatial

Amazon RDS supports Oracle Spatial through the use of the SPATIAL option. Oracle Spatial provides a SQL schema and functions that facilitate the storage, retrieval, update, and query of collections of spatial data in an Oracle database. For more information, see Spatial Concepts in the Oracle documentation.

Important
If you use Oracle Spatial, Amazon RDS automatically updates your DB instance to the latest Oracle PSU when any of the following exist:

- Security vulnerabilities with a Common Vulnerability Scoring System (CVSS) score of 9+
- Other announced security vulnerabilities

Amazon RDS supports Oracle Spatial only in Oracle Enterprise Edition (EE) and Oracle Standard Edition 2 (SE2). The following table shows the versions of the DB engine that support EE and SE2.

<table>
<thead>
<tr>
<th>Oracle DB Version</th>
<th>EE</th>
<th>SE2</th>
</tr>
</thead>
<tbody>
<tr>
<td>21.0.0.0, all versions</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>19.0.0.0, all versions</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>12.2.0.1, all versions</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>12.1.0.2.v13 or later</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

Prerequisites for Oracle Spatial

The following are prerequisites for using Oracle Spatial:

- Make sure that your DB instance is of a sufficient instance class. Oracle Spatial isn't supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see RDS for Oracle instance classes (p. 1812).
- Make sure that your DB instance has Auto Minor Version Upgrade enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available and is required for any options that install the Oracle Java Virtual Machine (JVM). Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance (p. 401).

Best practices for Oracle Spatial

The following are best practices for using Oracle Spatial:

- For maximum security, use the SPATIAL option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer (p. 2084).
- Configure your DB instance to restrict access to your DB instance. For more information, see Scenarios for accessing a DB instance in a VPC (p. 2718) and Working with a DB instance in a VPC (p. 2705).

Adding the Oracle Spatial option

The following is the general process for adding the SPATIAL option to a DB instance:
1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the SPATIAL option is added. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle Spatial is available.

**Note**
During this outage, password verification functions are disabled briefly. You can also expect to see events related to password verification functions during the outage. Password verification functions are enabled again before the Oracle DB instance is available.

**To add the SPATIAL option to a DB instance**

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine**, choose the Oracle edition for your DB instance.
   b. For **Major engine version**, choose the version of your DB instance.

   For more information, see Creating an option group (p. 332).

2. Add the **SPATIAL** option to the option group. For more information about adding options, see Adding an option to an option group (p. 335).

3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 300).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 401).

**Removing the Oracle Spatial option**

After you drop all objects that use data types provided by the SPATIAL option, you can drop the option from a DB instance. If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the SPATIAL option is removed. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you remove the SPATIAL option, you don't need to restart your DB instance.

**To drop the SPATIAL option**

1. Back up your data.
   - **Warning**
     If the instance uses data types that were enabled as part of the option, and if you remove the SPATIAL option, you can lose data. For more information, see Backing up and restoring (p. 590).

2. Check whether any existing objects reference data types or features of the SPATIAL option.
   - If SPATIAL options exist, the instance can get stuck when applying the new option group that doesn't have the SPATIAL option. You can identify the objects by using the following queries:

   ```sql
   SELECT OWNER, SEGMENT_NAME, TABLESPACE_NAME, BYTES/1024/1024 mbytes
   ```
FROM DBA_SEGMENTS
WHERE SEGMENT_TYPE LIKE '%TABLE%
AND (OWNER, SEGMENT_NAME) IN
   (SELECT DISTINCT OWNER, TABLE_NAME
    FROM DBA_TAB_COLUMNS
    WHERE DATA_TYPE='SDO_GEOMETRY'
    AND OWNER <> 'MDSYS')
ORDER BY 1,2,3,4;

SELECT OWNER, TABLE_NAME, COLUMN_NAME
FROM DBA_TAB_COLUMNS
WHERE DATA_TYPE = 'SDO_GEOMETRY'
AND OWNER <> 'MDSYS'
ORDER BY 1,2,3;

3. Drop any objects that reference data types or features of the SPATIAL option.
4. Do one of the following:

   • Remove the SPATIAL option from the option group it belongs to. This change affects all DB
     instances that use the option group. For more information, see Removing an option from an
     option group (p. 343).

   • Modify the DB instance and specify a different option group that doesn't include the SPATIAL
     option. This change affects a single DB instance. You can specify the default (empty) option group,
     or a different custom option group. For more information, see Modifying an Amazon RDS DB
     instance (p. 401).
Oracle SQLT

Amazon RDS supports Oracle SQLT (SQLT) through the use of the SQLT option.

The Oracle EXPLAIN PLAN statement can determine the execution plan of a SQL statement. It can verify whether the Oracle optimizer chooses a certain execution plan, such as a nested loops join. It also helps you understand the optimizer's decisions, such as why it chose a nested loops join over a hash join. So EXPLAIN PLAN helps you understand the statement's performance.

SQLT is an Oracle utility that produces a report. The report includes object statistics, object metadata, optimizer-related initialization parameters, and other information that a database administrator can use to tune a SQL statement for optimal performance. SQLT produces an HTML report with hyperlinks to all of the sections in the report.

Unlike Automatic Workload Repository or Statspack reports, SQLT works on individual SQL statements. SQLT is a collection of SQL, PL/SQL, and SQL*Plus files that collect, store, and display performance data.

Following are the supported Oracle versions for each SQLT version.

<table>
<thead>
<tr>
<th>SQLT version</th>

To download SQLT and access instructions for using it:

- Log in to your My Oracle Support account, and open the following documents:
  - To download SQLT: [Document 215187.1](#)
  - For SQLT usage instructions: [Document 1614107.1](#)
  - For frequently asked questions about SQLT: [Document 1454160.1](#)
  - For information about reading SQLT output: [Document 1456176.1](#)
  - For interpreting the Main report: [Document 1922234.1](#)

You can use SQLT with any edition of the following Oracle Database versions:

- Oracle Database 21c (21.0.0.0)
- Oracle Database 19c (19.0.0.0)
- Oracle Database 12c Release 2 (12.2.0.1)
- Oracle Database 12c Release 1 (12.1.0.2)

Amazon RDS does not support the following SQLT methods:

- XPLORE
- XHUME

Prerequisites for SQLT

The following are prerequisites for using SQLT:
• You must remove users and roles that are required by SQLT, if they exist.

The SQLT option creates the following users and roles on a DB instance:
• SQLTXPLAIN user
• SQLTXADMIN user
• SQLT_USER_ROLE role

If your DB instance has any of these users or roles, log in to the DB instance using a SQL client, and drop them using the following statements:

```
DROP USER SQLTXPLAIN CASCADE;
DROP USER SQLTXADMIN CASCADE;
DROP ROLE SQLT_USER_ROLE CASCADE;
```

• You must remove tablespaces that are required by SQLT, if they exist.

The SQLT option creates the following tablespaces on a DB instance:
• RDS_SQLT_TS
• RDS_TEMP_SQLT_TS

If your DB instance has these tablespaces, log in to the DB instance using a SQL client, and drop them.

### SQLT option settings

SQLT can work with licensed features that are provided by the Oracle Tuning Pack and the Oracle Diagnostics Pack. The Oracle Tuning Pack includes the SQL Tuning Advisor, and the Oracle Diagnostics Pack includes the Automatic Workload Repository. The SQLT settings enable or disable access to these features from SQLT.

Amazon RDS supports the following settings for the SQLT option.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
</table>
| LICENSE_PACK   | T, D, N      | N             | The Oracle Management Packs that you want to access with SQLT. Enter one of the following values:  
• T indicates that you have a license for the Oracle Tuning Pack and the Oracle Diagnostics Pack, and you want to access the SQL Tuning Advisor and Automatic Workload Repository from SQLT.  
• D indicates that you have a license for the Oracle Diagnostics Pack, and you want to access the Automatic Workload Repository from SQLT.  
• N indicates that you don't have a license for the Oracle Tuning Pack and the Oracle Diagnostics Pack, or that you have a license for one or both of them, but you don't want SQLT to access them. |
Adding the SQLT option

The following is the general process for adding the SQLT option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the SQLT option to the option group.
3. Associate the option group with the DB instance.

After you add the SQLT option, as soon as the option group is active, SQLT is active.

**To add the SQLT option to a DB instance**

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine**, choose the Oracle edition that you want to use. The SQLT option is supported on all editions.
   b. For **Major engine version**, choose the version of your DB instance.

   For more information, see Creating an option group (p. 332).

2. Add the **SQLT** option to the option group. For more information about adding options, see Adding an option to an option group (p. 335).

3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 300).
For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 401).

4. (Optional) Verify the SQLT installation on each DB instance with the SQLT option.
   a. Use a SQL client to connect to the DB instance as the master user.
      
      For information about connecting to an Oracle DB instance using a SQL client, see Connecting to your RDS for Oracle DB instance (p. 1822).
   b. Run the following query:

      ```sql
      SELECT sqlt$xplain.sqlt$a.get_param('tool_version') sqlt_version FROM DUAL;
      ```

      The query returns the current version of the SQLT option on Amazon RDS. 12.1.160429 is an example of a version of SQLT that is available on Amazon RDS.

5. Change the passwords of the users that are created by the SQLT option.
   a. Use a SQL client to connect to the DB instance as the master user.
   b. Run the following SQL statement to change the password for the SQLTXADMIN user:

      ```sql
      ALTER USER SQLTXADMIN IDENTIFIED BY new_password ACCOUNT UNLOCK;
      ```

      Note
      Specify a password other than the prompt shown here as a security best practice.
   c. Run the following SQL statement to change the password for the SQLTXPLAIN user:

      ```sql
      ALTER USER SQLTXPLAIN IDENTIFIED BY new_password ACCOUNT UNLOCK;
      ```

      Note
      Specify a password other than the prompt shown here as a security best practice.

      Note
      Upgrading SQLT requires uninstalling an older version of SQLT and then installing the new version. So, all SQLT metadata can be lost when you upgrade SQLT. A major version upgrade of a database also uninstalls and re-installs SQLT. An example of a major version upgrade is an upgrade from Oracle Database 12c Release 2 (12.2) to Oracle Database 19c.

**Using SQLT**

SQLT works with the Oracle SQL*Plus utility.

**To use SQLT**

1. Download the SQLT .zip file from Document 215187.1 on the My Oracle Support site.
Note
You can't download SQLT 12.1.160429 from the My Oracle Support site. Oracle has deprecated this older version.

2. Unzip the SQLT .zip file.
3. From a command prompt, change to the sqlt/run directory on your file system.
4. From the command prompt, open SQL*Plus, and connect to the DB instance as the master user.

For information about connecting to a DB instance using SQL*Plus, see Connecting to your RDS for Oracle DB instance (p. 1822).

5. Get the SQL ID of a SQL statement:

   ```sql
   SELECT SQL_ID FROM V$SQL WHERE SQL_TEXT='sql_statement';
   ```

   Your output is similar to the following:

<table>
<thead>
<tr>
<th>SQL_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>chvsmttqjzjkn</td>
</tr>
</tbody>
</table>

6. Analyze a SQL statement with SQLT:

   ```sql
   START sqltxtract.sql sql_id sqltxplain_user_password
   ```

   For example, for the SQL ID chvsmttqjzjkn, enter the following:

   ```sql
   START sqltxtract.sql chvsmttqjzjkn sqltxplain_user_password
   ```

   SQLT generates the HTML report and related resources as a .zip file in the directory from which the SQLT command was run.

7. (Optional) To enable application users to diagnose SQL statements with SQLT, grant SQLT_USER_ROLE to each application user with the following statement:

   ```sql
   GRANT SQLT_USER_ROLE TO application_user_name;
   ```

Note
Oracle does not recommend running SQLT with the SYS user or with users that have the DBA role. It is a best practice to run SQLT diagnostics using the application user's account, by granting SQLT_USER_ROLE to the application user.

### Upgrading the SQLT option

With Amazon RDS for Oracle, you can upgrade the SQLT option from your existing version to a higher version. To upgrade the SQLT option, complete steps 1–3 in Using SQLT (p. 2097) for the new version of.
SQLT. Also, if you granted privileges for the previous version of SQLT in step 7 of that section, grant the privileges again for the new SQLT version.

Upgrading the SQLT option results in the loss of the older SQLT version's metadata. The older SQLT version's schema and related objects are dropped, and the newer version of SQLT is installed. For more information about the changes in the latest SQLT version, see Document 1614201.1 on the My Oracle Support site.

**Note**
Version downgrades are not supported.

**Modifying SQLT settings**

After you enable SQLT, you can modify the LICENSE_PACK and VERSION settings for the option.

For more information about how to modify option settings, see Modifying an option setting (p. 340). For more information about each setting, see SQLT option settings (p. 2095).

**Removing the SQLT option**

You can remove SQLT from a DB instance.

To remove SQLT from a DB instance, do one of the following:

- To remove SQLT from multiple DB instances, remove the SQLT option from the option group to which the DB instances belong. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 343).

- To remove SQLT from a single DB instance, modify the DB instance and specify a different option group that doesn't include the SQLT option. You can specify the default (empty) option group or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 401).
Oracle Statspack

The Oracle Statspack option installs and enables the Oracle Statspack performance statistics feature. Oracle Statspack is a collection of SQL, PL/SQL, and SQL*Plus scripts that collect, store, and display performance data. For information about using Oracle Statspack, see Oracle Statspack in the Oracle documentation.

**Note**
Oracle Statspack is no longer supported by Oracle and has been replaced by the more advanced Automatic Workload Repository (AWR). AWR is available only for Oracle Enterprise Edition customers who have purchased the Diagnostics Pack. You can use Oracle Statspack with any Oracle DB engine on Amazon RDS. You can't run Oracle Statspack on Amazon RDS read replicas.

Setting up Oracle Statspack

To run Statspack scripts, you must add the Statspack option.

**To set up Oracle Statspack**

1. In a SQL client, log in to the Oracle DB with an administrative account.
2. Do either of the following actions, depending on whether Statspack is installed:
   - If Statspack is installed, and the PERFSTAT account is associated with Statspack, skip to Step 4.
   - If Statspack is not installed, and the PERFSTAT account exists, drop the account as follows:

   ```sql
   DROP USER PERFSTAT CASCADE;
   ```

   Otherwise, attempting to add the Statspack option generates an error and RDS-Event-0058.
3. Add the Statspack option to an option group. See Adding an option to an option group (p. 335).

   Amazon RDS automatically installs the Statspack scripts on the DB instance and then sets up the PERFSTAT account.
4. Reset the password using the following SQL statement, replacing `pwd` with your new password:

   ```sql
   ALTER USER PERFSTAT IDENTIFIED BY pwd ACCOUNT UNLOCK;
   ```

   You can log in using the PERFSTAT user account and run the Statspack scripts.
5. Do either of the following actions, depending on your DB engine version:
   - If you are using Oracle Database 12c Release 2 (12.2) or lower, skip this step.
   - If you are using Oracle Database 19c or higher, grant the CREATE JOB privilege to the PERFSTAT account using the following statement:

     ```sql
     GRANT CREATE JOB TO PERFSTAT;
     ```
6. Ensure that idle wait events in the PERFSTAT.STATS$IDLE_EVENT table are populated.

   Because of Oracle Bug 28523746, the idle wait events in PERFSTAT.STATS$IDLE_EVENT may not be populated. To ensure all idle events are available, run the following statement:

   ```sql
   INSERT INTO PERFSTAT.STATS$IDLE_EVENT (EVENT)
   SELECT NAME FROM V$EVENT_NAME WHERE WAIT_CLASS='Idle'
   MINUS
   SELECT EVENT FROM PERFSTAT.STATS$IDLE_EVENT;
   ```
Generating Statspack reports

A Statspack report compares two snapshots.

To generate Statspack reports

1. In a SQL client, log in to the Oracle DB with the PERFSTAT account.
2. Create a snapshot using either of the following techniques:
   - Create a Statspack snapshot manually.
   - Create a job that takes a Statspack snapshot after a given time interval. For example, the following job creates a Statspack snapshot every hour:

   ```
   VARIABLE jn NUMBER;
   exec dbms_job.submit(:jn, 'statspack.snap;',SYSDATE,'TRUNC(SYSDATE+1/24,''HH24'')');
   COMMIT;
   ```

3. View the snapshots using the following query:

   ```
   SELECT SNAP_ID, SNAP_TIME FROM STATS$SNAPSHOT ORDER BY 1;
   ```

4. Run the Amazon RDS procedure `rdsadmin.rds_run_spreport`, replacing `begin_snap` and `end_snap` with the snapshot IDs:

   ```
   exec rdsadmin.rds_run_spreport('begin_snap','end_snap');
   ```

   For example, the following command creates a report based on the interval between Statspack snapshots 1 and 2:

   ```
   exec rdsadmin.rds_run_spreport(1,2);
   ```

   The file name of the Statspack report includes the number of the two snapshots. For example, a report file created using Statspack snapshots 1 and 2 would be named `ORCL_spreport_1_2.lst`.

5. Monitor the output for errors.

   Oracle Statspack performs checks before running the report. Therefore, you could also see error messages in the command output. For example, you might try to generate a report based on an invalid range, where the beginning Statspack snapshot value is larger than the ending value. In this case, the output shows the error message, but the DB engine does not generate an error file.

   ```
   exec rdsadmin.rds_run_spreport(2,1);
   * ERROR at line 1:
   ORA-20000: Invalid snapshot IDs. Find valid ones in perfstat.stats$snapshot.
   ```

   If you use an invalid number a Statspack snapshot, the output shows an error. For example, if you try to generate a report for snapshots 1 and 50, but snapshot 50 doesn't exist, the output shows an error.

   ```
   exec rdsadmin.rds_run_spreport(1,50);
   * ERROR at line 1:
   ```
ORA-20000: Could not find both snapshot IDs

6. (Optional)

To retrieve the report, call the trace file procedures, as explained in Working with Oracle trace files (p. 924).

Alternatively, download the Statspack report from the RDS console. Go to the Log section of the DB instance details and choose Download:

If an error occurs while generating a report, the DB engine uses the same naming conventions as for a report but with an extension of .err. For example, if an error occurred while creating a report using Statspack snapshots 1 and 7, the report file would be named ORCL_spreport_1_7.err. You can download the error report using the same techniques as for a standard Snapshot report.

Removing Statspack snapshots

To remove a range of Oracle Statspack snapshots, use the following command:

```
exec statspack.purge(begin snap, end snap);
```
Oracle time zone

To change the system time zone used by your Oracle DB instance, use the time zone option. For example, you might change the time zone of a DB instance to be compatible with an on-premises environment, or a legacy application. The time zone option changes the time zone at the host level. Changing the time zone impacts all date columns and values, including SYSDATE and SYSTIMESTAMP.

The time zone option differs from the rdsadmin_util.alter_db_time_zone command. The alter_db_time_zone command changes the time zone only for certain data types. The time zone option changes the time zone for all date columns and values. For more information about alter_db_time_zone, see Setting the database time zone (p. 1889). For more information about upgrade considerations, see Time zone considerations (p. 2127).

Considerations for setting the time zone

The time zone option is a permanent and persistent option. Therefore, you can't do the following:

• Remove the option from an option group after you add the option.
• Remove the option group from a DB instance after you add the group.
• Modify the time zone setting of the option to a different time zone.

If you accidentally set the time zone incorrectly, you must recover your DB instance to its previous time zone setting. We strongly urge you to use one of the following strategies, depending on your situation:

Your DB instance currently uses the default option group. In this case, complete the following steps:

1. Take a snapshot of your DB instance. For more information, see Creating a DB snapshot (p. 613).
2. Add the time zone option to your DB instance.

Your DB instance currently uses a nondefault option group. In this case, complete the following steps:

1. Take a snapshot of your DB instance. For more information, see Creating a DB snapshot (p. 613).
2. Create a new option group with the time zone option.
3. Add the option group to your DB instance.

We strongly urge you to test the time zone option on a test DB instance before you add it to a production DB instance. Adding the time zone option can cause problems with tables that use system date to add dates or times. We recommend that you analyze your data and applications to assess the impact of changing the time zone.

Time zone option settings

Amazon RDS supports the following settings for the time zone option.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIME_ZONE</td>
<td>One of the available time zones. For the full list, see Available time zones (p. 2105).</td>
<td>The new time zone for your DB instance.</td>
</tr>
</tbody>
</table>

Adding the time zone option

The general process for adding the time zone option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

When you add the time zone option, a brief outage occurs while your DB instance is automatically restarted.

**Console**

**To add the time zone option to a DB instance**

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine** choose the oracle edition for your DB instance.
   b. For **Major engine version** choose the version of your DB instance.

   For more information, see [Creating an option group](p. 332).

2. Add the **Timezone** option to the option group, and configure the option settings.
   **Important**
   
   If you add the time zone option to an existing option group that is already attached to one or more DB instances, a brief outage occurs while all the DB instances are automatically restarted.

   For more information about adding options, see [Adding an option to an option group](p. 335). For more information about each setting, see [Time zone option settings](p. 2103).

3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](p. 300).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. When you add the time zone option to an existing DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see [Modifying an Amazon RDS DB instance](p. 401).

**AWS CLI**

The following example uses the AWS CLI `add-option-to-option-group` command to add the Timezone option and the TIME_ZONE option setting to an option group called `myoptiongroup`. The time zone is set to Africa/Cairo.

For Linux, macOS, or Unix:

```bash
aws rds add-option-to-option-group \
   --option-group-name "myoptiongroup" \
   --options "OptionName=Timezone,OptionSettings=[{Name=TIME_ZONE,Value=Africa/Cairo}]" \
   --apply-immediately
```

For Windows:

```bash
aws rds add-option-to-option-group ^
   --option-group-name "myoptiongroup" ^
   --options "OptionName=Timezone,OptionSettings=[{Name=TIME_ZONE,Value=Africa/Cairo}]" ^
   --apply-immediately
```
Modifying time zone settings

The time zone option is a permanent and persistent option. You can't remove the option from an option group after you add it. You can't remove the option group from a DB instance after you add it. You can't modify the time zone setting of the option to a different time zone. If you set the time zone incorrectly, restore a snapshot of your DB instance from before you added the time zone option.

Removing the time zone option

The time zone option is a permanent and persistent option. You can't remove the option from an option group after you add it. You can't remove the option group from a DB instance after you add it. To remove the time zone option, restore a snapshot of your DB instance from before you added the time zone option.

Available time zones

You can use the following values for the time zone option.

<table>
<thead>
<tr>
<th>Zone</th>
<th>Time zone</th>
</tr>
</thead>
<tbody>
<tr>
<td>Africa</td>
<td>Africa/Cairo, Africa/Casablanca, Africa/Harare, Africa/Lagos, Africa/Luanda, Africa/Monrovia, Africa/Nairobi, Africa/Tripoli, Africa/Windhoek</td>
</tr>
<tr>
<td>America</td>
<td>America/Araguaina, America/Argentina/Buenos_Aires, America/Asuncion, America/Bogota, America/Caracas, America/Chicago, America/Chihuahua, America/Cuiaba, America/Denver, America/Detroit, America/Fortaleza, America/Godthab, America/Guatemala, America/Halifax, America/Lima, America/Los_Angeles, America/Manaus, America/Matamoros, America/Mexico_City, America/Monterrey, America/Montevideo, America/New_York, America/Phoenix, America/Santiago, America/Sao_Paulo, America/Tijuana, America/Toronto</td>

</tbody>
</table>
Oracle time zone file autoupgrade

With the TIMEZONE_FILE_AUTOUPGRADE option, you can upgrade the current time zone file to the latest version on your DB instance.

Topics

• Overview of Oracle time zone files (p. 2107)
• Strategies for updating your time zone file (p. 2108)
• Downtime during the time zone file update (p. 2109)
• Preparing to update the time zone file (p. 2110)
• Adding the time zone file autoupgrade option (p. 2111)
• Checking your data after the update of the time zone file (p. 2112)

Overview of Oracle time zone files

An Oracle Database time zone file stores the following information:

• Offset from Coordinated Universal Time (UTC)
• Transition times for Daylight Saving Time (DST)
• Abbreviations for standard time and DST

Oracle Database supplies multiple versions of time zone files. When you create an Oracle database in an on-premises environment, you choose the time zone file version. For more information, see Choosing a Time Zone File in the Oracle Database Globalization Support Guide.

If the rules change for DST, Oracle publishes new time zone files. Oracle releases these new time zone files independently of the schedule for quarterly RUs and RURs. The time zone files reside on the database host in the directory $ORACLE_HOME/oracore/zoneinfo/. The time zone file names use the format DSTvversion, as in DSTv35.

How the time zone file affects data transfer

In Oracle Database, the TIMESTAMP WITH TIME ZONE data type stores time stamp and time zone data. Data with the TIMESTAMP WITH TIME ZONE data type uses the rules in the associated time zone file version. Thus, the existing data is affected when you update the time zone file.

Problems can occur when you transfer data between databases that use different versions of the time zone file. For example, if you try to import data from a source database with a higher time zone file version than the target database, you receive the ORA-39405 error. Previously, you had to work around this error by using either of the following techniques:

• Create an RDS for Oracle DB instance with the desired time zone file, export data from your source database, and then import it into the new database.
• Use AWS DMS or logical replication to migrate your data.

Automatic updates using the TIMEZONE_FILE_AUTOUPGRADE option

When you add the TIMEZONE_FILE_AUTOUPGRADE option in RDS for Oracle, RDS for Oracle updates your time zone files automatically. By ensuring that your databases use the same time zone file version, you avoid time-consuming manual techniques when you move data between different environments.
The TIMEZONE_FILE_AUTOUPGRADE option is supported for both container databases (CDBs) and non-CDBs.

When you add the TIMESTAMP WITH TIME_ZONE option to your option group, you can choose whether to add the option immediately or during the maintenance window. After your DB instance uses the new option, RDS checks whether it can install a newer DSTvversion file. The target DSTvversion depends on the following:

- The minor engine version that your DB instance is currently running
- The minor engine version to which you want to upgrade your DB instance

For example, if your current time zone file version is DSTv33, RDS might determine that DSTv34 is currently available on your DB instance file system. In this case, when you add the TIMESTAMP WITH TIME_ZONE option, RDS immediately updates your time zone file to DSTv34.

To find the available DST versions in the supported RDS release updates, look at the patches in Release notes for Amazon Relational Database Service (Amazon RDS) for Oracle. For example, version version 19.0.0.0.ru-2022-10.rur-2022-10.r1 lists patch 34533061: RDBMS - DSTV39 UPDATE - TZDATA2022C.

**Strategies for updating your time zone file**

You can upgrade your DB engine and update your time zone file independently. Thus, you must choose among different update strategies, depending on whether you want to upgrade your database and time zone file at the same time.

The examples in this section assume the following:

- You have not yet added TIMEZONE_FILE_AUTOUPGRADE to the option group used by your DB instance.
- Your DB instance file system includes file DSTv34.

To update your time zone file, you can use the following strategies.

**Topics**

- [Update the time zone file without upgrading the engine](#)
- [Upgrade the time zone file and DB engine version](#)
- [Upgrade your DB engine version without updating the time zone file](#)

**Update the time zone file without upgrading the engine**

In this scenario, your database is using DSTv33, but DSTv34 is available on your DB instance file system. You want to update the time zone file used by your DB instance from DSTv33 to DSTv34, but you don't want to upgrade your engine to a new minor version, which includes DSTv35. In your modify DB instance operation, do the following:

- Add TIMEZONE_FILE_AUTOUPGRADE to the option group used by your DB instance. Specify whether to add the option immediately or defer it to the maintenance window.
- Don't change your engine version.

After the TIMEZONE_FILE_AUTOUPGRADE option is applied, RDS checks for a new DST version, sees that DSTv34 is available on the file system, and immediately starts the update.
Upgrade the time zone file and DB engine version

In this scenario, your database is using DSTv33, but DSTv34 is available on your DB instance file system. You want to upgrade your DB engine to minor version 19.0.0.0.ru-2022-10.rur-2022-10.r1, which includes DSTv35, and update your time zone file to DSTv35 during the engine upgrade. Thus, your goal is to skip DSTv34 and update your time zone files directly to DSTv35. In your modify DB instance operation, do the following:

- Add TIMEZONE_FILE_AUTOUPGRADE to the option group used by your DB instance. Specify whether to add the option immediately or defer it to the maintenance window.
- Change your minor engine version.

After the TIMEZONE_FILE_AUTOUPGRADE option is applied, RDS checks for a new DST version, sees that DSTv35 is available in 19.0.0.0.ru-2022-10.rur-2022-10.r1, and immediately starts the update to DSTv35. At the same time, RDS upgrades your DB engine to version 19.0.0.0.ru-2022-10.rur-2022-10.r1.

Upgrade your DB engine version without updating the time zone file

In this scenario, your database is using DSTv33, but DSTv34 is available on your DB instance file system. You want to upgrade your DB engine to version 19.0.0.0.ru-2022-10.rur-2022-10.r1, which includes DSTv35, but retain time zone file DSTv33. You might choose this strategy for the following reasons:

- Your data doesn't use the TIMESTAMP WITH TIME ZONE data type.
- Your data uses the TIMESTAMP WITH TIME ZONE data type, but your data is not affected by the time zone changes.
- You want to postpone updating the time zone file because you can't tolerate the extra downtime.

Your strategy depends on which of the following possibilities are true:

- Your DB instance isn't associated with an option group that includes TIMEZONE_FILE_AUTOUPGRADE. Leave your option group as it is so that RDS doesn't update your time zone file.
- Your DB instance is associated with an option group that includes TIMEZONE_FILE_AUTOUPGRADE. Associate your DB instance with an option group that doesn't include TIMEZONE_FILE_AUTOUPGRADE, and then upgrade your DB engine to 19.0.0.0.ru-2022-10.rur-2022-10.r1.

Downtime during the time zone file update

When RDS updates your time zone file, existing data that uses TIMESTAMP WITH TIME ZONE might change. In this case, your primary consideration is downtime.

Warning

If you add the TIMEZONE_FILE_AUTOUPGRADE option, your engine upgrade might have prolonged downtime. Updating time zone data for a large database might take hours or even days.

The length of the time zone file update depends on factors such as the following:

- The amount of TIMESTAMP WITH TIME ZONE data in your database
- The DB instance configuration
- The DB instance class
- The storage configuration
- The database configuration
- The database parameter settings
Additional downtime can occur when you do the following:

- Add the option to the option group when the DB instance uses an outdated time zone file
- Upgrade the Oracle database engine when the new engine version contains a new version of the time zone file

**Note**
During the time zone file update, RDS for Oracle calls `PURGE DBA_RECYCLEBIN`.

**Preparing to update the time zone file**

A time zone file upgrade has two separate phases: prepare and upgrade. While not required, we strongly recommend that you perform the prepare step. In this step, you find out which data will be affected by running the PL/SQL procedure `DBMS_DST.FIND_AFFECTED_TABLES`. For more information about the prepare window, see [Upgrading the Time Zone File and Timestamp with Time Zone Data](#) in the Oracle Database documentation.

**To prepare to update the time zone file**

1. Connect to your Oracle database using a SQL client.
2. Determine the current timezone file version used.

   ```sql
   SELECT * FROM V$TIMEZONE_FILE;
   ```

3. Determine the latest timezone file version available on your DB instance. This step is only applicable if you use Oracle Database 12c Release 2 (12.2) or higher.

   ```sql
   SELECT DBMS_DST.GET_LATEST_TIMEZONE_VERSION FROM DUAL;
   ```

4. Determine the total size of tables that have columns of type `TIMESTAMP WITH LOCAL TIME ZONE` or `TIMESTAMP WITH TIME ZONE`.

   ```sql
   SELECT SUM(BYTES)/1024/1024/1024 "Total_size_w_TSTZ_columns_GB"
   FROM   DBA_SEGMENTS
   WHERE  SEGMENT_TYPE LIKE 'TABLE%'
   AND    (OWNER, SEGMENT_NAME) IN
   (SELECT OWNER, TABLE_NAME
    FROM   DBA_TAB_COLUMNS
    WHERE  DATA_TYPE LIKE 'TIMESTAMP%TIME ZONE');
   ```

5. Determine the names and sizes of segments that have columns of type `TIMESTAMP WITH LOCAL TIME ZONE` or `TIMESTAMP WITH TIME ZONE`.

   ```sql
   SELECT OWNER, SEGMENT_NAME, SUM(BYTES)/1024/1024/1024 "SEGMENT_SIZE_W_TSTZ_COLUMNS_GB"
   FROM   DBA_SEGMENTS
   WHERE  SEGMENT_TYPE LIKE 'TABLE%'
   AND    (OWNER, SEGMENT_NAME) IN
   (SELECT OWNER, TABLE_NAME
    FROM   DBA_TAB_COLUMNS
    WHERE  DATA_TYPE LIKE 'TIMESTAMP%TIME ZONE')
   GROUP BY OWNER, SEGMENT_NAME;
   ```

6. Run the prepare step.

   - The procedure `DBMS_DST.CREATE_AFFECTED_TABLE` creates a table to store any affected data. You pass the name of this table to the `DBMS_DST.FIND_AFFECTED_TABLES` procedure. For more information, see [CREATE_AFFECTED_TABLE Procedure](#) in the Oracle Database documentation.
• This procedure CREATE_ERROR_TABLE creates a table to log errors. For more information, see CREATE_ERROR_TABLE Procedure in the Oracle Database documentation.

The following example creates the affected data and error tables, and finds all affected tables.

```sql
EXEC DBMS_DST.CREATE_ERROR_TABLE('my_error_table')
EXEC DBMS_DST.CREATE_AFFECTED_TABLE('my_affected_table')
EXEC DBMS_DST.BEGIN_PREPARE(new_version);
EXEC DBMS_DST.FIND_AFFECTED_TABLES('my_affected_table', TRUE, 'my_error_table');
EXEC DBMS_DST.END_PREPARE;
SELECT * FROM my_affected_table;
SELECT * FROM my_error_table;
```

7. Query the affected and error tables.

```sql
SELECT * FROM my_affected_table;
SELECT * FROM my_error_table;
```

Adding the time zone file autoupgrade option

When you add the option to an option group, the option group is in one of the following states:

- An existing option group is currently attached to at least one DB instance. When you add the option, all DB instances that use this option group automatically restart. This causes a brief outage.
- An existing option group is not attached to any DB instance. You plan to add the option and then associate the existing option group with existing DB instances or with a new DB instance.
- You create a new option group and add the option. You plan to associate the new option group with existing DB instances or with a new DB instance.

Console

To add the time zone file autoupgrade option to a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For Engine choose the Oracle Database edition for your DB instance.
   b. For Major engine version choose the version of your DB instance.

   For more information, see Creating an option group (p. 332).
4. Choose the option group that you want to modify, and then choose Add option.
5. In the Add option window, do the following:
   a. Choose TIMEZONE_FILE_AUTOUPGRADE.
   b. To enable the option on all associated DB instances as soon as you add it, for Apply Immediately, choose Yes. If you choose No (the default), the option is enabled for each associated DB instance during its next maintenance window.
6. When the settings are as you want them, choose **Add option**.

**AWS CLI**

The following example uses the AWS CLI `add-option-to-option-group` command to add the `TIMEZONE_FILE_AUTOUPGRADE` option to an option group called `myoptiongroup`.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
  --option-group-name "myoptiongroup" \
  --options "OptionName=TIMEZONE_FILE_AUTOUPGRADE" \
  --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
  --option-group-name "myoptiongroup" ^
  --options "OptionName=TIMEZONE_FILE_AUTOUPGRADE" ^
  --apply-immediately
```

**Checking your data after the update of the time zone file**

We recommend that you check your data after you update the time zone file. During the prepare step, RDS for Oracle automatically creates the following tables:

- `rdsadmin.rds_dst_affected_tables` – Lists the tables that contain data affected by the update
- `rdsadmin.rds_dst_error_table` – Lists the errors generated during the update

These tables are independent of any tables that you create in the prepare window. To see the results of the update, query the tables as follows.

```
SELECT * FROM rdsadmin.rds_dst_affected_tables;
SELECT * FROM rdsadmin.rds_dst_error_table;
```

For more information about the schema for the affected data and error tables, see [FIND_AFFECTED_TABLES Procedure](#) in the Oracle documentation.
Oracle Transparent Data Encryption

Amazon RDS supports Oracle Transparent Data Encryption (TDE), a feature of the Oracle Advanced Security option available in Oracle Enterprise Edition. This feature automatically encrypts data before it is written to storage and automatically decrypts data when the data is read from storage.

Oracle Transparent Data Encryption is used in scenarios where you need to encrypt sensitive data in case data files and backups are obtained by a third party or when you need to address security-related regulatory compliance issues.

The TDE option is a permanent option that can't be removed from an option group. You can't disable TDE from a DB instance once that instance is associated with an option group with the Oracle TDE option. You can change the option group of a DB instance that is using the TDE option, but the option group associated with the DB instance must include the TDE option. You can also modify an option group that includes the TDE option by adding or removing other options.

A detailed explanation about Oracle Transparent Data Encryption is beyond the scope of this guide. For information about using Oracle Transparent Data Encryption, see Securing stored data using Transparent Data Encryption. For more information about Oracle Advanced Security, see Oracle advanced security in the Oracle documentation. For more information on AWS security, see the AWS security center.

**Note**

You can't share a DB snapshot that uses this option. For more information about sharing DB snapshots, see Sharing a DB snapshot (p. 633).

**TDE encryption modes**

Oracle Transparent Data Encryption supports two encryption modes: TDE tablespace encryption and TDE column encryption. TDE tablespace encryption is used to encrypt entire application tables. TDE column encryption is used to encrypt individual data elements that contain sensitive data. You can also apply a hybrid encryption solution that uses both TDE tablespace and column encryption.

**Note**

Amazon RDS manages the Oracle Wallet and TDE master key for the DB instance. You do not need to set the encryption key using the command ALTER SYSTEM set encryption key.

For information about TDE best practices, see Oracle advanced security Transparent Data Encryption best practices.

Once the option is enabled, you can check the status of the Oracle Wallet by using the following command:

```
SELECT * FROM v$encryption_wallet;
```

To create an encrypted tablespace, use the following command:

```
CREATE TABLESPACE encrypt_ts ENCRYPTION DEFAULT STORAGE (ENCRYPT);
```

To specify the encryption algorithm, use the following command:

```
CREATE TABLESPACE encrypt_ts ENCRYPTION USING 'AES256' DEFAULT STORAGE (ENCRYPT);
```

Note that the previous commands for encrypting a tablespace are the same as the commands you would use with an Oracle installation not on Amazon RDS, and the ALTER TABLE syntax to encrypt a column is also the same as the commands you would use for an Oracle installation not on Amazon RDS.
You should determine if your DB instance is associated with an option group that has the **TDE** option. To view the option group that a DB instance is associated with, you can use the RDS console, the `describe-db-instance` AWS CLI command, or the API operation `DescribeDBInstances`.

To comply with several security standards, Amazon RDS is working to implement automatic periodic master key rotation.

**Adding the TDE option**

The process for using Oracle Transparent Data Encryption (TDE) with Amazon RDS is as follows:

1. If the DB instance is not associated with an option group that has the **TDE** option enabled, you must either create an option group and add the **TDE** option or modify the associated option group to add the **TDE** option. For information about creating or modifying an option group, see [Working with option groups](p. 331). For information about adding an option to an option group, see [Adding an option to an option group](p. 335).
2. Associate the DB instance with the option group with the **TDE** option. For information about associating a DB instance with an option group, see [Modifying an Amazon RDS DB instance](p. 401).

**Removing the TDE option**

To remove the **TDE** option with a DB instance, complete the following steps:

1. Decrypt all your data on the DB instance.
2. Copy the data to a new DB instance that is not associated with an option group with **TDE** enabled.
3. Delete the original instance.

You can name the new instance the same name as the previous DB instance.

**Using TDE with Oracle Data Pump**

You can use Oracle Data Pump to import or export encrypted dump files. Amazon RDS supports the password encryption mode (ENCRYPTION_MODE=PASSWORD) for Oracle Data Pump. Amazon RDS does not support transparent encryption mode (ENCRYPTION_MODE=TRANSPARENT) for Oracle Data Pump. For more information about using Oracle Data Pump with Amazon RDS, see [Importing using Oracle Data Pump](p. 1964).
Oracle UTL_MAIL

Amazon RDS supports Oracle UTL_MAIL through the use of the UTL_MAIL option and SMTP servers. You can send email directly from your database by using the UTL_MAIL package. Amazon RDS supports UTL_MAIL for the following versions of Oracle:

- Oracle Database 21c (21.0.0.0), all versions
- Oracle Database 19c (19.0.0.0), all versions
- Oracle Database 12c Release 2 (12.2), all versions
- Oracle Database 12c Release 1 (12.1), version 12.1.0.2.v5 and later

The following are some limitations to using UTL_MAIL:

- UTL_MAIL does not support Transport Layer Security (TLS) and therefore emails are not encrypted.
  
  To connect securely to remote SSL/TLS resources by creating and uploading custom Oracle wallets, follow the instructions in Configuring UTL_HTTP access using certificates and an Oracle wallet (p. 1848).
  
  The specific certificates that are required for your wallet vary by service. For AWS services, these can typically be found in the Amazon trust services repository.
- UTL_MAIL does not support authentication with SMTP servers.
- You can only send a single attachment in an email.
- You can't send attachments larger than 32 K.
- You can only use ASCII and Extended Binary Coded Decimal Interchange Code (EBCDIC) character encodings.
- SMTP port (25) is throttled based on the elastic network interface owner's policies.

When you enable UTL_MAIL, only the master user for your DB instance is granted the execute privilege. If necessary, the master user can grant the execute privilege to other users so that they can use UTL_MAIL.

**Important**

We recommend that you enable Oracle's built-in auditing feature to track the use of UTL_MAIL procedures.

Prerequisites for Oracle UTL_MAIL

The following are prerequisites for using Oracle UTL_MAIL:

- One or more SMTP servers, and the corresponding IP addresses or public or private Domain Name Server (DNS) names. For more information about private DNS names resolved through a custom DNS server, see Setting up a custom DNS server (p. 1881).
- For Oracle versions prior to 12c, your DB instance must also use the XML DB option. For more information, see Oracle XML DB (p. 2118).

Adding the Oracle UTL_MAIL option

The general process for adding the Oracle UTL_MAIL option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

After you add the UTL_MAIL option, as soon as the option group is active, UTL_MAIL is active.

To add the UTL_MAIL option to a DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For Engine, choose the edition of Oracle you want to use.
   b. For Major engine version, choose the version of your DB instance.

   For more information, see Creating an option group (p. 332).

2. Add the UTL_MAIL option to the option group. For more information about adding options, see Adding an option to an option group (p. 335).

3. Apply the option group to a new or existing DB instance:
   • For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 300).
   • For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 401).

Using Oracle UTL_MAIL

After you enable the UTL_MAIL option, you must configure the SMTP server before you can begin using it.

You configure the SMTP server by setting the SMTP_OUT_SERVER parameter to a valid IP address or public DNS name. For the SMTP_OUT_SERVER parameter, you can specify a comma-separated list of the addresses of multiple servers. If the first server is unavailable, UTL_MAIL tries the next server, and so on.

You can set the default SMTP_OUT_SERVER for a DB instance by using a DB parameter group. You can set the SMTP_OUT_SERVER parameter for a session by running the following code on your database on your DB instance.

```
ALTER SESSION SET smtp_out_server = mailserver.domain.com:25;
```

After the UTL_MAIL option is enabled, and your SMTP_OUT_SERVER is configured, you can send mail by using the SEND procedure. For more information, see UTL_MAIL in the Oracle documentation.

Removing the Oracle UTL_MAIL option

You can remove Oracle UTL_MAIL from a DB instance.

To remove UTL_MAIL from a DB instance, do one of the following:

• To remove UTL_MAIL from multiple DB instances, remove the UTL_MAIL option from the option group they belong to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 343).

• To remove UTL_MAIL from a single DB instance, modify the DB instance and specify a different option group that doesn't include the UTL_MAIL option. You can specify the default (empty) option
group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 401).

Troubleshooting

The following are issues you might encounter when you use UTL_MAIL with Amazon RDS.

- Throttling. SMTP port (25) is throttled based on the elastic network interface owner's policies. If you can successfully send email by using UTL_MAIL, and you see the error ORA-29278: SMTP transient error: 421 Service not available, you are possibly being throttled. If you experience throttling with email delivery, we recommend that you implement a backoff algorithm. For more information about backoff algorithms, see Error retries and exponential backoff in AWS and How to handle a "throttling – Maximum sending rate exceeded" error.

You can request that this throttle be removed. For more information, see How do I remove the throttle on port 25 from my EC2 instance?
Oracle XML DB

Oracle XML DB adds native XML support to your DB instance. With XML DB, you can store and retrieve structured or unstructured XML, in addition to relational data. XML DB is preinstalled on Oracle version 12c and later.
Upgrading the RDS for Oracle DB engine

When Amazon RDS supports a new version of Oracle Database, you can upgrade your DB instances to the new version. For information about which Oracle versions are available on Amazon RDS, see Amazon RDS for Oracle Release Notes.

Important
RDS for Oracle Databases 11g, 12c, and 18c are no longer supported. If you maintain Oracle Database 11g, 12c, or 18c snapshots, you can upgrade them to a later release. For more information, see Upgrading an Oracle DB snapshot (p. 2128).

Topics
- Overview of RDS for Oracle engine upgrades (p. 2119)
- Oracle major version upgrades (p. 2122)
- Oracle minor version upgrades (p. 2123)
- Considerations for Oracle DB upgrades (p. 2126)
- Testing an Oracle DB upgrade (p. 2127)
- Upgrading an Oracle DB instance (p. 2128)
- Upgrading an Oracle DB snapshot (p. 2128)

Overview of RDS for Oracle engine upgrades

Before upgrading your RDS for Oracle DB instance, familiarize yourself with the following concepts.

Topics
- Major and minor version upgrades (p. 2119)
- Expected support dates for RDS for Oracle major releases (p. 2120)
- Oracle engine version management (p. 2120)
- Automatic snapshots during engine upgrades (p. 2121)
- Oracle upgrades in a Multi-AZ deployment (p. 2121)
- Oracle upgrades of read replicas (p. 2121)
- Oracle upgrades of micro DB instances (p. 2121)

Major and minor version upgrades

Major versions are major releases of Oracle Database that occur every 1-2 years. Examples of major releases are Oracle Database 19c and Oracle Database 21c.

Minor versions, which are also called Release Updates (RUs), are typically released by Oracle every quarter. Minor versions contain small feature enhancements and bug fixes. Examples of minor versions are 21.0.0.0.ru-2022-10.rur-2022-10.r1 and 19.0.0.0.ru-2022-10.rur-2022-10.r1. For more information, see Release notes for Amazon Relational Database Service (Amazon RDS) for Oracle.

RDS for Oracle supports the following upgrades to a DB instance.

<table>
<thead>
<tr>
<th>Upgrade type</th>
<th>Application compatibility</th>
<th>Upgrade methods</th>
<th>Sample upgrade path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Major version</td>
<td>A major version upgrade can introduce changes that aren't</td>
<td>Manual only</td>
<td>From Oracle Database 19c to Oracle Database 21c</td>
</tr>
<tr>
<td>Upgrade type</td>
<td>Application compatibility</td>
<td>Upgrade methods</td>
<td>Sample upgrade path</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------------------------------------------------------------</td>
<td>-------------------</td>
<td>----------------------------------------</td>
</tr>
<tr>
<td>Minor version</td>
<td>A minor version upgrade includes only changes that are</td>
<td>Automatic or</td>
<td>From 21.0.0.0.ru-2022-07.rur-2022-07.r1</td>
</tr>
<tr>
<td></td>
<td>backward-compatible with existing applications.</td>
<td>manual</td>
<td>to 21.0.0.0.ru-2022-10.rur-2022-10.r1</td>
</tr>
</tbody>
</table>

**Important**
When you upgrade your DB engine, an outage occurs. The duration of the outage depends on your engine version and DB instance size. Make sure that you thoroughly test any upgrade to verify that your applications work correctly before applying the upgrade to your production databases. For more information, see Testing an Oracle DB upgrade (p. 2127).

**Expected support dates for RDS for Oracle major releases**

RDS for Oracle major versions remain available at least until the end of support date for the corresponding Oracle Database release version. You can use the following dates to plan your testing and upgrade cycles. These dates represent the earliest date that an upgrade to a newer version might be required. If Amazon extends support for an RDS for Oracle version for longer than originally stated, we plan to update this table to reflect the later date.

<table>
<thead>
<tr>
<th>Oracle Database major release version</th>
<th>Expected date for upgrading to a newer version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle Database 19c</td>
<td>April 30, 2024 without Extended Support or an Unlimited License Agreement</td>
</tr>
<tr>
<td></td>
<td>April 30, 2027 with Extended Support or an Unlimited License Agreement</td>
</tr>
<tr>
<td>Oracle Database 21c</td>
<td>April 30, 2024</td>
</tr>
</tbody>
</table>

Before we ask you to upgrade to a newer major version, we remind you at least 12 months in advance. We detail the upgrade process, including the timing of important milestones, the impact on your DB instances, and recommended actions. You should thoroughly test your applications with new RDS for Oracle versions before you upgrade to a major version.

After this advance notification period, an automatic upgrade to the subsequent major version might be applied to any RDS for Oracle DB instance still running the older version. If so, the upgrade is started during scheduled maintenance windows.

**Oracle engine version management**

With DB engine version management, you control when and how the database engine is patched and upgraded. You get the flexibility to maintain compatibility with database engine patch versions. You can also test new patch versions of RDS for Oracle to ensure they work with your application before deploying them in production. In addition, you upgrade the versions on your own terms and timelines.

**Note**
Amazon RDS periodically aggregates official Oracle database patches using an Amazon RDS-specific DB engine version. To see a list of which Oracle patches are contained in an Amazon RDS Oracle-specific engine version, go to Amazon RDS for Oracle Release Notes.
Automatic snapshots during engine upgrades

During upgrades of an Oracle DB instance, snapshots offer protection against upgrade issues. If the backup retention period for your DB instance is greater than 0, Amazon RDS takes the following DB snapshots during the upgrade:

1. A snapshot of the DB instance before any upgrade changes have been made. If the upgrade fails, you can restore this snapshot to create a DB instance running the old version.
2. A snapshot of the DB instance after the upgrade completes.

Note
To change your backup retention period, see Modifying an Amazon RDS DB instance (p. 401).

After an upgrade, you can't revert to the previous engine version. However, you can create a new Oracle DB instance by restoring the pre-upgrade snapshot.

Oracle upgrades in a Multi-AZ deployment

If your DB instance is in a Multi-AZ deployment, Amazon RDS upgrades both the primary and standby replicas. If no operating system updates are required, the primary and standby upgrades occur simultaneously. The instances are not available until the upgrade completes.

If operating system updates are required in a Multi-AZ deployment, Amazon RDS applies the updates when you request the DB upgrade. Amazon RDS performs the following steps:

1. Updates the operating system on the standby DB instance.
2. Upgrades the standby DB instance.
3. Fails over the primary instance to the standby DB instance.
4. Upgrades the operating system on the new standby DB instance, which was formerly the primary instance.
5. Upgrades the new standby DB instance.

Oracle upgrades of read replicas

The Oracle DB engine version of the source DB instance and all of its read replicas must be the same. Amazon RDS performs the upgrade in the following stages:

1. Upgrades the source DB instance. The read replicas are available during this stage.
2. Upgrades the read replicas in parallel, regardless of the replica maintenance windows. The source DB is available during this stage.

For major version upgrades of cross-Region read replicas, Amazon RDS performs additional actions:

- Generates an option group for the target version automatically
- Copies all options and option settings from the original option group to the new option group
- Associates the upgraded cross-Region read replica with the new option group

Oracle upgrades of micro DB instances

We don't recommend upgrading databases running on micro DB instances. Because these instances have limited CPU, the upgrade can take hours to complete.
You can upgrade micro DB instances with small amounts of storage (10–20 GiB) by copying your data using Data Pump. Before you migrate your production DB instances, we recommend that you test by copying data using Data Pump.

**Oracle major version upgrades**

To perform a major version upgrade, modify the DB instance manually. Major version upgrades don't occur automatically.

**Important**

Make sure that you thoroughly test any upgrade to verify that your applications work correctly before applying the upgrade to your production databases. For more information, see [Testing an Oracle DB upgrade](#).

**Topics**

- Supported versions for major upgrades (p. 2122)
- Supported instance classes for major upgrades (p. 2122)
- Gathering statistics before major upgrades (p. 2122)
- Allowing major upgrades (p. 2123)

**Supported versions for major upgrades**

Amazon RDS supports the following major version upgrades.

<table>
<thead>
<tr>
<th>Current version</th>
<th>Upgrade supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>19.0.0.0 using the CDB architecture</td>
<td>21.0.0.0</td>
</tr>
</tbody>
</table>

A major version upgrade of Oracle Database must upgrade to a Release Update (RU) that was released in the same month or later. Major version downgrades aren't supported for any Oracle Database versions.

**Supported instance classes for major upgrades**

Your current Oracle DB instance might run on a DB instance class that isn't supported for the version to which you are upgrading. In this case, before you upgrade, migrate the DB instance to a supported DB instance class. For more information about the supported DB instance classes for each version and edition of Amazon RDS for Oracle, see [DB instance classes](#).

**Gathering statistics before major upgrades**

Before you perform a major version upgrade, Oracle recommends that you gather optimizer statistics on the DB instance that you are upgrading. This action can reduce DB instance downtime during the upgrade.

To gather optimizer statistics, connect to the DB instance as the master user, and run the `DBMS_STATS.GATHER_DICTIONARY_STATS` procedure, as in the following example.

```
EXEC DBMS_STATS.GATHER_DICTIONARY_STATS;
```

For more information, see [Gathering optimizer statistics to decrease Oracle database downtime](#) in the Oracle documentation.
Allowing major upgrades

A major engine version upgrade might be incompatible with your application. The upgrade is irreversible. If you specify a major version for the EngineVersion parameter that is different from the current major version, you must allow major version upgrades.

If you upgrade a major version using the CLI command `modify-db-instance`, specify `--allow-major-version-upgrade`. This setting isn't persistent, so you must specify `--allow-major-version-upgrade` whenever you perform a major upgrade. This parameter has no impact on upgrades of minor engine versions. For more information, see Upgrading a DB instance engine version (p. 429).

If you upgrade a major version using the console, you don't need to choose an option to allow the upgrade. Instead, the console displays a warning that major upgrades are irreversible.

Oracle minor version upgrades

A minor version upgrade applies an Oracle Database Patch Set Update (PSU) or Release Update (RU) to a major engine version. For example, if your DB instance runs major version Oracle Database 21c and minor version 21.0.0.0.ru-2022-07.rur-2022-07.r1, you can upgrade your upgrade to minor version 21.0.0.0.ru-2022-10.rur-2022-10.r1. Typically, a new minor version is available every quarter.

Note
RDS for Oracle doesn't support minor version downgrades.

You can upgrade your DB engine to a minor version manually or automatically. To learn how to upgrade manually, see Manually upgrading the engine version (p. 429). To learn how to configure automatic upgrades, see Automatically upgrading the minor engine version (p. 431). Whether you upgrade manually or automatically, a minor version upgrade entails downtime. Keep this in mind when planning your upgrades.

Important
Make sure that you thoroughly test any upgrade to verify that your applications work correctly before applying the upgrade to your production databases. For more information, see Testing an Oracle DB upgrade (p. 2127).

Topics
- Turning on automatic minor version upgrades for Oracle (p. 2123)
- Before an automatic minor version upgrade for Oracle is scheduled (p. 2124)
- When RDS schedules automatic minor version upgrades for Oracle (p. 2125)
- Managing an automatic minor version upgrade for Oracle (p. 2125)

Turning on automatic minor version upgrades for Oracle

In an automatic minor version upgrade, RDS applies the latest available minor version to your Oracle database without manual intervention. An Amazon RDS for Oracle DB instance schedules your upgrade during the next maintenance window in the following circumstances:

- Your DB instance has the Auto minor version upgrade option turned on.
- Your DB instance isn't already running the latest minor DB engine version.
- Your DB instance doesn't already have a pending upgrade scheduled.

To learn how to turn on automatic upgrades, see Automatically upgrading the minor engine version (p. 431).
Before an automatic minor version upgrade for Oracle is scheduled

RDS publishes an advance notice before it begins scheduling automatic upgrades. You can find the notification in the Maintenance & backups tab of the database details page. The message has the following format:

```
An automatic minor version upgrade to engine version will become available on availability-date and should be applied during a subsequent maintenance window.
```

The availability-date in the preceding message is the date when RDS starts scheduling upgrades for DB instances in your AWS Region. It is not the date on which the upgrade of your DB instance is scheduled to occur.

You can also get the upgrade availability date by using the describe-pending-maintenance-actions command in the AWS CLI, as shown in the following example:

```
aws rds describe-pending-maintenance-actions
{
 "PendingMaintenanceActions": [
  {
   "PendingMaintenanceActionDetails": [
    {
      "Action": "db-upgrade",
      "Description": "Automatic minor version upgrade to 21.0.0.0.ru-2022-10.rur-2022-10.r1",
      "CurrentApplyDate": "2022-12-02T08:10:00Z",
      "OptInStatus": "next-maintenance"
    }
  ]
  }, ...
}
```

The following table describes your options for each type of pending maintenance action message.

<table>
<thead>
<tr>
<th>Pending maintenance action message</th>
<th>When message appears</th>
<th>Eligible to be applied at the next maintenance window?</th>
<th>Eligible to be applied immediately?</th>
<th>Eligible to have the opt-in undone?</th>
</tr>
</thead>
<tbody>
<tr>
<td>An automatic minor version upgrade to <strong>engine-version</strong> will become available on <strong>availability-date</strong> and should be applied during a subsequent maintenance window.</td>
<td>4-6 weeks before automatic upgrades are scheduled.</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Automatic minor version upgrade to <strong>engine-version</strong></td>
<td>On or after <strong>availability-date</strong>. RDS automatically applies this upgrade in the</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>
Pending maintenance action message | When message appears | Eligible to be applied at the next maintenance window? | Eligible to be applied immediately? | Eligible to have the opt-in undone?
--- | --- | --- | --- | ---
next maintenance window of the DB instance. | | | | |

For more information about `describe-pending-maintenance-actions`, see the *AWS CLI Command Reference*.

### When RDS schedules automatic minor version upgrades for Oracle

When the availability date for automatic upgrades arrives, RDS begins scheduling upgrades. For most AWS Regions, RDS schedules your upgrade to the latest quarterly RU approximately four to six weeks after the availability date. The scheduled date varies depending on the AWS Region and other factors. For more information about RUs and RURs, see *Amazon RDS for Oracle Release Notes*.

When RDS schedules the upgrade, the following notification appears in the **Maintenance & backups** tab of the database details page:

**Automatic minor version upgrade to engine-version**

The preceding message indicates that RDS has scheduled your DB engine to be upgraded in the next maintenance window.

### Managing an automatic minor version upgrade for Oracle

When a new minor version becomes available, you can upgrade your DB instance to this version manually. The following example upgrades the DB instance named `orclinst1` immediately:

```
aws rds apply-pending-maintenance-action \
   --resource-identifier arn:aws:rds:us-east-1:123456789012:db:orclinst1 \
   --apply-action db-upgrade \
   --opt-in-type immediate
```

To opt out of an automatic minor version upgrade that hasn't been scheduled yet, set `opt-in-type` to `undo-opt-in`, as in the following example:

```
aws rds apply-pending-maintenance-action \
   --resource-identifier arn:aws:rds:us-east-1:123456789012:db:orclinst1 \
   --apply-action db-upgrade \
   --opt-in-type undo-opt-in
```

If RDS has already scheduled an upgrade for your DB instance, you can't use `apply-pending-maintenance-action` to cancel it. But you can modify your DB instance and turn off the automatic minor upgrade feature, which then unschedules the upgrade.

To learn how to turn off automatic minor version upgrades, see *Automatically upgrading the minor engine version (p. 431)*. For more information about `apply-pending-maintenance-action`, see the *AWS CLI Command Reference*. 

---

2125
Considerations for Oracle DB upgrades

Before you upgrade your Oracle instance, review the following information.

Topics
- Oracle Multitenant considerations (p. 2126)
- Option group considerations (p. 2126)
- Parameter group considerations (p. 2127)
- Time zone considerations (p. 2127)

Oracle Multitenant considerations

The following table describes the architectures supported in different releases.

<table>
<thead>
<tr>
<th>Oracle Database release</th>
<th>RDS support status</th>
<th>Architecture</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle Database 21c</td>
<td>Supported</td>
<td>CDB only</td>
</tr>
<tr>
<td>Oracle Database 19c</td>
<td>Supported</td>
<td>CDB or non-CDB</td>
</tr>
<tr>
<td>Oracle Database 12c Release 2 (12.2)</td>
<td>Desupported</td>
<td>Non-CDB only</td>
</tr>
<tr>
<td>Oracle Database 12c Release 1 (12.1)</td>
<td>Desupported</td>
<td>Non-CDB only</td>
</tr>
</tbody>
</table>

The following table describes supported and unsupported upgrade paths.

<table>
<thead>
<tr>
<th>Upgrade path</th>
<th>Supported?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-CDB to non-CDB</td>
<td>Yes</td>
</tr>
<tr>
<td>CDB to CDB</td>
<td>Yes</td>
</tr>
<tr>
<td>Non-CDB to CDB</td>
<td>No</td>
</tr>
<tr>
<td>CDB to non-CDB</td>
<td>No</td>
</tr>
</tbody>
</table>

For more information about Oracle Multitenant in RDS for Oracle, see Overview of RDS for Oracle CDBs (p. 1856).

Option group considerations

If your DB instance uses a custom option group, sometimes Amazon RDS can't automatically assign a new option group. For example, this situation occurs when you upgrade to a new major version. In such cases, specify a new option group when you upgrade. We recommend that you create a new option group, and add the same options to it as in your existing custom option group.

For more information, see Creating an option group (p. 332) or Copying an option group (p. 334).

If your DB instance uses a custom option group that contains the APEX option, you can sometimes reduce the upgrade time. To do this, upgrade your version of APEX at the same time as your DB instance. For more information, see Upgrading the APEX version (p. 2034).
Parameter group considerations

If your DB instance uses a custom parameter group, sometimes Amazon RDS can't automatically assign your DB instance a new parameter group. For example, this situation occurs when you upgrade to a new major version. In such cases, make sure to specify a new parameter group when you upgrade. We recommend that you create a new parameter group, and configure the parameters as in your existing custom parameter group.

For more information, see Creating a DB parameter group (p. 350) or Copying a DB parameter group (p. 356).

Time zone considerations

You can use the time zone option to change the system time zone used by your Oracle DB instance. For example, you might change the time zone of a DB instance to be compatible with an on-premises environment, or a legacy application. The time zone option changes the time zone at the host level. Amazon RDS for Oracle updates the system time zone automatically throughout the year. For more information about the system time zone, see Oracle time zone (p. 2103).

When you create an Oracle DB instance, the database automatically sets the database time zone. The database time zone is also known as the Daylight Saving Time (DST) time zone. The database time zone is distinct from the system time zone.

Between Oracle Database releases, patch sets or individual patches may include new DST versions. These patches reflect the changes in transition rules for various time zone regions. For example, a government might change when DST takes effect. Changes to DST rules may affect existing data of the TIMESTAMP WITH TIME ZONE data type.

If you upgrade an RDS for Oracle DB instance, Amazon RDS doesn't upgrade the database time zone file automatically. To upgrade the database time zone file automatically, you can include the TIMEZONE_FILE_AUTOPURGE option in the option group associated with your DB instance during or after the engine version upgrade. For more information, see Oracle time zone file autoupgrade (p. 2107).

Alternatively, to upgrade the database time zone file manually, create a new Oracle DB instance that has the desired DST patch. However, we recommend that you upgrade the database time zone file using the TIMEZONE_FILE_AUTOPURGE option.

After upgrading the time zone file, migrate the data from your current instance to the new instance. You can migrate data using several techniques, including the following:

- AWS Database Migration Service
- Oracle GoldenGate
- Oracle Data Pump
- Original Export/Import (desupported for general use)

Note

When you migrate data using Oracle Data Pump, the utility raises the error ORA-39405 when the target time zone version is lower than the source time zone version.

For more information, see TIMESTAMP WITH TIMEZONE restrictions in the Oracle documentation.

Testing an Oracle DB upgrade

Before you upgrade your DB instance to a major version, thoroughly test your database and all applications that access the database for compatibility with the new version. We recommend that you use the following procedure.
To test a major version upgrade

1. Review the Oracle upgrade documentation for the new version of the database engine to see if there are compatibility issues that might affect your database or applications. For more information, see Database Upgrade Guide in the Oracle documentation.

2. If your DB instance uses a custom option group, create a new option group compatible with the new version you are upgrading to. For more information, see Option group considerations (p. 2126).

3. If your DB instance uses a custom parameter group, create a new parameter group compatible with the new version you are upgrading to. For more information, see Parameter group considerations (p. 2127).

4. Create a DB snapshot of the DB instance to be upgraded. For more information, see Creating a DB snapshot (p. 613).

5. Restore the DB snapshot to create a new test DB instance. For more information, see Restoring from a DB snapshot (p. 615).

6. Modify this new test DB instance to upgrade it to the new version, by using one of the following methods:
   - Console (p. 430)
   - AWS CLI (p. 430)
   - RDS API (p. 430)

7. Perform testing:
   - Run as many of your quality assurance tests against the upgraded DB instance as needed to ensure that your database and application work correctly with the new version.
   - Implement any new tests needed to evaluate the impact of any compatibility issues that you identified in step 1.
   - Test all stored procedures, functions, and triggers.
   - Direct test versions of your applications to the upgraded DB instance. Verify that the applications work correctly with the new version.
   - Evaluate the storage used by the upgraded instance to determine if the upgrade requires additional storage. You might need to choose a larger instance class to support the new version in production. For more information, see DB instance classes (p. 11).

8. If all tests pass, upgrade your production DB instance. We recommend that you confirm that the DB instance working correctly before allowing write operations to the DB instance.

Upgrading an Oracle DB instance

To learn how to upgrade an Oracle DB instance, see Upgrading a DB instance engine version (p. 429).

Upgrading an Oracle DB snapshot

If you have existing manual DB snapshots, you can upgrade them to a later version of the Oracle database engine.

When Oracle stops providing patches for a version, and Amazon RDS deprecates the version, you can upgrade your snapshots that correspond to the deprecated version. For more information, see Oracle engine version management (p. 2120).

Amazon RDS supports upgrading snapshots in all AWS Regions.
Console

To upgrade an Oracle DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots, and then select the DB snapshot that you want to upgrade.
3. For Actions, choose Upgrade snapshot. The Upgrade snapshot page appears.
4. Choose the New engine version to upgrade the snapshot to.
5. (Optional) For Option group, choose the option group for the upgraded DB snapshot. The same option group considerations apply when upgrading a DB snapshot as when upgrading a DB instance. For more information, see Option group considerations (p. 2126).
6. Choose Save changes to save your changes.

During the upgrade process, all snapshot actions are disabled for this DB snapshot. Also, the DB snapshot status changes from available to upgrading, and then changes to active upon completion. If the DB snapshot can't be upgraded because of snapshot corruption issues, the status changes to unavailable. You can't recover the snapshot from this state.

Note
If the DB snapshot upgrade fails, the snapshot is rolled back to the original state with the original version.

AWS CLI

To upgrade an Oracle DB snapshot by using the AWS CLI, call the modify-db-snapshot command with the following parameters:

- --db-snapshot-identifier – The name of the DB snapshot.
- --engine-version – The version to upgrade the snapshot to.

You might also need to include the following parameter. The same option group considerations apply when upgrading a DB snapshot as when upgrading a DB instance. For more information, see Option group considerations (p. 2126).

- --option-group-name – The option group for the upgraded DB snapshot.

Example

The following example upgrades a DB snapshot.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-snapshot \ 
--db-snapshot-identifier mydbsnapshot \ 
--engine-version 19.0.0.0.ru-2020-10.rur-2020-10.r1 \ 
--option-group-name default:oracle-se2-19
```

For Windows:

```bash
aws rds modify-db-snapshot ^
--db-snapshot-identifier mydbsnapshot ^
--engine-version 19.0.0.0.ru-2020-10.rur-2020-10.r1 ^
```
To upgrade an Oracle DB snapshot by using the Amazon RDS API, call the ModifyDBSnapshot operation with the following parameters:

- DBSnapshotIdentifier – The name of the DB snapshot.
- EngineVersion – The version to upgrade the snapshot to.

You might also need to include the OptionGroupName parameter. The same option group considerations apply when upgrading a DB snapshot as when upgrading a DB instance. For more information, see Option group considerations (p. 2126).
Using third-party software with your RDS for Oracle DB instance

To use tools and third-party software with RDS for Oracle DB instances, review the information in the following sections.

**Topics**
- Setting up Amazon RDS to host tools and third-party software for Oracle (p. 2132)
- Using Oracle GoldenGate with Amazon RDS for Oracle (p. 2138)
- Using the Oracle Repository Creation Utility on RDS for Oracle (p. 2152)
- Configuring Oracle Connection Manager on an Amazon EC2 instance (p. 2158)
- Installing a Siebel database on Oracle on Amazon RDS (p. 2160)
Setting up Amazon RDS to host tools and third-party software for Oracle

You can use Amazon RDS to host an Oracle DB instance that supports software and components such as the following:

- Siebel Customer Relationship Management (CRM)
- Oracle Fusion Middleware Metadata — installed by the Repository Creation Utility (RCU)

The following procedures help you create an Oracle DB instance on Amazon RDS that you can use to host additional software and components for Oracle.

**Topics**

- [Creating a VPC for use with an Oracle database](#)
- Creating an Oracle DB instance
- Additional Amazon RDS interfaces

**Creating a VPC for use with an Oracle database**

In the following procedure, you create a virtual private cloud (VPC) based on the Amazon VPC service, a private subnet, and a security group. Your Amazon RDS DB instance needs to be available only to your middle-tier components, and not to the public internet. Thus, your Amazon RDS DB instance is hosted in a private subnet, providing greater security.

**To create a VPC based on Amazon VPC**

1. Sign in to the AWS Management Console and open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
2. In the upper-right corner of the AWS Management Console, choose the AWS Region for your VPC. This example uses the US West (Oregon) region.
3. In the upper-left corner, choose **VPC Dashboard**, and then choose **Start VPC Wizard**.
4. On the page **Step 1: Select a VPC Configuration**, choose **VPC with Public and Private Subnets**, and then choose **Select**.
5. On the page **Step 2: VPC with Public and Private Subnets**, shown following, set the following values.

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPv4 CIDR block</td>
<td>10.0.0.0/16</td>
</tr>
<tr>
<td></td>
<td>For more information about selecting CIDR blocks for your VPC, see <a href="#">VPC sizing</a>.</td>
</tr>
<tr>
<td>IPv6 CIDR block</td>
<td>No IPv6 CIDR Block</td>
</tr>
<tr>
<td>VPC name</td>
<td>The name for your VPC, for example <strong>vpc-1</strong>.</td>
</tr>
<tr>
<td>Public subnet's IPv4 CIDR</td>
<td>10.0.0.0/24</td>
</tr>
<tr>
<td></td>
<td>For more information about subnet sizing, see <a href="#">Subnet sizing</a>.</td>
</tr>
<tr>
<td>Availability Zone</td>
<td>An Availability Zone for your AWS Region.</td>
</tr>
<tr>
<td>Option</td>
<td>Value</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>Public subnet name</td>
<td>The name for your public subnet, for example <code>subnet-public-1</code>.</td>
</tr>
<tr>
<td>Private subnet's IPv4 CIDR</td>
<td>10.0.1.0/24</td>
</tr>
<tr>
<td></td>
<td>For more information about subnet sizing, see <a href="#">Subnet sizing</a>.</td>
</tr>
<tr>
<td>Availability Zone</td>
<td>An Availability Zone for your AWS Region.</td>
</tr>
<tr>
<td>Private subnet name</td>
<td>The name for your private subnet, for example <code>subnet-private-1</code>.</td>
</tr>
<tr>
<td>Instance type</td>
<td>An instance type for your NAT instance, for example <code>t2.small</code>.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong></td>
</tr>
<tr>
<td></td>
<td>If you don't see <strong>Instance type</strong> in the console, choose <strong>Use a NAT instance instead</strong>.</td>
</tr>
<tr>
<td>Key pair name</td>
<td>No key pair</td>
</tr>
<tr>
<td>Service endpoints</td>
<td>None</td>
</tr>
<tr>
<td>Enable DNS hostnames</td>
<td>Yes</td>
</tr>
<tr>
<td>Hardware tenancy</td>
<td>Default</td>
</tr>
</tbody>
</table>
6. Choose Create VPC.

An Amazon RDS DB instance in a VPC requires at least two private subnets or at least two public subnets, to support Multi-AZ deployment. For more information about working with multiple Availability Zones, see Regions, Availability Zones, and Local Zones (p. 110). Because your database is private, add a second private subnet to your VPC.

**To create an additional subnet**

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the upper-right corner of the AWS Management Console, confirm that you are in the correct AWS Region for your VPC.
3. In the upper-left corner, choose VPC Dashboard, choose Subnets, and then choose Create Subnet.
4. On the **Create Subnet** page, set the following values.

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name tag</td>
<td>The name for your second private subnet, for example <code>subnet-private-2</code>.</td>
</tr>
<tr>
<td>VPC</td>
<td>Your VPC, for example <code>vpc-1</code>.</td>
</tr>
<tr>
<td>Availability Zone</td>
<td>An Availability Zone for your AWS Region.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong></td>
</tr>
<tr>
<td></td>
<td>Choose an Availability Zone different from the one that you</td>
</tr>
<tr>
<td></td>
<td>chose for the first private subnet.</td>
</tr>
<tr>
<td>CIDR block</td>
<td>10.0.2.0/24</td>
</tr>
</tbody>
</table>

5. Choose **Yes, Create**.

Both private subnets must use the same route table. In the following procedure, you check to make sure the route tables match, and if not you edit one of them.

**To ensure the subnets use the same route table.**

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the upper-right corner of the AWS Management Console, confirm that you are in the correct AWS Region for your VPC.
3. In the upper-left corner, choose **VPC Dashboard**, choose **Subnets**, and then choose your first private subnet, for example `subnet-private-1`.
4. At the bottom of the console, choose the **Route Table** tab, shown following.

5. Make a note of the route table, for example `rtb-0d9fc668`.
6. In the list of subnets, choose the second private subnet, for example `subnet-private-2`.
7. At the bottom of the console, choose the **Route Table** tab.
8. If the route table for the second subnet is not the same as the route table for the first subnet, edit it to match:
   a. Choose **Edit**.
   b. For **Change to**, choose the route table that matches your first subnet.
   c. Choose **Save**.
A security group acts as a virtual firewall for your DB instance to control inbound and outbound traffic. In the following procedure, you create a security group for your DB instance. For more information about security groups, see Security groups for your VPC.

**To create a VPC security group for a private Amazon RDS DB instance**

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the upper-right corner of the AWS Management Console, confirm that you are in the correct AWS Region for your VPC.
3. In the upper-left corner, choose VPC Dashboard, choose Security Groups, and then choose Create Security Group.
4. On the page Create Security Group, set the following values.

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name tag</td>
<td>The name for your security group, for example sgdb-1.</td>
</tr>
<tr>
<td>Group name</td>
<td>The name for your security group, for example sgdb-1.</td>
</tr>
<tr>
<td>Description</td>
<td>A description for your security group.</td>
</tr>
<tr>
<td>VPC</td>
<td>Your VPC, for example vpc-1.</td>
</tr>
</tbody>
</table>

5. Choose Yes, Create.

In the following procedure, you add rules to your security group to control inbound traffic to your DB instance. For more information about inbound rules, see Security group rules.

**To add inbound rules to the security group**

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the upper-right corner of the AWS Management Console, confirm that you are in the correct AWS Region for your VPC.
3. In the upper-left corner, choose VPC Dashboard, choose Security Groups, and then choose your security group, for example sgdb-1.
4. At the bottom of the console, choose the Inbound Rules tab, and then choose Edit.
5. Set these values, as shown following.

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Oracle (1521)</td>
</tr>
<tr>
<td>Protocol</td>
<td>TCP (6)</td>
</tr>
<tr>
<td>Port Range</td>
<td>1521</td>
</tr>
<tr>
<td>Source</td>
<td>The identifier of your security group. When you choose the box, you see the name of your security group, for example sgdb-1.</td>
</tr>
</tbody>
</table>
6. Choose Save.

**Creating an Oracle DB instance**

You can use Amazon RDS to host an Oracle DB instance. When you create the new DB instance, specify the VPC and security group you created previously using the instructions in Creating a VPC for use with an Oracle database (p. 2132). Also, choose No for Publicly accessible.

For information about creating a DB instance, see Creating an Amazon RDS DB instance (p. 300).

**Additional Amazon RDS interfaces**

In the preceding tasks, you use the AWS Management Console to perform tasks. Amazon Web Services also provides the AWS Command Line Interface (AWS CLI), and an application programming interface (API). You can use the AWS CLI or the API to automate many of the tasks for managing Amazon RDS, including tasks to manage an Oracle DB instance with Amazon RDS.

For more information, see AWS Command Line Interface reference for Amazon RDS and Amazon RDS API Reference.
Using Oracle GoldenGate with Amazon RDS for Oracle

Oracle GoldenGate collects, replicates, and manages transactional data between databases. It is a log-based change data capture (CDC) and replication software package used with databases for online transaction processing (OLTP) systems. Oracle GoldenGate creates trail files that contain the most recent changed data from the source database. It then pushes these files to the server, where a process converts the trail file into standard SQL to be applied to the target database.

Oracle GoldenGate with RDS for Oracle supports the following features:

- Active-Active database replication
- Disaster recovery
- Data protection
- In-Region and cross-Region replication
- Zero-downtime migration and upgrades
- Data replication between an RDS for Oracle DB instance and a non-Oracle database

Note
For a list of supported databases, see Oracle Fusion Middleware Supported System Configurations in the Oracle documentation.

You can use Oracle GoldenGate with RDS for Oracle to upgrade to major versions of Oracle Database. For example, you can use Oracle GoldenGate to upgrade from an Oracle Database 11g on-premises database to Oracle Database 19c on an Amazon RDS DB instance.

Topics

- Supported versions and licensing options for Oracle GoldenGate (p. 2138)
- Requirements and limitations for Oracle GoldenGate (p. 2139)
- Oracle GoldenGate architecture (p. 2139)
- Setting up Oracle GoldenGate (p. 2142)
- Working with the EXTRACT and REPLICAT utilities of Oracle GoldenGate (p. 2147)
- Monitoring Oracle GoldenGate (p. 2149)
- Troubleshooting Oracle GoldenGate (p. 2149)

Supported versions and licensing options for Oracle GoldenGate

You can use Standard Edition Two (SE2) or Enterprise Edition (EE) of RDS for Oracle with Oracle GoldenGate version 12c and higher. You can use the following Oracle GoldenGate features:

- Oracle GoldenGate Remote Capture (extract) is supported.
- Capture (extract) is supported on RDS for Oracle DB instances that use the traditional non-CDB database architecture. Oracle GoldenGate Remote PDB capture is supported on Oracle Database 21c container databases (CDBs).
- Oracle GoldenGate Remote Delivery (replicat) is supported on RDS for Oracle DB instances that use either the non-CDB or CDB architectures. Remote Delivery supports Integrated Replicat, Parallel Replicat, Coordinated Replicat, and classic Replicat.
- RDS for Oracle supports the Classic and Microservices architectures of Oracle GoldenGate.
- Oracle GoldenGate DDL and Sequence value replication is supported when using Integrated capture mode.
You are responsible for managing Oracle GoldenGate licensing (BYOL) for use with Amazon RDS in all AWS Regions. For more information, see RDS for Oracle licensing options (p. 1809).

Requirements and limitations for Oracle GoldenGate

When you're working with Oracle GoldenGate and RDS for Oracle, consider the following requirements and limitations:

- You're responsible for setting up and managing Oracle GoldenGate for use with RDS for Oracle.
- You're responsible for setting up an Oracle GoldenGate version that is certified with the source and the target databases. For more information, see Oracle Fusion Middleware Supported System Configurations in the Oracle documentation.
- You can use Oracle GoldenGate on many different AWS environments for many different use cases. If you have a support-related issue relating to Oracle GoldenGate, contact Oracle Support Services.
- You can use Oracle GoldenGate on RDS for Oracle DB instances that use Oracle Transparent Data Encryption (TDE). To maintain the integrity of replicated data, configure encryption on the Oracle GoldenGate hub using Amazon EBS encrypted volumes or trail file encryption. Also configure encryption for data sent between the Oracle GoldenGate hub and the source and target database instances. RDS for Oracle DB instances support encryption with Oracle Secure Sockets Layer (p. 2084) or Oracle native network encryption (p. 2073).

Oracle GoldenGate architecture

The Oracle GoldenGate architecture for use with Amazon RDS consists of the following decoupled modules:

Source database

Your source database can be either an on-premises Oracle database, an Oracle database on an Amazon EC2 instance, or an Oracle database on an Amazon RDS DB instance.

Oracle GoldenGate hub

An Oracle GoldenGate hub moves transaction information from the source database to the target database. Your hub can be either of the following:

- An Amazon EC2 instance with Oracle Database and Oracle GoldenGate installed
- An on-premises Oracle installation

You can have more than one Amazon EC2 hub. We recommend that you use two hubs if you use Oracle GoldenGate for cross-Region replication.

Target database

Your target database can be on either an Amazon RDS DB instance, an Amazon EC2 instance, or an on-premises location.

The following sections describe common scenarios for Oracle GoldenGate on Amazon RDS.

Topics

- On-premises source database and Oracle GoldenGate hub (p. 2140)
- On-premises source database and Amazon EC2 hub (p. 2140)
- Amazon RDS source database and Amazon EC2 hub (p. 2140)
- Amazon EC2 source database and Amazon EC2 hub (p. 2141)
- Amazon EC2 hubs in different AWS Regions (p. 2141)
On-premises source database and Oracle GoldenGate hub

In this scenario, an on-premises Oracle source database and on-premises Oracle GoldenGate hub provides data to a target Amazon RDS DB instance.

On-premises source database and Amazon EC2 hub

In this scenario, an on-premises Oracle database acts as the source database. It's connected to an Amazon EC2 instance hub. This hub provides data to a target RDS for Oracle DB instance.

Amazon RDS source database and Amazon EC2 hub

In this scenario, an RDS for Oracle DB instance acts as the source database. It's connected to an Amazon EC2 instance hub. This hub provides data to a target RDS for Oracle DB instance.
In this scenario, an Oracle database on an Amazon EC2 instance acts as the source database. It's connected to an Amazon EC2 instance hub. This hub provides data to a target RDS for Oracle DB instance.

In this scenario, an Oracle database on an Amazon RDS DB instance is connected to an Amazon EC2 instance hub in the same AWS Region. The hub is connected to an Amazon EC2 instance hub in a different AWS Region. This second hub provides data to the target RDS for Oracle DB instance in the same AWS Region as the second Amazon EC2 instance hub.
Note
Any issues that affect running Oracle GoldenGate on an on-premises environment also affect running Oracle GoldenGate on AWS. We strongly recommend that you monitor the Oracle GoldenGate hub to ensure that EXTRACT and REPLICAT are resumed if a failover occurs. Because the Oracle GoldenGate hub is run on an Amazon EC2 instance, Amazon RDS does not manage the Oracle GoldenGate hub and cannot ensure that it is running.

Setting up Oracle GoldenGate

To set up Oracle GoldenGate using Amazon RDS, configure the hub on an Amazon EC2 instance, and then configure the source and target databases. The following sections give an example of how to set up Oracle GoldenGate for use with Amazon RDS for Oracle.

Topics
- Setting up an Oracle GoldenGate hub on Amazon EC2 (p. 2142)
- Setting up a source database for use with Oracle GoldenGate on Amazon RDS (p. 2143)
- Setting up a target database for use with Oracle GoldenGate on Amazon RDS (p. 2145)

Setting up an Oracle GoldenGate hub on Amazon EC2

To create an Oracle GoldenGate hub on an Amazon EC2 instance, you first create an Amazon EC2 instance with a full client installation of Oracle RDBMS. The Amazon EC2 instance must also have Oracle GoldenGate software installed. The Oracle GoldenGate software versions depend on the source and target database versions. For more information about installing Oracle GoldenGate, see the Oracle GoldenGate documentation.

The Amazon EC2 instance that serves as the Oracle GoldenGate hub stores and processes the transaction information from the source database into trail files. To support this process, make sure that you meet the following requirements:

- You have allocated enough storage for the trail files.
- The Amazon EC2 instance has enough processing power to manage the amount of data.
- The EC2 instance has enough memory to store the transaction information before it's written to the trail file.
To set up an Oracle GoldenGate classic architecture hub on an Amazon EC2 instance

1. Create subdirectories in the Oracle GoldenGate directory.

   In the Amazon EC2 command line shell, start ggsci, the Oracle GoldenGate command interpreter. The CREATE_SUBDIRS command creates subdirectories under the /gg directory for parameter, report, and checkpoint files.

   ```
   prompt$ cd /gg
   prompt$.ggsci
   GGSCI> CREATE SUBDIRS
   ```

2. Configure the mgr.prm file.

   The following example adds lines to the $GGHOME/dirprm/mgr.prm file.

   ```
   PORT 8199
   PurgeOldExtracts ./dirdat/*, UseCheckpoints, MINKEEPDAYS 5
   ```

3. Start the manager.

   The following example starts ggsci and runs the start mgr command.

   ```
   GGSCI> start mgr
   ```

The Oracle GoldenGate hub is now ready for use.

Setting up a source database for use with Oracle GoldenGate on Amazon RDS

When your source database is running Oracle Database 12c or later, complete the following tasks to set up a source database for use with Oracle GoldenGate.

Setup steps

- **Step 1: Turn on supplemental logging on the source database (p. 2143)**
- **Step 2: Set the ENABLE_GOLDENGATE_REPLICATION initialization parameter to true (p. 2143)**
- **Step 3: Set the log retention period on the source database (p. 2144)**
- **Step 4: Create an Oracle GoldenGate user account on the source database (p. 2144)**
- **Step 5: Grant user account privileges on the source database (p. 2144)**
- **Step 6: Add a TNS alias for the source database (p. 2145)**

Step 1: Turn on supplemental logging on the source database

To turn on the minimum database-level supplemental logging, run the following PL/SQL procedure:

```
EXEC rdsadmin.rdsadmin_util.alter_supplemental_logging(p_action => 'ADD')
```

Step 2: Set the ENABLE_GOLDENGATE_REPLICATION initialization parameter to true

When you set the ENABLE_GOLDENGATE_REPLICATION initialization parameter to true, it allows database services to support logical replication. If your source database is on an Amazon RDS DB instance, make sure that you have a parameter group assigned to the DB instance with the ENABLE_GOLDENGATE_REPLICATION initialization parameter set to true. For more information about the ENABLE_GOLDENGATE_REPLICATION initialization parameter, see the Oracle Database documentation.
Step 3: Set the log retention period on the source database

Make sure that you configure the source database to retain archived redo logs. Consider the following guidelines:

- Specify the duration for log retention in hours. The minimum value is one hour.
- Set the duration to exceed any potential downtime of the source DB instance, any potential period of communication, and any potential period of networking issues for the source instance. Such a duration lets Oracle GoldenGate recover logs from the source instance as needed.
- Ensure that you have sufficient storage on your instance for the files.

For example, set the retention period for archived redo logs to 24 hours.

```
EXEC rdsadmin.rdsadmin_util.set_configuration('archivelog retention hours',24)
```

If you don't have log retention enabled, or if the retention value is too small, you receive an error message similar to the following.

```
2022-03-06 06:17:27  ERROR   OGG-00446  error 2 (No such file or directory)
opening redo log /rdsdbdata/db/GGTEST3_A/onlinelog/o1_mf_2_9k4bp1n6_.log for sequence 1306
Not able to establish initial position for begin time 2022-03-06 06:16:55.
```

Because your DB instance retains your archived redo logs, make sure that you have sufficient space for the files. To see how much space you have used in the last \textit{num\_hours} hours, run the following query, replacing \textit{num\_hours} with the number of hours.

```
SELECT SUM(BLOCKS * BLOCK_SIZE) BYTES FROM V$ARCHIVED_LOG
WHERE NEXT_TIME>=SYSDATE-\textit{num\_hours}/24 AND DEST_ID=1;
```

Step 4: Create an Oracle GoldenGate user account on the source database

Oracle GoldenGate runs as a database user and requires the appropriate database privileges to access the redo and archived redo logs for the source database. To provide these, create a user account on the source database. For more information about the permissions for an Oracle GoldenGate user account, see the Oracle documentation.

The following statements create a user account named oggadm1.

```
CREATE TABLESPACE administrator;
CREATE USER oggadm1 IDENTIFIED BY "password"
    DEFAULT TABLESPACE ADMINISTRATOR TEMPORARY TABLESPACE TEMP;
ALTER USER oggadm1 QUOTA UNLIMITED ON administrator;
```

\textbf{Note}

Specify a password other than the prompt shown here as a security best practice.

Step 5: Grant user account privileges on the source database

In this task, you grant necessary account privileges for database users on your source database.

\textbf{To grant account privileges on the source database}

1. Grant the necessary privileges to the Oracle GoldenGate user account using the SQL command grant and the `rdsadmin.rdsadmin_util` procedure `grant_sys_object`. The following statements grant privileges to a user named oggadm1.

```
```
GRANT CREATE SESSION, ALTER SESSION TO oggadm1;
GRANT RESOURCE TO oggadm1;
GRANT SELECT ANY DICTIONARY TO oggadm1;
GRANT FLASHBACK ANY TABLE TO oggadm1;
GRANT SELECT ANY TABLE TO oggadm1;
GRANT SELECT_CATALOG_ROLE TO rds_master_user_name WITH ADMIN OPTION;
EXEC rdsadmin.rdsadmin_util.grant_sys_object ('DBA_CLUSTERS', 'OGGADM1');
GRANT EXECUTE ON DBMS_FLASHBACK TO oggadm1;
GRANT SELECT ON SYS.V_$DATABASE TO oggadm1;
GRANT ALTER ANY TABLE TO oggadm1;

2. Grant the privileges needed by a user account to be an Oracle GoldenGate administrator.
The package that you use to perform the grant, dbms_goldengate_auth or rdsadmin_dbms_goldengate_auth, depends on the Oracle DB engine version.

   • For Oracle DB versions that are later than or equal to Oracle Database 12c Release 2 (12.2), which requires patch level 12.2.0.1.ru-2019-04.rur-2019-04.r1 or later, run the following PL/SQL program.

```sql
EXEC rdsadmin.rdsadmin_dbms_goldengate_auth.grant_admin_privilege (  
grantee => 'OGGADM1',  
privilege_type => 'capture',  
grant_select_privileges => true,  
do_grants => TRUE);
```

   • For Oracle database versions that are earlier than Oracle Database 12c Release 2 (12.2), run the following PL/SQL program.

```sql
EXEC dbms_goldengate_auth.grant_admin_privilege (  
grantee => 'OGGADM1',  
privilege_type => 'capture',  
grant_select_privileges => true,  
do_grants => TRUE);
```

To revoke privileges, use the procedure revoke_admin_privilege in the same package.

**Step 6: Add a TNS alias for the source database**

Add the following entry to $ORACLE_HOME/network/admin/tnsnames.ora in the Oracle home to be used by the EXTRACT process. For more information on the tnsnames.ora file, see the Oracle documentation.

```ora
OGGSOURCE=  
    (DESCRIPTION=  
        (ENABLE=BROKEN)  
        (ADDRESS_LIST=  
            (ADDRESS=(PROTOCOL=TCP)(HOST=goldengate-source.abcdef12345.us-west-2.rds.amazonaws.com)(PORT=8200)))  
        (CONNECT_DATA=(SERVICE_NAME=ORCL))  
    )
```

**Setting up a target database for use with Oracle GoldenGate on Amazon RDS**

In this task, you set up a target DB instance for use with Oracle GoldenGate.

**Setup steps**

   • **Step 1: Set the ENABLE_GOLDENGATE_REPLICATION initialization parameter to true (p. 2146)**
- Step 2: Create an Oracle GoldenGate user account on the target database (p. 2146)
- Step 3: Grant account privileges on the target database (p. 2146)
- Step 4: Add a TNS alias for the target database (p. 2147)

Step 1: Set the ENABLE_GOLDENGATE_REPLICATION initialization parameter to true

When you set the ENABLE_GOLDENGATE_REPLICATION initialization parameter to true, it allows database services to support logical replication. If your source database is on an Amazon RDS DB instance, make sure that you have a parameter group assigned to the DB instance with the ENABLE_GOLDENGATE_REPLICATION initialization parameter set to true. For more information about the ENABLE_GOLDENGATE_REPLICATION initialization parameter, see the Oracle Database documentation.

Step 2: Create an Oracle GoldenGate user account on the target database

Oracle GoldenGate runs as a database user and requires the appropriate database privileges. To make sure it has these privileges, create a user account on the target database.

The following statement creates a user named oggadm1.

```
CREATE TABLESPACE administrator;
CREATE USER oggadm1 IDENTIFIED by "password"
    DEFAULT TABLESPACE administrator
    TEMPORARY TABLESPACE temp;
ALTER USER oggadm1 QUOTA UNLIMITED ON administrator;
```

**Note**
Specify a password other than the prompt shown here as a security best practice.

Step 3: Grant account privileges on the target database

In this task, you grant necessary account privileges for database users on your target database.

To **grant account privileges on the target database**

1. Grant necessary privileges to the Oracle GoldenGate user account on the target database. In the following example, you grant privileges to oggadm1.

```
GRANT CREATE SESSION TO oggadm1;
GRANT ALTER SESSION TO oggadm1;
GRANT CREATE CLUSTER TO oggadm1;
GRANT CREATE INDEXTYPE TO oggadm1;
GRANT CREATE OPERATOR TO oggadm1;
GRANT CREATE PROCEDURE TO oggadm1;
GRANT CREATE SEQUENCE TO oggadm1;
GRANT CREATE TRIGGER TO oggadm1;
GRANT CREATE TYPE TO oggadm1;
GRANT SELECT ANY DICTIONARY TO oggadm1;
GRANT CREATE ANY TABLE TO oggadm1;
GRANT ALTER ANY TABLE TO oggadm1;
GRANT LOCK ANY TABLE TO oggadm1;
GRANT SELECT ANY TABLE TO oggadm1;
GRANT INSERT ANY TABLE TO oggadm1;
GRANT UPDATE ANY TABLE TO oggadm1;
GRANT DELETE ANY TABLE TO oggadm1;
```

2. Grant the privileges needed by a user account to be an Oracle GoldenGate administrator. The package that you use to perform the grant, dbms_goldengate_auth or rdsadmin_dbms_goldengate_auth, depends on the Oracle DB engine version.
• For Oracle database versions that are later than or equal to Oracle Database 12c Release 2 (12.2), which requires patch level 12.2.0.1.ru-2019-04.rur-2019-04.r1 or later, run the following PL/SQL program.

```sql
EXEC rdsadmin.rdsadmin_dbms_goldengate_auth.grant_admin_privilege (grantee       => 'OGGADM1',
privilege_type  => 'apply',
grant_select_privileges => true,
do_grants      => TRUE);
```

• For Oracle database versions that are lower than Oracle Database 12c Release 2 (12.2), run the following PL/SQL program.

```sql
EXEC dbms_goldengate_auth.grant_admin_privilege (grantee       => 'OGGADM1',
privilege_type  => 'apply',
grant_select_privileges => true,
do_grants      => TRUE);
```

To revoke privileges, use the procedure `revoke_admin_privilege` in the same package.

Step 4: Add a TNS alias for the target database

Add the following entry to `$ORACLE_HOME/network/admin/tnsnames.ora` in the Oracle home to be used by the `REPLICAT` process. For Oracle Multitenant databases, make sure that the TNS alias points to the service name of the PDB. For more information on the `tnsnames.ora` file, see the Oracle documentation.

```ora
OGGTARGET=
   (DESCRIPTION= (ENABLE=BROKEN)
    (ADDRESS_LIST= (ADDRESS=(PROTOCOL=TCP)(HOST=goldengate-target.abcdef12345.us-west-2.rds.amazonaws.com)(PORT=8200)))
    (CONNECT_DATA=(SERVICE_NAME=ORCL))
  )
```

Working with the EXTRACT and REPLICAT utilities of Oracle GoldenGate

The Oracle GoldenGate utilities EXTRACT and REPLICAT work together to keep the source and target databases in sync via incremental transaction replication using trail files. All changes that occur on the source database are automatically detected by EXTRACT, then formatted and transferred to trail files on the Oracle GoldenGate on-premises or Amazon EC2 instance hub. After initial load is completed, the data is read from these files and replicated to the target database by the REPLICAT utility.

Running the Oracle GoldenGate EXTRACT utility

The EXTRACT utility retrieves, converts, and outputs data from the source database to trail files. The basic process is as follows:

1. EXTRACT queues transaction details to memory or to temporary disk storage.
2. The source database commits the transaction.
3. EXTRACT writes the transaction details to a trail file.
4. The trail file routes these details to the Oracle GoldenGate on-premises or the Amazon EC2 instance hub and then to the target database.

The following steps start the EXTRACT utility, capture the data from EXAMPLE_TABLE in source database OGGSOURCE, and create the trail files.

**To run the EXTRACT utility**

1. Configure the EXTRACT parameter file on the Oracle GoldenGate hub (on-premises or Amazon EC2 instance). The following listing shows an example EXTRACT parameter file named $GGHOME/dirprm/eabc.prm.

```
EXTRACT EABC
USERID oggadm1@OGGSOURCE, PASSWORD "my-password"
EXTRAIL /path/to/goldengate/dirdat/ab
IGNOREREPLICATES
GETAPPLLOPS
TRANLOGOPTIONS EXCLUDEUSER OGGADM1
TABLE EXAMPLE.TABLE;
```

2. On the Oracle GoldenGate hub, log in to the source database and launch the Oracle GoldenGate command line interface ggsci. The following example shows the format for logging in.

```
dblogin oggadm1@OGGSOURCE
```

3. Add transaction data to turn on supplemental logging for the database table.

```
add trandata EXAMPLE.TABLE
```

4. Using the ggsci command line, enable the EXTRACT utility using the following commands.

```
add extract EABC tranlog, INTEGRATED tranlog, begin now
add exttrail /path/to/goldengate/dirdat/ab
extract EABC,
 MEGABYTES 100
```

5. Register the EXTRACT utility with the database so that the archive logs are not deleted. This task allows you to recover old, uncommitted transactions if necessary. To register the EXTRACT utility with the database, use the following command.

```
register EXTRACT EABC, DATABASE
```

6. Start the EXTRACT utility with the following command.

```
start EABC
```

**Running the Oracle GoldenGate REPLICAT utility**

The REPLICAT utility "pushes" transaction information in the trail files to the target database.

The following steps enable and start the REPLICAT utility so that it can replicate the captured data to the table EXAMPLE_TABLE in target database OGGTARGET.
To run the REPLICATE utility

1. Configure the REPLICAT parameter file on the Oracle GoldenGate hub (on-premises or EC2 instance). The following listing shows an example REPLICAT parameter file named $GGHOME/ dirprm/rabc.prm.

   ```
   REPLICAT RABC
   USERID oggadm1@OGGTARGET, password "my-password"
   ASSUMETARGETDEFS
   MAP EXAMPLE.TABLE, TARGET EXAMPLE.TABLE;
   ```

   **Note**
   Specify a password other than the prompt shown here as a security best practice.

2. Log in to the target database and launch the Oracle GoldenGate command line interface (ggsci). The following example shows the format for logging in.

   ```
   dblogin userid oggadm1@OGGTARGET
   ```

3. Using the ggsci command line, add a checkpoint table. The user indicated should be the Oracle GoldenGate user account, not the target table schema owner. The following example creates a checkpoint table named gg_checkpoint.

   ```
   add checkpointtable oggadm1.oggchkpt
   ```

4. To enable the REPLICAT utility, use the following command.

   ```
   add replicat RABC EXTTRAIL /path/to/goldengate/dirdat/ab CHECKPOINTTABLE oggadm1.oggchkpt
   ```

5. Start the REPLICAT utility by using the following command.

   ```
   start RABC
   ```

**Monitoring Oracle GoldenGate**

When you use Oracle GoldenGate for replication, make sure that the Oracle GoldenGate process is up and running and the source and target databases are synchronized. You can use the following monitoring tools:

- **Amazon CloudWatch** is a monitoring service that is used in this pattern to monitor GoldenGate error logs.
- **Amazon SNS** is a message notification service that is used in this pattern to send email notifications.

For detailed instructions, see [Monitor Oracle GoldenGate logs by using Amazon CloudWatch](#).

**Troubleshooting Oracle GoldenGate**

This section explains the most common issues when using Oracle GoldenGate with Amazon RDS for Oracle.

**Topics**

- [Error opening an online redo log (p. 2150)](#)
• Oracle GoldenGate appears to be properly configured but replication is not working (p. 2150)
• Integrated REPLICAT slow due to query on SYS."_DBA_APPLY_CDR_INFO" (p. 2150)

Error opening an online redo log

Make sure that you configure your databases to retain archived redo logs. Consider the following guidelines:

• Specify the duration for log retention in hours. The minimum value is one hour.
• Set the duration to exceed any potential downtime of the source DB instance, any potential period of communication, and any potential period of networking issues for the source DB instance. Such a duration lets Oracle GoldenGate recover logs from the source DB instance as needed.
• Ensure that you have sufficient storage on your instance for the files.

If you don’t have log retention enabled, or if the retention value is too small, you receive an error message similar to the following.

```
2022-03-06 06:17:27   ERROR   OGG-00446  error 2 (No such file or directory)
opening redo log /rdsdbdata/db/GGTEST3_A/online_log/o1_mf_2_9k4bp1n6_.log for sequence 1306
Not able to establish initial position for begin time 2022-03-06 06:16:55.
```

Oracle GoldenGate appears to be properly configured but replication is not working

For pre-existing tables, you must specify the SCN that Oracle GoldenGate works from.

To fix this issue

1. Log in to the source database and launch the Oracle GoldenGate command line interface (ggsci). The following example shows the format for logging in.

   ```
dblogin userid oggadm1@OGGSOURCE
   ```

2. Using the ggsci command line, set up the start SCN for the EXTRACT process. The following example sets the SCN to 223274 for the EXTRACT.

   ```
ALTER EXTRACT EABC SCN 223274
start EABC
   ```

3. Log in to the target database. The following example shows the format for logging in.

   ```
dblogin userid oggadm1@OGGTARGET
   ```

4. Using the ggsci command line, set up the start SCN for the REPLICAT process. The following example sets the SCN to 223274 for the REPLICAT.

   ```
start RABC atcsn 223274
   ```

Integrated REPLICAT slow due to query on SYS._DBA_APPLY_CDR_INFO"

Oracle GoldenGate Conflict Detection and Resolution (CDR) provides basic conflict resolution routines. For example, CDR can resolve a unique conflict for an INSERT statement.
When CDR resolves a collision, it can insert records into the exception table `_DBA_APPLY_CDR_INFO` temporarily. Integrated REPLICAT deletes these records later. In a rare scenario, the integrated REPLICAT can process a large number of collisions, but a new integrated REPLICAT does not replace it. Instead of being removed, the existing rows in `_DBA_APPLY_CDR_INFO` are orphaned. Any new integrated REPLICAT processes slow down because they are querying orphaned rows in `_DBA_APPLY_CDR_INFO`.

To remove all rows from `_DBA_APPLY_CDR_INFO`, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.truncate_apply$_cdr_info`. This procedure is released as part of the October 2020 release and patch update. The procedure is available in the following database versions:

- Version 21.0.0.0.ru-2022-01.rur-2022-01.r1 and higher
- Version 19.0.0.0.ru-2020-10.rur-2020-10.r1 and higher

The following example truncates the table `_DBA_APPLY_CDR_INFO`.

```
SET SERVEROUTPUT ON SIZE 2000
EXEC rdsadmin.rdsadmin_util.truncate_apply$_cdr_info;
```
You can use Amazon RDS to host an RDS for Oracle DB instance that holds the schemas to support your Oracle Fusion Middleware components. Before you can use Fusion Middleware components, create and populate schemas for them in your database. You create and populate the schemas by using the Oracle Repository Creation Utility (RCU).

### Supported versions and licensing options for RCU

Amazon RDS supports Oracle Repository Creation Utility (RCU) version 12c only. You can use the RCU in the following configurations:

- RCU 12c with Oracle Database 21c
- RCU 12c with Oracle Database 19c
- RCU 12c with Oracle Database 12c Release 2 (12.2)
- RCU 12c with Oracle Database 12c Release 1 (12.1) using 12.1.0.2.v4 or higher

Before you can use RCU, make sure that you do the following:

- Obtain a license for Oracle Fusion Middleware.
- Follow the Oracle licensing guidelines for the Oracle database that hosts the repository. For more information, see [Oracle Fusion Middleware Licensing Information User Manual](http://example.com) in the Oracle documentation.

Fusion MiddleWare supports repositories on Oracle Database Enterprise Edition and Standard Edition Two. Oracle recommends Enterprise Edition for production installations that require partitioning and installations that require online index rebuild.

Before you create your RDS for Oracle instance, confirm the Oracle database version that you need to support the components that you want to deploy. To find the requirements for the Fusion Middleware components and versions you want to deploy, use the Certification Matrix. For more information, see [Oracle Fusion Middleware Supported System Configurations](http://example.com) in the Oracle documentation.

Amazon RDS supports Oracle database version upgrades as needed. For more information, see [Upgrading a DB instance engine version](p. 429).

### Requirements and limitations for RCU

To use RCU, you need an Amazon VPC. Your Amazon RDS DB instance must be available only to your Fusion Middleware components, and not to the public Internet. Thus, host your Amazon RDS DB instance in a private subnet, which provides greater security. For information about how to create an Amazon VPC for use with an RDS for Oracle instance, see [Creating a VPC for use with an Oracle database](p. 2132).

You also need an RDS for Oracle DB instance. For information about how to create an RDS for Oracle DB instance for use with Fusion Middleware metadata, see [Creating an Oracle DB instance](p. 2137).

You can store the schemas for any Fusion Middleware components in your Amazon RDS DB instance. The following schemas have been verified to install correctly:

- Analytics (ACTIVITIES)
- Audit Services (IAU)
• Audit Services Append (IAU_APPEND)
• Audit Services Viewer (IAU_VIEWER)
• Discussions (DISCUSSIONS)
• Metadata Services (MDS)
• Oracle Business Intelligence (BIPLATFORM)
• Oracle Platform Security Services (OPSS)
• Portal and Services (WEBCENTER)
• Portlet Producers (PORTLET)
• Service Table (STB)
• SOA Infrastructure (SOAINFRA)
• User Messaging Service (UCSUMS)
• WebLogic Services (WLS)

Guidelines for using RCU

The following are some recommendations for working with your DB instance in this scenario:

• We recommend that you use Multi-AZ for production workloads. For more information about working with multiple Availability Zones, see Regions, Availability Zones, and Local Zones (p. 110).
• For additional security, Oracle recommends that you use Transparent Data Encryption (TDE) to encrypt your data at rest. If you have an Enterprise Edition license that includes the Advanced Security Option, you can enable encryption at rest by using the TDE option. For more information, see Oracle Transparent Data Encryption (p. 2113).

Amazon RDS also provides an encryption at rest option for all database editions. For more information, see Encrypting Amazon RDS resources (p. 2603).
• Configure your VPC Security Groups to allow communication between your application servers and your Amazon RDS DB instance. The application servers that host the Fusion Middleware components can be on Amazon EC2 or on-premises.

Running RCU

To create and populate the schemas to support your Fusion Middleware components, use the Oracle Repository Creation Utility (RCU). You can run RCU in different ways.

Topics

• Running RCU using the command line in one step (p. 2153)
• Running RCU using the command line in multiple steps (p. 2154)
• Running RCU in interactive mode (p. 2155)

Running RCU using the command line in one step

If you don't need to edit any of your schemas before populating them, you can run RCU in a single step. Otherwise, see the following section for running RCU in multiple steps.

You can run the RCU in silent mode by using the command-line parameter -silent. When you run RCU in silent mode, you can avoid typing passwords on the command line by creating a text file containing the passwords. Create a text file with the password for dbUser on the first line, and the password for each component on subsequent lines. You specify the name of the password file as the last parameter to the RCU command.
Example

The following example creates and populates schemas for the SOA Infrastructure component (and its dependencies) in a single step.

For Linux, macOS, or Unix:

```
export ORACLE_HOME=/u01/app/oracle/product/12.2.1.0/fmw
export JAVA_HOME=/usr/java/jdk1.8.0_65
${ORACLE_HOME}/oracle_common/bin/rcu \
  -silent \n  -createRepository \n  -connectString ${dbhost}:${dbport}:${dbname} \n  -dbUser ${dbuser} \n  -dbRole Normal \n  -honorOMF \n  -schemaPrefix ${SCHEMA_PREFIX} \n  -component MDS \n  -component STB \n  -component OPSS \n  -component IAU \n  -component IAU_APPEND \n  -component IAU_VIEWER \n  -component UCSUMS \n  -component WLS \n  -component SOAINFRA \n  -f < /tmp/passwordfile.txt
```

For more information, see Running Repository Creation Utility from the command line in the Oracle documentation.

Running RCU using the command line in multiple steps

To manually edit your schema scripts, run RCU in multiple steps:

1. Run RCU in Prepare Scripts for System Load mode by using the -generateScript command-line parameter to create the scripts for your schemas.
2. Manually edit and run the generated script `script_systemLoad.sql`.
3. Run RCU again in Perform Product Load mode by using the -dataLoad command-line parameter to populate the schemas.
4. Run the generated cleanup script `script_postDataLoad.sql`.

To run RCU in silent mode, specify the command-line parameter -silent. When you run RCU in silent mode, you can avoid typing passwords on the command line by creating a text file containing the passwords. Create a text file with the password for dbUser on the first line, and the password for each component on subsequent lines. Specify the name of the password file as the last parameter to the RCU command.

Example

The following example creates schema scripts for the SOA Infrastructure component and its dependencies.

For Linux, macOS, or Unix:

```
export ORACLE_HOME=/u01/app/oracle/product/12.2.1.0/fmw
export JAVA_HOME=/usr/java/jdk1.8.0_65
${ORACLE_HOME}/oracle_common/bin/rcu \
  -silent \n  -generateScript \n```
Now you can edit the generated script, connect to your Oracle DB instance, and run the script. The generated script is named `script_systemLoad.sql`. For information about connecting to your Oracle DB instance, see [Step 3: Connect your SQL client to an Oracle DB instance (p. 231)](http://example.com).

The following example populates the schemas for the SOA Infrastructure component (and its dependencies).

For Linux, macOS, or Unix:

```bash
export JAVA_HOME=/usr/java/jdk1.8.0_65
${(ORACLE_HOME)/oracle_common/bin/rcu
 -silent
 -dataLoad
 -connectString ${dbhost}:${dbport}:${dbname}
 -dbUser ${dbuser}
 -dbRole Normal
 -honorOMF
 -schemaPrefix ${SCHEMA_PREFIX}
 -component MDS
 -component STB
 -component OPSS
 -component IAU
 -component IAU_APPEND
 -component IAU_VIEWER
 -component UCSUMS
 -component WLS
 -component SOAINFRA
 -scriptLocation /tmp/rcuscripts
 -f < /tmp/passwordfile.txt
```

To finish, you connect to your Oracle DB instance, and run the clean-up script. The script is named `script_postDataLoad.sql`.

For more information, see [Running Repository Creation Utility from the command line](http://example.com) in the Oracle documentation.

**Running RCU in interactive mode**

To use the RCU graphical user interface, run RCU in interactive mode. Include the `-interactive` parameter and omit the `-silent` parameter. For more information, see [Understanding Repository Creation Utility screens](http://example.com) in the Oracle documentation.

**Example**

The following example starts RCU in interactive mode and pre-populates the connection information.
For Linux, macOS, or Unix:

```bash
export ORACLE_HOME=/u01/app/oracle/product/12.2.1.0/fmw
export JAVA_HOME=/usr/java/jdk1.8.0_65
$ORACLE_HOME/oracle_common/bin/rcu \\
  -i -createRepository -c ${dbhost}:${dbport}:${dbname} \\
  -dbUser ${dbuser} -dbRole Normal
```

## Troubleshooting RCU

Be mindful of the following issues.

**Topics**

- Oracle Managed Files (OMF) (p. 2156)
- Object privileges (p. 2156)
- Enterprise Scheduler Service (p. 2157)

### Oracle Managed Files (OMF)

Amazon RDS uses OMF data files to simplify storage management. You can customize tablespace attributes, such as size and extent management. However, if you specify a data file name when you run RCU, the tablespace code fails with ORA-20900. You can use RCU with OMF in the following ways:

- In RCU 12.2.1.0 and later, use the `--honorOMF` command-line parameter.
- In RCU 12.1.0.3 and later, use multiple steps and edit the generated script. For more information, see Running RCU using the command line in multiple steps (p. 2154).

### Object privileges

Because Amazon RDS is a managed service, you don't have full SYSDBA access to your RDS for Oracle DB instance. However, RCU 12c supports users with lower privileges. In most cases, the master user privilege is sufficient to create repositories.

The master account can directly grant privileges that it has already been granted WITH GRANT OPTION. In some cases, when you attempt to grant SYS object privileges, the RCU might fail with ORA-01031. You can retry and run the `rdsadmin_util.grant_sys_object` stored procedure, as shown in the following example:

```sql
BEGIN
  rdsadmin.rdsadmin_util.grant_sys_object('GV_$SESSION','MY_DBA','SELECT');
END;
/
```

If you attempt to grant SYS privileges on the object SCHEMA_VERSION_REGISTRY, the operation might fail with ORA-20199: Error in rdsadmin_util.grant_sys_object. You can qualify the table `SCHEMA_VERSION_REGISTRY$` and the view `SCHEMA_VERSION_REGISTRY` with the schema owner name, which is SYSTEM, and retry the operation. Or, you can create a synonym. Log in as the master user and run the following statements:

```sql
CREATE OR REPLACE VIEW SYSTEM.SCHEMA_VERSION_REGISTRY AS SELECT * FROM SYSTEM.SCHEMA_VERSION_REGISTRY$;
```
CREATE OR REPLACE PUBLIC SYNONYM SCHEMA_VERSION_REGISTRY FOR SYSTEM.SCHEMA_VERSION_REGISTRY;
CREATE OR REPLACE PUBLIC SYNONYM SCHEMA_VERSION_REGISTRY$ FOR SCHEMA_VERSION_REGISTRY;

**Enterprise Scheduler Service**

When you use the RCU to drop an Enterprise Scheduler Service repository, the RCU might fail with **Error: Component drop check failed.**
Configuring Oracle Connection Manager on an Amazon EC2 instance

Oracle Connection Manager (CMAN) is a proxy server that forwards connection requests to database servers or other proxy servers. You can use CMAN to configure the following:

Access control

You can create rules that filter out user-specified client requests and accept others.

Session multiplexing

You can funnel multiple client sessions through a network connection to a shared server destination.

Typically, CMAN resides on a host separate from the database server and client hosts. For more information, see Configuring Oracle Connection Manager in the Oracle Database documentation.

Topics

- Supported versions and licensing options for CMAN (p. 2158)
- Requirements and limitations for CMAN (p. 2158)
- Configuring CMAN (p. 2158)

Supported versions and licensing options for CMAN

CMAN supports the Enterprise Edition of all versions of Oracle Database that Amazon RDS supports. For more information, see RDS for Oracle releases (p. 1805).

You can install Oracle Connection Manager on a separate host from the host where Oracle Database is installed. You don't need a separate license for the host that runs CMAN.

Requirements and limitations for CMAN

To provide a fully managed experience, Amazon RDS restricts access to the operating system. You can't modify database parameters that require operating system access. Thus, Amazon RDS doesn't support features of CMAN that require you to log in to the operating system.

Configuring CMAN

When you configure CMAN, you perform most of the work outside of your RDS for Oracle database.

Topics

- Step 1: Configure CMAN on an Amazon EC2 instance in the same VPC as the RDS for Oracle instance (p. 2158)
- Step 2: Configure database parameters for CMAN (p. 2159)
- Step 3: Associate your DB instance with the parameter group (p. 2159)

Step 1: Configure CMAN on an Amazon EC2 instance in the same VPC as the RDS for Oracle instance

To learn how to set up CMAN, follow the detailed instructions in the blog post Configuring and using Oracle Connection Manager on Amazon EC2 for Amazon RDS for Oracle.
Step 2: Configure database parameters for CMAN

For CMAN features such as Traffic Director Mode and session multiplexing, set REMOTE_LISTENER parameter to the address of CMAN instance in a DB parameter group. Consider the following scenario:

- The CMAN instance resides on a host with IP address 10.0.159.100 and uses port 1521.
- The databases orcla, orclb, and orclc reside on separate RDS for Oracle DB instances.

The following table shows how to set the REMOTE_LISTENER value. The LOCAL_LISTENER value is set automatically by Amazon RDS.

<table>
<thead>
<tr>
<th>DB instance name</th>
<th>DB instance IP</th>
<th>Local listener value (set automatically)</th>
<th>Remote listener value (set by user)</th>
</tr>
</thead>
<tbody>
<tr>
<td>orcla</td>
<td>10.0.159.200</td>
<td>( address= (protocol=tcp) (host=10.0.159.200) (port=1521) )</td>
<td>10.0.159.100:1521</td>
</tr>
<tr>
<td>orclb</td>
<td>10.0.159.300</td>
<td>( address= (protocol=tcp) (host=10.0.159.300) (port=1521) )</td>
<td>10.0.159.100:1521</td>
</tr>
<tr>
<td>orclc</td>
<td>10.0.159.400</td>
<td>( address= (protocol=tcp) (host=10.0.159.400) (port=1521) )</td>
<td>10.0.159.100:1521</td>
</tr>
</tbody>
</table>

Step 3: Associate your DB instance with the parameter group

Create or modify your DB instance to use the parameter group that you configured in Step 2: Configure database parameters for CMAN (p. 2159). For more information, see Associating a DB parameter group with a DB instance (p. 351).
Installing a Siebel database on Oracle on Amazon RDS

You can use Amazon RDS to host a Siebel Database on an Oracle DB instance. The Siebel Database is part of the Siebel Customer Relationship Management (CRM) application architecture. For an illustration, see Generic architecture of Siebel business application.

Use the following topic to help set up a Siebel Database on an Oracle DB instance on Amazon RDS. You can also find out how to use Amazon Web Services to support the other components required by the Siebel CRM application architecture.

Note
To install a Siebel Database on Oracle on Amazon RDS, you need to use the master user account. You don't need SYSDBA privilege; master user privilege is sufficient. For more information, see Master user account privileges (p. 2699).

Licensing and versions
To install a Siebel Database on Amazon RDS, you must use your own Oracle Database license, and your own Siebel license. You must have the appropriate Oracle Database license (with Software Update License and Support) for the DB instance class and Oracle Database edition. For more information, see RDS for Oracle licensing options (p. 1809).

Oracle Database Enterprise Edition is the only edition certified by Siebel for this scenario. Amazon RDS supports Siebel CRM version 15.0 or 16.0. Use Oracle Database 12c Release 1 (12.1.0.2.0). For the procedures following, we use Siebel CRM version 15.0 and Oracle Database Release 1 (12.1.0.2) or Oracle Database Release 2 (12.2.0.1). For more information, see Oracle Database 12c with Amazon RDS (p. 1808).

Amazon RDS supports database version upgrades. For more information, see Upgrading a DB instance engine version (p. 429).

Before you begin
Before you begin, you need an Amazon VPC. Because your Amazon RDS DB instance needs to be available only to your Siebel Enterprise Server, and not to the public Internet, your Amazon RDS DB instance is hosted in a private subnet, providing greater security. For information about how to create an Amazon VPC for use with Siebel CRM, see Creating a VPC for use with an Oracle database (p. 2132).

Before you begin, you also need an Oracle DB instance. For information about how to create an Oracle DB instance for use with Siebel CRM, see Creating an Oracle DB instance (p. 2137).

Installing and configuring a Siebel database
After you create your Oracle DB instance, you can install your Siebel Database. You install the database by creating table owner and administrator accounts, installing stored procedures and functions, and then running the Siebel Database Configuration Wizard. For more information, see Installing the Siebel database on the RDBMS.

To run the Siebel Database Configuration Wizard, you need to use the master user account. You don't need SYSDBA privilege; master user privilege is sufficient. For more information, see Master user account privileges (p. 2699).

Using other Amazon RDS features with a Siebel database
After you create your Oracle DB instance, you can use additional Amazon RDS features to help you customize your Siebel Database.
Collecting statistics with the Oracle Statspack option

You can add features to your DB instance through the use of options in DB option groups. When you created your Oracle DB instance, you used the default DB option group. If you want to add features to your database, you can create a new option group for your DB instance.

If you want to collect performance statistics on your Siebel Database, you can add the Oracle Statspack feature. For more information, see Oracle Statspack (p. 2100).

Some option changes are applied immediately, and some option changes are applied during the next maintenance window for the DB instance. For more information, see Working with option groups (p. 331). After you create a customized option group, modify your DB instance to attach it. For more information, see Modifying an Amazon RDS DB instance (p. 401).

Performance tuning with parameters

You manage your DB engine configuration through the use of parameters in a DB parameter group. When you created your Oracle DB instance, you used the default DB parameter group. If you want to customize your database configuration, you can create a new parameter group for your DB instance.

When you change a parameter, depending on the type of the parameter, the changes are applied either immediately or after you manually reboot the DB instance. For more information, see Working with parameter groups (p. 347). After you create a customized parameter group, modify your DB instance to attach it. For more information, see Modifying an Amazon RDS DB instance (p. 401).

To optimize your Oracle DB instance for Siebel CRM, you can customize certain parameters. The following table shows some recommended parameter settings. For more information about performance tuning Siebel CRM, see Siebel CRM Performance Tuning Guide.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Default value</th>
<th>Guidance for optimal Siebel CRM performance</th>
</tr>
</thead>
<tbody>
<tr>
<td>_always_semi_join chooser</td>
<td>OFF</td>
<td></td>
</tr>
<tr>
<td>_b_tree_bitmap_plan</td>
<td>FALSE</td>
<td></td>
</tr>
<tr>
<td>_like_with_bind_if_equality</td>
<td>TRUE</td>
<td></td>
</tr>
<tr>
<td>_no_or_expansion</td>
<td>FALSE</td>
<td></td>
</tr>
<tr>
<td>_optimizer_join thể</td>
<td>TRUE</td>
<td></td>
</tr>
<tr>
<td>_optimizer_sort_merge</td>
<td>TRUE</td>
<td></td>
</tr>
<tr>
<td>_optimizer_sort_merge_enabled</td>
<td>FALSE</td>
<td></td>
</tr>
<tr>
<td>_partition_view</td>
<td>TRUE</td>
<td></td>
</tr>
<tr>
<td>open_cursors</td>
<td>300</td>
<td>At least <strong>2000</strong>.</td>
</tr>
</tbody>
</table>

Creating snapshots

After you create your Siebel Database, you can copy the database by using the snapshot features of Amazon RDS. For more information, see Creating a DB snapshot (p. 613) and Restoring from a DB snapshot (p. 615).
Support for other Siebel CRM components

In addition to your Siebel Database, you can also use Amazon Web Services to support the other components of your Siebel CRM application architecture. You can find more information about the support provided by Amazon AWS for additional Siebel CRM components in the following table.

<table>
<thead>
<tr>
<th>Siebel CRM component</th>
<th>Amazon AWS Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Siebel Enterprise</td>
<td>You can host your Siebel Servers on Amazon Elastic Compute Cloud (Amazon EC2) instances. You can use Amazon EC2 to launch as many or as few virtual servers as you need. Using Amazon EC2, you can scale up or down easily to handle changes in requirements. For more information, see <a href="#">What is Amazon EC2?</a>. You can put your servers in the same VPC with your DB instance and use the VPC security group to access the database. For more information, see <a href="#">Working with a DB instance in a VPC</a>.</td>
</tr>
<tr>
<td>(with one or more Siebel Servers)</td>
<td></td>
</tr>
<tr>
<td>Web Servers</td>
<td>You can install multiple Web Servers on multiple EC2 instances. You can then use Elastic Load Balancing to distribute incoming traffic among the instances. For more information, see <a href="#">What is Elastic Load Balancing?</a>.</td>
</tr>
<tr>
<td>(with Siebel Web Server Extensions)</td>
<td></td>
</tr>
<tr>
<td>Siebel Gateway Name Server</td>
<td>You can host your Siebel Gateway Name Server on an EC2 instance. You can then put your server in the same VPC with the DB instance and use the VPC security group to access the database. For more information, see <a href="#">Working with a DB instance in a VPC</a>.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Oracle Database engine release notes

Updates to your Amazon RDS for Oracle DB instances keep them current. If you apply updates, you can be confident that your DB instance is running a version of the database software that has been tested by both Oracle and Amazon. We don't support applying one-off patches to individual RDS for Oracle DB instances.

You can specify any currently supported Oracle Database version when you create a new DB instance. You can specify the major version, such as Oracle Database 19c, and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version that you have specified. To see a list of supported versions and defaults for newly created DB instances, use the `describe-db-engine-versions` AWS CLI command.

For details about the Oracle Database versions that Amazon RDS supports, see the Amazon RDS for Oracle Release Notes.
Amazon RDS for PostgreSQL

Amazon RDS supports DB instances running several versions of PostgreSQL. For a list of available versions, see Available PostgreSQL database versions (p. 2171).

Note
Deprecation of PostgreSQL 9.6 is scheduled for April 26, 2022. For more information, see Deprecation of PostgreSQL version 9.6 (p. 2172).

You can create DB instances and DB snapshots, point-in-time restores and backups. DB instances running PostgreSQL support Multi-AZ deployments, read replicas, Provisioned IOPS, and can be created inside a virtual private cloud (VPC). You can also use Secure Socket Layer (SSL) to connect to a DB instance running PostgreSQL.

Before creating a DB instance, make sure to complete the steps in Setting up for Amazon RDS (p. 174).

You can use any standard SQL client application to run commands for the instance from your client computer. Such applications include pgAdmin, a popular Open Source administration and development tool for PostgreSQL, or psql, a command line utility that is part of a PostgreSQL installation. To deliver a managed service experience, Amazon RDS doesn't provide host access to DB instances. Also, it restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application. Amazon RDS doesn't allow direct host access to a DB instance by using Telnet or Secure Shell (SSH).

Amazon RDS for PostgreSQL is compliant with many industry standards. For example, you can use Amazon RDS for PostgreSQL databases to build HIPAA-compliant applications and to store healthcare-related information. This includes storage for protected health information (PHI) under a completed Business Associate Agreement (BAA) with AWS. Amazon RDS for PostgreSQL also meets Federal Risk and Authorization Management Program (FedRAMP) security requirements. Amazon RDS for PostgreSQL has received a FedRAMP Joint Authorization Board (JAB) Provisional Authority to Operate (P-ATO) at the FedRAMP HIGH Baseline within the AWS GovCloud (US) Regions. For more information on supported compliance standards, see AWS cloud compliance.

To import PostgreSQL data into a DB instance, follow the information in the Importing data into PostgreSQL on Amazon RDS (p. 2240) section.

Topics
- Common management tasks for Amazon RDS for PostgreSQL (p. 2165)
- Working with the database preview environment (p. 2168)
- PostgreSQL version 16 in the database preview environment (p. 2170)
- Available PostgreSQL database versions (p. 2171)
- Supported PostgreSQL extension versions (p. 2173)
- Working with PostgreSQL features supported by Amazon RDS for PostgreSQL (p. 2175)
- Connecting to a DB instance running the PostgreSQL database engine (p. 2184)
- Securing connections to RDS for PostgreSQL with SSL/TLS (p. 2191)
- Using Kerberos authentication with Amazon RDS for PostgreSQL (p. 2198)
- Using a custom DNS server for outbound network access (p. 2212)
- Upgrading the PostgreSQL DB engine for Amazon RDS (p. 2214)
- Upgrading a PostgreSQL DB snapshot engine version (p. 2227)
- Working with read replicas for Amazon RDS for PostgreSQL (p. 2229)
- Improving query performance for RDS for PostgreSQL with Amazon RDS Optimized Reads (p. 2237)
- Importing data into PostgreSQL on Amazon RDS (p. 2240)
• Exporting data from an RDS for PostgreSQL DB instance to Amazon S3 (p. 2264)
• Invoking an AWS Lambda function from an RDS for PostgreSQL DB instance (p. 2276)
• Common DBA tasks for Amazon RDS for PostgreSQL (p. 2287)
• Tuning with wait events for RDS for PostgreSQL (p. 2323)
• Tuning RDS for PostgreSQL with Amazon DevOps Guru proactive insights (p. 2370)
• Using PostgreSQL extensions with Amazon RDS for PostgreSQL (p. 2373)
• Working with the supported foreign data wrappers for Amazon RDS for PostgreSQL (p. 2418)
• Working with Trusted Language Extensions for PostgreSQL (p. 2429)

Common management tasks for Amazon RDS for PostgreSQL

The following are the common management tasks you perform with an Amazon RDS for PostgreSQL DB instance, with links to relevant documentation for each task.

<table>

Understanding the best practices for PostgreSQL DB instances

Find some of the best practices for working with PostgreSQL on Amazon RDS.

Best practices for working with PostgreSQL (p. 294)

Following is a list of other sections in this guide that can help you understand and use important features of RDS for PostgreSQL:

- Understanding PostgreSQL roles and permissions (p. 2288)
- Controlling user access to the PostgreSQL database (p. 2290)
- Working with parameters on your RDS for PostgreSQL DB instance (p. 2313)
- Understanding logging mechanisms supported by RDS for PostgreSQL (p. 2307)
- Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL (p. 2297)
- Using a custom DNS server for outbound network access (p. 2212)
Working with the database preview environment

The PostgreSQL community continuously releases new PostgreSQL version and extensions, including beta versions. This gives PostgreSQL users the opportunity to try out a new PostgreSQL version early. To learn more about the PostgreSQL community beta release process, see Beta Information in the PostgreSQL documentation. Similarly, Amazon RDS makes certain PostgreSQL beta versions available as Preview releases. This allows you to create DB instances using the Preview version and test out its features in the Database Preview Environment.

RDS for PostgreSQL DB instances in the Database Preview Environment are functionally similar to other RDS for PostgreSQL instances. However, you can't use a Preview version for production.

Keep in mind the following important limitations:

- All DB instances are deleted 60 days after you create them, along with any backups and snapshots.
- You can only create a DB instance in a virtual private cloud (VPC) based on the Amazon VPC service.
- You can only use General Purpose SSD and Provisioned IOPS SSD storage.
- You can't get help from AWS Support with DB instances. Instead, you can post your questions to the AWS-managed Q&A community, AWS re:Post.
- You can't copy a snapshot of a DB instance to a production environment.

The following options are supported by the Preview.

- You can create DB instances using M6i, R6i, M6g, M5, T3, R6g, and R5 instance types only. For more information about RDS instance classes, see DB instance classes (p. 11).
- You can use both single-AZ and multi-AZ deployments.
- You can use standard PostgreSQL dump and load functions to export databases from or import databases to the Database Preview Environment.

Features not supported in the preview environment

The following features aren't available in the preview environment:

- Cross-Region snapshot copy
- Cross-Region read replicas

Creating a new DB instance in the preview environment

Use the following procedure to create a DB instance in the preview environment.

To create a DB instance in the preview environment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Dashboard from the navigation pane.
3. In the Dashboard page, locate the Database Preview Environment section on the Dashboard page, as shown in the following image.
You can navigate directly to the Database preview environment. Before you can proceed, you must acknowledge and accept the limitations.

4. To create the RDS for PostgreSQL DB instance, follow the same process as that for creating any Amazon RDS DB instance. For more information, see the Console (p. 303) procedure in Creating a DB instance (p. 303).

To create an instance in the Database Preview Environment using the RDS API or the AWS CLI, use the following endpoint.

```
rgds-preview.us-east-2.amazonaws.com
```
This is preview documentation for Amazon RDS PostgreSQL version 16. It is subject to change.

**Note**
RDS for PostgreSQL versions 16 RC1, 16 Beta 3, 16 Beta 2, and 16 Beta 1 will not be supported after RDS for PostgreSQL version 16.0 is released in the database preview environment.

PostgreSQL version 16.0 is now available in the Amazon RDS database preview environment. PostgreSQL version 16 contains several improvements that are described in the following PostgreSQL documentation:

- [PostgreSQL 16 Released](#)
- [PostgreSQL 16 RC1 Released](#)
- [PostgreSQL 16 Beta 1 Released](#)
- [PostgreSQL 16 Beta 2 Released](#)
- [PostgreSQL 16 Beta 3 Released](#)

For information on the Database Preview Environment, see the section called "The database preview environment" (p. 2168). To access the Preview Environment from the console, select [https://console.aws.amazon.com/rds-preview/](https://console.aws.amazon.com/rds-preview/).
Available PostgreSQL database versions

Amazon RDS supports DB instances running several editions of PostgreSQL. You can specify any currently available PostgreSQL version when creating a new DB instance. You can specify the major version (such as PostgreSQL 14), and any available minor version for the specified major version. If no version is specified, Amazon RDS defaults to an available version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified.

To see a list of available versions, as well as defaults for newly created DB instances, use the `describe-db-engine-versions` AWS CLI command. For example, to display the default PostgreSQL engine version, use the following command:

```
aws rds describe-db-engine-versions --default-only --engine postgres
```

For details about the PostgreSQL versions that are supported on Amazon RDS, see the Amazon RDS for PostgreSQL Release Notes.

If you aren't ready to manually upgrade to a new major engine version before the RDS end of standard support date, or for Amazon RDS to automatically upgrade your major engine version after the RDS end of standard support date, you can enable Amazon RDS Extended Support on your DB instances that are running RDS for PostgreSQL version 11 and higher. For more information, see Using Amazon RDS Extended Support (p. 565) and Amazon RDS pricing.

### Deprecation of PostgreSQL version 10

On April 17, 2023, Amazon RDS plans to deprecate PostgreSQL 10 using the following schedule. We recommend that you take action and upgrade your PostgreSQL databases running on major version 10 to a later version, such as PostgreSQL version 14. To upgrade your RDS for PostgreSQL major version 10 DB instance from a PostgreSQL version older than 10.19, we recommend that you first upgrade to version 10.19 and then upgrade to version 14. For more information, see Upgrading the PostgreSQL DB engine for Amazon RDS (p. 2214).

<table>
<thead>
<tr>
<th>Action or recommendation</th>
<th>Dates</th>
</tr>
</thead>
<tbody>
<tr>
<td>The PostgreSQL community plans to deprecate PostgreSQL 10 and won't provide any security patches after this date.</td>
<td>November 10, 2022</td>
</tr>
<tr>
<td>Start upgrading RDS for PostgreSQL 10 DB instances to a later major version, such as PostgreSQL 14. Although you can continue to restore PostgreSQL 10 snapshots and create read replicas with version 10, be aware of the other critical dates in this deprecation schedule and their impact.</td>
<td>Until February 14, 2023</td>
</tr>
<tr>
<td>After this date, you can't create new Amazon RDS instances with PostgreSQL major version 10 from either the AWS Management Console or the AWS CLI.</td>
<td>February 14, 2023</td>
</tr>
<tr>
<td>After this date, Amazon RDS automatically upgrades PostgreSQL 10 instances to version 14. If you restore a PostgreSQL 10 database snapshot, Amazon RDS automatically upgrades the restored database to PostgreSQL 14.</td>
<td>April 17, 2023</td>
</tr>
</tbody>
</table>
Deprecation of PostgreSQL version 9.6

On March 31, 2022, Amazon RDS plans to deprecate PostgreSQL 9.6 using the following schedule. This extends the previously announced date of January 18, 2022 to April 26, 2022. You should upgrade all your PostgreSQL 9.6 DB instances to PostgreSQL 12 or higher as soon as possible. We recommend that you first upgrade to minor version 9.6.20 or higher and then upgrade directly to PostgreSQL 12 rather than upgrading to an intermediate major version. For more information, see Upgrading the PostgreSQL DB engine for Amazon RDS (p. 2214).

</table>

Deprecated versions for Amazon RDS for PostgreSQL

RDS for PostgreSQL 9.5 is deprecated as of March, 2021. For more information about RDS for PostgreSQL 9.5 deprecation, see Upgrading from Amazon RDS for PostgreSQL version 9.5.

To learn more about deprecation policy for RDS for PostgreSQL, see Amazon RDS FAQs. For more information about PostgreSQL versions, see Versioning Policy in the PostgreSQL documentation.
Supported PostgreSQL extension versions

RDS for PostgreSQL supports many PostgreSQL extensions. The PostgreSQL community sometimes refers to these as modules. Extensions expand on the functionality provided by the PostgreSQL engine. You can find a list of extensions supported by Amazon RDS in the default DB parameter group for that PostgreSQL version. You can also see the current extensions list using `psql` by showing the `rds.extensions` parameter as in the following example.

```
SHOW rds.extensions;
```

**Note**

Parameters added in a minor version release might display inaccurately when using the `rds.extensions` parameter in `psql`.

As of RDS for PostgreSQL 13, certain extensions can be installed by database users other than the `rds_superuser`. These are known as trusted extensions. To learn more, see PostgreSQL trusted extensions (p. 2174).

Certain versions of RDS for PostgreSQL support the `rds.allowed_extensions` parameter. This parameter lets an `rds_superuser` limit the extensions that can be installed in the RDS for PostgreSQL DB instance. For more information, see Restricting installation of PostgreSQL extensions (p. 2173).

For lists of PostgreSQL extensions and versions that are supported by each available RDS for PostgreSQL version, see PostgreSQL extensions supported on Amazon RDS in Amazon RDS for PostgreSQL Release Notes.

Restricting installation of PostgreSQL extensions

You can restrict which extensions can be installed on a PostgreSQL DB instance. By default, this parameter isn't set, so any supported extension can be added if the user has permissions to do so. To do so, set the `rds.allowed_extensions` parameter to a string of comma-separated extension names. By adding a list of extensions to this parameter, you explicitly identify the extensions that your RDS for PostgreSQL DB instance can use. Only these extensions can then be installed in the PostgreSQL DB instance.

The default string for the `rds.allowed_extensions` parameter is "", which means that any extension available for the engine version can be installed. Changing the `rds.allowed_extensions` parameter does not require a database restart because it's a dynamic parameter.

The PostgreSQL DB instance engine must be one of the following versions for you to use the `rds.allowed_extensions` parameter:

- PostgreSQL 14 and all higher versions
- PostgreSQL 13.3 and higher minor versions
- PostgreSQL 12.7 and higher minor versions

To see which extension installations are allowed, use the following `psql` command.

```
postgres=> SHOW rds.allowed_extensions;
 rds.allowed_extensions
------------------------
 *
```

If an extension was installed prior to it being left out of the list in the `rds.allowed_extensions` parameter, the extension can still be used normally, and commands such as `ALTER EXTENSION` and
DROP EXTENSION will continue to work. However, after an extension is restricted, CREATE EXTENSION commands for the restricted extension will fail.

Installation of extension dependencies with CREATE EXTENSION CASCADE are also restricted. The extension and its dependencies must be specified in rds.allowed_extensions. If an extension dependency installation fails, the entire CREATE EXTENSION CASCADE statement will fail.

If an extension is not included with the rds.allowed_extensions parameter, you will see an error such as the following if you try to install it.

```
ERROR: permission denied to create extension "extension-name"
HINT: This extension is not specified in "rds.allowed_extensions".
```

**PostgreSQL trusted extensions**

To install most PostgreSQL extensions requires rds_superuser privileges. PostgreSQL 13 introduced trusted extensions, which reduce the need to grant rds_superuser privileges to regular users. With this feature, users can install many extensions if they have the CREATE privilege on the current database instead of requiring the rds_superuser role. For more information, see the SQL CREATE EXTENSION command in the PostgreSQL documentation.

The following lists the extensions that can be installed by a user who has the CREATE privilege on the current database and do not require the rds_superuser role:

- bool_plperl
- btree_gin
- btree_gist
- citext
- cube
- dict_int
- fuzzystromatch
- hstore
- intarray
- isn
- jsonb_plperl
- ltree
- pg_trgm
- pgcrypto
- plperl
- plpgsql
- pltcl
- tablefunc
- tsm_system_rows
- tsm_system_time
- unaccent
- uuid-ossp

For lists of PostgreSQL extensions and versions that are supported by each available RDS for PostgreSQL version, see PostgreSQL extensions supported on Amazon RDS in Amazon RDS for PostgreSQL Release Notes.
Working with PostgreSQL features supported by Amazon RDS for PostgreSQL

Amazon RDS for PostgreSQL supports many of the most common PostgreSQL features. For example, PostgreSQL has an autovacuum feature that performs routine maintenance on the database. The autovacuum feature is active by default. Although you can turn off this feature, we highly recommend that you keep it on. Understanding this feature and what you can do to make sure it works as it should is a basic task of any DBA. For more information about the autovacuum, see Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL (p. 2297). To learn more about other common DBA tasks, Common DBA tasks for Amazon RDS for PostgreSQL (p. 2287).

RDS for PostgreSQL also supports extensions that add important functionality to the DB instance. For example, you can use the PostGIS extension to work with spatial data, or use the pg_cron extension to schedule maintenance from within the instance. For more information about PostgreSQL extensions, see Using PostgreSQL extensions with Amazon RDS for PostgreSQL (p. 2373).

Foreign data wrappers are a specific type of extension designed to let your RDS for PostgreSQL DB instance work with other commercial databases or data types. For more information about foreign data wrappers supported by RDS for PostgreSQL, see Working with the supported foreign data wrappers for Amazon RDS for PostgreSQL (p. 2418).

Following, you can find information about some other features supported by RDS for PostgreSQL.

Topics
- Custom data types and enumerations with RDS for PostgreSQL (p. 2175)
- Event triggers for RDS for PostgreSQL (p. 2176)
- Huge pages for RDS for PostgreSQL (p. 2176)
- Performing logical replication for Amazon RDS for PostgreSQL (p. 2177)
- RAM disk for the stats_temp_directory (p. 2179)
- Tablespaces for RDS for PostgreSQL (p. 2179)
- RDS for PostgreSQL collations for EBCDIC and other mainframe migrations (p. 2180)

Custom data types and enumerations with RDS for PostgreSQL

PostgreSQL supports creating custom data types and working with enumerations. For more information about creating and working with enumerations and other data types, see Enumerated types in the PostgreSQL documentation.

The following is an example of creating a type as an enumeration and then inserting values into a table.

```
CREATE TYPE rainbow AS ENUM ('red', 'orange', 'yellow', 'green', 'blue', 'purple');
CREATE TYPE
CREATE TABLE t1 (colors rainbow);
CREATE TABLE
INSERT INTO t1 VALUES ('red'), ('orange');
INSERT 0 2
SELECT * FROM t1;
colors
--------
red
orange
```
Event triggers for RDS for PostgreSQL

All current PostgreSQL versions support event triggers, and so do all available versions of RDS for PostgreSQL. You can use the main user account (default, postgres) to create, modify, rename, and delete event triggers. Event triggers are at the DB instance level, so they can apply to all databases on an instance.

For example, the following code creates an event trigger that prints the current user at the end of every data definition language (DDL) command.

```sql
CREATE OR REPLACE FUNCTION raise_notice_func()
RETURNS event_trigger
LANGUAGE plpgsql AS
$$
BEGIN
RAISE NOTICE 'In trigger function: %', current_user;
END;
$$;
CREATE EVENT TRIGGER event_trigger_1
ON ddl_command_end
EXECUTE PROCEDURE raise_notice_func();
```

For more information about PostgreSQL event triggers, see [Event triggers](#) in the PostgreSQL documentation.

There are several limitations to using PostgreSQL event triggers on Amazon RDS. These include the following:

- You can’t create event triggers on read replicas. You can, however, create event triggers on a read replica source. The event triggers are then copied to the read replica. The event triggers on the read replica don’t fire on the read replica when changes are pushed from the source. However, if the read replica is promoted, the existing event triggers fire when database operations occur.
- To perform a major version upgrade to a PostgreSQL DB instance that uses event triggers, make sure to delete the event triggers before you upgrade the instance.

Huge pages for RDS for PostgreSQL

Huge pages are a memory management feature that reduces overhead when a DB instance is working with large contiguous chunks of memory, such as that used by shared buffers. This PostgreSQL feature is supported by all currently available RDS for PostgreSQL versions. You allocate huge pages for your application by using calls to mmap or SYSV shared memory. RDS for PostgreSQL supports both 4-KB and 2-MB page sizes.

You can turn huge pages on or off by changing the value of the `huge_pages` parameter. The feature is turned on by default for all the DB instance classes other than micro, small, and medium DB instance classes.
RDS for PostgreSQL uses huge pages based on the available shared memory. If the DB instance can't use huge pages due to shared memory constraints, Amazon RDS prevents the DB instance from starting. In this case, Amazon RDS sets the status of the DB instance to an incompatible parameters state. If this occurs, you can set the `huge_pages` parameter to `off` to allow Amazon RDS to start the DB instance.

The `shared_buffers` parameter is key to setting the shared memory pool that is required for using huge pages. The default value for the `shared_buffers` parameter uses a database parameters macro. This macro sets a percentage of the total 8 KB pages available for the DB instance's memory. When you use huge pages, those pages are located with the huge pages. Amazon RDS puts a DB instance into an incompatible parameters state if the shared memory parameters are set to require more than 90 percent of the DB instance memory.

To learn more about PostgreSQL memory management, see Resource Consumption in the PostgreSQL documentation.

**Performing logical replication for Amazon RDS for PostgreSQL**

Starting with version 10.4, RDS for PostgreSQL supports the publication and subscription SQL syntax that was introduced in PostgreSQL 10. To learn more, see Logical replication in the PostgreSQL documentation.

> **Note**
> In addition to the native PostgreSQL logical replication feature introduced in PostgreSQL 10, RDS for PostgreSQL also supports the `pglogical` extension. For more information, see Using `pglogical` to synchronize data across instances (p. 2395).

Following, you can find information about setting up logical replication for an RDS for PostgreSQL DB instance.

**Topics**
- Understanding logical replication and logical decoding (p. 2177)
- Working with logical replication slots (p. 2178)

**Understanding logical replication and logical decoding**

RDS for PostgreSQL supports the streaming of write-ahead log (WAL) changes using PostgreSQL's logical replication slots. It also supports using logical decoding. You can set up logical replication slots on your instance and stream database changes through these slots to a client such as `pg_recvlogical`. You create logical replication slots at the database level, and they support replication connections to a single database.

The most common clients for PostgreSQL logical replication are AWS Database Migration Service or a custom-managed host on an Amazon EC2 instance. The logical replication slot has no information about the receiver of the stream. Also, there's no requirement that the target be a replica database. If you set up a logical replication slot and don't read from the slot, data can be written and quickly fill up your DB instance's storage.

You turn on PostgreSQL logical replication and logical decoding for Amazon RDS with a parameter, a replication connection type, and a security role. The client for logical decoding can be any client that can establish a replication connection to a database on a PostgreSQL DB instance.

**To turn on logical decoding for an RDS for PostgreSQL DB instance**

1. Make sure that the user account that you're using has these roles:
Logical replication

- The rds_superuser role so you can turn on logical replication
- The rds_replication role to grant permissions to manage logical slots and to stream data using logical slots

2. Set the rds.logical_replication static parameter to 1. As part of applying this parameter, also set the parameters wal_level, max_wal_senders, max_replication_slots, and max_connections. These parameter changes can increase WAL generation, so set the rds.logical_replication parameter only when you are using logical slots.

3. Reboot the DB instance for the static rds.logical_replication parameter to take effect.

4. Create a logical replication slot as explained in the next section. This process requires that you specify a decoding plugin. Currently, RDS for PostgreSQL supports the test_decoding and wal2json output plugins that ship with PostgreSQL.

For more information on PostgreSQL logical decoding, see the PostgreSQL documentation.

Working with logical replication slots

You can use SQL commands to work with logical slots. For example, the following command creates a logical slot named test_slot using the default PostgreSQL output plugin test_decoding.

```
SELECT * FROM pg_create_logical_replication_slot('test_slot', 'test_decoding');
```

```
slot_name    | xlog_position
-------------+---------------
regression_slot | 0/1681970
(1 row)
```

To list logical slots, use the following command.

```
SELECT * FROM pg_replication_slots;
```

To drop a logical slot, use the following command.

```
SELECT pg_drop_replication_slot('test_slot');
```

```
pg_drop_replication_slot
------------------------
(1 row)
```

For more examples on working with logical replication slots, see Logical decoding examples in the PostgreSQL documentation.

After you create the logical replication slot, you can start streaming. The following example shows how logical decoding is controlled over the streaming replication protocol. This example uses the program pg_recvlogical, which is included in the PostgreSQL distribution. Doing this requires that client authentication is set up to allow replication connections.

```
pg_recvlogical -d postgres --slot test_slot -U postgres
   --host -instance-name.111122223333.aws-region.rds.amazonaws.com
   -f - --start
```

To see the contents of the pg_replication_origin_status view, query the pg_show_replication_origin_status function.

```
SELECT * FROM pg_show_replication_origin_status();
```

```
local_id | external_id | remote_lsn | local_lsn
----------+------------+------------+----------
2178
```
RAM disk for the stats_temp_directory

You can use the RDS for PostgreSQL parameter rds.pg_stat_ramdisk_size to specify the system memory allocated to a RAM disk for storing the PostgreSQL stats_temp_directory. The RAM disk parameter is available for all PostgreSQL versions on Amazon RDS.

Under certain workloads, setting this parameter can improve performance and decrease I/O requirements. For more information about the stats_temp_directory, see the PostgreSQL documentation.

To set up a RAM disk for your stats_temp_directory, set the rds.pg_stat_ramdisk_size parameter to an integer literal value in the parameter group used by your DB instance. This parameter denotes MB, so you must use an integer value. Expressions, formulas, and functions aren't valid for the rds.pg_stat_ramdisk_size parameter. Be sure to reboot the DB instance so that the change takes effect. For information about setting parameters, see Working with parameter groups (p. 347).

For example, the following AWS CLI command sets the RAM disk parameter to 256 MB.

```bash
aws rds modify-db-parameter-group \
  --db-parameter-group-name pg-95-ramdisk-testing \
  --parameters "ParameterName=rds.pg_stat_ramdisk_size, ParameterValue=256, ApplyMethod=pending-reboot"
```

After you reboot, run the following command to see the status of the stats_temp_directory.

```bash
postgres=> SHOW stats_temp_directory;
```

The command should return the following.

```
stats_temp_directory
---------------------------
/rdsdbramdisk/pg_stat_tmp
(1 row)
```

Tablespaces for RDS for PostgreSQL

RDS for PostgreSQL supports tablespaces for compatibility. Because all storage is on a single logical volume, you can't use tablespaces for I/O splitting or isolation. Our benchmarks and experience indicate that a single logical volume is the best setup for most use cases.

To create and use tablespaces with your RDS for PostgreSQL DB instance requires the rds_superuser role. Your RDS for PostgreSQL DB instance's main user account (default name, postgres) is a member of this role. For more information, see Understanding PostgreSQL roles and permissions (p. 2288).

If you specify a file name when you create a tablespace, the path prefix is /rdsdbdata/db/base/tables. The following example places tablespace files in /rdsdbdata/db/base/tables/data. This example assumes that a dbadmin user (role) exists and that it's been granted the rds_superuser role needed to work with tablespaces.

```sql
postgres=> CREATE TABLESPACE act_data 
  OWNER dbadmin 
  LOCATION '/data';
```
RDS for PostgreSQL collations for EBCDIC and other mainframe migrations

RDS for PostgreSQL versions 10 and higher include ICU version 60.2, which is based on Unicode 10.0 and includes collations from the Unicode Common Locale Data Repository, CLDR 32. These software internationalization libraries ensure that character encodings are presented in a consistent way, regardless of operating system or platform. For more information about Unicode CLDR-32, see the CLDR 32 Release Note on the Unicode CLDR website. You can learn more about the internationalization components for Unicode (ICU) at the ICU Technical Committee (ICU-TC) website. For information about ICU-60, see Download ICU 60.

Starting with version 14.3, RDS for PostgreSQL also includes collations that help with data integration and conversion from EBCDIC-based systems. The extended binary coded decimal interchange code or EBCDIC encoding is commonly used by mainframe operating systems. These Amazon RDS-provided collations are narrowly defined to sort only those Unicode characters that directly map to EBCDIC code pages. The characters are sorted in EBCDIC code-point order to allow for data validation after conversion. These collations don't include denormalized forms, nor do they include Unicode characters that don't directly map to a character on the source EBCDIC code page.

The character mappings between EBCDIC code pages and Unicode code points are based on tables published by IBM. The complete set is available from IBM as a compressed file for download. RDS for PostgreSQL used these mappings with tools provided by the ICU to create the collations listed in this section. The collation names include a language and country as required by the ICU. However, EBCDIC code pages don't specify languages, and some EBCDIC code pages cover multiple countries. That means that the language and country portion of the collation names in the table are arbitrary, and they don't need to match the current locale. In other words, the code page number is the most important part of the collation name in this table. You can use any of the collations listed in the following tables in any RDS for PostgreSQL database.

- **Unicode to EBCDIC collations table** – Some mainframe data migration tools internally use LATIN1 or LATIN9 to encode and process data. Such tools use round-trip schemes to preserve data integrity and support reverse conversion. The collations in this table can be used by tools that process data using LATIN1 encoding, which doesn't require special handling.
- **Unicode to LATIN9 collations table** – You can use these collations in any RDS for PostgreSQL database.

In the following table, you find collations available in RDS for PostgreSQL that map EBCDIC code pages to Unicode code points. We recommend that you use the collations in this table for application development that requires sorting based on the ordering of IBM code pages.

<table>
<thead>
<tr>
<th>PostgreSQL collation name</th>
<th>Description of code-page mapping and sort order</th>
</tr>
</thead>
<tbody>
<tr>
<td>da-DK-cp277-x-icu</td>
<td>Unicode characters that directly map to IBM EBCDIC Code Page 277 (per conversion tables) are sorted in IBM CP 277 code point order</td>
</tr>
<tr>
<td>de-DE-cp273-x-icu</td>
<td>Unicode characters that directly map to IBM EBCDIC Code Page 273 (per conversion tables) are sorted in IBM CP 273 code point order</td>
</tr>
<tr>
<td>PostgreSQL collation name</td>
<td>Description of code-page mapping and sort order</td>
</tr>
<tr>
<td>---------------------------</td>
<td>------------------------------------------------</td>
</tr>
<tr>
<td>en-GB-cp285-x-icu</td>
<td>Unicode characters that directly map to IBM EBCDIC Code Page 285 (per conversion tables) are sorted in IBM CP 285 code point order</td>
</tr>
<tr>
<td>en-US-cp037-x-icu</td>
<td>Unicode characters that directly map to IBM EBCDIC Code Page 037 (per conversion tables) are sorted in IBM CP 37 code point order</td>
</tr>
<tr>
<td>es-ES-cp284-x-icu</td>
<td>Unicode characters that directly map to IBM EBCDIC Code Page 284 (per conversion tables) are sorted in IBM CP 284 code point order</td>
</tr>
<tr>
<td>fi-FI-cp278-x-icu</td>
<td>Unicode characters that directly map to IBM EBCDIC Code Page 278 (per conversion tables) are sorted in IBM CP 278 code point order</td>
</tr>
<tr>
<td>fr-FR-cp297-x-icu</td>
<td>Unicode characters that directly map to IBM EBCDIC Code Page 297 (per conversion tables) are sorted in IBM CP 297 code point order</td>
</tr>
<tr>
<td>it-IT-cp280-x-icu</td>
<td>Unicode characters that directly map to IBM EBCDIC Code Page 280 (per conversion tables) are sorted in IBM CP 280 code point order</td>
</tr>
<tr>
<td>nl-BE-cp500-x-icu</td>
<td>Unicode characters that directly map to IBM EBCDIC Code Page 500 (per conversion tables) are sorted in IBM CP 500 code point order</td>
</tr>
</tbody>
</table>

Amazon RDS provides a set of additional collations that sort Unicode code points that map to LATIN9 characters using the tables published by IBM, in the order of the original code points according to the EBCDIC code page of the source data.

<table>
<thead>
<tr>
<th>PostgreSQL collation name</th>
<th>Description of code-page mapping and sort order</th>
</tr>
</thead>
<tbody>
<tr>
<td>da-DK-cp1142m-x-icu</td>
<td>Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1142 (per conversion tables) are sorted in IBM CP 1142 code point order</td>
</tr>
<tr>
<td>de-DE-cp1141m-x-icu</td>
<td>Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1141 (per conversion tables) are sorted in IBM CP 1141 code point order</td>
</tr>
<tr>
<td>en-GB-cp1146m-x-icu</td>
<td>Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1146 (per conversion tables) are sorted in IBM CP 1146 code point order</td>
</tr>
<tr>
<td>en-US-cp1140m-x-icu</td>
<td>Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1140 (per conversion tables) are sorted in IBM CP 1140 code point order</td>
</tr>
</tbody>
</table>
### PostgreSQL collation name | Description of code-page mapping and sort order
---|---
es-ES-cp1145m-x-icu | Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1145 (per conversion tables) are sorted in IBM CP 1145 code point order
fi-FI-cp1143m-x-icu | Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1143 (per conversion tables) are sorted in IBM CP 1143 code point order
fr-FR-cp1147m-x-icu | Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1147 (per conversion tables) are sorted in IBM CP 1147 code point order
it-IT-cp1144m-x-icu | Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1144 (per conversion tables) are sorted in IBM CP 1144 code point order
nl-BE-cp1148m-x-icu | Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1148 (per conversion tables) are sorted in IBM CP 1148 code point order

In the following, you can find an example of using an RDS for PostgreSQL collation.

```sql
db1=> SELECT pg_import_system_collations('pg_catalog');
pg_import_system_collations
-------------------------
| 36 |
```

```sql
db1=> SELECT '¤' < 'a' col1;
col1
------
t
db1=> SELECT '¤' < 'a' COLLATE "da-DK-cp277-x-icu" col1;
col1
------
f
```

We recommend that you use the collations in the [Unicode to EBCDIC collations table](#) and in the [Unicode to LATIN9 collations table](#) for application development that requires sorting based on the ordering of IBM code pages. The following collations (suffixed with the letter "b") are also visible in `pg_collation`, but are intended for use by mainframe data integration and migration tools at AWS that map code pages with specific code point shifts and require special handling in collation. In other words, the following collations aren't recommended for use.

- da-DK-277b-x-icu
- da-DK-1142b-x-icu
- de-DE-cp273b-x-icu
- de-DE-cp1141b-x-icu
- en-GB-cp1146b-x-icu
- en-GB-cp285b-x-icu
• en-US-cp037b-x-icu
• en-US-cp1140b-x-icu
• es-ES-cp1145b-x-icu
• es-ES-cp284b-x-icu
• fi-FI-cp1143b-x-icu
• fr-FR-cp1147b-x-icu
• fr-FR-cp297b-x-icu
• it-IT-cp1144b-x-icu
• it-IT-cp280b-x-icu
• nl-BE-cp1148b-x-icu
• nl-BE-cp500b-x-icu

To learn more about migrating applications from mainframe environments to AWS, see What is AWS Mainframe Modernization?.

For more information about managing collations in PostgreSQL, see Collation Support in the PostgreSQL documentation.
Connecting to a DB instance running the PostgreSQL database engine

After Amazon RDS provisions your DB instance, you can use any standard SQL client application to connect to the instance. Before you can connect, the DB instance must be available and accessible. Whether you can connect to the instance from outside the VPC depends on how you created the Amazon RDS DB instance:

- If you created your DB instance as *public*, devices and Amazon EC2 instances outside the VPC can connect to your database.
- If you created your DB instance as *private*, only Amazon EC2 instances and devices inside the Amazon VPC can connect to your database.

To connect to your DB instance from an EC2 instance, you can install a PostgreSQL client on the EC2 instance. To install the psql client on Amazon Linux 2023, run the following command:

```
sudo dnf install postgresql15
```

To install the psql client on Amazon Linux 2, run the following command:

```
sudo amazon-linux-extras install postgresql14
```

To install the psql client on Ubuntu, run the following command:

```
sudo apt-get install -y postgresql14
```

To check whether your DB instance is public or private, use the AWS Management Console to view the Connectivity & security tab for your instance. Under Security, you can find the "Publicly accessible" value, with No for private, Yes for public.

To learn more about different Amazon RDS and Amazon VPC configurations and how they affect accessibility, see [Scenarios for accessing a DB instance in a VPC](p. 2718).

If the DB instance is available and accessible, you can connect by providing the following information to the SQL client application:

- The DB instance endpoint, which serves as the host name (DNS name) for the instance.
- The port on which the DB instance is listening. For PostgreSQL, the default port is 5432.
- The user name and password for the DB instance. The default 'master username' for PostgreSQL is postgres.
- The name and password of the database (DB name).

You can obtain these details by using the AWS Management Console, the AWS CLI `describe-db-instances` command, or the Amazon RDS API `DescribeDBInstances` operation.

**To find the endpoint, port number, and DB name using the AWS Management Console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Open the RDS console and then choose **Databases** to display a list of your DB instances.
3. Choose the PostgreSQL DB instance name to display its details.
4. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.

5. On the **Configuration** tab, note the DB name. If you created a database when you created the RDS for PostgreSQL instance, you see the name listed under DB name. If you didn’t create a database, the DB name displays a dash (-).
Using pgAdmin to connect to a RDS for PostgreSQL DB instance

You can use the open-source tool pgAdmin to connect to your RDS for PostgreSQL DB instance. You can download and install pgAdmin from [http://www.pgadmin.org/](http://www.pgadmin.org/) without having a local instance of PostgreSQL on your client computer.

**To connect to your RDS for PostgreSQL DB instance using pgAdmin**

1. Launch the pgAdmin application on your client computer.
2. On the **Dashboard** tab, choose **Add New Server**.
3. In the **Create - Server** dialog box, type a name on the **General** tab to identify the server in pgAdmin.
4. On the **Connection** tab, type the following information from your DB instance:
   - **For Host**, type the endpoint, for example `mypostgresql.c6c8dntfzghgv0.us-east-2.rds.amazonaws.com`.

Following are two ways to connect to a PostgreSQL DB instance. The first example uses pgAdmin, a popular open-source administration and development tool for PostgreSQL. The second example uses psql, a command line utility that is part of a PostgreSQL installation.

**Topics**

- [Using pgAdmin to connect to a RDS for PostgreSQL DB instance (p. 2186)](#)
- [Using psql to connect to your RDS for PostgreSQL DB instance (p. 2188)](#)
- [Connecting with the AWS JDBC Driver for PostgreSQL (p. 2188)](#)
- [Troubleshooting connections to your RDS for PostgreSQL instance (p. 2189)](#)
Using pgAdmin to connect to a RDS for PostgreSQL DB instance

- For **Port**, type the assigned port.
- For **Username**, type the user name that you entered when you created the DB instance (if you changed the 'master username' from the default, `postgres`).
- For **Password**, type the password that you entered when you created the DB instance.

5. Choose **Save**.

If you have any problems connecting, see [Troubleshooting connections to your RDS for PostgreSQL instance](#) (p. 2189).

6. To access a database in the pgAdmin browser, expand **Servers**, the DB instance, and **Databases**. Choose the DB instance’s database name.

7. To open a panel where you can enter SQL commands, choose **Tools, Query Tool**.
Using psql to connect to your RDS for PostgreSQL DB instance

You can use a local instance of the psql command line utility to connect to a RDS for PostgreSQL DB instance. You need either PostgreSQL or the psql client installed on your client computer.

You can download the PostgreSQL client from the PostgreSQL website. Follow the instructions specific to your operating system version to install psql.

To connect to your RDS for PostgreSQL DB instance using psql, you need to provide host (DNS) information, access credentials, and the name of the database.

Use one of the following formats to connect to your RDS for PostgreSQL DB instance. When you connect, you're prompted for a password. For batch jobs or scripts, use the --no-password option. This option is set for the entire session.

Note
A connection attempt with --no-password fails when the server requires password authentication and a password is not available from other sources. For more information, see the psql documentation.

If this is the first time you are connecting to this DB instance, or if you didn't yet create a database for this RDS for PostgreSQL instance, you can connect to the postgres database using the 'master username' and password.

For Unix, use the following format.

```bash
csql \
  --host=<DB instance endpoint> \ 
  --port=<port> \ 
  --username=<master username> \ 
  --password \ 
  --dbname=<database name>
```

For Windows, use the following format.

```bash
csql ^
  --host=<DB instance endpoint> ^
  --port=<port> ^
  --username=<master username> ^
  --password ^
  --dbname=<database name>
```

For example, the following command connects to a database called mypgdb on a PostgreSQL DB instance called mypostgresql using fictitious credentials.

```bash
csql --host=mypostgresql.c6c8mwwf0dv0.us-west-2.rds.amazonaws.com --port=5432 --username=awsuser --password --dbname=mypgdb
```

Connecting with the AWS JDBC Driver for PostgreSQL

The AWS JDBC Driver for PostgreSQL is a client wrapper designed for use with RDS for PostgreSQL. The AWS JDBC Driver for PostgreSQL extends the functionality of the community pgJDBC driver by enabling AWS features such as authentication. For more information about the AWS JDBC Driver for PostgreSQL and complete instructions for using it, see the AWS JDBC Driver for PostgreSQL GitHub repository.
The AWS JDBC Driver for PostgreSQL supports AWS Identity and Access Management (IAM) database authentication and AWS Secrets Manager. For more information on using these authentication mechanisms with the driver, see AWS IAM Authentication Plugin and AWS Secrets Manager Plugin in the AWS JDBC Driver for PostgreSQL GitHub repository.

For more information about IAM database authentication, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 2659). For more information about Secrets Manager, see the AWS Secrets Manager User Guide.

Troubleshooting connections to your RDS for PostgreSQL instance

Topics
- Error – FATAL: database name does not exist (p. 2189)
- Error – Could not connect to server: Connection timed out (p. 2189)
- Errors with security group access rules (p. 2189)

Error – FATAL: database name does not exist

If when trying to connect you receive an error like FATAL: database name does not exist, try using the default database name postgres for the --dbname option.

Error – Could not connect to server: Connection timed out

If you can't connect to the DB instance, the most common error is Could not connect to server: Connection timed out. If you receive this error, check the following:

- Check that the host name used is the DB instance endpoint and that the port number used is correct.
- Make sure that the DB instance's public accessibility is set to Yes to allow external connections. To modify the Public access setting, see Modifying an Amazon RDS DB instance (p. 401).
- Make sure that the user connecting to the database has CONNECT access to it. You can use the following query to provide connect access to the database.

  GRANT CONNECT ON DATABASE database name TO username;

- Check that the security group assigned to the DB instance has rules to allow access through any firewall your connection might go through. For example, if the DB instance was created using the default port of 5432, your company might have firewall rules blocking connections to that port from external company devices.

  To fix this, modify the DB instance to use a different port. Also, make sure that the security group applied to the DB instance allows connections to the new port. To modify the Database port setting, see Modifying an Amazon RDS DB instance (p. 401).
- See also Errors with security group access rules (p. 2189).

Errors with security group access rules

By far the most common connection problem is with the security group's access rules assigned to the DB instance. If you used the default security group when you created the DB instance, the security group likely didn't have access rules that allow you to access the instance.

For the connection to work, the security group you assigned to the DB instance at its creation must allow access to the DB instance. For example, if the DB instance was created in a VPC, it must have a VPC
security group that authorizes connections. Check if the DB instance was created using a security group that doesn't authorize connections from the device or Amazon EC2 instance where the application is running.

You can add or edit an inbound rule in the security group. For **Source**, choosing **My IP** allows access to the DB instance from the IP address detected in your browser. For more information, see [Provide access to your DB instance in your VPC by creating a security group](p. 177).

Alternatively, if the DB instance was created outside of a VPC, it must have a database security group that authorizes those connections.

For more information about Amazon RDS security groups, see [Controlling access with security groups](p. 2697).
Securing connections to RDS for PostgreSQL with SSL/TLS

RDS for PostgreSQL supports Secure Socket Layer (SSL) encryption for PostgreSQL DB instances. Using SSL, you can encrypt a PostgreSQL connection between your applications and your PostgreSQL DB instances. You can also force all connections to your PostgreSQL DB instance to use SSL. RDS for PostgreSQL also supports Transport Layer Security (TLS), the successor protocol to SSL.

To learn more about Amazon RDS and data protection, including encrypting connections using SSL/TLS, see Data protection in Amazon RDS (p. 2602).

Topics
- Using SSL with a PostgreSQL DB instance (p. 2191)
- Updating applications to connect to PostgreSQL DB instances using new SSL/TLS certificates (p. 2194)

Using SSL with a PostgreSQL DB instance

Amazon RDS supports Secure Socket Layer (SSL) encryption for PostgreSQL DB instances. Using SSL, you can encrypt a PostgreSQL connection between your applications and your PostgreSQL DB instances. By default, RDS for PostgreSQL uses and expects all clients to connect using SSL/TLS, but you can also require it. RDS for PostgreSQL supports Transport Layer Security (TLS) versions 1.1 and 1.2.

For general information about SSL support and PostgreSQL databases, see SSL support in the PostgreSQL documentation. For information about using an SSL connection over JDBC, see Configuring the client in the PostgreSQL documentation.

SSL support is available in all AWS Regions for PostgreSQL. Amazon RDS creates an SSL certificate for your PostgreSQL DB instance when the instance is created. If you enable SSL certificate verification, then the SSL certificate includes the DB instance endpoint as the Common Name (CN) for the SSL certificate to guard against spoofing attacks.

Topics
- Connecting to a PostgreSQL DB instance over SSL (p. 2191)
- Requiring an SSL connection to a PostgreSQL DB instance (p. 2192)
- Determining the SSL connection status (p. 2192)
- SSL cipher suites in RDS for PostgreSQL (p. 2194)

Connecting to a PostgreSQL DB instance over SSL

To connect to a PostgreSQL DB instance over SSL

1. Download the certificate.

   For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2608).

2. Import the certificate into your operating system.

   For sample scripts that import certificates, see Sample script for importing certificates into your trust store (p. 2620).
3. Connect to your PostgreSQL DB instance over SSL.

When you connect using SSL, your client can choose whether to verify the certificate chain. If your connection parameters specify `sslmode=verify-ca` or `sslmode=verify-full`, then your client requires the RDS CA certificates to be in their trust store or referenced in the connection URL. This requirement is to verify the certificate chain that signs your database certificate.

When a client, such as psql or JDBC, is configured with SSL support, the client first tries to connect to the database with SSL by default. If the client can't connect with SSL, it reverts to connecting without SSL. The default `sslmode` mode used is different between libpq-based clients (such as psql) and JDBC. The libpq-based clients default to `prefer`, and JDBC clients default to `verify-full`.

Use the `sslrootcert` parameter to reference the certificate, for example `sslrootcert=rds-ca-2019-root.pem`.

The following is an example of using psql to connect to a PostgreSQL DB instance using SSL with certificate verification.

```
$ psql -h db-name.555555555555.ap-southeast-1.rds.amazonaws.com
     -p 5432 dbname=testDB user=testuser sslrootcert=rds-ca-2019-root.pem sslmode=verify-full
```

### Requiring an SSL connection to a PostgreSQL DB instance

You can require that connections to your PostgreSQL DB instance use SSL by using the `rds.force_ssl` parameter. The default `rds.force_ssl` parameter is set to 1 (on) for RDS for PostgreSQL version 15. All other RDS for PostgreSQL major version 14 and older have the default value for `rds.force_ssl` parameter set to 0 (off). You can set the `rds.force_ssl` parameter to 1 (on) to require SSL for connections to your DB instance.

To change the value of this parameter, you need to create a custom DB parameter group. You then change the value for `rds.force_ssl` in your custom DB parameter group to 1 to turn on this feature. If you prepare the custom DB parameter group before creating your RDS for PostgreSQL DB instance you can choose it (instead of a default parameter group) during the creation process. If you do this after your RDS for PostgreSQL DB instance is already running, you need to reboot the instance so that your instance uses the custom parameter group. For more information, see Working with parameter groups (p. 347).

When the `rds.force_ssl` feature is active on your DB instance, connection attempts that aren't using SSL are rejected with the following message:

```
$ psql -h db-name.555555555555.ap-southeast-1.rds.amazonaws.com -p 5432 dbname=testDB
     user=testuser
psql: error: FATAL: no pg_hba.conf entry for host "w.x.y.z", user "testuser", database "testDB", SSL off
```

### Determining the SSL connection status

The encrypted status of your connection is shown in the logon banner when you connect to the DB instance:

```
Password for user master:
psql (10.3)
SSL connection (cipher: DHE-RSA-AES256-SHA, bits: 256)
Type "help" for help.
postgres=>
```
You can also load the `sslinfo` extension and then call the `ssl_is_used()` function to determine if SSL is being used. The function returns `t` if the connection is using SSL, otherwise it returns `f`.

```sql
postgres=> CREATE EXTENSION sslinfo;
CREATE EXTENSION
postgres=> SELECT ssl_is_used();
ssl_is_used
-------
t
(1 row)
```

For more detailed information, you can use the following query to get information from `pg_settings`:

```sql
SELECT name as "Parameter name", setting as value, short_desc FROM pg_settings WHERE name LIKE '%ssl%';
```

```
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>value</th>
<th>short_desc</th>
</tr>
</thead>
<tbody>
<tr>
<td>ssl</td>
<td>on</td>
<td>Enables SSL connections.</td>
</tr>
<tr>
<td>ssl_ca_file</td>
<td>/rdsdbdata/rds-metadata/ca-cert.pem</td>
<td>Location of the SSL certificate authority file.</td>
</tr>
<tr>
<td>ssl_cert_file</td>
<td>/rdsdbdata/rds-metadata/server-cert.pem</td>
<td>Location of the SSL server certificate file.</td>
</tr>
<tr>
<td>ssl_ciphers</td>
<td>HIGH:!aNULL:!3DES</td>
<td>Sets the list of allowed SSL ciphers.</td>
</tr>
<tr>
<td>ssl_crl_file</td>
<td></td>
<td>Location of the SSL certificate revocation list file.</td>
</tr>
<tr>
<td>ssl_dh_params_file</td>
<td></td>
<td>Location of the SSL DH parameters file.</td>
</tr>
<tr>
<td>ssl_ecdh_curve</td>
<td>prime256v1</td>
<td>the curve to use for ECDH.</td>
</tr>
<tr>
<td>ssl_key_file</td>
<td>/rdsdbdata/rds-metadata/server-key.pem</td>
<td>Location of the SSL server private key file.</td>
</tr>
<tr>
<td>ssl_library</td>
<td>OpenSSL</td>
<td>Name of the SSL library.</td>
</tr>
<tr>
<td>ssl_max_protocol_version</td>
<td></td>
<td>the maximum SSL/TLS protocol version to use.</td>
</tr>
<tr>
<td>ssl_min_protocol_version</td>
<td>TLSv1.2</td>
<td>the minimum SSL/TLS protocol version to use.</td>
</tr>
<tr>
<td>ssl_passphrase_command</td>
<td></td>
<td>Command to obtain passphrases for SSL.</td>
</tr>
<tr>
<td>ssl_passphrase_command_supports_reload</td>
<td>off</td>
<td>Also use ssl_passphrase_command during server reload.</td>
</tr>
<tr>
<td>ssl_prefer_server_ciphers</td>
<td>on</td>
<td>Give priority to server ciphersuite order.</td>
</tr>
</tbody>
</table>
```

You can also collect all the information about your RDS for PostgreSQL DB instance's SSL usage by process, client, and application by using the following query:

```sql
SELECT datname as "Database name", usename as "User name", ssl, client_addr, application_name, backend_type
FROM pg_stat_ssl
JOIN pg_stat_activity
ON pg_stat_ssl.pid = pg_stat_activity.pid
ORDER BY ssl;
```

```
Database name | User name | ssl | client_addr | application_name | backend_type
----------------------------------------+------------------+-----------------+------------------+
```
Updating applications to use new SSL/TLS certificates

To identify the cipher used for your SSL connection, you can query as follows:

```
postgres=> SELECT ssl_cipher();
ssl_cipher
---------------------
DHE-RSA-AES256-SHA
(1 row)
```

To learn more about the `sslmode` option, see Database connection control functions in the PostgreSQL documentation.

SSL cipher suites in RDS for PostgreSQL

The PostgreSQL configuration parameter `ssl_ciphers` specifies the categories of cipher suites that are allowed for SSL connections. The following table lists the default cipher suites used in RDS for PostgreSQL.

<table>
<thead>
<tr>
<th>PostgreSQL engine version</th>
<th>Cipher suites</th>
</tr>
</thead>
<tbody>
<tr>
<td>15</td>
<td>HIGH:!aNULL:!3DES</td>
</tr>
<tr>
<td>14</td>
<td>HIGH:!aNULL:!3DES</td>
</tr>
<tr>
<td>13</td>
<td>HIGH:!aNULL:!3DES</td>
</tr>
<tr>
<td>12</td>
<td>HIGH:!aNULL:!3DES</td>
</tr>
<tr>
<td>11.4 and higher minor versions</td>
<td>HIGH: MEDIUM:+3DES:!aNULL:!RC4</td>
</tr>
<tr>
<td>11.1, 11.2</td>
<td>HIGH: MEDIUM:+3DES:!aNULL</td>
</tr>
<tr>
<td>10.9 and higher minor versions</td>
<td>HIGH: MEDIUM:+3DES:!aNULL:!RC4</td>
</tr>
<tr>
<td>10.7 and lower minor versions</td>
<td>HIGH: MEDIUM:+3DES:!aNULL</td>
</tr>
</tbody>
</table>

Updating applications to connect to PostgreSQL DB instances using new SSL/TLS certificates

Certificates used for Secure Socket Layer or Transport Layer Security (SSL/TLS) typically have a set lifetime. When service providers update their Certificate Authority (CA) certificates, clients must update their applications to use the new certificates. Following, you can find information about how to determine if your client applications use SSL/TLS to connect to your Amazon RDS for PostgreSQL DB
instance. You also find information about how to check if those applications verify the server certificate when they connect.

**Note**
A client application that’s configured to verify the server certificate before SSL/TLS connection must have a valid CA certificate in the client’s trust store. Update the client trust store when necessary for new certificates.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a nonproduction environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate (p. 2613). For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2608). For information about using SSL/TLS with PostgreSQL DB instances, see Using SSL with a PostgreSQL DB instance (p. 2191).

**Topics**
- Determining whether applications are connecting to PostgreSQL DB instances using SSL (p. 2195)
- Determining whether a client requires certificate verification in order to connect (p. 2196)
- Updating your application trust store (p. 2196)
- Using SSL/TLS connections for different types of applications (p. 2196)

**Determining whether applications are connecting to PostgreSQL DB instances using SSL**

Check the DB instance configuration for the value of the `rds.force_ssl` parameter. By default, the `rds.force_ssl` parameter is set to 0 (off) for DB instances using PostgreSQL versions before version 15. By default, `rds.force_ssl` is set to 1 (on) for DB instances using PostgreSQL version 15 and later major versions. If the `rds.force_ssl` parameter is set to 1 (on), clients are required to use SSL/TLS for connections. For more information about parameter groups, see Working with parameter groups (p. 347).

If you are using RDS PostgreSQL version 9.5 or later major version and `rds.force_ssl` is not set to 1 (on), query the `pg_stat_ssl` view to check connections using SSL. For example, the following query returns only SSL connections and information about the clients using SSL. For example, the following query returns only SSL connections and information about the clients using SSL.

```sql
SELECT datname, usename, ssl, client_addr
FROM pg_stat_ssl INNER JOIN pg_stat_activity ON pg_stat_ssl.pid = pg_stat_activity.pid
WHERE ssl is true and usename<>'rdsadmin';
```

This query displays only the current connections at the time of the query. The absence of results doesn't indicate that no applications are using SSL connections. Other SSL connections might be established at a different time.
Determining whether a client requires certificate verification in order to connect

When a client, such as psql or JDBC, is configured with SSL support, the client first tries to connect to the database with SSL by default. If the client can't connect with SSL, it reverts to connecting without SSL. The default sslmode mode used is different between libpq-based clients (such as psql) and JDBC. The libpq-based clients default to prefer, where JDBC clients default to verify-full. The certificate on the server is verified only when sslrootcert is provided with sslmode set to require, verify-ca, or verify-full. An error is thrown if the certificate is invalid.

Use PGSSLROOTCERT to verify the certificate with the PGSSLMODE environment variable, with PGSSLMODE set to require, verify-ca, or verify-full.

```
PGSSLMODE=require PGSSLROOTCERT=/fullpath/ssl-cert.pem psql -h pgdbidentifier.cxxxxxxxx.us-east-2.rds.amazonaws.com -U masteruser -d postgres
```

Use the sslrootcert argument to verify the certificate with sslmode in connection string format, with sslmode set to require, verify-ca, or verify-full to verify the certificate.

```
psql "host=pgdbidentifier.cxxxxxxxx.us-east-2.rds.amazonaws.com sslmode=require sslrootcert=/full/path/ssl-cert.pem user=masteruser dbname=postgres"
```

For example, in the preceding case, if you are using an invalid root certificate, then you see an error similar to the following on your client.

```
psql: SSL error: certificate verify failed
```

Updating your application trust store

For information about updating the trust store for PostgreSQL applications, see Secure TCP/IP connections with SSL in the PostgreSQL documentation.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2608).

For sample scripts that import certificates, see Sample script for importing certificates into your trust store (p. 2620).

**Note**

When you update the trust store, you can retain older certificates in addition to adding the new certificates.

Using SSL/TLS connections for different types of applications

The following provides information about using SSL/TLS connections for different types of applications:

- **psql**

  The client is invoked from the command line by specifying options either as a connection string or as environment variables. For SSL/TLS connections, the relevant options are sslmode (environment variable PGSSLMODE), sslrootcert (environment variable PGSSLROOTCERT).

  For the complete list of options, see Parameter key words in the PostgreSQL documentation. For the complete list of environment variables, see Environment variables in the PostgreSQL documentation.

- **pgAdmin**
This browser-based client is a more user-friendly interface for connecting to a PostgreSQL database.

For information about configuring connections, see the pgAdmin documentation.

- **JDBC**
  
  JDBC enables database connections with Java applications.
  
  For general information about connecting to a PostgreSQL database with JDBC, see Connecting to the database in the PostgreSQL JDBC driver documentation. For information about connecting with SSL/TLS, see Configuring the client in the PostgreSQL JDBC driver documentation.

- **Python**
  
  A popular Python library for connecting to PostgreSQL databases is psycopg2.
  
  For information about using psycopg2, see the psycopg2 documentation. For a short tutorial on how to connect to a PostgreSQL database, see Psycopg2 tutorial. You can find information about the options the connect command accepts in The psycopg2 module content.

**Important**

After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-rsa2048-g1 certificates. For instructions, see step 3 in Updating your CA certificate by modifying your DB instance (p. 2614).
Using Kerberos authentication with Amazon RDS for PostgreSQL

You can use Kerberos to authenticate users when they connect to your DB instance running PostgreSQL. To do so, configure your DB instance to use AWS Directory Service for Microsoft Active Directory for Kerberos authentication. AWS Directory Service for Microsoft Active Directory is also called AWS Managed Microsoft AD. It's a feature available with AWS Directory Service. To learn more, see What is AWS Directory Service? in the AWS Directory Service Administration Guide.

To start, create an AWS Managed Microsoft AD directory to store user credentials. Then, provide to your PostgreSQL DB instance the Active Directory's domain and other information. When users authenticate with the PostgreSQL DB instance, authentication requests are forwarded to the AWS Managed Microsoft AD directory.

Keeping all of your credentials in the same directory can save you time and effort. You have a centralized location for storing and managing credentials for multiple DB instances. Using a directory can also improve your overall security profile.

In addition, you can access credentials from your own on-premises Microsoft Active Directory. To do so, create a trusting domain relationship so that the AWS Managed Microsoft AD directory trusts your on-premises Microsoft Active Directory. In this way, your users can access your PostgreSQL instances with the same Windows single sign-on (SSO) experience as when they access workloads in your on-premises network.

A database can use password authentication or password authentication with either Kerberos or AWS Identity and Access Management (IAM) authentication. For more information about IAM authentication, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 2659).

Topics
- Region and version availability (p. 2198)
- Overview of Kerberos authentication for PostgreSQL DB instances (p. 2198)
- Setting up Kerberos authentication for PostgreSQL DB instances (p. 2199)
- Managing a DB instance in a Domain (p. 2208)
- Connecting to PostgreSQL with Kerberos authentication (p. 2209)

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of RDS for PostgreSQL with Kerberos authentication, see Kerberos authentication (p. 141).

Overview of Kerberos authentication for PostgreSQL DB instances

To set up Kerberos authentication for a PostgreSQL DB instance, take the following steps, described in more detail later:

1. Use AWS Managed Microsoft AD to create an AWS Managed Microsoft AD directory. You can use the AWS Management Console, the AWS CLI, or the AWS Directory Service API to create the directory. Make sure to open the relevant outbound ports on the directory security group so that the directory can communicate with the instance.
2. Create a role that provides Amazon RDS access to make calls to your AWS Managed Microsoft AD directory. To do so, create an AWS Identity and Access Management (IAM) role that uses the managed IAM policy AmazonRDSDirectoryServiceAccess.

For the IAM role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the correct AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Activating and deactivating AWS STS in an AWS Region in the IAM User Guide.

3. Create and configure users in the AWS Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users in your Active Directory, see Manage users and groups in AWS Managed Microsoft AD in the AWS Directory Service Administration Guide.

4. If you plan to locate the directory and the DB instance in different AWS accounts or virtual private clouds (VPCs), configure VPC peering. For more information, see What is VPC peering? in the Amazon VPC Peering Guide.

5. Create or modify a PostgreSQL DB instance either from the console, CLI, or RDS API using one of the following methods:
   - Creating an Amazon RDS DB instance (p. 300)
   - Modifying an Amazon RDS DB instance (p. 401)
   - Restoring from a DB snapshot (p. 615)
   - Restoring a DB instance to a specified time (p. 660)

You can locate the instance in the same Amazon Virtual Private Cloud (VPC) as the directory or in a different AWS account or VPC. When you create or modify the PostgreSQL DB instance, do the following:
   - Provide the domain identifier (d-* identifier) that was generated when you created your directory.
   - Provide the name of the IAM role that you created.
   - Ensure that the DB instance security group can receive inbound traffic from the directory security group.

6. Use the RDS master user credentials to connect to the PostgreSQL DB instance. Create the user in PostgreSQL to be identified externally. Externally identified users can log in to the PostgreSQL DB instance using Kerberos authentication.

Setting up Kerberos authentication for PostgreSQL DB instances

You use AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to set up Kerberos authentication for a PostgreSQL DB instance. To set up Kerberos authentication, take the following steps.

Topics
   - Step 1: Create a directory using AWS Managed Microsoft AD (p. 2200)
   - Step 2: (Optional) Create a trust relationship between your on-premises Active Directory and AWS Directory Service (p. 2203)
   - Step 3: Create an IAM role for Amazon RDS to access the AWS Directory Service (p. 2204)
   - Step 4: Create and configure users (p. 2205)
   - Step 5: Enable cross-VPC traffic between the directory and the DB instance (p. 2205)
   - Step 6: Create or modify a PostgreSQL DB instance (p. 2206)
   - Step 7: Create PostgreSQL users for your Kerberos principals (p. 2207)
   - Step 8: Configure a PostgreSQL client (p. 2207)
Step 1: Create a directory using AWS Managed Microsoft AD

AWS Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and DNS servers for you. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

- Sets up an Active Directory within your VPC.
- Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.

  **Important**
  
  Make sure to save this password. AWS Directory Service doesn't store this password, and it can't be retrieved or reset.

- Creates a security group for the directory controllers. The security group must permit communication with the PostgreSQL DB instance.

When you launch AWS Directory Service for Microsoft Active Directory, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU, which has the NetBIOS name that you entered when you created your directory, is located in the domain root. The domain root is owned and managed by AWS.

The Admin account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
- Create additional OUs and containers
- Delegate authority
- Restore deleted objects from the Active Directory Recycle Bin
- Run Active Directory and Domain Name Service (DNS) modules for Windows PowerShell on the Active Directory Web Service

The Admin account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders)
- View DNS event logs
- View security event logs

To create a directory with AWS Managed Microsoft AD

1. In the AWS Directory Service console navigation pane, choose Directories, and then choose Set up directory.
2. Choose AWS Managed Microsoft AD. AWS Managed Microsoft AD is the only option currently supported for use with Amazon RDS.
3. Choose Next.
4. On the Enter directory information page, provide the following information:
Edition

Choose the edition that meets your requirements.

Directory DNS name

The fully qualified name for the directory, such as corp.example.com.

Directory NetBIOS name

An optional short name for the directory, such as CORP.

Directory description

An optional description for the directory.

Admin password

The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.

The directory administrator password can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:

- Lowercase letters (a–z)
- Uppercase letters (A–Z)
- Numbers (0–9)
- Nonalphanumeric characters (~!#$%^&*_-+=`|(){}[\]:;"'<>,.?/)

Confirm password

Retype the administrator password.

Important

Make sure that you save this password. AWS Directory Service doesn't store this password, and it can't be retrieved or reset.

5. Choose Next.

6. On the Choose VPC and subnets page, provide the following information:

VPC

Choose the VPC for the directory. You can create the PostgreSQL DB instance in this same VPC or in a different VPC.

Subnets

Choose the subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Choose Next.

8. Review the directory information. If changes are needed, choose Previous and make the changes. When the information is correct, choose Create directory.
Setting up

It takes several minutes for the directory to be created. When it has been successfully created, the **Status** value changes to **Active**.

To see information about your directory, choose the directory ID in the directory listing. Make a note of the **Directory ID** value. You need this value when you create or modify your PostgreSQL DB instance.
Setting up

Step 2: (Optional) Create a trust relationship between your on-premises Active Directory and AWS Directory Service

If you don’t plan to use your own on-premises Microsoft Active Directory, skip to Step 3: Create an IAM role for Amazon RDS to access the AWS Directory Service (p. 2204).

To get Kerberos authentication using your on-premises Active Directory, you need to create a trusting domain relationship using a forest trust between your on-premises Microsoft Active Directory and the AWS Managed Microsoft AD directory (created in Step 1: Create a directory using AWS Managed Microsoft AD (p. 2200)). The trust can be one-way, where the AWS Managed Microsoft AD directory trusts the on-premises Microsoft Active Directory. The trust can also be two-way, where both Active Directories trust each other. For more information about setting up trusts using AWS Directory Service, see When to create a trust relationship in the AWS Directory Service Administration Guide.

Note

If you use an on-premises Microsoft Active Directory, Windows clients connect using the domain name of the AWS Directory Service in the endpoint rather than rds.amazonaws.com. To learn more, see Connecting to PostgreSQL with Kerberos authentication (p. 2209).
Make sure that your on-premises Microsoft Active Directory domain name includes a DNS suffix routing that corresponds to the newly created trust relationship. The following screenshot shows an example.

Step 3: Create an IAM role for Amazon RDS to access the AWS Directory Service

For Amazon RDS to call AWS Directory Service for you, your AWS account needs an IAM role that uses the managed IAM policy AmazonRDSDirectoryServiceAccess. This role allows Amazon RDS to make calls to AWS Directory Service.

When you create a DB instance using the AWS Management Console and your console user account has the iam:CreateRole permission, the console creates the needed IAM role automatically. In this case, the role name is rds-directoryservice-kerberos-access-role. Otherwise, you must create the IAM role manually. When you create this IAM role, choose Directory Service, and attach the AWS managed policy AmazonRDSDirectoryServiceAccess to it.

For more information about creating IAM roles for a service, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

Note
The IAM role used for Windows Authentication for RDS for Microsoft SQL Server can't be used for Amazon RDS for PostgreSQL.

As an alternative to using the AmazonRDSDirectoryServiceAccess managed policy, you can create policies with the required permissions. In this case, the IAM role must have the following IAM trust policy.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "",
            "Effect": "Allow",
            "Principal": {
                "Service": [
                    "directoryservice.rds.amazonaws.com",
                    "rds.amazonaws.com"
                ],
                "rds.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

The role must also have the following IAM role policy.
Step 4: Create and configure users

You can create users by using the Active Directory Users and Computers tool. This is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. For more information, see Add Users and Computers to the Active Directory domain in the Microsoft documentation. In this case, users are individuals or other entities, such as their computers that are part of the domain and whose identities are being maintained in the directory.

To create users in an AWS Directory Service directory, you must be connected to a Windows-based Amazon EC2 instance that’s a member of the AWS Directory Service directory. At the same time, you must be logged in as a user that has privileges to create users. For more information, see Create a user in the AWS Directory Service Administration Guide.

Step 5: Enable cross-VPC traffic between the directory and the DB instance

If you plan to locate the directory and the DB instance in the same VPC, skip this step and move on to Step 6: Create or modify a PostgreSQL DB instance (p. 2206).

If you plan to locate the directory and the DB instance in different VPCs, configure cross-VPC traffic using VPC peering or AWS Transit Gateway.

The following procedure enables traffic between VPCs using VPC peering. Follow the instructions in What is VPC peering? in the Amazon Virtual Private Cloud Peering Guide.

To enable cross-VPC traffic using VPC peering

1. Set up appropriate VPC routing rules to ensure that network traffic can flow both ways.
2. Ensure that the DB instance security group can receive inbound traffic from the directory security group.
3. Ensure that there is no network access control list (ACL) rule to block traffic.

If a different AWS account owns the directory, you must share the directory.

To share the directory between AWS accounts

1. Start sharing the directory with the AWS account that the DB instance will be created in by following the instructions in Tutorial: Sharing your AWS Managed Microsoft AD directory for seamless EC2 Domain-join in the AWS Directory Service Administration Guide.
2. Sign in to the AWS Directory Service console using the account for the DB instance, and ensure that the domain has the SHARED status before proceeding.
3. While signed into the AWS Directory Service console using the account for the DB instance, note the Directory ID value. You use this directory ID to join the DB instance to the domain.

Step 6: Create or modify a PostgreSQL DB instance

Create or modify a PostgreSQL DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new PostgreSQL DB instance using the console, the create-db-instance CLI command, or the CreateDBInstance RDS API operation. For instructions, see Creating an Amazon RDS DB instance (p. 300).
- Modify an existing PostgreSQL DB instance using the console, the modify-db-instance CLI command, or the ModifyDBInstance RDS API operation. For instructions, see Modifying an Amazon RDS DB instance (p. 401).
- Restore a PostgreSQL DB instance from a DB snapshot using the console, the restore-db-instance-from-db-snapshot CLI command, or the RestoreDBInstanceFromDBSnapshot RDS API operation. For instructions, see Restoring from a DB snapshot (p. 615).
- Restore a PostgreSQL DB instance to a point-in-time using the console, the restore-db-instance-to-point-in-time CLI command, or the RestoreDBInstanceToPointInTime RDS API operation. For instructions, see Restoring a DB instance to a specified time (p. 660).

Kerberos authentication is only supported for PostgreSQL DB instances in a VPC. The DB instance can be in the same VPC as the directory, or in a different VPC. The DB instance must use a security group that allows ingress and egress within the directory's VPC so the DB instance can communicate with the directory.

Console

When you use the console to create, modify, or restore a DB instance, choose Password and Kerberos authentication in the Database authentication section. Then choose Browse Directory. Select the directory or choose Create a new directory to use the Directory Service.

AWS CLI

When you use the AWS CLI, the following parameters are required for the DB instance to be able to use the directory that you created:

- For the --domain parameter, use the domain identifier ("d-*" identifier) generated when you created the directory.
- For the --domain-iam-role-name parameter, use the role you created that uses the managed IAM policy AmazonRDSDirectoryServiceAccess.
For example, the following CLI command modifies a DB instance to use a directory.

```
aws rds modify-db-instance --db-instance-identifier mydbinstance --domain Directory-ID --domain-iam-role-name role-name
```

**Important**
If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

### Step 7: Create PostgreSQL users for your Kerberos principals

At this point, your RDS for PostgreSQL DB instance is joined to the AWS Managed Microsoft AD domain. The users that you created in the directory in Step 4: Create and configure users (p. 2205) need to be set up as PostgreSQL database users and granted privileges to login to the database. You do that by signing in as the database user with `rds_superuser` privileges. For example, if you accepted the defaults when you created your RDS for PostgreSQL DB instance, you use `postgres`, as shown in the following steps.

**To create PostgreSQL database users for Kerberos principals**

1. Use `psql` to connect to your RDS for PostgreSQL DB instance endpoint using `psql`. The following example uses the default `postgres` account for the `rds_superuser` role.

   ```bash
   psql --host=cluster-instance-1.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   ```

2. Create a database user name for each Kerberos principal (Active Directory username) that you want to have access to the database. Use the canonical username (identity) as defined in the Active Directory instance, that is, a lower-case alias (username in Active Directory) and the upper-case name of the Active Directory domain for that user name. The Active Directory user name is an externally authenticated user, so use quotes around the name as shown following.

   ```sql
   postgres=> CREATE USER "username@CORP.EXAMPLE.COM" WITH LOGIN;
   CREATE ROLE
   ```

3. Grant the `rds_ad` role to the database user.

   ```sql
   postgres=> GRANT rds_ad TO "username@CORP.EXAMPLE.COM";
   GRANT ROLE
   ```

After you finish creating all the PostgreSQL users for your Active Directory user identities, users can access the RDS for PostgreSQL DB instance by using their Kerberos credentials.

It's assumed that the database users who authenticate using Kerberos are doing so from client machines that are members of the Active Directory domain.

Database users that have been granted the `rds_ad` role can't also have the `rds_iam` role. This also applies to nested memberships. For more information, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 2659).

### Step 8: Configure a PostgreSQL client

To configure a PostgreSQL client, take the following steps:

- Create a `krb5.conf` file (or equivalent) to point to the domain.
- Verify that traffic can flow between the client host and AWS Directory Service. Use a network utility such as `Netcat` for the following:
• Verify traffic over DNS for port 53.
• Verify traffic over TCP/UDP for port 53 and for Kerberos, which includes ports 88 and 464 for AWS Directory Service.
• Verify that traffic can flow between the client host and the DB instance over the database port. For example, use psql to connect and access the database.

The following is sample krb5.conf content for AWS Managed Microsoft AD.

```
[libdefaults]
default_realm = EXAMPLE.COM
[realms]
EXAMPLE.COM = {
  kdc = example.com
  admin_server = example.com
}
[domain_realm]
.example.com = EXAMPLE.COM
e.example.com = EXAMPLE.COM
```

The following is sample krb5.conf content for an on-premises Microsoft Active Directory.

```
[libdefaults]
default_realm = EXAMPLE.COM
[realms]
EXAMPLE.COM = {
  kdc = example.com
  admin_server = example.com
}
ONPREM.COM = {
  kdc = onprem.com
  admin_server = onprem.com
}
[domain_realm]
.example.com = EXAMPLE.COM
e.example.com = EXAMPLE.COM
.onprem.com = ONPREM.COM
onprem.com = ONPREM.COM
.rds.amazonaws.com = EXAMPLE.COM
.amazonaws.com.cn = EXAMPLE.COM
.amazon.com = EXAMPLE.COM
```

Managing a DB instance in a Domain

You can use the console, the CLI, or the RDS API to manage your DB instance and its relationship with your Microsoft Active Directory. For example, you can associate an Active Directory to enable Kerberos authentication. You can also remove the association for an Active Directory to disable Kerberos authentication. You can also move a DB instance to be externally authenticated by one Microsoft Active Directory to another.

For example, using the CLI, you can do the following:

• To reattempt enabling Kerberos authentication for a failed membership, use the `modify-db-instance` CLI command. Specify the current membership's directory ID for the `--domain` option.
• To disable Kerberos authentication on a DB instance, use the `modify-db-instance` CLI command. Specify `none` for the `--domain` option.
• To move a DB instance from one domain to another, use the `modify-db-instance` CLI command. Specify the domain identifier of the new domain for the `--domain` option.
Understanding Domain membership

After you create or modify your DB instance, it becomes a member of the domain. You can view the status of the domain membership in the console or by running the `describe-db-instances` CLI command. The status of the DB instance can be one of the following:

- `kerberos-enabled` – The DB instance has Kerberos authentication enabled.
- `enabling-kerberos` – AWS is in the process of enabling Kerberos authentication on this DB instance.
- `pending-enable-kerberos` – Enabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-enable-kerberos` – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `pending-disable-kerberos` – Disabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-disable-kerberos` – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `enable-kerberos-failed` – A configuration problem prevented AWS from enabling Kerberos authentication on the DB instance. Correct the configuration problem before reissuing the command to modify the DB instance.
- `disabling-kerberos` – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. In some cases, the attempt to enable Kerberos authentication might fail when you create or modify a DB instance. If so, make sure that you are using the correct IAM role, then modify the DB instance to join the domain.

**Note**

Only Kerberos authentication with RDS for PostgreSQL sends traffic to the domain's DNS servers. All other DNS requests are treated as outbound network access on your DB instances running PostgreSQL. For more information about outbound network access with RDS for PostgreSQL, see [Using a custom DNS server for outbound network access](p. 2212).

Connecting to PostgreSQL with Kerberos authentication

You can connect to PostgreSQL with Kerberos authentication with the pgAdmin interface or with a command-line interface such as `psql`. For more information about connecting, see [Connecting to a DB instance running the PostgreSQL database engine](p. 2184). For information about obtaining the endpoint, port number, and other details needed for connection, see [Step 3: Connect to a PostgreSQL DB instance](p. 245).

**pgAdmin**

To use pgAdmin to connect to PostgreSQL with Kerberos authentication, take the following steps:

1. Launch the pgAdmin application on your client computer.
2. On the **Dashboard** tab, choose **Add New Server**.
3. In the **Create - Server** dialog box, enter a name on the **General** tab to identify the server in pgAdmin.
4. On the **Connection** tab, enter the following information from your RDS for PostgreSQL database.
   - For **Host**, enter the endpoint for the RDS for PostgreSQL DB instance. An endpoint looks similar to the following:

```
RDS-DB-instance.111122223333.aws-region.rds.amazonaws.com
```
To connect to an on-premises Microsoft Active Directory from a Windows client, you use the domain name of the AWS Managed Active Directory instead of \texttt{rds.amazonaws.com} in the host endpoint. For example, suppose that the domain name for the AWS Managed Active Directory is \texttt{corp.example.com}. Then for \textbf{Host}, the endpoint would be specified as follows:

\begin{verbatim}
RDS-DB-instance.111122223333.aws-region.corp.example.com
\end{verbatim}

- For \textbf{Port}, enter the assigned port.
- For \textbf{Maintenance database}, enter the name of the initial database to which the client will connect.
- For \textbf{Username}, enter the user name that you entered for Kerberos authentication in \textit{Step 7: Create PostgreSQL users for your Kerberos principals} (p. 2207).

5. Choose \textbf{Save}.

\textbf{Psq1}

To use \texttt{psql} to connect to PostgreSQL with Kerberos authentication, take the following steps:

1. At a command prompt, run the following command.

   \begin{verbatim}
   kinit username
   \end{verbatim}

   Replace \texttt{username} with the user name. At the prompt, enter the password stored in the Microsoft Active Directory for the user.

2. If the PostgreSQL DB instance is using a publicly accessible VPC, put IP address for your DB instance endpoint in your \texttt{/etc/hosts} file on the EC2 client. For example, the following commands obtain the IP address and then put it in the \texttt{/etc/hosts} file.

   \begin{verbatim}
   % dig +short PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com ;; Truncated, retrying in TCP mode.
   ec2-34-210-197-118.AWS-Region.compute.amazonaws.com.
   34.210.197.118
   % echo "34.210.197.118 PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com" >> /etc/hosts
   \end{verbatim}

   If you're using an on-premises Microsoft Active Directory from a Windows client, then you need to connect using a specialized endpoint. Instead of using the Amazon domain \texttt{rds.amazonaws.com} in the host endpoint, use the domain name of the AWS Managed Active Directory.

   For example, suppose that the domain name for your AWS Managed Active Directory is \texttt{corp.example.com}. Then use the format \texttt{PostgreSQL-endpoint.AWS-Region.corp.example.com} for the endpoint and put it in the \texttt{/etc/hosts} file.

   \begin{verbatim}
   % echo "34.210.197.118 PostgreSQL-endpoint.AWS-Region.corp.example.com" >> /etc/hosts
   \end{verbatim}

3. Use the following \texttt{psql} command to log in to a PostgreSQL DB instance that is integrated with Active Directory.

   \begin{verbatim}
   psql -U username@CORP.EXAMPLE.COM -p 5432 -h PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com postgres
   \end{verbatim}

   To log in to the PostgreSQL DB cluster from a Windows client using an on-premises Active Directory, use the following \texttt{psql} command with the domain name from the previous step (\texttt{corp.example.com}):
psql -U username@CORP.EXAMPLE.COM -p 5432 -h PostgreSQL-endpoint.AWS-Region.corp.example.com postgres
Using a custom DNS server for outbound network access

RDS for PostgreSQL supports outbound network access on your DB instances and allows Domain Name Service (DNS) resolution from a custom DNS server owned by the customer. You can resolve only fully qualified domain names from your RDS for PostgreSQL DB instance through your custom DNS server.

Topics

- Turning on custom DNS resolution (p. 2212)
- Turning off custom DNS resolution (p. 2212)
- Setting up a custom DNS server (p. 2212)

Turning on custom DNS resolution

To turn on DNS resolution in your customer VPC, first associate a custom DB parameter group to your RDS for PostgreSQL instance. Then turn on the rds.custom_dns_resolution parameter by setting it to 1, and then restart the DB instance for the changes to take place.

Turning off custom DNS resolution

To turn off DNS resolution in your customer VPC, first turn off the rds.custom_dns_resolution parameter of your custom DB parameter group by setting it to 0. Then restart the DB instance for the changes to take place.

Setting up a custom DNS server

After you set up your custom DNS name server, it takes up to 30 minutes to propagate the changes to your DB instance. After the changes are propagated to your DB instance, all outbound network traffic requiring a DNS lookup queries your DNS server over port 53.

Note

If you don't set up a custom DNS server and rds.custom_dns_resolution is set to 1, hosts are resolved using an Amazon Route 53 private zone. For more information, see Working with private hosted zones.

To set up a custom DNS server for your RDS for PostgreSQL DB instance

1. From the Dynamic Host Configuration Protocol (DHCP) options set attached to your VPC, set the domain-name-servers option to the IP address of your DNS name server. For more information, see DHCP options sets.

    Note

    The domain-name-servers option accepts up to four values, but your Amazon RDS DB instance uses only the first value.

2. Ensure that your DNS server can resolve all lookup queries, including public DNS names, Amazon EC2 private DNS names, and customer-specific DNS names. If the outbound network traffic contains any DNS lookups that your DNS server can't handle, your DNS server must have appropriate upstream DNS providers configured.

3. Configure your DNS server to produce User Datagram Protocol (UDP) responses of 512 bytes or less.

4. Configure your DNS server to produce Transmission Control Protocol (TCP) responses of 1,024 bytes or less.
5. Configure your DNS server to allow inbound traffic from your Amazon RDS DB instances over port 53. If your DNS server is in an Amazon VPC, the VPC must have a security group that contains inbound rules that allow UDP and TCP traffic on port 53. If your DNS server is not in an Amazon VPC, it must have appropriate firewall settings to allow UDP and TCP inbound traffic on port 53.

For more information, see Security groups for your VPC and Adding and removing rules.

6. Configure the VPC of your Amazon RDS DB instance to allow outbound traffic over port 53. Your VPC must have a security group that contains outbound rules that allow UDP and TCP traffic on port 53.

For more information, see Security groups for your VPC and Adding and removing rules in the Amazon VPC User Guide.

7. Make sure that the routing path between the Amazon RDS DB instance and the DNS server is configured correctly to allow DNS traffic.

Also, if the Amazon RDS DB instance and the DNS server are not in the same VPC, make sure that a peering connection is set up between them. For more information, see What is VPC peering? in Amazon VPC Peering Guide.
Upgrading the PostgreSQL DB engine for Amazon RDS

There are two types of upgrades you can manage for your PostgreSQL database:

- Operating system updates – Occasionally, Amazon RDS might need to update the underlying operating system of your database to apply security fixes or OS changes. You can decide when Amazon RDS applies OS updates by using the RDS console, AWS Command Line Interface (AWS CLI), or RDS API. For more information about OS updates, see Applying updates for a DB instance (p. 421).
- Database engine upgrades – When Amazon RDS supports a new version of a database engine, you can upgrade your databases to the new version.

A **database** in this context is an RDS for PostgreSQL DB instance or Multi-AZ DB cluster.

There are two kinds of upgrades for PostgreSQL databases: major version upgrades and minor version upgrades.

**Major version upgrades**

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your databases. You can initiate a major version upgrade by modifying your DB instance or Multi-AZ DB cluster. However, before you perform a major version upgrade, we recommend that you follow the steps described in Choosing a major version upgrade for PostgreSQL (p. 2217).

If you're upgrading a DB instance that has in-Region read replicas, Amazon RDS upgrades the replicas along with the primary DB instance.

Amazon RDS doesn't upgrade Multi-AZ DB cluster read replicas. If you perform a major version upgrade of a Multi-AZ DB cluster, the replication state of its read replicas changes to terminated. You must manually delete and recreate the read replicas after the upgrade completes.

**Minor version upgrades**

In contrast, minor version upgrades include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your database. Or you can enable the Auto minor version upgrade option when creating or modifying a database. Doing so means that your database is automatically upgraded after Amazon RDS tests and approves the new version. If your PostgreSQL database is using read replicas, you must first upgrade all of the read replicas before upgrading the source instance or cluster.

If your database is a Multi-AZ DB instance deployment, the primary and any standby instances are upgraded simultaneously. If your database is a Multi-AZ DB cluster deployment, the writer and reader instances are upgraded simultaneously. Therefore, your database might not be available until the upgrade is complete. For more details, see Automatic minor version upgrades for PostgreSQL (p. 2224). For information about manually performing a minor version upgrade, see Manually upgrading the engine version (p. 429).

For more information about database engine versions, and the policy for deprecating database engine versions, see Database Engine Versions in the Amazon RDS FAQs.

**Topics**

- Overview of upgrading PostgreSQL (p. 2215)
- PostgreSQL version numbers (p. 2216)
- RDS version number (p. 2216)
Overview of upgrading PostgreSQL

To safely upgrade your databases, Amazon RDS uses the `pg_upgrade` utility described in the PostgreSQL documentation.

When you use the AWS Management Console to upgrade a database, it shows the valid upgrade targets for the database. You can also use the following AWS CLI command to identify the valid upgrade targets for a database:

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions \
   --engine postgres \
   --engine-version version-number \
   --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

For Windows:

```bash
aws rds describe-db-engine-versions ^
   --engine postgres ^
   --engine-version version-number ^
   --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

For example, to identify the valid upgrade targets for a PostgreSQL version 12.13 database, run the following AWS CLI command:

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions \
   --engine postgres \
   --engine-version 12.13 \
   --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

For Windows:

```bash
aws rds describe-db-engine-versions ^
   --engine postgres ^
   --engine-version 12.13 ^
   --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

If your backup retention period is greater than 0, Amazon RDS takes two DB snapshots during the upgrade process. The first DB snapshot is of the database before any upgrade changes have been made. If the upgrade fails for your databases, you can restore this snapshot to create a database running the old version. The second DB snapshot is taken after the upgrade completes.

**Note**

Amazon RDS takes DB snapshots during the upgrade process only if you have set the backup retention period for your database to a number greater than 0. To change the backup retention
period for a DB instance, see the section called “Modifying a DB instance” (p. 401). You can’t configure a custom backup retention period for a Multi-AZ DB cluster.

When you perform a major version upgrade of a DB instance, any in-Region read replicas are also automatically upgraded. After the upgrade workflow starts, the read replicas wait for the pg_upgrade to complete successfully on the primary DB instance. Then the primary DB instance upgrade waits for the read replica upgrades to complete. You experience an outage until the upgrade is complete. When you perform a major version upgrade of a Multi-AZ DB cluster, the replication state of its read replicas changes to terminated.

If your database is in a Multi-AZ DB instance deployment, both the primary DB instance and standby replicas are upgraded simultaneously. If your database is a Multi-AZ DB cluster deployment, the writer DB instance is upgraded first, then the reader DB instances are upgraded simultaneously.

After an upgrade is complete, you can’t revert to the previous version of the DB engine. If you want to return to the previous version, restore the DB snapshot that was taken before the upgrade to create a new database.

**PostgreSQL version numbers**

The version numbering sequence for the PostgreSQL database engine is as follows:

- For PostgreSQL versions 10 and later, the engine version number is in the form `major.minor`. The major version number is the integer part of the version number. The minor version number is the fractional part of the version number.

  A major version upgrade increases the integer part of the version number, such as upgrading from `10.minor` to `11.minor`.

- For PostgreSQL versions earlier than 10, the engine version number is in the form `major.major.minor`. The major engine version number is both the integer and the first fractional part of the version number. For example, 9.6 is a major version. The minor version number is the third part of the version number. For example, for version 9.6.12, the 12 is the minor version number.

  A major version upgrade increases the major part of the version number. For example, an upgrade from `9.6.12` to `11.14` is a major version upgrade, where `9.6` and `11` are the major version numbers.

**RDS version number**

RDS version numbers use the `major.minor.patch` naming scheme. An RDS patch version includes important bug fixes added to a minor version after its release. To identify the Amazon RDS version number of your database, you must first create the `rds_tools` extension by using the following command:

```
CREATE EXTENSION rds_tools;
```

Starting with the release of PostgreSQL version 15.2-R2, you can find out the RDS version number of your RDS for PostgreSQL database with the following SQL query:

```
postgres=> SELECT rds_tools.rds_version();
```

For example, querying an RDS for PostgreSQL 15.2 database returns the following:

```
rds_version
----------------
15.2.R2
(1 row)
```
Choosing a major version upgrade for PostgreSQL

Major version upgrades can contain changes that are not backward-compatible with previous versions of the database. New functionality can cause your existing applications to stop working correctly. For this reason, Amazon RDS doesn't apply major version upgrades automatically. To perform a major version upgrade, you modify your database manually. Make sure that you thoroughly test any upgrade to verify that your applications work correctly before applying the upgrade to your production databases. When you do a PostgreSQL major version upgrade, we recommend that you follow the steps described in How to perform a major version upgrade (p. 2220).

When you upgrade a PostgreSQL Single-AZ DB instance or Multi-AZ DB instance deployment to its next major version, any read replicas associated with the database are also upgraded to that next major version. In some cases, you can skip to a higher major version when upgrading. If your upgrade skips a major version, the read replicas are also upgraded to that target major version. Upgrades to version 11 that skip other major versions have certain limitations. You can find the details in the steps described in How to perform a major version upgrade (p. 2220).

Most PostgreSQL extensions aren't upgraded during a PostgreSQL engine upgrade. These must be upgraded separately. For more information, see Upgrading PostgreSQL extensions (p. 2226).

You can find out which major versions are available for your RDS for PostgreSQL database by running the following AWS CLI query:

```bash
aws rds describe-db-engine-versions --engine postgres --engine-version your-version --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

The following table summarizes the results of this query for all available versions. An asterisk (*) on the version number means that version is deprecated. If your current version is deprecated, we recommend that you upgrade to the newest minor version upgrade target or to one of the other available upgrade targets for that version. For more information about the RDS for PostgreSQL version 9.6 deprecation, see Deprecation of PostgreSQL version 9.6 (p. 2172). For more information about the RDS for PostgreSQL version 10 deprecation, see Deprecation of PostgreSQL version 10 (p. 2171).

*Deprecated*
How to perform a major version upgrade

We recommend the following process when performing a major version upgrade on an Amazon RDS for PostgreSQL database:

1. **Have a version-compatible parameter group ready** – If you are using a custom parameter group, you have two options. You can specify a default parameter group for the new DB engine version. Or you can create your own custom parameter group for the new DB engine version. For more information, see the section called “Working with parameter groups” (p. 347) and the section called “Working with DB cluster parameter groups” (p. 360).

2. **Check for unsupported database classes** – Check that your database's instance class is compatible with the PostgreSQL version you are upgrading to. For more information, see Supported DB engines for DB instance classes (p. 14).

3. **Check for unsupported usage:**
   - **Prepared transactions** – Commit or roll back all open prepared transactions before attempting an upgrade.
     
     You can use the following query to verify that there are no open prepared transactions on your database.
     
     ```sql
     SELECT count(*) FROM pg_catalog.pg_prepared_xacts;
     ```
   
   - **Reg* data types** – Remove all uses of the reg* data types before attempting an upgrade. Except for regtype and regclass, you can't upgrade the reg* data types. The pg_upgrade utility can't persist this data type, which is used by Amazon RDS to do the upgrade.
     
     To verify that there are no uses of unsupported reg* data types, use the following query for each database.
     
     ```sql
     SELECT count(*) FROM pg_catalog.pg_class c, pg_catalog.pg_namespace n, pg_catalog.pg_attribute a
     WHERE c.oid = a.attrelid
     AND NOT a.attisdropped
     AND a.atttypid IN ('pg_catalog.regproc'::pg_catalog.regtype,
     'pg_catalog.regprocedure'::pg_catalog.regtype,
     'pg_catalog.regoper'::pg_catalog.regtype,
     'pg_catalog.regoperator'::pg_catalog.regtype,
     'pg_catalog.regconfig'::pg_catalog.regtype,
     'pg_catalog.regdictionary'::pg_catalog.regtype)
     AND c.relnamespace = n.oid
     AND n.nspname NOT IN ('pg_catalog', 'information_schema');
     ```

4. **Handle logical replication slots** – An upgrade can't occur if the database has any logical replication slots. Logical replication slots are typically used for AWS DMS migration and for replicating tables from the database to data lakes, BI tools, and other targets. Before upgrading, make sure that you know the purpose of any logical replication slots that are in use, and confirm that it's okay to delete them. If the logical replication slots are still being used, you shouldn't delete them, and you can't proceed with the upgrade.

   If the logical replication slots aren't needed, you can delete them using the following SQL:

   ```sql
   SELECT * FROM pg_replication_slots;
   SELECT pg_drop_replication_slot(slot_name);
   ```
Logical replication setups that use the `pglogical` extension also need to have slots dropped for a successful major version upgrade. For information about how to identify and drop slots created using the `pglogical` extension, see Managing logical replication slots for RDS for PostgreSQL (p. 2402).

5. **Handle read replicas** – An upgrade of a Single-AZ DB instance or Multi-AZ DB instance deployment also upgrades the in-Region read replicas along with the primary DB instance. Amazon RDS doesn't upgrade Multi-AZ DB cluster read replicas.

   You can’t upgrade read replicas separately. If you could, it could lead to situations where the primary and replica databases have different PostgreSQL major versions. However, read replica upgrades might increase downtime on the primary DB instance. To prevent a read replica upgrade, promote the replica to a standalone instance or delete it before starting the upgrade process.

   The upgrade process recreates the read replica's parameter group based on the read replica's current parameter group. You can apply a custom parameter group to a read replica only after the upgrade completes by modifying the read replica. For more information about read replicas, see Working with read replicas for Amazon RDS for PostgreSQL (p. 2229).

6. **Perform a backup** – We recommend that you perform a backup before performing the major version upgrade so that you have a known restore point for your database. If your backup retention period is greater than 0, the upgrade process creates DB snapshots of your database before and after upgrading. To change your backup retention period, see Modifying an Amazon RDS DB instance (p. 401) and the section called “Modifying a Multi-AZ DB cluster” (p. 539).

   To perform a backup manually, see the section called “Creating a DB snapshot” (p. 613) and the section called “Creating a Multi-AZ DB cluster snapshot” (p. 669).

7. **Upgrade certain extensions before a major version upgrade** – If you plan to skip a major version with the upgrade, you need to update certain extensions before performing the major version upgrade. For example, upgrading from versions 9.5.x or 9.6.x to version 11.x skips a major version. The extensions to update include PostGIS and related extensions for processing spatial data.
   
   - address_standardizer
   - address_standardizer_data_us
   - postgis_raster
   - postgis_tiger_geocoder
   - postgis_topology

   Run the following command for each extension that you're using:

   ```sql
   ALTER EXTENSION PostgreSQL-extension UPDATE TO 'new-version';
   ```

   For more information, see Upgrading PostgreSQL extensions (p. 2226). To learn more about upgrading PostGIS, see Step 6: Upgrade the PostGIS extension (p. 2414).

8. **Drop certain extensions before the major version upgrade** – An upgrade that skips a major version to version 11.x doesn’t support updating the `pgRouting` extension. Upgrading from versions 9.4.x, 9.5.x, or 9.6.x to versions 11.x skips a major version. It’s safe to drop the `pgRouting` extension and then reinstall it to a compatible version after the upgrade. For the extension versions you can update to, see Supported PostgreSQL extension versions (p. 2173).

   The `tsearch2` and `chkpass` extensions are no longer supported for PostgreSQL versions 11 or later. If you are upgrading to version 11.x, drop the `tsearch2`, and `chkpass` extensions before the upgrade.

9. **Drop unknown data types** – Drop unknown data types depending on the target version.

   PostgreSQL version 10 stopped supporting the unknown data type. If a version 9.6 database uses the unknown data type, an upgrade to a version 10 shows an error message such as the following:
Database instance is in a state that cannot be upgraded: PreUpgrade checks failed: The instance could not be upgraded because the 'unknown' data type is used in user tables. 
Please remove all usages of the 'unknown' data type and try again."

To find the unknown data type in your database so you can remove the offending column or change it to a supported data type, use the following SQL:

```
SELECT DISTINCT data_type FROM information_schema.columns WHERE data_type ILIKE 'unknown';
```

10. **Perform an upgrade dry run** – We highly recommend testing a major version upgrade on a duplicate of your production database before attempting the upgrade on your production database. You can monitor the execution plans on the duplicate test database for any possible execution plan regressions and to evaluate its performance. To create a duplicate test instance, you can either restore your database from a recent snapshot or do a point-in-time restore of your database to its latest restorable time.

For more information, see the section called “Restoring from a snapshot” (p. 617) or the section called “Restoring a DB instance to a specified time” (p. 660). For Multi-AZ DB clusters, see the section called “Restoring from a snapshot to a Multi-AZ DB cluster” (p. 671) or the section called “Restoring a Multi-AZ DB cluster to a specified time” (p. 675).

For details on performing the upgrade, see the section called “Manually upgrading the engine version” (p. 429).

In upgrading a version 9.6 database to version 10, be aware that PostgreSQL 10 enables parallel queries by default. You can test the impact of parallelism before the upgrade by changing the max_parallel_workers_per_gather parameter on your test database to 2.

**Note**
The default value for max_parallel_workers_per_gather parameter in the default.postgresql10 DB parameter group is 2.

For more information, see Parallel Query in the PostgreSQL documentation. To disable parallelism on version 10, set the max_parallel_workers_per_gather parameter to 0.

During the major version upgrade, the public and template1 databases and the public schema in every database are temporarily renamed. These objects appear in the logs with their original name and a random string appended. The string is appended so that custom settings such as locale and owner are preserved during the major version upgrade. After the upgrade completes, the objects are renamed back to their original names.

**Note**
During the major version upgrade process, you can’t do a point-in-time restore of your DB instance or Multi-AZ DB cluster. After Amazon RDS performs the upgrade, it takes an automatic backup of the database. You can perform a point-in-time restore to times before the upgrade began and after the automatic backup of your database has completed.

11. **If an upgrade fails with precheck procedure errors, resolve the issues** – During the major version upgrade process, Amazon RDS for PostgreSQL first runs a precheck procedure to identify any issues that might cause the upgrade to fail. The precheck procedure checks all potential incompatible conditions across all databases in the instance.

If the precheck encounters an issue, it creates a log event indicating the upgrade precheck failed. The precheck process details are in an upgrade log named pg upgrade precheck . log for all the databases of a database. Amazon RDS appends a timestamp to the file name. For more information about viewing logs, see Monitoring Amazon RDS log files (p. 895).
If a read replica upgrade fails at precheck, replication on the failed read replica is broken and the read replica is put in the terminated state. Delete the read replica and recreate a new read replica based on the upgraded primary DB instance.

Resolve all of the issues identified in the precheck log and then retry the major version upgrade. The following is an example of a precheck log.

```
Upgrade could not be run on Wed Apr 4 18:30:52 2018

The instance could not be upgraded from 9.6.11 to 10.6 for the following reasons.
Please take appropriate action on databases that have usage incompatible with the requested major engine version upgrade and try the upgrade again.

* There are uncommitted prepared transactions. Please commit or rollback all prepared transactions.* One or more role names start with 'pg_'. Rename all role names that start with 'pg_'.

* The following issues in the database 'my"million$"db' need to be corrected before upgrading:** The "["line","reg*"] data types are used in user tables. Remove all usage of these data types.
** The database name contains characters that are not supported by RDS for PostgreSQL. Rename the database.
** The database has extensions installed that are not supported on the target database version. Drop the following extensions from your database: ["tsearch2"].

* The following issues in the database 'mydb' need to be corrected before upgrading:** The database has views or materialized views that depend on 'pg_stat_activity'. Drop the views.
```

12If a read replica upgrade fails while upgrading the database, resolve the issue – A failed read replica is placed in the incompatible-restore state and replication is terminated on the database. Delete the read replica and recreate a new read replica based on the upgraded primary DB instance.

**Note**
Amazon RDS doesn't upgrade read replicas for Multi-AZ DB clusters. If you perform a major version upgrade on a Multi-AZ DB cluster, the replication state of its read replicas changes to terminated.

A read replica upgrade might fail for the following reasons:

- It was unable to catch up with the primary DB instance even after a wait time.
- It was in a terminal or incompatible lifecycle state such as storage-full, incompatible-restore, and so on.
- When the primary DB instance upgrade started, there was a separate minor version upgrade running on the read replica.
- The read replica used incompatible parameters.
- The read replica was unable to communicate with the primary DB instance to synchronize the data folder.

13Upgrade your production database – When the dry-run major version upgrade is successful, you should be able to upgrade your production database with confidence. For more information, see Manually upgrading the engine version (p. 429).

14Run the ANALYZE operation to refresh the pg_statistic table. You should do this for every database on all your PostgreSQL databases. Optimizer statistics aren't transferred during a major version upgrade, so you need to regenerate all statistics to avoid performance issues. Run the command without any parameters to generate statistics for all regular tables in the current database, as follows:
Analysis VERBOSE;

The VERBOSE flag is optional, but using it shows you the progress. For more information, see `ANALYZE` in the PostgreSQL documentation.

**Note**
Run ANALYZE on your system after the upgrade to avoid performance issues.

After the major version upgrade is complete, we recommend the following:

- A PostgreSQL upgrade doesn't upgrade any PostgreSQL extensions. To upgrade extensions, see [Upgrading PostgreSQL extensions](p. 2226).
- Optionally, use Amazon RDS to view two logs that the `pg_upgrade` utility produces. These are `pg_upgrade_internal.log` and `pg_upgrade_server.log`. Amazon RDS appends a timestamp to the file name for these logs. You can view these logs as you can any other log. For more information, see [Monitoring Amazon RDS log files](p. 895).

  You can also upload the upgrade logs to Amazon CloudWatch Logs. For more information, see [Publishing PostgreSQL logs to Amazon CloudWatch Logs](p. 936).
- To verify that everything works as expected, test your application on the upgraded database with a similar workload. After the upgrade is verified, you can delete this test instance.

### Automatic minor version upgrades for PostgreSQL

If you enable the **Auto minor version upgrade** option when creating or modifying a DB instance or Multi-AZ DB cluster, you can have your database automatically upgraded.

For each RDS for PostgreSQL major version, one minor version is designated by RDS as the automatic upgrade version. After a minor version has been tested and approved by Amazon RDS, the minor version upgrade occurs automatically during your maintenance window. RDS doesn't automatically set newer released minor versions as the automatic upgrade version. Before RDS designates a newer automatic upgrade version, several criteria are considered, such as the following:

- Known security issues
- Bugs in the PostgreSQL community version
- Overall fleet stability since the minor version was released

You can use the following AWS CLI command to determine the current automatic minor upgrade target version for a specified PostgreSQL minor version in a specific AWS Region.

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions
  --engine postgres
  --engine-version minor-version
  --region region
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" 
  --output text
```

For Windows:

```bash
aws rds describe-db-engine-versions ^
  --engine postgres ^
```

2224
For example, the following AWS CLI command determines the automatic minor upgrade target for PostgreSQL minor version 12.13 in the US East (Ohio) AWS Region (us-east-2).

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions \
  --engine postgres \
  --engine-version 12.13 \
  --region us-east-2 \
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].\n    {AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
  --output table
```

For Windows:

```bash
aws rds describe-db-engine-versions ^
  --engine postgres ^
  --engine-version 12.13 ^
  --region us-east-2 ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].\n    {AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
  --output table
```

Your output is similar to the following.

```
<table>
<thead>
<tr>
<th>DescribeDBEngineVersions</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>AutoUpgrade</td>
<td>EngineVersion</td>
</tr>
<tr>
<td>True</td>
<td>12.14</td>
</tr>
<tr>
<td>False</td>
<td>12.15</td>
</tr>
<tr>
<td>False</td>
<td>13.9</td>
</tr>
<tr>
<td>False</td>
<td>13.10</td>
</tr>
<tr>
<td>False</td>
<td>13.11</td>
</tr>
<tr>
<td>False</td>
<td>14.6</td>
</tr>
</tbody>
</table>
```

In this example, the `AutoUpgrade` value is `True` for PostgreSQL version 12.14. So, the automatic minor upgrade target is PostgreSQL version 12.14, which is highlighted in the output.

A PostgreSQL database is automatically upgraded during your maintenance window if the following criteria are met:

- The database has the **Auto minor version upgrade** option enabled.
- The database is running a minor DB engine version that is less than the current automatic upgrade minor version.

For more information, see [Automatically upgrading the minor engine version (p. 431)](https://docs.aws.amazon.com/rds/latest/relnotes/index.html#rds-relnotes-mysql-8.0.25).

**Note**

2225
Upgrading PostgreSQL extensions

A PostgreSQL engine upgrade doesn't upgrade most PostgreSQL extensions. To update an extension after a version upgrade, use the `ALTER EXTENSION UPDATE` command.

**Note**

For information about updating the PostGIS extension, see [Managing spatial data with the PostGIS extension (p. 2411)](https://example.com) ([Step 6: Upgrade the PostGIS extension (p. 2414)](https://example.com)).

To update the `pg_repack` extension, drop the extension and then create the new version in the upgraded database. For more information, see [pg_repack installation](https://example.com) in the `pg_repack` documentation.

To upgrade an extension, use the following command.

```
ALTER EXTENSION extension_name UPDATE TO 'new_version';
```

For the list of supported versions of PostgreSQL extensions, see [Supported PostgreSQL extension versions (p. 2173)](https://example.com).

To list your currently installed extensions, use the PostgreSQL `pg_extension` catalog in the following command.

```
SELECT * FROM pg_extension;
```

To view a list of the specific extension versions that are available for your installation, use the PostgreSQL `pg_available_extension_versions` view in the following command.

```
SELECT * FROM pg_available_extension_versions;
```
Upgrading a PostgreSQL DB snapshot engine version

With Amazon RDS, you can create a storage volume DB snapshot of your PostgreSQL DB instance. When you create a DB snapshot, the snapshot is based on the engine version used by your Amazon RDS instance. In addition to upgrading the DB engine version of your DB instance, you can also upgrade the engine version for your DB snapshots.

After restoring a DB snapshot upgraded to a new engine version, make sure to test that the upgrade was successful. For more information about a major version upgrade, see Upgrading the PostgreSQL DB engine for Amazon RDS (p. 2214). To learn how to restore a DB snapshot, see Restoring from a DB snapshot (p. 615).

You can upgrade manual DB snapshots that are either encrypted or not encrypted.

For the list of engine versions that are available for upgrading a DB snapshot, see Upgrading the PostgreSQL DB engine for Amazon RDS.

Note
You can't upgrade automated DB snapshots that are created during the automated backup process.

Console

To upgrade a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Choose the snapshot that you want to upgrade.
4. For Actions, choose Upgrade snapshot. The Upgrade snapshot page appears.
5. Choose the New engine version to upgrade to.
6. Choose Save changes to upgrade the snapshot.

During the upgrade process, all snapshot actions are disabled for this DB snapshot. Also, the DB snapshot status changes from available to upgrading, and then changes to active upon completion. If the DB snapshot can't be upgraded because of snapshot corruption issues, the status changes to unavailable. You can't recover the snapshot from this state.

Note
If the DB snapshot upgrade fails, the snapshot is rolled back to the original state with the original version.

AWS CLI

To upgrade a DB snapshot to a new database engine version, use the AWS CLI modify-db-snapshot command.

Parameters

- --db-snapshot-identifier – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 471).
- --engine-version – The engine version to upgrade the DB snapshot to.
Example

For Linux, macOS, or Unix:

```bash
aws rds modify-db-snapshot \
    --db-snapshot-identifier my_db_snapshot \
    --engine-version new_version
```

For Windows:

```bash
aws rds modify-db-snapshot ^
    --db-snapshot-identifier my_db_snapshot ^
    --engine-version new_version
```

RDS API

To upgrade a DB snapshot to a new database engine version, call the Amazon RDS API `ModifyDBSnapshot` operation.

- **DBSnapshotIdentifier** – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 471).
- **EngineVersion** – The engine version to upgrade the DB snapshot to.
You can scale reads for your Amazon RDS for PostgreSQL DB instance by adding read replicas to the instance. As with other Amazon RDS database engines, RDS for PostgreSQL uses the native replication mechanisms of PostgreSQL to keep read replicas up to date with changes on the source DB. For general information about read replicas and Amazon RDS, see Working with DB instance read replicas (p. 438).

Following, you can find information specific to working with read replicas with RDS for PostgreSQL.

Contents

- Read replica limitations with PostgreSQL (p. 2229)

- How streaming replication works for different RDS for PostgreSQL versions (p. 2232)
  - Understanding the parameters that control PostgreSQL replication (p. 2233)
    - Example: How a read replica recovers from replication interruptions (p. 2234)
  - Setting the parameters that control shared memory (p. 2234)
- Monitoring and tuning the replication process (p. 2235)
  - Monitoring replication slots for your RDS for PostgreSQL DB instance (p. 2236)

Read replica limitations with PostgreSQL

The following are limitations for PostgreSQL read replicas:

- PostgreSQL read replicas are read-only. Although a read replica isn't a writeable DB instance, you can promote it to become a standalone RDS for PostgreSQL DB instance. However, the process isn't reversible.

- You can't create a read replica from another read replica if your RDS for PostgreSQL DB instance is running a PostgreSQL version earlier than 14.1. RDS for PostgreSQL supports cascading read replicas on RDS for PostgreSQL version 14.1 and higher releases only. For more information, see Using cascading read replicas with RDS for PostgreSQL (p. 2231).

- If you promote a PostgreSQL read replica, it becomes a writable DB instance. It stops receiving write-ahead log (WAL) files from a source DB instance, and it's no longer a read-only instance. You can create new read replicas from the promoted DB instance as you do for any RDS for PostgreSQL DB instance. For more information, see Promoting a read replica to be a standalone DB instance (p. 447).

- If you promote a PostgreSQL read replica from within a replication chain (a series of cascading read replicas), any existing downstream read replicas continue receiving WAL files from the promoted instance, automatically. For more information, see Using cascading read replicas with RDS for PostgreSQL (p. 2231).

- If no user transactions are running on the source DB instance, the associated PostgreSQL read replica reports a replication lag of up to five minutes. The replica lag is calculated as \( \text{currentTime} - \text{lastCommittedTransactionTimestamp} \), which means that when no transactions are being processed, the value of replica lag increases for a period of time until the write-ahead log (WAL) segment switches. By default RDS for PostgreSQL switches the WAL segment every 5 minutes, which results in a transaction record and a decrease in the reported lag.

- You can't turn on automated backups for PostgreSQL read replicas for RDS for PostgreSQL versions earlier than 14.1. Automated backups for read replicas are supported for RDS for PostgreSQL 14.1 and
higher versions only. For RDS for PostgreSQL 13 and earlier versions, create a snapshot from a read replica if you want a backup of it.

- Point-in-time recovery (PITR) isn’t supported for read replicas. You can use PITR with a primary (writer) instance only, not a read replica. To learn more, see Restoring a DB instance to a specified time (p. 660).

Read replica configuration with PostgreSQL

RDS for PostgreSQL uses PostgreSQL native streaming replication to create a read-only copy of a source DB instance. This read replica DB instance is an asynchronously created physical replica of the source DB instance. It’s created by a special connection that transmits write ahead log (WAL) data from the source DB instance to the read replica. For more information, see Streaming Replication in the PostgreSQL documentation.

PostgreSQL asynchronously streams database changes to this secure connection as they’re made on the source DB instance. You can encrypt communications from your client applications to the source DB instance or any read replicas by setting the ssl parameter to 1. For more information, see Using SSL with a PostgreSQL DB instance (p. 2191).

PostgreSQL uses a replication role to perform streaming replication. The role is privileged, but you can’t use it to modify any data. PostgreSQL uses a single process for handling replication.

You can create a PostgreSQL read replica without affecting operations or users of the source DB instance. Amazon RDS sets the necessary parameters and permissions for you, on the source DB instance and the read replica, without affecting the service. A snapshot is taken of the source DB instance, and this snapshot is used to create the read replica. If you delete the read replica at some point in the future, no outage occurs.

You can create up to 15 read replicas from one source DB instance within the same Region. As of RDS for PostgreSQL 14.1, you can also create up to three levels of read replica in a chain (cascade) from a source DB instance. For more information, see Using cascading read replicas with RDS for PostgreSQL (p. 2231). In all cases, the source DB instance needs to have automated backups configured. You do this by setting the backup retention period on your DB instance to any value other than 0. For more information, see Creating a read replica (p. 445).

You can create read replicas for your RDS for PostgreSQL DB instance in the same AWS Region as your source DB instance. This is known as in-Region replication. You can also create read replicas in different AWS Regions than the source DB instance. This is known as cross-Region replication. For more information about setting up cross-Region read replicas, see Creating a read replica in a different AWS Region (p. 452). The various mechanisms supporting the replication process for in-Region and cross-Region differ slightly depending on the RDS for PostgreSQL version as explained in How streaming replication works for different RDS for PostgreSQL versions (p. 2232).

For replication to operate effectively, each read replica should have the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, be sure to also scale the read replicas.

Amazon RDS overrides any incompatible parameters on a read replica if they prevent the read replica from starting. For example, suppose that the max_connections parameter value is higher on the source DB instance than on the read replica. In that case, Amazon RDS updates the parameter on the read replica to be the same value as that on the source DB instance.

RDS for PostgreSQL read replicas have access to external databases that are available through foreign data wrappers (FDWs) on the source DB instance. For example, suppose that your RDS for PostgreSQL DB instance is using the mysql_fdw wrapper to access data from RDS for MySQL. If so, your read replicas can also access that data. Other supported FDWs include oracle_fdw, postgres_fdw, and tds_fdw.
For more information, see Working with the supported foreign data wrappers for Amazon RDS for PostgreSQL (p. 2418).

Using RDS for PostgreSQL read replicas with Multi-AZ configurations

You can create a read replica from a single-AZ or Multi-AZ DB instance. You can use Multi-AZ deployments to improve the durability and availability of critical data, with a standby replica. A **standby replica** is a dedicated read replica that can assume the workload if the source DB fails over. You can't use your standby replica to serve read traffic. However, you can create read replicas from high-traffic Multi-AZ DB instances to offload read-only queries. To learn more about Multi-AZ deployments, see Multi-AZ DB instance deployments (p. 493).

If the source DB instance of a Multi-AZ deployment fails over to a standby, the associated read replicas switch to using the standby (now primary) as their replication source. The read replicas might need to restart, depending on the RDS for PostgreSQL version, as follows:

- **PostgreSQL 13 and higher versions** – Restarting isn't required. The read replicas are automatically synchronized with the new primary. However, in some cases your client application might cache Domain Name Service (DNS) details for your read replicas. If so, set the time-to-live (TTL) value to less than 30 seconds. Doing this prevents the read replica from holding on to a stale IP address (and thus, prevents it from synchronizing with the new primary). To learn more about this and other best practices, see Amazon RDS basic operational guidelines (p. 286).

- **PostgreSQL 12 and all earlier versions** – The read replicas restart automatically after a fail over to the standby replica because the standby (now primary) has a different IP address and a different instance name. Restarting synchronizes the read replica with the new primary.

To learn more about failover, see Failover process for Amazon RDS (p. 495). To learn more about how read replicas work in a Multi-AZ deployment, see Working with DB instance read replicas (p. 438).

To provide failover support for a read replica, you can create the read replica as a Multi-AZ DB instance so that Amazon RDS creates a standby of your replica in another Availability Zone (AZ). Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.

Using cascading read replicas with RDS for PostgreSQL

As of version 14.1, RDS for PostgreSQL supports cascading read replicas. With **cascading read replicas**, you can scale reads without adding overhead to your source RDS for PostgreSQL DB instance. Updates to the WAL log aren't sent by the source DB instance to each read replica. Instead, each read replica in a cascading series sends WAL log updates to the next read replica in the series. This reduces the burden on the source DB instance.

With cascading read replicas, your RDS for PostgreSQL DB instance sends WAL data to the first read replica in the chain. That read replica then sends WAL data to the second replica in the chain, and so on. The end result is that all read replicas in the chain have the changes from the RDS for PostgreSQL DB instance, but without the overhead solely on the source DB instance.

You can create a series of up to three read replicas in a chain from a source RDS for PostgreSQL DB instance. For example, suppose that you have an RDS for PostgreSQL 14.1 DB instance, `rpg-db-main`. You can do the following:

- Starting with `rpg-db-main`, create the first read replica in the chain, `read-replica-1`.
- Next, from `read-replica-1`, create the next read replica in the chain, `read-replica-2`.
- Finally, from `read-replica-2`, create the third read replica in the chain, `read-replica-3`. 

2231
You can't create another read replica beyond this third cascading read replica in the series for \texttt{rpg-db-main}. A complete series of instances from an RDS for PostgreSQL source DB instance through to the end of a series of cascading read replicas can consist of at most four DB instances.

For cascading read replicas to work, turn on automatic backups on your RDS for PostgreSQL. Create the read replica first and then turn on automatic backups on the RDS for PostgreSQL DB instance. The process is the same as for other Amazon RDS DB engines. For more information, see Creating a read replica (p. 445).

As with any read replica, you can promote a read replica that's part of a cascade. Promoting a read replica from within a chain of read replicas removes that replica from the chain. For example, suppose that you want to move some of the workload off of your \texttt{rpg-db-main} DB instance to a new instance for use by the accounting department only. Assuming the chain of three read replicas from the example, you decide to promote \texttt{read-replica-2}. The chain is affected as follows:

- Promoting \texttt{read-replica-2} removes it from the replication chain.
- It is now a full read/write DB instance.
- It continues replicating to \texttt{read-replica-3}, just as it was doing before promotion.
- Your \texttt{rpg-db-main} continues replicating to \texttt{read-replica-1}.

For more information about promoting read replicas, see Promoting a read replica to be a standalone DB instance (p. 447).

\textbf{Note}

For cascading read replicas, RDS for PostgreSQL supports 15 read replicas for each source DB instance at first level of replication, and 5 read replicas for each source DB instance at the second and third level of replication.

\section*{How streaming replication works for different RDS for PostgreSQL versions}

As discussed in Read replica configuration with PostgreSQL (p. 2230), RDS for PostgreSQL uses PostgreSQL's native streaming replication protocol to send WAL data from the source DB instance. It sends source WAL data to read replicas for both in-Region and cross-Region read replicas. With version 9.4, PostgreSQL introduced physical replication slots as a supporting mechanism for the replication process.

A physical replication slot prevents a source DB instance from removing WAL data before it's consumed by all read replicas. Each read replica has its own physical slot on the source DB instance. The slot keeps track of the oldest WAL (by logical sequence number, LSN) that might be needed by the replica. After all slots and DB connections have progressed beyond a given WAL (LSN), that LSN becomes a candidate for removal at the next checkpoint.

Amazon RDS uses Amazon S3 to archive WAL data. For in-Region read replicas, you can use this archived data to recover the read replica when necessary. An example of when you might do so is if the connection between source DB and read replica is interrupted for any reason.

In the following table, you can find a summary of differences between PostgreSQL versions and the supporting mechanisms for in-Region and cross-Region used by RDS for PostgreSQL.

<table>
<thead>
<tr>
<th>In-Region</th>
<th>Cross-Region</th>
</tr>
</thead>
<tbody>
<tr>
<td>PostgreSQL 14.1 and higher versions</td>
<td>• Replication slots</td>
</tr>
<tr>
<td>• Replication slots</td>
<td>• Replication slots</td>
</tr>
<tr>
<td>• Amazon S3 archive</td>
<td></td>
</tr>
</tbody>
</table>
How replication works for different RDS for PostgreSQL versions

<table>
<thead>
<tr>
<th>In-Region</th>
<th>Cross-Region</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>PostgreSQL 13 and lower versions</strong></td>
<td><strong>Replication slots</strong></td>
</tr>
<tr>
<td>• Amazon S3 archive</td>
<td></td>
</tr>
</tbody>
</table>

For more information, see Monitoring and tuning the replication process (p. 2235).

Understanding the parameters that control PostgreSQL replication

The following parameters affect the replication process and determine how well read replicas stay up to date with the source DB instance:

**max_wal_senders**

The `max_wal_senders` parameter specifies the maximum number of connections that the source DB instance can support at the same time over the streaming replication protocol. The default for RDS for PostgreSQL 13 and higher releases is 20. This parameter should be set to slightly higher than the actual number of read replicas. If this parameter is set too low for the number of read replicas, replication stops.

For more information, see `max_wal_senders` in the PostgreSQL documentation.

**wal_keep_segments**

The `wal_keep_segments` parameter specifies the number of write-ahead log (WAL) files that the source DB instance keeps in the `pg_wal` directory. The default setting is 32.

If `wal_keep_segments` isn't set to a large enough value for your deployment, a read replica can fall so far behind that streaming replication stops. If that happens, Amazon RDS generates a replication error and begins recovery on the read replica. It does so by replaying the source DB instance's archived WAL data from Amazon S3. This recovery process continues until the read replica has caught up enough to continue streaming replication. You can see this process in action as captured by the PostgreSQL log in Example: How a read replica recovers from replication interruptions (p. 2234).

**Note**

In PostgreSQL version 13, the `wal_keep_segments` parameter is named `wal_keep_size`. It serves the same purpose as `wal_keep_segments`, but its default value is in megabytes (MB) (2048 MB) rather than the number of files. For more information, see `wal_keep_segments` and `wal_keep_size` in the PostgreSQL documentation.

**max_slot_wal_keep_size**

The `max_slot_wal_keep_size` parameter controls the quantity of WAL data that the RDS for PostgreSQL DB instance retains in the `pg_wal` directory to serve slots. This parameter is used for configurations that use replication slots. The default value for this parameter is -1, meaning that there's no limit to how much WAL data is kept on the source DB instance. For information about monitoring your replication slots, see Monitoring replication slots for your RDS for PostgreSQL DB instance (p. 2236).

For more information about this parameter, see `max_slot_wal_keep_size` in the PostgreSQL documentation.

Whenever the stream that provides WAL data to a read replica is interrupted, PostgreSQL switches into recovery mode. It restores the read replica by using archived WAL data from Amazon S3 or by using
the using WAL data associated with the replication slot. When this process is complete, PostgreSQL re-estabishes streaming replication.

**Example: How a read replica recovers from replication interruptions**

In the following example, you find the log details that demonstrate the recovery process for a read replica. The example is from an RDS for PostgreSQL DB instance running PostgreSQL version 12.9 in the same AWS Region as the source DB, so replication slots aren't used. The recovery process is the same for other RDS for PostgreSQL DB instances running PostgreSQL earlier than version 14.1 with in-Region read replicas.

When the read replica lost contact with the source DB instance, Amazon RDS records the issue in the log as **FATAL: could not receive data from WAL stream** message, along with the **ERROR: requested WAL segment ... has already been removed**. As shown in the bold line, Amazon RDS recovers the replica by replaying an archived WAL file.

```
2014-11-07 19:01:10 UTC::@:[23180]:DEBUG: switched WAL source from archive to stream after failure
2014-11-07 19:01:10 UTC::@:[11575]:LOG: started streaming WAL from primary at 1A/D3000000 on timeline 1
2014-11-07 19:01:10 UTC::@:[11575]:FATAL: could not receive data from WAL stream:
ERROR: requested WAL segment 00000010000001A000000D3 has already been removed
2014-11-07 19:01:10 UTC::@:[23180]:DEBUG: could not restore file "00000002.history" from archive: return code 0
2014-11-07 19:01:15 UTC::@:[23180]:DEBUG: switched WAL source from stream to archive after failure recovering 000000010000001A000000D3
2014-11-07 19:01:16 UTC::@:[23180]:LOG: restored log file "000000010000001A000000D3" from archive
```

When Amazon RDS replays enough archived WAL data on the replica to catch up, streaming to the read replica begins again. When streaming resumes, Amazon RDS writes an entry to the log file similar to the following.

```
2014-11-07 19:41:36 UTC::@:[24714]:LOG:started streaming WAL from primary at 1B/B6000000 on timeline 1
```

**Setting the parameters that control shared memory**

The parameters you set determine the size of shared memory for tracking transaction IDs, locks, and prepared transactions. **The shared memory structure of a standby instance must be equal or greater than that of a primary instance.** This ensures that the former doesn't run out of shared memory during recovery. If the parameter values on the replica are less than the parameter values on the primary, Amazon RDS will automatically adjust the replica parameters and restart the engine.

The parameters affected are:

- `max_connections`
- `max_worker_processes`
- `max_wal_senders`
- `max_prepared_transactions`
- `max_locks_per_transaction`

To avoid RDS reboots of replicas due to insufficient memory, we recommend applying the parameter changes as a rolling reboot to each replica. You must apply the following rules, when you set the parameters:

- **Increasing the parameter values:**
Monitoring and tuning the replication process

You should always increase the parameter values of all the read replicas first, and perform a rolling reboot of all replicas. Then, apply the parameter changes on the primary instance and reboot.

Decreasing the parameter values:

You should first decrease the parameter values of the primary instance and perform a reboot. Then, apply the parameter changes to all the associated read replicas and perform a rolling reboot.

Monitoring and tuning the replication process

We strongly recommend that you routinely monitor your RDS for PostgreSQL DB instance and read replicas. You need to ensure that your read replicas are keeping up with changes on the source DB instance. Amazon RDS transparently recovers your read replicas when interruptions to the replication process occur. However, it's best to avoid needing to recover at all. Recovering using replication slots is faster than using the Amazon S3 archive, but any recovery process can affect read performance.

To determine how well your read replicas are keeping up with the source DB instance, you can do the following:

Check the amount of ReplicaLag between source DB instance and replicas. Replica lag is the amount of time, in milliseconds, that a read replica lags behind its source DB instance. This metric reports the result of the following query.

```
SELECT extract(epoch from now() - pg_last_xact_replay_timestamp()) AS replica_lag
```

Replica lag is an indication of how well a read replica is keeping up with the source DB instance. It's the amount of latency between the source DB instance and a specific read instance. A high value for replica lag can indicate a mismatch between the DB instance classes or storage types (or both) used by the source DB instance and its read replicas. The DB instance class and storage types for DB source instance and all read replicas should be the same.

Replica lag can also be the result of intermittent connection issues. You can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS ReplicaLag metric. To learn more about ReplicaLag and other metrics for Amazon RDS, see Amazon CloudWatch metrics for Amazon RDS (p. 806).

Check the PostgreSQL log for information you can use to adjust your settings. At every checkpoint, the PostgreSQL log captures the number of recycled transaction log files, as shown in the following example.

```
2014-11-07 19:59:35 UTC::@:
[26820]:LOG: checkpoint complete: wrote 376 buffers (0.2%);
0 transaction log file(s) added, 0 removed, 1 recycled;
write=35.681 s, sync=0.013 s, total=35.703 s;
sync files=10, longest=0.013 s, average=0.001 s
```

You can use this information to figure out how many transaction files are being recycled in a given time period. You can then change the setting for wal_keep_segments if necessary. For example, suppose that the PostgreSQL log at checkpoint complete shows 35 recycled for a 5-minute interval. In this case, the wal_keep_segments default value of 32 isn't sufficient to keep pace with the streaming activity, so you should increase the value of this parameter.

Use Amazon CloudWatch to monitor metrics that can predict replication issues. Rather than analyzing the PostgreSQL log directly, you can use Amazon CloudWatch to check metrics that have been collected. For example, you can check the value of the TransactionLogsGeneration metric to see how much WAL data is being generated by the source DB instance. In some cases, the workload on your DB instance might generate a large amount of WAL data. If so, you might need to change the DB instance class for your source DB instance and read replicas. Using an instance class with high (10 Gbps) network performance can reduce replica lag.
Monitoring replication slots for your RDS for PostgreSQL DB instance

All versions of RDS for PostgreSQL use replication slots for cross-Region read replicas. RDS for PostgreSQL 14.1 and higher versions use replication slots for in-Region read replicas. In-region read replicas also use Amazon S3 to archive WAL data. In other words, if your DB instance and read replicas are running PostgreSQL 14.1 or higher, replication slots and Amazon S3 archives are both available for recovering the read replica. Recovering a read replica using its replication slot is faster than recovering from Amazon S3 archive. So, we recommend that you monitor the replication slots and related metrics.

You can view the replication slots on your RDS for PostgreSQL DB instances by querying the `pg_replication_slots` view, as follows.

```
postgres=> SELECT * FROM pg_replication_slots;
slot_name                  | plugin | slot_type | datoid | database | temporary | active |
| active_pid | xmin | catalog_xmin | restart_lsn | confirmed_flush_lsn | wal_status | safe_wal_size | two_phase
---------------------------+--------+-----------+--------+----------+-----------+--------
+------------+------+--------------+-------------+---------------------+------------+-----------------------+------------+
| rds_us_west_1_db_555555555 |        | physical  |        |          | f         | t      | f            |           |
| 13194      |      |              | 23/D8000060 |                     | reserved   |         |             |           |
(1 row)
```

The `wal_status` of reserved value means that the amount of WAL data held by the slot is within the bounds of the `max_wal_size` parameter. In other words, the replication slot is properly sized. Other possible status values are as follows:

- **extended** – The slot exceeds the `max_wal_size` setting, but the WAL data is retained.
- **unreserved** – The slot no longer has the all required WAL data. Some of it will be removed at the next checkpoint.
- **lost** – Some required WAL data has been removed. The slot is no longer usable.

The `pg_replication_slots` view shows you the current state of your replication slots. To assess the performance of your replication slots, you can use Amazon CloudWatch and monitor the following metrics:

- **OldestReplicationSlotLag** – Lists the slot that has the most lag, that is the one that's furthest behind the primary. This lag can be associated with the read replica but also the connection.
- **TransactionLogsDiskUsage** – Shows how much storage is being used for WAL data. When a read replica lags significantly, the value of this metric can increase substantially.

To learn more about using Amazon CloudWatch and its metrics for RDS for PostgreSQL, see Monitoring Amazon RDS metrics with Amazon CloudWatch (p. 706). For more information about monitoring streaming replication on your RDS for PostgreSQL DB instances, see Best practices for Amazon RDS PostgreSQL replication on the AWS Database Blog.
Improving query performance for RDS for PostgreSQL with Amazon RDS Optimized Reads

You can achieve faster query processing for RDS for PostgreSQL with Amazon RDS Optimized Reads. An RDS for PostgreSQL DB instance or Multi-AZ DB cluster that uses RDS Optimized Reads can achieve up to 50% faster query processing compared to one that doesn't use it.

Topics
- Overview of RDS Optimized Reads in PostgreSQL (p. 2237)
- Use cases for RDS Optimized Reads (p. 2238)
- Best practices for RDS Optimized Reads (p. 2238)
- Using RDS Optimized Reads (p. 2238)
- Monitoring DB instances that use RDS Optimized Reads (p. 2239)
- Limitations for RDS Optimized Reads in PostgreSQL (p. 2239)

Overview of RDS Optimized Reads in PostgreSQL

Optimized Reads is available by default on RDS for PostgreSQL versions 15.2 and higher, 14.7 and higher, and 13.10 and higher.

When you use an RDS for PostgreSQL DB instance or Multi-AZ DB cluster that has RDS Optimized Reads turned on, it achieves up to 50% faster query performance using the local Non-Volatile Memory Express (NVMe) based solid state drive (SSD) block-level storage. You can achieve faster query processing by placing the temporary tables that are generated by PostgreSQL on the local storage, which reduces the traffic to Elastic Block Storage (EBS) over the network.

In PostgreSQL, temporary objects are assigned to a temporary namespace that drops automatically at the end of the session. The temporary namespace while dropping removes any objects that are session-dependent, including schema-qualified objects, such as tables, functions, operators, or even extensions.

In RDS for PostgreSQL, the temp_tablespaces parameter is configured for this temporary work area where the temporary objects are stored.

The following queries return the name of the tablespace and its location.

```
postgres=> show temp_tablespaces;
temp_tablespaces
---------------------
  rds_temp_tablespace
(1 row)
```

The rds_temp_tablespace is a tablespace configured by RDS that points to the NVMe local storage. You can always switch back to Amazon EBS storage by modifying this parameter in the Parameter group using the AWS Management Console to point to any tablespace other than rds_temp_tablespace. For more information, see Modifying parameters in a DB parameter group.

You can also use the SET command to modify the value of the temp_tablespaces parameter to pg_default at the session level using SET command. Modifying the parameter redirects the temporary work area to Amazon EBS. Switching back to Amazon EBS helps when the local storage for your RDS instance or cluster isn't sufficient to perform a specific SQL operation.

```
postgres=> SET temp_tablespaces TO 'pg_default';
```
Use cases for RDS Optimized Reads

The following are some use cases that can benefit from Optimized Reads:

- Analytical queries that include Common Table Expressions (CTEs), derived tables, and grouping operations.
- Read replicas that handle the unoptimized queries for an application.
- On-demand or dynamic reporting queries with complex operations such as GROUP BY and ORDER BY that can't always use appropriate indexes.
- Other workloads that use internal temporary tables.

Best practices for RDS Optimized Reads

Use the following best practices for RDS Optimized Reads:

- Add retry logic for read-only queries in case they fail because the instance store is full during the execution.
- Monitor the storage space available on the instance store with the CloudWatch metric `FreeLocalStorage`. If the instance store is reaching its limit because of the workload on the DB instance or Multi-AZ DB cluster, modify it to use a larger DB instance class.

Using RDS Optimized Reads

When you provision an RDS for PostgreSQL DB instance with one of the NVMe based DB instance classes in a Single-AZ DB instance deployment, Multi-AZ DB instance deployment, or Multi-AZ DB cluster deployment, the DB instance automatically uses RDS Optimized Reads.

For more information about Multi-AZ deployment, see Configuring and managing a Multi-AZ deployment.

To turn on RDS Optimized Reads, do one of the following:

- Create an RDS for PostgreSQL DB instance or Multi-AZ DB cluster using one of the NVMe based DB instance classes. For more information, see Creating an Amazon RDS DB instance (p. 300).
- Modify an existing RDS for PostgreSQL DB instance or Multi-AZ DB cluster to use one of the NVMe based DB instance classes. For more information, see Modifying an Amazon RDS DB instance (p. 401).

RDS Optimized Reads is available in all AWS Regions where one or more of the DB instance classes with local NVMe SSD storage are supported. For more information, see DB instance classes (p. 11).

To switch back to a non-optimized reads RDS instance, modify the DB instance class of your RDS instance or cluster to the similar class that only supports EBS storage for your database workloads. For example, if the current DB instance class is `db.r6gd.4xlarge`, choose `db.r6g.4xlarge` to switch back. For more information, see Modifying an Amazon RDS DB instance.
Monitoring DB instances that use RDS Optimized Reads

You can monitor DB instances that use RDS Optimized Reads using the following CloudWatch metrics:

- FreeLocalStorage
- ReadIOPSLocalStorage
- ReadLatencyLocalStorage
- ReadThroughputLocalStorage
- WriteIOPSLocalStorage
- WriteLatencyLocalStorage
- WriteThroughputLocalStorage

These metrics provide data about available instance store storage, IOPS, and throughput. For more information about these metrics, see Amazon CloudWatch instance-level metrics for Amazon RDS (p. 806).

To monitor current usage of your local storage, log in to your database using the following query:

```sql
SELECT spcname AS "Name",
       pg_catalog.pg_size_pretty(pg_catalog.pg_tablespace_size(oid)) AS "size"
FROM pg_catalog.pg_tablespace
WHERE spcname IN ('rds_temp_tablespace');
```

For more information about the temporary files and their usage, see Managing temporary files with PostgreSQL.

Limitations for RDS Optimized Reads in PostgreSQL

The following limitation apply to RDS Optimized Reads in PostgreSQL:

- Transactions can fail when the instance store is full.
Importing data into PostgreSQL on Amazon RDS

Suppose that you have an existing PostgreSQL deployment that you want to move to Amazon RDS. The complexity of your task depends on the size of your database and the types of database objects that you're transferring. For example, consider a database that contains datasets on the order of gigabytes, along with stored procedures and triggers. Such a database is going to be more complicated than a simple database with only a few megabytes of test data and no triggers or stored procedures.

We recommend that you use native PostgreSQL database migration tools under the following conditions:

- You have a homogeneous migration, where you are migrating from a database with the same database engine as the target database.
- You are migrating an entire database.
- The native tools allow you to migrate your system with minimal downtime.

In most other cases, performing a database migration using AWS Database Migration Service (AWS DMS) is the best approach. AWS DMS can migrate databases without downtime and, for many database engines, continue ongoing replication until you are ready to switch over to the target database. You can migrate to either the same database engine or a different database engine using AWS DMS. If you are migrating to a different database engine than your source database, you can use the AWS Schema Conversion Tool (AWS SCT). You use AWS SCT to migrate schema objects that are not migrated by AWS DMS. For more information about AWS DMS, see [What is AWS Database Migration Service?](#).

Modify your DB parameter group to include the following settings for your import only. You should test the parameter settings to find the most efficient settings for your DB instance size. You also need to revert back to production values for these parameters after your import completes.

Modify your DB instance settings to the following:

- Disable DB instance backups (set backup_retention to 0).
- Disable Multi-AZ.

Modify your DB parameter group to include the following settings. You should only use these settings when importing data. You should test the parameter settings to find the most efficient settings for your DB instance size. You also need to revert back to production values for these parameters after your import completes.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Recommended value when importing</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>maintenance_work_mem</code></td>
<td>524288, 1048576, 2097152, or 4194304 (in KB)</td>
<td>The value for this setting depends on the size of your host. This parameter is used during CREATE INDEX statements and each parallel command can use this much memory. Calculate the best value so that you don't set this value so high that you run out of memory.</td>
</tr>
<tr>
<td><code>max_wal_size</code></td>
<td>256 (for version 9.6), 4096 (for versions 10 and higher)</td>
<td>Maximum size to let the WAL grow during automatic checkpoints. Increasing this parameter can increase the amount of time needed for crash recovery. This parameter replaces <code>checkpoint_segments</code> for PostgreSQL 9.6 and later.</td>
</tr>
</tbody>
</table>
Importing a PostgreSQL database from an Amazon EC2 instance

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Recommended value when importing</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>For PostgreSQL version 9.6, this value is in 16 MB units. For later versions, the value is in 1 MB units. For example, in version 9.6, 128 means 128 chunks that are each 16 MB in size. In version 12.4, 2048 means 2048 chunks that are each 1 MB in size.</td>
</tr>
<tr>
<td>checkpoint_timeout</td>
<td>1800</td>
<td>The value for this setting allows for less frequent WAL rotation.</td>
</tr>
<tr>
<td>synchronous_commit</td>
<td>Off</td>
<td>Disable this setting to speed up writes. Turning this parameter off can increase the risk of data loss in the event of a server crash (do not turn off FSYNC).</td>
</tr>
<tr>
<td>wal_buffers</td>
<td>8192</td>
<td>This is value is in 8 KB units. This again helps your WAL generation speed.</td>
</tr>
<tr>
<td>autovacuum</td>
<td>0</td>
<td>Disable the PostgreSQL auto vacuum parameter while you are loading data so that it doesn't use resources.</td>
</tr>
</tbody>
</table>

Use the `pg_dump -Fc` (compressed) or `pg_restore -j` (parallel) commands with these settings.

**Note**
The PostgreSQL command `pg_dumpall` requires super_user permissions that are not granted when you create a DB instance, so it cannot be used for importing data.

**Topics**
- Importing a PostgreSQL database from an Amazon EC2 instance (p. 2241)
- Using the `\copy` command to import data to a table on a PostgreSQL DB instance (p. 2243)
- Importing data from Amazon S3 into an RDS for PostgreSQL DB instance (p. 2244)
- Transporting PostgreSQL databases between DB instances (p. 2257)

**Importing a PostgreSQL database from an Amazon EC2 instance**

If you have data in a PostgreSQL server on an Amazon EC2 instance and want to move it to a PostgreSQL DB instance, you can use the following process. The following list shows the steps to take. Each step is discussed in more detail in the following sections.

1. Create a file using `pg_dump` that contains the data to be loaded
2. Create the target DB instance
3. Use `psql` to create the database on the DB instance and load the data
4. Create a DB snapshot of the DB instance
Step 1: Create a file using pg_dump that contains the data to load

The pg_dump utility uses the COPY command to create a schema and data dump of a PostgreSQL database. The dump script generated by pg_dump loads data into a database with the same name and recreates the tables, indexes, and foreign keys. You can use the pg_restore command and the -d parameter to restore the data to a database with a different name.

Before you create the data dump, you should query the tables to be dumped to get a row count so you can confirm the count on the target DB instance.

The following command creates a dump file called mydb2dump.sql for a database called mydb2.

```
prompt>pg_dump dbname=mydb2 -f mydb2dump.sql
```

Step 2: Create the target DB instance

Create the target PostgreSQL DB instance using either the Amazon RDS console, AWS CLI, or API. Create the instance with the backup retention setting set to 0 and disable Multi-AZ. Doing so allows faster data import. You must create a database on the instance before you can dump the data. The database can have the same name as the database that is contained the dumped data. Alternatively, you can create a database with a different name. In this case, you use the pg_restore command and the -d parameter to restore the data into the newly named database.

For example, the following commands can be used to dump, restore, and rename a database.

```
pg_dump -Fc -v -h [endpoint of instance] -U [master username] [database] > [database].dump
createdb [new database name]
pg_restore -v -h [endpoint of instance] -U [master username] -d [new database name] [database].dump
```

Step 3: Use psql to create the database on the DB instance and load data

You can use the same connection you used to run the pg_dump command to connect to the target DB instance and recreate the database. Using psql, you can use the master user name and master password to create the database on the DB instance.

The following example uses psql and a dump file named mydb2dump.sql to create a database called mydb2 on a PostgreSQL DB instance called mypginstance:

For Linux, macOS, or Unix:

```
psql \
  -f mydb2dump.sql \
  --host mypginstance.555555555555.aws-region.rds.amazonaws.com \
  --port 5432 \
  --username myawsuser \
  --dbname mydb2
```

For Windows:

```
psql ^
  -f mydb2dump.sql ^
  --host mypginstance.555555555555.aws-region.rds.amazonaws.com ^
```
Using the \copy command to import data to a table on a PostgreSQL DB instance

The PostgreSQL \copy command is a meta-command available from the psql interactive client tool. You can use \copy to import data into a table on your RDS for PostgreSQL DB instance. To use the \copy command, you need to first create the table structure on the target DB instance so that \copy has a destination for the data being copied.

You can use \copy to load data from a comma-separated values (CSV) file, such as one that's been exported and saved to your client workstation.

To import the CSV data to the target RDS for PostgreSQL DB instance, first connect to the target DB instance using psql.

```
psql --host=host --username=postgres --password --dbname=target-db
```

You then run \copy command with the following parameters to identify the target for the data and its format.

- `target_table` – The name of the table that should receive the data being copied from the CSV file.
- `column_list` – Column specifications for the table.
- `filename` – The complete path to the CSV file on your local workstation.

```
\copy target_table from '/path/to/local/filename.csv' WITH DELIMITER ',' CSV;
```

If your CSV file has column heading information, you can use this version of the command and parameters.

```
\copy target_table (column-1, column-2, column-3, ...) from '/path/to/local/filename.csv' WITH DELIMITER ',', CSV HEADER;
```

If the \copy command fails, PostgreSQL outputs error messages.

Creating a new DB instance in the preview environment psql command with the \copy meta-command as shown in the following examples. This example uses `source-table` as the source table name, `source-table.csv` as the .csv file, and `target-db` as the target database.
For Linux, macOS, or Unix:

```
$psql target-db \
   -U <admin user> \
   -p <port> \
   -h <DB instance name> \
   -c "\"copy source-table from 'source-table.csv' with DELIMITER ",;""
```

For Windows:

```
$psql target-db ^
   -U <admin user> ^
   -p <port> ^
   -h <DB instance name> ^
   -c "\"copy source-table from 'source-table.csv' with DELIMITER ",;""
```

For complete details about the `\copy` command, see the `psql` page in the PostgreSQL documentation, in the Meta-Commands section.

## Importing data from Amazon S3 into an RDS for PostgreSQL DB instance

You can import data that's been stored using Amazon Simple Storage Service into a table on an RDS for PostgreSQL DB instance. To do this, you first install the RDS for PostgreSQL `aws_s3` extension. This extension provides the functions that you use to import data from an Amazon S3 bucket. A bucket is an Amazon S3 container for objects and files. The data can be in a comma-separate value (CSV) file, a text file, or a compressed (gzip) file. Following, you can learn how to install the extension and how to import data from Amazon S3 into a table.

Your database must be running PostgreSQL version 10.7 or higher to import from Amazon S3 into RDS for PostgreSQL.

If you don’t have data stored on Amazon S3, you need to first create a bucket and store the data. For more information, see the following topics in the `Amazon Simple Storage Service User Guide`.

- Create a bucket
- Add an object to a bucket

Cross-account import from Amazon S3 is supported. For more information, see `Granting cross-account permissions` in the `Amazon Simple Storage Service User Guide`.

You can use the customer managed key for encryption while importing data from S3. For more information, see `KMS keys stored in AWS KMS` in the `Amazon Simple Storage Service User Guide`.

**Note**

Importing data from Amazon S3 isn't supported for Aurora Serverless v1. It is supported for Aurora Serverless v2.

**Topics**

- Installing the `aws_s3` extension (p. 2245)
- Overview of importing data from Amazon S3 data (p. 2245)
- Setting up access to an Amazon S3 bucket (p. 2247)
- Importing data from Amazon S3 to your RDS for PostgreSQL DB instance (p. 2251)
- Function reference (p. 2254)
Installing the aws_s3 extension

Before you can use Amazon S3 with your RDS for PostgreSQL DB instance, you need to install the aws_s3 extension. This extension provides functions for importing data from an Amazon S3. It also provides functions for exporting data from an RDS for PostgreSQL DB instance to an Amazon S3 bucket. For more information, see Exporting data from an RDS for PostgreSQL DB instance to Amazon S3. The aws_s3 extension depends on some of the helper functions in the aws_commons extension, which is installed automatically when needed.

To install the aws_s3 extension

1. Use psql (or pgAdmin) to connect to the RDS for PostgreSQL DB instance as a user that has rds_superuser privileges. If you kept the default name during the setup process, you connect as postgres.

   ```
   psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   ```

2. To install the extension, run the following command.

   ```
   postgres=> CREATE EXTENSION aws_s3 CASCADE;
   NOTICE: installing required extension "aws_commons"
   CREATE EXTENSION
   ```

3. To verify that the extension is installed, you can use the psql \dx metacommand.

   ```
   postgres=> \dx
   List of installed extensions
   Name | Version | Schema | Description
   ---------------------------------------------
   aws_commons | 1.2 | public | Common data types across AWS services
   aws_s3 | 1.1 | public | AWS S3 extension for importing data from S3
   plpgsql | 1.0 | pg_catalog | PL/pgSQL procedural language
   (3 rows)
   ```

The functions for importing data from Amazon S3 and exporting data to Amazon S3 are now available to use.

Overview of importing data from Amazon S3 data

To import S3 data into Amazon RDS

First, gather the details that you need to supply to the function. These include the name of the table on your RDS for PostgreSQL DB instance, and the bucket name, file path, file type, and AWS Region where the Amazon S3 data is stored. For more information, see View an object in the Amazon Simple Storage Service User Guide.

**Note**

Multi part data import from Amazon S3 isn't currently supported.

1. Get the name of the table into which the aws_s3.table_import_from_s3 function is to import the data. As an example, the following command creates a table t1 that can be used in later steps.

   ```
   postgres=> CREATE TABLE t1
             (col1 varchar(80),
              col2 varchar(80),
   ```
col3 varchar(80));

2. Get the details about the Amazon S3 bucket and the data to import. To do this, open the Amazon S3 console at https://console.aws.amazon.com/s3/, and choose Buckets. Find the bucket containing your data in the list. Choose the bucket, open its Object overview page, and then choose Properties. Make a note of the bucket name, path, the AWS Region, and file type. You need the Amazon Resource Name (ARN) later, to set up access to Amazon S3 through an IAM role. For more information, see Setting up access to an Amazon S3 bucket (p. 2247). The image following shows an example.

![Amazon S3 Object Overview](image)

3. You can verify the path to the data on the Amazon S3 bucket by using the AWS CLI command aws s3 cp. If the information is correct, this command downloads a copy of the Amazon S3 file.

   ```
   aws s3 cp s3://sample_s3_bucket/sample_file_path ./
   ```

4. Set up permissions on your RDS for PostgreSQL DB instance to allow access to the file on the Amazon S3 bucket. To do so, you use either an AWS Identity and Access Management (IAM) role or security credentials. For more information, see Setting up access to an Amazon S3 bucket (p. 2247).

5. Supply the path and other Amazon S3 object details gathered (see step 2) to the create_s3_uri function to construct an Amazon S3 URI object. To learn more about this function, see aws_commons.create_s3_uri (p. 2256). The following is an example of constructing this object during a psql session.

   ```
   postgres=> SELECT aws_commons.create_s3_uri('docs-lab-store-for-rpg', 'versions_and_jdks_listing.csv', 'us-west-1') AS s3_uri \gset
   ```

   In the next step, you pass this object (aws_commons._s3_uri_1) to the aws_s3.table_import_from_s3 function to import the data to the table.

6. Invoke the aws_s3.table_import_from_s3 function to import the data from Amazon S3 into your table. For reference information, see aws_s3.table_import_from_s3 (p. 2254). For examples, see Importing data from Amazon S3 to your RDS for PostgreSQL DB instance (p. 2251).
Setting up access to an Amazon S3 bucket

To import data from an Amazon S3 file, give the RDS for PostgreSQL DB instance permission to access the Amazon S3 bucket containing the file. You provide access to an Amazon S3 bucket in one of two ways, as described in the following topics.

Topics
- Using an IAM role to access an Amazon S3 bucket (p. 2247)
- Using security credentials to access an Amazon S3 bucket (p. 2251)
- Troubleshooting access to Amazon S3 (p. 2251)

Using an IAM role to access an Amazon S3 bucket

Before you load data from an Amazon S3 file, give your RDS for PostgreSQL DB instance permission to access the Amazon S3 bucket the file is in. This way, you don't have to manage additional credential information or provide it in the `aws_s3.table_import_from_s3` function call.

To do this, create an IAM policy that provides access to the Amazon S3 bucket. Create an IAM role and attach the policy to the role. Then assign the IAM role to your DB instance.

Note
You can't associate an IAM role with an Aurora Serverless v1 DB cluster, so the following steps don't apply.

To give an RDS for PostgreSQL DB instance access to Amazon S3 through an IAM role

1. Create an IAM policy.

   This policy provides the bucket and object permissions that allow your RDS for PostgreSQL DB instance to access Amazon S3.

   Include in the policy the following required actions to allow the transfer of files from an Amazon S3 bucket to Amazon RDS:

   • `s3:GetObject`
   • `s3:ListBucket`

   Include in the policy the following resources to identify the Amazon S3 bucket and objects in the bucket. This shows the Amazon Resource Name (ARN) format for accessing Amazon S3.

   • `arn:aws:s3:::your-s3-bucket`
   • `arn:aws:s3:::your-s3-bucket/*`

   For more information on creating an IAM policy for RDS for PostgreSQL, see Creating and using an IAM policy for IAM database access (p. 2663). See also Tutorial: Create and attach your first customer managed policy in the IAM User Guide.

   The following AWS CLI command creates an IAM policy named `rds-s3-import-policy` with these options. It grants access to a bucket named `your-s3-bucket`.

   Note
   Make a note of the Amazon Resource Name (ARN) of the policy returned by this command. You need the ARN in a subsequent step when you attach the policy to an IAM role.
Example

For Linux, macOS, or Unix:

```bash
aws iam create-policy \
  --policy-name rds-s3-import-policy \
  --policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Sid": "s3import",
        "Action": [
          "s3:GetObject",
          "s3:ListBucket"
        ],
        "Effect": "Allow",
        "Resource": [
          "arn:aws:s3:::your-s3-bucket",
          "arn:aws:s3:::your-s3-bucket/*"
        ]
      }
    ]
  }'
```

For Windows:

```bash
aws iam create-policy ^
  --policy-name rds-s3-import-policy ^
  --policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Sid": "s3import",
        "Action": [
          "s3:GetObject",
          "s3:ListBucket"
        ],
        "Effect": "Allow",
        "Resource": [
          "arn:aws:s3:::your-s3-bucket",
          "arn:aws:s3:::your-s3-bucket/*"
        ]
      }
    ]
  }'
```

2. Create an IAM role.

You do this so Amazon RDS can assume this IAM role to access your Amazon S3 buckets. For more information, see Creating a role to delegate permissions to an IAM user in the IAM User Guide.

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
• Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the policy, be sure to use the `aws:SourceArn` global condition context key with the full ARN of the resource. The following example shows how to do so using the AWS CLI command to create a role named `rds-s3-import-role`.

**Example**

For Linux, macOS, or Unix:

```bash
aws iam create-role \\
--role-name rds-s3-import-role \\
--assume-role-policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": "111122223333",
        }
      }
    }
  ]
}'
```

For Windows:

```bash
aws iam create-role ^
--role-name rds-s3-import-role ^
--assume-role-policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": "111122223333",
        }
      }
    }
  ]
}'
```

3. Attach the IAM policy that you created to the IAM role that you created.

The following AWS CLI command attaches the policy created in the previous step to the role named `rds-s3-import-role` Replace `your-policy-arn` with the policy ARN that you noted in an earlier step.
Example

For Linux, macOS, or Unix:

```bash
aws iam attach-role-policy
    --policy-arn your-policy-arn
    --role-name rds-s3-import-role
```

For Windows:

```bash
aws iam attach-role-policy
    --policy-arn your-policy-arn
    --role-name rds-s3-import-role
```

4. Add the IAM role to the DB instance.
   You do so by using the AWS Management Console or AWS CLI, as described following.

Console

To add an IAM role for a PostgreSQL DB instance using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the PostgreSQL DB instance name to display its details.
3. On the Connectivity & security tab, in the Manage IAM roles section, choose the role to add under Add IAM roles to this instance.
4. Under Feature, choose s3Import.
5. Choose Add role.

AWS CLI

To add an IAM role for a PostgreSQL DB instance using the CLI

- Use the following command to add the role to the PostgreSQL DB instance named my-db-instance. Replace your-role-arn with the role ARN that you noted in a previous step. Use s3Import for the value of the --feature-name option.

Example

For Linux, macOS, or Unix:

```bash
aws rds add-role-to-db-instance
    --db-instance-identifier my-db-instance
    --feature-name s3Import
    --role-arn your-role-arn
    --region your-region
```

For Windows:

```bash
aws rds add-role-to-db-instance
    --db-instance-identifier my-db-instance
    --feature-name s3Import
    --role-arn your-role-arn
```
RDS API

To add an IAM role for a PostgreSQL DB instance using the Amazon RDS API, call the `AddRoleToDBInstance` operation.

Using security credentials to access an Amazon S3 bucket

If you prefer, you can use security credentials to provide access to an Amazon S3 bucket instead of providing access with an IAM role. You do so by specifying the `credentials` parameter in the `aws_s3.table_import_from_s3` function call.

The `credentials` parameter is a structure of type `aws_commons._aws_credentials_1`, which contains AWS credentials. Use the `aws_commons.create_aws_credentials` function to set the access key and secret key in an `aws_commons._aws_credentials_1` structure, as shown following.

```sql
postgres=> SELECT aws_commons.create_aws_credentials(
    'sample_access_key', 'sample_secret_key', '')
AS creds \gset
```

After creating the `aws_commons._aws_credentials_1` structure, use the `aws_s3.table_import_from_s3` function with the `credentials` parameter to import the data, as shown following.

```sql
postgres=> SELECT aws_s3.table_import_from_s3(
    't', '', '(format csv)',
    :s3_uri,
    :creds
);
```

Or you can include the `aws_commons.create_aws_credentials` function call inline within the `aws_s3.table_import_from_s3` function call.

```sql
postgres=> SELECT aws_s3.table_import_from_s3(
    't', '', '(format csv)',
    :s3_uri,
    aws_commons.create_aws_credentials('sample_access_key', 'sample_secret_key', '')
);
```

Troubleshooting access to Amazon S3

If you encounter connection problems when attempting to import data from Amazon S3, see the following for recommendations:

- Troubleshooting Amazon RDS identity and access (p. 2687)
- Troubleshooting Amazon S3 in the Amazon Simple Storage Service User Guide
- Troubleshooting Amazon S3 and IAM in the IAM User Guide

Importing data from Amazon S3 to your RDS for PostgreSQL DB instance

You import data from your Amazon S3 bucket by using the `table_import_from_s3` function of the `aws_s3` extension. For reference information, see `aws_s3.table_import_from_s3` (p. 2254).
The following examples use the IAM role method to allow access to the Amazon S3 bucket. Thus, the `aws_s3.table_import_from_s3` function calls don't include credential parameters.

The following shows a typical example.

```sql
postgres=> SELECT aws_s3.table_import_from_s3(
    't1',
    '',
    '(format csv)',
    ':s3_uri'
);
```

The parameters are the following:

- `t1` – The name for the table in the PostgreSQL DB instance to copy the data into.
- `'` – An optional list of columns in the database table. You can use this parameter to indicate which columns of the S3 data go in which table columns. If no columns are specified, all the columns are copied to the table. For an example of using a column list, see Importing an Amazon S3 file that uses a custom delimiter.
- `(format csv)` – PostgreSQL COPY arguments. The copy process uses the arguments and format of the PostgreSQL COPY command to import the data. Choices for format include comma-separated value (CSV) as shown in this example, text, and binary. The default is text.
- `:s3_uri` – A structure that contains the information identifying the Amazon S3 file. For an example of using the `aws_commons.create_s3_uri` function to create an `s3_uri` structure, see Overview of importing data from Amazon S3 data.

For more information about this function, see `aws_s3.table_import_from_s3`.

The `aws_s3.table_import_from_s3` function returns text. To specify other kinds of files for import from an Amazon S3 bucket, see one of the following examples.

**Note**
Importing 0 bytes file will cause an error.

**Topics**
- Importing an Amazon S3 file that uses a custom delimiter
- Importing an Amazon S3 compressed (gzip) file
- Importing an encoded Amazon S3 file

**Importing an Amazon S3 file that uses a custom delimiter**

The following example shows how to import a file that uses a custom delimiter. It also shows how to control where to put the data in the database table using the `column_list` parameter of the `aws_s3.table_import_from_s3` function.

For this example, assume that the following information is organized into pipe-delimited columns in the Amazon S3 file.

```
1|foo1|bar1|elephant1
2|foo2|bar2|elephant2
3|foo3|bar3|elephant3
4|foo4|bar4|elephant4
...```
To import a file that uses a custom delimiter

1. Create a table in the database for the imported data.

   postgres=> CREATE TABLE test (a text, b text, c text, d text, e text);

2. Use the following form of the **aws_s3.table_import_from_s3** function to import data from the Amazon S3 file.

   You can include the **aws_commons.create_s3_uri** function call inline within the **aws_s3.table_import_from_s3** function call to specify the file.

   postgres=> SELECT aws_s3.table_import_from_s3('test', 'a,b,d,e', 'DELIMITER ''|'''
   aws_commons.create_s3_uri('sampleBucket', 'pipeDelimitedSampleFile', 'us-east-2')
   );

The data is now in the table in the following columns.

   postgres=> SELECT * FROM test;
   a | b | c | d | e
   ---+-----+---+---+-------
   1 | foo1 | | | bar1 | elephant1
   2 | foo2 | | | bar2 | elephant2
   3 | foo3 | | | bar3 | elephant3
   4 | foo4 | | | bar4 | elephant4

Importing an Amazon S3 compressed (gzip) file

The following example shows how to import a file from Amazon S3 that is compressed with gzip. The file that you import needs to have the following Amazon S3 metadata:

- **Key:** Content-Encoding
- **Value:** gzip

If you upload the file using the AWS Management Console, the metadata is typically applied by the system. For information about uploading files to Amazon S3 using the AWS Management Console, the AWS CLI, or the API, see [Uploading objects](https://docs.aws.amazon.com/AmazonS3/latest/userguide/uploading-objects.html) in the *Amazon Simple Storage Service User Guide*.

For more information about Amazon S3 metadata and details about system-provided metadata, see [Editing object metadata in the Amazon S3 console](https://docs.aws.amazon.com/AmazonS3/latest/userguide/edit-object-metadata.html) in the *Amazon Simple Storage Service User Guide*.

Import the gzip file into your RDS for PostgreSQL DB instance as shown following.

   postgres=> CREATE TABLE test_gzip(id int, a text, b text, c text, d text);
   postgres=> SELECT aws_s3.table_import_from_s3('test_gzip', '', '(format csv)',
   myS3Bucket', 'test-data.gz', 'us-east-2')
   );

Importing an encoded Amazon S3 file

The following example shows how to import a file from Amazon S3 that has Windows-1252 encoding.

   postgres=> SELECT aws_s3.table_import_from_s3('test_gzip', '', '(format csv)',
   myS3Bucket', 'test-data.gz', 'us-east-2')
   );
'test_table', '', 'encoding ''WIN1252''',
aws_commons.create_s3_uri('sampleBucket', 'SampleFile', 'us-east-2'))

Function reference

Functions

- **aws_s3.table_import_from_s3** (p. 2254)
- **aws_commons.create_s3_uri** (p. 2256)
- **aws_commons.create_aws_credentials** (p. 2256)

**aws_s3.table_import_from_s3**

Imports Amazon S3 data into an Amazon RDS table. The *aws_s3* extension provides the *aws_s3.table_import_from_s3* function. The return value is text.

**Syntax**

The required parameters are *table_name*, *column_list* and *options*. These identify the database table and specify how the data is copied into the table.

You can also use the following parameters:

- The *s3_info* parameter specifies the Amazon S3 file to import. When you use this parameter, access to Amazon S3 is provided by an IAM role for the PostgreSQL DB instance.

```python
aws_s3.table_import_from_s3 (  
    table_name text,  
    column_list text,  
    options text,  
    s3_info aws_commons._s3_uri_1
)
```

- The *credentials* parameter specifies the credentials to access Amazon S3. When you use this parameter, you don't use an IAM role.

```python
aws_s3.table_import_from_s3 (  
    table_name text,  
    column_list text,  
    options text,  
    s3_info aws_commons._s3_uri_1,  
    credentials aws_commons._aws_credentials_1
)
```

**Parameters**

*table_name*

A required text string containing the name of the PostgreSQL database table to import the data into.

*column_list*

A required text string containing an optional list of the PostgreSQL database table columns in which to copy the data. If the string is empty, all columns of the table are used. For an example, see Importing an Amazon S3 file that uses a custom delimiter (p. 2252).
options

A required text string containing arguments for the PostgreSQL COPY command. These arguments specify how the data is to be copied into the PostgreSQL table. For more details, see the PostgreSQL COPY documentation.

s3_info

An awsi.s3_uri composite type containing the following information about the S3 object:
- **bucket** – The name of the Amazon S3 bucket containing the file.
- **file_path** – The Amazon S3 file name including the path of the file.
- **region** – The AWS Region that the file is in. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones (p. 110).

credentials

An awsi.aws_credentials composite type containing the following credentials to use for the import operation:
- Access key
- Secret key
- Session token

For information about creating an awsi.aws_credentials composite structure, see awsi.create_aws_credentials (p. 2256).

Alternate syntax

To help with testing, you can use an expanded set of parameters instead of the s3_info and credentials parameters. Following are additional syntax variations for the awsi.table_import_from_s3 function:

- Instead of using the s3_info parameter to identify an Amazon S3 file, use the combination of the bucket, file_path, and region parameters. With this form of the function, access to Amazon S3 is provided by an IAM role on the PostgreSQL DB instance.

```python
aws_s3.table_import_from_s3 (  
    table_name text,  
    column_list text,  
    options text,  
    bucket text,  
    file_path text,  
    region text
)
```

- Instead of using the credentials parameter to specify Amazon S3 access, use the combination of the access_key, session_key, and session_token parameters.

```python
aws_s3.table_import_from_s3 (  
    table_name text,  
    column_list text,  
    options text,  
    bucket text,  
    file_path text,  
    region text,  
    access_key text,  
    secret_key text,  
    session_token text
)
```
Alternate parameters

**bucket**

A text string containing the name of the Amazon S3 bucket that contains the file.

**file_path**

A text string containing the Amazon S3 file name including the path of the file.

**region**

A text string identifying the AWS Region location of the file. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones (p. 110).

**access_key**

A text string containing the access key to use for the import operation. The default is NULL.

**secret_key**

A text string containing the secret key to use for the import operation. The default is NULL.

**session_token**

(Optional) A text string containing the session key to use for the import operation. The default is NULL.

**aws_commons.create_s3_uri**

Creates an `aws_commons._s3_uri_1` structure to hold Amazon S3 file information. Use the results of the `aws_commons.create_s3_uri` function in the `s3_info` parameter of the `aws_s3.table_import_from_s3` function.

**Syntax**

```python
aws_commons.create_s3_uri(
    bucket text,
    file_path text,
    region text
)
```

**Parameters**

**bucket**

A required text string containing the Amazon S3 bucket name for the file.

**file_path**

A required text string containing the Amazon S3 file name including the path of the file.

**region**

A required text string containing the AWS Region that the file is in. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones (p. 110).

**aws_commons.create_aws_credentials**

Sets an access key and secret key in an `aws_commons._aws_credentials_1` structure. Use the results of the `aws_commons.create_aws_credentials` function in the `credentials` parameter of the `aws_s3.table_import_from_s3` function.
Transporting PostgreSQL databases between DB instances

By using PostgreSQL transportable databases for Amazon RDS, you can move a PostgreSQL database between two DB instances. This is a very fast way to migrate large databases between different DB instances. To use this approach, your DB instances must both run the same major version of PostgreSQL.

This capability requires that you install the pg_transport extension on both the source and the destination DB instance. The pg_transport extension provides a physical transport mechanism that moves the database files with minimal processing. This mechanism moves data much faster than traditional dump and load processes, with less downtime.

Note
PostgreSQL transportable databases are available in RDS for PostgreSQL 11.5 and higher, and RDS for PostgreSQL version 10.10 and higher.

To transport a PostgreSQL DB instance from one RDS for PostgreSQL DB instance to another, you first set up the source and destination instances as detailed in Setting up a DB instance for transport (p. 2258). You can then transport the database by using the function described in Transporting a PostgreSQL database (p. 2259).

Topics
- Limitations for using PostgreSQL transportable databases (p. 2258)
- Setting up to transport a PostgreSQL database (p. 2258)
- Transporting a PostgreSQL database to the destination from the source (p. 2259)
- What happens during database transport (p. 2261)
- Transportable databases function reference (p. 2261)
- Transportable databases parameter reference (p. 2262)
Limitations for using PostgreSQL transportable databases

Transportable databases have the following limitations:

- **Read replicas** – You can't use transportable databases on read replicas or parent instances of read replicas.
- **Unsupported column types** – You can't use the `reg` data types in any database tables that you plan to transport with this method. These types depend on system catalog object IDs (OIDs), which often change during transport.
- **Tablespaces** – All source database objects must be in the default `pg_default` tablespace.
- **Compatibility** – Both the source and destination DB instances must run the same major version of PostgreSQL.
- **Extensions** – The source DB instance can have only the `pg_transport` installed.
- **Roles and ACLs** – The source database's access privileges and ownership information aren't carried over to the destination database. All database objects are created and owned by the local destination user of the transport.
- **Concurrent transports** – A single DB instance can support up to 32 concurrent transports, including both imports and exports, if worker processes have been configured properly.
- **RDS for PostgreSQL DB instances only** – PostgreSQL transportable databases are supported on RDS for PostgreSQL DB instances only. You can't use it with on-premises databases or databases running on Amazon EC2.

Setting up to transport a PostgreSQL database

Before you begin, make sure that your RDS for PostgreSQL DB instances meet the following requirements:

- The RDS for PostgreSQL DB instances for source and destination must run the same version of PostgreSQL.
- The destination DB can't have a database of the same name as the source DB that you want to transport.
- The account you use to run the transport needs `rds_superuser` privileges on both the source DB and the destination DB.
- The security group for the source DB instance must allow inbound access from the destination DB instance. This might already be the case if your source and destination DB instances are located in the VPC. For more information about security groups, see [Controlling access with security groups](p. 2697).

Transporting databases from a source DB instance to a destination DB instance requires several changes to the DB parameter group associated with each instance. That means that you must create a custom DB parameter group for the source DB instance and create a custom DB parameter group for the destination DB instance.

**Note**

If your DB instances are already configured using custom DB parameter groups, you can start with step 2 in the following procedure.

To configure the custom DB group parameters for transporting databases

For the following steps, use an account that has `rds_superuser` privileges.

1. If the source and destination DB instances use a default DB parameter group, you need to create a custom DB parameter using the appropriate version for your instances. You do this so you
can change values for several parameters. For more information, see Working with parameter groups (p. 347).

2. In the custom DB parameter group, change values for the following parameters:
   - `shared_preload_libraries` – Add `pg_transport` to the list of libraries.
   - `pg_transport.num_workers` – The default value is 3. Increase or reduce this value as needed for your database. For a 200 GB database, we recommend no larger than 8. Keep in mind that if you increase the default value for this parameter, you should also increase the value of `max_worker_processes`.
   - `pg_transport.work_mem` – The default value is either 128 MB or 256 MB, depending on the PostgreSQL version. The default setting can typically be left unchanged.
   - `max_worker_processes` – The value of this parameter needs to be set using the following calculation:

   \[
   3 \times \text{pg\_transport\_num\_workers} + 9
   \]

   This value is required on the destination to handle various background worker processes involved in the transport. To learn more about `max_worker_processes`, see Resource Consumption in the PostgreSQL documentation.

   For more information about `pg_transport` parameters, see Transportable databases parameter reference (p. 2262).

3. Reboot the source RDS for PostgreSQL DB instance and the destination instance so that the settings for the parameters take effect.

4. Connect to your RDS for PostgreSQL source DB instance.

   ```
   psql --host=source-instance.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   ```

5. Remove extraneous extensions from the public schema of the DB instance. Only the `pg_transport` extension is allowed during the actual transport operation.

6. Install the `pg_transport` extension as follows:

   ```
   postgres=> CREATE EXTENSION pg_transport;
   CREATE EXTENSION
   ```

7. Connect to your RDS for PostgreSQL destination DB instance. Remove any extraneous extensions, and then install the `pg_transport` extension.

   ```
   postgres=> CREATE EXTENSION pg_transport;
   CREATE EXTENSION
   ```

### Transporting a PostgreSQL database to the destination from the source

After you complete the process described in Setting up to transport a PostgreSQL database (p. 2258), you can start the transport. To do so, run the `transport.import_from_server` function on the destination DB instance. In the syntax following you can find the function parameters:

```
SELECT transport.import_from_server(
    'source-db-instance-endpoint',
    source-db-instance-port,
```
Amazon Relational Database Service User Guide
Transporting PostgreSQL databases between DB instances

The false value shown in the example tells the function that this is not a dry run. To test your transport setup, you can specify true for the dry_run option when you call the function, as shown following:

```
postgres=> SELECT transport.import_from_server(
  'docs-lab-source-db.666666666666.aws-region.rds.amazonaws.com', 5432,
  'postgres', '********', 'labdb', '******', true);
```

INFO: Starting dry-run of import of database "labdb".
INFO: Created connections to remote database (took 0.03 seconds).
INFO: Checked remote cluster compatibility (took 0.05 seconds).
INFO: Dry-run complete (took 0.08 seconds total).

The INFO lines are output because the pg_transport.timing parameter is set to its default value, true. Set the dry_run to false when you run the command and the source database is imported to the destination, as shown following:

```
INFO: Starting import of database "labdb".
INFO: Created connections to remote database (took 0.02 seconds).
INFO: Marked remote database as read only (took 0.13 seconds).
INFO: Checked remote cluster compatibility (took 0.03 seconds).
INFO: Signaled creation of PITR blackout window (took 2.01 seconds).
INFO: Applied remote database schema pre-data (took 0.50 seconds).
INFO: Created connections to local cluster (took 0.01 seconds).
INFO: Lockdown destination database (took 0.00 seconds).
INFO: Completed transfer of database files (took 0.24 seconds).
INFO: Completed cleanup (took 1.02 seconds).
INFO: Physical transport complete (took 3.97 seconds total).
```

This function requires that you provide database user passwords. Thus, we recommend that you change the passwords of the user roles you used after transport is complete. Or, you can use SQL bind variables to create temporary user roles. Use these temporary roles for the transport and then discard the roles afterwards.

If your transport isn't successful, you might see an error message similar to the following:

```
pg_transport.num_workers=8 25% of files transported failed to download file data
```

The "failed to download file data" error message indicates that the number of worker processes isn't set correctly for the size of the database. You might need to increase or decrease the value set for pg_transport.num_workers. Each failure reports the percentage of completion, so you can see the impact of your changes. For example, changing the setting from 8 to 4 in one case resulted in the following:

```
pg_transport.num_workers=4 75% of files transported failed to download file data
```

Keep in mind that the max_worker_processes parameter is also taken into account during the transport process. In other words, you might need to modify both pg_transport.num_workers and

2260
max_worker_processes to successfully transport the database. The example shown finally worked when the pg_transport.num_workers was set to 2:

```sql
pg_transport.num_workers=2 100% of files transported
```

For more information about the `transport.import_from_server` function and its parameters, see
Transportable databases function reference (p. 2261).

**What happens during database transport**

The PostgreSQL transportable databases feature uses a pull model to import the database from the source DB instance to the destination. The `transport.import_from_server` function creates the in-transit database on the destination DB instance. The in-transit database is inaccessible on the destination DB instance for the duration of the transport.

When transport begins, all current sessions on the source database are ended. Any databases other than the source database on the source DB instance aren't affected by the transport.

The source database is put into a special read-only mode. While it's in this mode, you can connect to the source database and run read-only queries. However, write-enabled queries and some other types of commands are blocked. Only the specific source database that is being transported is affected by these restrictions.

During transport, you can't restore the destination DB instance to a point in time. This is because the transport isn't transactional and doesn't use the PostgreSQL write-ahead log to record changes. If the destination DB instance has automatic backups enabled, a backup is automatically taken after transport completes. Point-in-time restores are available for times after the backup finishes.

If the transport fails, the pg_transport extension attempts to undo all changes to the source and destination DB instances. This includes removing the destination's partially transported database. Depending on the type of failure, the source database might continue to reject write-enabled queries. If this happens, use the following command to allow write-enabled queries.

```sql
ALTER DATABASE db-name SET default_transaction_read_only = false;
```

**Transportable databases function reference**

The `transport.import_from_server` function transports a PostgreSQL database by importing it from a source DB instance to a destination DB instance. It does this by using a physical database connection transport mechanism.

Before starting the transport, this function verifies that the source and the destination DB instances are the same version and are compatible for the migration. It also confirms that the destination DB instance has enough space for the source.

**Syntax**

```sql
transport.import_from_server(
    host text,
    port int,
    username text,
    password text,
    database text,
    local_password text,
    dry_run bool
)
```
Return Value

None.

Parameters

You can find descriptions of the transport.import_from_server function parameters in the following table.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>The endpoint of the source DB instance.</td>
</tr>
<tr>
<td>port</td>
<td>An integer representing the port of the source DB instance. PostgreSQL DB instances often use port 5432.</td>
</tr>
<tr>
<td>username</td>
<td>The user of the source DB instance. This user must be a member of the rds_superuser role.</td>
</tr>
<tr>
<td>password</td>
<td>The user password of the source DB instance.</td>
</tr>
<tr>
<td>database</td>
<td>The name of the database in the source DB instance to transport.</td>
</tr>
<tr>
<td>local_password</td>
<td>The local password of the current user for the destination DB instance. This user must be a member of the rds_superuser role.</td>
</tr>
<tr>
<td>dry_run</td>
<td>An optional Boolean value specifying whether to perform a dry run. The default is false, which means the transport proceeds. To confirm compatibility between the source and destination DB instances without performing the actual transport, set dry_run to true.</td>
</tr>
</tbody>
</table>

Example

For an example, see Transporting a PostgreSQL database to the destination from the source (p. 2259).

Transportable databases parameter reference

Several parameters control the behavior of the pg_transport extension. Following, you can find descriptions of these parameters.

pg_transport.num_workers

The number of workers to use for the transport process. The default is 3. Valid values are 1–32. Even the largest database transports typically require fewer than 8 workers. The value of this setting on the destination DB instance is used by both destination and source during transport.

pg_transport.timing

Specifies whether to report timing information during the transport. The default is true, meaning that timing information is reported. We recommend that you leave this parameter set to true so you can monitor progress. For example output, see Transporting a PostgreSQL database to the destination from the source (p. 2259).

pg_transport.work_mem

The maximum amount of memory to allocate for each worker. The default is 131072 kilobytes (KB) or 262144 KB (256 MB), depending on the PostgreSQL version. The minimum value is 64 megabytes (65536 KB). Valid values are in kilobytes (KBs) as binary base-2 units, where 1 KB = 1024 bytes.
The transport might use less memory than is specified in this parameter. Even large database transports typically require less than 256 MB (262144 KB) of memory per worker.
Exporting data from an RDS for PostgreSQL DB instance to Amazon S3

You can query data from an RDS for PostgreSQL DB instance and export it directly into files stored in an Amazon S3 bucket. To do this, you first install the RDS for PostgreSQL aws_s3 extension. This extension provides you with the functions that you use to export the results of queries to Amazon S3. Following, you can find out how to install the extension and how to export data to Amazon S3.

You can export from a provisioned or an Aurora Serverless v2 DB instance. These steps aren't supported for Aurora Serverless v1.

**Note**

Cross-account export to Amazon S3 isn't supported.

All currently available versions of RDS for PostgreSQL support exporting data to Amazon Simple Storage Service. For detailed version information, see Amazon RDS for PostgreSQL updates in the Amazon RDS for PostgreSQL Release Notes.

If you don't have a bucket set up for your export, see the following topics in the Amazon Simple Storage Service User Guide.

- Setting up Amazon S3
- Create a bucket

The upload to Amazon S3 uses server-side encryption by default. If you are using encryption, the Amazon S3 bucket must be encrypted with an AWS managed key. Currently, you can't export data to a bucket that's encrypted with a customer managed key.

**Note**

You can save DB snapshot data to Amazon S3 using the AWS Management Console, AWS CLI, or Amazon RDS API. For more information, see Exporting DB snapshot data to Amazon S3 (p. 642).

**Topics**

- Installing the aws_s3 extension (p. 2264)
- Overview of exporting data to Amazon S3 (p. 2265)
- Specifying the Amazon S3 file path to export to (p. 2266)
- Setting up access to an Amazon S3 bucket (p. 2267)
- Exporting query data using the aws_s3.query_export_to_s3 function (p. 2270)
- Troubleshooting access to Amazon S3 (p. 2272)
- Function reference (p. 2272)

**Installing the aws_s3 extension**

Before you can use Amazon Simple Storage Service with your RDS for PostgreSQL DB instance, you need to install the aws_s3 extension. This extension provides functions for exporting data from an RDS for PostgreSQL DB instance to an Amazon S3 bucket. It also provides functions for importing data from an Amazon S3. For more information, see Importing data from Amazon S3 into an RDS for PostgreSQL DB instance (p. 2244). The aws_s3 extension depends on some of the helper functions in the aws_commons extension, which is installed automatically when needed.
To install the \texttt{aws\_s3} extension

1. Use \texttt{psql} (or \texttt{pgAdmin}) to connect to the RDS for PostgreSQL DB instance as a user that has \texttt{rds\_superuser} privileges. If you kept the default name during the setup process, you connect as \texttt{postgres}.

\begin{verbatim}
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
\end{verbatim}

2. To install the extension, run the following command.

\begin{verbatim}
postgres=> CREATE EXTENSION aws_s3 CASCADE;
NOTICE: installing required extension "aws_commons"
CREATE EXTENSION
\end{verbatim}

3. To verify that the extension is installed, you can use the \texttt{psql \textbackslash dx} metacommand.

\begin{verbatim}
postgres=> \dx
List of installed extensions
Name     | Version |   Schema   |                 Description
-------------+---------+------------+---------------------------------------------
aws_commons | 1.2     | public     | Common data types across AWS services
aws_s3      | 1.1     | public     | AWS S3 extension for importing data from S3
plpgsql     | 1.0     | pg_catalog | PL/pgSQL procedural language
(3 rows)
\end{verbatim}

The functions for importing data from Amazon S3 and exporting data to Amazon S3 are now available to use.

Verify that your RDS for PostgreSQL version supports exports to Amazon S3

You can verify that your RDS for PostgreSQL version supports export to Amazon S3 by using the \texttt{describe-db-engine-versions} command. The following example verifies support for version 10.14.

\begin{verbatim}
aws rds describe-db-engine-versions --region us-east-1 --engine postgres --engine-version 10.14 | grep s3Export
\end{verbatim}

If the output includes the string "s3Export", then the engine supports Amazon S3 exports. Otherwise, the engine doesn't support them.

Overview of exporting data to Amazon S3

To export data stored in an RDS for PostgreSQL database to an Amazon S3 bucket, use the following procedure.

To export RDS for PostgreSQL data to S3

1. Identify an Amazon S3 file path to use for exporting data. For details about this process, see \texttt{Specifying the Amazon S3 file path to export to (p. 2266)}.

2. Provide permission to access the Amazon S3 bucket.

To export data to an Amazon S3 file, give the RDS for PostgreSQL DB instance permission to access the Amazon S3 bucket that the export will use for storage. Doing this includes the following steps:

1. Create an IAM policy that provides access to an Amazon S3 bucket that you want to export to.
2. Create an IAM role.
3. Attach the policy you created to the role you created.
4. Add this IAM role to your DB instance.

For details about this process, see Setting up access to an Amazon S3 bucket (p. 2267).

3. Identify a database query to get the data. Export the query data by calling the aws_s3.query_export_to_s3 function.

After you complete the preceding preparation tasks, use the aws_s3.query_export_to_s3 function to export query results to Amazon S3. For details about this process, see Exporting query data using the aws_s3.query_export_to_s3 function (p. 2270).

Specifying the Amazon S3 file path to export to

Specify the following information to identify the location in Amazon S3 where you want to export data to:

- **Bucket name** – A *bucket* is a container for Amazon S3 objects or files.
  
  For more information on storing data with Amazon S3, see Create a bucket and View an object in the Amazon Simple Storage Service User Guide.

- **File path** – The file path identifies where the export is stored in the Amazon S3 bucket. The file path consists of the following:
  - An optional path prefix that identifies a virtual folder path.
  - A file prefix that identifies one or more files to be stored. Larger exports are stored in multiple files, each with a maximum size of approximately 6 GB. The additional file names have the same file prefix but with _partXX appended. The XX represents 2, then 3, and so on.

  For example, a file path with an exports folder and a query-1-export file prefix is /exports/query-1-export.

- **AWS Region (optional)** – The AWS Region where the Amazon S3 bucket is located. If you don't specify an AWS Region value, then Amazon RDS saves your files into Amazon S3 in the same AWS Region as the exporting DB instance.

  **Note**
  Currently, the AWS Region must be the same as the region of the exporting DB instance.

  For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones (p. 110).

To hold the Amazon S3 file information about where the export is to be stored, you can use the aws_commons.create_s3_uri function to create an aws_commons._s3_uri_1 composite structure as follows.

```
psql=> SELECT aws_commons.create_s3_uri(
    'sample-bucket',
    'sample-filepath',
    'us-west-2'
) AS s3_uri_1 \gset
```

You later provide this s3_uri_1 value as a parameter in the call to the aws_s3.query_export_to_s3 function. For examples, see Exporting query data using the aws_s3.query_export_to_s3 function (p. 2270).
Setting up access to an Amazon S3 bucket

To export data to Amazon S3, give your PostgreSQL DB instance permission to access the Amazon S3 bucket that the files are to go in.

To do this, use the following procedure.

To give a PostgreSQL DB instance access to Amazon S3 through an IAM role

1. Create an IAM policy.

   This policy provides the bucket and object permissions that allow your PostgreSQL DB instance to access Amazon S3.

   As part of creating this policy, take the following steps:

   a. Include in the policy the following required actions to allow the transfer of files from your PostgreSQL DB instance to an Amazon S3 bucket:
      
         • s3:PutObject
         • s3:AbortMultipartUpload

   b. Include the Amazon Resource Name (ARN) that identifies the Amazon S3 bucket and objects in the bucket. The ARN format for accessing Amazon S3 is: arn:aws:s3:::your-s3-bucket/*

   For more information on creating an IAM policy for Amazon RDS for PostgreSQL, see Creating and using an IAM policy for IAM database access (p. 2663). See also Tutorial: Create and attach your first customer managed policy in the IAM User Guide.

   The following AWS CLI command creates an IAM policy named rds-s3-export-policy with these options. It grants access to a bucket named your-s3-bucket.

   Warning

   We recommend that you set up your database within a private VPC that has endpoint policies configured for accessing specific buckets. For more information, see Using endpoint policies for Amazon S3 in the Amazon VPC User Guide.

   We strongly recommend that you do not create a policy with all-resource access. This access can pose a threat for data security. If you create a policy that gives s3:PutObject access to all resources using "Resource":"*", then a user with export privileges can export data to all buckets in your account. In addition, the user can export data to any publicly writable bucket within your AWS Region.

   After you create the policy, note the Amazon Resource Name (ARN) of the policy. You need the ARN for a subsequent step when you attach the policy to an IAM role.

   ```
   aws iam create-policy --policy-name rds-s3-export-policy --policy-document '{
   "Version": "2012-10-17",
   "Statement": [
   {
   "Sid": "s3export",
   "Action": [
   "s3:PutObject",
   "s3:AbortMultipartUpload"
   ],
   "Effect": "Allow",
   "Resource": [
   "arn:aws:s3:::your-s3-bucket/*"
   ]
   }
   ]
   }
   '}
   ```
2. Create an IAM role.

You do this so Amazon RDS can assume this IAM role on your behalf to access your Amazon S3 buckets. For more information, see Creating a role to delegate permissions to an IAM user in the IAM User Guide.

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the policy, be sure to use the `aws:SourceArn` global condition context key with the full ARN of the resource. The following example shows how to do so using the AWS CLI command to create a role named `rds-s3-export-role`.

**Example**

For Linux, macOS, or Unix:

```bash
aws iam create-role \
  --role-name rds-s3-export-role \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [ 
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
          "StringEquals": {
            "aws:SourceAccount": "111122223333",
          }
        }
      }
    ]
  }'
```

For Windows:

```bash
aws iam create-role ^
  --role-name rds-s3-export-role ^
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [ 
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
          "StringEquals": {
            "aws:SourceAccount": "111122223333",
          }
        }
      }
    ]
  }'
```
3. Attach the IAM policy that you created to the IAM role that you created.

The following AWS CLI command attaches the policy created earlier to the role named rds-s3-export-role. Replace your-policy-arn with the policy ARN that you noted in an earlier step.

```bash
aws iam attach-role-policy --policy-arn your-policy-arn --role-name rds-s3-export-role
```

4. Add the IAM role to the DB instance. You do so by using the AWS Management Console or AWS CLI, as described following.

**Console**

**To add an IAM role for a PostgreSQL DB instance using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the PostgreSQL DB instance name to display its details.
3. On the Connectivity & security tab, in the Manage IAM roles section, choose the role to add under Add IAM roles to this instance.
4. Under Feature, choose s3Export.
5. Choose Add role.

**AWS CLI**

**To add an IAM role for a PostgreSQL DB instance using the CLI**

- Use the following command to add the role to the PostgreSQL DB instance named my-db-instance. Replace your-role-arn with the role ARN that you noted in a previous step. Use s3Export for the value of the --feature-name option.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds add-role-to-db-instance \
--db-instance-identifier my-db-instance \
--feature-name s3Export \
--role-arn your-role-arn \
--region your-region
```

For Windows:

```bash
aws rds add-role-to-db-instance ^
```
Exporting query data using the `aws_s3.query_export_to_s3` function

Export your PostgreSQL data to Amazon S3 by calling the `aws_s3.query_export_to_s3` function.

Topics

- Prerequisites (p. 2270)
- Calling `aws_s3.query_export_to_s3` (p. 2270)
- Exporting to a CSV file that uses a custom delimiter (p. 2271)
- Exporting to a binary file with encoding (p. 2272)

Prerequisites

Before you use the `aws_s3.query_export_to_s3` function, be sure to complete the following prerequisites:

- Install the required PostgreSQL extensions as described in Overview of exporting data to Amazon S3 (p. 2265).
- Determine where to export your data to Amazon S3 as described in Specifying the Amazon S3 file path to export to (p. 2266).
- Make sure that the DB instance has export access to Amazon S3 as described in Setting up access to an Amazon S3 bucket (p. 2267).

The examples following use a database table called `sample_table`. These examples export the data into a bucket called `sample-bucket`. The example table and data are created with the following SQL statements in `psql`.

```
psql=> CREATE TABLE sample_table (bid bigint PRIMARY KEY, name varchar(80));
psql=> INSERT INTO sample_table (bid,name) VALUES (1, 'Monday'), (2,'Tuesday'), (3, 'Wednesday');
```

Calling `aws_s3.query_export_to_s3` function

The following shows the basic ways of calling the `aws_s3.query_export_to_s3` function.

These examples use the variable `s3_uri_1` to identify a structure that contains the information identifying the Amazon S3 file. Use the `aws_commons.create_s3_uri` function to create the structure.

```
psql=> SELECT aws_commons.create_s3_uri('sample-bucket', 'sample-filepath', 'us-west-2') AS s3_uri_1 \
       AS s3_uri_1 \gset
```
Although the parameters vary for the following two `aws_s3.query_export_to_s3` function calls, the results are the same for these examples. All rows of the `sample_table` table are exported into a bucket called `sample-bucket`.

```sql
psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM sample_table', :'s3_uri_1');
psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM sample_table', :'s3_uri_1',
     options :='format text');
```

The parameters are described as follows:

- `'SELECT * FROM sample_table'` – The first parameter is a required text string containing an SQL query. The PostgreSQL engine runs this query. The results of the query are copied to the S3 bucket identified in other parameters.

- `'s3_uri_1'` – This parameter is a structure that identifies the Amazon S3 file. This example uses a variable to identify the previously created structure. You can instead create the structure by including the `aws_commons.create_s3_uri` function call inline within the `aws_s3.query_export_to_s3` function call as follows.

```sql
SELECT * from aws_s3.query_export_to_s3('select * from sample_table',
     aws_commons.create_s3_uri('sample-bucket', 'sample-filepath', 'us-west-2'))
```

- `options :='format text'` – The `options` parameter is an optional text string containing PostgreSQL `COPY` arguments. The copy process uses the arguments and format of the `PostgreSQL COPY` command.

If the file specified doesn't exist in the Amazon S3 bucket, it's created. If the file already exists, it's overwritten. The syntax for accessing the exported data in Amazon S3 is the following.

```
s3-region://bucket-name[/path-prefix]/file-prefix
```

Larger exports are stored in multiple files, each with a maximum size of approximately 6 GB. The additional file names have the same file prefix but with `_partXX` appended. The `XX` represents 2, then 3, and so on. For example, suppose that you specify the path where you store data files as the following.

```
s3-us-west-2://my-bucket/my-prefix
```

If the export has to create three data files, the Amazon S3 bucket contains the following data files.

```
s3-us-west-2://my-bucket/my-prefix
s3-us-west-2://my-bucket/my-prefix_part2
s3-us-west-2://my-bucket/my-prefix_part3
```

For the full reference for this function and additional ways to call it, see `aws_s3.query_export_to_s3` (p. 2272). For more about accessing files in Amazon S3, see View an object in the Amazon Simple Storage Service User Guide.

### Exporting to a CSV file that uses a custom delimiter

The following example shows how to call the `aws_s3.query_export_to_s3` function to export data to a file that uses a custom delimiter. The example uses arguments of the `PostgreSQL COPY` command to specify the comma-separated value (CSV) format and a colon (`:`) delimiter.
**Troubleshooting access to Amazon S3**

If you encounter connection problems when attempting to export data to Amazon S3, first confirm that the outbound access rules for the VPC security group associated with your DB instance permit network connectivity. Specifically, the security group must have a rule that allows the DB instance to send TCP traffic to port 443 and to any IPv4 addresses (0.0.0.0/0). For more information, see [Provide access to your DB instance in your VPC by creating a security group](p. 177).

See also the following for recommendations:

- [Troubleshooting Amazon RDS identity and access](p. 2687)
- [Troubleshooting Amazon S3](p. 2272) in the *Amazon Simple Storage Service User Guide*
- [Troubleshooting Amazon S3 and IAM](p. 2272) in the *IAM User Guide*

**Function reference**

**Functions**

- `aws_s3.query_export_to_s3` *(p. 2272)*
- `aws_commons.create_s3_uri` *(p. 2274)*

**aws_s3.query_export_to_s3**

Exports a PostgreSQL query result to an Amazon S3 bucket. The `aws_s3` extension provides the `aws_s3.query_export_to_s3` function.

The two required parameters are `query` and `s3_info`. These define the query to be exported and identify the Amazon S3 bucket to export to. An optional parameter called `options` provides for defining various export parameters. For examples of using the `aws_s3.query_export_to_s3` function, see [Exporting query data using the `aws_s3.query_export_to_s3` function](p. 2270).

**Syntax**

```sql
aws_s3.query_export_to_s3(
    query text,
    s3_info aws_commons._s3_uri_1,
    options text
)
```
Input parameters

query

A required text string containing an SQL query that the PostgreSQL engine runs. The results of this query are copied to an S3 bucket identified in the s3_info parameter.

s3_info

An aws_commons._s3_uri_1 composite type containing the following information about the S3 object:

- bucket – The name of the Amazon S3 bucket to contain the file.
- file_path – The Amazon S3 file name and path.
- region – The AWS Region that the bucket is in. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones (p. 110).

Currently, this value must be the same AWS Region as that of the exporting DB instance. The default is the AWS Region of the exporting DB instance.

To create an aws_commons._s3_uri_1 composite structure, see the aws_commons.create_s3_uri function.

options

An optional text string containing arguments for the PostgreSQL COPY command. These arguments specify how the data is to be copied when exported. For more details, see the PostgreSQL COPY documentation.

Alternate input parameters

To help with testing, you can use an expanded set of parameters instead of the s3_info parameter. Following are additional syntax variations for the aws_s3.query_export_to_s3 function.

Instead of using the s3_info parameter to identify an Amazon S3 file, use the combination of the bucket, file_path, and region parameters.

```python
aws_s3.query_export_to_s3(
    query text,
    bucket text,
    file_path text,
    region text,
    options text
)
```

query

A required text string containing an SQL query that the PostgreSQL engine runs. The results of this query are copied to an S3 bucket identified in the s3_info parameter.

bucket

A required text string containing the name of the Amazon S3 bucket that contains the file.

file_path

A required text string containing the Amazon S3 file name including the path of the file.

region

An optional text string containing the AWS Region that the bucket is in. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones (p. 110).
Currently, this value must be the same AWS Region as that of the exporting DB instance. The default is the AWS Region of the exporting DB instance.

**options**

An optional text string containing arguments for the PostgreSQL COPY command. These arguments specify how the data is to be copied when exported. For more details, see the PostgreSQL COPY documentation.

**Output parameters**

```pseudocode
aws_s3.query_export_to_s3(
    OUT rows_uploaded bigint,
    OUT files_uploaded bigint,
    OUT bytes_uploaded bigint
)
```

**rows_uploaded**

The number of table rows that were successfully uploaded to Amazon S3 for the given query.

**files_uploaded**

The number of files uploaded to Amazon S3. Files are created in sizes of approximately 6 GB. Each additional file created has _partXX appended to the name. The XX represents 2, then 3, and so on as needed.

**bytes_uploaded**

The total number of bytes uploaded to Amazon S3.

**Examples**

```sql
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'sample-bucket', 'sample-filepath');
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'sample-bucket', 'sample-filepath','us-west-2');
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'sample-bucket', 'sample-filepath','us-west-2','format text');
```

**aws_commons.create_s3_uri**

Creates an aws_commons._s3_uri_1 structure to hold Amazon S3 file information. You use the results of the aws_commons.create_s3_uri function in the s3_info parameter of the aws_s3.query_export_to_s3 function. For an example of using the aws_commons.create_s3_uri function, see Specifying the Amazon S3 file path to export to (p. 2266).

**Syntax**

```pseudocode
aws_commons.create_s3_uri(
    bucket text,
    file_path text,
    region text
)
```
Input parameters

(bucket)

A required text string containing the Amazon S3 bucket name for the file.

(file_path)

A required text string containing the Amazon S3 file name including the path of the file.

(region)

A required text string containing the AWS Region that the file is in. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones (p. 110).
Invoking an AWS Lambda function from an RDS for PostgreSQL DB instance

AWS Lambda is an event-driven compute service that lets you run code without provisioning or managing servers. It's available for use with many AWS services, including RDS for PostgreSQL. For example, you can use Lambda functions to process event notifications from a database, or to load data from files whenever a new file is uploaded to Amazon S3. To learn more about Lambda, see What is AWS Lambda? in the AWS Lambda Developer Guide.

**Note**
Invoking an AWS Lambda function is supported in these RDS for PostgreSQL versions:

- All PostgreSQL 15 versions
- PostgreSQL 14.1 and higher minor versions
- PostgreSQL 13.2 and higher minor versions
- PostgreSQL 12.6 and higher minor versions

Setting up RDS for PostgreSQL to work with Lambda functions is a multi-step process involving AWS Lambda, IAM, your VPC, and your RDS for PostgreSQL DB instance. Following, you can find summaries of the necessary steps.

For more information about Lambda functions, see Getting started with Lambda and AWS Lambda foundations in the AWS Lambda Developer Guide.

**Topics**

- Step 1: Configure your RDS for PostgreSQL DB instance for outbound connections to AWS Lambda (p. 2276)
- Step 2: Configure IAM for your RDS for PostgreSQL DB instance and AWS Lambda (p. 2277)
- Step 3: Install the aws_lambda extension for an RDS for PostgreSQL DB instance (p. 2278)
- Step 4: Use Lambda helper functions with your RDS for PostgreSQL DB instance (Optional) (p. 2279)
- Step 5: Invoke a Lambda function from your RDS for PostgreSQL DB instance (p. 2279)
- Step 6: Grant other users permission to invoke Lambda functions (p. 2280)
- Examples: Invoking Lambda functions from your RDS for PostgreSQL DB instance (p. 2281)
- Lambda function error messages (p. 2283)
- AWS Lambda function reference (p. 2284)

**Step 1: Configure your RDS for PostgreSQL DB instance for outbound connections to AWS Lambda**

Lambda functions always run inside an Amazon VPC that's owned by the AWS Lambda service. Lambda applies network access and security rules to this VPC and it maintains and monitors the VPC automatically. Your RDS for PostgreSQL DB instance sends network traffic to the Lambda service's VPC. How you configure this depends on whether your DB instance is public or private.

- **Public RDS for PostgreSQL DB instance** – A DB instance is public if it's located in a public subnet on your VPC, and if the instance's "PubliclyAccessible" property is true. To find the value of this property, you can use the describe-db-instances AWS CLI command. Or, you can use the AWS Management Console to open the Connectivity & security tab and check that Publicly accessible is Yes. To verify that the instance is in the public subnet of your VPC, you can use the AWS Management Console or the AWS CLI.
To set up access to Lambda, you use the AWS Management Console or the AWS CLI to create an outbound rule on your VPC's security group. The outbound rule specifies that TCP can use port 443 to send packets to any IPv4 addresses (0.0.0.0/0).

- **Private RDS for PostgreSQL DB instance** – In this case, the instance's "PubliclyAccessible" property is `false` or it's in a private subnet. To allow the instance to work with Lambda, you can use a Network Address Translation (NAT) gateway. For more information, see [NAT gateways](#). Or, you can configure your VPC with a VPC endpoint for Lambda. For more information, see [VPC endpoints](#) in the Amazon VPC User Guide. The VPC endpoint responds to calls made by your RDS for PostgreSQL DB instance to your Lambda functions. The VPC endpoint uses its own private DNS resolution. RDS for PostgreSQL can't use the Lambda VPC endpoint until you change the value of the `rds.custom_dns_resolution` parameter from its default value of 0 (not enabled) to 1. To do so:
  - Create a custom DB parameter group.
  - Change the value of the `rds.custom_dns_resolution` parameter from its default of 0 to 1.
  - Modify your DB instance to use your custom DB parameter group.
  - Reboot the instance to have the modified parameter take effect.

Your VPC can now interact with the AWS Lambda VPC at the network level. Next, you configure the permissions using IAM.

**Step 2: Configure IAM for your RDS for PostgreSQL DB instance and AWS Lambda**

Invoking Lambda functions from your RDS for PostgreSQL DB instance requires certain privileges. To configure the necessary privileges, we recommend that you create an IAM policy that allows invoking Lambda functions, assign that policy to a role, and then apply the role to your DB instance. This approach gives the DB instance privileges to invoke the specified Lambda function on your behalf. The following steps show you how to do this using the AWS CLI.

### To configure IAM permissions for using your Amazon RDS instance with Lambda

1. Use the `create-policy` AWS CLI command to create an IAM policy that allows your RDS for PostgreSQL DB instance to invoke the specified Lambda function. (The statement ID (Sid) is an optional description for your policy statement and has no effect on usage.) This policy gives your DB instance the minimum permissions needed to invoke the specified Lambda function.

```bash
aws iam create-policy  --policy-name rds-lambda-policy --policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccessToExampleFunction",
      "Effect": "Allow",
      "Action": "lambda:InvokeFunction",
    }
  ]
}
'
```

Alternatively, you can use the predefined AWSLambdaRole policy that allows you to invoke any of your Lambda functions. For more information, see [Identity-based IAM policies for Lambda](#).

2. Use the `create-role` AWS CLI command to create an IAM role that the policy can assume at runtime.

```bash
aws iam create-role  --role-name rds-lambda-role --assume-role-policy-document '{
  "Version": "2012-10-17",
}
'
```
Step 3: Install the extension

```
"Statement": [
  {
    "Effect": "Allow",
    "Principal": {
      "Service": "rds.amazonaws.com"
    },
    "Action": "sts:AssumeRole"
  }
]
```

3. Apply the policy to the role by using the `attach-role-policy` AWS CLI command.

```
aws iam attach-role-policy
  --policy-arn arn:aws:iam::444455556666:policy/rds-lambda-policy
  --role-name rds-lambda-role --region aws-region
```

4. Apply the role to your RDS for PostgreSQL DB instance by using the `add-role-to-db-instance` AWS CLI command. This last step allows your DB instance's database users to invoke Lambda functions.

```
aws rds add-role-to-db-instance
  --db-cluster-identifier my-cluster-name
  --feature-name Lambda
  --role-arn arn:aws:iam::444455556666:role/rds-lambda-role
  --region aws-region
```

With the VPC and the IAM configurations complete, you can now install the `aws_lambda` extension. (Note that you can install the extension at any time, but until you set up the correct VPC support and IAM privileges, the `aws_lambda` extension adds nothing to your RDS for PostgreSQL DB instance's capabilities.)

**Step 3: Install the `aws_lambda` extension for an RDS for PostgreSQL DB instance**

To use AWS Lambda with your RDS for PostgreSQL DB instance, add the `aws_lambda` PostgreSQL extension to your RDS for PostgreSQL DB instance. This extension provides your RDS for PostgreSQL DB instance with the ability to call Lambda functions from PostgreSQL.

**To install the `aws_lambda` extension in your RDS for PostgreSQL DB instance**

Use the PostgreSQL `psql` command-line or the pgAdmin tool to connect to your RDS for PostgreSQL DB instance.

1. Connect to your RDS for PostgreSQL DB instance as a user with `rds_superuser` privileges. The default `postgres` user is shown in the example.

```
psql -h instance.444455556666.aws-region.rds.amazonaws.com -U postgres -p 5432
```

2. Install the `aws_lambda` extension. The `aws_commons` extension is also required. It provides helper functions to `aws_lambda` and many other Aurora extensions for PostgreSQL. If it's not already on your RDS for PostgreSQL DB instance, it's installed with `aws_lambda` as shown following.

```
CREATE EXTENSION IF NOT EXISTS aws_lambda CASCADE;
NOTICE:  installing required extension "aws_commons"
CREATE EXTENSION
```
The aws_lambda extension is installed in your DB instance. You can now create convenience structures for invoking your Lambda functions.

**Step 4: Use Lambda helper functions with your RDS for PostgreSQL DB instance (Optional)**

You can use the helper functions in the aws_commons extension to prepare entities that you can more easily invoke from PostgreSQL. To do this, you need to have the following information about your Lambda functions:

- **Function name** – The name, Amazon Resource Name (ARN), version, or alias of the Lambda function. The IAM policy created in [Step 2: Configure IAM for your instance and Lambda (p. 2277)](#) requires the ARN, so we recommend that you use your function’s ARN.

- **AWS Region** – (Optional) The AWS Region where the Lambda function is located if it’s not in the same Region as your RDS for PostgreSQL DB instance.

To hold the Lambda function name information, you use the `aws_commons.create_lambda_function_arn` function. This helper function creates an `aws_commons._lambda_function_arn_1` composite structure with the details needed by the invoke function. Following, you can find three alternative approaches to setting up this composite structure.

```sql
SELECT aws_commons.create_lambda_function_arn(  
  'my-function',  
  'aws-region'  
) AS aws_lambda_arn_1 \gset

SELECT aws_commons.create_lambda_function_arn(  
  '111122223333:function:my-function',  
  'aws-region'  
) AS lambda_partial_arn_1 \gset

SELECT aws_commons.create_lambda_function_arn(  
) AS lambda_arn_1 \gset
```

Any of these values can be used in calls to the `aws_lambda.invoke` function. For examples, see [Step 5: Invoke a Lambda function from your RDS for PostgreSQL DB instance (p. 2279)](#).

**Step 5: Invoke a Lambda function from your RDS for PostgreSQL DB instance**

The `aws_lambda.invoke` function behaves synchronously or asynchronously, depending on the invocation_type. The two alternatives for this parameter are RequestResponse (the default) and Event, as follows:

- **RequestResponse** – This invocation type is **synchronous**. It’s the default behavior when the call is made without specifying an invocation type. The response payload includes the results of the `aws_lambda.invoke` function. Use this invocation type when your workflow requires receiving results from the Lambda function before proceeding.

- **Event** – This invocation type is **asynchronous**. The response doesn’t include a payload containing results. Use this invocation type when your workflow doesn't need a result from the Lambda function to continue processing.
As a simple test of your setup, you can connect to your DB instance using `psql` and invoke an example function from the command line. Suppose that you have one of the basic functions set up on your Lambda service, such as the simple Python function shown in the following screenshot.

To invoke an example function

1. Connect to your DB instance using `psql` or pgAdmin.

   ```
   psql -h instance.444455556666.aws-region.rds.amazonaws.com -U postgres -p 5432
   ```

2. Invoke the function using its ARN.

   ```
   SELECT * from aws_lambda.invoke(aws_commons.create_lambda_function_arn('arn:aws:lambda:aws-region:444455556666:function:simple', 'us-west-1'), '{"body": "Hello from Postgres!"'}::json )
   ```

   The response looks as follows.

<table>
<thead>
<tr>
<th>status_code</th>
<th>payload</th>
<th>executed_version</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>{&quot;statusCode&quot;: 200, &quot;body&quot;: &quot;Hello from Lambda!&quot;}</td>
<td>$LATEST</td>
</tr>
</tbody>
</table>

   If your invocation attempt doesn't succeed, see [Lambda function error messages](p. 2283).

Step 6: Grant other users permission to invoke Lambda functions

At this point in the procedures, only you as `rds_superuser` can invoke your Lambda functions. To allow other users to invoke any functions that you create, you need to grant them permission.

To grant others permission to invoke Lambda functions

1. Connect to your DB instance using `psql` or pgAdmin.
Examples: Invoking Lambda functions from your RDS for PostgreSQL DB instance

Following, you can find several examples of calling the `aws_lambda.invoke` function. Most all the examples use the composite structure `aws_lambda_arn_1` that you create in Step 4: Use Lambda helper functions with your RDS for PostgreSQL DB instance (Optional) (p. 2279) to simplify passing the function details. For an example of asynchronous invocation, see Example: Asynchronous (Event) invocation of Lambda functions (p. 2282). All the other examples listed use synchronous invocation.

To learn more about Lambda invocation types, see Invoking Lambda functions in the AWS Lambda Developer Guide. For more information about `aws_lambda_arn_1`, see `aws_commons.create_lambda_function_arn` (p. 2286).

Examples list
- Example: Synchronous (RequestResponse) invocation of Lambda functions (p. 2281)
- Example: Asynchronous (Event) invocation of Lambda functions (p. 2282)
- Example: Capturing the Lambda execution log in a function response (p. 2282)
- Example: Including client context in a Lambda function (p. 2282)
- Example: Invoking a specific version of a Lambda function (p. 2282)

Example: Synchronous (RequestResponse) invocation of Lambda functions

Following are two examples of a synchronous Lambda function invocation. The results of these `aws_lambda.invoke` function calls are the same.

```sql
SELECT * FROM aws_lambda.invoke(':aws_lambda_arn_1', '{"body": "Hello from Postgres!"}':json);
```

```sql
SELECT * FROM aws_lambda.invoke(':aws_lambda_arn_1', '{"body": "Hello from Postgres!"}':json, 'RequestResponse');
```

The parameters are described as follows:

- `':aws_lambda_arn_1'` – This parameter identifies the composite structure created in Step 4: Use Lambda helper functions with your RDS for PostgreSQL DB instance (Optional) (p. 2279), with the `aws_commons.create_lambda_function_arn` helper function. You can also create this structure inline within your `aws_lambda.invoke` call as follows.

```sql
SELECT * FROM aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-function', 'aws-region'), '{"body": "Hello from Postgres!"}':json
```
Examples: Invoking Lambda functions

- '{"body": "Hello from PostgreSQL!"}::json' – The JSON payload to pass to the Lambda function.
- 'RequestResponse' – The Lambda invocation type.

**Example: Asynchronous (Event) invocation of Lambda functions**

Following is an example of an asynchronous Lambda function invocation. The Event invocation type schedules the Lambda function invocation with the specified input payload and returns immediately. Use the Event invocation type in certain workflows that don't depend on the results of the Lambda function.

```sql
SELECT * FROM aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"}'::json, 'Event');
```

**Example: Capturing the Lambda execution log in a function response**

You can include the last 4 KB of the execution log in the function response by using the log_type parameter in your `aws_lambda.invoke` function call. By default, this parameter is set to None, but you can specify Tail to capture the results of the Lambda execution log in the response, as shown following.

```sql
SELECT *, select convert_from(decode(log_result, 'base64'), 'utf-8') as log FROM aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"}'::json, 'RequestResponse', 'Tail');
```

Set the `aws_lambda.invoke` function's log_type parameter to Tail to include the execution log in the response. The default value for the log_type parameter is None.

The log_result that's returned is a base64 encoded string. You can decode the contents using a combination of the decode and convert_from PostgreSQL functions.

For more information about log_type, see `aws_lambda.invoke` (p. 2284).

**Example: Including client context in a Lambda function**

The `aws_lambda.invoke` function has a context parameter that you can use to pass information separate from the payload, as shown following.

```sql
SELECT *, convert_from(decode(log_result, 'base64'), 'utf-8') as log FROM aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"}'::json, 'RequestResponse', 'Tail');
```

To include client context, use a JSON object for the `aws_lambda.invoke` (p. 2284) function's context parameter.

For more information about the context parameter, see the `aws_lambda.invoke` (p. 2284) reference.

**Example: Invoking a specific version of a Lambda function**

You can specify a particular version of a Lambda function by including the qualifier parameter with the `aws_lambda.invoke` call. Following, you can find an example that does this using 'custom_version' as an alias for the version.
Lambda function error messages

In the following list you can find information about error messages, with possible causes and solutions.

- **VPC configuration issues**

  VPC configuration issues can raise the following error messages when trying to connect:

  ```sql
  SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}', 'RequestResponse', 'None', NULL, 'custom_version');
  ```

  A common cause for this error is improperly configured VPC security group. Make sure you have an outbound rule for TCP open on port 443 of your VPC security group so that your VPC can connect to the Lambda VPC.

  If your DB instance is private, check the private DNS setup for your VPC. Make sure that you set the `rds.custom_dns_resolution` parameter to 1 and setup AWS PrivateLink as outlined in Step 1: Configure your RDS for PostgreSQL DB instance for outbound connections to AWS Lambda. For more information, see Interface VPC endpoints (AWS PrivateLink).

  ```sql
  SELECT * FROM aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-function:custom_version', 'us-west-2'), '{"body": "Hello from Postgres!"}');
  ```

- **Lack of permissions needed to invoke Lambda functions**

  If you see either of the following error messages, the user (role) invoking the function doesn't have proper permissions.

  ```sql
  ERROR:  permission denied for schema aws_lambda
  ```

  ```sql
  ERROR:  permission denied for function invoke
  ```

  A user (role) must be given specific grants to invoke Lambda functions. For more information, see Step 6: Grant other users permission to invoke Lambda functions.

- **Improper handling of errors in your Lambda functions**

  If a Lambda function throws an exception during request processing, `aws_lambda.invoke` fails with a PostgreSQL error such as the following.

  ```sql
  SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}');
  ```

  ```sql
  ERROR:  lambda invocation failed
  ```

  ```sql
  ```
Be sure to handle errors in your Lambda functions or in your PostgreSQL application.

AWS Lambda function reference

Following is the reference for the functions to use for invoking Lambda functions with RDS for PostgreSQL.

Functions

- `aws_lambda.invoke (p. 2284)`
- `aws_commons.create_lambda_function_arn (p. 2286)`

**aws_lambda.invoke**

Runs a Lambda function for an RDS for PostgreSQL DB instance.

For more details about invoking Lambda functions, see also `Invoke` in the *AWS Lambda Developer Guide*.

**Syntax**

**JSON**

```javascript
aws_lambda.invoke(
    IN function_name TEXT,
    IN payload JSON,
    IN region TEXT DEFAULT NULL,
    IN invocation_type TEXT DEFAULT 'RequestResponse',
    IN log_type TEXT DEFAULT 'None',
    IN context JSON DEFAULT NULL,
    IN qualifier VARCHAR(128) DEFAULT NULL,
    OUT status_code INT,
    OUT payload JSON,
    OUT executed_version TEXT,
    OUT log_result TEXT)
```

**JSONB**

```javascript
aws_lambda.invoke(
    IN function_name TEXT,
    IN payload JSONB,
    IN region TEXT DEFAULT NULL,
    IN invocation_type TEXT DEFAULT 'RequestResponse',
    IN log_type TEXT DEFAULT 'None',
    IN context JSON DEFAULT NULL,
    IN qualifier VARCHAR(128) DEFAULT NULL,
    OUT status_code INT,
    OUT payload JSONB,
    OUT executed_version TEXT,
    OUT log_result TEXT)
```

**Parameter Descriptions**

- **function_name**
  - Required
  - The name of the Lambda function to invoke.

- **payload**
  - Required
  - The input payload for the Lambda function.

- **region**
  - Optional
  - The AWS region where the Lambda function is deployed.

- **invocation_type**
  - Required
  - The type of invocation:
    - `RequestResponse`: The Lambda function is invoked with the `aws invoke` command.
    - `RequestOnly`: The Lambda function is invoked with the `aws invoke --request-only` command.

- **log_type**
  - Required
  - The log type:
    - `None`: No logs are sent.
    - `Tail`: Logs are sent to the terminal as they are generated.
    - `TailWithErrors`: Logs are sent to the terminal with errors.
    - `TailWithErrorsAndSTDOUT`: Logs are sent to the terminal with errors and standard output.

- **context**
  - Optional
  - Additional context for the Lambda function.

- **qualifier**
  - Optional
  - The version of the Lambda function to invoke.

- **status_code**
  - Output
  - The status code of the Lambda function.

- **payload**
  - Output
  - The output payload from the Lambda function.

- **executed_version**
  - Output
  - The version of the Lambda function that was executed.

- **log_result**
  - Output
  - The log result from the Lambda function.
OUT status_code INT,
OUT payload JSONB,
OUT executed_version TEXT,
OUT log_result TEXT)

aws_lambda.invoke(
  IN function_name aws_commons._lambda_function_arn_1,
  IN payload JSONB,
  IN invocation_type TEXT DEFAULT 'RequestResponse',
  IN log_type TEXT DEFAULT 'None',
  IN context JSONB DEFAULT NULL,
  IN qualifier VARCHAR(128) DEFAULT NULL,
  OUT status_code INT,
  OUT payload JSONB,
  OUT executed_version TEXT,
  OUT log_result TEXT
)

Input parameters

function_name

The identifying name of the Lambda function. The value can be the function name, an ARN, or a partial ARN. For a listing of possible formats, see Lambda function name formats in the AWS Lambda Developer Guide.

payload

The input for the Lambda function. The format can be JSON or JSONB. For more information, see JSON Types in the PostgreSQL documentation.

region

(Optional) The Lambda Region for the function. By default, RDS resolves the AWS Region from the full ARN in the function_name or it uses the RDS for PostgreSQL DB instance Region. If this Region value conflicts with the one provided in the function_name ARN, an error is raised.

invocation_type

The invocation type of the Lambda function. The value is case-sensitive. Possible values include the following:

• RequestResponse – The default. This type of invocation for a Lambda function is synchronous and returns a response payload in the result. Use the RequestResponse invocation type when your workflow depends on receiving the Lambda function result immediately.

• Event – This type of invocation for a Lambda function is asynchronous and returns immediately without a returned payload. Use the Event invocation type when you don’t need results of the Lambda function before your workflow moves on.

• DryRun – This type of invocation tests access without running the Lambda function.

log_type

The type of Lambda log to return in the log_result output parameter. The value is case-sensitive. Possible values include the following:

• Tail – The returned log_result output parameter will include the last 4 KB of the execution log.

• None – No Lambda log information is returned.

context

Client context in JSON or JSONB format. Fields to use include than custom and env.
qualifier

A qualifier that identifies a Lambda function's version to be invoked. If this value conflicts with one provided in the function_name ARN, an error is raised.

Output parameters

status_code

An HTTP status response code. For more information, see Lambda Invoke response elements in the AWS Lambda Developer Guide.

payload

The information returned from the Lambda function that ran. The format is in JSON or JSONB.

executed_version

The version of the Lambda function that ran.

log_result

The execution log information returned if the log_type value is Tail when the Lambda function was invoked. The result contains the last 4 KB of the execution log encoded in Base64.

aws_commons.create_lambda_function_arn

Creates an aws_commons._lambda_function_arn_1 structure to hold Lambda function name information. You can use the results of the aws_commons.create_lambda_function_arn function in the function_name parameter of the aws_lambda.invoke aws_lambda.invoke (p. 2284) function.

Syntax

```sql
aws_commons.create_lambda_function_arn(
    function_name TEXT,
    region TEXT DEFAULT NULL
) 
RETURNS aws_commons._lambda_function_arn_1
```

Input parameters

function_name

A required text string containing the Lambda function name. The value can be a function name, a partial ARN, or a full ARN.

region

An optional text string containing the AWS Region that the Lambda function is in. For a listing of Region names and associated values, see Regions, Availability Zones, and Local Zones (p. 110).
Common DBA tasks for Amazon RDS for PostgreSQL

Database administrators (DBAs) perform a variety of tasks when administering an Amazon RDS for PostgreSQL DB instance. If you’re a DBA already familiar with PostgreSQL, you need to be aware of some of the important differences between running PostgreSQL on your hardware and RDS for PostgreSQL. For example, because it’s a managed service, Amazon RDS doesn’t allow shell access to your DB instances. That means that you don’t have direct access to \texttt{pg\_hba\_conf} and other configuration files. For RDS for PostgreSQL, changes that are typically made to the PostgreSQL configuration file of an on-premises instance are made to a custom DB parameter group associated with the RDS for PostgreSQL DB instance. For more information, see Working with parameter groups (p. 347).

You also can't access log files in the same way that you do with an on-premises PostgreSQL instance. To learn more about logging, see RDS for PostgreSQL database log files (p. 931).

As another example, you don't have access to the PostgreSQL superuser account. On RDS for PostgreSQL, the \texttt{rds\_superuser} role is the most highly privileged role, and it’s granted to postgres at set up time. Whether you’re familiar with using PostgreSQL on-premises or completely new to RDS for PostgreSQL, we recommend that you understand the \texttt{rds\_superuser} role, and how to work with roles, users, groups, and permissions. For more information, see Understanding PostgreSQL roles and permissions (p. 2288).

Following are some common DBA tasks for RDS for PostgreSQL.

Topics
- Collations supported in RDS for PostgreSQL (p. 2287)
- Understanding PostgreSQL roles and permissions (p. 2288)
- Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL (p. 2297)
- Working with logging mechanisms supported by RDS for PostgreSQL (p. 2307)
- Managing temporary files with PostgreSQL (p. 2308)
- Using pgBadger for log analysis with PostgreSQL (p. 2312)
- Using PGSnapper for monitoring PostgreSQL (p. 2312)
- Working with parameters on your RDS for PostgreSQL DB instance (p. 2313)

Collations supported in RDS for PostgreSQL

Collations are set of rules that determine how character strings stored in the database are sorted and compared. Collations play a fundamental role in the computer system and are included as part of the operating system. Collations change over time when new characters are added to languages or when ordering rules change.

Collation libraries define specific rules and algorithms for a collation. The most popular collation libraries used within PostgreSQL are GNU C (glibc) and Internationalization components for Unicode (ICU). By default, RDS for PostgreSQL uses the glibc collation that includes unicode character sort orders for multi-byte character sequences.

When you create a new DB instance in RDS for PostgreSQL, it checks the operating system for the available collation. The PostgreSQL parameters of the CREATE DATABASE command \texttt{LC\_COLLATE} and \texttt{LC\_CTYPE} are used to specify a collation, which stands as the default collation in that database. Alternatively, you can also use the \texttt{LOCALE} parameter in CREATE DATABASE to set these parameters. This determines the default collation for character strings in the database and the rules for classifying characters as letters, numbers, or symbols. You can also choose a collation to use on a column, index, or on a query.
RDS for PostgreSQL depends on the glibc library in the operating system for collation support. RDS for PostgreSQL instance is periodically updated with the latest versions of the operating system. These updates sometimes include a newer version of the glibc library. Rarely, newer versions of glibc change the sort order or collation of some characters, which can cause the data to sort differently or produce invalid index entries. If you discover sort order issues for collation during an update, you might need to rebuild the indexes.

To reduce the possible impacts of the glibc updates, RDS for PostgreSQL now includes an independent default collation library. This collation library is available in RDS for PostgreSQL 14.6, 13.9, 12.13, 11.18, 10.23 and newer minor version releases. It is compatible with glibc 2.26-59.amzn2, and provides sort order stability to prevent incorrect query results.

Understanding PostgreSQL roles and permissions

When you create an RDS for PostgreSQL DB instance using the AWS Management Console, an administrator account is created at the same time. By default, its name is postgres, as shown in the following screenshot:

You can choose another name rather than accept the default (postgres). If you do, the name you choose must start with a letter and be between 1 and 16 alphanumeric characters. For simplicity's sake, we refer to this main user account by its default value (postgres) throughout this guide.

If you use the create-db-instance AWS CLI rather than the AWS Management Console, you create the name by passing it with the master-username parameter in the command. For more information, see Creating an Amazon RDS DB instance (p. 300).

Whether you use the AWS Management Console, the AWS CLI, or the Amazon RDS API, and whether you use the default postgres name or choose a different name, this first database user account is a member of the rds_superuser group and has rds_superuser privileges.

Topics

- Understanding the rds_superuser role (p. 2288)
- Controlling user access to the PostgreSQL database (p. 2290)
- Delegating and controlling user password management (p. 2291)
- Using SCRAM for PostgreSQL password encryption (p. 2292)

Understanding the rds_superuser role

In PostgreSQL, a role can define a user, a group, or a set of specific permissions granted to a group or user for various objects in the database. PostgreSQL commands to CREATE USER and CREATE GROUP
have been replaced by the more general, CREATE ROLE with specific properties to distinguish database users. A database user can be thought of as a role with the LOGIN privilege.

Note
The CREATE USER and CREATE GROUP commands can still be used. For more information, see Database Roles in the PostgreSQL documentation.

The postgres user is the most highly privileged database user on your RDS for PostgreSQL DB instance. It has the characteristics defined by the following CREATE ROLE statement.

```
CREATE ROLE postgres WITH LOGIN NOSUPERUSER INHERIT CREATEDB CREATEROLE NOREPLICATION VALID UNTIL 'infinity'
```

The properties NOSUPERUSER, NOREPLICATION, INHERIT, and VALID UNTIL 'infinity' are the default options for CREATE ROLE, unless otherwise specified.

By default, postgres has privileges granted to the rds_superuser role, and permissions to create roles and databases. The rds_superuser role allows the postgres user to do the following:

- Add extensions that are available for use with Amazon RDS. For more information, see Working with PostgreSQL features supported by Amazon RDS for PostgreSQL (p. 2175)
- Create roles for users and grant privileges to users. For more information, see CREATE ROLE and GRANT in the PostgreSQL documentation.
- Create databases. For more information, see CREATE DATABASE in the PostgreSQL documentation.
- Grant rds_superuser privileges to user roles that don't have these privileges, and revoke privileges as needed. We recommend that you grant this role only to those users who perform superuser tasks. In other words, you can grant this role to database administrators (DBAs) or system administrators.
- Grant (and revoke) the rds_replication role to database users that don't have the rds_superuser role.
- Grant (and revoke) the rds_password role to database users that don't have the rds_superuser role.
- Obtain status information about all database connections by using the pg_stat_activity view. When needed, rds_superuser can stop any connections by using pg_terminate_backend or pg_cancel_backend.

In the CREATE ROLE postgres... statement, you can see that the postgres user role specifically disallows PostgreSQL superuser permissions. RDS for PostgreSQL is a managed service, so you can't access the host OS, and you can't connect using the PostgreSQL superuser account. Many of the tasks that require superuser access on a stand-alone PostgreSQL are managed automatically by Amazon RDS.

For more information about granting privileges, see GRANT in the PostgreSQL documentation.

The rds_superuser role is one of several predefined roles in an RDS for PostgreSQL DB instance.

Note
In PostgreSQL 13 and earlier releases, predefined roles are known as default roles.

In the following list, you find some of the other predefined roles that are created automatically for a new RDS for PostgreSQL DB instance. Predefined roles and their privileges can't be changed. You can't drop, rename, or modify privileges for these predefined roles. Attempting to do so results in an error.

- rds_password – A role that can change passwords and set up password constraints for database users. The rds_superuser role is granted this role by default, and can grant the role to database users. For more information, see Controlling user access to the PostgreSQL database (p. 2290).
• **rdsadmin** – A role that's created to handle many of the management tasks that the administrator with superuser privileges would perform on a standalone PostgreSQL database. This role is used internally by RDS for PostgreSQL for many management tasks.

• **rdstopmgr** – A role that's used internally by Amazon RDS to support Multi-AZ deployments.

To see all predefined roles, you can connect to your RDS for PostgreSQL DB instance and use the psql `\du` metacommand. The output looks as follows:

<table>
<thead>
<tr>
<th>List of roles</th>
<th>Attributes</th>
<th>Member of</th>
</tr>
</thead>
<tbody>
<tr>
<td>postgres</td>
<td>Create role, Create DB</td>
<td>{rds_superuser}</td>
</tr>
<tr>
<td>rds_superuser</td>
<td>Cannot login</td>
<td>{pg_monitor, pg_signal_backend, rds_replication, rds_password}</td>
</tr>
</tbody>
</table>

In the output, you can see that *rds_superuser* isn't a database user role (it can't login), but it has the privileges of many other roles. You can also see that database user *postgres* is a member of the *rds_superuser* role. As mentioned previously, *postgres* is the default value in the Amazon RDS console's *Create database* page. If you chose another name, that name is shown in the list of roles instead.

**Controlling user access to the PostgreSQL database**

New databases in PostgreSQL are always created with a default set of privileges in the database's public schema that allow all database users and roles to create objects. These privileges allow database users to connect to the database, for example, and create temporary tables while connected.

To better control user access to the databases instances that you create on your RDS for PostgreSQL DB instance, we recommend that you revoke these default public privileges. After doing so, you then grant specific privileges for database users on a more granular basis, as shown in the following procedure.

**To set up roles and privileges for a new database instance**

Suppose you're setting up a database on a newly created RDS for PostgreSQL DB instance for use by several researchers, all of whom need read-write access to the database.

1. Use psql (or pgAdmin) to connect to your RDS for PostgreSQL DB instance:

   ```
   psql --host=your-db-instance.666666666666.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   ```

   When prompted, enter your password. The psql client connects and displays the default administrative connection database, postgres=>, as the prompt.

2. To prevent database users from creating objects in the public schema, do the following:

   ```
   postgres=> REVOKE CREATE ON SCHEMA public FROM PUBLIC;
   REVOKE
   ```

3. Next, you create a new database instance:

   ```
   postgres=> CREATE DATABASE lab_db;
   CREATE DATABASE
   ```

4. Revoke all privileges from the PUBLIC schema on this new database.
5. Create a role for database users.

```
postgres=> CREATE ROLE lab_tech;
```

6. Give database users that have this role the ability to connect to the database.

```
postgres=> GRANT CONNECT ON DATABASE lab_db TO lab_tech;
```

7. Grant all users with the lab_tech role all privileges on this database.

```
postgres=> GRANT ALL PRIVILEGES ON DATABASE lab_db TO lab_tech;
```

8. Create database users, as follows:

```
postgres=> CREATE ROLE lab_user1 LOGIN PASSWORD 'change_me';
postgres=> CREATE ROLE lab_user2 LOGIN PASSWORD 'change_me';
```

9. Grant these two users the privileges associated with the lab_tech role:

```
postgres=> GRANT lab_tech TO lab_user1;
postgres=> GRANT lab_tech TO lab_user2;
```

At this point, lab_user1 and lab_user2 can connect to the lab_db database. This example doesn't follow best practices for enterprise usage, which might include creating multiple database instances, different schemas, and granting limited permissions. For more complete information and additional scenarios, see Managing PostgreSQL Users and Roles.

For more information about privileges in PostgreSQL databases, see the GRANT command in the PostgreSQL documentation.

**Delegating and controlling user password management**

As a DBA, you might want to delegate the management of user passwords. Or, you might want to prevent database users from changing their passwords or reconfiguring password constraints, such as password lifetime. To ensure that only the database users that you choose can change password settings, you can turn on the restricted password management feature. When you activate this feature, only those database users that have been granted the rds_password role can manage passwords.

**Note**
To use restricted password management, your RDS for PostgreSQL DB instance must be running PostgreSQL 10.6 or higher.

By default, this feature is off, as shown in the following:

```
postgres=> SHOW rds.restrict_password_commands;
rds.restrict_password_commands
```
To turn on this feature, you use a custom parameter group and change the setting for `rds.restrict_password_commands` to 1. Be sure to reboot your RDS for PostgreSQL DB instance so that the setting takes effect.

With this feature active, `rds_password` privileges are needed for the following SQL commands:

```sql
CREATE ROLE myrole WITH PASSWORD 'mypassword';
CREATE ROLE myrole WITH PASSWORD 'mypassword' VALID UNTIL '2023-01-01';
ALTER ROLE myrole WITH PASSWORD 'mypassword' VALID UNTIL '2023-01-01';
ALTER ROLE myrole WITH PASSWORD 'mypassword';
ALTER ROLE myrole VALID UNTIL '2023-01-01';
ALTER ROLE myrole RENAME TO myrole2;
```

Renaming a role (ALTER ROLE myrole RENAME TO newname) is also restricted if the password uses the MD5 hashing algorithm.

With this feature active, attempting any of these SQL commands without the `rds_password` role permissions generates the following error:

```
ERROR: must be a member of rds_password to alter passwords
```

We recommend that you grant the `rds_password` to only a few roles that you use solely for password management. If you grant `rds_password` privileges to database users that don't have `rds_superuser` privileges, you need to also grant them the `CREATEROLE` attribute.

Make sure that you verify password requirements such as expiration and needed complexity on the client side. If you use your own client-side utility for password related changes, the utility needs to be a member of `rds_password` and have `CREATE ROLE` privileges.

## Using SCRAM for PostgreSQL password encryption

The **Salted Challenge Response Authentication Mechanism (SCRAM)** is an alternative to PostgreSQL's default message digest (MD5) algorithm for encrypting passwords. The SCRAM authentication mechanism is considered more secure than MD5. To learn more about these two different approaches to securing passwords, see **Password Authentication** in the PostgreSQL documentation.

We recommend that you use SCRAM rather than MD5 as the password encryption scheme for your RDS for PostgreSQL DB instance. It's a cryptographic challenge-response mechanism that uses the scram-sha-256 algorithm for password authentication and encryption.

You might need to update libraries for your client applications to support SCRAM. For example, JDBC versions before 42.2.0 don't support SCRAM. For more information, see **PostgreSQL JDBC Driver** in the PostgreSQL JDBC Driver documentation. For a list of other PostgreSQL drivers and SCRAM support, see **List of drivers** in the PostgreSQL documentation.

**Note**
RDS for PostgreSQL version 13.1 and higher support scram-sha-256. These versions also let you configure your DB instance to require SCRAM, as discussed in the following procedures.

## Setting up RDS for PostgreSQL DB instance to require SCRAM

you can require the RDS for PostgreSQL DB instance to accept only passwords that use the scram-sha-256 algorithm.
Important
For existing RDS Proxies with PostgreSQL databases, if you modify the database authentication to use SCRAM only, the proxy becomes unavailable for up to 60 seconds. To avoid the issue, do one of the following:

- Ensure that the database allows both SCRAM and MD5 authentication.
- To use only SCRAM authentication, create a new proxy, migrate your application traffic to the new proxy, then delete the proxy previously associated with the database.

Before making changes to your system, be sure you understand the complete process, as follows:

- Get information about all roles and password encryption for all database users.
- Double-check the parameter settings for your RDS for PostgreSQL DB instance for the parameters that control password encryption.
- If your RDS for PostgreSQL DB instance uses a default parameter group, you need to create a custom DB parameter group and apply it to your RDS for PostgreSQL DB instance so that you can modify parameters when needed. If your RDS for PostgreSQL DB instance uses a custom parameter group, you can modify the necessary parameters later in the process, as needed.
- Change the password_encryption parameter to scram-sha-256.
- Notify all database users that they need to update their passwords. Do the same for your postgres account. The new passwords are encrypted and stored using the scram-sha-256 algorithm.
- Verify that all passwords are encrypted using as the type of encryption.
- If all passwords use scram-sha-256, you can change the rds.accepted_password_auth_method parameter from md5+scram to scram-sha-256.

Warning
After you change rds.accepted_password_auth_method to scram-sha-256 alone, any users (roles) with md5-encrypted passwords can't connect.

Getting ready to require SCRAM for your RDS for PostgreSQL DB instance

Before making any changes to your RDS for PostgreSQL DB instance, check all existing database user accounts. Also, check the type of encryption used for passwords. You can do these tasks by using the rds_tools extension. This extension is supported on RDS for PostgreSQL 13.1 and higher releases.

To get a list of database users (roles) and password encryption methods

1. Use `psql` to connect to your RDS for PostgreSQL DB instance, as shown in the following.

   ```bash
   psql --host=host-db-name.111122233333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   ```

2. Install the rds_tools extension.

   ```bash
   postgres=> CREATE EXTENSION rds_tools;
   CREATE EXTENSION
   ```

3. Get a listing of roles and encryption.

   ```bash
   postgres=> SELECT * FROM rds_tools.role_password_encryption_type();
   ```

   You see output similar to the following.
Creating a custom DB parameter group

**Note**
If your RDS for PostgreSQL DB instance already uses a custom parameter group, you don’t need to create a new one.

For an overview of parameter groups for Amazon RDS, see [Working with parameters on your RDS for PostgreSQL DB instance](p. 2313).

The password encryption type used for passwords is set in one parameter, `password_encryption`. The encryption that the RDS for PostgreSQL DB instance allows is set in another parameter, `rds.accepted_password_auth_method`. Changing either of these from the default values requires that you create a custom DB parameter group and apply it to your instance.

You can also use the AWS Management Console or the RDS API to create a custom DB parameter group. For more information, see [Creating a custom parameter group](p. 2294).

You can now associate the custom parameter group with your DB instance.

**To create a custom DB parameter group**

1. Use the `create-db-parameter-group` CLI command to create the custom DB parameter group. This example uses `postgres13` as the source for this custom parameter group.

   For Linux, macOS, or Unix:
   ```bash
   aws rds create-db-parameter-group --db-parameter-group-name 'docs-lab-scram-passwords' \
   --db-parameter-group-family postgres13  --description 'Custom parameter group for SCRAM'
   ```

   For Windows:
   ```bash
   aws rds create-db-parameter-group --db-parameter-group-name "docs-lab-scram-passwords" \
   --db-parameter-group-family postgres13  --description "Custom DB parameter group for SCRAM"
   ```

2. Use the `modify-db-instance` CLI command to apply this custom parameter group to your RDS for PostgreSQL DB cluster.

   For Linux, macOS, or Unix:
   ```bash
   aws rds modify-db-instance --db-instance-identifier 'your-instance-name' \
   --db-parameter-group-name 'docs-lab-scram-passwords'
   ```
Configuring password encryption to use SCRAM

The password encryption mechanism used by an RDS for PostgreSQL DB instance is set in the DB parameter group in the password_encryption parameter. Allowed values are unset, md5, or scram-sha-256. The default value depends on the RDS for PostgreSQL version, as follows:

- RDS for PostgreSQL 14 and above – Default is scram-sha-256
- RDS for PostgreSQL 13 – Default is md5

With a custom DB parameter group attached to your RDS for PostgreSQL DB instance, you can modify values for the password encryption parameter.

<table>
<thead>
<tr>
<th>Name</th>
<th>Values</th>
<th>Allowed values</th>
<th>Modifiable</th>
<th>Source</th>
<th>Apply type</th>
</tr>
</thead>
<tbody>
<tr>
<td>password_encryption</td>
<td>md5, scram-sha-256</td>
<td>true, system, dynamic</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>rdssupported_password_auth_method</td>
<td>md5=oracledb, md5=sqlserver, md5=postgresql</td>
<td>true, system, dynamic</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

To change password encryption setting to scram-sha-256

- Change the value of password encryption to scram-sha-256, as shown following. The change can be applied immediately because the parameter is dynamic, so a restart isn’t required for the change to take effect.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group --db-parameter-group-name 'docs-lab-scram-passwords' --parameters 'ParameterName=password_encryption,ParameterValue=scram-sha-256,ApplyMethod=immediate'
```

For Windows:

```
aws rds modify-db-parameter-group --db-parameter-group-name "docs-lab-scram-passwords" --parameters "ParameterName=password_encryption,ParameterValue=scram-sha-256,ApplyMethod=immediate"
```

Migrating passwords for user roles to SCRAM

You can migrate passwords for user roles to SCRAM as described following.

To migrate database user (role) passwords from MD5 to SCRAM

1. Log in as the administrator user (default user name, postgres) as shown following.
2. Check the setting of the password_encryption parameter on your RDS for PostgreSQL DB instance by using the following command.

```sql
postgres=> SHOW password_encryption;
password_encryption
---------------------
md5
(1 row)
```

3. Change the value of this parameter to scram-sha-256. This is a dynamic parameter, so you don’t need to reboot the instance after making this change. Check the value again to make sure that it’s now set to scram-sha-256, as follows.

```sql
postgres=> SHOW password_encryption;
password_encryption
---------------------
scram-sha-256
(1 row)
```

4. Notify all database users to change their passwords. Be sure to also change your own password for account postgres (the database user with rds_superuser privileges).

```sql
labdb=> ALTER ROLE postgres WITH LOGIN PASSWORD 'change_me';
ALTER ROLE
```

5. Repeat the process for all databases on your RDS for PostgreSQL DB instance.

### Changing parameter to require SCRAM

This is the final step in the process. After you make the change in the following procedure, any user accounts (roles) that still use md5 encryption for passwords can't log in to the RDS for PostgreSQL DB instance.

The `rds.accepted_password_auth_method` specifies the encryption method that the RDS for PostgreSQL DB instance accepts for a user password during the login process. The default value is `md5+scram`, meaning that either method is accepted. In the following image, you can find the default setting for this parameter.

<table>
<thead>
<tr>
<th>Name</th>
<th>Values</th>
<th>Allowed values</th>
<th>Modifiable</th>
<th>Source</th>
<th>Apply type</th>
</tr>
</thead>
<tbody>
<tr>
<td>password_encryption</td>
<td>scram-sha-256</td>
<td>md5, scram-sha-256</td>
<td>True</td>
<td>System</td>
<td>Dynamic</td>
</tr>
<tr>
<td>rds.accepted_password_auth_method</td>
<td>md5+scram</td>
<td>md5+scram [scram]</td>
<td>True</td>
<td>System</td>
<td>Dynamic</td>
</tr>
</tbody>
</table>

The allowed values for this parameter are `md5+scram` or `scram` alone. Changing this parameter value to `scram` makes this a requirement.

#### To change the parameter value to require SCRAM authentication for passwords

1. Verify that all database user passwords for all databases on your RDS for PostgreSQL DB instance use `scram-sha-256` for password encryption. To do so, query `rds_tools` for the role (user) and encryption type, as follows.
postgres=> SELECT * FROM rds_tools.role_password_encryption_type();

<table>
<thead>
<tr>
<th>rolname</th>
<th>encryption_type</th>
</tr>
</thead>
<tbody>
<tr>
<td>pg_monitor</td>
<td>scram-sha-256</td>
</tr>
<tr>
<td>pg_read_all_settings</td>
<td>scram-sha-256</td>
</tr>
<tr>
<td>pg_read_all_stats</td>
<td>scram-sha-256</td>
</tr>
<tr>
<td>pg_stat_scan_tables</td>
<td>scram-sha-256</td>
</tr>
<tr>
<td>pg_signal_backend</td>
<td>scram-sha-256</td>
</tr>
<tr>
<td>lab_tester</td>
<td>scram-sha-256</td>
</tr>
<tr>
<td>user_465</td>
<td>scram-sha-256</td>
</tr>
<tr>
<td>postgres</td>
<td>scram-sha-256</td>
</tr>
</tbody>
</table>

( rows)

2. Repeat the query across all DB instances in your RDS for PostgreSQL DB instance.

   If all passwords use scram-sha-256, you can proceed.

3. Change the value of the accepted password authentication to scram-sha-256, as follows.

   For Linux, macOS, or Unix:

   ```bash
   aws rds modify-db-parameter-group --db-parameter-group-name 'docs-lab-scram-passwords'
   \--parameters
   'ParameterName=rds.accepted_password_auth_method,ParameterValue=scram,ApplyMethod=immediate'
   ```

   For Windows:

   ```bash
   aws rds modify-db-parameter-group --db-parameter-group-name "docs-lab-scram-passwords"
   ^
   --parameters
   "ParameterName=rds.accepted_password_auth_method,ParameterValue=scram,ApplyMethod=immediate"
   ```

## Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL

We strongly recommend that you use the autovacuum feature to maintain the health of your PostgreSQL DB instance. Autovacuum automates the start of the VACUUM and the ANALYZE commands. It checks for tables with a large number of inserted, updated, or deleted tuples. After this check, it reclaims storage by removing obsolete data or tuples from the PostgreSQL database.

By default, autovacuum is turned on for the Amazon RDS for PostgreSQL DB instances that you create using any of the default PostgreSQL DB parameter groups. These include default.postgres10, default.postgres11, and so on. All default PostgreSQL DB parameter groups have an rds.adaptive_autovacuum parameter that’s set to 1, thus activating the feature. Other configuration parameters associated with the autovacuum feature are also set by default. Because these defaults are somewhat generic, you can benefit from tuning some of the parameters associated with the autovacuum feature for your specific workload.

Following, you can find more information about the autovacuum and how to tune some of its parameters on your RDS for PostgreSQL DB instance. For high-level information, see [Best practices for working with PostgreSQL](p. 294).

### Topics
- Allocating memory for autovacuum (p. 2298)
- Reducing the likelihood of transaction ID wraparound (p. 2298)
Allocating memory for autovacuum

One of the most important parameters influencing autovacuum performance is the maintenance_work_mem parameter. This parameter determines how much memory that you allocate for autovacuum to use to scan a database table and to hold all the row IDs that are going to be vacuumed. If you set the value of the maintenance_work_mem parameter too low, the vacuum process might have to scan the table multiple times to complete its work. Such multiple scans can have a negative impact on performance.

When doing calculations to determine the maintenance_work_mem parameter value, keep in mind two things:

- The default unit is kilobytes (KB) for this parameter.
- The maintenance_work_mem parameter works in conjunction with the autovacuum_max_workers parameter. If you have many small tables, allocate more autovacuum_max_workers and less maintenance_work_mem. If you have large tables (say, larger than 100 GB), allocate more memory and fewer worker processes. You need to have enough memory allocated to succeed on your biggest table. Each autovacuum_max_workers can use the memory that you allocate. Thus, make sure that the combination of worker processes and memory equal the total memory that you want to allocate.

In general terms, for large hosts set the maintenance_work_mem parameter to a value between one and two gigabytes (between 1,048,576 and 2,097,152 KB). For extremely large hosts, set the parameter to a value between two and four gigabytes (between 2,097,152 and 4,194,304 KB). The value that you set for this parameter depends on the workload. Amazon RDS has updated its default for this parameter to be kilobytes calculated as follows.

GREATEST({DBInstanceClassMemory/63963136*1024},65536).

Reducing the likelihood of transaction ID wraparound

In some cases, parameter group settings related to autovacuum might not be aggressive enough to prevent transaction ID wraparound. To address this, RDS for PostgreSQL provides a mechanism that adapts the autovacuum parameter values automatically. Adaptive autovacuum parameter tuning is a feature for RDS for PostgreSQL. A detailed explanation of TransactionID wraparound is found in the PostgreSQL documentation.

Adaptive autovacuum parameter tuning is turned on by default for RDS for PostgreSQL instances with the dynamic parameter rds.adaptive_autovacuum set to ON. We strongly recommend that you keep this turned on. However, to turn off adaptive autovacuum parameter tuning, set the rds.adaptive_autovacuum parameter to 0 or OFF.

Transaction ID wraparound is still possible even when Amazon RDS tunes the autovacuum parameters. We encourage you to implement an Amazon CloudWatch alarm for transaction ID wraparound. For more
information, see the post [Implement an early warning system for transaction ID wraparound in RDS for PostgreSQL](https://aws.amazon.com/blogs/database/implement-an-early-warning-system-for-transaction-id-wraparound-in-rds-for-postgresql/) on the AWS Database Blog.

With adaptive autovacuum parameter tuning turned on, Amazon RDS begins adjusting autovacuum parameters when the CloudWatch metric `MaximumUsedTransactionIDs` reaches the value of the `autovacuum_freeze_max_age` parameter or 500,000,000, whichever is greater.

Amazon RDS continues to adjust parameters for autovacuum if a table continues to trend toward transaction ID wraparound. Each of these adjustments dedicates more resources to autovacuum to avoid wraparound. Amazon RDS updates the following autovacuum-related parameters:

- `autovacuum_vacuum_cost_delay`
- `autovacuum_vacuum_cost_limit`
- `autovacuum_work_mem`
- `autovacuum_naptime`

RDS modifies these parameters only if the new value makes autovacuum more aggressive. The parameters are modified in memory on the DB instance. The values in the parameter group aren't changed. To view the current in-memory settings, use the PostgreSQL `SHOW` SQL command.

When Amazon RDS modifies any of these autovacuum parameters, it generates an event for the affected DB instance. This event is visible on the AWS Management Console and through the Amazon RDS API. After the `MaximumUsedTransactionIDs` CloudWatch metric returns below the threshold, Amazon RDS resets the autovacuum-related parameters in memory back to the values specified in the parameter group. It then generates another event corresponding to this change.

### Determining if the tables in your database need vacuuming

You can use the following query to show the number of unvacuumed transactions in a database. The `datfrozenxid` column of a database's `pg_database` row is a lower bound on the normal transaction IDs appearing in that database. This column is the minimum of the per-table `relfrozenxid` values within the database.

```sql
SELECT datname, age(datfrozenxid) FROM pg_database ORDER BY age(datfrozenxid) desc limit 20;
```

For example, the results of running the preceding query might be the following.

<table>
<thead>
<tr>
<th>datname</th>
<th>age</th>
</tr>
</thead>
<tbody>
<tr>
<td>mydb</td>
<td>1771757888</td>
</tr>
<tr>
<td>template0</td>
<td>1721757888</td>
</tr>
<tr>
<td>template1</td>
<td>1721757888</td>
</tr>
<tr>
<td>rdsadmin</td>
<td>1694008527</td>
</tr>
<tr>
<td>postgres</td>
<td>1693881061</td>
</tr>
<tr>
<td>(5 rows)</td>
<td></td>
</tr>
</tbody>
</table>

When the age of a database reaches 2 billion transaction IDs, transaction ID (XID) wraparound occurs and the database becomes read-only. You can use this query to produce a metric and run a few times a day. By default, autovacuum is set to keep the age of transactions to no more than 200,000,000 (`autovacuum_freeze_max_age`).

A sample monitoring strategy might look like this:

- Set the `autovacuum_freeze_max_age` value to 200 million transactions.
- If a table reaches 500 million unvacuumed transactions, that triggers a low-severity alarm. This isn't an unreasonable value, but it can indicate that autovacuum isn't keeping up.
• If a table ages to 1 billion, this should be treated as an alarm to take action on. In general, you want to keep ages closer to `autovacuum_freeze_max_age` for performance reasons. We recommend that you investigate using the recommendations that follow.

• If a table reaches 1.5 billion unvacuumed transactions, that triggers a high-severity alarm. Depending on how quickly your database uses transaction IDs, this alarm can indicate that the system is running out of time to run autovacuum. In this case, we recommend that you resolve this immediately.

If a table is constantly breaching these thresholds, modify your autovacuum parameters further. By default, using VACUUM manually (which has cost-based delays disabled) is more aggressive than using the default autovacuum, but it is also more intrusive to the system as a whole.

We recommend the following:

• Be aware and turn on a monitoring mechanism so that you are aware of the age of your oldest transactions.

  For information on creating a process that warns you about transaction ID wraparound, see the AWS Database Blog post [Implement an early warning system for transaction ID wraparound in Amazon RDS for PostgreSQL](https://aws.amazon.com/blogs/database/implement-an-early-warning-system-for-transaction-id-wraparound/).

• For busier tables, perform a manual vacuum freeze regularly during a maintenance window, in addition to relying on autovacuum. For information on performing a manual vacuum freeze, see [Performing a manual vacuum freeze](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/RDS-PostgreSQL-Tutorials-VacuumFreeze-Manual.html) (p. 2302).

### Determining which tables are currently eligible for autovacuum

Often, it is one or two tables in need of vacuuming. Tables whose `relfrozenxid` value is greater than the number of transactions in `autovacuum_freeze_max_age` are always targeted by autovacuum. Otherwise, if the number of tuples made obsolete since the last VACUUM exceeds the vacuum threshold, the table is vacuumed.

The [autovacuum threshold](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/RDS-PostgreSQL-Tutorials-VacuumFreeze-Manual.html) is defined as:

\[
\text{Vacuum-threshold} = \text{vacuum-base-threshold} + \text{vacuum-scale-factor} \times \text{number-of-tuples}
\]

While you are connected to your database, run the following query to see a list of tables that autovacuum sees as eligible for vacuuming.

```sql
WITH vbt AS (SELECT setting AS autovacuum_vacuum_threshold FROM pg_settings WHERE name = 'autovacuum_vacuum_threshold'),
vsf AS (SELECT setting AS autovacuum_vacuum_scale_factor FROM pg_settings WHERE name = 'autovacuum_vacuum_scale_factor'),
fma AS (SELECT setting AS autovacuum_freeze_max_age FROM pg_settings WHERE name = 'autovacuum_freeze_max_age'),
sto AS (select opt_oid, split_part(setting, '=', 1) as param, split_part(setting, '.equalsIgnoreCase', 2) as value from (select oid opt_oid, unnest(reloptions) setting from pg_class) opt)
SELECT '"'||ns.nspname||'"."'||c.relname||'"' as relation, pg_size_pretty(pg_table_size(c.oid)) as table_size, age(relfrozenxid) as xid_age, coalesce(cfma.value::float, autovacuum_freeze_max_age::float) autovacuum_freeze_max_age, (coalesce(cvbt.value::float, autovacuum_vacuum_threshold::float) + coalesce(cvsf.value::float,autovacuum_vacuum_scale_factor::float)) * c.reltuples AS autovacuum_vacuum_tuples, n_dead_tup as dead_tuples FROM pg_class c join pg_namespace ns on ns.oid = c.relnamespace
left join pg_stat_all_tables stat on stat.relid = c.oid
join vbt on (1=1) join vsf on (1=1) join fma on (1=1)
WHERE c.oid IN (select opt_oid from sto)
```
Determining if autovacuum is currently running and for how long

If you need to manually vacuum a table, make sure to determine if autovacuum is currently running. If it is, you might need to adjust parameters to make it run more efficiently, or turn off autovacuum temporarily so that you can manually run VACUUM.

Use the following query to determine if autovacuum is running, how long it has been running, and if it is waiting on another session.

```sql
SELECT datname, usename, pid, state, wait_event, current_timestamp - xact_start AS xact_runtime, query
FROM pg_stat_activity
WHERE upper(query) LIKE '%VACUUM%'
ORDER BY xact_start;
```

After running the query, you should see output similar to the following.

<table>
<thead>
<tr>
<th>datname</th>
<th>usename</th>
<th>pid</th>
<th>state</th>
<th>wait_event</th>
<th>xact_runtime</th>
<th>query</th>
</tr>
</thead>
<tbody>
<tr>
<td>mydb</td>
<td>rdsadmin</td>
<td>16473</td>
<td>active</td>
<td></td>
<td>33 days 16:32:11.600656</td>
<td>autovacuum: VACUUM ANALYZE public.mytable1 (to prevent wraparound)</td>
</tr>
<tr>
<td>mydb</td>
<td>rdsadmin</td>
<td>22553</td>
<td>active</td>
<td></td>
<td>14 days 09:15:34.073141</td>
<td>autovacuum: VACUUM ANALYZE public.mytable2 (to prevent wraparound)</td>
</tr>
<tr>
<td>mydb</td>
<td>rdsadmin</td>
<td>41909</td>
<td>active</td>
<td></td>
<td>3 days 02:43:54.203349</td>
<td>autovacuum: VACUUM ANALYZE public.mytable3</td>
</tr>
</tbody>
</table>
| mydb    | rdsadmin |   618| active  |            | 00:00:00              | SELECT datname, usename, pid, state, wait_event, current_timestamp - xact_start AS xact_runtime, query+ | pg_stat_activity + | WHERE query + | ORDER BY xact_start; +

Several issues can cause a long-running autovacuum session (that is, multiple days long). The most common issue is that your `maintenance_work_mem` parameter value is set too low for the size of the table or rate of updates.

We recommend that you use the following formula to set the `maintenance_work_mem` parameter value.

```sql
GREATEST((DBInstanceClassMemory/63963136*1024),65536)
```
Short running autovacuum sessions can also indicate problems:

- It can indicate that there aren't enough `autovacuum_max_workers` for your workload. In this case, you need to indicate the number of workers.
- It can indicate that there is an index corruption (autovacuum crashes and restarts on the same relation but makes no progress). In this case, run a manual `vacuum freeze verbose table` to see the exact cause.

**Performing a manual vacuum freeze**

You might want to perform a manual vacuum on a table that has a vacuum process already running. This is useful if you have identified a table with an age approaching 2 billion transactions (or above any threshold you are monitoring).

The following steps are guidelines, with several variations to the process. For example, during testing, suppose that you find that the `maintenance_work_mem` parameter value is set too small and that you need to take immediate action on a table. However, perhaps you don't want to bounce the instance at the moment. Using the queries in previous sections, you determine which table is the problem and notice a long running autovacuum session. You know that you need to change the `maintenance_work_mem` parameter setting, but you also need to take immediate action and vacuum the table in question. The following procedure shows what to do in this situation.

**To manually perform a vacuum freeze**

1. Open two sessions to the database containing the table you want to vacuum. For the second session, use "screen" or another utility that maintains the session if your connection is dropped.
2. In session one, get the process ID (PID) of the autovacuum session running on the table.
   
   Run the following query to get the PID of the autovacuum session.
   ```sql
   SELECT datname, usename, pid, current_timestamp - xact_start AS xact_runtime, query FROM pg_stat_activity WHERE upper(query) LIKE '%VACUUM%' ORDER BY xact_start;
   ```
3. In session two, calculate the amount of memory that you need for this operation. In this example, we determine that we can afford to use up to 2 GB of memory for this operation, so we set `maintenance_work_mem` for the current session to 2 GB.
   ```sql
   SET maintenance_work_mem='2 GB';
   ```
4. In session two, issue a `vacuum freeze verbose` command for the table. The verbose setting is useful because, although there is no progress report for this in PostgreSQL currently, you can see activity.
   ```sql
   \timing on
   Timing is on.
   vacuum freeze verbose pgbench_branches;
   ```
0 index pages have been deleted, 0 are currently reusable.
CPU 0.00s/0.00u sec elapsed 0.00 sec.
INFO: "pgbench_branches": found 0 removable, 50 nonremovable row versions
in 43 out of 43 pages
DETAIL: 0 dead row versions cannot be removed yet.
There were 9347 unused item pointers.
0 pages are entirely empty.
CPU 0.00s/0.00u sec elapsed 0.00 sec.
VACUUM
Time: 2.765 ms

5. In session one, if autovacuum was blocking the vacuum session, you see in \texttt{pg\_stat\_activity}
that waiting is "T" for your vacuum session. In this case, you need to end the autovacuum process as follows.

\begin{verbatim}
SELECT pg_terminate_backend('the_pid');
\end{verbatim}

At this point, your session begins. It's important to note that autovacuum restarts immediately
because this table is probably the highest on its list of work.

6. Initiate your \texttt{vacuum freeze verbose} command in session two, and then end the autovacuum
process in session one.

\section*{Reindexing a table when autovacuum is running}

If an index has become corrupt, autovacuum continues to process the table and fails. If you attempt a
manual vacuum in this situation, you receive an error message like the following.

\begin{verbatim}
postgres=> vacuum freeze pgbench_branches;
ERROR: index "pgbench_branches_test_index" contains unexpected
zero page at block 30521
HINT: Please REINDEX it.
\end{verbatim}

When the index is corrupted and autovacuum is attempting to run on the table, you contend with an
already running autovacuum session. When you issue a \texttt{REINDEX} command, you take out an exclusive
lock on the table. Write operations are blocked, and also read operations that use that specific index.

\section*{To reindex a table when autovacuum is running on the table}

1. Open two sessions to the database containing the table that you want to vacuum. For the second
session, use "screen" or another utility that maintains the session if your connection is dropped.

2. In session one, get the PID of the autovacuum session running on the table.

Run the following query to get the PID of the autovacuum session.

\begin{verbatim}
SELECT datname, usename, pid, current_timestamp - xact_start
AS xact_runtime, query
FROM pg_stat_activity WHERE upper(query) like '%VACUUM%'
ORDER BY xact_start;
\end{verbatim}

3. In session two, issue the reindex command.

\begin{verbatim}
\texttt{\textbackslash timing on}
Timing is on.
reindex index pgbench_branches_test_index;
REINDEX
Time: 9.966 ms
\end{verbatim}
4. In session one, if autovacuum was blocking the process, you see in \texttt{pg_stat_activity} that waiting is "T" for your vacuum session. In this case, you end the autovacuum process.

\begin{verbatim}
SELECT pg_terminate_backend('the_pid');
\end{verbatim}

At this point, your session begins. It's important to note that autovacuum restarts immediately because this table is probably the highest on its list of work.

5. Initiate your command in session two, and then end the autovacuum process in session 1.

### Managing autovacuum with large indexes

As part of its operation, \textit{autovacuum} performs several \textit{vacuum phases} while running on a table. Before the table is cleaned up, all of its indexes are first vacuumed. When removing multiple large indexes, this phase consumes a significant amount of time and resources. Therefore, as a best practice, be sure to control the number of indexes on a table and eliminate unused indexes.

For this process, first check the overall index size. Then, determine if there are potentially unused indexes that can be removed as shown in the following examples.

#### To check the size of the table and its indexes

\begin{verbatim}
postgres=> select pg_size_pretty(pg_relation_size('pgbench_accounts'));
pg_size_pretty
6404 MB
(1 row)

postgres=> select pg_size_pretty(pg_indexes_size('pgbench_accounts'));
pg_size_pretty
11 GB
(1 row)
\end{verbatim}

In this example, the size of indexes is larger than the table. This difference can cause performance issues as the indexes are bloated or unused, which impacts the autovacuum as well as insert operations.

#### To check for unused indexes

Using the \textit{pg_stat_user_indexes} view, you can check how frequently an index is used with the idx\_scan column. In the following example, the unused indexes have the idx\_scan value of 0.

\begin{verbatim}
postgres=> select * from pg_stat_user_indexes where relname = 'pgbench_accounts' order by idx_scan desc;
relid | indexrelid | schemaname | relname          | indexrelname          | idx_scan | idx_tup_read | idx_tup_fetch
----------+------------+------------+------------------+-----------------------+----------+---------------+---------------
16433  | 16454      | public     | pgbench_accounts | index_f               | 6        | 6             |               |
16433  | 16450      | public     | pgbench_accounts | index_b               | 3        |               |               |
199999 | 0          | public     | pgbench_accounts | pgbench_accounts_pkey | 0        | 0             |               |
16433  | 16447      | public     | pgbench_accounts | index_d               | 0        | 0             |               |
16433  | 16452      | public     | pgbench_accounts | index_e               | 0        | 0             |               |
16433  | 16453      | public     | pgbench_accounts | index_c               | 0        | 0             |               |
16433  | 16451      | public     | pgbench_accounts | index_d               | 0        | 0             |               |
\end{verbatim}
Note

These statistics are incremental from the time that the statistics are reset. Suppose you have an index that is only used at the end of a business quarter or just for a specific report. It's possible that this index hasn't been used since the statistics were reset. For more information, see Statistics Functions. Indexes that are used to enforce uniqueness won't have scans performed and shouldn't be identified as unused indexes. To identify the unused indexes, you should have in-depth knowledge of the application and its queries.

To check when the stats were last reset for a database, use `pg_stat_database`

```
postgres=> select datname, stats_reset from pg_stat_database where datname = 'postgres';
```

<table>
<thead>
<tr>
<th>datname</th>
<th>stats_reset</th>
</tr>
</thead>
<tbody>
<tr>
<td>postgres</td>
<td>2022-11-17 08:58:11.427224+00</td>
</tr>
</tbody>
</table>

Vacuuming a table as quickly as possible

RDS for PostgreSQL 12 and higher

If you have too many indexes in a large table, your DB instance could be nearing transaction ID wraparound (XID), which is when the XID counter wraps around to zero. Left unchecked, this situation could result in data loss. However, you can quickly vacuum the table without cleaning up the indexes. In RDS for PostgreSQL 12 and higher, you can use VACUUM with the `INDEX_CLEANUP` clause.

```
postgres=> VACUUM (INDEX_CLEANUP FALSE, VERbose TRUE) pgbench_accounts;
```

INFO: vacuuming "public.pgbench_accounts"
INFO: table "pgbench_accounts": found 0 removable, 8 nonremovable row versions in 1 out of 819673 pages
DETAIL: 0 dead row versions cannot be removed yet; oldest xmin: 7517
Skipped 0 pages due to buffer pins, 0 frozen pages.
CPU: user: 0.01 s, system: 0.00 s, elapsed: 0.01 s.

If an autovacuum session is already running, you must terminate it to begin the manual VACUUM. For information on performing a manual vacuum freeze, see  Performing a manual vacuum freeze (p. 2302)
Note
Skipping index cleanup regularly might cause index bloat, which impacts the overall scan performance. As a best practice, use the preceding procedure only to prevent transaction ID wraparound.

RDS for PostgreSQL 11 and older
However, in RDS for PostgreSQL 11 and lower versions, the only way to allow vacuum to complete faster is to reduce the number of indexes on a table. Dropping an index can affect query plans. We recommend that you drop unused indexes first, then drop the indexes when XID wraparound is very near. After the vacuum process completes, you can recreate these indexes.

Other parameters that affect autovacuum
The following query shows the values of some of the parameters that directly affect autovacuum and its behavior. The autovacuum parameters are described fully in the PostgreSQL documentation.

```
SELECT name, setting, unit, short_desc
FROM pg_settings
WHERE name IN (
    'autovacuum_max_workers',
    'autovacuum_analyze_scale_factor',
    'autovacuum_max_workers',
    'autovacuum_analyze_threshold',
    'autovacuum_analyze_scale_factor',
    'autovacuum_analyze_threshold',
    'autovacuum_analyze_cost_limit',
    'autovacuum_vacuum_cost_delay',
    'autovacuum_vacuum_cost_limit',
    'vacuum_cost_limit',
    'autovacuum_freeze_max_age',
    'maintenance_work_mem',
    'vacuum_freeze_min_age');
```

While these all affect autovacuum, some of the most important ones are:

- **maintenance_work_mem**
- **autovacuum_freeze_max_age**
- **autovacuum_max_workers**
- **autovacuum_vacuum_cost_delay**
- **autovacuum_vacuum_cost_limit**

Setting table-level autovacuum parameters
You can set autovacuum-related storage parameters at a table level, which can be better than altering the behavior of the entire database. For large tables, you might need to set aggressive settings and you might not want to make autovacuum behave that way for all tables.

The following query shows which tables currently have table-level options in place.

```
SELECT relname, reloptions
FROM pg_class
WHERE reloptions IS NOT null;
```

An example where this might be useful is on tables that are much larger than the rest of your tables. Suppose that you have one 300-GB table and 30 other tables less than 1 GB. In this case, you might set some specific parameters for your large table so you don’t alter the behavior of your entire system.
ALTER TABLE mytable set (autovacuum_vacuum_cost_delay=0);

Doing this turns off the cost-based autovacuum delay for this table at the expense of more resource usage on your system. Normally, autovacuum pauses for autovacuum_vacuum_cost_delay each time autovacuum_cost_limit is reached. For more details, see the PostgreSQL documentation about cost-based vacuuming.

Logging autovacuum and vacuum activities

Information about autovacuum activities is sent to the postgresql.log based on the level specified in the rds.force_autovacuum_logging_level parameter. Following are the values allowed for this parameter and the PostgreSQL versions for which that value is the default setting:

- disabled (PostgreSQL 10, PostgreSQL 9.6)
- debug5, debug4, debug3, debug2, debug1
- info (PostgreSQL 12, PostgreSQL 11)
- notice
- warning (PostgreSQL 13 and above)
- error, log, fatal, panic

The rds.force_autovacuum_logging_level works with the log_autovacuum_min_duration parameter. The log_autovacuum_min_duration parameter's value is the threshold (in milliseconds) above which autovacuum actions get logged. A setting of -1 logs nothing, while a setting of 0 logs all actions. As with rds.force_autovacuum_logging_level, default values for log_autovacuum_min_duration are version dependent, as follows:

- 10000 ms – PostgreSQL 14, PostgreSQL 13, PostgreSQL 12, and PostgreSQL 11
- (empty) – No default value for PostgreSQL 10 and PostgreSQL 9.6

We recommend that you set rds.force_autovacuum_logging_level to WARNING. We also recommend that you set log_autovacuum_min_duration to a value from 1000 to 5000. A setting of 5000 logs activity that takes longer than 5,000 milliseconds. Any setting other than -1 also logs messages if the autovacuum action is skipped because of a conflicting lock or concurrently dropped relations. For more information, see Automatic Vacuuming in the PostgreSQL documentation.

To troubleshoot issues, you can change the rds.force_autovacuum_logging_level parameter to one of the debug levels, from debug1 up to debug5 for the most verbose information. We recommend that you use debug settings for short periods of time and for troubleshooting purposes only. To learn more, see When to log in the PostgreSQL documentation.

Note

PostgreSQL allows the rds_superuser account to view autovacuum sessions in pg_stat_activity. For example, you can identify and end an autovacuum session that is blocking a command from running, or running slower than a manually issued vacuum command.

Working with logging mechanisms supported by RDS for PostgreSQL

There are several parameters, extensions, and other configurable items that you can set to log activities that occur on your PostgreSQL DB instance. These include the following:
• The log_statement parameter can be used to log user activity in your PostgreSQL database. To learn more about RDS for PostgreSQL logging and how to monitor the logs, see RDS for PostgreSQL database log files (p. 931).

• The rds.force_admin_logging_level parameter logs actions by the Amazon RDS internal user (rdsadmin) in the databases on the DB instance. It writes the output to the PostgreSQL error log. Allowed values are disabled, debug5, debug4, debug3, debug2, debug1, info, notice, warning, error, log, fatal, and panic. The default value is disabled.

• The rds.force_autovacuum_logging_level parameter can be set to capture various autovacuum operations in the PostgreSQL error log. For more information, see Logging autovacuum and vacuum activities (p. 2307).

• The PostgreSQL Audit (pgAudit) extension can be installed and configured to capture activities at the session level or at the object level. For more information, see Using pgAudit to log database activity (p. 2379).

• The log_fdw extension makes it possible for you to access the database engine log using SQL. For more information, see Using the log_fdw extension to access the DB log using SQL (p. 2418).

• The pg_stat_statements library is specified as the default for the shared_preload_libraries parameter in RDS for PostgreSQL version 10 and higher. It's this library that you can use to analyze running queries. Be sure that pg_stat_statements is set in your DB parameter group. For more information about monitoring your RDS for PostgreSQL DB instance using the information that this library provides, see SQL statistics for RDS PostgreSQL (p. 835).

• The log_hostname parameter captures to the log the hostname of each client connection. For RDS for PostgreSQL version 12 and higher versions, this parameter is set to off by default. If you turn it on, be sure to monitor session connection times. When turned on, the service uses the domain name system (DNS) reverse lookup request to get the hostname of the client that's making the connection and add it to the PostgreSQL log. This has a noticeable impact during session connection. We recommend that you turn on this parameter for troubleshooting purposes only.

In general terms, the point of logging is so that the DBA can monitor, tune performance, and troubleshoot. Many of the logs are uploaded automatically to Amazon CloudWatch or Performance Insights. Here, they're sorted and grouped to provide complete metrics for your DB instance. To learn more about Amazon RDS monitoring and metrics, see Monitoring metrics in an Amazon RDS instance (p. 678).

Managing temporary files with PostgreSQL

In PostgreSQL, a query performing sort and hash operations uses the instance memory to store results up to the value specified in the work_mem parameter. When the instance memory is not sufficient, temporary files are created to store the results. These are written to disk to complete the query execution. Later, these files are automatically removed after the query completes. In RDS for PostgreSQL, these files are stored in Amazon EBS on the data volume. For more information, see Amazon RDS DB instance storage. You can monitor the FreeStorageSpace metric published in CloudWatch to make sure that your DB instance has enough free storage space. For more information, see FreeStorageSpace.

We recommend using Amazon RDS Optimized Read instances for the workloads involving multiple concurrent queries that increase the usage of temporary files. These instances use local Non-Volatile Memory Express (NVMe) based solid state drive (SSD) block-level storage to place the temporary files. For more information, see Amazon RDS Optimized Reads.

You can use the following parameters and functions to manage the temporary files in your instance.

• temp_file_limit – This parameter cancels any query exceeding the size of temp_files in KB. This limit prevents any query from running endlessly and consuming disk space with temporary files. You can estimate the value using the results from the log_temp_files parameter. As a best practice,
examine the workload behavior and set the limit according to the estimation. The following example shows how a query is canceled when it exceeds the limit.

```sql
postgres=> select * from pgbench_accounts, pg_class, big_table;
```

```sql
ERROR: temporary file size exceeds temp_file_limit (64kB)
```

- **log_temp_files** – This parameter sends messages to the postgresql.log when the temporary files of a session are removed. This parameter produces logs after a query successfully completes. Therefore, it might not help in troubleshooting active, long-running queries.

The following example shows that when the query successfully completes, the entries are logged in the postgresql.log file while the temporary files are cleaned up.

```
2023-02-06 23:48:35 UTC:205.251.233.182(12456):adminuser@postgres:[31236]:STATEMENT:
  select a.aid from pgbench_accounts a, pgbench_accounts b where a.bid=b.bid order by a.bid limit 10;
2023-02-06 23:48:35 UTC:205.251.233.182(12456):adminuser@postgres:[31236]:STATEMENT:
  select a.aid from pgbench_accounts a, pgbench_accounts b where a.bid=b.bid order by a.bid limit 10;
```

- **pg_ls_tmpdir** – This function that is available from RDS for PostgreSQL 13 and above provides visibility into the current temporary file usage. The completed query doesn't appear in the results of the function. In the following example, you can view the results of this function.

```sql
postgres=> select * from pg_ls_tmpdir();
```

<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
<th>modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>pgsql_tmp8355.1</td>
<td>107250880</td>
<td>2023-02-06 22:54:56+00</td>
</tr>
<tr>
<td>pgsql_tmp8351.0</td>
<td>107250880</td>
<td>2023-02-06 22:54:36+00</td>
</tr>
<tr>
<td>pgsql_tmp8327.0</td>
<td>107250880</td>
<td>2023-02-06 22:54:56+00</td>
</tr>
<tr>
<td>pgsql_tmp8351.1</td>
<td>703168512</td>
<td>2023-02-06 22:54:56+00</td>
</tr>
<tr>
<td>pgsql_tmp8355.0</td>
<td>107250880</td>
<td>2023-02-06 22:54:36+00</td>
</tr>
<tr>
<td>pgsql_tmp8328.1</td>
<td>835031040</td>
<td>2023-02-06 22:54:36+00</td>
</tr>
<tr>
<td>pgsql_tmp8328.0</td>
<td>107250880</td>
<td>2023-02-06 22:54:40+00</td>
</tr>
</tbody>
</table>
(7 rows)

```sql
postgres=> select query from pg_stat_activity where pid = 8355;
```

```
query
| query | query | query | query | query | query | query | query | query | query | query | query | query | query | query | query | query | query | query | query | query | query | query | query | query |
```

The file name includes the processing ID (PID) of the session that generated the temporary file. A more advanced query, such as in the following example, performs a sum of the temporary files for each PID.
postgres=> select replace(left(name, strpos(name, '.')-1), 'pgsql_tmp','') as pid, count(*), sum(size) from pg_ls_tmpdir() group by pid;

<table>
<thead>
<tr>
<th>pid</th>
<th>count</th>
<th>sum</th>

</tr>
<tr>
<td>8328</td>
<td>2</td>
<td>2144501760</td>
</tr>
</tbody>
</table>

(4 rows)

- **pg_stat_statements** – If you activate the pg_stat_statements parameter, then you can view the average temporary file usage per call. You can identify the query_id of the query and use it to examine the temporary file usage as shown in the following example.

postgres=> select queryid from pg_stat_statements where query like 'select a.aid from pgbench%';

<table>
<thead>
<tr>
<th>queryid</th>
</tr>
</thead>
<tbody>
<tr>
<td>-7170349228837045701</td>
</tr>
</tbody>
</table>

(1 row)

postgres=> select queryid, substr(query,1,25), calls, temp_blks_read/calls temp_blks_read_per_call, temp_blks_written/calls temp_blks_written_per_call from pg_stat_statements where queryid = -7170349228837045701;

<table>
<thead>
<tr>
<th>queryid</th>
<th>substr</th>
<th>calls</th>
<th>temp_blks_read_per_call</th>
<th>temp_blks_written_per_call</th>
</tr>
</thead>
<tbody>
<tr>
<td>-7170349228837045701</td>
<td>select a.aid from pgbench</td>
<td>50</td>
<td>239226</td>
<td>388678</td>
</tr>
</tbody>
</table>

(1 row)

- **Performance Insights** – In the Performance Insights dashboard, you can view temporary file usage by turning on the metrics temp_bytes and temp_files. Then, you can see the average of both of these metrics and see how they correspond to the query workload. The view within Performance Insights doesn't show specifically the queries that are generating the temporary files. However, when you combine Performance Insights with the query shown for pg_ls_tmpdir, you can troubleshoot, analyze, and determine the changes in your query workload.

For more information about how to analyze metrics and queries with Performance Insights, see Analyzing metrics with the Performance Insights dashboard (p. 738)

To view the temporary file usage with Performance Insights

1. In the Performance Insights dashboard, choose Manage Metrics.
2. Choose Database metrics, and select the temp_bytes and temp_files metrics as shown in the following image.

2310
3. In the Top SQL tab, choose the Preferences icon.

4. In the Preferences window, turn on the following statistics to appear in the Top SQL tab and choose Continue.
   - Temp writes/sec
   - Temp reads/sec
   - Tmp blk write/call
   - Tmp blk read/call

5. The temporary file is broken out when combined with the query shown for pg_ls_tmpdir, as shown in the following example.
The IO:BufFileRead and IO:BufFileWrite events occur when the top queries in your workload often create temporary files. You can use Performance Insights to identify top queries waiting on IO:BufFileRead and IO:BufFileWrite by reviewing Average Active Session (AAS) in Database Load and Top SQL sections.

For more information on how to analyze top queries and load by wait event with Performance Insights, see Overview of the Top SQL tab (p. 756). You should identify and tune the queries that cause increase in temporary file usage and related wait events. For more information on these wait events and remediation, see IO:BufFileRead and IO:BufFileWrite.

**Note**
The work_mem parameter controls when the sort operation runs out of memory and results are written into temporary files. We recommend that you don't change the setting of this parameter higher than the default value because it would permit every database session to consume more memory. Also, a single session that performs complex joins and sorts can perform parallel operations in which each operation consumes memory.

As a best practice, when you have a large report with multiple joins and sorts, set this parameter at the session level by using the SET work_mem command. Then the change is only applied to the current session and doesn't change the value globally.

### Using pgBadger for log analysis with PostgreSQL

You can use a log analyzer such as pgBadger to analyze PostgreSQL logs. The pgBadger documentation states that the %l pattern (the log line for the session or process) should be a part of the prefix. However, if you provide the current RDS log_line_prefix as a parameter to pgBadger it should still produce a report.

For example, the following command correctly formats an Amazon RDS for PostgreSQL log file dated 2014-02-04 using pgBadger.

```
./pgbadger -f stderr -p '%t:%r:%u@%d:[%p]:' postgresql.log.2014-02-04-00
```

### Using PGSnapper for monitoring PostgreSQL

You can use PGSnapper to assist with periodic collection of Amazon RDS for PostgreSQL performance-related statistics and metrics. For more information, see Monitor Amazon RDS for PostgreSQL performance using PGSnapper.
Working with parameters on your RDS for PostgreSQL DB instance

In some cases, you might create an RDS for PostgreSQL DB instance without specifying a custom parameter group. If so, your DB instance is created using the default parameter group for the version of PostgreSQL that you choose. For example, suppose that you create an RDS for PostgreSQL DB instance using PostgreSQL 13.3. In this case, the DB instance is created using the values in the parameter group for PostgreSQL 13 releases, default.postgres13.

You can also create your own custom DB parameter group. You need to do this if you want to modify any settings for the RDS for PostgreSQL DB instance from their default values. To learn how, see Working with parameter groups (p. 347).

You can track the settings on your RDS for PostgreSQL DB instance in several different ways. You can use the AWS Management Console, the AWS CLI, or the Amazon RDS API. You can also query the values from the PostgreSQL pg_settings table of your instance, as shown following.

```
SELECT name, setting, boot_val, reset_val, unit
FROM pg_settings
ORDER BY name;
```

To learn more about the values returned from this query, see pg_settings in the PostgreSQL documentation.

Be especially careful when changing the settings for max_connections and shared_buffers on your RDS for PostgreSQL DB instance. For example, suppose that you modify settings for max_connections or shared_buffers and you use values that are too high for your actual workload. In this case, your RDS for PostgreSQL DB instance won't start. If this happens, you see an error such as the following in the postgres.log.

```
2018-09-18 21:13:15 UTC::@:8097:HINT:  This error usually means that PostgreSQL's request for a shared memory segment exceeded available memory or swap space. To reduce the request size (currently 3514134274048 bytes), reduce PostgreSQL's shared memory usage, perhaps by reducing shared_buffers or max_connections.
```

However, you can't change any values of the settings contained in the default RDS for PostgreSQL DB parameter groups. To change settings for any parameters, first create a custom DB parameter group. Then change the settings in that custom group, and then apply the custom parameter group to your RDS for PostgreSQL DB instance. To learn more, see Working with parameter groups (p. 347).

There are two types of RDS for PostgreSQL DB parameters.

- **Static parameters** – Static parameters require that the RDS for PostgreSQL DB instance be rebooted after a change so that the new value can take effect.
- **Dynamic parameters** – Dynamic parameters don't require a reboot after changing their settings.

**Note**

If your RDS for PostgreSQL DB instance is using your own custom DB parameter group, you can change the values of dynamic parameters on the running DB instance. You can do this by using the AWS Management Console, the AWS CLI, or the Amazon RDS API.

If you have privileges to do so, you can also change parameter values by using the ALTER DATABASE, ALTER ROLE, and SET commands.
RDS for PostgreSQL DB instance parameter list

The following table lists some (but not all) parameters available in an RDS for PostgreSQL DB instance. To view all available parameters, you use the `describe-db-parameters` AWS CLI command. For example, to get the list of all parameters available in the default parameter group for RDS for PostgreSQL version 13, run the following.

```bash
aws rds describe-db-parameters --db-parameter-group-name default.postgres13
```

You can also use the Console. Choose Parameter groups from the Amazon RDS menu, and then choose the parameter group from those available in your AWS Region.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Apply_Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>application_name</td>
<td>Dynamic</td>
<td>Sets the application name to be reported in statistics and logs.</td>

<td>Dynamic</td>
<td>Sets the shell command that will be called to archive a WAL file.</td>
</tr>
<tr>
<td>array_nulls</td>
<td>Dynamic</td>
<td>Enables input of NULL elements in arrays.</td>
</tr>
<tr>
<td>authentication_timeout</td>
<td>Dynamic</td>
<td>Sets the maximum allowed time to complete client authentication.</td>
</tr>
<tr>
<td>autovacuum</td>
<td>Dynamic</td>
<td>Starts the autovacuum subprocess.</td>
</tr>
<tr>
<td>autovacuum_analyze_scale_factor</td>
<td>Dynamic</td>
<td>Number of tuple inserts, updates, or deletes before analyze as a fraction of reltuples.</td>
</tr>
<tr>
<td>autovacuum_analyze_threshold</td>
<td>Dynamic</td>
<td>Minimum number of tuple inserts, updates, or deletes before analyze.</td>
</tr>
<tr>
<td>autovacuum_freeze_max_age</td>
<td>Static</td>
<td>Age at which to autovacuum a table to prevent transaction ID wraparound.</td>
</tr>
<tr>
<td>autovacuum_naptime</td>
<td>Dynamic</td>
<td>Time to sleep between autovacuum runs.</td>
</tr>
<tr>
<td>autovacuum_max_workers</td>
<td>Static</td>
<td>Sets the maximum number of simultaneously running autovacuum worker processes.</td>
</tr>
<tr>
<td>autovacuum_vacuum_cost_delay</td>
<td>Dynamic</td>
<td>Vacuum cost delay, in milliseconds, for autovacuum.</td>
</tr>
<tr>
<td>autovacuum_vacuum_cost_limit</td>
<td>Dynamic</td>
<td>Vacuum cost amount available before napping, for autovacuum.</td>
</tr>
<tr>
<td>autovacuum_vacuum_scale_factor</td>
<td>Dynamic</td>
<td>Number of tuple updates or deletes before vacuum as a fraction of reltuples.</td>
</tr>
<tr>
<td>autovacuum_vacuum_threshold</td>
<td>Dynamic</td>
<td>Minimum number of tuple updates or deletes before vacuum.</td>
</tr>
<tr>
<td>backslash_quote</td>
<td>Dynamic</td>
<td>Sets whether a backslash () is allowed in string literals.</td>
</tr>
<tr>
<td>bgwriter_delay</td>
<td>Dynamic</td>
<td>Background writer sleep time between rounds.</td>
</tr>
<tr>
<td>bgwriter_lru_maxpages</td>
<td>Dynamic</td>
<td>Background writer maximum number of LRU pages to flush per round.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Apply_Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>bgwriter_lru_multiplier</td>
<td>Dynamic</td>
<td>Multiple of the average buffer usage to free per round.</td>
</tr>
<tr>
<td>bytea_output</td>
<td>Dynamic</td>
<td>Sets the output format for bytes.</td>
</tr>
<tr>
<td>check_function_bodies</td>
<td>Dynamic</td>
<td>Checks function bodies during CREATE FUNCTION.</td>
</tr>
<tr>
<td>checkpoint_completion_target</td>
<td>Dynamic</td>
<td>Time spent flushing dirty buffers during checkpoint, as a fraction of the checkpoint interval.</td>
</tr>
<tr>
<td>checkpoint_segments</td>
<td>Dynamic</td>
<td>Sets the maximum distance in log segments between automatic write-ahead log (WAL) checkpoints.</td>
</tr>
<tr>
<td>checkpoint_timeout</td>
<td>Dynamic</td>
<td>Sets the maximum time between automatic WAL checkpoints.</td>
</tr>
<tr>
<td>checkpoint_warning</td>
<td>Dynamic</td>
<td>Enables warnings if checkpoint segments are filled more frequently than this.</td>
</tr>
<tr>
<td>client_encoding</td>
<td>Dynamic</td>
<td>Sets the client's character set encoding.</td>
</tr>
<tr>
<td>client_min_messages</td>
<td>Dynamic</td>
<td>Sets the message levels that are sent to the client.</td>
</tr>
<tr>
<td>commit_delay</td>
<td>Dynamic</td>
<td>Sets the delay in microseconds between transaction commit and flushing WAL to disk.</td>
</tr>
<tr>
<td>commit_siblings</td>
<td>Dynamic</td>
<td>Sets the minimum concurrent open transactions before performing commit_delay.</td>
</tr>
<tr>
<td>constraint_exclusion</td>
<td>Dynamic</td>
<td>Enables the planner to use constraints to optimize queries.</td>
</tr>
<tr>
<td>cpu_index_tuple_cost</td>
<td>Dynamic</td>
<td>Sets the planner's estimate of the cost of processing each index entry during an index scan.</td>
</tr>
<tr>
<td>cpu_operator_cost</td>
<td>Dynamic</td>
<td>Sets the planner's estimate of the cost of processing each operator or function call.</td>
</tr>
<tr>
<td>cpu_tuple_cost</td>
<td>Dynamic</td>
<td>Sets the planner's estimate of the cost of processing each tuple (row).</td>
</tr>
<tr>
<td>cursor_tuple_fraction</td>
<td>Dynamic</td>
<td>Sets the planner's estimate of the fraction of a cursor's rows that will be retrieved.</td>
</tr>
<tr>
<td>datestyle</td>
<td>Dynamic</td>
<td>Sets the display format for date and time values.</td>
</tr>
<tr>
<td>deadlock_timeout</td>
<td>Dynamic</td>
<td>Sets the time to wait on a lock before checking for deadlock.</td>
</tr>
<tr>
<td>debug_pretty_print</td>
<td>Dynamic</td>
<td>Indents parse and plan tree displays.</td>
</tr>
<tr>
<td>debug_print_parse</td>
<td>Dynamic</td>
<td>Logs each query's parse tree.</td>
</tr>
<tr>
<td>debug_print_plan</td>
<td>Dynamic</td>
<td>Logs each query's execution plan.</td>
</tr>
<tr>
<td>debug_print_rewritten</td>
<td>Dynamic</td>
<td>Logs each query's rewritten parse tree.</td>
</tr>
<tr>
<td>default_statistics_target</td>
<td>Dynamic</td>
<td>Sets the default statistics target.</td>
</tr>
<tr>
<td>default_tablespace</td>
<td>Dynamic</td>
<td>Sets the default tablespace to create tables and indexes in.</td>
</tr>
<tr>
<td>default_transaction_deferrable</td>
<td>Dynamic</td>
<td>Sets the default deferrable status of new transactions.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Apply_Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>default_transaction_isolation</td>
<td>Dynamic</td>
<td>Sets the transaction isolation level of each new transaction.</td>
</tr>
<tr>
<td>default_transaction_read_only</td>
<td>Dynamic</td>
<td>Sets the default read-only status of new transactions.</td>
</tr>
<tr>
<td>default_with_oids</td>
<td>Dynamic</td>
<td>Creates new tables with object IDs (OIDs) by default.</td>
</tr>
<tr>
<td>effective_cache_size</td>
<td>Dynamic</td>
<td>Sets the planner's assumption about the size of the disk cache.</td>
</tr>
<tr>
<td>effective_io_concurrency</td>
<td>Dynamic</td>
<td>Number of simultaneous requests that can be handled efficiently by the disk subsystem.</td>
</tr>
<tr>
<td>enable_bitmapscan</td>
<td>Dynamic</td>
<td>Enables the planner's use of bitmap-scan plans.</td>
</tr>
<tr>
<td>enable_hashagg</td>
<td>Dynamic</td>
<td>Enables the planner's use of hashed aggregation plans.</td>
</tr>
<tr>
<td>enable_hashjoin</td>
<td>Dynamic</td>
<td>Enables the planner's use of hash join plans.</td>
</tr>
<tr>
<td>enable_indexscan</td>
<td>Dynamic</td>
<td>Enables the planner's use of index-scan plans.</td>
</tr>
<tr>
<td>enable_material</td>
<td>Dynamic</td>
<td>Enables the planner's use of materialization.</td>
</tr>
<tr>
<td>enable_mergejoin</td>
<td>Dynamic</td>
<td>Enables the planner's use of merge join plans.</td>
</tr>
<tr>
<td>enable_nestloop</td>
<td>Dynamic</td>
<td>Enables the planner's use of nested-loop join plans.</td>
</tr>
<tr>
<td>enable_seqscan</td>
<td>Dynamic</td>
<td>Enables the planner's use of sequential-scan plans.</td>
</tr>
<tr>
<td>enable_sort</td>
<td>Dynamic</td>
<td>Enables the planner's use of explicit sort steps.</td>
</tr>
<tr>
<td>enable_tidscan</td>
<td>Dynamic</td>
<td>Enables the planner's use of TID scan plans.</td>
</tr>
<tr>
<td>escape_string_warning</td>
<td>Dynamic</td>
<td>Warns about backslash () escapes in ordinary string literals.</td>
</tr>
<tr>
<td>extra_float_digits</td>
<td>Dynamic</td>
<td>Sets the number of digits displayed for floating-point values.</td>
</tr>
<tr>
<td>fromCollapseLimit</td>
<td>Dynamic</td>
<td>Sets the FROM-list size beyond which subqueries are not collapsed.</td>
</tr>
<tr>
<td>fsync</td>
<td>Dynamic</td>
<td>Forces synchronization of updates to disk.</td>
</tr>
<tr>
<td>full_page_writes</td>
<td>Dynamic</td>
<td>Writes full pages to WAL when first modified after a checkpoint.</td>
</tr>
<tr>
<td>geqo</td>
<td>Dynamic</td>
<td>Enables genetic query optimization.</td>
</tr>
<tr>
<td>geqo_effort</td>
<td>Dynamic</td>
<td>GEQO: effort is used to set the default for other GEQO parameters.</td>
</tr>
<tr>
<td>geqo_generations</td>
<td>Dynamic</td>
<td>GEQO: number of iterations of the algorithm.</td>
</tr>
<tr>
<td>geqo_pool_size</td>
<td>Dynamic</td>
<td>GEQO: number of individuals in the population.</td>
</tr>
<tr>
<td>geqo_seed</td>
<td>Dynamic</td>
<td>GEQO: seed for random path selection.</td>
</tr>
<tr>
<td>geqo_selection_bias</td>
<td>Dynamic</td>
<td>GEQO: selective pressure within the population.</td>
</tr>
<tr>
<td>geqo_threshold</td>
<td>Dynamic</td>
<td>Sets the threshold of FROM items beyond which GEQO is used.</td>
</tr>
</tbody>
</table>

<tr>
<td>max_prepared_transactions</td>
<td>Static</td>
<td>Sets the maximum number of simultaneously prepared transactions.</td>
</tr>
<tr>
<td>max_stack_depth</td>
<td>Dynamic</td>
<td>Sets the maximum stack depth, in kilobytes.</td>
</tr>
<tr>
<td>max_standby_archive_delay</td>
<td>Dynamic</td>
<td>Sets the maximum delay before canceling queries when a hot standby server is processing archived WAL data.</td>
</tr>
<tr>
<td>max_standby_streaming_delay</td>
<td>Dynamic</td>
<td>Sets the maximum delay before canceling queries when a hot standby server is processing streamed WAL data.</td>
</tr>
<tr>
<td>max_wal_size</td>
<td>Dynamic</td>
<td>Sets the WAL size (MB) that triggers a checkpoint. For all versions after RDS for PostgreSQL 10, the default is at least 1 GB (1024 MB). For example, max_wal_size setting for RDS for PostgreSQL 14 is 2 GB (2048 MB). Use the SHOW max_wal_size; command on your RDS for PostgreSQL DB instance to see its current value.</td>
</tr>
<tr>
<td>min_wal_size</td>
<td>Dynamic</td>
<td>Sets the minimum size to shrink the WAL to. For PostgreSQL version 9.6 and earlier, min_wal_size is in units of 16 MB. For PostgreSQL version 10 and later, min_wal_size is in units of 1 MB.</td>
</tr>
<tr>
<td>quote_all_identifiers</td>
<td>Dynamic</td>
<td>Adds quotes (&quot;) to all identifiers when generating SQL fragments.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Apply_Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>random_page_cost</td>
<td>Dynamic</td>
<td>Sets the planner's estimate of the cost of a non-sequentially fetched disk page. This parameter has no value unless query plan management (QPM) is turned on. When QPM is on, the default value for this parameter is 4.</td>
</tr>
<tr>
<td>rds.adaptive_autovacuum</td>
<td>Dynamic</td>
<td>Automatically tunes the autovacuum parameters whenever the transaction ID thresholds are exceeded.</td>
</tr>
<tr>
<td>rds.force_ssl</td>
<td>Dynamic</td>
<td>Requires the use of SSL connections. The default value is set to 1 (on) for RDS for PostgreSQL version 15. All other RDS for PostgreSQL major version 14 and older have the default value set to 0 (off).</td>
</tr>
<tr>
<td>rds.log_retention_period</td>
<td>Dynamic</td>
<td>Sets log retention such that Amazon RDS deletes PostgreSQL logs that are older than ( n ) minutes.</td>
</tr>
<tr>
<td>rds.restrict_password_commands</td>
<td>Static</td>
<td>Restricts who can manage passwords to users with the rds_password role. Set this parameter to 1 to enable password restriction. The default is 0.</td>
</tr>
<tr>
<td>search_path</td>
<td>Dynamic</td>
<td>Sets the schema search order for names that are not schema-qualified.</td>
</tr>
<tr>
<td>seq_page_cost</td>
<td>Dynamic</td>
<td>Sets the planner's estimate of the cost of a sequentially fetched disk page.</td>
</tr>
<tr>
<td>session_replication_role</td>
<td>Dynamic</td>
<td>Sets the sessions behavior for triggers and rewrite rules.</td>
</tr>
<tr>
<td>shared_buffers</td>
<td>Static</td>
<td>Sets the number of shared memory buffers used by the server.</td>
</tr>
<tr>
<td>shared_preload_libraries</td>
<td>Static</td>
<td>Lists the shared libraries to preload into the RDS for PostgreSQL DB instance. Supported values include auto_explain, orafce, pgaudit, pglogical, pg_bigm, pg_cron, pg_hint_plan, pg_prewarm, pg_similarity, pg_stat_statements, pg_tle, pg_transport, piprofiler, and plrust.</td>
</tr>
<tr>
<td>ssl</td>
<td>Dynamic</td>
<td>Enables SSL connections.</td>
</tr>
<tr>
<td>sql_inheritance</td>
<td>Dynamic</td>
<td>Causes subtables to be included by default in various commands.</td>
</tr>
<tr>
<td>ssl_renegotiation_limit</td>
<td>Dynamic</td>
<td>Sets the amount of traffic to send and receive before renegotiating the encryption keys.</td>
</tr>
<tr>
<td>standard_conforming_strings</td>
<td>Dynamic</td>
<td>Causes ... strings to treat backslashes literally.</td>
</tr>
<tr>

Tuning with wait events for RDS for PostgreSQL

Wait events are an important tuning tool for RDS for PostgreSQL. When you can find out why sessions are waiting for resources and what they are doing, you’re better able to reduce bottlenecks. You can use the information in this section to find possible causes and corrective actions. This section also discusses basic PostgreSQL tuning concepts.

The wait events in this section are specific to RDS for PostgreSQL.

Topics
• Essential concepts for RDS for PostgreSQL tuning (p. 2323)
• RDS for PostgreSQL wait events (p. 2326)
• Client:ClientRead (p. 2328)
• Client:ClientWrite (p. 2330)
• CPU (p. 2331)
• IO:BufFileRead and IO:BufFileWrite (p. 2336)
• IO:DataFileRead (p. 2341)
• IO:WALWrite (p. 2346)
• Lock:advisory (p. 2348)
• Lock:extend (p. 2350)
• Lock:Relation (p. 2352)
• Lock:transactionid (p. 2354)
• Lock:tuple (p. 2356)
• LWLock:BufferMapping (LWLock:buffer_mapping) (p. 2359)
• LWLock:BufferIO (IPC:BufferIO) (p. 2361)
• LWLock:buffer_content (BufferContent) (p. 2362)
• LWLock:lock_manager (LWLock:lockmanager) (p. 2363)
• Timeout:PgSleep (p. 2367)
• Timeout:VacuumDelay (p. 2368)

Essential concepts for RDS for PostgreSQL tuning

Before you tune your RDS for PostgreSQL database, make sure to learn what wait events are and why they occur. Also review the basic memory and disk architecture of RDS for PostgreSQL. For a helpful architecture diagram, see the PostgreSQL wikibook.

Topics
• RDS for PostgreSQL wait events (p. 2323)
• RDS for PostgreSQL memory (p. 2324)
• RDS for PostgreSQL processes (p. 2325)

RDS for PostgreSQL wait events

A wait event is an indication that the session is waiting for a resource. For example, the wait event Client:ClientRead occurs when RDS for PostgreSQL is waiting to receive data from the client. Sessions typically wait for resources such as the following.

• Single-threaded access to a buffer, for example, when a session is attempting to modify a buffer
• A row that is currently locked by another session
Essential concepts for RDS for PostgreSQL tuning

- A data file read
- A log file write

For example, to satisfy a query, the session might perform a full table scan. If the data isn't already in memory, the session waits for the disk I/O to complete. When the buffers are read into memory, the session might need to wait because other sessions are accessing the same buffers. The database records the waits by using a predefined wait event. These events are grouped into categories.

By itself, a single wait event doesn't indicate a performance problem. For example, if requested data isn't in memory, reading data from disk is necessary. If one session locks a row for an update, another session waits for the row to be unlocked so that it can update it. A commit requires waiting for the write to a log file to complete. Waits are integral to the normal functioning of a database.

On the other hand, large numbers of wait events typically show a performance problem. In such cases, you can use wait event data to determine where sessions are spending time. For example, if a report that typically runs in minutes now takes hours to run, you can identify the wait events that contribute the most to total wait time. If you can determine the causes of the top wait events, you can sometimes make changes that improve performance. For example, if your session is waiting on a row that has been locked by another session, you can end the locking session.

RDS for PostgreSQL memory

RDS for PostgreSQL memory is divided into shared and local.

Topics
- Shared memory in RDS for PostgreSQL (p. 2324)
- Local memory in RDS for PostgreSQL (p. 2325)

Shared memory in RDS for PostgreSQL

RDS for PostgreSQL allocates shared memory when the instance starts. Shared memory is divided into multiple subareas. Following, you can find a description of the most important ones.

Topics
- Shared buffers (p. 2324)
- Write ahead log (WAL) buffers (p. 2324)

Shared buffers

The shared buffer pool is an RDS for PostgreSQL memory area that holds all pages that are or were being used by application connections. A page is the memory version of a disk block. The shared buffer pool caches the data blocks read from disk. The pool reduces the need to reread data from disk, making the database operate more efficiently.

Every table and index is stored as an array of pages of a fixed size. Each block contains multiple tuples, which correspond to rows. A tuple can be stored in any page.

The shared buffer pool has finite memory. If a new request requires a page that isn't in memory, and no more memory exists, RDS for PostgreSQL evicts a less frequently used page to accommodate the request. The eviction policy is implemented by a clock sweep algorithm.

The shared_buffers parameter determines how much memory the server dedicates to caching data.

Write ahead log (WAL) buffers

A write-ahead log (WAL) buffer holds transaction data that RDS for PostgreSQL later writes to persistent storage. Using the WAL mechanism, RDS for PostgreSQL can do the following:
• Recover data after a failure
• Reduce disk I/O by avoiding frequent writes to disk

When a client changes data, RDS for PostgreSQL writes the changes to the WAL buffer. When the client issues a COMMIT, the WAL writer process writes transaction data to the WAL file.

The wal_level parameter determines how much information is written to the WAL.

Local memory in RDS for PostgreSQL

Every backend process allocates local memory for query processing.

Topics
• Work memory area (p. 2325)
• Maintenance work memory area (p. 2325)
• Temporary buffer area (p. 2325)

Work memory area

The work memory area holds temporary data for queries that perform sorts and hashes. For example, a query with an ORDER BY clause performs a sort. Queries use hash tables in hash joins and aggregations.

The work_mem parameter specifies the amount of memory to be used by internal sort operations and hash tables before writing to temporary disk files. The default value is 4 MB. Multiple sessions can run simultaneously, and each session can run maintenance operations in parallel. For this reason, the total work memory used can be multiples of the work_mem setting.

Maintenance work memory area

The maintenance work memory area caches data for maintenance operations. These operations include vacuuming, creating an index, and adding foreign keys.

The maintenance_work_mem parameter specifies the maximum amount of memory to be used by maintenance operations. The default value is 64 MB. A database session can only run one maintenance operation at a time.

Temporary buffer area

The temporary buffer area caches temporary tables for each database session.

Each session allocates temporary buffers as needed up to the limit you specify. When the session ends, the server clears the buffers.

The temp_buffers parameter sets the maximum number of temporary buffers used by each session. Before the first use of temporary tables within a session, you can change the temp_buffers value.

RDS for PostgreSQL processes

RDS for PostgreSQL uses multiple processes.

Topics
• Postmaster process (p. 2326)
• Backend processes (p. 2326)
• Background processes (p. 2326)
Postmaster process

The postmaster process is the first process started when you start RDS for PostgreSQL. The postmaster process has the following primary responsibilities:

• Fork and monitor background processes
• Receive authentication requests from client processes, and authenticate them before allowing the database to service requests

Backend processes

If the postmaster authenticates a client request, the postmaster forks a new backend process, also called a postgres process. One client process connects to exactly one backend process. The client process and the backend process communicate directly without intervention by the postmaster process.

Background processes

The postmaster process forks several processes that perform different backend tasks. Some of the more important include the following:

• WAL writer

RDS for PostgreSQL writes data in the WAL (write ahead logging) buffer to the log files. The principle of write ahead logging is that the database can’t write changes to the data files until after the database writes log records describing those changes to disk. The WAL mechanism reduces disk I/O, and allows RDS for PostgreSQL to use the logs to recover the database after a failure.

• Background writer

This process periodically write dirty (modified) pages from the memory buffers to the data files. A page becomes dirty when a backend process modifies it in memory.

• Autovacuum daemon

The daemon consists of the following:

• The autovacuum launcher
• The autovacuum worker processes

When autovacuum is turned on, it checks for tables that have had a large number of inserted, updated, or deleted tuples. The daemon has the following responsibilities:

• Recover or reuse disk space occupied by updated or deleted rows
• Update statistics used by the planner
• Protect against loss of old data because of transaction ID wraparound

The autovacuum feature automates the execution of VACUUM and ANALYZE commands. VACUUM has the following variants: standard and full. Standard vacuum runs in parallel with other database operations. VACUUM FULL requires an exclusive lock on the table it is working on. Thus, it can’t run in parallel with operations that access the same table. VACUUM creates a substantial amount of I/O traffic, which can cause poor performance for other active sessions.

RDS for PostgreSQL wait events

The following table lists the wait events for RDS for PostgreSQL that most commonly indicate performance problems, and summarizes the most common causes and corrective actions.
### RDS for PostgreSQL wait events

<table>
<thead>
<tr>
<th>Wait event</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Client:ClientRead (p. 2328)</strong></td>
<td>This event occurs when RDS for PostgreSQL is waiting to receive data from the client.</td>
</tr>
<tr>
<td><strong>Client:ClientWrite (p. 2330)</strong></td>
<td>This event occurs when RDS for PostgreSQL is waiting to write data to the client.</td>
</tr>
<tr>
<td><strong>CPU (p. 2331)</strong></td>
<td>This event occurs when a thread is active in CPU or is waiting for CPU.</td>
</tr>
<tr>
<td><strong>IO:BufFileRead and IO:BufFileWrite (p. 2336)</strong></td>
<td>These events occur when RDS for PostgreSQL creates temporary files.</td>
</tr>
<tr>
<td><strong>IO:DataFileRead (p. 2341)</strong></td>
<td>This event occurs when a connection waits on a backend process to read a required page from storage because the page isn't available in shared memory.</td>
</tr>
<tr>
<td><strong>IO:WALWrite (p. 2346)</strong></td>
<td>This event occurs when RDS for PostgreSQL is waiting for the write-ahead log (WAL) buffers to be written to a WAL file.</td>
</tr>
<tr>
<td><strong>Lock:advisory (p. 2348)</strong></td>
<td>This event occurs when a PostgreSQL application uses a lock to coordinate activity across multiple sessions.</td>
</tr>
<tr>
<td><strong>Lock:extend (p. 2350)</strong></td>
<td>This event occurs when a backend process is waiting to lock a relation to extend it while another process has a lock on that relation for the same purpose.</td>
</tr>
<tr>
<td><strong>Lock:Relation (p. 2352)</strong></td>
<td>This event occurs when a query is waiting to acquire a lock on a table or view that's currently locked by another transaction.</td>
</tr>
<tr>
<td><strong>Lock:transactionid (p. 2354)</strong></td>
<td>This event occurs when a transaction is waiting for a row-level lock.</td>
</tr>
<tr>
<td><strong>Lock:tuple (p. 2356)</strong></td>
<td>This event occurs when a backend process is waiting to acquire a lock on a tuple.</td>
</tr>
<tr>
<td><strong>LWLock:BufferMapping (LWLock:buffer_mapping) (p. 2359)</strong></td>
<td>This event occurs when a session is waiting to associate a data block with a buffer in the shared buffer pool.</td>
</tr>
<tr>
<td><strong>LWLock:BufferIO (IPC:BufferIO) (p. 2361)</strong></td>
<td>This event occurs when RDS for PostgreSQL is waiting for other processes to finish their input/output (I/O) operations when concurrently trying to access a page.</td>
</tr>
<tr>
<td><strong>LWLock:buffer_content (BufferContent) (p. 2362)</strong></td>
<td>This event occurs when a session is waiting to read or write a data page in memory while another session has that page locked for writing.</td>
</tr>
<tr>
<td><strong>LWLock:lock_manager (LWLock:lockmanager) (p. 2363)</strong></td>
<td>This event occurs when the RDS for PostgreSQL engine maintains the shared lock's memory area to allocate, check, and deallocate a lock when a fast path lock isn't possible.</td>
</tr>
<tr>
<td><strong>Timeout:PgSleep (p. 2367)</strong></td>
<td>This event occurs when a server process has called the pg_sleep function and is waiting for the sleep timeout to expire.</td>
</tr>
<tr>
<td>Wait event</td>
<td>Definition</td>
</tr>
<tr>
<td>---------------------------</td>
<td>---------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Timeout:VacuumDelay (p. 2368)</td>
<td>This event indicates that the vacuum process is sleeping because the estimated cost limit has been reached.</td>
</tr>
</tbody>
</table>

**Client:ClientRead**

The **Client:ClientRead** event occurs when RDS for PostgreSQL is waiting to receive data from the client.

**Topics**
- [Supported engine versions (p. 2328)](#)
- [Context (p. 2328)](#)
- [Likely causes of increased waits (p. 2328)](#)
- [Actions (p. 2329)](#)

**Supported engine versions**

This wait event information is supported for RDS for PostgreSQL version 10 and higher.

**Context**

An RDS for PostgreSQL DB instance is waiting to receive data from the client. The RDS for PostgreSQL DB instance must receive the data from the client before it can send more data to the client. The time that the instance waits before receiving data from the client is a **Client:ClientRead** event.

**Likely causes of increased waits**

Common causes for the **Client:ClientRead** event to appear in top waits include the following:

**Increased network latency**

There might be increased network latency between the RDS for PostgreSQL DB instance and client. Higher network latency increases the time required for DB instance to receive data from the client.

**Increased load on the client**

There might be CPU pressure or network saturation on the client. An increase in load on the client can delay transmission of data from the client to the RDS for PostgreSQL DB instance.

**Excessive network round trips**

A large number of network round trips between the RDS for PostgreSQL DB instance and the client can delay transmission of data from the client to the RDS for PostgreSQL DB instance.

**Large copy operation**

During a copy operation, the data is transferred from the client's file system to the RDS for PostgreSQL DB instance. Sending a large amount of data to the DB instance can delay transmission of data from the client to the DB instance.

**Idle client connection**

When a client connects to the RDS for PostgreSQL DB instance in an idle in transaction state, the DB instance might wait for the client to send more data or issue a command. A connection in this state can lead to an increase in **Client:ClientRead** events.
PgBouncer used for connection pooling

PgBouncer has a low-level network configuration setting called \texttt{pkt\_buf}, which is set to 4,096 by default. If the workload is sending query packets larger than 4,096 bytes through PgBouncer, we recommend increasing the \texttt{pkt\_buf} setting to 8,192. If the new setting doesn't decrease the number of Client:ClientRead events, we recommend increasing the \texttt{pkt\_buf} setting to larger values, such as 16,384 or 32,768. If the query text is large, the larger setting can be particularly helpful.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Place the clients in the same Availability Zone and VPC subnet as the instance (p. 2329)
- Scale your client (p. 2329)
- Use current generation instances (p. 2329)
- Increase network bandwidth (p. 2329)
- Monitor maximums for network performance (p. 2330)
- Monitor for transactions in the "idle in transaction" state (p. 2330)

Place the clients in the same Availability Zone and VPC subnet as the instance

To reduce network latency and increase network throughput, place clients in the same Availability Zone and virtual private cloud (VPC) subnet as the RDS for PostgreSQL DB instance. Make sure that the clients are as geographically close to the DB instance as possible.

Scale your client

Using Amazon CloudWatch or other host metrics, determine if your client is currently constrained by CPU or network bandwidth, or both. If the client is constrained, scale your client accordingly.

Use current generation instances

In some cases, you might not be using a DB instance class that supports jumbo frames. If you're running your application on Amazon EC2, consider using a current generation instance for the client. Also, configure the maximum transmission unit (MTU) on the client operating system. This technique might reduce the number of network round trips and increase network throughput. For more information, see Jumbo frames (9001 MTU) in the Amazon EC2 User Guide for Linux Instances.

For information about DB instance classes, see DB instance classes (p. 11). To determine the DB instance class that is equivalent to an Amazon EC2 instance type, place \texttt{db.} before the Amazon EC2 instance type name. For example, the \texttt{r5.8xlarge} Amazon EC2 instance is equivalent to the \texttt{db.r5.8xlarge} DB instance class.

Increase network bandwidth

Use \texttt{NetworkReceiveThroughput} and \texttt{NetworkTransmitThroughput} Amazon CloudWatch metrics to monitor incoming and outgoing network traffic on the DB instance. These metrics can help you to determine if network bandwidth is sufficient for your workload.

If your network bandwidth isn't enough, increase it. If the AWS client or your DB instance is reaching the network bandwidth limits, the only way to increase the bandwidth is to increase your DB instance size. For more information, see DB instance class types (p. 11).
For more information about CloudWatch metrics, see Amazon CloudWatch metrics for Amazon RDS (p. 806).

**Monitor maximums for network performance**

If you are using Amazon EC2 clients, Amazon EC2 provides maximums for network performance metrics, including aggregate inbound and outbound network bandwidth. It also provides connection tracking to ensure that packets are returned as expected and link-local services access for services such as the Domain Name System (DNS). To monitor these maximums, use a current enhanced networking driver and monitor network performance for your client.

For more information, see Monitor network performance for your Amazon EC2 instance in the Amazon EC2 User Guide for Linux Instances and Monitor network performance for your Amazon EC2 instance in the Amazon EC2 User Guide for Windows Instances.

**Monitor for transactions in the "idle in transaction" state**

Check whether you have an increasing number of idle in transaction connections. To do this, monitor the state column in the pg_stat_activity table. You might be able to identify the connection source by running a query similar to the following.

```sql
SELECT client_addr, state, count(1) FROM pg_stat_activity WHERE state like 'idle in transaction%' GROUP BY 1, 2 ORDER BY 3 DESC
```

**Client:ClientWrite**

The Client:ClientWrite event occurs when RDS for PostgreSQL is waiting to write data to the client.

**Topics**

- Supported engine versions (p. 2330)
- Context (p. 2330)
- Likely causes of increased waits (p. 2330)
- Actions (p. 2331)

**Supported engine versions**

This wait event information is supported for RDS for PostgreSQL version 10 and higher.

**Context**

A client process must read all of the data received from an RDS for PostgreSQL DB cluster before the cluster can send more data. The time that the cluster waits before sending more data to the client is a Client:ClientWrite event.

Reduced network throughput between the RDS for PostgreSQL DB instance and the client can cause this event. CPU pressure and network saturation on the client can also cause this event. **CPU pressure** is when the CPU is fully utilized and there are tasks waiting for CPU time. **Network saturation** is when the network between the database and client is carrying more data than it can handle.

**Likely causes of increased waits**

Common causes for the Client:ClientWrite event to appear in top waits include the following:
**Increased network latency**

There might be increased network latency between the RDS for PostgreSQL DB instance and client. Higher network latency increases the time required for the client to receive the data.

**Increased load on the client**

There might be CPU pressure or network saturation on the client. An increase in load on the client delays the reception of data from the RDS for PostgreSQL DB instance.

**Large volume of data sent to the client**

The RDS for PostgreSQL DB instance might be sending a large amount of data to the client. A client might not be able to receive the data as fast as the cluster is sending it. Activities such as a copy of a large table can result in an increase in `Client:ClientWrite` events.

**Actions**

We recommend different actions depending on the causes of your wait event.

**Topics**

- Place the clients in the same Availability Zone and VPC subnet as the cluster (p. 2331)
- Use current generation instances (p. 2331)
- Reduce the amount of data sent to the client (p. 2331)
- Scale your client (p. 2331)

**Place the clients in the same Availability Zone and VPC subnet as the cluster**

To reduce network latency and increase network throughput, place clients in the same Availability Zone and virtual private cloud (VPC) subnet as the RDS for PostgreSQL DB instance.

**Use current generation instances**

In some cases, you might not be using a DB instance class that supports jumbo frames. If you're running your application on Amazon EC2, consider using a current generation instance for the client. Also, configure the maximum transmission unit (MTU) on the client operating system. This technique might reduce the number of network round trips and increase network throughput. For more information, see Jumbo frames (9001 MTU) in the *Amazon EC2 User Guide for Linux Instances*.

For information about DB instance classes, see DB instance classes (p. 11). To determine the DB instance class that is equivalent to an Amazon EC2 instance type, place `db.` before the Amazon EC2 instance type name. For example, the `r5.8xlarge` Amazon EC2 instance is equivalent to the `db.r5.8xlarge` DB instance class.

**Reduce the amount of data sent to the client**

When possible, adjust your application to reduce the amount of data that the RDS for PostgreSQL DB instance sends to the client. Making such adjustments relieves CPU and network contention on the client.

**Scale your client**

Using Amazon CloudWatch or other host metrics, determine if your client is currently constrained by CPU or network bandwidth, or both. If the client is constrained, scale your client accordingly.

**CPU**

This event occurs when a thread is active in CPU or is waiting for CPU.
Topics

- **Supported engine versions (p. 2332)**
- **Context (p. 2332)**
- **Likely causes of increased waits (p. 2333)**
- **Actions (p. 2334)**

**Supported engine versions**

This wait event information is relevant for all all versions of RDS for PostgreSQL.

**Context**

The central processing unit (CPU) is the component of a computer that runs instructions. For example, CPU instructions perform arithmetic operations and exchange data in memory. If a query increases the number of instructions that it performs through the database engine, the time spent running the query increases. CPU scheduling is giving CPU time to a process. Scheduling is orchestrated by the kernel of the operating system.

Topics

- **How to tell when this wait occurs (p. 2332)**
- **DBLoadCPU metric (p. 2332)**
- **os.cpuUtilization metrics (p. 2332)**
- **Likely cause of CPU scheduling (p. 2333)**

**How to tell when this wait occurs**

This CPU wait event indicates that a backend process is active in CPU or is waiting for CPU. You know that it's occurring when a query shows the following information:

- The `pg_stat_activity.state` column has the value `active`.
- The `wait_event_type` and `wait_event` columns in `pg_stat_activity` are both `null`.

To see the backend processes that are using or waiting on CPU, run the following query.

```sql
SELECT * FROM pg_stat_activity
WHERE state = 'active'
AND wait_event_type IS NULL
AND wait_event IS NULL;
```

**DBLoadCPU metric**

The Performance Insights metric for CPU is DBLoadCPU. The value for DBLoadCPU can differ from the value for the Amazon CloudWatch metric CPUUtilization. The latter metric is collected from the HyperVisor for a database instance.

**os.cpuUtilization metrics**

Performance Insights operating-system metrics provide detailed information about CPU utilization. For example, you can display the following metrics:

- `os.cpuUtilization.nice.avg`
- `os.cpuUtilization.total.avg`
• os.cpuUtilization.wait.avg
• os.cpuUtilization.idle.avg

Performance Insights reports the CPU usage by the database engine as os.cpuUtilization.nice.avg.

**Likely cause of CPU scheduling**

The operating system (OS) kernel handles scheduling for the CPU. When the CPU is *active*, a process might need to wait to get scheduled. The CPU is active while it's performing computations. It's also active while it has an idle thread that it's not running, that is, an idle thread that's waiting on memory I/O. This type of I/O dominates the typical database workload.

Processes are likely to wait to get scheduled on a CPU when the following conditions are met:

• The CloudWatch CPUUtilization metric is near 100 percent.
• The average load is greater than the number of vCPUs, indicating a heavy load. You can find the loadAverageMinute metric in the OS metrics section in Performance Insights.

**Likely causes of increased waits**

When the CPU wait event occurs more than normal, possibly indicating a performance problem, typical causes include the following.

**Topics**

• Likely causes of sudden spikes (p. 2333)
• Likely causes of long-term high frequency (p. 2333)
• Corner cases (p. 2334)

**Likely causes of sudden spikes**

The most likely causes of sudden spikes are as follows:

• Your application has opened too many simultaneous connections to the database. This scenario is known as a "connection storm."
• Your application workload changed in any of the following ways:
  • New queries
  • An increase in the size of your dataset
  • Index maintenance or creation
  • New functions
  • New operators
  • An increase in parallel query execution
• Your query execution plans have changed. In some cases, a change can cause an increase in buffers. For example, the query is now using a sequential scan when it previously used an index. In this case, the queries need more CPU to accomplish the same goal.

**Likely causes of long-term high frequency**

The most likely causes of events that recur over a long period:

• Too many backend processes are running concurrently on CPU. These processes can be parallel workers.
• Queries are performing suboptimally because they need a large number of buffers.

Corner cases

If none of the likely causes turn out to be actual causes, the following situations might be occurring:

• The CPU is swapping processes in and out.
• The CPU might be managing page table entries if the huge pages feature has been turned off. This memory management feature is turned on by default for all DB instance classes other than micro, small, and medium DB instance classes. For more information, see Huge pages for RDS for PostgreSQL (p. 2176).

Actions

If the CPU wait event dominates database activity, it doesn't necessarily indicate a performance problem. Respond to this event only when performance degrades.

Topics

• Investigate whether the database is causing the CPU increase (p. 2334)
• Determine whether the number of connections increased (p. 2334)
• Respond to workload changes (p. 2335)

Investigate whether the database is causing the CPU increase

Examine the os.cpuUtilization.nice.avg metric in Performance Insights. If this value is far less than the CPU usage, nondatabase processes are the main contributor to CPU.

Determine whether the number of connections increased

Examine the DatabaseConnections metric in Amazon CloudWatch. Your action depends on whether the number increased or decreased during the period of increased CPU wait events.

The connections increased

If the number of connections went up, compare the number of backend processes consuming CPU to the number of vCPUs. The following scenarios are possible:

• The number of backend processes consuming CPU is less than the number of vCPUs.
  In this case, the number of connections isn't an issue. However, you might still try to reduce CPU utilization.
• The number of backend processes consuming CPU is greater than the number of vCPUs.
  In this case, consider the following options:
  • Decrease the number of backend processes connected to your database. For example, implement a connection pooling solution such as RDS Proxy. To learn more, see Using Amazon RDS Proxy (p. 1215).
  • Upgrade your instance size to get a higher number of vCPUs.
  • Redirect some read-only workloads to reader nodes, if applicable.

The connections didn't increase

Examine the blks_hit metrics in Performance Insights. Look for a correlation between an increase in blks_hit and CPU usage. The following scenarios are possible:
- CPU usage and blks_hit are correlated.

  In this case, find the top SQL statements that are linked to the CPU usage, and look for plan changes. You can use either of the following techniques:
  - Explain the plans manually and compare them to the expected execution plan.
  - Look for an increase in block hits per second and local block hits per second. In the Top SQL section of Performance Insights dashboard, choose Preferences.

- CPU usage and blks_hit aren't correlated.

  In this case, determine whether any of the following occurs:
  - The application is rapidly connecting to and disconnecting from the database.

    Diagnose this behavior by turning on log_connections and log_disconnections, then analyzing the PostgreSQL logs. Consider using the pgbadger log analyzer. For more information, see https://github.com/darold/pgbadger.
  - The OS is overloaded.

    In this case, Performance Insights shows that backend processes are consuming CPU for a longer time than usual. Look for evidence in the Performance Insights os.cpuUtilization metrics or the CloudWatch CPUUtilization metric. If the operating system is overloaded, look at Enhanced Monitoring metrics to diagnose further. Specifically, look at the process list and the percentage of CPU consumed by each process.
  - Top SQL statements are consuming too much CPU.

    Examine statements that are linked to the CPU usage to see whether they can use less CPU. Run an EXPLAIN command, and focus on the plan nodes that have the most impact. Consider using a PostgreSQL execution plan visualizer. To try out this tool, see http://explain.dalibo.com/.

**Respond to workload changes**

If your workload has changed, look for the following types of changes:

New queries

  Check whether the new queries are expected. If so, ensure that their execution plans and the number of executions per second are expected.

An increase in the size of the data set

  Determine whether partitioning, if it's not already implemented, might help. This strategy might reduce the number of pages that a query needs to retrieve.

Index maintenance or creation

  Check whether the schedule for the maintenance is expected. A best practice is to schedule maintenance activities outside of peak activities.

New functions

  Check whether these functions perform as expected during testing. Specifically, check whether the number of executions per second is expected.

New operators

  Check whether they perform as expected during the testing.

An increase in running parallel queries

  Determine whether any of the following situations has occurred:
  - The relations or indexes involved have suddenly grown in size so that they differ significantly from min_parallel_table_scan_size or min_parallel_index_scan_size.
• Recent changes have been made to `parallel_setup_cost` or `parallel_tuple_cost`.
• Recent changes have been made to `max_parallel_workers` or `max_parallel_workers_per_gather`.

**IO:BufFileRead and IO:BufFileWrite**

The IO:BufFileRead and IO:BufFileWrite events occur when RDS for PostgreSQL creates temporary files. When operations require more memory than the working memory parameters currently define, they write temporary data to persistent storage. This operation is sometimes called "spilling to disk."

**Topics**
- Supported engine versions (p. 2336)
- Context (p. 2336)
- Likely causes of increased waits (p. 2336)
- Actions (p. 2337)

**Supported engine versions**

This wait event information is supported for all versions of RDS for PostgreSQL.

**Context**

IO:BufFileRead and IO:BufFileWrite relate to the work memory area and maintenance work memory area. For more information about these local memory areas, see Resource Consumption in the PostgreSQL documentation.

The default value for `work_mem` is 4 MB. If one session performs operations in parallel, each worker handling the parallelism uses 4 MB of memory. For this reason, set `work_mem` carefully. If you increase the value too much, a database running many sessions might consume too much memory. If you set the value too low, RDS for PostgreSQL creates temporary files in local storage. The disk I/O for these temporary files can reduce performance.

If you observe the following sequence of events, your database might be generating temporary files:

1. Sudden and sharp decreases in availability
2. Fast recovery for the free space

You might also see a "chainsaw" pattern. This pattern can indicate that your database is creating small files constantly.

**Likely causes of increased waits**

In general, these wait events are caused by operations that consume more memory than the `work_mem` or `maintenance_work_mem` parameters allocate. To compensate, the operations write to temporary files. Common causes for the IO:BufFileRead and IO:BufFileWrite events include the following:

**Queries that need more memory than exists in the work memory area**

Queries with the following characteristics use the work memory area:

- Hash joins
- `ORDER BY` clause
Statements that need more memory than exists in the maintenance work memory area

The following statements use the maintenance work memory area:
- CREATE_INDEX
- CLUSTER

Actions

We recommend different actions depending on the causes of your wait event.

Topics
- Identify the problem (p. 2337)

- Tune memory to prevent IO:BufFileRead and IO:BufFileWrite (p. 2340)

Identify the problem

Assume a situation in which Performance Insights isn't turned on and you suspect that IO:BufFileRead and IO:BufFileWrite are occurring more frequently than is normal. To identify the source of the problem, you can set the log_temp_files parameter to log all queries that generate more than your specified threshold KB of temporary files. By default, log_temp_files is set to -1, which turns off this logging feature. If you set this parameter to 0, RDS for PostgreSQL logs all temporary files. If you set it to 1024, RDS for PostgreSQL logs all queries that produce temporary files larger than 1 MB. For more information about log_temp_files, see Error Reporting and Logging in the PostgreSQL documentation.

Examine your join queries

It's likely that your query uses joins. For example, the following query joins four tables.

```
SELECT *
FROM "order"
INNER JOIN order_item
ON (order.id = order_item.order_id)
INNER JOIN customer
ON (customer.id = order.customer_id)
INNER JOIN customer_address
ON (customer_address.customer_id = customer.id AND order.customer_address_id = customer_address.id)
WHERE customer.id = 1234567890;
```
A possible cause of spikes in temporary file usage is a problem in the query itself. For example, a broken clause might not filter the joins properly. Consider the second inner join in the following example.

```sql
SELECT * 
FROM "order"
INNER JOIN order_item 
ON (order.id = order_item.order_id)
INNER JOIN customer
ON (customer.id = customer.id)
INNER JOIN customer_address
ON (customer_address.customer_id = customer.id AND 
order.customer_address_id = customer_address.id)
WHERE customer.id = 1234567890;
```

The preceding query mistakenly joins `customer.id` to `customer.id`, generating a Cartesian product between every customer and every order. This type of accidental join generates large temporary files. Depending on the size of the tables, a Cartesian query can even fill up storage. Your application might have Cartesian joins when the following conditions are met:

- You see large, sharp decreases in storage availability, followed by fast recovery.
- No indexes are being created.
- No `CREATE TABLE FROM SELECT` statements are being issued.
- No materialized views are being refreshed.

To see whether the tables are being joined using the proper keys, inspect your query and object-relational mapping directives. Bear in mind that certain queries of your application are not called all the time, and some queries are dynamically generated.

**Examine your ORDER BY and GROUP BY queries**

In some cases, an `ORDER BY` clause can result in excessive temporary files. Consider the following guidelines:

- Only include columns in an `ORDER BY` clause when they need to be ordered. This guideline is especially important for queries that return thousands of rows and specify many columns in the `ORDER BY` clause.
- Considering creating indexes to accelerate `ORDER BY` clauses when they match columns that have the same ascending or descending order. Partial indexes are preferable because they are smaller. Smaller indexes are read and traversed more quickly.
- If you create indexes for columns that can accept null values, consider whether you want the null values stored at the end or at the beginning of the indexes.

If possible, reduce the number of rows that need to be ordered by filtering the result set. If you use `WITH` clause statements or subqueries, remember that an inner query generates a result set and passes it to the outside query. The more rows that a query can filter out, the less ordering the query needs to do.

- If you don't need to obtain the full result set, use the `LIMIT` clause. For example, if you only want the top five rows, a query using the `LIMIT` clause doesn't keep generating results. In this way, the query requires less memory and temporary files.

A query that uses a `GROUP BY` clause can also require temporary files. `GROUP BY` queries summarize values by using functions such as the following:

- `COUNT`
- `AVG`
To tune GROUP BY queries, follow the recommendations for ORDER BY queries.

**Avoid using the DISTINCT operation**

If possible, avoid using the DISTINCT operation to remove duplicated rows. The more unnecessary and duplicated rows that your query returns, the more expensive the DISTINCT operation becomes. If possible, add filters in the WHERE clause even if you use the same filters for different tables. Filtering the query and joining correctly improves your performance and reduces resource use. It also prevents incorrect reports and results.

If you need to use DISTINCT for multiple rows of a same table, consider creating a composite index. Grouping multiple columns in an index can improve the time to evaluate distinct rows. Also, if you use RDS for PostgreSQL version 10 or higher, you can correlate statistics among multiple columns by using the CREATE STATISTICS command.

**Consider using window functions instead of GROUP BY functions**

Using GROUP BY, you change the result set, and then retrieve the aggregated result. Using window functions, you aggregate data without changing the result set. A window function uses the OVER clause to perform calculations across the sets defined by the query, correlating one row with another. You can use all the GROUP BY functions in window functions, but also use functions such as the following:

- RANK
- ARRAY_AGG
- ROW_NUMBER
- LAG
- LEAD

To minimize the number of temporary files generated by a window function, remove duplications for the same result set when you need two distinct aggregations. Consider the following query.

```sql
SELECT sum(salary) OVER (PARTITION BY dept ORDER BY salary DESC) as sum_salary ,
      avg(salary) OVER (PARTITION BY dept ORDER BY salary ASC) as avg_salary
FROM empsalary;
```

You can rewrite the query with the WINDOW clause as follows.

```sql
SELECT sum(salary) OVER w as sum_salary ,
      avg(salary) OVER w as avg_salary
FROM empsalary
WINDOW w AS (PARTITION BY dept ORDER BY salary DESC);
```

By default, the RDS for PostgreSQL execution planner consolidates similar nodes so that it doesn't duplicate operations. However, by using an explicit declaration for the window block, you can maintain the query more easily. You might also improve performance by preventing duplication.

**Investigate materialized views and CTAS statements**

When a materialized view refreshes, it runs a query. This query can contain an operation such as GROUP BY, ORDER BY, or DISTINCT. During a refresh, you might observe large numbers of temporary files and
the wait events IO:BufFileWrite and IO:BufFileRead. Similarly, when you create a table based on a SELECT statement, the CREATE TABLE statement runs a query. To reduce the temporary files needed, optimize the query.

Use pg_repack when you rebuild indexes

When you create an index, the engine orders the result set. As tables grow in size, and as values in the indexed column become more diverse, the temporary files require more space. In most cases, you can't prevent the creation of temporary files for large tables without modifying the maintenance work memory area. For more information about maintenance_work_mem, see https://www.postgresql.org/docs/current/runtime-config-resource.html in the PostgreSQL documentation.

A possible workaround when recreating a large index is to use the pg_repack extension. For more information, see Reorganize tables in PostgreSQL databases with minimal locks in the pg_repack documentation. For information about setting up the extension in your RDS for PostgreSQL DB instance, see Reducing bloat in tables and indexes with the pg_repack extension (p. 2405).

Increase maintenance_work_mem when you cluster tables

The CLUSTER command clusters the table specified by table_name based on an existing index specified by index_name. RDS for PostgreSQL physically recreates the table to match the order of a given index.

When magnetic storage was prevalent, clustering was common because storage throughput was limited. Now that SSD-based storage is common, clustering is less popular. However, if you cluster tables, you can still increase performance slightly depending on the table size, index, query, and so on.

If you run the CLUSTER command and observe the wait events IO:BufFileWrite and IO:BufFileRead, tune maintenance_work_mem. Increase the memory size to a fairly large amount. A high value means that the engine can use more memory for the clustering operation.

Tune memory to prevent IO:BufFileRead and IO:BufFileWrite

In some situations, you need to tune memory. Your goal is to balance memory across the following areas of consumption using the appropriate parameters, as follows.

- The work_mem value
- The memory remaining after discounting the shared_buffers value
- The maximum connections opened and in use, which is limited by max_connections

For more information about tuning memory, see Resource Consumption in the PostgreSQL documentation.

Increase the size of the work memory area

In some situations, your only option is to increase the memory used by your session. If your queries are correctly written and are using the correct keys for joins, consider increasing the work_mem value.

To find out how many temporary files a query generates, set log_temp_files to 0. If you increase the work_mem value to the maximum value identified in the logs, you prevent the query from generating temporary files. However, work_mem sets the maximum per plan node for each connection or parallel worker. If the database has 5,000 connections, and if each one uses 256 MiB memory, the engine needs 1.2 TiB of RAM. Thus, your instance might run out of memory.

Reserve sufficient memory for the shared buffer pool

Your database uses memory areas such as the shared buffer pool, not just the work memory area. Consider the requirements of these additional memory areas before you increase work_mem.

For example, assume that your RDS for PostgreSQL instance class is db.r5.2xlarge. This class has 64 GiB of memory. By default, 25 percent of the memory is reserved for the shared buffer pool. After
you subtract the amount allocated to the shared memory area, 16,384 MB remains. Don't allocate the remaining memory exclusively to the work memory area because the operating system and the engine also require memory.

The memory that you can allocate to `work_mem` depends on the instance class. If you use a larger instance class, more memory is available. However, in the preceding example, you can't use more than 16 GiB. Otherwise, your instance becomes unavailable when it runs out of memory. To recover the instance from the unavailable state, the RDS for PostgreSQL automation services automatically restart.

**Manage the number of connections**

Suppose that your database instance has 5,000 simultaneous connections. Each connection uses at least 4 MiB of `work_mem`. The high memory consumption of the connections is likely to degrade performance. In response, you have the following options:

- Upgrade to a larger instance class.
- Decrease the number of simultaneous database connections by using a connection proxy or pooler.

For proxies, consider Amazon RDS Proxy, pgBouncer, or a connection pooler based on your application. This solution alleviates the CPU load. It also reduces the risk when all connections require the work memory area. When fewer database connections exist, you can increase the value of `work_mem`. In this way, you reduce the occurrence of the `IO:BufFileRead` and `IO:BufFileWrite` wait events. Also, the queries waiting for the work memory area speed up significantly.

**IO:DataFileRead**

The `IO:DataFileRead` event occurs when a connection waits on a backend process to read a required page from storage because the page isn't available in shared memory.

**Topics**

- Supported engine versions (p. 2341)
- Context (p. 2341)
- Likely causes of increased waits (p. 2341)
- Actions (p. 2342)

**Supported engine versions**

This wait event information is supported for all versions of RDS for PostgreSQL.

**Context**

All queries and data manipulation (DML) operations access pages in the buffer pool. Statements that can induce reads include `SELECT`, `UPDATE`, and `DELETE`. For example, an `UPDATE` can read pages from tables or indexes. If the page being requested or updated isn't in the shared buffer pool, this read can lead to the `IO:DataFileRead` event.

Because the shared buffer pool is finite, it can fill up. In this case, requests for pages that aren't in memory force the database to read blocks from disk. If the `IO:DataFileRead` event occurs frequently, your shared buffer pool might be too small to accommodate your workload. This problem is acute for `SELECT` queries that read a large number of rows that don't fit in the buffer pool. For more information about the buffer pool, see [Resource Consumption](#) in the PostgreSQL documentation.

**Likely causes of increased waits**

Common causes for the `IO:DataFileRead` event include the following:
Connection spikes

You might find multiple connections generating the same number of IO:DataFileRead wait events. In this case, a spike (sudden and large increase) in IO:DataFileRead events can occur.

SELECT and DML statements performing sequential scans

Your application might be performing a new operation. Or an existing operation might change because of a new execution plan. In such cases, look for tables (particularly large tables) that have a greater seq_scan value. Find them by querying pg_stat_user_tables. To track queries that are generating more read operations, use the extension pg_stat_statements.

CTAS and CREATE INDEX for large data sets

A CTAS is a CREATE TABLE AS SELECT statement. If you run a CTAS using a large data set as a source, or create an index on a large table, the IO:DataFileRead event can occur. When you create an index, the database might need to read the entire object using a sequential scan. A CTAS generates IO:DataFile reads when pages aren't in memory.

Multiple vacuum workers running at the same time

Vacuum workers can be triggered manually or automatically. We recommend adopting an aggressive vacuum strategy. However, when a table has many updated or deleted rows, the IO:DataFileRead waits increase. After space is reclaimed, the vacuum time spent on IO:DataFileRead decreases.

Ingesting large amounts of data

When your application ingests large amounts of data, ANALYZE operations might occur more often. The ANALYZE process can be triggered by an autovacuum launcher or invoked manually.

The ANALYZE operation reads a subset of the table. The number of pages that must be scanned is calculated by multiplying 30 by the default_statistics_target value. For more information, see the PostgreSQL documentation. The default_statistics_target parameter accepts values between 1 and 10,000, where the default is 100.

Resource starvation

If instance network bandwidth or CPU are consumed, the IO:DataFileRead event might occur more frequently.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Check predicate filters for queries that generate waits (p. 2342)
- Minimize the effect of maintenance operations (p. 2343)
- Respond to high numbers of connections (p. 2346)

Check predicate filters for queries that generate waits

Assume that you identify specific queries that are generating IO:DataFileRead wait events. You might identify them using the following techniques:

- Performance Insights
- Catalog views such as the one provided by the extension pg_stat_statements
- The catalog view pg_stat_all_tables, if it periodically shows an increased number of physical reads
- The pg_statio_all_tables view, if it shows that _read counters are increasing
We recommend that you determine which filters are used in the predicate (WHERE clause) of these queries. Follow these guidelines:

- Run the EXPLAIN command. In the output, identify which types of scans are used. A sequential scan doesn't necessarily indicate a problem. Queries that use sequential scans naturally produce more IO:DataFileRead events when compared to queries that use filters.

Find out whether the column listed in the WHERE clause is indexed. If not, consider creating an index for this column. This approach avoids the sequential scans and reduces the IO:DataFileRead events. If a query has restrictive filters and still produces sequential scans, evaluate whether the proper indexes are being used.

- Find out whether the query is accessing a very large table. In some cases, partitioning a table can improve performance, allowing the query to only read necessary partitions.
- Examine the cardinality (total number of rows) from your join operations. Note how restrictive the values are that you're passing in the filters for your WHERE clause. If possible, tune your query to reduce the number of rows that are passed in each step of the plan.

**Minimize the effect of maintenance operations**

Maintenance operations such as VACUUM and ANALYZE are important. We recommend that you don't turn them off because you find IO:DataFileRead wait events related to these maintenance operations. The following approaches can minimize the effect of these operations:

- Run maintenance operations manually during off-peak hours. This technique prevents the database from reaching the threshold for automatic operations.
- For very large tables, consider partitioning the table. This technique reduces the overhead of maintenance operations. The database only accesses the partitions that require maintenance.
- When you ingest large amounts of data, consider disabling the autoanalyze feature.

The autovacuum feature is automatically triggered for a table when the following formula is true.

\[
\text{pg_stat_user_tables.n_dead_tup} > (\text{pg_class.reltuples} \times \text{autovacuum_vacuum_scale_factor}) + \text{autovacuum_vacuum_threshold}
\]

The view pg_stat_user_tables and catalog pg_class have multiple rows. One row can correspond to one row in your table. This formula assumes that the reltuples are for a specific table. The parameters autovacuum_vacuum_scale_factor (0.20 by default) and autovacuum_vacuum_threshold (50 tuples by default) are usually set globally for the whole instance. However, you can set different values for a specific table.

**Topics**

- Find tables consuming space unnecessarily (p. 2343)
- Find indexes consuming space unnecessarily (p. 2344)
- Find tables that are eligible to be autovacuumed (p. 2345)

**Find tables consuming space unnecessarily**

To find tables consuming space unnecessarily, you can use functions from the PostgreSQL pgstattuple extension. This extension (module) is available by default on all RDS for PostgreSQL DB instances and can be instantiated on the instance with the following command.

```
CREATE EXTENSION pgstattuple;
```
For more information about this extension, see `pgstattuple` in the PostgreSQL documentation.

You can check for table and index bloat in your application. For more information, see [Diagnosing table and index bloat](#).

Find indexes consuming space unnecessarily

To find bloated indexes and estimate the amount of space consumed unnecessarily on the tables for which you have read privileges, you can run the following query.

```sql
-- WARNING: rows with is_na = 't' are known to have bad statistics ("name" type is not supported).
-- This query is compatible with PostgreSQL 8.2 and later.
SELECT current_database(), nspname AS schemaname, tblname, idxname, bs*(relpages)::bigint AS real_size,
       bs*(relpages-est_pages)::bigint AS extra_size,
       100 * (relpages-est_pages)::float / relpages AS extra_ratio,
       fillfactor, bs*(relpages-est_pages_ff) AS bloat_size,
       100 * (relpages-est_pages_ff)::float / relpages AS bloat_ratio,
       is_na
FROM (SELECT coalesce(1 +
            ceil(reltuples/floor((bs-pageopqdata-pagehdr)/(4+nulldatahdrwidth)::float)), 0
-- ItemIdData size + computed avg size of a tuple (nulldatahdrwidth)
        ) AS est_pages,
        coalesce(1 +
            ceil(reltuples/floor((bs-pageopqdata-pagehdr)*fillfactor/ (100*(4+nulldatahdrwidth)::float))), 0
-- index_tuple_hdr_bm, maxalign, pagehdr, nulldatawidth, nulldatahdrwidth, reltuples, relpages
        ) AS est_pages_ff,
        bs, nspname, table_oid, tblname, idxname, relpages, fillfactor, is_na
        ) AS pst,
FROM (SELECT maxalign, bs, nspname, tblname, idxname, reltuples, relpages, relam, table_oid,
        fillfactor,
        ( index_tuple_hdr_bm +
        maxalign - CASE -- Add padding to the index tuple header to align on MAXALIGN
        WHEN index_tuple_hdr_bm%maxalign = 0 THEN maxalign
        ELSE index_tuple_hdr_bm%maxalign
        END
        + nulldatawidth + maxalign - CASE -- Add padding to the data to align on MAXALIGN
        WHEN nulldatawidth = 0 THEN 0
        WHEN nulldatawidth::integer%maxalign = 0 THEN maxalign
        ELSE nulldatawidth::integer%maxalign
        END
        )::numeric AS nulldatahdrwidth, pagehdr, pageopqdata, is_na
FROM (SELECT maxalign, bs, nspname, tblname, idxname, reltuples, relpages, relam, table_oid, fillfactor,
        ( index_tuple_hdr_bm +
        maxalign - CASE -- Add padding to the index tuple header to align on MAXALIGN
        WHEN index_tuple_hdr_bm%maxalign = 0 THEN maxalign
        ELSE index_tuple_hdr_bm%maxalign
        END
        + nulldatawidth + maxalign - CASE -- Add padding to the data to align on MAXALIGN
        WHEN nulldatawidth = 0 THEN 0
        WHEN nulldatawidth::integer%maxalign = 0 THEN maxalign
        ELSE nulldatawidth::integer%maxalign
        END
        )::numeric AS nulldatahdrwidth, pagehdr, pageopqdata, is_na
FROM (SELECT current_setting('block_size')::numeric AS bs, fillfactor,
        CASE -- MAXALIGN: 4 on 32bits, 8 on 64bits (and mingw32 ?)
        WHEN version() ~ 'mingw32' OR version() ~ '64-bit[x86_64|ppc64|ia64|amd64]' THEN 8
        ELSE 4
        END
        AS maxalign,
        /* per page header, fixed size: 20 for 7.X, 24 for others */
        24 AS pagehdr,
        /* per page btree opaque data */
        16 AS pageopqdata,
        )
```
/* per tuple header: add IndexAttributeBitMapData if some cols are null-able */
CASE WHEN max(coalesce(s.null_frac,0)) = 0
    THEN 2 -- IndexTupleData size
    ELSE 2 + (( 32 + 8 - 1 ) / 8)
END AS index_tuple_hdr_bm,
/* data len: we remove null values save space using it fractionnal part from stats */
sum( (1-coalesce(s.null_frac, 0)) * coalesce(s.avg_width, 1024)) AS nulldatawidth,
max( CASE WHEN a.atttypid = 'pg_catalog.name'::regtype THEN 1 ELSE 0 END ) > 0 AS is_na
FROM pg_attribute AS a
JOIN ( SELECT nspname, tbl.relname AS tblname, idx.relname AS idxname,
        idx.reltuples, idx.relpages, idx.relam,
        indrelid, indexrelid, indkey::smallint[] AS attnum,
        coalesce(substring(array_to_string(idx.reloptions, ' '),
    from 'fillfactor=(\[0-9]+)')::smallint, 90) AS fillfactor
    FROM pg_index
    JOIN pg_class idx ON idx.oid=pg_index.indexrelid
    JOIN pg_class tbl ON tbl.oid=pg_index.indrelid
    JOIN pg_namespace ON pg_namespace.oid = idx.relnamespace
    WHERE pg_index.indisvalid AND tbl.relkind = 'r' AND idx.relpages > 0
    ) AS s ON a.attrelid = s.indexrelid
JOIN pg_stats AS s2 ON s2.schemaname = s.nspname
AND ((s.tablename = s.tblname AND s.attname =
        pg_catalog.pg_get_indexdef(a.attrelid, a.attnum, TRUE))
    OR (s.tablename = a.idxname AND s.attname = a.attname))
    FROM pg_index
    JOIN pg_class idx ON idx.oid=pg_index.indexrelid
    JOIN pg_class tbl ON tbl.oid=pg_index.indrelid
    JOIN pg_namespace ON pg_namespace.oid = idx.relnamespace
    WHERE pg_index.indisvalid AND tbl.relkind = 'r' AND idx.relpages > 0
    ) AS s1
) AS sub
WHERE NOT is_na
ORDER BY 2,3,4;

Find tables that are eligible to be autovacuumed

To find tables that are eligible to be autovacuumed, run the following query.

--This query shows tables that need vacuuming and are eligible candidates.
--During normal operation, this query should return very little.
WITH vbt AS (SELECT setting AS autovacuum_vacuum_threshold
    FROM pg_settings WHERE name = 'autovacuum_vacuum_threshold')
, vsf AS (SELECT setting AS autovacuum_vacuum_scale_factor
    FROM pg_settings WHERE name = 'autovacuum_vacuum_scale_factor')
, fma AS (SELECT setting AS autovacuum_freeze_max_age
    FROM pg_settings WHERE name = 'autovacuum_freeze_max_age')
, sto AS (SELECT opt_oid, split_part(setting, '=', 1) as param,
    split_part(setting, '=', 2) as value
    FROM (SELECT oid opt_oid, unnest(reloptions) setting FROM pg_class) opt)
SELECT
    '"' ||ns.nspname||'"' ||c.relname||'"' as relation
    , pg_size_pretty(pg_table_size(c.oid)) as table_size
    , age(relfrozenxid) as xid_age
    , coalesce(cfma.value::float, autovacuum_freeze_max_age::float)
    as autovacuum_freeze_max_age
    FROM c
    JOIN (SELECT oid coid, unnest(reloptions) setting FROM pg_class) c
    ON coid = c.oid
    JOIN vbt ON vbt.param = 'autovacuum_vacuum_threshold'
    JOIN vsf ON vsf.param = 'autovacuum_vacuum_scale_factor'
    JOIN fma ON fma.param = 'autovacuum_freeze_max_age'
    JOIN sto ON sto.param = 'autovacuum_freeze_max_age'
### Respond to high numbers of connections

When you monitor Amazon CloudWatch, you might find that the `DatabaseConnections` metric spikes. This increase indicates an increased number of connections to your database. We recommend the following approach:

- Limit the number of connections that the application can open with each instance. If your application has an embedded connection pool feature, set a reasonable number of connections. Base the number on what the vCPUs in your instance can parallelize effectively.

  If your application doesn't use a connection pool feature, considering using Amazon RDS Proxy or an alternative. This approach lets your application open multiple connections with the load balancer. The balancer can then open a restricted number of connections with the database. As fewer connections are running in parallel, your DB instance performs less context switching in the kernel. Queries should progress faster, leading to fewer wait events. For more information, see [Using Amazon RDS Proxy](p. 1215).

-Whenever possible, take advantage of read replicas for RDS for PostgreSQL. When your application runs a read-only operation, send these requests to the read replica(s). This technique reduces the I/O pressure on the primary (writer) node.

- Consider scaling up your DB instance. A higher-capacity instance class gives more memory, which gives RDS for PostgreSQL a larger shared buffer pool to hold pages. The larger size also gives the DB instance more vCPUs to handle connections. More vCPUs are particularly helpful when the operations that are generating `IO:DataFileRead` wait events are writes.

### IO:WALWrite

**Topics**

- [Supported engine versions (p. 2347)]
- [Context (p. 2347)]
- [Likely causes of increased waits (p. 2347)]
Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL 10 and higher.

Context

Activity in the database that's generating write-ahead log data fills up the WAL buffers first and then writes to disk, asynchronously. The wait event IO:WALWrite is generated when the SQL session is waiting for the WAL data to complete writing to disk so that it can release the transaction's COMMIT call.

Likely causes of increased waits

If this wait event occurs often, you should review your workload and the type of updates that your workload performs and their frequency. In particular, look for the following types of activity.

Heavy DML activity

Changing data in database tables doesn't happen instantaneously. An insert to one table might need to wait for an insert or an update to the same table from another client. The data manipulation language (DML) statements for changing data values (INSERT, UPDATE, DELETE, COMMIT, ROLLBACK TRANSACTION) can result in contention that causes the write-ahead logfile to be waiting for the buffers to be flushed. This situation is captured in the following Amazon RDS Performance Insights metrics that indicate heavy DML activity.

- tup_inserted
- tup_updated
- tup_deleted
- xcat_rollback
- xact_commit

For more information about these metrics, see Performance Insights counters for Amazon RDS for PostgreSQL (p. 828).

Frequent checkpoint activity

Frequent checkpoints contribute to larger WAL size. In RDS for PostgreSQL, full page writes are always "on." Full page writes help protect against data loss. However, when checkpointing occurs too frequently, the system can suffer overall performance issues. This is especially true on systems with heavy DML activity. In some cases, you might find error messages in your postgresql.log stating that "checkpoints are occurring too frequently."

We recommend that when tuning checkpoints, you carefully balance performance against expected time need to recover in the event of an abnormal shutdown.

Actions

We recommend the following actions to reduce the numbers of this wait event.

Topics

- Reduce the number of commits (p. 2348)
- Monitor your checkpoints (p. 2348)
• **Scale up IO** (p. 2348)

**Reduce the number of commits**

To reduce the number of commits, you can combine statements into transaction blocks. Use Amazon RDS Performance Insights to examine the type of queries being run. You can also move large maintenance operations to off-peak hours. For example, create indexes or use `pg_repack` operations during non-production hours.

**Monitor your checkpoints**

There are two parameters that you can monitor to see how frequently your RDS for PostgreSQL DB instance is writing to the WAL file for checkpoints.

- `log_checkpoints` – This parameter is set to "on" by default. It causes a message to get sent to the PostgreSQL log for each checkpoint. These log messages include the number of buffers written, the time spent writing them, and the number of WAL files added, removed, or recycled for the given checkpoint.

  For more information about this parameter, see *Error Reporting and Logging* in the PostgreSQL documentation.

- `checkpoint_warning` – This parameter sets a threshold value (in seconds) for checkpoint frequency above which a warning is generated. By default, this parameter isn't set in RDS for PostgreSQL. You can set the value of this parameter to get a warning when the database changes in your RDS for PostgreSQL DB instance are written at a rate for which the WAL files are not sized to handle. For example, say you set this parameter to 30. If your RDS for PostgreSQL instance needs to write changes more often than every 30 seconds, the warning that "checkpoints are occurring too frequently" is sent to the PostgreSQL log. This can indicate that your `max_wal_size` value should be increased.

  For more information, see *Write Ahead Log* in the PostgreSQL documentation.

**Scale up IO**

This type of input/output (IO) wait event can remediated by scaling the input/output operations per second (IOPs) to provide faster IO. Scaling IO is preferable to scaling CPU, because scaling CPU can result in even more IO contention because the increased CPU can handle more work and thus make the IO bottleneck even worse. In general, we recommend that you consider tuning your workload before performing scaling operations.

**Lock:advisory**

The `Lock:advisory` event occurs when a PostgreSQL application uses a lock to coordinate activity across multiple sessions.

**Topics**

- **Relevant engine versions** (p. 2348)
- **Context** (p. 2349)
- **Causes** (p. 2349)
- **Actions** (p. 2349)

**Relevant engine versions**

This wait event information is relevant for RDS for PostgreSQL versions 9.6 and higher.
**Context**

PostgreSQL advisory locks are application-level, cooperative locks explicitly locked and unlocked by the user's application code. An application can use PostgreSQL advisory locks to coordinate activity across multiple sessions. Unlike regular, object- or row-level locks, the application has full control over the lifetime of the lock. For more information, see Advisory Locks in the PostgreSQL documentation.

Advisory locks can be released before a transaction ends or be held by a session across transactions. This isn't true for implicit, system-enforced locks, such as an access-exclusive lock on a table acquired by a CREATE INDEX statement.

For a description of the functions used to acquire (lock) and release (unlock) advisory locks, see Advisory Lock Functions in the PostgreSQL documentation.

Advisory locks are implemented on top of the regular PostgreSQL locking system and are visible in the pg_locks system view.

**Causes**

This lock type is exclusively controlled by an application explicitly using it. Advisory locks that are acquired for each row as part of a query can cause a spike in locks or a long-term buildup.

These effects happen when the query is run in a way that acquires locks on more rows than are returned by the query. The application must eventually release every lock, but if locks are acquired on rows that aren't returned, the application can't find all of the locks.

The following example is from Advisory Locks in the PostgreSQL documentation.

```
SELECT pg_advisory_lock(id) FROM foo WHERE id > 12345 LIMIT 100;
```

In this example, the LIMIT clause can only stop the query's output after the rows have already been internally selected and their ID values locked. This can happen suddenly when a growing data volume causes the planner to choose a different execution plan that wasn't tested during development. The buildup in this case happens because the application explicitly calls pg_advisory_unlock for every ID value that was locked. However, in this case it can't find the set of locks acquired on rows that weren't returned. Because the locks are acquired on the session level, they aren't released automatically at the end of the transaction.

Another possible cause for spikes in blocked lock attempts is unintended conflicts. In these conflicts, unrelated parts of the application share the same lock ID space by mistake.

**Actions**

Review application usage of advisory locks and detail where and when in the application flow each type of advisory lock is acquired and released.

Determine whether a session is acquiring too many locks or a long-running session isn't releasing locks early enough, leading to a slow buildup of locks. You can correct a slow buildup of session-level locks by ending the session using pg_terminate_backend(pid).

A client waiting for an advisory lock appears in pg_stat_activity with wait_event_type=Lock and wait_event=advisory. You can obtain specific lock values by querying the pg_locks system view for the same pid, looking for locktype=advisory and granted=f.

You can then identify the blocking session by querying pg_locks for the same advisory lock having granted=t, as shown in the following example.

```
SELECT blocked_locks.pid AS blocked_pid,
       blocking_locks.pid AS blocking_pid,
```
All of the advisory lock API functions have two sets of arguments, either one bigint argument or two integer arguments:

- For the API functions with one bigint argument, the upper 32 bits are in `pg_locks.classid` and the lower 32 bits are in `pg_locks.objid`.
- For the API functions with two integer arguments, the first argument is `pg_locks.classid` and the second argument is `pg_locks.objid`.

The `pg_locks.objsubid` value indicates which API form was used: 1 means one bigint argument; 2 means two integer arguments.

**Lock:extend**

The Lock:extend event occurs when a backend process is waiting to lock a relation to extend it while another process has a lock on that relation for the same purpose.

**Supported engine versions**

This wait event information is supported for all versions of RDS for PostgreSQL.
Context

The event Lock:extend indicates that a backend process is waiting to extend a relation that another backend process holds a lock on while it's extending that relation. Because only one process at a time can extend a relation, the system generates a Lock:extend wait event. INSERT, COPY, and UPDATE operations can generate this event.

Likely causes of increased waits

When the Lock:extend event appears more than normal, possibly indicating a performance problem, typical causes include the following:

Surge in concurrent inserts or updates to the same table

There might be an increase in the number of concurrent sessions with queries that insert into or update the same table.

Insufficient network bandwidth

The network bandwidth on the DB instance might be insufficient for the storage communication needs of the current workload. This can contribute to storage latency that causes an increase in Lock:extend events.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

• Reduce concurrent inserts and updates to the same relation (p. 2351)
• Increase network bandwidth (p. 2352)

Reduce concurrent inserts and updates to the same relation

First, determine whether there's an increase in tup_inserted and tup_updated metrics and an accompanying increase in this wait event. If so, check which relations are in high contention for insert and update operations. To determine this, query the pg_stat_all_tables view for the values in n_tup_ins and n_tup_upd fields. For information about the pg_stat_all_tables view, see pg_stat_all_tables in the PostgreSQL documentation.

To get more information about blocking and blocked queries, query pg_stat_activity as in the following example:

```
SELECT
    blocked.pid,
    blocked.usename,
    blocked.query,
    blocking.pid AS blocking_id,
    blocking.query AS blocking_query,
    blocking.wait_event AS blocking_wait_event,
    blocking.wait_event_type AS blocking_wait_event_type
FROM pg_stat_activity AS blocked
JOIN pg_stat_activity AS blocking ON blocking.pid = ANY(pg_blocking_pids(blocked.pid))
where
    blocked.wait_event = 'extend'
    and blocked.wait_event_type = 'Lock';
```

<table>
<thead>
<tr>
<th>pid</th>
<th>username</th>
<th>query</th>
<th>blocking_id</th>
<th>blocking_query</th>
<th>blocking_wait_event</th>
<th>blocking_wait_event_type</th>
</tr>
</thead>
</table>

2351
After you identify relations that contribute to increase Lock:extend events, use the following techniques to reduce the contention:

- Find out whether you can use partitioning to reduce contention for the same table. Separating inserted or updated tuples into different partitions can reduce contention. For information about partitioning, see Managing PostgreSQL partitions with the pg_partman extension (p. 2375).
- If the wait event is mainly due to update activity, consider reducing the relation's fillfactor value. This can reduce requests for new blocks during the update. The fillfactor is a storage parameter for a table that determines the maximum amount of space for packing a table page. It's expressed as a percentage of the total space for a page. For more information about the fillfactor parameter, see CREATE TABLE in the PostgreSQL documentation.

  **Important**
  We highly recommend that you test your system if you change the fillfactor because changing this value can negatively impact performance, depending on your workload.

### Increase network bandwidth

To see whether there's an increase in write latency, check the WriteLatency metric in CloudWatch. If there is, use the WriteThroughput and ReadThroughput Amazon CloudWatch metrics to monitor the storage related traffic on the DB instance. These metrics can help you to determine if network bandwidth is sufficient for the storage activity of your workload.

If your network bandwidth isn't enough, increase it. If your DB instance is reaching the network bandwidth limits, the only way to increase the bandwidth is to increase your DB instance size.

For more information about CloudWatch metrics, see Amazon CloudWatch instance-level metrics for Amazon RDS (p. 806). For information about network performance for each DB instance class, see Amazon CloudWatch instance-level metrics for Amazon RDS (p. 806).

### Lock:Relation

The Lock:Relation event occurs when a query is waiting to acquire a lock on a table or view (relation) that's currently locked by another transaction.

**Topics**

- Supported engine versions (p. 2352)
- Context (p. 2352)
- Likely causes of increased waits (p. 2353)
- Actions (p. 2353)

### Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

### Context

Most PostgreSQL commands implicitly use locks to control concurrent access to data in tables. You can also use these locks explicitly in your application code with the LOCK command. Many lock modes aren't
compatible with each other, and they can block transactions when they're trying to access the same object. When this happens, RDS for PostgreSQL generates a Lock:Relation event. Some common examples are the following:

- Exclusive locks such as ACCESS EXCLUSIVE can block all concurrent access. Data definition language (DDL) operations such as DROP TABLE, TRUNCATE, VACUUM FULL, and CLUSTER acquire ACCESS EXCLUSIVE locks implicitly. ACCESS EXCLUSIVE is also the default lock mode for LOCK TABLE statements that don't specify a mode explicitly.
- Using CREATE INDEX (without CONCURRENT) on a table conflicts with data manipulation language (DML) statements UPDATE, DELETE, and INSERT, which acquire ROW EXCLUSIVE locks.

For more information about table-level locks and conflicting lock modes, see Explicit Locking in the PostgreSQL documentation.

Blocking queries and transactions typically unblock in one of the following ways:

- Blocking query – The application can cancel the query or the user can end the process. The engine can also force the query to end because of a session's statement-timeout or a deadlock detection mechanism.
- Blocking transaction – A transaction stops blocking when it runs a ROLLBACK or COMMIT statement. Rollbacks also happen automatically when sessions are disconnected by a client or by network issues, or are ended. Sessions can be ended when the database engine is shut down, when the system is out of memory, and so forth.

**Likely causes of increased waits**

When the Lock:Relation event occurs more frequently than normal, it can indicate a performance issue. Typical causes include the following:

**Increased concurrent sessions with conflicting table locks**

There might be an increase in the number of concurrent sessions with queries that lock the same table with conflicting locking modes.

**Maintenance operations**

Health maintenance operations such as VACUUM and ANALYZE can significantly increase the number of conflicting locks. VACUUM FULL acquires an ACCESS EXCLUSIVE lock, and ANALYZE acquires a SHARE UPDATE EXCLUSIVE lock. Both types of locks can cause a Lock:Relation wait event. Application data maintenance operations such as refreshing a materialized view can also increase blocked queries and transactions.

**Locks on reader instances**

There might be a conflict between the relation locks held by the writer and readers. Currently, only ACCESS EXCLUSIVE relation locks are replicated to reader instances. However, the ACCESS EXCLUSIVE relation lock will conflict with any ACCESS SHARE relation locks held by the reader. This can cause an increase in lock relation wait events on the reader.

**Actions**

We recommend different actions depending on the causes of your wait event.

**Topics**

- Reduce the impact of blocking SQL statements (p. 2354)
- Minimize the effect of maintenance operations (p. 2354)
Reduce the impact of blocking SQL statements

To reduce the impact of blocking SQL statements, modify your application code where possible. Following are two common techniques for reducing blocks:

- Use the `NOWAIT` option – Some SQL commands, such as SELECT and LOCK statements, support this option. The `NOWAIT` directive cancels the lock-requesting query if the lock can't be acquired immediately. This technique can help prevent a blocking session from causing a pile-up of blocked sessions behind it.

  For example: Assume that transaction A is waiting on a lock held by transaction B. Now, if B requests a lock on a table that's locked by transaction C, transaction A might be blocked until transaction C completes. But if transaction B uses a `NOWAIT` when it requests the lock on C, it can fail fast and ensure that transaction A doesn't have to wait indefinitely.

- Use `SET lock_timeout` – Set a `lock_timeout` value to limit the time a SQL statement waits to acquire a lock on a relation. If the lock isn't acquired within the timeout specified, the transaction requesting the lock is cancelled. Set this value at the session level.

Minimize the effect of maintenance operations

Maintenance operations such as VACUUM and ANALYZE are important. We recommend that you don't turn them off because you find `Lock:Relation` wait events related to these maintenance operations. The following approaches can minimize the effect of these operations:

- Run maintenance operations manually during off-peak hours.
- To reduce `Lock:Relation` waits caused by autovacuum tasks, perform any needed autovacuum tuning. For information about tuning autovacuum, see Working with PostgreSQL autovacuum on Amazon RDS in the Amazon RDS User Guide.

Lock:transactionid

The `Lock:transactionid` event occurs when a transaction is waiting for a row-level lock.

Topics
- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

The event `Lock:transactionid` occurs when a transaction is trying to acquire a row-level lock that has already been granted to a transaction that is running at the same time. The session that shows the `Lock:transactionid` wait event is blocked because of this lock. After the blocking transaction ends in either a COMMIT or ROLLBACK statement, the blocked transaction can proceed.

The multiversion concurrency control semantics of RDS for PostgreSQL guarantee that readers don't block writers and writers don't block readers. For row-level conflicts to occur, blocking and blocked transactions must issue conflicting statements of the following types:
UPDATE
SELECT ... FOR UPDATE
SELECT ... FOR KEY SHARE

The statement SELECT ... FOR KEY SHARE is a special case. The database uses the clause FOR KEY SHARE to optimize the performance of referential integrity. A row-level lock on a row can block INSERT, UPDATE, and DELETE commands on other tables that reference the row.

Likely causes of increased waits

When this event appears more than normal, the cause is typically UPDATE, SELECT ... FOR UPDATE, or SELECT ... FOR KEY SHARE statements combined with the following conditions.

Topics
- High concurrency (p. 2355)
- Idle in transaction (p. 2355)
- Long-running transactions (p. 2355)

High concurrency

RDS for PostgreSQL can use granular row-level locking semantics. The probability of row-level conflicts increases when the following conditions are met:
- A highly concurrent workload contends for the same rows.
- Concurrency increases.

Idle in transaction

Sometimes the pg_stat_activity.state column shows the value idle in transaction. This value appears for sessions that have started a transaction, but haven't yet issued a COMMIT or ROLLBACK. If the pg_stat_activity.state value isn't active, the query shown in pg_stat_activity is the most recent one to finish running. The blocking session isn't actively processing a query because an open transaction is holding a lock.

If an idle transaction acquired a row-level lock, it might be preventing other sessions from acquiring it. This condition leads to frequent occurrence of the wait event Lock:transactionid. To diagnose the issue, examine the output from pg_stat_activity and pg_locks.

Long-running transactions

Transactions that run for a long time get locks for a long time. These long-held locks can block other transactions from running.

Actions

Row-locking is a conflict among UPDATE, SELECT ... FOR UPDATE, or SELECT ... FOR KEY SHARE statements. Before attempting a solution, find out when these statements are running on the same row. Use this information to choose a strategy described in the following sections.

Topics
- Respond to high concurrency (p. 2356)
- Respond to idle transactions (p. 2356)
- Respond to long-running transactions (p. 2356)
Respond to high concurrency

If concurrency is the issue, try one of the following techniques:

- Lower the concurrency in the application. For example, decrease the number of active sessions.
- Implement a connection pool. To learn how to pool connections with RDS Proxy, see Using Amazon RDS Proxy (p. 1215).
- Design the application or data model to avoid contending UPDATE and SELECT ... FOR UPDATE statements. You can also decrease the number of foreign keys accessed by SELECT ... FOR KEY SHARE statements.

Respond to idle transactions

If `pg_stat_activity.state` shows `idle in transaction`, use the following strategies:

- Turn on autocommit wherever possible. This approach prevents transactions from blocking other transactions while waiting for a COMMIT or ROLLBACK.
- Search for code paths that are missing COMMIT, ROLLBACK, or END.
- Make sure that the exception handling logic in your application always has a path to a valid end of transaction.
- Make sure that your application processes query results after ending the transaction with COMMIT or ROLLBACK.

Respond to long-running transactions

If long-running transactions are causing the frequent occurrence of `Lock:transactionid`, try the following strategies:

- Keep row locks out of long-running transactions.
- Limit the length of queries by implementing autocommit whenever possible.

Lock:tuple

The `Lock:tuple` event occurs when a backend process is waiting to acquire a lock on a tuple.

Topics

- Supported engine versions (p. 2356)
- Context (p. 2356)
- Likely causes of increased waits (p. 2357)
- Actions (p. 2357)

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

The event `Lock:tuple` indicates that a backend is waiting to acquire a lock on a tuple while another backend holds a conflicting lock on the same tuple. The following table illustrates a scenario in which sessions generate the `Lock:tuple` event.
<table>
<thead>
<tr>
<th>Time</th>
<th>Session 1</th>
<th>Session 2</th>
<th>Session 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>t1</td>
<td>Starts a transaction.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>t2</td>
<td>Updates row 1.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>t3</td>
<td></td>
<td>Updates row 1. The session acquires an exclusive lock on the tuple and then waits for session 1 to release the lock by committing or rolling back.</td>
<td></td>
</tr>
<tr>
<td>t4</td>
<td></td>
<td></td>
<td>Updates row 1. The session waits for session 2 to release the exclusive lock on the tuple.</td>
</tr>
</tbody>
</table>

Or you can simulate this wait event by using the benchmarking tool pgbench. Configure a high number of concurrent sessions to update the same row in a table with a custom SQL file.

To learn more about conflicting lock modes, see Explicit Locking in the PostgreSQL documentation. To learn more about pgbench, see pgbench in the PostgreSQL documentation.

**Likely causes of increased waits**

When this event appears more than normal, possibly indicating a performance problem, typical causes include the following:

- A high number of concurrent sessions are trying to acquire a conflicting lock for the same tuple by running UPDATE or DELETE statements.
- Highly concurrent sessions are running a SELECT statement using the FOR UPDATE or FOR NO KEY UPDATE lock modes.
- Various factors drive application or connection pools to open more sessions to execute the same operations. As new sessions are trying to modify the same rows, DB load can spike, and Lock:tuple can appear.

For more information, see Row-Level Locks in the PostgreSQL documentation.

**Actions**

We recommend different actions depending on the causes of your wait event.

**Topics**

- [Investigate your application logic](#)
- [Find the blocker session](#)
- [Reduce concurrency when it is high](#)
- [Troubleshoot bottlenecks](#)

**Investigate your application logic**

Find out whether a blocker session has been in the idle in transaction state for long time. If so, consider ending the blocker session as a short-term solution. You can use the pg_terminate_backend function. For more information about this function, see Server Signaling Functions in the PostgreSQL documentation.
For a long-term solution, do the following:

- Adjust the application logic.
- Use the `idle_in_transaction_session_timeout` parameter. This parameter ends any session with an open transaction that has been idle for longer than the specified amount of time. For more information, see Client Connection Defaults in the PostgreSQL documentation.
- Use autocommit as much as possible. For more information, see `SET AUTOCOMMIT` in the PostgreSQL documentation.

**Find the blocker session**

While the Lock:tuple wait event is occurring, identify the blocker and blocked session by finding out which locks depend on one another. For more information, see Lock dependency information in the PostgreSQL wiki.

The following example queries all sessions, filtering on `tuple` and ordering by `wait_time`.

```sql
SELECT blocked_locks.pid AS blocked_pid,
       blocking_locks.pid AS blocking_pid,
       blocked_activity.usename AS blocked_user,
       blocking_activity.usename AS blocking_user,
       now() - blocked_activity.xact_start AS blocked_transaction_duration,
       now() - blocking_activity.xact_start AS blocking_transaction_duration,
       concat(blocked_activity.wait_event_type, ':', blocked_activity.wait_event) AS blocked_wait_event,
       concat(blocking_activity.wait_event_type, ':', blocking_activity.wait_event) AS blocking_wait_event,
       blocked_activity.state AS blocked_state,
       blocking_activity.state AS blocking_state,
       blocked_locks.locktype AS blocked_locktype,
       blocking_locks.locktype AS blocking_locktype,
       blocked_activity.query AS blocked_statement,
       blocking_activity.query AS blocking_statement
FROM pg_catalog.pg_locks blocked_locks
     JOIN pg_catalog.pg_stat_activity blocked_activity ON blocked_activity.pid = blocked_locks.pid
     JOIN pg_catalog.pg_locks blocking_locks
           ON blocking_locks.locktype = blocked_locks.locktype
           AND blocking_locks.DATABASE IS NOT DISTINCT FROM blocked_locks.DATABASE
           AND blocking_locks.relation IS NOT DISTINCT FROM blocked_locks.relation
           AND blocking_locks.page IS NOT DISTINCT FROM blocked_locks.page
           AND blocking_locks.tuple IS NOT DISTINCT FROM blocked_locks.tuple
           AND blocking_locks.virtualxid IS NOT DISTINCT FROM blocked_locks.virtualxid
           AND blocking_locks.transactionid IS NOT DISTINCT FROM blocked_locks.transactionid
           AND blocking_locks.classid IS NOT DISTINCT FROM blocked_locks.classid
           AND blocking_locks.objid IS NOT DISTINCT FROM blocked_locks.objid
           AND blocking_locks.objsubid IS NOT DISTINCT FROM blocked_locks.objsubid
           WHERE NOT blocked_locks.GRANTED;
```

**Reduce concurrency when it is high**

The Lock:tuple event might occur constantly, especially in a busy workload time. In this situation, consider reducing the high concurrency for very busy rows. Often, just a few rows control a queue or the Boolean logic, which makes these rows very busy.

You can reduce concurrency by using different approaches based in the business requirement, application logic, and workload type. For example, you can do the following:
• Redesign your table and data logic to reduce high concurrency.
• Change the application logic to reduce high concurrency at the row level.
• Leverage and redesign queries with row-level locks.
• Use the NOWAIT clause with retry operations.
• Consider using optimistic and hybrid-locking logic concurrency control.
• Consider changing the database isolation level.

Troubleshoot bottlenecks

The Lock: tuple can occur with bottlenecks such as CPU starvation or maximum usage of Amazon EBS bandwidth. To reduce bottlenecks, consider the following approaches:

• Scale up your instance class type.
• Optimize resource-intensive queries.
• Change the application logic.
• Archive data that is rarely accessed.

LWLock:BufferMapping (LWLock:buffer_mapping)

This event occurs when a session is waiting to associate a data block with a buffer in the shared buffer pool.

Note
This event is named LWLock:BufferMapping for RDS for PostgreSQL version 13 and higher versions. For RDS for PostgreSQL version 12 and older versions, this event is named LWLock:buffer_mapping.

Topics
• Supported engine versions (p. 2359)
• Context (p. 2359)
• Causes (p. 2360)
• Actions (p. 2360)

Supported engine versions

This wait event information is relevant for RDS for PostgreSQL version 9.6 and higher.

Context

The shared buffer pool is a PostgreSQL memory area that holds all pages that are or were being used by processes. When a process needs a page, it reads the page into the shared buffer pool. The shared_buffers parameter sets the shared buffer size and reserves a memory area to store the table and index pages. If you change this parameter, make sure to restart the database.

The LWLock:buffer_mapping wait event occurs in the following scenarios:

• A process searches the buffer table for a page and acquires a shared buffer mapping lock.
• A process loads a page into the buffer pool and acquires an exclusive buffer mapping lock.
• A process removes a page from the pool and acquires an exclusive buffer mapping lock.
Causes

When this event appears more than normal, possibly indicating a performance problem, the database is paging in and out of the shared buffer pool. Typical causes include the following:

- Large queries
- Bloated indexes and tables
- Full table scans
- A shared pool size that is smaller than the working set

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Monitor buffer-related metrics (p. 2360)
- Assess your indexing strategy (p. 2360)
- Reduce the number of buffers that must be allocated quickly (p. 2361)

Monitor buffer-related metrics

When LWLock:buffer_mapping waits spike, investigate the buffer hit ratio. You can use these metrics to get a better understanding of what is happening in the buffer cache. Examine the following metrics:

blks_hit

This Performance Insights counter metric indicates the number of blocks that were retrieved from the shared buffer pool. After the LWLock:buffer_mapping wait event appears, you might observe a spike in blks_hit.

blks_read

This Performance Insights counter metric indicates the number of blocks that required I/O to be read into the shared buffer pool. You might observe a spike in blks_read in the lead-up to the LWLock:buffer_mapping wait event.

Assess your indexing strategy

To confirm that your indexing strategy is not degrading performance, check the following:

Index bloat

Ensure that index and table bloat aren't leading to unnecessary pages being read into the shared buffer. If your tables contain unused rows, consider archiving the data and removing the rows from the tables. You can then rebuild the indexes for the resized tables.

Indexes for frequently used queries

To determine whether you have the optimal indexes, monitor DB engine metrics in Performance Insights. The tup_returned metric shows the number of rows read. The tup_fetched metric shows the number of rows returned to the client. If tup_returned is significantly larger than tup_fetched, the data might not be properly indexed. Also, your table statistics might not be current.
Reduce the number of buffers that must be allocated quickly

To reduce the LWLock:buffer_mapping wait events, try to reduce the number of buffers that must be allocated quickly. One strategy is to perform smaller batch operations. You might be able to achieve smaller batches by partitioning your tables.

**LWLock:BufferIO (IPC:BufferIO)**

The LWLock:BufferIO event occurs when RDS for PostgreSQL is waiting for other processes to finish their input/output (I/O) operations when concurrently trying to access a page. Its purpose is for the same page to be read into the shared buffer.

**Topics**
- Relevant engine versions (p. 2361)
- Context (p. 2361)
- Causes (p. 2361)
- Actions (p. 2362)

**Relevant engine versions**

This wait event information is relevant for all RDS for PostgreSQL versions. For RDS for PostgreSQL 12 and earlier versions this wait event is named as lwlock:buffer_io whereas in RDS for PostgreSQL 13 version it is named as lwlock:bufferio. From RDS for PostgreSQL 14 version BufferIO wait event moved from LWLock to IPC wait event type (IPC:BufferIO).

**Context**

Each shared buffer has an I/O lock that is associated with the LWLock:BufferIO wait event, each time a block (or a page) has to be retrieved outside the shared buffer pool.

This lock is used to handle multiple sessions that all require access to the same block. This block has to be read from outside the shared buffer pool, defined by the shared_buffers parameter.

As soon as the page is read inside the shared buffer pool, the LWLock:BufferIO lock is released.

**Note**

The LWLock:BufferIO wait event precedes the IO:DataFileRead (p. 2341) wait event. The IO:DataFileRead wait event occurs while data is being read from storage.

For more information on lightweight locks, see Locking Overview.

**Causes**

Common causes for the LWLock:BufferIO event to appear in top waits include the following:

- Multiple backends or connections trying to access the same page that’s also pending an I/O operation
- The ratio between the size of the shared buffer pool (defined by the shared_buffers parameter) and the number of buffers needed by the current workload
- The size of the shared buffer pool not being well balanced with the number of pages being evicted by other operations
- Large or bloated indexes that require the engine to read more pages than necessary into the shared buffer pool
- Lack of indexes that forces the DB engine to read more pages from the tables than necessary
- Checkpoints occurring too frequently or needing to flush too many modified pages
• Sudden spikes for database connections trying to perform operations on the same page

Actions

We recommend different actions depending on the causes of your wait event:

• Observe Amazon CloudWatch metrics for correlation between sharp decreases in the BufferCacheHitRatio and LWLock:BufferIO wait events. This effect can mean that you have a small shared buffers setting. You might need to increase it or scale up your DB instance class. You can split your workload into more reader nodes.
• Tune max_wal_size and checkpoint_timeout based on your workload peak time if you see LWLock:BufferIO coinciding with BufferCacheHitRatio metric dips. Then identify which query might be causing it.
• Verify whether you have unused indexes, then remove them.
• Use partitioned tables (which also have partitioned indexes). Doing this helps to keep index reordering low and reduces its impact.
• Avoid indexing columns unnecessarily.
• Prevent sudden database connection spikes by using a connection pool.
• Restrict the maximum number of connections to the database as a best practice.

LWLock:buffer_content (BufferContent)

The LWLock:buffer_content event occurs when a session is waiting to read or write a data page in memory while another session has that page locked for writing. In RDS for PostgreSQL 13 and higher, this wait event is called BufferContent.

Topics

• Supported engine versions (p. 2362)
• Context (p. 2362)
• Likely causes of increased waits (p. 2362)
• Actions (p. 2363)

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

To read or manipulate data, PostgreSQL accesses it through shared memory buffers. To read from the buffer, a process gets a lightweight lock (LWLock) on the buffer content in shared mode. To write to the buffer, it gets that lock in exclusive mode. Shared locks allow other processes to concurrently acquire shared locks on that content. Exclusive locks prevent other processes from getting any type of lock on it.

The LWLock:buffer_content (BufferContent) event indicates that multiple processes are attempting to get a lock on contents of a specific buffer.

Likely causes of increased waits

When the LWLock:buffer_content (BufferContent) event appears more than normal, possibly indicating a performance problem, typical causes include the following:
Increased concurrent updates to the same data

There might be an increase in the number of concurrent sessions with queries that update the same buffer content. This contention can be more pronounced on tables with a lot of indexes.

Workload data is not in memory

When data that the active workload is processing is not in memory, these wait events can increase. This effect is because processes holding locks can keep them longer while they perform disk I/O operations.

Excessive use of foreign key constraints

Foreign key constraints can increase the amount of time a process holds onto a buffer content lock. This effect is because read operations require a shared buffer content lock on the referenced key while that key is being updated.

Actions

We recommend different actions depending on the causes of your wait event. You might identify LWLock:buffer_content (BufferContent) events by using Amazon RDS Performance Insights or by querying the view pg_stat_activity.

Topics

- Improve in-memory efficiency (p. 2363)
- Reduce usage of foreign key constraints (p. 2363)
- Remove unused indexes (p. 2363)
- Increase the cache size when using sequences (p. 2363)

Improve in-memory efficiency

To increase the chance that active workload data is in memory, partition tables or scale up your instance class. For information about DB instance classes, see DB instance classes (p. 11).

Reduce usage of foreign key constraints

Investigate workloads experiencing high numbers of LWLock:buffer_content (BufferContent) wait events for usage of foreign key constraints. Remove unnecessary foreign key constraints.

Remove unused indexes

For workloads experiencing high numbers of LWLock:buffer_content (BufferContent) wait events, identify unused indexes and remove them.

Increase the cache size when using sequences

If your tables uses sequences, increase the cache size to remove contention on sequence pages and index pages. Each sequence is a single page in shared memory. The pre-defined cache is per connection. This might not be enough to handle the workload when many concurrent sessions are getting a sequence value.

LWLock:lock_manager (LWLock:lockmanager)

This event occurs when the RDS for PostgreSQL engine maintains the shared lock's memory area to allocate, check, and deallocate a lock when a fast path lock isn't possible.

Topics
Supported engine versions

This wait event information is relevant for RDS for PostgreSQL version 9.6 and higher. For RDS for PostgreSQL releases older than version 13, the name of this wait event is `LWLock:lock_manager`. For RDS for PostgreSQL version 13 and higher, the name of this wait event is `LWLock:lockmanager`.

Context

When you issue a SQL statement, RDS for PostgreSQL records locks to protect the structure, data, and integrity of your database during concurrent operations. The engine can achieve this goal using a fast path lock or a path lock that isn’t fast. A path lock that isn’t fast is more expensive and creates more overhead than a fast path lock.

Fast path locking

To reduce the overhead of locks that are taken and released frequently, but that rarely conflict, backend processes can use fast path locking. The database uses this mechanism for locks that meet the following criteria:

- They use the DEFAULT lock method.
- They represent a lock on a database relation rather than a shared relation.
- They are weak locks that are unlikely to conflict.
- The engine can quickly verify that no conflicting locks can possibly exist.

The engine can’t use fast path locking when either of the following conditions is true:

- The lock doesn’t meet the preceding criteria.
- No more slots are available for the backend process.

To tune your queries for fast-path locking, you can use the following query.

```sql
SELECT count(*), pid, mode, fastpath
FROM pg_locks
WHERE fastpath IS NOT NULL
GROUP BY 4,3,2
ORDER BY pid, mode;
```

<table>
<thead>
<tr>
<th>count</th>
<th>pid</th>
<th>mode</th>
<th>fastpath</th>
</tr>
</thead>
<tbody>
<tr>
<td>16</td>
<td>9185</td>
<td>AccessShareLock</td>
<td>t</td>
</tr>
<tr>
<td>336</td>
<td>9185</td>
<td>AccessShareLock</td>
<td>f</td>
</tr>
<tr>
<td>1</td>
<td>9185</td>
<td>ExclusiveLock</td>
<td>t</td>
</tr>
</tbody>
</table>

The following query shows only the total across the database.

```sql
SELECT count(*), mode, fastpath
FROM pg_locks
WHERE fastpath IS NOT NULL
GROUP BY 3,2
ORDER BY mode,1;
```

<table>
<thead>
<tr>
<th>count</th>
<th>mode</th>
<th>fastpath</th>
</tr>
</thead>
<tbody>
<tr>
<td>2364</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Example of a scaling problem for the lock manager

In this example, a table named `purchases` stores five years of data, partitioned by day. Each partition has two indexes. The following sequence of events occurs:

1. You query many days worth of data, which requires the database to read many partitions.
2. The database creates a lock entry for each partition. If partition indexes are part of the optimizer access path, the database creates a lock entry for them, too.
3. When the number of requested locks entries for the same backend process is higher than 16, which is the value of `FP_LOCK_SLOTS_PER_BACKEND`, the lock manager uses the non–fast path lock method.

Modern applications might have hundreds of sessions. If concurrent sessions are querying the parent without proper partition pruning, the database might create hundreds or even thousands of non–fast path locks. Typically, when this concurrency is higher than the number of vCPUs, the `LWLock:lock_manager` wait event appears.

**Note**
The `LWLock:lock_manager` wait event isn't related to the number of partitions or indexes in a database schema. Instead, it's related to the number of non–fast path locks that the database must control.

Likely causes of increased waits

When the `LWLock:lock_manager` wait event occurs more than normal, possibly indicating a performance problem, the most likely causes of sudden spikes are as follows:

- Concurrent active sessions are running queries that don't use fast path locks. These sessions also exceed the maximum vCPU.
- A large number of concurrent active sessions are accessing a heavily partitioned table. Each partition has multiple indexes.
- The database is experiencing a connection storm. By default, some applications and connection pool software create more connections when the database is slow. This practice makes the problem worse. Tune your connection pool software so that connection storms don't occur.
- A large number of sessions query a parent table without pruning partitions.
- A data definition language (DDL), data manipulation language (DML), or a maintenance command exclusively locks either a busy relation or tuples that are frequently accessed or modified.

Actions

If the CPU wait event occurs, it doesn't necessarily indicate a performance problem. Respond to this event only when performance degrades and this wait event is dominating DB load.

Topics

- Use partition pruning (p. 2366)
- Remove unnecessary indexes (p. 2366)
- Tune your queries for fast path locking (p. 2366)
Use partition pruning

*Partition pruning* is a query optimization strategy for declaratively partitioned tables that excludes unneeded partitions from table scans, thereby improving performance. Partition pruning is turned on by default. If it is turned off, turn it on as follows.

```sql
SET enable_partition_pruning = on;
```

Queries can take advantage of partition pruning when their `WHERE` clause contains the column used for the partitioning. For more information, see [Partition Pruning](#) in the PostgreSQL documentation.

Remove unnecessary indexes

Your database might contain unused or rarely used indexes. If so, consider deleting them. Do either of the following:

- Learn how to find unnecessary indexes by reading [Unused Indexes](#) in the PostgreSQL wiki.
- Run PG Collector. This SQL script gathers database information and presents it in a consolidated HTML report. Check the "Unused indexes" section. For more information, see [pg-collector](#) in the AWS Labs GitHub repository.

Tune your queries for fast path locking

To find out whether your queries use fast path locking, query the `fastpath` column in the `pg_locks` table. If your queries aren’t using fast path locking, try to reduce number of relations per query to fewer than 16.

Tune for other wait events

If `LWLock:lock_manager` is first or second in the list of top waits, check whether the following wait events also appear in the list:

- `Lock:Relation`
- `Lock:transactionid`
- `Lock:tuple`

If the preceding events appear high in the list, consider tuning these wait events first. These events can be a driver for `LWLock:lock_manager`.

Reduce hardware bottlenecks

You might have a hardware bottleneck, such as CPU starvation or maximum usage of your Amazon EBS bandwidth. In these cases, consider reducing the hardware bottlenecks. Consider the following actions:

- Scale up your instance class.
- Optimize queries that consume large amounts of CPU and memory.
- Change your application logic.
- Archive your data.
For more information about CPU, memory, and EBS network bandwidth, see Amazon RDS Instance Types.

Use a connection pooler

If your total number of active connections exceeds the maximum vCPU, more OS processes require CPU than your instance type can support. In this case, consider using or tuning a connection pool. For more information about the vCPUs for your instance type, see Amazon RDS Instance Types.

For more information about connection pooling, see the following resources:

- Using Amazon RDS Proxy (p. 1215)
- pgbouncer
- Connection Pools and Data Sources in the PostgreSQL Documentation

Upgrade your RDS for PostgreSQL version

If your current version of RDS for PostgreSQL is lower than 12, upgrade to version 12 or higher. PostgreSQL versions 12 and later have an improved partition mechanism. For more information about version 12, see PostgreSQL 12.0 Release Notes. For more information about upgrading RDS for PostgreSQL, see Upgrading the PostgreSQL DB engine for Amazon RDS (p. 2214).

Timeout:PgSleep

The Timeout:PgSleep event occurs when a server process has called the pg_sleep function and is waiting for the sleep timeout to expire.

Topics

- Supported engine versions (p. 2367)
- Likely causes of increased waits (p. 2367)
- Actions (p. 2367)

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Likely causes of increased waits

This wait event occurs when an application, stored function, or user issues a SQL statement that calls one of the following functions:

- pg_sleep
- pg_sleep_for
- pg_sleep_until

The preceding functions delay execution until the specified number of seconds have elapsed. For example, SELECT pg_sleep(1) pauses for 1 second. For more information, see Delaying Execution in the PostgreSQL documentation.

Actions

Identify the statement that was running the pg_sleep function. Determine if the use of the function is appropriate.
Timeout:VacuumDelay

The Timeout:VacuumDelay event indicates that the cost limit for vacuum I/O has been exceeded and that the vacuum process has been put to sleep. Vacuum operations stop for the duration specified in the respective cost delay parameter and then it resumes its work. For the manual vacuum command, the delay is specified in the vacuum_cost_delay parameter. For the autovacuum daemon, the delay is specified in the autovacuum_vacuum_cost_delay parameter.

Topics
- Supported engine versions (p. 2368)
- Context (p. 2368)
- Likely causes of increased waits (p. 2369)
- Actions (p. 2369)

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

PostgreSQL has both an autovacuum daemon and a manual vacuum command. The autovacuum process is "on" by default for RDS for PostgreSQL DB instances. The manual vacuum command is used on an as-needed basis, for example, to purge tables of dead tuples or generate new statistics.

When vacuuming is underway, PostgreSQL uses an internal counter to keep track of estimated costs as the system performs various I/O operations. When the counter reaches the value specified by the cost limit parameter, the process performing the operation sleeps for the brief duration specified in the cost delay parameter. It then resets the counter and continues operations.

The vacuum process has parameters that can be used to regulate resource consumption. The autovacuum and the manual vacuum command have their own parameters for setting the cost limit value. They also have their own parameters to specify a cost delay, an amount of time to put the vacuum to sleep when the limit is reached. In this way, the cost delay parameter works as a throttling mechanism for resource consumption. In the following lists, you can find description of these parameters.

Parameters that affect throttling of the autovacuum daemon

- **autovacuum_vacuum_cost_limit** – Specifies the cost limit value to use in automatic vacuum operations. Increasing the setting for this parameter allows the vacuum process to use more resources and decreases the Timeout:VacuumDelay wait event.
- **autovacuum_vacuum_cost_delay** – Specifies the cost delay value to use in automatic vacuum operations. The default value is 2 milliseconds. Setting the delay parameter to 0 turns off the throttling mechanism and thus, the Timeout:VacuumDelay wait event won't appear.

For more information, see Automatic Vacuuming in the PostgreSQL documentation.

Parameters that affect throttling of the manual vacuum process

- **vacuum_cost_limit** – The threshold at which the vacuuming process is put to sleep. By default, the limit is 200. This number represents the accumulated cost estimates for extra I/O needed by various resources. Increasing this value reduces the number of the Timeout:VacuumDelay wait event.
- **vacuum_cost_delay** – The amount of time that the vacuum process sleeps when the vacuum cost limit has been reached. The default setting is 0, which means that this feature is off. You can set this to
an integer value to specify the number of milliseconds to turn on this feature, but we recommend that you leave it at its default setting.

For more information about the `vacuum_cost_delay` parameter, see Resource Consumption in the PostgreSQL documentation.

To learn more about how to configure and use the autovacuum with RDS for PostgreSQL, see Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL (p. 2297).

**Likely causes of increased waits**

The `Timeout:VacuumDelay` is affected by the balance between the cost limit parameter settings (`vacuum_cost_limit`, `autovacuum_vacuum_cost_limit`) and the cost delay parameters (`vacuum_cost_delay`, `autovacuum_vacuum_cost_delay`) that control the vacuum's sleep duration. Raising a cost limit parameter value allows more resources to be used by the vacuum before being put to sleep. That results in fewer `Timeout:VacuumDelay` wait events. Increasing either of the delay parameters causes the `Timeout:VacuumDelay` wait event to occur more frequently and for longer periods of time.

The `autovacuum_max_workers` parameter setting can also increase numbers of the `Timeout:VacuumDelay`. Each additional autovacuum worker process contributes to the internal counter mechanism, and thus the limit can be reached more quickly than with a single autovacuum worker process. As the cost limit is reached more quickly, the cost delay is put to effect more frequently, resulting in more `Timeout:VacuumDelay` wait events. For more information, see `autovacuum_max_workers` in the PostgreSQL documentation.

Large objects, such as 500GB or larger, also raise this wait event because it can take some time for the vacuum to complete processing large objects.

**Actions**

If the vacuum operations complete as expected, no remediation is needed. In other words, this wait event doesn't necessarily indicate a problem. It indicates that the vacuum is being put to sleep for the period of time specified in the delay parameter so that resources can be applied to other processes that need to complete.

If you want vacuum operations to complete faster, you can lower the delay parameters. This shortens the time that the vacuum sleeps.
Tuning RDS for PostgreSQL with Amazon DevOps Guru proactive insights

DevOps Guru proactive insights detects conditions on your RDS for PostgreSQL DB instances that can cause problems, and lets you know about them before they occur. DevOps Guru can do the following:

- Prevent many common database issues by cross-checking your database configuration against common recommended settings.
- Alert you to critical issues in your fleet that, if left unchecked, can lead to larger problems later.
- Alert you to newly discovered problems.

Every proactive insight contains an analysis of the cause of the problem and recommendations for corrective actions.

Topics
- Database has long running idle in transaction connection (p. 2370)

Database has long running idle in transaction connection

A connection to the database has been in the idle in transaction state for more than 1800 seconds.

Topics
- Supported engine versions (p. 2370)
- Context (p. 2370)
- Likely causes for this issue (p. 2370)
- Actions (p. 2370)
- Relevant metrics (p. 2372)

Supported engine versions

This insight information is supported for all versions of RDS for PostgreSQL.

Context

A transaction in the idle in transaction state can hold locks that block other queries. It can also prevent VACUUM (including autovacuum) from cleaning up dead rows, leading to index or table bloat or transaction ID wraparound.

Likely causes for this issue

A transaction initiated in an interactive session with BEGIN or START TRANSACTION hasn't ended by using a COMMIT, ROLLBACK, or END command. This causes the transaction to move to idle in transaction state.

Actions
You can find idle transactions by querying `pg_stat_activity`.

In your SQL client, run the following query to list all connections in `idle in transaction` state and to order them by duration:

```
SELECT now() - state_change as idle_in_transaction_duration, now() - xact_start as xact_duration,*
FROM  pg_stat_activity
WHERE state  = 'idle in transaction'
AND   xact_start is not null
ORDER BY 1 DESC;
```

We recommend different actions depending on the causes of your insight.

**Topics**
- [End transaction](p. 2371)
- [Terminate the connection](p. 2371)
- [Configure the `idle_in_transaction_session_timeout` parameter](p. 2371)
- [Check the AUTOCOMMIT status](p. 2371)
- [Check the transaction logic in your application code](p. 2372)

**End transaction**

When you initiate a transaction in an interactive session with BEGIN or START TRANSACTION, it moves to `idle in transaction` state. It remains in this state until you end the transaction by issuing a COMMIT, ROLLBACK, END command or disconnect the connection completely to roll back the transaction.

**Terminate the connection**

Terminate the connection with an idle transaction using the following query:

```
SELECT pg_terminate_backend(pid);
```

pid is the process ID of the connection.

**Configure the `idle_in_transaction_session_timeout` parameter**

Configure the `idle_in_transaction_session_timeout` parameter in the parameter group. The advantage of configuring this parameter is that it does not require a manual intervention to terminate the long idle in transaction. For more information on this parameter, see the PostgreSQL documentation.

The following message will be reported in the PostgreSQL log file after the connection is terminated, when a transaction is in the `idle_in_transaction` state for longer than the specified time.

```
FATAL: terminating connection due to idle in transaction timeout
```

**Check the AUTOCOMMIT status**

AUTOCOMMIT is turned on by default. But if it is accidentally turned off in the client ensure that you turn it back on.

- In your psql client, run the following command:
Database has long running idle in transaction connection

postgres=> \set AUTOCOMMIT on

- In pgadmin, turn it on by choosing the AUTOCOMMIT option from the down arrow.

Check the transaction logic in your application code

Investigate your application logic for possible problems. Consider the following actions:

- Check if the JDBC auto commit is set true in your application. Also, consider using explicit COMMIT commands in your code.
- Check your error handling logic to see whether it closes a transaction after errors.
- Check whether your application is taking long to process the rows returned by a query while the transaction is open. If so, consider coding the application to close the transaction before processing the rows.
- Check whether a transaction contains many long-running operations. If so, divide a single transaction into multiple transactions.

Relevant metrics

The following PI metrics are related to this insight:

- idle_in_transaction_count - Number of sessions in idle in transaction state.
- idle_in_transaction_max_time - The duration of the longest running transaction in the idle in transaction state.
Using PostgreSQL extensions with Amazon RDS for PostgreSQL

You can extend the functionality of PostgreSQL by installing a variety of extensions and modules. For example, to work with spatial data you can install and use the PostGIS extension. For more information, see Managing spatial data with the PostGIS extension (p. 2411). As another example, if you want to improve data entry for very large tables, you can consider partitioning your data by using the pg_partman extension. To learn more, see Managing PostgreSQL partitions with the pg_partman extension (p. 2375).

Note
As of RDS for PostgreSQL 14.5, RDS for PostgreSQL supports Trusted Language Extensions for PostgreSQL. This feature is implemented as the extension pg_tle, which you can add to your RDS for PostgreSQL DB instance. By using this extension, developers can create their own PostgreSQL extensions in a safe environment that simplifies the setup and configuration requirements. For more information, see Working with Trusted Language Extensions for PostgreSQL (p. 2429).

In some cases, rather than installing an extension, you might add a specific module to the list of shared_preload_libraries in your RDS for PostgreSQL DB instance's custom DB parameter group. Typically, the default DB cluster parameter group loads only the pg_stat_statements, but several other modules are available to add to the list. For example, you can add scheduling capability by adding the pg_cron module, as detailed in Scheduling maintenance with the PostgreSQL pg_cron extension (p. 2388). As another example, you can log query execution plans by loading the auto_explain module. To learn more, see Logging execution plans of queries in the AWS knowledge center.

Depending on your version of RDS for PostgreSQL, installing an extension might require rds_superuser permissions, as follows:

- For RDS for PostgreSQL versions 12 and earlier versions, installing extensions requires rds_superuser privileges.
- For RDS for PostgreSQL version 13 and higher versions, users (roles) with create permissions on a given database instance can install and use any trusted extensions. For a list of trusted extensions, see PostgreSQL trusted extensions (p. 2174).

You can also specify precisely which extensions can be installed on your RDS for PostgreSQL DB instance, by listing them in the rds.allowed_extensions parameter. For more information, see Restricting installation of PostgreSQL extensions (p. 2173).

To learn more about the rds_superuser role, see Understanding PostgreSQL roles and permissions (p. 2288).

Topics
- Using functions from the orafce extension (p. 2374)
- Managing PostgreSQL partitions with the pg_partman extension (p. 2375)
- Using pgAudit to log database activity (p. 2379)
- Scheduling maintenance with the PostgreSQL pg_cron extension (p. 2388)
- Using pglogical to synchronize data across instances (p. 2395)
- Reducing bloat in tables and indexes with the pg_repack extension (p. 2405)
- Upgrading and using the PLV8 extension (p. 2406)
- Using PL/Rust to write PostgreSQL functions in the Rust language (p. 2407)
- Managing spatial data with the PostGIS extension (p. 2411)
Using functions from the orafce extension

The orafce extension provides functions and operators that emulate a subset of functions and packages from an Oracle database. The orafce extension makes it easier for you to port an Oracle application to PostgreSQL. RDS for PostgreSQL versions 9.6.6 and higher support this extension. For more information about orafce, see orafce on GitHub.

**Note**

RDS for PostgreSQL doesn't support the utl_file package that is part of the orafce extension. This is because the utl_file schema functions provide read and write operations on operating-system text files, which requires superuser access to the underlying host. As a managed service, RDS for PostgreSQL doesn't provide host access.

**To use the orafce extension**

1. Connect to the DB instance with the primary user name that you used to create the DB instance.

   If you want to turn on orafce for a different database in the same DB instance, use the /c dbname psql command. Using this command, you change from the primary database after initiating the connection.

2. Turn on the orafce extension with the CREATE EXTENSION statement.

   ```sql
   CREATE EXTENSION orafce;
   ```

3. Transfer ownership of the oracle schema to the rds_superuser role with the ALTER SCHEMA statement.

   ```sql
   ALTER SCHEMA oracle OWNER TO rds_superuser;
   ```

   If you want to see the list of owners for the oracle schema, use the \dn psql command.
Managing PostgreSQL partitions with the pg_partman extension

PostgreSQL table partitioning provides a framework for high-performance handling of data input and reporting. Use partitioning for databases that require very fast input of large amounts of data. Partitioning also provides for faster queries of large tables. Partitioning helps maintain data without impacting the database instance because it requires less I/O resources.

By using partitioning, you can split data into custom-sized chunks for processing. For example, you can partition time-series data for ranges such as hourly, daily, weekly, monthly, quarterly, yearly, custom, or any combination of these. For a time-series data example, if you partition the table by hour, each partition contains one hour of data. If you partition the time-series table by day, the partitions holds one day's worth of data, and so on. The partition key controls the size of a partition.

When you use an INSERT or UPDATE SQL command on a partitioned table, the database engine routes the data to the appropriate partition. PostgreSQL table partitions that store the data are child tables of the main table.

During database query reads, the PostgreSQL optimizer examines the WHERE clause of the query and, if possible, directs the database scan to only the relevant partitions.

Starting with version 10, PostgreSQL uses declarative partitioning to implement table partitioning. This is also known as native PostgreSQL partitioning. Before PostgreSQL version 10, you used triggers to implement partitions.

PostgreSQL table partitioning provides the following features:

- Creation of new partitions at any time.
- Variable partition ranges.
- Detachable and reattachable partitions using data definition language (DDL) statements.

For example, detachable partitions are useful for removing historical data from the main partition but keeping historical data for analysis.

- New partitions inherit the parent database table properties, including the following:
  - Indexes
  - Primary keys, which must include the partition key column
  - Foreign keys
  - Check constraints
  - References
  - Creating indexes for the full table or each specific partition.

You can't alter the schema for an individual partition. However, you can alter the parent table (such as adding a new column), which propagates to partitions.

Topics

- Overview of the PostgreSQL pg_partman extension (p. 2376)
- Enabling the pg_partman extension (p. 2376)
- Configuring partitions using the create_parent function (p. 2377)
- Configuring partition maintenance using the run_maintenance_proc function (p. 2378)
Overview of the PostgreSQL pg_partman extension

You can use the PostgreSQL pg_partman extension to automate the creation and maintenance of table partitions. For more general information, see PG Partition Manager in the pg_partman documentation.

Note
The pg_partman extension is supported on RDS for PostgreSQL versions 12.5 and higher.

Instead of having to manually create each partition, you configure pg_partman with the following settings:

- Table to be partitioned
- Partition type
- Partition key
- Partition granularity
- Partition precreation and management options

After you create a PostgreSQL partitioned table, you register it with pg_partman by calling the create_parent function. Doing this creates the necessary partitions based on the parameters you pass to the function.

The pg_partman extension also provides the run_maintenance_proc function, which you can call on a scheduled basis to automatically manage partitions. To ensure that the proper partitions are created as needed, schedule this function to run periodically (such as hourly). You can also ensure that partitions are automatically dropped.

Enabling the pg_partman extension

If you have multiple databases inside the same PostgreSQL DB instance for which you want to manage partitions, enable the pg_partman extension separately for each database. To enable the pg_partman extension for a specific database, create the partition maintenance schema and then create the pg_partman extension as follows.

```
CREATE SCHEMA partman;
CREATE EXTENSION pg_partman WITH SCHEMA partman;
```

Note
To create the pg_partman extension, make sure that you have rds_superuser privileges.

If you receive an error such as the following, grant the rds_superuser privileges to the account or use your superuser account.

```
ERROR: permission denied to create extension "pg_partman"
HINT: Must be superuser to create this extension.
```

To grant rds_superuser privileges, connect with your superuser account and run the following command.

```
GRANT rds_superuser TO user-or-role;
```

For the examples that show using the pg_partman extension, we use the following sample database table and partition. This database uses a partitioned table based on a timestamp. A schema data_mart contains a table named events with a column named created_at. The following settings are included in the events table:
• Primary keys `event_id` and `created_at`, which must have the column used to guide the partition.
• A check constraint `ck_valid_operation` to enforce values for an operation table column.
• Two foreign keys, where one (`fk_orga_membership`) points to the external table `organization` and the other (`fk_parent_event_id`) is a self-referenced foreign key.
• Two indexes, where one (`idx_org_id`) is for the foreign key and the other (`idx_event_type`) is for the event type.

The following DDL statements create these objects, which are automatically included on each partition.

```sql
CREATE SCHEMA data_mart;
CREATE TABLE data_mart.organization ( org_id BIGSERIAL, org_name TEXT, CONSTRAINT pk_organization PRIMARY KEY (org_id) );
CREATE TABLE data_mart.events(
  event_id        BIGSERIAL,
  operation       CHAR(1),
  value           FLOAT(24),
  parent_event_id BIGINT,
  event_type      VARCHAR(25),
  org_id          BIGSERIAL,
  created_at      timestamp,
  CONSTRAINT pk_data_mart_event PRIMARY KEY (event_id, created_at),
  CONSTRAINT ck_valid_operation CHECK (operation = 'C' OR operation = 'D'),
  CONSTRAINT fk_orga_membership
    FOREIGN KEY(org_id)
    REFERENCES data_mart.organization (org_id),
  CONSTRAINT fk_parent_event_id
    FOREIGN KEY(parent_event_id, created_at)
    REFERENCES data_mart.events (event_id, created_at)
) PARTITION BY RANGE (created_at);
CREATE INDEX idx_org_id     ON  data_mart.events(org_id);
CREATE INDEX idx_event_type ON  data_mart.events(event_type);
```

Configuring partitions using the `create_parent` function

After you enable the `pg_partman` extension, use the `create_parent` function to configure partitions inside the partition maintenance schema. The following example uses the `events` table example created in **Enabling the pg_partman extension (p. 2376)**. Call the `create_parent` function as follows.

```sql
SELECT partman.create_parent( p_parent_table => 'data_mart.events',
  p_control => 'created_at',
  p_type => 'native',
  p_interval=> 'daily',
  p_premake => 30);
```

The parameters are as follows:

• `p_parent_table` – The parent partitioned table. This table must already exist and be fully qualified, including the schema.
• `p_control` – The column on which the partitioning is to be based. The data type must be an integer or time-based.
• `p_type` – The type is either 'native' or 'partman'. You typically use the native type for its performance improvements and flexibility. The partman type relies on inheritance.
Managing partitions with the pg_partman extension

- **p_interval** – The time interval or integer range for each partition. Example values include daily, hourly, and so on.
- **p_premake** – The number of partitions to create in advance to support new inserts.

For a complete description of the `create_parent` function, see [Creation Functions](#) in the pg_partman documentation.

### Configuring partition maintenance using the `run_maintenance_proc` function

You can run partition maintenance operations to automatically create new partitions, detach partitions, or remove old partitions. Partition maintenance relies on the `run_maintenance_proc` function of the pg_partman extension and the pg_cron extension, which initiates an internal scheduler. The pg_cron scheduler automatically executes SQL statements, functions, and procedures defined in your databases.

The following example uses the `events` table example created in [Enabling the pg_partman extension (p. 2376)](#) to set partition maintenance operations to run automatically. As a prerequisite, add pg_cron to the `shared_preload_libraries` parameter in the DB instance's parameter group.

```sql
CREATE EXTENSION pg_cron;
UPDATE partman.part_config
SET infinite_time_partitions = true,
    retention = '3 months',
    retention_keep_table=true
WHERE parent_table = 'data_mart.events';
SELECT cron.schedule('@hourly', $$CALL partman.run_maintenance_proc()$$);
```

Following, you can find a step-by-step explanation of the preceding example:

1. Modify the parameter group associated with your DB instance and add pg_cron to the `shared_preload_libraries` parameter value. This change requires a DB instance restart for it to take effect. For more information, see [Modifying parameters in a DB parameter group (p. 352)](#).
2. Run the command `CREATE EXTENSION pg_cron;` using an account that has the `rds_superuser` permissions. Doing this enables the pg_cron extension. For more information, see [Scheduling maintenance with the PostgreSQL pg_cron extension (p. 2388)](#).
3. Run the command `UPDATE partman.part_config` to adjust the pg_partman settings for the `data_mart.events` table.
4. Run the command `SET ...` to configure the `data_mart.events` table, with these clauses:
   a. `infinite_time_partitions = true`, – Configures the table to be able to automatically create new partitions without any limit.
   b. `retention = '3 months'`, – Configures the table to have a maximum retention of three months.
   c. `retention_keep_table=true` – Configures the table so that when the retention period is due, the table isn't deleted automatically. Instead, partitions that are older than the retention period are only detached from the parent table.
5. Run the command `SELECT cron.schedule ...` to make a pg_cron function call. This call defines how often the scheduler runs the pg_partman maintenance procedure, `partman.run_maintenance_proc`. For this example, the procedure runs every hour.

For a complete description of the `run_maintenance_proc` function, see [Maintenance Functions](#) in the pg_partman documentation.
Using pgAudit to log database activity

Financial institutions, government agencies, and many industries need to keep audit logs to meet regulatory requirements. By using the PostgreSQL Audit extension (pgAudit) with your RDS for PostgreSQL DB instance, you can capture the detailed records that are typically needed by auditors or to meet regulatory requirements. For example, you can set up the pgAudit extension to track changes made to specific databases and tables, to record the user who made the change, and many other details.

The pgAudit extension builds on the functionality of the native PostgreSQL logging infrastructure by extending the log messages with more detail. In other words, you use the same approach to view your audit log as you do to view any log messages. For more information about PostgreSQL logging, see RDS for PostgreSQL database log files (p. 931).

The pgAudit extension redacts sensitive data such as cleartext passwords from the logs. If your RDS for PostgreSQL DB instance is configured to log data manipulation language (DML) statements as detailed in Turning on query logging for your RDS for PostgreSQL DB instance (p. 933), you can avoid the cleartext password issue by using the PostgreSQL Audit extension.

You can configure auditing on your database instances with a great degree of specificity. You can audit all databases and all users. Or, you can choose to audit only certain databases, users, and other objects. You can also explicitly exclude certain users and databases from being audited. For more information, see Excluding users or databases from audit logging (p. 2384).

Given the amount of detail that can be captured, we recommend that if you do use pgAudit, you monitor your storage consumption.

The pgAudit extension is supported on all available RDS for PostgreSQL versions. For a list of pgAudit versions supported by available RDS for PostgreSQL versions, see Extension versions for Amazon RDS for PostgreSQL in the Amazon RDS for PostgreSQL Release Notes.

Topics
- Setting up the pgAudit extension (p. 2379)
- Auditing database objects (p. 2382)
- Excluding users or databases from audit logging (p. 2384)
- Reference for the pgAudit extension (p. 2386)

Setting up the pgAudit extension

To set up the pgAudit extension on your RDS for PostgreSQL DB instance, you first add pgAudit to the shared libraries on the custom DB parameter group for your RDS for PostgreSQL DB instance. For information about creating a custom DB parameter group, see Working with parameter groups (p. 347). Next, you install the pgAudit extension. Finally, you specify the databases and objects that you want to audit. The procedures in this section show you how. You can use the AWS Management Console or the AWS CLI.

You must have permissions as the rds_superuser role to perform all these tasks.

The steps following assume that your RDS for PostgreSQL DB instance is associated with a custom DB parameter group.

Console

To set up the pgAudit extension

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose your RDS for PostgreSQL DB instance.
3. Open the Configuration tab for your RDS for PostgreSQL DB instance. Among the Instance details, find the Parameter group link.
4. Choose the link to open the custom parameters associated with your RDS for PostgreSQL DB instance.
5. In the Parameters search field, type shared_pre to find the shared_preload_libraries parameter.
6. Choose Edit parameters to access the property values.
7. Add pgaudit to the list in the Values field. Use a comma to separate items in the list of values.

8. Reboot the RDS for PostgreSQL DB instance so that your change to the shared_preload_libraries parameter takes effect.
9. When the instance is available, verify that pgAudit has been initialized. Use psql to connect to the RDS for PostgreSQL DB instance, and then run the following command.

```
SHOW shared_preload_libraries;
shared_preload_libraries
--------------------------
rdsutils,pgaudit
(1 row)
```

10. With pgAudit initialized, you can now create the extension. You need to create the extension after initializing the library because the pgaudit extension installs event triggers for auditing data definition language (DDL) statements.

```
CREATE EXTENSION pgaudit;
```

11. Close the psql session.

```
labdb=> \q
```

12. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
13. Find the pgaudit.log parameter in the list and set to the appropriate value for your use case. For example, setting the pgaudit.log parameter to write as shown in the following image captures inserts, updates, deletes, and some other types changes to the log.
You can also choose one of the following values for the `pgaudit.log` parameter:

- **none** – This is the default. No database changes are logged.
- **all** – Logs everything (read, write, function, role, ddl, misc).
- **ddl** – Logs all data definition language (DDL) statements that aren't included in the ROLE class.
- **function** – Logs function calls and DO blocks.
- **misc** – Logs miscellaneous commands, such as DISCARD, FETCH, CHECKPOINT, VACUUM, and SET.
- **read** – Logs SELECT and COPY when the source is a relation (such as a table) or a query.
- **role** – Logs statements related to roles and privileges, such as GRANT, REVOKE, CREATE ROLE, ALTER ROLE, and DROP ROLE.
- **write** – Logs INSERT, UPDATE, DELETE, TRUNCATE, and COPY when the destination is a relation (table).

14. Choose **Save changes**.
15. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
16. Choose your RDS for PostgreSQL DB instance from the Databases list to select it, and then choose **Reboot** from the Actions menu.

**AWS CLI**

**To setup pgAudit**

To setup pgAudit using the AWS CLI, you call the `modify-db-parameter-group` operation to modify the audit log parameters in your custom parameter group, as shown in the following procedure.

1. Use the following AWS CLI command to add `pgaudit` to the `shared_preload_libraries` parameter.

   ```bash
   aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters "ParameterName=shared_preload_libraries,ParameterValue=pgaudit,ApplyMethod=pending-reboot" \
   --region aws-region
   ```

2. Use the following AWS CLI command to reboot the RDS for PostgreSQL DB instance so that the pgaudit library is initialized.

   ```bash
   aws rds reboot-db-instance \
   --db-instance-identifier your-instance \
   --region aws-region
   ```
3. When the instance is available, you can verify that pgaudit has been initialized. Use psql to connect to the RDS for PostgreSQL DB instance, and then run the following command:

```
SHOW shared_preload_libraries;
shared_preload_libraries
--------------------------
rdsutils,pgaudit
(1 row)
```

With pgAudit initialized, you can now create the extension.

```
CREATE EXTENSION pgaudit;
```

4. Close the psql session so that you can use the AWS CLI.

```
labdb=> \q
```

5. Use the following AWS CLI command to specify the classes of statement that want logged by session audit logging. The example sets the pgaudit.log parameter to write, which captures inserts, updates, and deletes to the log.

```
aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters "ParameterName=pgaudit.log,ParameterValue=write,ApplyMethod=pending-reboot" \
   --region aws-region
```

You can also choose one of the following values for the pgaudit.log parameter.

- none – This is the default. No database changes are logged.
- all – Logs everything (read, write, function, role, ddl, misc).
- ddl – Logs all data definition language (DDL) statements that aren’t included in the ROLE class.
- function – Logs function calls and DO blocks.
- misc – Logs miscellaneous commands, such as DISCARD, FETCH, CHECKPOINT, VACUUM, and SET.
- read – Logs SELECT and COPY when the source is a relation (such as a table) or a query.
- role – Logs statements related to roles and privileges, such as GRANT, REVOKE, CREATE ROLE, ALTER ROLE, and DROP ROLE.
- write – Logs INSERT, UPDATE, DELETE, TRUNCATE, and COPY when the destination is a relation (table).

Reboot the RDS for PostgreSQL DB instance using the following AWS CLI command.

```
aws rds reboot-db-instance \
   --db-instance-identifier your-instance \
   --region aws-region
```

Auditing database objects

With pgAudit set up on your RDS for PostgreSQL DB instance and configured for your requirements, more detailed information is captured in the PostgreSQL log. For example, while the default PostgreSQL logging configuration identifies the date and time that a change was made in a database table, with the pgAudit extension the log entry can include the schema, user who made the change, and other details.
depending on how the extension parameters are configured. You can set up auditing to track changes in the following ways.

- For each session, by user. For the session level, you can capture the fully qualified command text.
- For each object, by user and by database.

The object auditing capability is activated when you create the `rds_pgaudit` role on your system and then add this role to the `pgaudit.role` parameter in your custom parameter parameter group. By default, the `pgaudit.role` parameter is unset and the only allowable value is `rds_pgaudit`. The following steps assume that `pgaudit` has been initialized and that you have created the `pgaudit` extension by following the procedure in Setting up the pgAudit extension (p. 2379).

As shown in this example, the "LOG: AUDIT: SESSION" line provides information about the table and its schema, among other details.

**To set up object auditing**

1. Use `psql` to connect to the RDS for PostgreSQL DB instance.

   ```
   psql --host=your-instance-name.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
   ```

2. Create a database role named `rds_pgaudit` using the following command.

   ```
   labdb=> CREATE ROLE rds_pgaudit;
   CREATE ROLE
   ```

3. Close the `psql` session.

   ```
   labdb=> \q
   ```

   In the next few steps, use the AWS CLI to modify the audit log parameters in your custom parameter group.

4. Use the following AWS CLI command to set the `pgaudit.role` parameter to `rds_pgaudit`. By default, this parameter is empty, and `rds_pgaudit` is the only allowable value.

   ```
   aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters "ParameterName=pgaudit.role,ParameterValue=rds_pgaudit,ApplyMethod=pending-reboot" \ 
   --region aws-region
   ```

5. Use the following AWS CLI command to reboot the RDS for PostgreSQL DB instance so that your changes to the parameters take effect.

   ```
   aws rds reboot-db-instance \
   --db-instance-identifier your-instance \ 
   --region aws-region
   ```
6. Run the following command to confirm that the `pgaudit.role` is set to `rds_pgaudit`.

```sql
SHOW pgaudit.role;
pgaudit.role
------------------
rds_pgaudit
```

To test pgAudit logging, you can run several example commands that you want to audit. For example, you might run the following commands.

```sql
CREATE TABLE t1 (id int);
GRANT SELECT ON t1 TO rds_pgaudit;
SELECT * FROM t1;
```

id
----
(0 rows)

The database logs should contain an entry similar to the following.

```
2017-06-12 19:09:49 UTC:...:rds_test@postgres:[11701]:LOG: AUDIT:
OBJECT,1,1,READ,SELECT,TABLE,public.t1,select * from t1;
```

For information on viewing the logs, see Monitoring Amazon RDS log files (p. 895).

To learn more about the pgAudit extension, see pgAudit on GitHub.

## Excluding users or databases from audit logging

As discussed in RDS for PostgreSQL database log files (p. 931), PostgreSQL logs consume storage space. Using the pgAudit extension adds to the volume of data gathered in your logs to varying degrees, depending on the changes that you track. You might not need to audit every user or database in your RDS for PostgreSQL DB instance.

To minimize impacts to your storage and to avoid needlessly capturing audit records, you can exclude users and databases from being audited. You can also change logging within a given session. The following examples show you how.

**Note**

Parameter settings at the session level take precedence over the settings in the custom DB parameter group for the RDS for PostgreSQL DB instance. If you don't want database users to bypass your audit logging configuration settings, be sure to change their permissions.

Suppose that your RDS for PostgreSQL DB instance is configured to audit the same level of activity for all users and databases. You then decide that you don't want to audit the user `myuser`. You can turn off auditing for `myuser` with the following SQL command.

```sql
ALTER USER myuser SET pgaudit.log TO 'NONE';
```

Then, you can use the following query to check the `user_specific_settings` column for `pgaudit.log` to confirm that the parameter is set to `NONE`.

```sql
SELECT usename AS user_name, useconfig AS user_specific_settings
```
FROM

    pg_user
WHERE

  usename = 'myuser';

You see output such as the following.

<table>
<thead>
<tr>
<th>user_name</th>
<th>user_specific_settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>myuser</td>
<td>{pgaudit.log=NONE}</td>
</tr>
</tbody>
</table>

(1 row)

You can turn off logging for a given user in the midst of their session with the database with the following command.

ALTER USER myuser IN DATABASE mydatabase SET pgaudit.log TO 'none';

Use the following query to check the settings column for pgaudit.log for a specific user and database combination.

SELECT

  usename AS "user_name",
  datname AS "database_name",
  pg_catalog.array_to_string(setconfig, E'\n') AS "settings"
FROM

  pg_catalog.pg_db_role_setting s
LEFT JOIN pg_catalog.pg_database d ON d.oid = setdatabase
LEFT JOIN pg_catalog.pg_user r ON r.usesysid = setrole
WHERE

  usename = 'myuser'
  AND datname = 'mydatabase'
ORDER BY

  1,
  2;

You see output similar to the following.

<table>
<thead>
<tr>
<th>user_name</th>
<th>database_name</th>
<th>settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>myuser</td>
<td>mydatabase</td>
<td>pgaudit.log=none</td>
</tr>
</tbody>
</table>

(1 row)

After turning off auditing for myuser, you decide that you don’t want to track changes to mydatabase. You turn off auditing for that specific database by using the following command.

ALTER DATABASE mydatabase SET pgaudit.log to 'NONE';

Then, use the following query to check the database_specific_settings column to confirm that pgaudit.log is set to NONE.

SELECT

  a.datname AS database_name,
  b.setconfig AS database_specific_settings
FROM

  pg_database a
FULL JOIN pg_db_role_setting b ON a.oid = b.setdatabase
WHERE

  a.datname = 'mydatabase'
  AND b.setconfig = 'pgaudit.log=none';

(1 row)
You see output such as the following.

```
database_name | database_specific_settings
---------------+----------------------------
mydatabase    | {pgaudit.log=NONE}
(1 row)
```

To return settings to the default setting for myuser, use the following command:

```
ALTER USER myuser RESET pgaudit.log;
```

To return settings to their default setting for a database, use the following command.

```
ALTER DATABASE mydatabase RESET pgaudit.log;
```

To reset user and database to the default setting, use the following command.

```
ALTER USER myuser IN DATABASE mydatabase RESET pgaudit.log;
```

You can also capture specific events to the log by setting the `pgaudit.log` to one of the other allowed values for the `pgaudit.log` parameter. For more information, see List of allowable settings for the `pgaudit.log` parameter (p. 2387).

```
ALTER USER myuser SET pgaudit.log TO 'read';
ALTER DATABASE mydatabase SET pgaudit.log TO 'function';
ALTER USER myuser IN DATABASE mydatabase SET pgaudit.log TO 'read,function'
```

### Reference for the pgAudit extension

You can specify the level of detail that you want for your audit log by changing one or more of the parameters listed in this section.

#### Controlling pgAudit behavior

You can control the audit logging by changing one or more of the parameters listed in the following table.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pgaudit.log</code></td>
<td>Specifies the statement classes that will be logged by session audit logging. Allowable values include ddl, function, misc, read, role, write, none, all. For more information, see List of allowable settings for the <code>pgaudit.log</code> parameter (p. 2387).</td>
</tr>
<tr>
<td><code>pgaudit.log_catalog</code></td>
<td>When turned on (set to 1), adds statements to audit trail if all relations in a statement are in pg_catalog.</td>
</tr>
<tr>
<td><code>pgaudit.log_level</code></td>
<td>Specifies the log level to use for log entries. Allowed values: debug5, debug4, debug3, debug2, debug1, info, notice, warning, log</td>
</tr>
<tr>
<td><code>pgaudit.log_parameter</code></td>
<td>When turned on (set to 1), parameters passed with the statement are captured in the audit log.</td>
</tr>
</tbody>
</table>
Using pgAudit to log database activity

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pgaudit.log_relation</code></td>
<td>When turned on (set to 1), the audit log for the session creates a separate log entry for each relation (TABLE, VIEW, and so on) referenced in a SELECT or DML statement.</td>
</tr>
<tr>
<td><code>pgaudit.log_statement_once</code></td>
<td>Specifies whether logging will include the statement text and parameters with the first log entry for a statement/substatement combination or with every entry.</td>
</tr>
<tr>
<td><code>pgaudit.role</code></td>
<td>Specifies the master role to use for object audit logging. The only allowable entry is <code>rds_pgaudit</code>.</td>
</tr>
</tbody>
</table>

**List of allowable settings for the `pgaudit.log` parameter**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>This is the default. No database changes are logged.</td>
</tr>
<tr>
<td>all</td>
<td>Logs everything (read, write, function, role, ddl, misc).</td>
</tr>
<tr>
<td>ddl</td>
<td>Logs all data definition language (DDL) statements that aren't included in the ROLE class.</td>
</tr>
<tr>
<td>function</td>
<td>Logs function calls and DO blocks.</td>
</tr>
<tr>
<td>misc</td>
<td>Logs miscellaneous commands, such as DISCARD, FETCH, CHECKPOINT, VACUUM, and SET.</td>
</tr>
<tr>
<td>read</td>
<td>Logs SELECT and COPY when the source is a relation (such as a table) or a query.</td>
</tr>
<tr>
<td>role</td>
<td>Logs statements related to roles and privileges, such as GRANT, REVOKE, CREATE ROLE, ALTER ROLE, and DROP ROLE.</td>
</tr>
<tr>
<td>write</td>
<td>Logs INSERT, UPDATE, DELETE, TRUNCATE, and COPY when the destination is a relation (table).</td>
</tr>
</tbody>
</table>

To log multiple event types with session auditing, use a comma-separated list. To log all event types, set `pgaudit.log` to ALL. Reboot your DB instance to apply the changes.

With object auditing, you can refine audit logging to work with specific relations. For example, you can specify that you want audit logging for READ operations on one or more tables.
Scheduling maintenance with the PostgreSQL pg_cron extension

You can use the PostgreSQL pg_cron extension to schedule maintenance commands within a PostgreSQL database. For more information about the extension, see What is pg_cron? in the pg_cron documentation.

The pg_cron extension is supported on RDS for PostgreSQL engine versions 12.5 and higher.

To learn more about using pg_cron, see Schedule jobs with pg_cron on your RDS for PostgreSQL or your Aurora PostgreSQL-Compatible Edition databases.

Topics

• Setting up the pg_cron extension (p. 2388)
• Granting database users permissions to use pg_cron (p. 2388)
• Scheduling pg_cron jobs (p. 2389)
• Reference for the pg_cron extension (p. 2391)

Setting up the pg_cron extension

Set up the pg_cron extension as follows:

1. Modify the custom parameter group associated with your PostgreSQL DB instance by adding pg_cron to the shared_preload_libraries parameter value.
   • If your RDS for PostgreSQL DB instance uses the rds.allowed_extensions parameter to explicitly list extensions that can be installed, you need to add the pg_cron extension to the list. Only certain versions of RDS for PostgreSQL support the rds.allowed_extensions parameter. By default, all available extensions are allowed. For more information, see Restricting installation of PostgreSQL extensions (p. 2173).

   Restart the PostgreSQL DB instance to have changes to the parameter group take effect. To learn more about working with parameter groups, see Modifying parameters in a DB parameter group (p. 352).

2. After the PostgreSQL DB instance has restarted, run the following command using an account that has rds_superuser permissions. For example, if you used the default settings when you created your RDS for PostgreSQL DB instance, connect as user postgres and create the extension.

   ```sql
   CREATE EXTENSION pg_cron;
   ```

   The pg_cron scheduler is set in the default PostgreSQL database named postgres. The pg_cron objects are created in this postgres database and all scheduling actions run in this database.

3. You can use the default settings, or you can schedule jobs to run in other databases within your PostgreSQL DB instance. To schedule jobs for other databases within your PostgreSQL DB instance, see the example in Scheduling a cron job for a database other than the default database (p. 2390).

Granting database users permissions to use pg_cron

Installing the pg_cron extension requires the rds_superuser privileges. However, permissions to use the pg_cron can be granted (by a member of the rds_superuser group/role) to other database users, so that they can schedule their own jobs. We recommend that you grant permissions to the cron schema only as needed if it improves operations in your production environment.
To grant a database user permission in the `cron` schema, run the following command:

```
postgres=> GRANT USAGE ON SCHEMA cron TO db-user;
```

This gives `db-user` permission to access the `cron` schema to schedule cron jobs for the objects that they have permissions to access. If the database user doesn't have permissions, the job fails after posting the error message to the `postgresql.log` file, as shown in the following:

```
2020-12-08 16:41:00 UTC::@:@[30647]:ERROR: permission denied for table table-name
2020-12-08 16:41:00 UTC::@:@[27071]:LOG: background worker "pg_cron" (PID 30647) exited with exit code 1
```

In other words, make sure that database users that are granted permissions on the `cron` schema also have permissions on the objects (tables, schemas, and so on) that they plan to schedule.

The details of the cron job and its success or failure are also captured in the `cron.job_run_details` table. For more information, see [Tables for scheduling jobs and capturing status](p. 2393).

**Scheduling pg_cron jobs**

The following sections show how you can schedule various management tasks using `pg_cron` jobs.

**Note**

When you create `pg_cron` jobs, check that the `max_worker_processes` setting is larger than the number of `cron.max_running_jobs`. A `pg_cron` job fails if it runs out of background worker processes. The default number of `pg_cron` jobs is 5. For more information, see [Parameters for managing the `pg_cron` extension](p. 2391).

**Topics**

- [Vacuuming a table](p. 2389)
- [Purging the `pg_cron` history table](p. 2390)
- [Logging errors to the `postgresql.log` file only](p. 2390)
- [Scheduling a cron job for a database other than the default database](p. 2390)

**Vacuuming a table**

Autovacuum handles vacuum maintenance for most cases. However, you might want to schedule a vacuum of a specific table at a time of your choosing.

See also, [Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL](p. 2297).

Following is an example of using the `cron.schedule` function to set up a job to use `VACUUM FREEZE` on a specific table every day at 22:00 (GMT).

```
SELECT cron.schedule('manual vacuum', '0 22 * * *', 'VACUUM FREEZE pgbench_accounts');
```

```
schedule ----------
1 (1 row)
```

After the preceding example runs, you can check the history in the `cron.job_run_details` table as follows.

```
postgres=> SELECT * FROM cron.job_run_details;
```

```
jobid | runid | job_pid | database | username | command                        | status | return_message | start_time | end_time
------|-------|---------|----------|----------|---------------------------------|--------|----------------|------------|------------
```
|-------+-------+---------+----------+----------+--------------------------------------------------|
|       | 1     | 3395    | postgres | adminuser| vacuum freeze pgbench_accounts | succeeded |
|-------+-------+---------+----------+----------+--------------------------------------------------|
|       | VACUUM | 2020-12-04 21:10:00.050386+00 | 2020-12-04 21:10:00.072028+00 |

Following is an querying the cron.job_run_details table to see failed jobs.

```
postgres=> SELECT * FROM cron.job_run_details WHERE status = 'failed';

      jobid | runid | job_pid | database | username | command                      | status
      -----+-------+---------+----------+----------+-------------------------------+--------
          |       |         |          |          | return_message                | start_time | end_time
      -----+-------+---------+----------+----------+-------------------------------+--------+
          | 5     | 4      | 30339    | postgres | adminuser| vacuum freeze pgbench_account | failed   |
          |       |       |          |          | ERROR: relation "pgbench_account" does not exist | 2020-12-04 21:48:00.015145+00 | 2020-12-04 21:48:00.029567+00 |

(1 row)
```

For more information, see [Tables for scheduling jobs and capturing status](p. 2393).

**Purging the pg_cron history table**

The cron.job_run_details table contains a history of cron jobs that can become very large over time. We recommend that you schedule a job that purges this table. For example, keeping a week's worth of entries might be sufficient for troubleshooting purposes.

The following example uses the cron.schedule (p. 2392) function to schedule a job that runs every day at midnight to purge the cron.job_run_details table. The job keeps only the last seven days. Use your rds_superuser account to schedule the job such as the following.

```
SELECT cron.schedule('0 0 * * *', $$DELETE FROM cron.job_run_details
WHERE end_time < now() - interval '7 days'$$);
```

For more information, see [Tables for scheduling jobs and capturing status](p. 2393).

**Logging errors to the postgresql.log file only**

To prevent writing to the cron.job_run_details table, modify the parameter group associated with the PostgreSQL DB instance and set the cron.log_run parameter to off. The pg_cron extension no longer writes to the table and captures errors to the postgresql.log file only. For more information, see [Modifying parameters in a DB parameter group](p. 352).

Use the following command to check the value of the cron.log_run parameter.

```
postgres=> SHOW cron.log_run;
```

For more information, see [Parameters for managing the pg_cron extension](p. 2391).

**Scheduling a cron job for a database other than the default database**

The metadata for pg_cron is all held in the PostgreSQL default database named postgres. Because background workers are used for running the maintenance cron jobs, you can schedule a job in any of your databases within the PostgreSQL DB instance:

1. In the cron database, schedule the job as you normally do using the cron.schedule (p. 2392).
pg_cron.schedule('database1 manual vacuum', '29 03 * * *', 'vacuum freeze test_table');

2. As a user with the rds_superuser role, update the database column for the job that you just created so that it runs in another database within your PostgreSQL DB instance.

UPDATE cron.job SET database = 'database1' WHERE jobid = 106;

3. Verify by querying the cron.job table.

Note
In some situations, you might add a cron job that you intend to run on a different database. In such cases, the job might try to run in the default database (postgres) before you update the correct database column. If the user name has permissions, the job successfully runs in the default database.

Reference for the pg_cron extension

You can use the following parameters, functions, and tables with the pg_cron extension. For more information, see What is pg_cron? in the pg_cron documentation.

Topics
- Parameters for managing the pg_cron extension (p. 2391)
- Function reference: cron.schedule (p. 2392)
- Function reference: cron.unschedule (p. 2393)
- Tables for scheduling jobs and capturing status (p. 2393)

Parameters for managing the pg_cron extension

Following is a list of parameters that control the pg_cron extension behavior.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cron.database_name</td>
<td>The database in which pg_cron metadata is kept.</td>
</tr>
<tr>
<td>cron.host</td>
<td>The hostname to connect to PostgreSQL. You can't modify this value.</td>
</tr>
<tr>
<td>cron.log_run</td>
<td>Log every job that runs in the job_run_details table. Values are on or off. For more information, see Tables for scheduling jobs and capturing status (p. 2393).</td>
</tr>
</tbody>
</table>
### Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cron.log_statement</code></td>
<td>Log all cron statements before running them. Values are on or off.</td>
</tr>
<tr>
<td><code>cron.max_running_jobs</code></td>
<td>The maximum number of jobs that can run concurrently.</td>
</tr>
<tr>
<td><code>cron.use_background_workers</code></td>
<td>Use background workers instead of client sessions. You can't modify this value.</td>
</tr>
</tbody>
</table>

Use the following SQL command to display these parameters and their values.

```sql
postgres=> SELECT name, setting, short_desc FROM pg_settings WHERE name LIKE 'cron.%' ORDER BY name;
```

**Function reference: cron.schedule**

This function schedules a cron job. The job is initially scheduled in the default `postgres` database. The function returns a bigint value representing the job identifier. To schedule jobs to run in other databases within your PostgreSQL DB instance, see the example in [Scheduling a cron job for a database other than the default database (p. 2390)](#).

The function has two syntax formats.

**Syntax**

```sql
cron.schedule (job_name, schedule, command);
cron.schedule (schedule, command);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>job_name</code></td>
<td>The name of the cron job.</td>
</tr>
<tr>
<td><code>schedule</code></td>
<td>Text indicating the schedule for the cron job. The format is the standard cron format.</td>
</tr>
<tr>
<td><code>command</code></td>
<td>Text of the command to run.</td>
</tr>
</tbody>
</table>

**Examples**

```sql
postgres=> SELECT cron.schedule ('test', '0 10 * * *', 'VACUUM pgbench_history');
```

```
<table>
<thead>
<tr>
<th>schedule</th>
</tr>
</thead>
<tbody>
<tr>
<td>145</td>
</tr>
</tbody>
</table>

(1 row)
postgres=> SELECT cron.schedule ('0 15 * * *', 'VACUUM pgbench_accounts');
    schedule
   ---------
     146
(1 row)

Function reference: cron.unschedule

This function deletes a cron job. You can specify either the job_name or the job_id. A policy makes sure that you are the owner to remove the schedule for the job. The function returns a Boolean indicating success or failure.

The function has the following syntax formats.

Syntax

```
cron.unschedule (job_id);
cron.unschedule (job_name);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_id</td>
<td>A job identifier that was returned from the cron.schedule function when the cron job was scheduled.</td>
</tr>
<tr>
<td>job_name</td>
<td>The name of a cron job that was scheduled with the cron.schedule function.</td>
</tr>
</tbody>
</table>

Examples

```
postgres=> SELECT cron.unschedule(108);
 unschedule
  ---------
   t
(1 row)

postgres=> SELECT cron.unschedule('test');
 unschedule
  ---------
   t
(1 row)
```

Tables for scheduling jobs and capturing status

The following tables are used to schedule the cron jobs and record how the jobs completed.

<table>
<thead>
<tr>
<th>Table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cron.job</td>
<td>Contains the metadata about each scheduled job. Most interactions with this table should be done by using the cron.schedule and cron.unschedule functions.</td>
</tr>
<tr>
<td>Table</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td><strong>Important</strong>&lt;br&gt;We recommend that you don’t give update or insert privileges directly to this table. Doing so would allow the user to update the <code>username</code> column to run as <code>rds-superuser</code>.</td>
</tr>
<tr>
<td>cron.job_run_details</td>
<td>Contains historic information about past scheduled jobs that ran. This is useful to investigate the status, return messages, and start and end time from the job that ran.&lt;br&gt;&lt;br&gt;<strong>Note</strong>&lt;br&gt;To prevent this table from growing indefinitely, purge it on a regular basis. For an example, see [Purging the pg_cron history table](p. 2390).</td>
</tr>
</tbody>
</table>
Using pglogical to synchronize data across instances

All currently available RDS for PostgreSQL versions support the pglogical extension. The pglogical extension predates the functionally similar logical replication feature that was introduced by PostgreSQL in version 10. For more information, see Performing logical replication for Amazon RDS for PostgreSQL (p. 2177).

The pglogical extension supports logical replication between two or more RDS for PostgreSQL DB instances. It also supports replication between different PostgreSQL versions, and between databases running on RDS for PostgreSQL DB instances and Aurora PostgreSQL DB clusters. The pglogical extension uses a publish-subscribe model to replicate changes to tables and other objects, such as sequences, from a publisher to a subscriber. It relies on a replication slot to ensure that changes are synchronized from a publisher node to a subscriber node, defined as follows.

- The **publisher node** is the RDS for PostgreSQL DB instance that's the source of data to be replicated to other nodes. The publisher node defines the tables to be replicated in a publication set.
- The **subscriber node** is the RDS for PostgreSQL DB instance that receives WAL updates from the publisher. The subscriber creates a subscription to connect to the publisher and get the decoded WAL data. When the subscriber creates the subscription, the replication slot is created on the publisher node.

Following, you can find information about setting up the pglogical extension.

**Topics**

- Requirements and limitations for the pglogical extension (p. 2395)
- Setting up the pglogical extension (p. 2395)
- Setting up logical replication for RDS for PostgreSQL DB instance (p. 2398)
- Reestablishing logical replication after a major upgrade (p. 2400)
- Managing logical replication slots for RDS for PostgreSQL (p. 2402)
- Parameter reference for the pglogical extension (p. 2403)

**Requirements and limitations for the pglogical extension**

All currently available releases of RDS for PostgreSQL support the pglogical extension.

Both the publisher node and the subscriber node must be set up for logical replication.

The tables that you want to replicate from subscriber to publisher must have the same names and the same schema. These tables must also contain the same columns, and the columns must use the same data types. Both publisher and subscriber tables must have the same primary keys. We recommend that you use only the PRIMARY KEY as the unique constraint.

The tables on the subscriber node can have more permissive constraints than those on the publisher node for CHECK constraints and NOT NULL constraints.

The pglogical extension provides features such as two-way replication that aren't supported by the logical replication feature built into PostgreSQL (version 10 and higher). For more information, see PostgreSQL bi-directional replication using pglogical.

**Setting up the pglogical extension**

To set up the pglogical extension on your RDS for PostgreSQL DB instance, you add pglogical to the shared libraries on the custom DB parameter group for your RDS for PostgreSQL DB instance.
You also need to set the value of the `rds.logical_replication` parameter to 1, to turn on logical decoding. Finally, you create the extension in the database. You can use the AWS Management Console or the AWS CLI for these tasks.

You must have permissions as the `rds_superuser` role to perform these tasks.

The steps following assume that your RDS for PostgreSQL DB instance is associated with a custom DB parameter group. For information about creating a custom DB parameter group, see Working with parameter groups (p. 347).

**Console**

**To set up the pglogical extension**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose your RDS for PostgreSQL DB instance.
3. Open the Configuration tab for your RDS for PostgreSQL DB instance. Among the Instance details, find the Parameter group link.
4. Choose the link to open the custom parameters associated with your RDS for PostgreSQL DB instance.
5. In the Parameters search field, type `shared_pre` to find the `shared_preload_libraries` parameter.
6. Choose Edit parameters to access the property values.
7. Add `pglogical` to the list in the Values field. Use a comma to separate items in the list of values.

<table>
<thead>
<tr>
<th>RDS</th>
<th>Parameter groups</th>
<th>docs-lab-rpg-12-parameter-group</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Parameters</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Name</td>
<td>Values</td>
</tr>
<tr>
<td></td>
<td>shared_preload_libraries</td>
<td>pglogical, pg_stat_statements</td>
</tr>
<tr>
<td></td>
<td>auto_explain, orafce, pgaudit, pglogical, pg_bigm, pg_cron, pg_hint_plan, pg_growmon, pg_similarity, pg_stat_statements, pg_transport, pgprofiler</td>
<td></td>
</tr>
</tbody>
</table>

8. Find the `rds.logical_replication` parameter and set it to 1, to turn on logical replication.
9. Reboot the RDS for PostgreSQL DB instance so that your changes take effect.
10. When the instance is available, you can use `psql` (or `pgAdmin`) to connect to the RDS for PostgreSQL DB instance.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
```

11. To verify that pglogical is initialized, run the following command.

```
SHOW shared_preload_libraries;
shared_preload_libraries
---------------------------
pglogical, rdsutils
```

2396
12. Verify the setting that enables logical decoding, as follows.

```
SHOW wal_level;
wal_level
--------
logical
(1 row)
```

13. Create the extension, as follows.

```
CREATE EXTENSION pglogical;
EXTENSION CREATED
```

14. Choose Save changes.

15. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.

16. Choose your RDS for PostgreSQL DB instance from the Databases list to select it, and then choose Reboot from the Actions menu.

**AWS CLI**

To setup the pglogical extension

To setup pglogical using the AWS CLI, you call the modify-db-parameter-group operation to modify certain parameters in your custom parameter group as shown in the following procedure.

1. Use the following AWS CLI command to add pglogical to the shared_preload_libraries parameter.

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name custom-param-group-name \
  --parameters "ParameterName=shared_preload_libraries,ParameterValue=pglogical,ApplyMethod=pending-reboot" \
  --region aws-region
```

2. Use the following AWS CLI command to set rds.logical_replication to 1 to turn on the logical decoding capability for the RDS for PostgreSQL DB instance.

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name custom-param-group-name \
  --parameters "ParameterName=rds.logical_replication,ParameterValue=1,ApplyMethod=pending-reboot" \
  --region aws-region
```

3. Use the following AWS CLI command to reboot the RDS for PostgreSQL DB instance so that the pglogical library is initialized.

```
aws rds reboot-db-instance \
  --db-instance-identifier your-instance \
  --region aws-region
```

4. When the instance is available, use psql to connect to the RDS for PostgreSQL DB instance.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
```

5. Create the extension, as follows.
CREATE EXTENSION pglogical;
EXTENSION CREATED

6. Reboot the RDS for PostgreSQL DB instance using the following AWS CLI command.

```
aws rds reboot-db-instance \
   --db-instance-identifier your-instance \
   --region aws-region
```

Setting up logical replication for RDS for PostgreSQL DB instance

The following procedure shows you how to start logical replication between two RDS for PostgreSQL DB instances. The steps assume that both the source (publisher) and the target (subscriber) have the pglogical extension set up as detailed in Setting up the pglogical extension (p. 2395).

To create the publisher node and define the tables to replicate

These steps assume that your RDS for PostgreSQL DB instance has a database that has one or more tables that you want to replicate to another node. You need to recreate the table structure from the publisher on the subscriber, so first, get the table structure if necessary. You can do that by using the psql metacommand `\d tablename` and then creating the same table on the subscriber instance. The following procedure creates an example table on the publisher (source) for demonstration purposes.

1. Use psql to connect to the instance that has the table you want to use as a source for subscribers.

   ```
   psql --host=source-instance.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
   ```

   If you don't have an existing table that you want to replicate, you can create a sample table as follows.

   a. Create an example table using the following SQL statement.

      ```
      CREATE TABLE docs_lab_table (a int PRIMARY KEY);
      ```

   b. Populate the table with generated data by using the following SQL statement.

      ```
      INSERT INTO docs_lab_table VALUES (generate_series(1,5000));
      ```

   c. Verify that data exists in the table by using the following SQL statement.

      ```
      SELECT count(*) FROM docs_lab_table;
      ```

2. Identify this RDS for PostgreSQL DB instance as the publisher node, as follows.

   ```
   SELECT pglogical.create_node(
       node_name := 'docs_lab_provider',
       dsn := 'host=source-instance.aws-region.rds.amazonaws.com port=5432 dbname=labdb');
   create_node
   ----------
   541095529
   (1 row)
   ```
3. Add the table that you want to replicate to the default replication set. For more information about replication sets, see `Replication sets` in the pglogical documentation.

```sql
SELECT pglogical.replication_set_add_table('default', 'docs_lab_table', 'true', NULL, NULL);
```

The publisher node setup is complete. You can now set up the subscriber node to receive the updates from the publisher.

**To set up the subscriber node and create a subscription to receive updates**

These steps assume that the RDS for PostgreSQL DB instance has been set up with the pglogical extension. For more information, see `Setting up the pglogical extension (p. 2395)`.

1. Use `psql` to connect to the instance that you want to receive updates from the publisher.

```bash
cqosql --host=target-instance.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
```

2. On the subscriber RDS for PostgreSQL DB instance, create the same table that exists on the publisher. For this example, the table is `docs_lab_table`. You can create the table as follows.

```sql
CREATE TABLE docs_lab_table (a int PRIMARY KEY);
```

3. Verify that this table is empty.

```sql
SELECT count(*) FROM docs_lab_table;
```

4. Identify this RDS for PostgreSQL DB instance as the subscriber node, as follows.

```sql
SELECT pglogical.create_node(
    node_name := 'docs_lab_target',
    dsn := 'host=target-instance.aws-region.rds.amazonaws.com port=5432 sslmode=require dbname=labdb user=postgres password=********
);
```

5. Create the subscription.

```sql
SELECT pglogical.create_subscription(
    subscription_name := 'docs_lab_subscription',
    provider_dsn := 'host=source-instance.aws-region.rds.amazonaws.com port=5432 sslmode=require dbname=labdb user=postgres password=******',
    replication_sets := ARRAY['default'],
    synchronize_data := true,
    forward_origins := '{}');
```
When you complete this step, the data from the table on the publisher is created in the table on the subscriber. You can verify that this has occurred by using the following SQL query.

```
SELECT count(*) FROM docs_lab_table;
```

```
<table>
<thead>
<tr>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>5000</td>
</tr>
</tbody>
</table>
```

From this point forward, changes made to the table on the publisher are replicated to the table on the subscriber.

**Reestablishing logical replication after a major upgrade**

Before you can perform a major version upgrade of an RDS for PostgreSQL DB instance that's set up as a publisher node for logical replication, you must drop all replication slots, even those that aren't active. We recommend that you temporarily divert database transactions from the publisher node, drop the replication slots, upgrade the RDS for PostgreSQL DB instance, and then re-establish and restart replication.

The replication slots are hosted on the publisher node only. The RDS for PostgreSQL subscriber node in a logical replication scenario has no slots to drops, but it can't be upgraded to a major version while it's designated as a subscriber node with a subscription to the publisher. Before upgrading the RDS for PostgreSQL subscriber node, drop the subscription and the node. For more information, see [Managing logical replication slots for RDS for PostgreSQL](p. 2402).

**Determining that logical replication has been disrupted**

You can determine that the replication process has been disrupted by querying either the publisher node or the subscriber node, as follows.

**To check the publisher node**

- Use `psql` to connect to the publisher node, and then query the `pg_replication_slots` function. Note the value in the active column. Normally, this will return `t` (true), showing that replication is active. If the query returns `f` (false), it's an indication that replication to the subscriber has stopped.

```
SELECT slot_name, plugin, slot_type, active FROM pg_replication_slots;
```

```
<table>
<thead>
<tr>
<th>slot_name</th>
<th>plugin</th>
<th>slot_type</th>
<th>active</th>
</tr>
</thead>
<tbody>
<tr>
<td>pgl_labdb_docs_labcb4fa94_docs_lab3de412c</td>
<td>pglogical_output</td>
<td>logical</td>
<td>f</td>
</tr>
</tbody>
</table>
```

**To check the subscriber node**

On the subscriber node, you can check the status of replication in three different ways.

- Look through the PostgreSQL logs on the subscriber node to find failure messages. The log identifies failure messages that include exit code 1, as shown following.

```
2022-07-06 16:17:03 UTC::@:
2022-07-06 16:19:44 UTC::@:
```

2400
• Query the `pg_replication_origin` function. Connect to the database on the subscriber node using `psql` and query the `pg_replication_origin` function, as follows.

```sql
SELECT * FROM pg_replication_origin;
roident | roname
---------+--------
        (0 rows)
```

The empty result set means that replication has been disrupted. Normally, you see output such as the following.

```sql
roident | roname
---------+-------------------------------------
1 | pgl_labdb_docs_labcb4fa94_docs_lab3de412c
(1 row)
```

• Query the `pglogical.show_subscription_status` function as shown in the following example.

```sql
SELECT subscription_name,status,slot_name FROM pglogical.show_subscription_status();
subscription_name | status | slot_name
---====----------------+--------+-------------------------------------
docs_lab_subscription | down   | pgl_labdb_docs_labcb4fa94_docs_lab3de412c
(1 row)
```

This output shows that replication has been disrupted. Its status is `down`. Normally, the output shows the status as `replicating`.

If your logical replication process has been disrupted, you can re-establish replication by following these steps.

**To reestablish logical replication between publisher and subscriber nodes**

To re-establish replication, you first disconnect the subscriber from the publisher node and then re-establish the subscription, as outlined in these steps.

1. Connect to the subscriber node using `psql` as follows.

   ```bash
   psql --host=222222222222.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
   ```

2. Deactivate the subscription by using the `pglogical.alter_subscription_disable` function.

   ```sql
   SELECT pglogical.alter_subscription_disable('docs_lab_subscription',true);
   alter_subscription_disable
   --------------------------
t   (1 row)
   ```

3. Get the publisher node's identifier by querying the `pg_replication_origin`, as follows.

   ```sql
   SELECT * FROM pg_replication_origin;
   roident | roname
   ---------+--------
   1 | pgl_labdb_docs_labcb4fa94_docs_lab3de412c
   (1 row)
   ```

4. Use the response from the previous step with the `pg_replication_origin_create` command to assign the identifier that can be used by the subscription when re-established.
5. Turn on the subscription by passing its name with a status of `true`, as shown in the following example.

```
SELECT pglogical.alter_subscription_enable('docs_lab_subscription',true);
```

```
alter_subscription_enable
---------------------------
t (1 row)
```

Check the status of the node. Its status should be `replicating` as shown in this example.

```
SELECT subscription_name,status,slot_name
FROM pglogical.show_subscription_status();
```

```
subscription_name |   status    |              slot_name
-------------------------------+-------------+-------------------------------------
docs_lab_subscription         | replicating | pgl_labdb_docs_lab98f517b_docs_lab3de412c
```

(1 row)

Check the status of the subscriber's replication slot on the publisher node. The slot's active column should return `t` (true), indicating that replication has been re-established.

```
SELECT slot_name,plugin,slot_type,active
FROM pg_replication_slots;
```

```
slot_name              |      plugin      | slot_type | active
-------------------------------------------+------------------+-----------+--------
pgl_labdb_docs_lab98f517b_docs_lab3de412c | pglogical_output | logical   | t
```

(1 row)

**Managing logical replication slots for RDS for PostgreSQL**

Before you can perform a major version upgrade on an RDS for PostgreSQL DB instance that's serving as a publisher node in a logical replication scenario, you must drop the replication slots on the instance. The major version upgrade pre-check process notifies you that the upgrade can't proceed until the slots are dropped.

To drop slots from your RDS for PostgreSQL DB instance, first drop the subscription and then drop the slot.

To identify replication slots that were created using the `pglogical` extension, log in to each database and get the name of the nodes. When you query the subscriber node, you get both the publisher and the subscriber nodes in the output, as shown in this example.

```
SELECT node_id, node_name
FROM pglogical.node;
```

```
node_id   |     node_name
------------+-------------------
2182738256 | docs_lab_target
3410995529 | docs_lab_provider
```

(2 rows)

You can get the details about the subscription with the following query.
You can now drop the subscription, as follows.

```sql
SELECT pglogical.drop_subscription(subscription_name := 'docs_lab_subscription');
```

You can verify that the node no longer exists, as follows.

```sql
SELECT * FROM pglogical.node;
```

Parameter reference for the pglogical extension

In the table you can find parameters associated with the pglogical extension. Parameters such as `pglogical.conflict_log_level` and `pglogical.conflict_resolution` are used to handle update conflicts. Conflicts can emerge when changes are made locally to the same tables that are subscribed to changes from the publisher. Conflicts can also occur during various scenarios, such as two-way replication or when multiple subscribers are replicating from the same publisher. For more information, see [PostgreSQL bi-directional replication using pglogical](https://www.postgresql.org/docs/current/pglogical.html).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pglogical.batch_inserts</code></td>
<td>Batch inserts if possible. Not set by default. Change to '1' to turn on, '0' to turn off.</td>
</tr>
<tr>
<td><code>pglogical.conflict_log_level</code></td>
<td>Sets the log level to use for logging resolved conflicts. Supported string values are debug5, debug4, debug3, debug2, debug1, info, notice, warning, error, log, fatal, panic.</td>
</tr>
<tr>
<td><code>pglogical.conflict_resolution</code></td>
<td>Sets method to use to resolve conflicts when conflicts are resolvable. Supported string values are error, apply_remote, keep_local, last_update_wins, first_update_wins.</td>
</tr>
<tr>
<td><code>pglogical.extra_connection_options</code></td>
<td>Connection options to add to all peer node connections.</td>
</tr>
<tr>
<td><code>pglogical.synchronous_commit</code></td>
<td>pglogical specific synchronous commit value</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>pglogical.use_spi</td>
<td>Use SPI (server programming interface) instead of low-level API to apply changes. Set to '1' to turn on, '0' to turn off. For more information about SPI, see <a href="#">Server Programming Interface</a> in the PostgreSQL documentation.</td>
</tr>
</tbody>
</table>
Reducing bloat in tables and indexes with the pg_repack extension

You can use the pg_repack extension to remove bloat from tables and indexes. This extension is supported on RDS for PostgreSQL versions 9.6.3 and higher. For more information on the pg_repack extension, see the GitHub project documentation.

To use the pg_repack extension

1. Install the pg_repack extension on your RDS for PostgreSQL DB instance by running the following command.

   ```sql
   CREATE EXTENSION pg_repack;
   ```

2. Run the following commands to grant write access to repack temporary log tables created by pg_repack.

   ```sql
   ALTER DEFAULT PRIVILEGES IN SCHEMA repack GRANT INSERT ON TABLES TO PUBLIC;
   ALTER DEFAULT PRIVILEGES IN SCHEMA repack GRANT USAGE, SELECT ON SEQUENCES TO PUBLIC;
   ```

3. Connect to the database using the pg_repack client utility. Use an account that has rds_superuser privileges. As an example, assume that rds_test role has rds_superuser privileges. The command syntax is shown following.

   ```bash
   pg_repack -h db-instance-name.1112223333.aws-region.rds.amazonaws.com -U rds_test -k postgres
   ```

   Connect using the -k option. The -a option is not supported.

4. The response from the pg_repack client provides information on the tables on the DB instance that are repacked.

   ```text
   INFO: repacking table "pgbench_tellers"
   INFO: repacking table "pgbench_accounts"
   INFO: repacking table "pgbench_branches"
   ```
Upgrading and using the PLV8 extension

PLV8 is a trusted Javascript language extension for PostgreSQL. You can use it for stored procedures, triggers, and other procedural code that’s callable from SQL. This language extension is supported by all current releases of PostgreSQL.

If you use PLV8 and upgrade PostgreSQL to a new PLV8 version, you immediately take advantage of the new extension. Take the following steps to synchronize your catalog metadata with the new version of PLV8. These steps are optional, but we highly recommend that you complete them to avoid metadata mismatch warnings.

The upgrade process drops all your existing PLV8 functions. Thus, we recommend that you create a snapshot of your RDS for PostgreSQL DB instance before upgrading. For more information, see Creating a DB snapshot (p. 613).

To synchronize your catalog metadata with a new version of PLV8

1. Verify that you need to update. To do this, run the following command while connected to your instance.

   SELECT * FROM pg_available_extensions WHERE name IN ('plv8','plls','plcoffee');

   If your results contain values for an installed version that is a lower number than the default version, continue with this procedure to update your extensions. For example, the following result set indicates that you should update.

<table>
<thead>
<tr>
<th>name</th>
<th>default_version</th>
<th>installed_version</th>
<th>comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>plls</td>
<td>2.1.0</td>
<td>1.5.3</td>
<td>PL/LiveScript (v8) trusted procedural language</td>
</tr>
<tr>
<td>plcoffee</td>
<td>2.1.0</td>
<td>1.5.3</td>
<td>PL/CoffeeScript (v8) trusted procedural language</td>
</tr>
<tr>
<td>plv8</td>
<td>2.1.0</td>
<td>1.5.3</td>
<td>PL/JavaScript (v8) trusted procedural language</td>
</tr>
</tbody>
</table>
   (3 rows)

2. Create a snapshot of your RDS for PostgreSQL DB instance if you haven’t done so yet. You can continue with the following steps while the snapshot is being created.

3. Get a count of the number of PLV8 functions in your DB instance so you can validate that they are all in place after the upgrade. For example, the following SQL query returns the number of functions written in plv8, plcoffee, and plls.

   SELECT proname, nspname, lanname
   FROM pg_proc p, pg_language l, pg_namespace n
   WHERE p.prolang = l.oid
   AND n.oid = p.pronamespace
   AND lanname IN ('plv8','plcoffee','plls');

4. Use pg_dump to create a schema-only dump file. For example, create a file on your client machine in the /tmp directory.

   ./pg_dump -Fc --schema-only -U master postgres >/tmp/test.dmp

This example uses the following options:

- `-Fc` – Custom format
Using PL/Rust to write PostgreSQL functions in the Rust language

PL/Rust is a trusted Rust language extension for PostgreSQL. You can use it for stored procedures, functions, and other procedural code that's callable from SQL. The PL/Rust language extension is available in the following versions:

- RDS for PostgreSQL 15.2-R2 and higher 15 versions
- RDS for PostgreSQL 14.9 and higher 14 versions

For more information on pg_dump, see pg_dump in the PostgreSQL documentation.

Extract the "CREATE FUNCTION" DDL statement that is present in the dump file. The following example uses the grep command to extract the DDL statement that creates the functions and save them to a file. You use this in subsequent steps to recreate the functions.

```
./pg_restore -l /tmp/test.dmp | grep FUNCTION > /tmp/function_list/
```

For more information on pg_restore, see pg_restore in the PostgreSQL documentation.

Drop the functions and extensions. The following example drops any PLV8 based objects. The cascade option ensures that any dependent are dropped.

```
DROP EXTENSION plv8 CASCADE;
```

If your PostgreSQL instance contains objects based on plcoffee or plls, repeat this step for those extensions.

Create the extensions. The following example creates the plv8, plcoffee, and plls extensions.

```
CREATE EXTENSION plv8;
CREATE EXTENSION plcoffee;
CREATE EXTENSION plls;
```

Create the functions using the dump file and "driver" file.

The following example recreates the functions that you extracted previously.

```
./pg_restore -U master -d postgres -Fc -L /tmp/function_list /tmp/test.dmp
```

Verify that all your functions have been recreated by using the following query.

```
SELECT * FROM pg_available_extensions WHERE name IN ('plv8','plls','plcoffee');
```

The PLV8 version 2 adds the following extra row to your result set:

```
<table>
<thead>
<tr>
<th>proname</th>
<th>nspname</th>
<th>lanname</th>
</tr>
</thead>
<tbody>
<tr>
<td>plv8_version</td>
<td>pg_catalog</td>
<td>plv8</td>
</tr>
</tbody>
</table>
```

Using PL/Rust to write PostgreSQL functions in the Rust language

PL/Rust is a trusted Rust language extension for PostgreSQL. You can use it for stored procedures, functions, and other procedural code that's callable from SQL. The PL/Rust language extension is available in the following versions:

- RDS for PostgreSQL 15.2-R2 and higher 15 versions
- RDS for PostgreSQL 14.9 and higher 14 versions
• RDS for PostgreSQL 13.12 and higher 13 versions

For more information, see PL/Rust on GitHub.

Topics
• Setting up PL/Rust (p. 2408)
• Creating functions with PL/Rust (p. 2409)
• Using crates with PL/Rust (p. 2410)
• PL/Rust limitations (p. 2410)

Setting up PL/Rust

To install the plrust extension on your DB instance, add plrust to the shared_preload_libraries parameter in the DB parameter group associated with your DB instance. With the plrust extension installed, you can create functions.

To modify the shared_preload_libraries parameter, your DB instance must be associated with a custom parameter group. For information about creating a custom DB parameter group, see Working with parameter groups (p. 347).

You can install the plrust extension using the AWS Management Console or the AWS CLI.

The following steps assume that your DB instance is associated with a custom DB parameter group.

Console

Install the plrust extension in the shared_preload_libraries parameter

Complete the following steps using an account that is a member of the rds_superuser group (role).

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the name of your DB instance to display its details.
4. Open the Configuration tab for your DB instance and find the DB instance parameter group link.
5. Choose the link to open the custom parameters associated with your DB instance.
6. In the Parameters search field, type shared_pre to find the shared_preload_libraries parameter.
7. Choose Edit parameters to access the property values.
8. Add plrust to the list in the Values field. Use a comma to separate items in the list of values.
9. Reboot the DB instance so that your change to the shared_preload_libraries parameter takes effect. The initial reboot may require additional time to complete.
10. When the instance is available, verify that plrust has been initialized. Use psql to connect to the DB instance, and then run the following command.

```
SHOW shared_preload_libraries;
```

Your output should look similar to the following:

```
shared_preload_libraries
--------------------------
rdsutils,plrust
```
AWS CLI

Install the plrust extension in the shared_preload_libraries parameter

Complete the following steps using an account that is a member of the rds_superuser group (role).

1. Use the modify-db-parameter-group AWS CLI command to add plrust to the shared_preload_libraries parameter.

   ```bash
   aws rds modify-db-parameter-group 
   --db-parameter-group-name custom-param-group-name 
   --parameters 
   "ParameterName=shared_preload_libraries,ParameterValue=plrust,ApplyMethod=pending-reboot" 
   --region aws-region
   ```

2. Use the reboot-db-instance AWS CLI command to reboot the DB instance and initialize the plrust library. The initial reboot may require additional time to complete.

   ```bash
   aws rds reboot-db-instance 
   --db-instance-identifier your-instance 
   --region aws-region
   ```

3. When the instance is available, you can verify that plrust has been initialized. Use psql to connect to the DB instance, and then run the following command.

   ```sql
   SHOW shared_preload_libraries;
   ```

   Your output should look similar to the following:

   ```sql
   shared_preload_libraries
   --------------------------
   rdsutils,plrust
   (1 row)
   ```

Creating functions with PL/Rust

PL/Rust will compile the function as a dynamic library, load it, and execute it.

The following Rust function filters multiples out of an array.

```sql
postgres=> CREATE LANGUAGE plrust;
CREATE EXTENSION
```

```sql
CREATE OR REPLACE FUNCTION filter_multiples(a BIGINT[], multiple BIGINT) RETURNS BIGINT[] IMMUTABLE STRICT LANGUAGE PLRUST AS $$
Ok(Some(a.into_iter().filter(|x| x.unwrap() % multiple != 0).collect()))
$$;
```

```sql
WITH gen_values AS (SELECT ARRAY(SELECT * FROM generate_series(1,100)) as arr)
SELECT filter_multiples(arr, 3)
```
Using PL/Rust to write functions in the Rust language

Using crates with PL/Rust

Starting with Amazon RDS for PostgreSQL versions 15.4, 14.9, and 13.12, PL/Rust supports the aes, ctr, and rand crates. Only the default features are supported for these crates. New RDS for PostgreSQL versions might contain updated versions of crates, and older versions of crates may no longer be supported.

Follow the best practices for performing a major version upgrade to test whether your PL/Rust functions are compatible with the new major version. For more information, see the blog Best practices for upgrading Amazon RDS to major and minor versions of PostgreSQL and Upgrading the PostgreSQL DB engine for Amazon RDS in the Amazon RDS User Guide.

Examples of using dependencies when creating a PL/Rust function are available at Use dependencies.

PL/Rust limitations

By default, database users can't use PL/Rust. To provide access to PL/Rust, connect as a user with rds_superuser privilege, and run the following command:

```
postgres=> GRANT USAGE ON LANGUAGE PLRUST TO user;
```
Managing spatial data with the PostGIS extension

PostGIS is an extension to PostgreSQL for storing and managing spatial information. To learn more about PostGIS, see PostGIS.net.

Starting with version 10.5, PostgreSQL supports the libprotobuf 1.3.0 library used by PostGIS for working with map box vector tile data.

Setting up the PostGIS extension requires rds_superuser privileges. We recommend that you create a user (role) to manage the PostGIS extension and your spatial data. The PostGIS extension and its related components add thousands of functions to PostgreSQL. Consider creating the PostGIS extension in its own schema if that makes sense for your use case. The following example shows how to install the extension in its own database, but this isn't required.

Topics
- Step 1: Create a user (role) to manage the PostGIS extension (p. 2411)
- Step 2: Load the PostGIS extensions (p. 2412)
- Step 3: Transfer ownership of the extensions (p. 2412)
- Step 4: Transfer ownership of the PostGIS objects (p. 2413)
- Step 5: Test the extensions (p. 2413)
- Step 6: Upgrade the PostGIS extension (p. 2414)
- PostGIS extension versions (p. 2414)
- Upgrading PostGIS 2 to PostGIS 3 (p. 2415)

Step 1: Create a user (role) to manage the PostGIS extension

First, connect to your RDS for PostgreSQL DB instance as a user that has rds_superuser privileges. If you kept the default name when you set up your instance, you connect as postgres.

```bash
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
```

Create a separate role (user) to administer the PostGIS extension.

```bash
postgres=> CREATE ROLE gis_admin LOGIN PASSWORD 'change_me';
CREATE ROLE
```

Grant this role rds_superuser privileges, to allow the role to install the extension.

```bash
postgres=> GRANT rds_superuser TO gis_admin;
GRANT
```

Create a database to use for your PostGIS artifacts. This step is optional. Or you can create a schema in your user database for the PostGIS extensions, but this also isn't required.

```bash
postgres=> CREATE DATABASE lab_gis;
CREATE DATABASE
```

Give the gis_admin all privileges on the lab_gis database.

```bash
postgres=> GRANT ALL PRIVILEGES ON DATABASE lab_gis TO gis_admin;
GRANT
```
Exit the session and reconnect to your RDS for PostgreSQL DB instance as `gis_admin`.

```sql
postgres=> psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=gis_admin --password --dbname=lab_gis
Password for user gis_admin:...
lab_gis=>
```

Continue setting up the extension as detailed in the next steps.

**Step 2: Load the PostGIS extensions**

The PostGIS extension includes several related extensions that work together to provide geospatial functionality. Depending on your use case, you might not need all the extensions created in this step.

Use `CREATE EXTENSION` statements to load the PostGIS extensions.

```sql
CREATE EXTENSION postgis;
CREATE EXTENSION postgis_raster;
CREATE EXTENSION fuzzystrmatch;
CREATE EXTENSION postgis_tiger_geocoder;
CREATE EXTENSION postgis_topology;
CREATE EXTENSION address_standardizer_data_us;
```

You can verify the results by running the SQL query shown in the following example, which lists the extensions and their owners.

```
SELECT n.nspname AS "Name",
       pg_catalog.pg_get_userbyid(n.nspowner) AS "Owner"
FROM pg_catalog.pg_namespace n
WHERE n.nspname !~ '^pg_' AND n.nspname <> 'information_schema'
ORDER BY 1;
```

List of schemas

<table>
<thead>
<tr>
<th>Name</th>
<th>Owner</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>postgres</td>
</tr>
<tr>
<td>tiger</td>
<td>rdsadmin</td>
</tr>
<tr>
<td>tiger_data</td>
<td>rdsadmin</td>
</tr>
<tr>
<td>topology</td>
<td>rdsadmin</td>
</tr>
</tbody>
</table>

(4 rows)

**Step 3: Transfer ownership of the extensions**

Use the `ALTER SCHEMA` statements to transfer ownership of the schemas to the `gis_admin` role.

```sql
ALTER SCHEMA tiger OWNER TO gis_admin;
ALTER SCHEMA tiger_data OWNER TO gis_admin;
ALTER SCHEMA topology OWNER TO gis_admin;
```

You can confirm the ownership change by running the following SQL query. Or you can use the `\dn` metacommand from the `psql` command line.
Step 4: Transfer ownership of the PostGIS objects

Use the following function to transfer ownership of the PostGIS objects to the gis_admin role. Run the following statement from the psql prompt to create the function.

```sql
CREATE FUNCTION exec(text) returns text language plpgsql volatile AS $f$
BEGIN EXECUTE $1;
RETURN $1;
END;
$$;
```

Next, run the following query to run the `exec` function that in turn runs the statements and alters the permissions.

```sql
SELECT exec('ALTER TABLE ' || quote_ident(s.nspname) || '.' || quote_ident(s.relname) || ' OWNER TO gis_admin;')
FROM (SELECT nspname, relname FROM pg_class c JOIN pg_namespace n ON (c.relnamespace = n.oid)
WHERE nspname in ('tiger','topology') AND relkind IN ('r','S','v') ORDER BY relkind = 'S') s;
```

Step 5: Test the extensions

To avoid needing to specify the schema name, add the tiger schema to your search path using the following command.

```sql
SET search_path=public,tiger;
```

Test the tiger schema by using the following SELECT statement.

```sql
SELECT address, streetname, streettypeabbrev, zip
FROM normalize_address('1 Devonshire Place, Boston, MA 02109') AS na;
```

To learn more about this extension, see Tiger Geocoder in the PostGIS documentation.

Test access to the topology schema by using the following SELECT statement. This calls the createtopology function to register a new topology object (my_new_topo) with the specified spatial
reference identifier (26986) and default tolerance (0.5). To learn more, see `CreateTopology` in the PostGIS documentation.

```
SELECT topology.createtopology('my_new_topo',26986,0.5);
createtopology
----------------
1
(1 row)
```

### Step 6: Upgrade the PostGIS extension

Each new release of PostgreSQL supports one or more versions of the PostGIS extension compatible with that release. Upgrading the PostgreSQL engine to a new version doesn't automatically upgrade the PostGIS extension. Before upgrading the PostgreSQL engine, you typically upgrade PostGIS to the newest available version for the current PostgreSQL version. For details, see PostGIS extension versions (p. 2414).

After the PostgreSQL engine upgrade, you then upgrade the PostGIS extension again, to the version supported for the newly upgraded PostgreSQL engine version. For more information about upgrading the PostgreSQL engine, see How to perform a major version upgrade (p. 2220).

You can check for available PostGIS extension version updates on your RDS for PostgreSQL DB instance at any time. To do so, run the following command. This function is available with PostGIS 2.5.0 and higher versions.

```
SELECT postGIS_extensions_upgrade();
```

If your application doesn't support the latest PostGIS version, you can install an older version of PostGIS that's available in your major version as follows.

```
CREATE EXTENSION postgis VERSION "2.5.5";
```

If you want to upgrade to a specific PostGIS version from an older version, you can also use the following command.

```
ALTER EXTENSION postgis UPDATE TO "2.5.5";
```

Depending on the version that you're upgrading from, you might need to use this function again. The result of the first run of the function determines if an additional upgrade function is needed. For example, this is the case for upgrading from PostGIS 2 to PostGIS 3. For more information, see Upgrading PostGIS 2 to PostGIS 3 (p. 2415).

If you upgraded this extension to prepare for a major version upgrade of the PostgreSQL engine, you can continue with other preliminary tasks. For more information, see How to perform a major version upgrade (p. 2220).

### PostGIS extension versions

We recommend that you install the versions of all extensions such as PostGIS as listed in Extension versions for Amazon RDS for PostgreSQL in the Amazon RDS for PostgreSQL Release Notes. To get a list of versions that are available in your release, use the following command.

```
SELECT * FROM pg_available_extension_versions WHERE name='postgis';
```

You can find version information in the following sections in the Amazon RDS for PostgreSQL Release Notes:
Managing spatial data with PostGIS

- PostgreSQL version 15 extensions supported on Amazon RDS
- PostgreSQL version 14 extensions supported on Amazon RDS
- PostgreSQL version 13 extensions supported on Amazon RDS
- PostgreSQL version 12 extensions supported on Amazon RDS
- PostgreSQL version 11 extensions supported on Amazon RDS
- PostgreSQL version 10 extensions supported on Amazon RDS
- PostgreSQL version 9.6.x extensions supported on Amazon RDS

Upgrading PostGIS 2 to PostGIS 3

Starting with version 3.0, the PostGIS raster functionality is now a separate extension, `postgis_raster`. This extension has its own installation and upgrade path. This removes dozens of functions, data types, and other artifacts required for raster image processing from the core `postgis` extension. That means that if your use case doesn't require raster processing, you don't need to install the `postgis_raster` extension.

In the following upgrade example, the first upgrade command extracts raster functionality into the `postgis_raster` extension. A second upgrade command is then required to upgrade `postgres_raster` to the new version.

To upgrade from PostGIS 2 to PostGIS 3

1. Identify the default version of PostGIS that's available to the PostgreSQL version on your RDS for PostgreSQL DB instance. To do so, run the following query.

   ```sql
   SELECT * FROM pg_available_extensions
   WHERE default_version > installed_version;
   
   | name    | default_version | installed_version | comment |
   +---------+-----------------+-------------------+---------|
   | postgis | 3.1.4           | 2.3.7             | PostGIS geometry and geography spatial types and functions |
   (1 row)
   ```

2. Identify the versions of PostGIS installed in each database on your RDS for PostgreSQL DB instance. In other words, query each user database as follows.

   ```sql
   SELECT e.extname AS "Name",
          e.extversion AS "Version",
          n.nspname AS "Schema",
          c.description AS "Description"
   FROM pg_catalog.pg_extension e
   LEFT JOIN pg_catalog.pg_namespace n ON n.oid = e.extnamespace
   LEFT JOIN pg_catalog.pg_description c ON c.objoid = e.oid
   AND c.classoid = 'pg_catalog.pg_extension'::pg_catalog.regclass
   WHERE e.extname LIKE '%postgis%'
   ORDER BY 1;
   
   | Name     | Version | Schema | Description |
   +----------+---------+--------+-------------|
   | postgis  | 2.3.7   | public | PostGIS geometry, geography, and raster spatial types and functions |
   (1 row)
   ```
This mismatch between the default version (PostGIS 3.1.4) and the installed version (PostGIS 2.3.7) means that you need to upgrade the PostGIS extension.

```
ALTER EXTENSION postgis UPDATE;
ALTER EXTENSION
WARNING: unpackaging raster
WARNING: PostGIS Raster functionality has been unpackaged
```

3. Run the following query to verify that the raster functionality is now in its own package.

```
SELECT
    probin,
    count(*)
FROM
    pg_proc
WHERE
    probin LIKE '%postgis%'
GROUP BY
    probin;
```

<table>
<thead>
<tr>
<th>probin</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>$libdir/rtpostgis-2.3</td>
<td>107</td>
</tr>
<tr>
<td>$libdir/postgis-3</td>
<td>487</td>
</tr>
</tbody>
</table>

The output shows that there's still a difference between versions. The PostGIS functions are version 3 (postgis-3), while the raster functions (rtpostgis) are version 2 (rtpostgis-2.3). To complete the upgrade, you run the upgrade command again, as follows.

```
postgres=> SELECT postgis_extensions_upgrade();
```

You can safely ignore the warning messages. Run the following query again to verify that the upgrade is complete. The upgrade is complete when PostGIS and all related extensions aren't marked as needing upgrade.

```
SELECT postgis_full_version();
```

4. Use the following query to see the completed upgrade process and the separately packaged extensions, and verify that their versions match.

```
SELECT
    e.extname AS "Name",
    e.extversion AS "Version",
    n.nspname AS "Schema",
    c.description AS "Description"
FROM
    pg_catalog.pg_extension e
    LEFT JOIN pg_catalog.pg_namespace n ON n.oid = e.extnamespace
    LEFT JOIN pg_catalog.pg_description c ON c.objoid = e.oid
    AND c.classoid = 'pg_catalog.pg_extension'::pg_catalog.regclass
WHERE
    e.extname LIKE '%postgis%'
ORDER BY
    1;
```

<table>
<thead>
<tr>
<th>Name</th>
<th>Version</th>
<th>Schema</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>postgis</td>
<td>3.1.5</td>
<td>public</td>
<td>PostGIS geometry, geography, and raster spatial types and functions</td>
</tr>
</tbody>
</table>
The output shows that the PostGIS 2 extension was upgraded to PostGIS 3, and both postgis and the now separate postgis_raster extension are version 3.1.5.

After this upgrade completes, if you don't plan to use the raster functionality, you can drop the extension as follows.

```sql
DROP EXTENSION postgis_raster;
```
Working with the supported foreign data wrappers for Amazon RDS for PostgreSQL

A foreign data wrapper (FDW) is a specific type of extension that provides access to external data. For example, the oracle_fdw extension allows your RDS for PostgreSQL DB cluster to work with Oracle databases. As another example, by using the PostgreSQL native postgres_fdw extension you can access data stored in PostgreSQL DB instances external to your RDS for PostgreSQL DB instance.

Following, you can find information about several supported PostgreSQL foreign data wrappers.

Topics

- Using the log_fdw extension to access the DB log using SQL (p. 2418)
- Using the postgres_fdw extension to access external data (p. 2419)
- Working with MySQL databases by using the mysql_fdw extension (p. 2420)
- Working with Oracle databases by using the oracle_fdw extension (p. 2423)
- Working with SQL Server databases by using the tds_fdw extension (p. 2426)

Using the log_fdw extension to access the DB log using SQL

RDS for PostgreSQL supports the log_fdw extension, which you can use to access your database engine log using a SQL interface. The log_fdw extension provides two functions that make it easy to create foreign tables for database logs:

- list_postgres_log_files – Lists the files in the database log directory and the file size in bytes.
- create_foreign_table_for_log_file(table_name text, server_name text, log_file_name text) – Builds a foreign table for the specified file in the current database.

All functions created by log_fdw are owned by rds_superuser. Members of the rds_superuser role can grant access to these functions to other database users.

By default, the log files are generated by Amazon RDS in stderr (standard error) format, as specified in log_destination parameter. There are only two options for this parameter, stderr and csvlog (comma-separated values, CSV). If you add the csvlog option to the parameter, Amazon RDS generates both stderr and csvlog logs. This can affect the storage capacity on your instance, so you need to be aware of the other parameters that affect log handling. For more information, see Setting the log destination (stderr, csvlog) (p. 933).

One benefit of generating csvlog logs is that the log_fdw extension lets you build foreign tables with the data neatly split into several columns. To do this, your instance needs to be associated with a custom DB parameter group so that you can change the setting for log_destination. For more information about how to do so, see Working with parameters on your RDS for PostgreSQL DB instance (p. 2313).

The following example assumes that the log_destination parameter includes csvlog.

To use the log_fdw extension

1. Get the log_fdw extension.

   postgres=> CREATE EXTENSION log_fdw;
   CREATE EXTENSION
2. Create the log server as a foreign data wrapper.

```sql
postgres=> CREATE SERVER log_server FOREIGN DATA WRAPPER log_fdw;
```

3. Select all from a list of log files.

```sql
postgres=> SELECT * FROM list_postgres_log_files() ORDER BY 1;
```

A sample response is as follows.

<table>
<thead>
<tr>
<th>file_name</th>
<th>file_size_bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>postgresql.log.2016-08-09-22.csv</td>
<td>1111</td>
</tr>
<tr>
<td>postgresql.log.2016-08-09-23.csv</td>
<td>1172</td>
</tr>
<tr>
<td>postgresql.log.2016-08-10-00.csv</td>
<td>1744</td>
</tr>
<tr>
<td>postgresql.log.2016-08-10-01.csv</td>
<td>1102</td>
</tr>
</tbody>
</table>

(4 rows)

4. Create a table with a single 'log_entry' column for the selected file.

```sql
postgres=> SELECT create_foreign_table_for_log_file('my_postgres_error_log', 'log_server', 'postgresql.log.2016-08-09-22.csv');
```

The response provides no detail other than that the table now exists.

```
(1 row)
```

5. Select a sample of the log file. The following code retrieves the log time and error message description.

```sql
postgres=> SELECT log_time, message FROM my_postgres_error_log ORDER BY 1;
```

A sample response is as follows.

<table>
<thead>
<tr>
<th>log_time</th>
<th>message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tue Aug 09 15:45:18.172 2016 PDT</td>
<td>ending log output to stderr</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.175 2016 PDT</td>
<td>database system was interrupted; last known up at 2016-08-09 22:43:34 UTC</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.223 2016 PDT</td>
<td>checkpoint record is at 0/90002E0</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.225 2016 PDT</td>
<td>redo record is at 0/90002A8; shutdown FALSE</td>
</tr>
<tr>

Using the postgres_fdw extension to access external data

You can access data in a table on a remote database server with the `postgres_fdw` extension. If you set up a remote connection from your PostgreSQL DB instance, access is also available to your read replica.
To use `postgres_fdw` to access a remote database server

1. Install the `postgres_fdw` extension.

   ```sql
   CREATE EXTENSION postgres_fdw;
   ```

2. Create a foreign data server using `CREATE SERVER`.

   ```sql
   CREATE SERVER foreign_server
   FOREIGN DATA WRAPPER postgres_fdw
   OPTIONS (host 'xxx.xx.xxx.xx', port '5432', dbname 'foreign_db');
   ```

3. Create a user mapping to identify the role to be used on the remote server.

   ```sql
   CREATE USER MAPPING FOR local_user
   SERVER foreign_server
   OPTIONS (user 'foreign_user', password 'password');
   ```

4. Create a table that maps to the table on the remote server.

   ```sql
   CREATE FOREIGN TABLE foreign_table (
       id integer NOT NULL,
       data text
   )
   SERVER foreign_server
   OPTIONS (schema_name 'some_schema', table_name 'some_table');
   ```

---

Working with MySQL databases by using the `mysql_fdw` extension

To access a MySQL-compatible database from your RDS for PostgreSQL DB instance, you can install and use the `mysql_fdw` extension. This foreign data wrapper lets you work with RDS for MySQL, Aurora MySQL, MariaDB, and other MySQL-compatible databases. The connection from RDS for PostgreSQL to the MySQL database is encrypted on a best-effort basis, depending on the client and server configurations. However, you can enforce encryption if you like. For more information, see Using encryption in transit with the extension (p. 2423).

The `mysql_fdw` extension is supported on Amazon RDS for PostgreSQL version 14.2, 13.6, and higher releases. It supports selects, inserts, updates, and deletes from an RDS for PostgreSQL DB to tables on a MySQL-compatible database instance.

Topics

- Setting up your RDS for PostgreSQL DB to use the `mysql_fdw` extension (p. 2420)
- Example: Working with an RDS for MySQL database from RDS for PostgreSQL (p. 2422)
- Using encryption in transit with the extension (p. 2423)

Setting up your RDS for PostgreSQL DB to use the `mysql_fdw` extension

Setting up the `mysql_fdw` extension on your RDS for PostgreSQL DB instance involves loading the extension in your DB instance and then creating the connection point to the MySQL DB instance. For that task, you need to have the following details about the MySQL DB instance:
• Hostname or endpoint. For an RDS for MySQL DB instance, you can find the endpoint by using the Console. Choose the Connectivity & security tab and look in the "Endpoint and port" section.
• Port number. The default port number for MySQL is 3306.
• Name of the database. The DB identifier.

You also need to provide access on the security group or the access control list (ACL) for the MySQL port, 3306. Both the RDS for PostgreSQL DB instance and the RDS for MySQL DB instance need access to port 3306. If access isn't configured correctly, when you try to connect to MySQL-compatible table you see an error message similar to the following:

```
ERROR: failed to connect to MySQL: Can't connect to MySQL server on 'hostname.aws-region.rds.amazonaws.com:3306' (110)
```

In the following procedure, you (as the rds_superuser account) create the foreign server. You then grant access to the foreign server to specific users. These users then create their own mappings to the appropriate MySQL user accounts to work with the MySQL DB instance.

To use mysql_fdw to access a MySQL database server

1. Connect to your PostgreSQL DB instance using an account that has the rds_superuser role. If you accepted the defaults when you created your RDS for PostgreSQL DB instance, the user name is postgres, and you can connect using the psql command line tool as follows:

```
psql --host=your-DB-instance.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
```

2. Install the mysql_fdw extension as follows:

```
postgres=> CREATE EXTENSION mysql_fdw;
CREATE EXTENSION
```

After the extension is installed on your RDS for PostgreSQL DB instance, you set up the foreign server that provides the connection to a MySQL database.

To create the foreign server

Perform these tasks on the RDS for PostgreSQL DB instance. The steps assume that you're connected as a user with rds_superuser privileges, such as postgres.

1. Create a foreign server in the RDS for PostgreSQL DB instance:

```
postgres=> CREATE SERVER mysql-db FOREIGN DATA WRAPPER mysql_fdw OPTIONS (host 'db-name.111122223333.aws-region.rds.amazonaws.com', port '3306');
CREATE SERVER
```

2. Grant the appropriate users access to the foreign server. These should be non-administrator users, that is, users without the rds_superuser role.

```
postgres=> GRANT USAGE ON FOREIGN SERVER mysql-db to user1;
GRANT
```

PostgreSQL users create and manage their own connections to the MySQL database through the foreign server.
Example: Working with an RDS for MySQL database from RDS for PostgreSQL

Suppose that you have a simple table on an RDS for MySQL DB instance. Your RDS for PostgreSQL users want to query (SELECT), INSERT, UPDATE, and DELETE items on that table. Assume that the mysql_fdw extension was created on your RDS for PostgreSQL DB instance, as detailed in the preceding procedure. After you connect to the RDS for PostgreSQL DB instance as a user that has rds_superuser privileges, you can proceed with the following steps.

1. On the RDS for PostgreSQL DB instance, create a foreign server:

   ```
   test=> CREATE SERVER mysqldb FOREIGN DATA WRAPPER mysql_fdw OPTIONS (host 'your-DB.aws-region.rds.amazonaws.com', port '3306');
   CREATE SERVER
   ```

2. Grant usage to a user who doesn't have rds_superuser permissions, for example, user1:

   ```
   test=> GRANT USAGE ON FOREIGN SERVER mysqldb TO user1;
   GRANT
   ```

3. Connect as user1, and then create a mapping to the MySQL user:

   ```
   test=> CREATE USER MAPPING FOR user1 SERVER mysqldb OPTIONS (username 'myuser', password 'mypassword');
   CREATE USER MAPPING
   ```

4. Create a foreign table linked to the MySQL table:

   ```
   test=> CREATE FOREIGN TABLE mytab (a int, b text) SERVER mysqldb OPTIONS (dbname 'test', table_name '');
   CREATE FOREIGN TABLE
   ```

5. Run a simple query against the foreign table:

   ```
   test=> SELECT * FROM mytab;
   a |   b
   ---+-------
   1 | apple
   (1 row)
   ```

6. You can add, change, and remove data from the MySQL table. For example:

   ```
   test=> INSERT INTO mytab values (2, 'mango');
   INSERT 0 1
   ```

   Run the SELECT query again to see the results:

   ```
   test=> SELECT * FROM mytab ORDER BY 1;
   a |   b
   ---+-------
   1 | apple
   2 | mango
   (2 rows)
   ```
Using encryption in transit with the extension

The connection to MySQL from RDS for PostgreSQL uses encryption in transit (TLS/SSL) by default. However, the connection falls back to non-encrypted when the client and server configuration differ. You can enforce encryption for all outgoing connections by specifying the REQUIRE SSL option on the RDS for MySQL user accounts. This same approach also works for MariaDB and Aurora MySQL user accounts.

For MySQL user accounts configured to REQUIRE SSL, the connection attempt fails if a secure connection can't be established.

To enforce encryption for existing MySQL database user accounts, you can use the ALTER USER command. The syntax varies, depending on the MySQL version, as shown in the following table. For more information, see ALTER USER in MySQL Reference Manual.

<table>
<thead>
<tr>
<th>MySQL 5.7, MySQL 8.0</th>
<th>MySQL 5.6</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTER USER 'user'@'%' REQUIRE SSL;</td>
<td>GRANT USAGE ON <em>.</em> to 'user'@'%' REQUIRE SSL;</td>
</tr>
</tbody>
</table>

For more information about the mysql_fdw extension, see the mysql_fdw documentation.

Working with Oracle databases by using the oracle_fdw extension

To access an Oracle database from your RDS for PostgreSQL DB instance you can install and use the oracle_fdw extension. This extension is a foreign data wrapper for Oracle databases. To learn more about this extension, see the oracle_fdw documentation.

The oracle_fdw extension is supported on RDS for PostgreSQL 12.7, 13.3, and higher versions.

Topics

- Turning on the oracle_fdw extension (p. 2423)
- Example: Using a foreign server linked to an Amazon RDS for Oracle database (p. 2423)
- Working with encryption in transit (p. 2424)
- Understanding the pg_user_mappings view and permissions (p. 2424)

Turning on the oracle_fdw extension

To use the oracle_fdw extension, perform the following procedure.

To turn on the oracle_fdw extension

- Run the following command using an account that has rds_superuser permissions.

```
CREATE EXTENSION oracle_fdw;
```

Example: Using a foreign server linked to an Amazon RDS for Oracle database

The following example shows the use of a foreign server linked to an Amazon RDS for Oracle database.
To create a foreign server linked to an RDS for Oracle database

1. Note the following on the RDS for Oracle DB instance:
   - Endpoint
   - Port
   - Database name

2. Create a foreign server.

   ```sql
   test=> CREATE SERVER oradb FOREIGN DATA WRAPPER oracle_fdw OPTIONS (dbserver '://endpoint:port/DB_name');
   CREATE SERVER
   ```

3. Grant usage to a user who doesn't have rds_superuser privileges, for example user1.

   ```sql
   test=> GRANT USAGE ON FOREIGN SERVER oradb TO user1;
   GRANT
   ```

4. Connect as user1, and create a mapping to an Oracle user.

   ```sql
   test=> CREATE USER MAPPING FOR user1 SERVER oradb OPTIONS (user 'oracleuser', password 'mypassword');
   CREATE USER MAPPING
   ```

5. Create a foreign table linked to an Oracle table.

   ```sql
   test=> CREATE FOREIGN TABLE mytab (a int) SERVER oradb OPTIONS (table 'MYTABLE');
   CREATE FOREIGN TABLE
   ```

6. Query the foreign table.

   ```sql
   test=> SELECT * FROM mytab;
   a
   ---
   1
   (1 row)
   ```

If the query reports the following error, check your security group and access control list (ACL) to make sure that both instances can communicate.

```
ERROR: connection for foreign table "mytab" cannot be established
DETAIL: ORA-12170: TNS:Connect timeout occurred
```

Working with encryption in transit

PostgreSQL-to-Oracle encryption in transit is based on a combination of client and server configuration parameters. For an example using Oracle 21c, see About the Values for Negotiating Encryption and Integrity in the Oracle documentation. The client used for oracle_fdw on Amazon RDS is configured with ACCEPTED, meaning that the encryption depends on the Oracle database server configuration.

If your database is on RDS for Oracle, see Oracle native network encryption to configure the encryption.

Understanding the pg_user_mappings view and permissions

The PostgreSQL catalog pg_user_mappings stores the mapping from an RDS for PostgreSQL user to the user on a foreign data (remote) server. Access to the catalog is restricted, but you use the

2424
pg_user_mappings view to see the mappings. In the following, you can find an example that shows how permissions apply with an example Oracle database, but this information applies more generally to any foreign data wrapper.

In the following output, you can find roles and permissions mapped to three different example users. Users rdssu1 and rdssu2 are members of the rds_superuser role, and user1 isn’t. The example uses the psql metacommand \\du to list existing roles.

<table>
<thead>
<tr>
<th>Role name</th>
<th>Attributes</th>
<th>Member of</th>
</tr>
</thead>
<tbody>
<tr>
<td>rdssu1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>rdssu2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>user1</td>
<td></td>
<td>{}</td>
</tr>
</tbody>
</table>

All users, including users that have rds_superuser privileges, are allowed to view their own user mappings (umoptions) in the pg_user_mappings table. As shown in the following example, when rdssu1 tries to obtain all user mappings, an error is raised even though rdssu1 rds_superuser privileges:

```
test=> SELECT * FROM pg_user_mapping;
ERROR: permission denied for table pg_user_mapping
```

Following are some examples.

```
test=> SET SESSION AUTHORIZATION rdssu1;
SET
test=> SELECT * FROM pg_user_mappings;
umid | srvid | srvname | umuser | usename    |            umoptions
-------+-------+---------+--------+------------+----------------------------------
16414 | 16411 | oradb   |  16412 | user1      |
16423 | 16411 | oradb   |  16421 | rdssu1     | {user=oracleuser,password=mypwd}
16424 | 16411 | oradb   |  16422 | rdssu2     | {user=oracleuser,password=mypwd}
(3 rows)
```

```
test=> SET SESSION AUTHORIZATION rdssu2;
SET
```

```
test=> SELECT * FROM pg_user_mappings;
umid | srvid | srvname | umuser | usename    |            umoptions
-------+-------+---------+--------+------------+----------------------------------
16414 | 16411 | oradb   |  16412 | user1      |
16423 | 16411 | oradb   |  16421 | rdssu1     |
16424 | 16411 | oradb   |  16422 | rdssu2     | {user=oracleuser,password=mypwd}
(3 rows)
```

```
test=> SET SESSION AUTHORIZATION user1;
SET
```

```
test=> SELECT * FROM pg_user_mappings;
umid | srvid | srvname | umuser | usename    |           umoptions
-------+-------+---------+--------+------------+--------------------------------
16414 | 16411 | oradb   |  16412 | user1      | {user=oracleuser,password=mypwd}
16423 | 16411 | oradb   |  16421 | rdssu1     |
16424 | 16411 | oradb   |  16422 | rdssu2     |
(3 rows)
```
Because of implementation differences between `information_schema._pg_user_mappings` and `pg_catalog.pg_user_mappings`, a manually created `rds_superuser` requires additional permissions to view passwords in `pg_catalog.pg_user_mappings`.

No additional permissions are required for an `rds_superuser` to view passwords in `information_schema._pg_user_mappings`.

Users who don't have the `rds_superuser` role can view passwords in `pg_user_mappings` only under the following conditions:

- The current user is the user being mapped and owns the server or holds the `USAGE` privilege on it.
- The current user is the server owner and the mapping is for PUBLIC.

**Working with SQL Server databases by using the `tds_fdw` extension**

You can use the PostgreSQL `tds_fdw` extension to access databases that support the tabular data stream (TDS) protocol, such as Sybase and Microsoft SQL Server databases. This foreign data wrapper lets you connect from your RDS for PostgreSQL DB instance to databases that use the TDS protocol, including Amazon RDS for Microsoft SQL Server. For more information, see [tds-fdw/tds_fdw](https://github.com/) documentation on GitHub.

The `tds_fdw` extension is supported on Amazon RDS for PostgreSQL version 14.2, 13.6, and higher releases.

**Setting up your RDS for PostgreSQL DB to use the `tds_fdw` extension**

In the following procedures, you can find an example of setting up and using the `tds_fdw` with an RDS for PostgreSQL DB instance. Before you can connect to a SQL Server database using `tds_fdw`, you need to get the following details for the instance:

- Hostname or endpoint. For an RDS for SQL Server DB instance, you can find the endpoint by using the Console. Choose the Connectivity & security tab and look in the "Endpoint and port" section.
- Port number. The default port number for Microsoft SQL Server is 1433.
- Name of the database. The DB identifier.

You also need to provide access on the security group or the access control list (ACL) for the SQL Server port, 1433. Both the RDS for PostgreSQL DB instance and the RDS for SQL Server DB instance need access to port 1433. If access isn't configured correctly, when you try to query the Microsoft SQL Server you see the following error message:

```
ERROR: DB-Library error: DB #: 20009, DB Msg: Unable to connect: Adaptive Server is unavailable or does not exist (mssql2019.aws-region.rds.amazonaws.com), OS #: 0, OS Msg: Success, Level: 9
```

**To use `tds_fdw` to connect to a SQL Server database**

1. Connect to your PostgreSQL DB instance using an account that has the `rds_superuser` role:

   ```
   psql --host=your-DB-instance.aws-region.rds.amazonaws.com --port=5432 --username=test --password
   ```

2. Install the `tds_fdw` extension:
After the extension is installed on your RDS for PostgreSQL DB instance, you set up the foreign server.

**To create the foreign server**

Perform these tasks on the RDS for PostgreSQL DB instance using an account that has `rds_superuser` privileges.

1. Create a foreign server in the RDS for PostgreSQL DB instance:

   ```sql
   test=> CREATE SERVER sqlserverdb FOREIGN DATA WRAPPER tds_fdw OPTIONS (servername 'mssql2019.aws-region.rds.amazonaws.com', port '1433', database 'tds_fdw_testing');
   CREATE SERVER
   ```

   To access non-ASCII data on the SQLServer side, create a server link with the `character_set` option in the RDS for PostgreSQL DB instance:

   ```sql
   test=> CREATE SERVER sqlserverdb FOREIGN DATA WRAPPER tds_fdw OPTIONS (servername 'mssql2019.aws-region.rds.amazonaws.com', port '1433', database 'tds_fdw_testing', character_set 'UTF-8');
   CREATE SERVER
   ```

2. Grant permissions to a user who doesn't have `rds_superuser` role privileges, for example, user1:

   ```sql
   test=> GRANT USAGE ON FOREIGN SERVER sqlserverdb TO user1;
   ```

3. Connect as user1 and create a mapping to a SQL Server user:

   ```sql
   test=> CREATE USER MAPPING FOR user1 SERVER sqlserverdb OPTIONS (username 'sqlserveruser', password 'password');
   CREATE USER MAPPING
   ```

4. Create a foreign table linked to a SQL Server table:

   ```sql
   test=> CREATE FOREIGN TABLE mytab (a int) SERVER sqlserverdb OPTIONS (table 'MYTABLE');
   CREATE FOREIGN TABLE
   ```

5. Query the foreign table:

   ```sql
   test=> SELECT * FROM mytab;
   a
   ---
   1
   (1 row)
   ```

**Using encryption in transit for the connection**

The connection from RDS for PostgreSQL to SQL Server uses encryption in transit (TLS/SSL) depending on the SQL Server database configuration. If the SQL Server isn't configured for encryption, the RDS for PostgreSQL client making the request to the SQL Server database falls back to unencrypted.

You can enforce encryption for the connection to RDS for SQL Server DB instances by setting the `rds.force_ssl` parameter. To learn how, see [Forcing connections to your DB instance to use SSL](#). For
more information about SSL/TLS configuration for RDS for SQL Server, see Using SSL with a Microsoft SQL Server DB instance.
Working with Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL is an open source development kit for building PostgreSQL extensions. It allows you to build high performance PostgreSQL extensions and safely run them on your RDS for PostgreSQL DB instance. By using Trusted Language Extensions (TLE) for PostgreSQL, you can create PostgreSQL extensions that follow the documented approach for extending PostgreSQL functionality. For more information, see Packaging Related Objects into an Extension in the PostgreSQL documentation.

One key benefit of TLE is that you can use it in environments that don’t provide access to the file system underlying the PostgreSQL instance. Previously, installing a new extension required access to the file system. TLE removes this constraint. It provides a development environment for creating new extensions for any PostgreSQL database, including those running on your RDS for PostgreSQL DB instances.

TLE is designed to prevent access to unsafe resources for the extensions that you create using TLE. Its runtime environment limits the impact of any extension defect to a single database connection. TLE also gives database administrators fine-grained control over who can install extensions, and it provides a permissions model for running them.

TLE is supported on the following RDS for PostgreSQL versions:

- Version 15.2 and higher 15 versions.
- Version 14.5 and higher 14 versions.
- Version 13.12 and higher 13 versions.

The Trusted Language Extensions development environment and runtime are packaged as the pg_tle PostgreSQL extension, version 1.0.1. It supports creating extensions in JavaScript, Perl, Tcl, PL/pgSQL, and SQL. You install the pg_tle extension in your RDS for PostgreSQL DB instance in the same way that you install other PostgreSQL extensions. After the pg_tle is set up, developers can use it to create new PostgreSQL extensions, known as TLE extensions.

In the following topics, you can find information about how to set up Trusted Language Extensions and how to get started creating your own TLE extensions.

Topics

- Terminology (p. 2430)
- Requirements for using Trusted Language Extensions for PostgreSQL (p. 2430)
- Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance (p. 2432)
- Overview of Trusted Language Extensions for PostgreSQL (p. 2435)
- Creating TLE extensions for RDS for PostgreSQL (p. 2436)
- Dropping your TLE extensions from a database (p. 2439)
- Uninstalling Trusted Language Extensions for PostgreSQL (p. 2440)
- Using PostgreSQL hooks with your TLE extensions (p. 2441)
- Using Custom Data Types in TLE (p. 2445)
- Functions reference for Trusted Language Extensions for PostgreSQL (p. 2445)
- Hooks reference for Trusted Language Extensions for PostgreSQL (p. 2455)
Terminology

To help you better understand Trusted Language Extensions, view the following glossary for terms used in this topic.

Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL is the official name of the open source development kit that's packaged as the pg_tle extension. It's available for use on any PostgreSQL system. For more information, see aws/pg_tle on GitHub.

Trusted Language Extensions

Trusted Language Extensions is the short name for Trusted Language Extensions for PostgreSQL. This shortened name and its abbreviation (TLE) are also used in this documentation.

tested language

A trusted language is a programming or scripting language that has specific security attributes. For example, trusted languages typically restrict access to the file system, and they limit use of specified networking properties. The TLE development kit is designed to support trusted languages. PostgreSQL supports several different languages that are used to create trusted or untrusted extensions. For an example, see Trusted and Untrusted PL/Perl in the PostgreSQL documentation. When you create an extension using Trusted Language Extensions, the extension inherently uses trusted language mechanisms.

TLE extension

A TLE extension is a PostgreSQL extension that's been created by using the Trusted Language Extensions (TLE) development kit.

Requirements for using Trusted Language Extensions for PostgreSQL

The following are requirements for setting up and using the TLE development kit.

- **RDS for PostgreSQL versions** – Trusted Language Extensions is supported on RDS for PostgreSQL versions 13.12 and higher 13 versions, 14.5 and higher 14 versions, and 15.2 and higher versions only.
  - If you need to upgrade your RDS for PostgreSQL instance, see Upgrading the PostgreSQL DB engine for Amazon RDS (p. 2214).
  - If you don't yet have an Amazon RDS DB instance running PostgreSQL, you can create one. For more information, see RDS for PostgreSQL DB instance, see Creating and connecting to a PostgreSQL DB instance (p. 235).
- **Requires rds_superuser privileges** – To set up and configure the pg_tle extension, your database user role must have the permissions of the rds_superuser role. By default, this role is granted to the postgres user that creates the RDS for PostgreSQL DB instance.
- **Requires a custom DB parameter group** – Your RDS for PostgreSQL DB instance must be configured with a custom DB parameter group.
  - If your RDS for PostgreSQL DB instance isn't configured with a custom DB parameter group, you should create one and associate it with your RDS for PostgreSQL DB instance. For a short summary of steps, see Creating and applying a custom DB parameter group (p. 2431).
  - If your RDS for PostgreSQL DB instance is already configured using a custom DB parameter group, you can set up Trusted Language Extensions. For details, see Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance (p. 2432).
Creating and applying a custom DB parameter group

Use the following steps to create a custom DB parameter group and configure your RDS for PostgreSQL DB instance to use it.

**Console**

To create a custom DB parameter group and use it with your RDS for PostgreSQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Parameter groups from the Amazon RDS menu.
3. Choose Create parameter group.
4. In the **Parameter group details** page, enter the following information.
   - For **Parameter group family**, choose postgres14.
   - For **Type**, choose DB Parameter Group.
   - For **Group name**, give your parameter group a meaningful name in the context of your operations.
   - For **Description**, enter a useful description so that others on your team can easily find it.
5. Choose **Create**. Your custom DB parameter group is created in your AWS Region. You can now modify your RDS for PostgreSQL DB instance to use it by following the next steps.
6. Choose Databases from the Amazon RDS menu.
7. Choose the RDS for PostgreSQL DB instance that you want to use with TLE from among those listed, and then choose **Modify**.
8. In the Modify DB instance settings page, find **Database options** in the Additional configuration section and choose your custom DB parameter group from the selector.
9. Choose **Continue** to save the change.
10. Choose **Apply immediately** so that you can continue setting up the RDS for PostgreSQL DB instance to use TLE.

To continue setting up your system for Trusted Language Extensions, see Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance (p. 2432).

For more information working with DB parameter groups, see Working with DB parameter groups (p. 349).

**AWS CLI**

You can avoid specifying the --region argument when you use CLI commands by configuring your AWS CLI with your default AWS Region. For more information, see Configuration basics in the AWS Command Line Interface User Guide.

To create a custom DB parameter group and use it with your RDS for PostgreSQL DB instance

1. Use the create-db-parameter-group AWS CLI command to create a custom DB parameter group based on postgres14 for your AWS Region.

   For Linux, macOS, or Unix:

   ```bash
   aws rds create-db-parameter-group \
   --region aws-region \
   --db-parameter-group-name custom-params-for-pg-tle \
   --db-parameter-group-family postgres14 \
   --description "My custom DB parameter group for Trusted Language Extensions"
   ```
Setting up Trusted Language Extensions

For Windows:

```
aws rds create-db-parameter-group ^
  --region aws-region ^
  --db-parameter-group-name custom-params-for-pg-tle ^
  --db-parameter-group-family postgres14 ^
  --description "My custom DB parameter group for Trusted Language Extensions"
```

Your custom DB parameter group is available in your AWS Region, so you can modify RDS for PostgreSQL DB instance to use it.

2. Use the modify-db-instance AWS CLI command to apply your custom DB parameter group to your RDS for PostgreSQL DB instance. This command immediately reboots the active instance.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --region aws-region \
  --db-instance-identifier your-instance-name \
  --db-parameter-group-name custom-params-for-pg-tle \
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --region aws-region ^
  --db-instance-identifier your-instance-name ^
  --db-parameter-group-name custom-params-for-pg-tle ^
  --apply-immediately
```

To continue setting up your system for Trusted Language Extensions, see Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance (p. 2432).

For more information, see Working with parameter groups (p. 347).

**Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance**

The following steps assume that your RDS for PostgreSQL DB instance is associated with a custom DB parameter group. You can use the AWS Management Console or the AWS CLI for these steps.

When you set up Trusted Language Extensions in your RDS for PostgreSQL DB instance, you install it in a specific database for use by the database users who have permissions on that database.

**Console**

To set up Trusted Language Extensions

Perform the following steps using an account that's a member of the rds_superuser group (role).

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose your RDS for PostgreSQL DB instance.
3. Open the Configuration tab for your RDS for PostgreSQL DB instance. Among the Instance details, find the Parameter group link.
4. Choose the link to open the custom parameters associated with your RDS for PostgreSQL DB instance.
5. In the **Parameters** search field, type `shared_pre` to find the `shared_preload_libraries` parameter.
6. Choose **Edit parameters** to access the property values.
7. Add `pg_tle` to the list in the **Values** field. Use a comma to separate items in the list of values.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Cancel editing</th>
<th>Preview changes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Values</td>
<td>Allowed values</td>
</tr>
<tr>
<td>shared_preload_libraries</td>
<td>pg_tle</td>
<td>auto_explain, orafce, pgaudit, pglogical, pg_bigm, pg_cron, pg_hint_plan, pg_prewarm, pg_similarity, pg_stat_statements, pg_tle, pg_transport, piprofiler</td>
</tr>
</tbody>
</table>

8. Reboot the RDS for PostgreSQL DB instance so that your change to the `shared_preload_libraries` parameter takes effect.
9. When the instance is available, verify that `pg_tle` has been initialized. Use `psql` to connect to the RDS for PostgreSQL DB instance, and then run the following command.

```
SHOW shared_preload_libraries;
shared_preload_libraries
--------------------------
rdsutils, pg_tle          
(1 row)
```

10. With the `pg_tle` extension initialized, you can now create the extension.

```
CREATE EXTENSION pg_tle;
```

You can verify that the extension is installed by using the following `psql` metacommand.

```
labdb=> \dx
List of installed extensions
-----------------------------------------
Name | Version | Schema | Description
--------------------------+----------+--------+--------------------------------------------
pg_tle | 1.0.1 | pgtle | Trusted-Language Extensions for PostgreSQL
plpgsql | 1.0 | pg_catalog | PL/pgSQL procedural language
```

11. Grant the `pgtle_admin` role to the primary user name that you created for your RDS for PostgreSQL DB instance when you set it up. If you accepted the default, it's `postgres`.

```
labdb=> GRANT pgtle_admin TO postgres;
GRANT ROLE
```

You can verify that the grant has occurred by using the `psql` metacommand as shown in the following example. Only the `pgtle_admin` and `postgres` roles are shown in the output. For more information, see [Understanding the `rds_superuser` role](p. 2288).

```
labdb=> \du
List of roles
```
Amazon Relational Database Service User Guide
Setting up Trusted Language Extensions

<table>
<thead>
<tr>
<th>Role name</th>
<th>Attributes</th>
<th>Member of</th>
</tr>
</thead>
<tbody>
<tr>
<td>pgtle_admin</td>
<td>Cannot login</td>
<td>{}</td>
</tr>
<tr>
<td>postgres</td>
<td>Create role, Create DB, Password valid until infinity</td>
<td>{rds_superuser, pgtle_admin}</td>
</tr>
</tbody>
</table>

12. Close the psql session using the \q metacommand.

\q

To get started creating TLE extensions, see Example: Creating a trusted language extension using SQL (p. 2436).

AWS CLI

You can avoid specifying the --region argument when you use CLI commands by configuring your AWS CLI with your default AWS Region. For more information, see Configuration basics in the AWS Command Line Interface User Guide.

To set up Trusted Language Extensions

1. Use the modify-db-parameter-group AWS CLI command to add pg_tle to the shared_preload_libraries parameter.

```bash
aws rds modify-db-parameter-group \
  --db-parameter-group-name custom-param-group-name \
  --parameters "ParameterName=shared_preload_libraries,ParameterValue=pg_tle,ApplyMethod=pending-reboot" \
  --region aws-region
```

2. Use the reboot-db-instance AWS CLI command to reboot the RDS for PostgreSQL DB instance and initialize the pg_tle library.

```bash
aws rds reboot-db-instance \
  --db-instance-identifier your-instance \
  --region aws-region
```

3. When the instance is available, you can verify that pg_tle has been initialized. Use psql to connect to the RDS for PostgreSQL DB instance, and then run the following command.

```sql
SHOW shared_preload_libraries;
shared_preload_libraries
--------------------
rdsutils,pg_tle
(1 row)
```

With pg_tle initialized, you can now create the extension.

```sql
CREATE EXTENSION pg_tle;
```

4. Grant the pgtle_admin role to the primary user name that you created for your RDS for PostgreSQL DB instance when you set it up. If you accepted the default, it's postgres.

```sql
GRANT pgtle_admin TO postgres;
GRANT ROLE
```

5. Close the psql session as follows.

```
2434```
To get started creating TLE extensions, see Example: Creating a trusted language extension using SQL (p. 2436).

Overview of Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL is a PostgreSQL extension that you install in your RDS for PostgreSQL DB instance in the same way that you set up other PostgreSQL extensions. In the following image of an example database in the pgAdmin client tool, you can view some of the components that comprise the `pg_tle` extension.

You can see the following details.

1. The Trusted Language Extensions (TLE) for PostgreSQL development kit is packaged as the `pg_tle` extension. As such, `pg_tle` is added to the available extensions for the database in which it’s installed.
2. TLE has its own schema, `pgtle`. This schema contains helper functions (3) for installing and managing the extensions that you create.
3. TLE provides over a dozen helper functions for installing, registering, and managing your extensions. To learn more about these functions, see Functions reference for Trusted Language Extensions for PostgreSQL (p. 2445).
Other components of the pg_tle extension include the following:

- **The pgtle_admin role** – The pgtle_admin role is created when the pg_tle extension is installed. This role is privileged and should be treated as such. We strongly recommend that you follow the principle of least privilege when granting the pgtle_admin role to database users. In other words, grant the pgtle_admin role only to database users that are allowed to create, install, and manage new TLE extensions, such as postgres.

- **The pgtle.feature_info table** – The pgtle.feature_info table is a protected table that contains information about your TLEs, hooks, and the custom stored procedures and functions that they use. If you have pgtle_admin privileges, you use the following Trusted Language Extensions functions to add and update that information in the table.
  - `pgtle.register_feature (p. 2449)`
  - `pgtle.register_feature_if_not_exists (p. 2450)`
  - `pgtle.unregister_feature (p. 2454)`
  - `pgtle.unregister_feature_if_exists (p. 2454)`

### Creating TLE extensions for RDS for PostgreSQL

You can install any extensions that you create with TLE in any RDS for PostgreSQL DB instance that has the pg_tle extension installed. The pg_tle extension is scoped to the PostgreSQL database in which it's installed. The extensions that you create using TLE are scoped to the same database.

Use the various pgtle functions to install the code that makes up your TLE extension. The following Trusted Language Extensions functions all require the pgtle_admin role.

- `pgtle.install_extension (p. 2448)`
- `pgtle.install_update_path (p. 2448)`
- `pgtle.register_feature (p. 2449)`
- `pgtle.register_feature_if_not_exists (p. 2450)`
- `pgtle.set_default_version (p. 2450)`
- `pgtle.uninstall_extension(name) (p. 2451)`
- `pgtle.uninstall_extension(name, version) (p. 2452)`
- `pgtle.uninstall_extension_if_exists (p. 2452)`
- `pgtle.uninstall_update_path (p. 2453)`
- `pgtle.uninstall_update_path_if_exists (p. 2453)`
- `pgtle.unregister_feature (p. 2454)`
- `pgtle.unregister_feature_if_exists (p. 2454)`

### Example: Creating a trusted language extension using SQL

The following example shows you how to create a TLE extension named pg_distance that contains a few SQL functions for calculating distances using different formulas. In the listing, you can find the function for calculating the Manhattan distance and the function for calculating the Euclidean distance. For more information about the difference between these formulas, see [Taxicab geometry](https://en.wikipedia.org/wiki/Taxicab_geometry) and [Euclidean geometry](https://en.wikipedia.org/wiki/Euclidean_geometry) in Wikipedia.

You can use this example in your own RDS for PostgreSQL DB instance if you have the pg_tle extension set up as detailed in Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance (p. 2432).

**Note**

You need to have the privileges of the pgtle_admin role to follow this procedure.
To create the example TLE extension

The following steps use an example database named labdb. This database is owned by the postgres primary user. The postgres role also has the permissions of the pgtle_admin role.

1. Use psql to connect to RDS for PostgreSQL DB instance.

   ```
   psql --host=db-instance-123456789012.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
   ```

2. Create a TLE extension named pg_distance by copying the following code and pasting it into your psql session console.

   ```
   SELECT pgtle.install_extension
   ( 'pg_distance',
     '0.1',
     'Distance functions for two points',
     $pg_tle_$
     CREATE FUNCTION dist(x1 float8, y1 float8, x2 float8, y2 float8, norm int)
     RETURNS float8
     AS $$
     SELECT (abs(x2 - x1) ^ norm + abs(y2 - y1) ^ norm) ^ (1::float8 / norm);
     $$ LANGUAGE SQL;

     CREATE FUNCTION manhattan_dist(x1 float8, y1 float8, x2 float8, y2 float8)
     RETURNS float8
     AS $$
     SELECT dist(x1, y1, x2, y2, 1);
     $$ LANGUAGE SQL;

     CREATE FUNCTION euclidean_dist(x1 float8, y1 float8, x2 float8, y2 float8)
     RETURNS float8
     AS $$
     SELECT dist(x1, y1, x2, y2, 2);
     $$ LANGUAGE SQL;
   $pg_tle_$
   );
   ```

   You see the output, such as the following.

   ```
   install_extension
   ------------------
t
   (1 row)
   ```

   The artifacts that make up the pg_distance extension are now installed in your database. These artifacts include the control file and the code for the extension, which are items that need to be present so that the extension can be created using the CREATE EXTENSION command. In other words, you still need to create the extension to make its functions available to database users.

3. To create the extension, use the CREATE EXTENSION command as you do for any other extension. As with other extensions, the database user needs to have the CREATE permissions in the database.

   ```
   CREATE EXTENSION pg_distance;
   ```

4. To test the pg_distance TLE extension, you can use it to calculate the Manhattan distance between four points.

   ```
   labdb=> SELECT manhattan_dist(1, 1, 5, 5);
   2437
   ```
To calculate the Euclidean distance between the same set of points, you can use the following.

```
labdb=> SELECT euclidean_dist(1, 1, 5, 5);
5.656854249492381
```

The `pg_distance` extension loads the functions in the database and makes them available to any users with permissions on the database.

### Modifying your TLE extension

To improve query performance for the functions packaged in this TLE extension, add the following two PostgreSQL attributes to their specifications.

- **IMMUTABLE** – The IMMUTABLE attribute ensures that the query optimizer can use optimizations to improve query response times. For more information, see [Function Volatility Categories](#) in the PostgreSQL documentation.
- **PARALLEL SAFE** – The PARALLEL SAFE attribute is another attribute that allows PostgreSQL to run the function in parallel mode. For more information, see [CREATE FUNCTION](#) in the PostgreSQL documentation.

In the following example, you can see how the `pgtle.install_update_path` function is used to add these attributes to each function to create a version 0.2 of the `pg_distance` TLE extension. For more information about this function, see [pgtle.install_update_path](#). You need to have the `pgtle_admin` role to perform this task.

### To update an existing TLE extension and specify the default version

1. Connect to RDS for PostgreSQL DB instance using `psql` or another client tool, such as pgAdmin.

```sql
psql --host=db-instance-123456789012.aws-region.rds.amazonaws.com
      --port=5432 --username=postgres --password --dbname=labdb
```

2. Modify the existing TLE extension by copying the following code and pasting it into your `psql` session console.

```sql
SELECT pgtle.install_update_path
('pg_distance',
 '0.1',
 '0.2',
$_pg_tle_$
CREATE OR REPLACE FUNCTION dist(x1 float8, y1 float8, x2 float8, y2 float8, norm int)
RETURNS float8
AS $$
SELECT (abs(x2 - x1) ^ norm + abs(y2 - y1) ^ norm) ^ (1::float8 / norm);
$$ LANGUAGE SQL IMMUTABLE PARALLEL SAFE;

CREATE OR REPLACE FUNCTION manhattan_dist(x1 float8, y1 float8, x2 float8, y2 float8)
RETURNS float8
AS $$
SELECT dist(x1, y1, x2, y2, 1);
$$ LANGUAGE SQL IMMUTABLE PARALLEL SAFE;
```
CREATE OR REPLACE FUNCTION euclidean_dist(x1 float8, y1 float8, x2 float8, y2 float8)  
RETURNS float8  
AS $$  
SELECT dist(x1, y1, x2, y2, 2);  
$$ LANGUAGE SQL IMMUTABLE PARALLEL SAFE;  
$$_pg_tle_$$;

You see a response similar to the following.

install_update_path  
---------------------  
t  
(1 row)

You can make this version of the extension the default version, so that database users don’t have to specify a version when they create or update the extension in their database.

3. To specify that the modified version (version 0.2) of your TLE extension is the default version, use the `pgtle.set_default_version` function as shown in the following example.

```sql
SELECT pgtle.set_default_version('pg_distance', '0.2');
```

For more information about this function, see `pgtle.set_default_version` (p. 2450).

4. With the code in place, you can update the installed TLE extension in the usual way, by using `ALTER EXTENSION` ... `UPDATE` command, as shown here:

```sql
ALTER EXTENSION pg_distance UPDATE;
```

## Dropping your TLE extensions from a database

You can drop your TLE extensions by using the `DROP EXTENSION` command in the same way that you do for other PostgreSQL extensions. Dropping the extension doesn’t remove the installation files that make up the extension, which allows users to re-create the extension. To remove the extension and its installation files, do the following two-step process.

### To drop the TLE extension and remove its installation files

1. Use `psql` or another client tool to connect to the RDS for PostgreSQL DB instance.

```sql
psql --host=.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=dbname
```

2. Drop the extension as you would any PostgreSQL extension.

```sql
DROP EXTENSION your-TLE-extension
```

For example, if you create the `pg_distance` extension as detailed in *Example: Creating a trusted language extension using SQL* (p. 2436), you can drop the extension as follows.

```sql
DROP EXTENSION pg_distance;
```

You see output confirming that the extension has been dropped, as follows.
Uninstalling Trusted Language Extensions

If you no longer want to create your own TLE extensions using TLE, you can drop the pg_tle extension and remove all artifacts. This action includes dropping any TLE extensions in the database and dropping the pgtle schema.

To drop the pg_tle extension and its schema from a database

1. Use psql or another client tool to connect to the RDS for PostgreSQL DB instance.

```
psql --host=.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --dbname=dbname
```

2. Drop the pg_tle extension from the database. If the database has your own TLE extensions still running in the database, you need to also drop those extensions. To do so, you can use the CASCADE keyword, as shown in the following.

```
DROP EXTENSION pg_tle CASCADE;
```

If the pg_tle extension isn't still active in the database, you don't need to use the CASCADE keyword.

3. Drop the pgtle schema. This action removes all the management functions from the database.

```
DROP SCHEMA pgtle CASCADE;
```

The command returns the following when the process completes.

```
2440
```
Using PostgreSQL hooks with your TLE extensions

A hook is a callback mechanism available in PostgreSQL that allows developers to call custom functions or other routines during regular database operations. The TLE development kit supports PostgreSQL hooks so that you can integrate custom functions with PostgreSQL behavior at runtime. For example, you can use a hook to associate the authentication process with your own custom code, or to modify the query planning and execution process for your specific needs.

Your TLE extensions can use hooks. If a hook is global in scope, it applies across all databases. Therefore, if your TLE extension uses a global hook, then you need to create your TLE extension in all databases that your users can access.

When you use the pg_tle extension to build your own Trusted Language Extensions, you can use the available hooks from a SQL API to build out the functions of your extension. You should register any hooks with pg_tle. For some hooks, you might also need to set various configuration parameters. For example, the passcode check hook can be set to on, off, or require. For more information about specific requirements for available pg_tle hooks, see Hooks reference for Trusted Language Extensions for PostgreSQL (p. 2455).

Example: Creating an extension that uses a PostgreSQL hook

The example discussed in this section uses a PostgreSQL hook to check the password provided during specific SQL operations and prevents database users from setting their passwords to any of those contained in the password_check.bad_passwords table. The table contains the top-ten most commonly used, but easily breakable choices for passwords.

To set up this example in your RDS for PostgreSQL DB instance, you must have already installed Trusted Language Extensions. For details, see Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance (p. 2432).

To set up the password-check hook example

1. Use psql to connect to RDS for PostgreSQL DB instance.

   ```
   psql --host=db-instance-123456789012.aws-region.rds.amazonaws.com
   --port=5432 --username=postgres --password --dbname=labdb
   ```

2. Copy the code from the Password-check hook code listing (p. 2444) and paste it into your database.

   ```
   SELECT pgtle.install_extension (  
       'my_password_check_rules',  
       '1.0',  
       'Do not let users use the 10 most commonly used passwords',  
       $pgtle$_
   CREATE SCHEMA password_check;  
   REVOKE ALL ON SCHEMA password_check FROM PUBLIC;  
   GRANT USAGE ON SCHEMA password_check TO PUBLIC;  
   CREATE TABLE password_check.bad_passwords (plaintext) AS
   ```
VALUES
    ('123456'),
    ('password'),
    ('12345678'),
    ('qwert'),
    ('123456789'),
    ('12345'),
    ('1234'),
    ('111111'),
    ('1234567'),
    ('dragon');
CREATE UNIQUE INDEX ON password_check.bad_passwords (plaintext);

CREATE FUNCTION password_check.passcheck_hook(username text, password text,
    password_type pgtle.password_types, valid_until timestamptz, valid_null boolean)
    RETURNS void AS $$
    DECLARE
        invalid bool := false;
    BEGIN
        IF password_type = 'PASSWORD_TYPE_MD5' THEN
            SELECT EXISTS(
                SELECT 1
                FROM password_check.bad_passwords bp
                WHERE ('md5' || md5(bp.plaintext || username)) = password
            ) INTO invalid;
            IF invalid THEN
                RAISE EXCEPTION 'Cannot use passwords from the common password dictionary';
            END IF;
        ELSIF password_type = 'PASSWORD_TYPE_PLAINTEXT' THEN
            SELECT EXISTS(
                SELECT 1
                FROM password_check.bad_passwords bp
                WHERE bp.plaintext = password
            ) INTO invalid;
            IF invalid THEN
                RAISE EXCEPTION 'Cannot use passwords from the common password dictionary';
            END IF;
        END IF;
    END
    $$ LANGUAGE plpgsql SECURITY DEFINER;

GRANT EXECUTE ON FUNCTION password_check.passcheck_hook TO PUBLIC;
SELECT pgtle.register_feature('password_check.passcheck_hook', 'passcheck');
$_pgtle_$

When the extension has been loaded into your database, you see the output such as the following.

install_extension
-------------------
t
(1 row)

3. While still connected to the database, you can now create the extension.

CREATE EXTENSION my_password_check_rules;

4. You can confirm that the extension has been created in the database by using the following psql metacommand.

\dx
5. Open another terminal session to work with the AWS CLI. You need to modify your custom DB parameter group to turn on the password-check hook. To do so, use the `modify-db-parameter-group` CLI command as shown in the following example.

```bash
aws rds modify-db-parameter-group \
  --region aws-region \
  --db-parameter-group-name your-custom-parameter-group \
  --parameters "ParameterName=pgtle.enable_password_check,ParameterValue=on,ApplyMethod=immediate"
```

When the parameter is successfully turned on, you see the output such as the following.

```json
{
  "DBParameterGroupName": "docs-lab-parameters-for-tle"
}
```

It might take a few minutes for the change to the parameter group setting to take effect. This parameter is dynamic, however, so you don't need to restart the RDS for PostgreSQL DB instance for the setting to take effect.

6. Open the `psql` session and query the database to verify that the password_check hook has been turned on.

```sql
labdb=> SHOW pgtle.enable_password_check;
pgtle.enable_password_check
-----------------------------
on
(1 row)
```

The password-check hook is now active. You can test it by creating a new role and using one of the bad passwords, as shown in the following example.

```sql
CREATE ROLE test_role PASSWORD 'password';
ERROR:  Cannot use passwords from the common password dictionary
CONTEXT:  PL/pgSQL function password_check.passcheck_hook(text,text,pgtle.password_types,timestamptz with time zone,boolean) line 21 at RAISE
SQL statement "SELECT password_check.passcheck_hook(  
  $1::pg_catalog.text,  
  $2::pg_catalog.text,  
  $3::pgtle.password_types,  
  $4::pg_catalog.timestamptz,  
  $5::pg_catalog.bool)"
```

The output has been formatted for readability.

The following example shows that `pgsql` interactive metacommand `\password` behavior is also affected by the password_check hook.
postgres=> SET password_encryption TO 'md5';
SET
postgres=> \password
Enter new password for user "postgres":*****
Enter it again:*****
ERROR:  Cannot use passwords from the common password dictionary
CONTEXT:  PL/pgSQL function
password_check.passcheck_hook(text,text,pgtle.password_types,timestamptz,boolean) line 12 at RAISE
SQL statement "SELECT password_check.passcheck_hook($1::pg_catalog.text, $2::pg_catalog.text, $3::pgtle.password_types, $4::pg_catalog.timestamptz, $5::pg_catalog.bool)"

You can drop this TLE extension and uninstall its source files if you want. For more information, see Dropping your TLE extensions from a database (p. 2439).

Password-check hook code listing

The example code shown here defines the specification for the my_password_check_rules TLE extension. When you copy this code and paste it into your database, the code for the my_password_check_rules extension is loaded into the database, and the password_check hook is registered for use by the extension.

```sql
SELECT pgtle.install_extension ('my_password_check_rules', '1.0', 'Do not let users use the 10 most commonly used passwords',
$pgtle$
CREATE SCHEMA password_check;
REVOKE ALL ON SCHEMA password_check FROM PUBLIC;
GRANT USAGE ON SCHEMA password_check TO PUBLIC;
CREATE TABLE password_check.bad_passwords (plaintext) AS
VALUES
('123456'),
('password'),
('12345678'),
('qwerty'),
('123456789'),
('12345'),
('1234'),
('111111'),
('1234567'),
('dragon');
CREATE UNIQUE INDEX ON password_check.bad_passwords (plaintext);
CREATE FUNCTION password_check.passcheck_hook(username text, password text, password_type pgtle.password_types, valid_until timestamptz, valid_null boolean)
RETURNS void AS $$
DECLARE
invalid bool := false;
BEGIN
IF password_type = 'PASSWORD_TYPE_MD5' THEN
SELECT EXISTS(
SELECT 1
FROM password_check.bad_passwords bp
WHERE ('md5' || md5(bp.plaintext || username)) = password
) INTO invalid;
ELSEIF password_type = 'PASSWORD_TYPE_PLAINTEXT' THEN
RAISE EXCEPTION 'Cannot use passwords from the common password dictionary';
END IF;
END IF;
SELECT EXISTS(
```

2444
SELECT 1
FROM password_check.bad_passwords bp
WHERE bp.plaintext = password
) INTO invalid;
IF invalid THEN
    RAISE EXCEPTION 'Cannot use passwords from the common password
dictionary';
END IF;
END IF;
END
$$ LANGUAGE plpgsql SECURITY DEFINER;

GRANT EXECUTE ON FUNCTION password_check.passcheck_hook TO PUBLIC;

SELECT pgtle.register_feature('password_check.passcheck_hook', 'passcheck');
$_pgtle_$

Using Custom Data Types in TLE

PostgreSQL supports commands to register new base types (also known as scalar types) for efficiently
handling complex data structures in your database. A base type allows you to customize how the data
is stored internally, and how to convert it to and from an external textual representation. These custom
data types are helpful when extending PostgreSQL to support functional domains where a built-in type
such as number or text can't provide sufficient search semantics.

RDS for PostgreSQL enables you to create custom data types in your trusted language extension and
define functions that support SQL and index operations for these new data types. Custom data types are
available for the following versions:

- RDS for PostgreSQL 15.4 and higher 15 versions
- RDS for PostgreSQL 14.9 and higher 14 versions
- RDS for PostgreSQL 13.12 and higher 13 versions

For more information, see Trusted Language Base types.

Functions reference for Trusted Language Extensions for PostgreSQL

View the following reference documentation about functions available in Trusted Language Extensions
for PostgreSQL. Use these functions to install, register, update, and manage your TLE extensions, that is, the
PostgreSQL extensions that you develop using the Trusted Language Extensions development kit.

Topics
- pgtle.available_extensions (p. 2446)
- pgtle.available_extension_versions (p. 2446)
- pgtle.extension_update_paths (p. 2447)
- pgtle.install_extension (p. 2448)
- pgtle.install_update_path (p. 2448)
- pgtle.register_feature (p. 2449)
- pgtle.register_feature_if_not_exists (p. 2450)
- pgtle.set_default_version (p. 2450)
- pgtle.uninstall_extension(name) (p. 2451)
• `pgtle.uninstall_extension(name, version)` (p. 2452)
• `pgtle.uninstall_extension_if_exists` (p. 2452)
• `pgtle.uninstall_update_path` (p. 2453)
• `pgtle.uninstall_update_path_if_exists` (p. 2453)
• `pgtle.unregister_feature` (p. 2454)
• `pgtle.unregister_feature_if_exists` (p. 2454)

`pgtle.available_extensions`

The `pgtle.available_extensions` function is a set-returning function. It returns all available TLE extensions in the database. Each returned row contains information about a single TLE extension.

**Function prototype**

```
pgtle.available_extensions()
```

**Role**

None.

**Arguments**

None.

**Output**

- **name** – The name of the TLE extension.
- **default_version** – The version of the TLE extension to use when `CREATE EXTENSION` is called without a version specified.
- **description** – A more detailed description about the TLE extension.

**Usage example**

```
SELECT * FROM pgtle.available_extensions();
```

`pgtle.available_extension_versions`

The `available_extension_versions` function is a set-returning function. It returns a list of all available TLE extensions and their versions. Each row contains information about a specific version of the given TLE extension, including whether it requires a specific role.

**Function prototype**

```
pgtle.available_extension_versions()
```

**Role**

None.
Arguments

None.

Output

- **name** – The name of the TLE extension.
- **version** – The version of the TLE extension.
- **superuser** – This value is always false for your TLE extensions. The permissions needed to create the TLE extension or update it are the same as for creating other objects in the given database.
- **trusted** – This value is always false for a TLE extension.
- **relocatable** – This value is always false for a TLE extension.
- **schema** – Specifies the name of the schema in which the TLE extension is installed.
- **requires** – An array containing the names of other extensions needed by this TLE extension.
- **description** – A detailed description of the TLE extension.

For more information about output values, see [Packaging Related Objects into an Extension > Extension Files](https://www.postgresql.org/docs/current/extension-files.html) in the PostgreSQL documentation.

Usage example

```sql
SELECT * FROM pgtle.available_extension_versions();
```

**pgtle.extension_update_paths**

The `extension_update_paths` function is a set-returning function. It returns a list of all the possible update paths for a TLE extension. Each row includes the available upgrades or downgrades for that TLE extension.

Function prototype

```sql
pgtle.extension_update_paths(name)
```

Role

None.

Arguments

name – The name of the TLE extension from which to get upgrade paths.

Output

- **source** – The source version for an update.
- **target** – The target version for an update.
- **path** – The upgrade path used to update a TLE extension from source version to target version, for example, 0.1--0.2.

Usage example

```sql
SELECT * FROM pgtle.extension_update_paths('your-TLE');
```
pgtle.install_extension

The `install_extension` function lets you install the artifacts that make up your TLE extension in the database, after which it can be created using the `CREATE EXTENSION` command.

### Function prototype

```sql
pgtle.install_extension(name text, version text, description text, ext text, requires text[] DEFAULT NULL::text[])
```

### Role

None.

### Arguments

- **name** – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- **version** – The version of the TLE extension.
- **description** – A detailed description about the TLE extension. This description is displayed in the comment field in `pgtle.available_extensions()`.
- **ext** – The contents of the TLE extension. This value contains objects such as functions.
- **requires** – An optional parameter that specifies dependencies for this TLE extension. The `pg_tle` extension is automatically added as a dependency.

Many of these arguments are the same as those that are included in an extension control file for installing a PostgreSQL extension on the file system of a PostgreSQL instance. For more information, see the Extension Files in Packaging Related Objects into an Extension in the PostgreSQL documentation.

### Output

This function returns OK on success and NULL on error.

- **OK** – The TLE extension has been successfully installed in the database.
- **NULL** – The TLE extension hasn't been successfully installed in the database.

### Usage example

```sql
SELECT pgtle.install_extension(  
    'pg_tle_test',  
    '0.1',  
    'My first pg_tle extension',  
    $_pgtle_$  
    CREATE FUNCTION my_test()  
    RETURNS INT  
    AS $$  
    SELECT 42;  
    $$ LANGUAGE SQL IMMUTABLE;  
$_pgtle_$$
)
```

pgtle.install_update_path

The `install_update_path` function provides an update path between two different versions of a TLE extension. This function allows users of your TLE extension to update its version by using the `ALTER EXTENSION ... UPDATE` syntax.
Function prototype

```
pgtle.install_update_path(name text, fromvers text, tovers text, ext text)
```

Role

```
pgtle_admin
```

Arguments

- name – The name of the TLE extension. This value is used when calling CREATE EXTENSION.
- fromvers – The source version of the TLE extension for the upgrade.
- tovers – The destination version of the TLE extension for the upgrade.
- ext – The contents of the update. This value contains objects such as functions.

Output

None.

Usage example

```
SELECT pgtle.install_update_path('pg_tle_test', '0.1', '0.2',
$pgtle$
CREATE OR REPLACE FUNCTION my_test()
RETURNS INT
AS $$
SELECT 21;
$$ LANGUAGE SQL IMMUTABLE;
$pgtle$
);
```

pgtle.register_feature

The register_feature function adds the specified internal PostgreSQL feature to the pgtle.feature_info table. PostgreSQL hooks are an example of an internal PostgreSQL feature. The Trusted Language Extensions development kit supports the use of PostgreSQL hooks. Currently, this function supports the following feature.

- passcheck – Registers the password-check hook with your procedure or function that customizes PostgreSQL’s password-check behavior.

Function prototype

```
pgtle.register_feature(proc regproc, feature pg_tle_feature)
```

Role

```
pgtle_admin
```

Arguments

- proc – The name of a stored procedure or function to use for the feature.
• feature – The name of the pg_tle feature (such as passcheck) to register with the function.

Output

None.

Usage example

```
SELECT pgtle.register_feature('pw_hook', 'passcheck');
```

**pgtle.register_feature_if_not_exists**

The `pgtle.register_feature_if_not_exists` function adds the specified PostgreSQL feature to the `pgtle.feature_info` table and identifies the TLE extension or other procedure or function that uses the feature. For more information about hooks and Trusted Language Extensions, see [*Using PostgreSQL hooks with your TLE extensions*](p. 2441).

Function prototype

```
pgtle.register_feature_if_not_exists(proc regproc, feature pg_tle_feature)
```

Role

*pgtle_admin*

Arguments

• proc – The name of a stored procedure or function that contains the logic (code) to use as a feature for your TLE extension. For example, the `pw_hook` code.

• feature – The name of the PostgreSQL feature to register for the TLE function. Currently, the only available feature is the `passcheck` hook. For more information, see [*Password-check hook (passcheck)*](p. 2455).

Output

Returns true after registering the feature for the specified extension. Returns false if the feature is already registered.

Usage example

```
SELECT pgtle.register_feature_if_not_exists('pw_hook', 'passcheck');
```

**pgtle.set_default_version**

The `pgtle.set_default_version` function lets you specify a `default_version` for your TLE extension. You can use this function to define an upgrade path and designate the version as the default for your TLE extension. When database users specify your TLE extension in the `CREATE EXTENSION` and `ALTER EXTENSION ... UPDATE` commands, that version of your TLE extension is created in the database for that user.

This function returns true on success. If the TLE extension specified in the name argument doesn't exist, the function returns an error. Similarly, if the version of the TLE extension doesn't exist, it returns an error.
Function prototype

```
pgtle.set_default_version(name text, version text)
```

Role

`pgtle_admin`

Arguments

- `name` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- `version` – The version of the TLE extension to set the default.

Output

- `true` – When setting default version succeeds, the function returns `true`.
- `ERROR` – Returns an error message if a TLE extension with the specified name or version doesn't exist.

Usage example

```
SELECT * FROM pgtle.set_default_version('my-extension', '1.1');
```

```
pgtle.uninstall_extension(name)
```

The `uninstall_extension` function removes all versions of a TLE extension from a database. This function prevents future calls of `CREATE EXTENSION` from installing the TLE extension. If the TLE extension doesn't exist in the database, an error is raised.

The `uninstall_extension` function won't drop a TLE extension that's currently active in the database. To remove a TLE extension that's currently active, you need to explicitly call `DROP EXTENSION` to remove it.

Function prototype

```
pgtle.uninstall_extension(extname text)
```

Role

`pgtle_admin`

Arguments

- `extname` – The name of the TLE extension to uninstall. This name is the same as the one used with `CREATE EXTENSION` to load the TLE extension for use in a given database.

Output

None.

Usage example

```
SELECT * FROM pgtle.uninstall_extension('pg_tle_test');
```
pgtle.uninstall_extension(name, version)

The uninstall_extension(name, version) function removes the specified version of the TLE extension from the database. This function prevents CREATE EXTENSION and ALTER EXTENSION from installing or updating a TLE extension to the specified version. This function also removes all update paths for the specified version of the TLE extension. This function won't uninstall the TLE extension if it's currently active in the database. You must explicitly call DROP EXTENSION to remove the TLE extension. To uninstall all versions of a TLE extension, see pgtle.uninstall_extension(name) (p. 2451).

Function prototype

```sql
pgtle.uninstall_extension(extname text, version text)
```

Role

pgtle_admin

Arguments

- extname – The name of the TLE extension. This value is used when calling CREATE EXTENSION.
- version – The version of the TLE extension to uninstall from the database.

Output

None.

Usage example

```sql
SELECT * FROM pgtle.uninstall_extension('pg_tle_test', '0.2');
```

pgtle.uninstall_extension_if_exists

The uninstall_extension_if_exists function removes all versions of a TLE extension from a given database. If the TLE extension doesn't exist, the function returns silently (no error message is raised). If the specified extension is currently active within a database, this function doesn't drop it. You must explicitly call DROP EXTENSION to remove the TLE extension before using this function to uninstall its artifacts.

Function prototype

```sql
pgtle.uninstall_extension_if_exists(extname text)
```

Role

pgtle_admin

Arguments

- extname – The name of the TLE extension. This value is used when calling CREATE EXTENSION.

Output

The uninstall_extension_if_exists function returns true after uninstalling the specified extension. If the specified extension doesn't exist, the function returns false.
- true – Returns true after uninstalling the TLE extension.
- false – Returns false when the TLE extension doesn't exist in the database.

Usage example

```sql
SELECT * FROM pgtle.uninstall_extension_if_exists('pg_tle_test');
```

pgtle.uninstall_update_path

The `uninstall_update_path` function removes the specific update path from a TLE extension. This prevents `ALTER EXTENSION ... UPDATE TO` from using this as an update path.

If the TLE extension is currently being used by one of the versions on this update path, it remains in the database.

If the update path specified doesn't exist, this function raises an error.

Function prototype

```
pgtle.uninstall_update_path(extname text, fromvers text, tovers text)
```

Role

`pgtle_admin`

Arguments

- `extname` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- `fromvers` – The source version of the TLE extension used on the update path.
- `tovers` – The destination version of the TLE extension used on the update path.

Output

None.

Usage example

```sql
SELECT * FROM pgtle.uninstall_update_path('pg_tle_test', '0.1', '0.2');
```

pgtle.uninstall_update_path_if_exists

The `uninstall_update_path_if_exists` function is similar to `uninstall_update_path` in that it removes the specified update path from a TLE extension. However, if the update path doesn't exist, this function doesn't raise an error message. Instead, the function returns false.

Function prototype

```
pgtle.uninstall_update_path_if_exists(extname text, fromvers text, tovers text)
```

Role

`pgtle_admin`
Arguments

- **extname** – The name of the TLE extension. This value is used when calling CREATE EXTENSION.
- **fromvers** – The source version of the TLE extension used on the update path.
- **tovers** – The destination version of the TLE extension used on the update path.

Output

- **true** – The function has successfully updated the path for the TLE extension.
- **false** – The function wasn't able to update the path for the TLE extension.

Usage example

```
SELECT * FROM pgtle.uninstall_update_path_if_exists('pg_tle_test', '0.1', '0.2');
```

### pgtle.unregister_feature

The `unregister_feature` function provides a way to remove functions that were registered to use `pg_tle` features, such as hooks. For information about registering a feature, see [pgtle.register_feature](p. 2449).

Function prototype

```
pgtle.unregister_feature(proc regproc, feature pg_tle_features)
```

Role

`pgtle_admin`

Arguments

- **proc** – The name of a stored function to register with a `pg_tle` feature.
- **feature** – The name of the `pg_tle` feature to register with the function. For example, `passcheck` is a feature that can be registered for use by the trusted language extensions that you develop. For more information, see [Password-check hook (passcheck)](p. 2455).

Output

None.

Usage example

```
SELECT * FROM pgtle.unregister_feature('pw_hook', 'passcheck');
```

### pgtle.unregister_feature_if_exists

The `unregister_feature` function provides a way to remove functions that were registered to use `pg_tle` features, such as hooks. For more information, see [Using PostgreSQL hooks with your TLE extensions](p. 2441). Returns **true** after successfully unregistering the feature. Returns **false** if the feature wasn't registered.
For information about registering `pg_tle` features for your TLE extensions, see `pgtle.register_feature (p. 2449)`.

Function prototype

```sql
pgtle.unregister_feature_if_exists('proc regproc', 'feature pg_tle_features')
```

**Role**

`pgtle_admin`

**Arguments**

- `proc` – The name of the stored function that was registered to include a `pg_tle` feature.
- `feature` – The name of the `pg_tle` feature that was registered with the trusted language extension.

**Output**

Returns true or false, as follows.

- `true` – The function has successfully unregistered the feature from extension.
- `false` – The function wasn't able to unregister the feature from the TLE extension.

**Usage example**

```sql
SELECT * FROM pgtle.unregister_feature_if_exists('pw_hook', 'passcheck');
```

Hooks reference for Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL supports PostgreSQL hooks. A **hook** is an internal callback mechanism available to developers for extending PostgreSQL's core functionality. By using hooks, developers can implement their own functions or procedures for use during various database operations, thereby modifying PostgreSQL's behavior in some way. For example, you can use a `passcheck` hook to customize how PostgreSQL handles the passwords supplied when creating or changing passwords for users (roles).

View the following documentation to learn about the hooks available for your TLE extensions.

**Topics**

- [Password-check hook (passcheck) (p. 2455)](#)

**Password-check hook (passcheck)**

The `passcheck` hook is used to customize PostgreSQL behavior during the password-checking process for the following SQL commands and `psql` metacommand.

- `CREATE ROLE username ... PASSWORD` – For more information, see [CREATE ROLE](#) in the PostgreSQL documentation.
- `ALTER ROLE username ... PASSWORD` – For more information, see [ALTER ROLE](#) in the PostgreSQL documentation.
• \password **username** – This interactive psql metacommand securely changes the password for the specified user by hashing the password before transparently using the ALTER ROLE ... PASSWORD syntax. The metacommand is a secure wrapper for the ALTER ROLE ... PASSWORD command, thus the hook applies to the behavior of the psql metacommand.

For an example, see Password-check hook code listing (p. 2444).

**Function prototype**

```sql
passcheck_hook(username text, password text, password_type pgtle.password_types, valid_until timestamptz, valid_null boolean)
```

**Arguments**

A passcheck hook function takes the following arguments.

• **username** – The name (as text) of the role (username) that's setting a password.
• **password** – The plaintext or hashed password. The password entered should match the type specified in password_type.
• **password_type** – Specify the pgtle.password_type format of the password. This format can be one of the following options.
  • PASSWORD_TYPE_PLAINTEXT – A plaintext password.
  • PASSWORD_TYPE_MD5 – A password that's been hashed using MD5 (message digest 5) algorithm.
  • PASSWORD_TYPE_SCRAM_SHA_256 – A password that's been hashed using SCRAM-SHA-256 algorithm.
• **valid_until** – Specify the time when the password becomes invalid. This argument is optional. If you use this argument, specify the time as a timestamptz value.
• **valid_null** – If this Boolean is set to true, the valid_until option is set to NULL.

**Configuration**

The function pgtle.enable_password_check controls whether the passcheck hook is active. The passcheck hook has three possible settings.

• **off** – Turns off the passcheck password-check hook. This is the default value.
• **on** – Turns on the passcode password-check hook so that passwords are checked against the table.
• **require** – Requires a password check hook to be defined.

**Usage notes**

To turn the passcheck hook on or off, you need to modify the custom DB parameter group for your RDS for PostgreSQL DB instance.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --region aws-region \
  --db-parameter-group-name your-custom-parameter-group \
  --parameters "ParameterName=pgtle.enable_password_check,ParameterValue=on,ApplyMethod=immediate"
```

For Windows:
aws rds modify-db-parameter-group
  --region aws-region
  --db-parameter-group-name your-custom-parameter-group
  --parameters
  "ParameterName=pgtle.enable_password_check,ParameterValue=on,ApplyMethod=immediate"
Amazon Relational Database Service User Guide

Code examples for Amazon RDS
using AWS SDKs
The following code examples show how to use Amazon RDS with an AWS software development kit
(SDK).
Actions are code excerpts from larger programs and must be run in context. While actions show you how
to call individual service functions, you can see actions in context in their related scenarios and crossservice examples.
Scenarios are code examples that show you how to accomplish a speciﬁc task by calling multiple
functions within the same service.
Cross-service examples are sample applications that work across multiple AWS services.
For a complete list of AWS SDK developer guides and code examples, see Using this service with an AWS
SDK (p. 285). This topic also includes information about getting started and details about previous SDK
versions.
Get started

Hello Amazon RDS
The following code examples show how to get started using Amazon RDS.
.NET
AWS SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in
the AWS Code Examples Repository.

using
using
using
using

System;
System.Threading.Tasks;
Amazon.RDS;
Amazon.RDS.Model;

namespace RDSActions;
public static class HelloRds
{
static async Task Main(string[] args)
{
var rdsClient = new AmazonRDSClient();
Console.WriteLine($"Hello Amazon RDS! Following are some of your DB
instances:");
Console.WriteLine();
// You can use await and any of the async methods to get a response.
// Let's get the first twenty DB instances.
var response = await rdsClient.DescribeDBInstancesAsync(
new DescribeDBInstancesRequest()

2458


```
{
    MaxRecords = 20 // Must be between 20 and 100.
};

foreach (var instance in response.DBInstances)
{
    Console.WriteLine($"DB name: {instance.DBName}");
    Console.WriteLine($"Arn: {instance.DBInstanceArn}");
    Console.WriteLine($"Identifier: {instance.DBInstanceIdentifier}");
    Console.WriteLine();
}

• For API details, see DescribeDBInstances in AWS SDK for .NET API Reference.

C++

SDK for C++

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Code for the CMakeLists.txt CMake file.

```
# Set the minimum required version of CMake for this project.
cmake_minimum_required(V3.13)

# Set the AWS service components used by this project.
set(SERVICE_COMPONENTS rds)

# Set this project's name.
project("hello_rds")

# Set the C++ standard to use to build this target.
# At least C++ 11 is required for the AWS SDK for C++.
set(CMAKE_CXX_STANDARD 11)

# Use the MSVC variable to determine if this is a Windows build.
set(WINDOWS_BUILD ${MSVC})

if (WINDOWS_BUILD) # Set the location where CMake can find the installed libraries
    set(WINDOWS_BUILD_DIRS "C:/aws-cpp-sdk-all")
    set(WINDOWS_LIBRARY_DIRS "C:/aws-cpp-sdk-all")
    set(WINDOWS_FRAMEWORK_DIRS "C:/aws-cpp-sdk-all")
endif()

# Find the AWS SDK for C++ package.
find_package(AWSSDK REQUIRED COMPONENTS ${SERVICE_COMPONENTS})

if (WINDOWS_BUILD)
    # Copy relevant AWS SDK for C++ libraries into the current binary directory
    # set(BIN_SUB_DIR "/Debug") # If you are building from the command line, you
    # may need to uncomment this
    # and set the proper subdirectory to the
    # executables' location.

Go

SDK for Go V2

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

package main

import (  
    "context"  
    "fmt"  
    "github.com/aws/aws-sdk-go-v2/aws"  
    "github.com/aws/aws-sdk-go-v2/config"  
    "github.com/aws/aws-sdk-go-v2/service/rds"
)

// main uses the AWS SDK for Go V2 to create an Amazon Relational Database Service (Amazon RDS)  
// client and list up to 20 DB instances in your account.  
// This example uses the default settings specified in your shared credentials  
// and config files.
func main() {  
    sdkConfig, err := config.LoadDefaultConfig(context.TODO())  
    if err != nil {  
        fmt.Println("Couldn't load default configuration. Have you set up your AWS account?")  
        fmt.Println(err)  
        return  
    }
    rdsClient := rds.NewFromConfig(sdkConfig)
    const maxInstances = 20
    fmt.Printf("Let's list up to %v DB instances.\n", maxInstances)
    output, err := rdsClient.DescribeDBInstances(context.TODO(),  
                                                 &rds.DescribeDBInstancesInput{MaxRecords: aws.Int32(maxInstances)})
    if err != nil {  
        fmt.Printf("Couldn't list DB instances: %v\n", err)  
        return  
    }
    if len(output.DBInstances) == 0 {  
        fmt.Println("No DB instances found.")  
    } else {  
        for _, instance := range output.DBInstances {  
            fmt.Printf("DB instance %v has database %v.\n", *instance.DBInstanceIdentifier,  
                      *instance.DBName)
        }
    }
Actions for Amazon RDS using AWS SDKs

The following code examples demonstrate how to perform individual Amazon RDS actions with AWS SDKs. These excerpts call the Amazon RDS API and are code excerpts from larger programs that must be run in context. Each example includes a link to GitHub, where you can find instructions for setting up and running the code.

The following examples include only the most commonly used actions. For a complete list, see the Amazon Relational Database Service (Amazon RDS) API Reference.

Examples

• Create an Amazon RDS DB instance using an AWS SDK (p. 2463)
• Create an Amazon RDS DB parameter group using an AWS SDK (p. 2470)
• Create a snapshot of an Amazon RDS DB instance using an AWS SDK (p. 2473)
• Create an authentication token for IAM authentication to an Amazon RDS database using an AWS SDK (p. 2477)
• Delete an Amazon RDS DB instance using an AWS SDK (p. 2478)
• Delete an Amazon RDS DB parameter group using an AWS SDK (p. 2482)
• Describe Amazon RDS DB instances using an AWS SDK (p. 2486)
• Describe Amazon RDS DB parameter groups using an AWS SDK (p. 2490)
• Describe Amazon RDS database engine versions using an AWS SDK (p. 2494)
• Describe options for Amazon RDS DB instances using an AWS SDK (p. 2498)
• Describe parameters in an Amazon RDS DB parameter group using an AWS SDK (p. 2503)
• Describe snapshots of Amazon RDS DB instances using an AWS SDK (p. 2508)

Create an authentication token for IAM authentication to an Amazon RDS database using an AWS SDK

The following code example shows how to create an authentication token for IAM authentication.

Java

SDK for Java 2.x

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Use the RdsUtilities class to generate an authentication token.

```java
public class GenerateRDSAuthToken {
    public static void main(String[] args) {
        final String usage = "\n" +
            "Usage:\n" +
            "<dbInstanceIdentifier> <masterUsername>\n\n" +
            "Where:\n" +
            "dbInstanceIdentifier - The database instance identifier. \n" +
            "masterUsername - The master user name. \n";

        if (args.length != 2) {
            System.out.println(usage);
            System.exit(1);
        }
    }
}
```
String dbInstanceIdentifier = args[0];
String masterUsername = args[1];
Region region = Region.US_WEST_2;
RdsClient rdsClient = RdsClient.builder()
    .region(region)
    .credentialsProvider(ProfileCredentialsProvider.create())
    .build();

String token = getAuthToken(rdsClient, dbInstanceIdentifier, masterUsername);
System.out.println("The token response is "+token);
}

public static String getAuthToken(RdsClient rdsClient, String dbInstanceIdentifier, String masterUsername)
{
    RdsUtilities utilities = rdsClient.utilities();
    try {
        GenerateAuthenticationTokenRequest tokenRequest =
            GenerateAuthenticationTokenRequest.builder()
                .credentialsProvider(ProfileCredentialsProvider.create())
                .username(masterUsername)
                .port(3306)
                .hostname(dbInstanceIdentifier)
                .build();
        return utilities.generateAuthenticationToken(tokenRequest);
    } catch (RdsException e) {
        System.out.println(e.getLocalizedMessage());
        System.exit(1);
    }
    return "";
}

For API details, see GenerateRDSAuthToken in AWS SDK for Java 2.x API Reference.

Describe Amazon RDS DB instances using an AWS SDK

The following code examples show how to describe Amazon RDS DB instances.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Get started with DB instances (p. 2518)

.NET

AWS SDK for .NET

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```csharp
/// <summary>
/// Returns a list of DB instances.
/// </summary>
/// <param name="dbInstanceIdentifier">Optional name of a specific DB instance.</param>
/// <returns>List of DB instances.</returns>
public async Task<List<DBInstance>> DescribeDBInstances(string dbInstanceIdentifier = null)
{
    var results = new List<DBInstance>();
    var instancesPaginator = _amazonRDS.Paginators.DescribeDBInstances(
        new DescribeDBInstancesRequest
        {
            DBInstanceIdentifier = dbInstanceIdentifier
        });
    // Get the entire list using the paginator.
    await foreach (var instances in instancesPaginator.DBInstances)
    {
        results.Add(instances);
    }
    return results;
}
```

- For API details, see DescribeDBInstances in AWS SDK for .NET API Reference.

C++

SDK for C++

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```cpp
Aws::Client::ClientConfiguration clientConfig;
// Optional: Set to the AWS Region (overrides config file).
// clientConfig.region = "us-east-1";
```
bool AwsDoc::RDS::describeDBInstance(const Aws::String &dbInstanceIdentifier,  
   Aws::RDS::Model::DBInstance &instanceResult,  
   const Aws::RDS::RDSClient &client) {  
    Aws::RDS::Model::DescribeDBInstancesRequest request;  
    request.SetDBInstanceIdentifier(dbInstanceIdentifier);  
    Aws::RDS::Model::DescribeDBInstancesOutcome outcome =  
        client.DescribeDBInstances(request);  
    bool result = true;  
    if (outcome.IsSuccess()) {  
        instanceResult = outcome.GetResult().GetDBInstances()[0];  
    }  
    else if (outcome.GetError().GetErrorType() !=  
             Aws::RDS::RDSErrors::D_B_INSTANCE_NOT_FOUND_FAULT) {  
        result = false;  
        std::cerr << "Error with RDS::DescribeDBInstances. "  
                  << outcome.GetError().GetMessage()  
                  << std::endl;  
    }  
    // This example does not log an error if the DB instance does not exist.  
    // Instead, instanceResult is set to empty.  
    else {  
        instanceResult = Aws::RDS::Model::DBInstance();  
    }  
    return result;  
}
Describe DB instances

```go
&rds.DescribeDBInstancesInput{
    DBInstanceIdentifier: aws.String(instanceName),
})
if err != nil {
    var notFoundError *types.DBInstanceNotFoundFault
    if errors.As(err, &notFoundError) {
        log.Printf("DB instance %v does not exist.\n", instanceName)
        err = nil
    } else {
        log.Printf("Couldn't get instance %v: %v\n", instanceName, err)
        return nil, err
    }
}
```

Update parameters in a DB parameter group

```go
// UpdateParameters updates parameters in a named DB parameter group.
func (instances *DbInstances) UpdateParameters(parameterGroupName string, params []types.Parameter) error {
    _, err := instances.RdsClient.ModifyDBParameterGroup(context.TODO(),
        &rds.ModifyDBParameterGroupInput{
            DBParameterGroupName: aws.String(parameterGroupName),
            Parameters:           params,
        })
    if err != nil {
        log.Printf("Couldn't update parameters in %v: %v\n", parameterGroupName, err)
        return err
    } else {
        return nil
    }
}
```

**Scenarios for Amazon RDS using AWS SDKs**

The following code examples show you how to implement common scenarios in Amazon RDS with AWS SDKs. These scenarios show you how to accomplish specific tasks by calling multiple functions within
Amazon RDS. Each scenario includes a link to GitHub, where you can find instructions on how to set up and run the code.

Examples

- Get started with Amazon RDS DB instances using an AWS SDK (p. 2518)

Get started with Amazon RDS DB instances using an AWS SDK

The following code examples show how to:

- Create a custom DB parameter group and set parameter values.
- Create a DB instance that's configured to use the parameter group. The DB instance also contains a database.
- Take a snapshot of the instance.
- Delete the instance and parameter group.

.NET

AWS SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario at a command prompt.

```csharp
/// <summary>
/// Scenario for RDS DB instance example.
/// </summary>
public class RDSInstanceScenario
{
    /*
     * Before running this .NET code example, set up your development environment, including your credentials.
     *
     * This .NET example performs the following tasks:
     * 1. Returns a list of the available DB engine families using the DescribeDBEngineVersionsAsync method.
     * 2. Selects an engine family and creates a custom DB parameter group using the CreateDBParameterGroupAsync method.
     * 3. Gets the parameter groups using the DescribeDBParameterGroupsAsync method.
     * 4. Gets parameters in the group using the DescribeDBParameters method.
     * 5. Parses and displays parameters in the group.
     * 6. Modifies both the auto_increment_offset and auto_increment_increment parameters using the ModifyDBParameterGroupAsync method.
     * 7. Gets and displays the updated parameters using the DescribeDBParameters method with a source of "user".
     * 8. Gets a list of allowed engine versions using the DescribeDBEngineVersionsAsync method.
     * 9. Displays and selects from a list of micro instance classes available for the selected engine and version.
     * 10. Creates an RDS DB instance that contains a MySql database and uses the parameter group using the CreateDBInstanceAsync method.
    */

**Go SDK for Go V2**

**Note**
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario at a command prompt.

```go
// GetStartedInstances is an interactive example that shows you how to use the AWS SDK for Go
// with Amazon Relation Database Service (Amazon RDS) to do the following:
// 1. Create a custom DB parameter group and set parameter values.
// 2. Create a DB instance that is configured to use the parameter group. The DB instance
//    also contains a database.
// 3. Take a snapshot of the DB instance.
// 4. Delete the DB instance and parameter group.
type GetStartedInstances struct {
    sdkConfig  aws.Config
    instances  actions.DbInstances
    questioner demotools.IQuestioner
    helper     IScenarioHelper
    isTestRun  bool
}

// NewGetStartedInstances constructs a GetStartedInstances instance from a configuration.
// It uses the specified config to get an Amazon RDS client and create wrappers for the actions used in the scenario.

  • DescribeDBParameters
  • DescribeDBSnapshots
  • DescribeOrderableDBInstanceOptions
  • ModifyDBParameterGroup
Run multiple operations.

```java
/**
 * Before running this Java (v2) code example, set up your development environment,
 * including your credentials.
 *
 * For more information, see the following documentation topic:
 * 
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * This example requires an AWS Secrets Manager secret that contains the database credentials. If you do not create a
 * secret, this example will not work. For details, see:
 * 
 * https://docs.aws.amazon.com/secretsmanager/latest/userguide/integrating_how-services-use-secrets_RS.html
 *
 * This Java example performs these tasks:
 *
 * 1. Returns a list of the available DB engines.
 * 2. Selects an engine family and create a custom DB parameter group.
 * 3. Gets the parameter groups.
 * 4. Gets parameters in the group.
 * 5. Modifies the auto_increment_offset parameter.
 * 6. Gets and displays the updated parameters.
 * 7. Gets a list of allowed engine versions.
 * 8. Gets a list of micro instance classes available for the selected engine.
 * 9. Creates an RDS database instance that contains a MySql database and uses the
 * parameter group.
 * 10. Wait for the DB instance to be ready and prints out the connection endpoint
 * value.
 * 11. Creates a snapshot of the DB instance.
 * 12. Wait for an RDS DB snapshot to be ready.
 * 13. Deletes the RDS DB instance.
 * 14. Deletes the parameter group.

Kotlin

SDK for Kotlin

**Note**
This is prerelease documentation for a feature in preview release. It is subject to change.

**Note**
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```kotlin
/**
 * Before running this code example, set up your development environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-kotlin/latest/developer-guide/setup.html
 *
 * This example requires an AWS Secrets Manager secret that contains the database credentials. If you do not create a secret, this example will not work. For more details, see:
 *
 * https://docs.aws.amazon.com/secretsmanager/latest/userguide/integrating_how-services-use-secrets_RS.html
 *
 * This example performs the following tasks:
 *
 * 1. Returns a list of the available DB engines by invoking the DescribeDbEngineVersions method.
 * 2. Selects an engine family and create a custom DB parameter group by invoking the createDBParameterGroup method.
 * 3. Gets the parameter groups by invoking the DescribeDbParameterGroups method.
 * 4. Gets parameters in the group by invoking the DescribeDbParameters method.
 * 5. Modifies both the auto_increment_offset and auto_increment_increment parameters by invoking the modifyDbParameterGroup method.
 * 6. Gets and displays the updated parameters.
 * 7. Gets a list of allowed engine versions by invoking the describeDbEngineVersions method.
 */
```
8. Gets a list of micro instance classes available for the selected engine.
9. Creates an Amazon Relational Database Service (Amazon RDS) database instance that contains a MySQL database and uses the parameter group.
10. Waits for DB instance to be ready and prints out the connection endpoint value.
11. Creates a snapshot of the DB instance.
12. Waits for the DB snapshot to be ready.
13. Deletes the DB instance.
14. Deletes the parameter group.

```kotlin
var sleepTime: Long = 20
suspend fun main(args: Array<String>) {
    val usage = ""
    Usage:
    <dbGroupName> <dbParameterGroupFamily> <dbInstanceIdentifier> <dbName>
    <dbSnapshotIdentifier> <secretName>
    Where:
    dbGroupName - The database group name.
    dbParameterGroupFamily - The database parameter group name.
    dbInstanceIdentifier - The database instance identifier.
    dbName - The database name.
    dbSnapshotIdentifier - The snapshot identifier.
    secretName - The name of the AWS Secrets Manager secret that contains the database credentials.

Cross-service examples for Amazon RDS using AWS SDKs

The following sample applications use AWS SDKs to combine Amazon RDS with other AWS services. Each example includes a link to GitHub, where you can find instructions on how to set up and run the application.

Examples
  • Create an Aurora Serverless work item tracker (p. 2579)
Create an Aurora Serverless work item tracker

The following code examples show how to create a web application that tracks work items in an Amazon Aurora Serverless database and uses Amazon Simple Email Service (Amazon SES) to send reports.

.NET

AWS SDK for .NET

Shows how to use the AWS SDK for .NET to create a web application that tracks work items in an Amazon Aurora database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with a RESTful .NET backend.

- Integrate a React web application with AWS services.
- List, add, update, and delete items in an Aurora table.
- Send an email report of filtered work items using Amazon SES.
- Deploy and manage example resources with the included AWS CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

C++

SDK for C++

Shows how to create a web application that tracks and reports on work items stored in an Amazon Aurora Serverless database.

For complete source code and instructions on how to set up a C++ REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

Java

SDK for Java 2.x

Shows how to create a web application that tracks and reports on work items stored in an Amazon RDS database.

For complete source code and instructions on how to set up a Spring REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on GitHub.
For complete source code and instructions on how to set up and run an example that uses the JDBC API, see the full example on [GitHub](https://github.com/).

**Services used in this example**
- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

**JavaScript**

**SDK for JavaScript (v3)**

Shows how to use the AWS SDK for JavaScript (v3) to create a web application that tracks work items in an Amazon Aurora database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with an Express Node.js backend.

- Integrate a React.js web application with AWS services.
- List, add, and update items in an Aurora table.
- Send an email report of filtered work items by using Amazon SES.
- Deploy and manage example resources with the included AWS CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](https://github.com/).

**Services used in this example**
- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

**Kotlin**

**SDK for Kotlin**

**Note**
This is prerelease documentation for a feature in preview release. It is subject to change.

Shows how to create a web application that tracks and reports on work items stored in an Amazon RDS database.

For complete source code and instructions on how to set up a Spring REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on [GitHub](https://github.com/).

**Services used in this example**
- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES
Create an Aurora Serverless work item tracker

PHP

SDK for PHP

Shows how to use the AWS SDK for PHP to create a web application that tracks work items in an Amazon RDS database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with a RESTful PHP backend.

- Integrate a React.js web application with AWS services.
- List, add, update, and delete items in an Amazon RDS table.
- Send an email report of filtered work items using Amazon SES.
- Deploy and manage example resources with the included AWS CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

Python

SDK for Python (Boto3)

Shows how to use the AWS SDK for Python (Boto3) to create a REST service that tracks work items in an Amazon Aurora Serverless database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses the Flask web framework to handle HTTP routing and integrates with a React webpage to present a fully functional web application.

- Build a Flask REST service that integrates with AWS services.
- Read, write, and update work items that are stored in an Aurora Serverless database.
- Create an AWS Secrets Manager secret that contains database credentials and use it to authenticate calls to the database.
- Use Amazon SES to send email reports of work items.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

For a complete list of AWS SDK developer guides and code examples, see Using this service with an AWS SDK (p. 285). This topic also includes information about getting started and details about previous SDK versions.
Security in Amazon RDS

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS compliance programs. To learn about the compliance programs that apply to Amazon RDS, see AWS services in scope by compliance program.

- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your organization's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Amazon RDS. The following topics show you how to configure Amazon RDS to meet your security and compliance objectives. You also learn how to use other AWS services that help you monitor and secure your Amazon RDS resources.

You can manage access to your Amazon RDS resources and your databases on a DB instance. The method you use to manage access depends on what type of task the user needs to perform with Amazon RDS:

- Run your DB instance in a virtual private cloud (VPC) based on the Amazon VPC service for the greatest possible network access control. For more information about creating a DB instance in a VPC, see Amazon VPC VPCs and Amazon RDS (p. 2705).

- Use AWS Identity and Access Management (IAM) policies to assign permissions that determine who is allowed to manage Amazon RDS resources. For example, you can use IAM to determine who is allowed to create, describe, modify, and delete DB instances, tag resources, or modify security groups.

- Use security groups to control what IP addresses or Amazon EC2 instances can connect to your databases on a DB instance. When you first create a DB instance, its firewall prevents any database access except through rules specified by an associated security group.

- Use Secure Socket Layer (SSL) or Transport Layer Security (TLS) connections with DB instances running the MySQL, MariaDB, PostgreSQL, Oracle, or Microsoft SQL Server database engines. For more information on using SSL/TLS with a DB instance, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2608).

- Use Amazon RDS encryption to secure your DB instances and snapshots at rest. Amazon RDS encryption uses the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your DB instance. For more information, see Encrypting Amazon RDS resources (p. 2603).

- Use network encryption and transparent data encryption with Oracle DB instances; for more information, see Oracle native network encryption (p. 2073) and Oracle Transparent Data Encryption (p. 2113).

- Use the security features of your DB engine to control who can log in to the databases on a DB instance. These features work just as if the database was on your local network.

**Note**
You have to configure security only for your use cases. You don't have to configure security access for processes that Amazon RDS manages. These include creating backups, replicating data between a primary DB instance and a read replica, and other processes.
For more information on managing access to Amazon RDS resources and your databases on a DB instance, see the following topics.

Topics

- Using service-linked roles for Amazon RDS (p. 2701)
- Amazon VPC VPCs and Amazon RDS (p. 2705)

Database authentication with Amazon RDS

Amazon RDS supports several ways to authenticate database users.

Password, Kerberos, and IAM database authentication use different methods of authenticating to the database. Therefore, a specific user can log in to a database using only one authentication method.

For PostgreSQL, use only one of the following role settings for a user of a specific database:

- To use IAM database authentication, assign the rds_iam role to the user.
- To use Kerberos authentication, assign the rds_ad role to the user.
- To use password authentication, don’t assign either the rds_iam or rds_ad roles to the user.

Don't assign both the rds_iam and rds_ad roles to a user of a PostgreSQL database either directly or indirectly by nested grant access. If the rds_iam role is added to the master user, IAM authentication takes precedence over password authentication so the master user has to log in as an IAM user.

Important
We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

Topics
- Password authentication (p. 2583)
- IAM database authentication (p. 2584)
- Kerberos authentication (p. 2584)

Password authentication

With *password authentication*, your database performs all administration of user accounts. You create users with SQL statements such as CREATE USER, with the appropriate clause required by the DB engine
for specifying passwords. For example, in MySQL the statement is `CREATE USER name IDENTIFIED BY password`, while in PostgreSQL, the statement is `CREATE USER name WITH PASSWORD password`.

With password authentication, your database controls and authenticates user accounts. If a DB engine has strong password management features, they can enhance security. Database authentication might be easier to administer using password authentication when you have small user communities. Because clear text passwords are generated in this case, integrating with AWS Secrets Manager can enhance security.

For information about using Secrets Manager with Amazon RDS, see Creating a basic secret and Rotating secrets for supported Amazon RDS databases in the AWS Secrets Manager User Guide. For information about programatically retrieving your secrets in your custom applications, see Retrieving the secret value in the AWS Secrets Manager User Guide.

**IAM database authentication**

You can authenticate to your DB instance using AWS Identity and Access Management (IAM) database authentication. IAM database authentication works with MySQL and PostgreSQL. With this authentication method, you don't need to use a password when you connect to a DB instance. Instead, you use an authentication token.

For more information about IAM database authentication, including information about availability for specific DB engines, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 2659).

**Kerberos authentication**

Amazon RDS supports external authentication of database users using Kerberos and Microsoft Active Directory. Kerberos is a network authentication protocol that uses tickets and symmetric-key cryptography to eliminate the need to transmit passwords over the network. Kerberos has been built into Active Directory and is designed to authenticate users to network resources, such as databases.

Amazon RDS support for Kerberos and Active Directory provides the benefits of single sign-on and centralized authentication of database users. You can keep your user credentials in Active Directory. Active Directory provides a centralized place for storing and managing credentials for multiple DB instances.

You can make it possible for your database users to authenticate against DB instances in two ways. They can use credentials stored either in AWS Directory Service for Microsoft Active Directory or in your on-premises Active Directory.

Microsoft SQL Server and PostgreSQL DB instances support one- and two-way forest trust relationships. Oracle DB instances support one- and two-way external and forest trust relationships. For more information, see When to create a trust relationship in the AWS Directory Service Administration Guide.

For information about Kerberos authentication with a specific DB engine, see the following:

- Working with AWS Managed Active Directory with RDS for SQL Server (p. 1417)
- Using Kerberos authentication for MySQL (p. 1661)
- Configuring Kerberos authentication for Amazon RDS for Oracle (p. 1835)
- Using Kerberos authentication with Amazon RDS for PostgreSQL (p. 2198)

**Note**

Currently, Kerberos authentication isn't supported for MariaDB DB instances.
Password management with Amazon RDS and AWS Secrets Manager

Amazon RDS integrates with Secrets Manager to manage master user passwords for your DB instances and Multi-AZ DB clusters.

Topics
- Limitations for Secrets Manager integration with Amazon RDS (p. 2585)
- Overview of managing master user passwords with AWS Secrets Manager (p. 2585)
- Benefits of managing master user passwords with Secrets Manager (p. 2586)
- Permissions required for Secrets Manager integration (p. 2586)
- Enforcing RDS management of the master user password in AWS Secrets Manager (p. 2587)
- Managing the master user password for a DB instance with Secrets Manager (p. 2587)
- Managing the master user password for a Multi-AZ DB cluster with Secrets Manager (p. 2590)
- Rotating the master user password secret for a DB instance (p. 2593)
- Rotating the master user password secret for a Multi-AZ DB cluster (p. 2595)
- Viewing the details about a secret for a DB instance (p. 2596)
- Viewing the details about a secret for a Multi-AZ DB cluster (p. 2599)
- Region and version availability (p. 2602)

Limitations for Secrets Manager integration with Amazon RDS

Managing master user passwords with Secrets Manager isn't supported for the following features:

- For all DB engines except for RDS for SQL Server, creating a read replica when the source DB or DB cluster manages credentials with Secrets Manager
- Amazon RDS Blue/Green Deployments
- Amazon RDS Custom
- Oracle Data Guard switchover
- RDS for Oracle with CDB

Overview of managing master user passwords with AWS Secrets Manager

With AWS Secrets Manager, you can replace hard-coded credentials in your code, including database passwords, with an API call to Secrets Manager to retrieve the secret programmatically. For more information about Secrets Manager, see AWS Secrets Manager User Guide. For pricing information, see AWS Secrets Manager pricing.

You can specify that RDS manages the master user password in Secrets Manager for an Amazon RDS DB instance or Multi-AZ DB cluster when you perform one of the following operations:

- Create the DB instance
- Create the Multi-AZ DB cluster
- Modify the DB instance
• Modify the Multi-AZ DB cluster
• Restore the DB instance from Amazon S3

When you specify that RDS manages the master user password in Secrets Manager, RDS generates the password and stores it in Secrets Manager. You can interact directly with the secret to retrieve the credentials for the master user. You can also specify a customer managed key to encrypt the secret, or use the KMS key that is provided by Secrets Manager.

RDS manages the settings for the secret and rotates the secret every seven days by default. You can modify some of the settings, such as the rotation schedule after the DB instance creation. If you delete a DB instance that manages a secret in Secrets Manager, the secret and its associated metadata are also deleted.

To connect to a DB instance or Multi-AZ DB cluster with the credentials in a secret, you can retrieve the secret from Secrets Manager. For more information, see Retrieve secrets from AWS Secrets Manager and Connect to a SQL database with credentials in an AWS Secrets Manager secret in the AWS Secrets Manager User Guide.

Benefits of managing master user passwords with Secrets Manager

Managing RDS master user passwords with Secrets Manager provides the following benefits:

• RDS automatically generates database credentials.
• RDS automatically stores and manages database credentials in AWS Secrets Manager.
• RDS rotates database credentials regularly, without requiring application changes.
• Secrets Manager secures database credentials from human access and plain text view.
• Secrets Manager allows retrieval of database credentials in secrets for database connections.
• Secrets Manager allows fine-grained control of access to database credentials in secrets using IAM.
• You can optionally separate database encryption from credentials encryption with different KMS keys.
• You can eliminate manual management and rotation of database credentials.
• You can monitor database credentials easily with AWS CloudTrail and Amazon CloudWatch.

For more information about the benefits of Secrets Manager, see AWS Secrets Manager User Guide.

Permissions required for Secrets Manager integration

Users must have the required permissions to perform operations related to Secrets Manager integration. You can create IAM policies that grant permissions to perform specific API operations on the specified resources they need. You can then attach those policies to the IAM permission sets or roles that require those permissions. For more information, see Identity and access management for Amazon RDS (p. 2623).

For create, modify, or restore operations, the user who specifies that Amazon RDS manages the master user password in Secrets Manager must have permissions to perform the following operations:

• kms:DescribeKey
• secretsmanager:CreateSecret
• secretsmanager:TagResource

For create, modify, or restore operations, the user who specifies the customer managed key to encrypt the secret in Secrets Manager must have permissions to perform the following operations:
• kms:Decrypt
• kms:GenerateDataKey
• kms:CreateGrant

For modify operations, the user who rotates the master user password in Secrets Manager must have permissions to perform the following operation:

• secretsmanager:RotateSecret

### Enforcing RDS management of the master user password in AWS Secrets Manager

You can use IAM condition keys to enforce RDS management of the master user password in AWS Secrets Manager. The following policy doesn’t allow users to create or restore DB instances or DB clusters unless the master user password is managed by RDS in Secrets Manager.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Deny",
         "Action": ["rds:CreateDBInstance", "rds:CreateDBCluster",
                     "rds:RestoreDBInstanceFromS3", "rds:RestoreDBClusterFromS3"],
         "Resource": "*",
         "Condition": {
            "Bool": {
               "rds:ManageMasterUserPassword": false
            }
         }
      }
   ]
}
```

**Note**
This policy enforces password management in AWS Secrets Manager at creation. However, you can still disable Secrets Manager integration and manually set a master password by modifying the instance.
To prevent this, include rds:ModifyDBInstance, rds:ModifyDBCluster in the Action block of the policy. Be aware, this prevents the user from applying any further modifications to existing instances which do not have Secrets Manager integration enabled.

For more information about using condition keys in IAM policies, see [Policy condition keys for Amazon RDS (p. 2630)](p.2630) and Example policies: Using condition keys (p. 2639).

### Managing the master user password for a DB instance with Secrets Manager

You can configure RDS management of the master user password in Secrets Manager when you perform the following actions:

• [Creating an Amazon RDS DB instance (p. 300)](p.300)
• [Modifying an Amazon RDS DB instance (p. 401)](p.401)
• [Restoring a backup into a MySQL DB instance (p. 1696)](p.1696)
You can use the RDS console, the AWS CLI, or the RDS API to perform these actions.

**Console**

Follow the instructions for creating or modifying a DB instance with the RDS console:

- [Creating a DB instance](p. 303)
- [Modifying an Amazon RDS DB instance](p. 401)
- [Importing data from Amazon S3 to a new MySQL DB instance](p. 1701)

When you use the RDS console to perform one of these operations, you can specify that the master user password is managed by RDS in Secrets Manager. To do so when you are creating or restoring a DB instance, select **Manage master credentials in AWS Secrets Manager** in Credential settings. When you are modifying a DB instance, select **Manage master credentials in AWS Secrets Manager** in Settings.

The following image is an example of the Manage master credentials in AWS Secrets Manager setting when you are creating or restoring a DB instance.

![Credential Settings](image)

When you select this option, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.
You can choose to encrypt the secret with a KMS key that Secrets Manager provides or with a customer managed key that you create. After RDS is managing the database credentials for a DB instance, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements. For more information about the available settings when you are creating a DB instance, see Settings for DB instances (p. 308). For more information about the available settings when you are modifying a DB instance, see Settings for DB instances (p. 402).

**AWS CLI**

To manage the master user password with RDS in Secrets Manager, specify the --manage-master-user-password option in one of the following AWS CLI commands:

- `create-db-instance`
- `modify-db-instance`
- `restore-db-instance-from-s3`

When you specify the --manage-master-user-password option in these commands, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the --master-user-secret-kms-key-id option to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN. After RDS is managing the database credentials for a DB instance, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements. For more information about the available settings when you are creating a DB instance, see Settings for DB instances (p. 308). For more information about the available settings when you are modifying a DB instance, see Settings for DB instances (p. 402).

This example creates a DB instance and specifies that RDS manages the master user password in Secrets Manager. The secret is encrypted using the KMS key that is provided by Secrets Manager.
Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --engine mysql \
    --engine-version 8.0.30 \
    --db-instance-class db.r5b.large \
    --allocated-storage 200 \
    --manage-master-user-password
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --engine mysql ^
    --engine-version 8.0.30 ^
    --db-instance-class db.r5b.large ^
    --allocated-storage 200 ^
    --manage-master-user-password
```

RDS API

To specify that RDS manages the master user password in Secrets Manager, set the `ManageMasterUserPassword` parameter to `true` in one of the following RDS API operations:

- CreateDBInstance
- ModifyDBInstance
- RestoreDBInstanceFromS3

When you set the `ManageMasterUserPassword` parameter to `true` in one of these operations, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `MasterUserSecretKmsKeyId` parameter to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN. After RDS is managing the database credentials for a DB instance, you can’t change the KMS key that is used to encrypt the secret.

Managing the master user password for a Multi-AZ DB cluster with Secrets Manager

You can configure RDS management of the master user password in Secrets Manager when you perform the following actions:

- Creating a Multi-AZ DB cluster (p. 508)
- Modifying a Multi-AZ DB cluster (p. 539)

You can use the RDS console, the AWS CLI, or the RDS API to perform these actions.

Console

Follow the instructions for creating or modifying a Multi-AZ DB cluster with the RDS console:
• **Creating a DB cluster (p. 511)**
• **Modifying a Multi-AZ DB cluster (p. 539)**

When you use the RDS console to perform one of these operations, you can specify that the master user password is managed by RDS in Secrets Manager. To do so when you are creating a DB cluster, select **Manage master credentials in AWS Secrets Manager** in **Credential settings**. When you are modifying a DB cluster, select **Manage master credentials in AWS Secrets Manager** in **Settings**.

The following image is an example of the **Manage master credentials in AWS Secrets Manager** setting when you are creating a DB cluster.

When you select this option, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.
You can choose to encrypt the secret with a KMS key that Secrets Manager provides or with a customer managed key that you create. After RDS is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements.

For more information about the available settings when you are creating a Multi-AZ DB cluster, see Settings for creating Multi-AZ DB clusters (p. 514). For more information about the available settings when you are modifying a Multi-AZ DB cluster, see Settings for modifying Multi-AZ DB clusters (p. 540).

AWS CLI

To specify that RDS manages the master user password in Secrets Manager, specify the --manage-master-user-password option in one of the following commands:

- `create-db-cluster`
- `modify-db-cluster`

When you specify the --manage-master-user-password option in these commands, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the --master-user-secret-kms-key-id option to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN. After RDS is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements.

For more information about the available settings when you are creating a Multi-AZ DB cluster, see Settings for creating Multi-AZ DB clusters (p. 514). For more information about the available settings when you are modifying a Multi-AZ DB cluster, see Settings for modifying Multi-AZ DB clusters (p. 540).

This example creates a Multi-AZ DB cluster and specifies that RDS manages the password in Secrets Manager. The secret is encrypted using the KMS key that is provided by Secrets Manager.

Example

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster
   --db-cluster-identifier mysql-multi-az-db-cluster
   --engine mysql
   --engine-version 8.0.28
   --backup-retention-period 1
   --allocated-storage 4000
   --storage-type io1
   --iops 10000
   --db-cluster-instance-class db.r6gd.xlarge
   --manage-master-user-password
```

For Windows:

```bash
aws rds create-db-cluster
   --db-cluster-identifier mysql-multi-az-db-cluster
```

2592
Rotating the master user password secret for a DB instance

RDS API

To specify that RDS manages the master user password in Secrets Manager, set the `ManageMasterUserPassword` parameter to `true` in one of the following operations:

- `CreateDBCluster`
- `ModifyDBCluster`

When you set the `ManageMasterUserPassword` parameter to `true` in one of these operations, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `MasterUserSecretKmsKeyId` parameter to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN. After RDS is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

Rotating the master user password secret for a DB instance

When RDS rotates a master user password secret, Secrets Manager generates a new secret version for the existing secret. The new version of the secret contains the new master user password. Amazon RDS changes the master user password for the DB instance to match the password for the new secret version.

You can rotate a secret immediately instead of waiting for a scheduled rotation. To rotate a master user password secret in Secrets Manager, modify the DB instance. For information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](p. 401).

You can rotate a master user password secret immediately with the RDS console, the AWS CLI, or the RDS API.

**Console**

To rotate a master user password secret using the RDS console, modify the DB instance and select *Rotate secret immediately* in *Settings*. 
Follow the instructions for modifying a DB instance with the RDS console in *Modifying an Amazon RDS DB instance (p. 401)*. You must choose **Apply immediately** on the confirmation page.

**AWS CLI**

To rotate a master user password secret using the AWS CLI, use the `modify-db-instance` command and specify the **--rotate-master-user-password** option. You must specify the **--apply-immediately** option when you rotate the master password.

This example rotates a master user password secret.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance
   --db-instance-identifier mydbinstance
   --rotate-master-user-password
   --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
   --db-instance-identifier mydbinstance ^
   --rotate-master-user-password ^
   --apply-immediately ^
```

**RDS API**

You can rotate a master user password secret using the `ModifyDBInstance` operation and setting the `RotateMasterUserPassword` parameter to `true`. You must set the `ApplyImmediately` parameter to `true` when you rotate the master password.
Rotating the master user password secret for a Multi-AZ DB cluster

When RDS rotates a master user password secret, Secrets Manager generates a new secret version for the existing secret. The new version of the secret contains the new master user password. Amazon RDS changes the master user password for the Multi-AZ DB cluster to match the password for the new secret version.

You can rotate a secret immediately instead of waiting for a scheduled rotation. To rotate a master user password secret in Secrets Manager, modify the Multi-AZ DB cluster. For information about modifying a Multi-AZ DB cluster, see Modifying a Multi-AZ DB cluster (p. 539).

You can rotate a master user password secret immediately with the RDS console, the AWS CLI, or the RDS API.

Console

To rotate a master user password secret using the RDS console, modify the Multi-AZ DB cluster and select **Rotate secret immediately** in Settings.

Follow the instructions for modifying a Multi-AZ DB cluster with the RDS console in Modifying a Multi-AZ DB cluster (p. 539). You must choose **Apply immediately** on the confirmation page.

AWS CLI

To rotate a master user password secret using the AWS CLI, use the `modify-db-cluster` command and specify the `--rotate-master-user-password` option. You must specify the `--apply-immediately` option when you rotate the master password.
This example rotates a master user password secret.

**Example**

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster
  --db-cluster-identifier mydbcluster
  --rotate-master-user-password
  --apply-immediately
```

For Windows:

```
aws rds modify-db-cluster
  --db-cluster-identifier mydbcluster
  --rotate-master-user-password
  --apply-immediately
```

**RDS API**

You can rotate a master user password secret using the `ModifyDBCluster` operation and setting the `RotateMasterUserPassword` parameter to `true`. You must set the `ApplyImmedately` parameter to `true` when you rotate the master password.

**Viewing the details about a secret for a DB instance**

You can retrieve your secrets using the console ([https://console.aws.amazon.com/secretsmanager/](https://console.aws.amazon.com/secretsmanager/)) or the AWS CLI (`get-secret-value` Secrets Manager command).

You can find the Amazon Resource Name (ARN) of a secret managed by RDS in Secrets Manager with the RDS console, the AWS CLI, or the RDS API.

**Console**

**To view the details about a secret managed by RDS in Secrets Manager**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance to show its details.
4. Choose the **Configuration** tab.

   In **Master Credentials ARN**, you can view the secret ARN.
You can follow the Manage in Secrets Manager link to view and manage the secret in the Secrets Manager console.

AWS CLI

You can use the `describe-db-instances` RDS CLI command to find the following information about a secret managed by RDS in Secrets Manager:

- **SecretArn** – The ARN of the secret
- **SecretStatus** – The status of the secret

The possible status values include the following:

- **creating** – The secret is being created.
- **active** – The secret is available for normal use and rotation.
- **rotating** – The secret is being rotated.
• impaired – The secret can be used to access database credentials, but it can't be rotated. A secret might have this status if, for example, permissions are changed so that RDS can no longer access the secret or the KMS key for the secret.

When a secret has this status, you can correct the condition that caused the status. If you correct the condition that caused status, the status remains impaired until the next rotation. Alternatively, you can modify the DB instance to turn off automatic management of database credentials, and then modify the DB instance again to turn on automatic management of database credentials. To modify the DB instance, use the `--manage-master-user-password` option in the `modify-db-instance` command.

• KmsKeyId – The ARN of the KMS key that is used to encrypt the secret

Specify the `--db-instance-identifier` option to show output for a specific DB instance. This example shows the output for a secret that is used by a DB instance.

**Example**

```bash
aws rds describe-db-instances --db-instance-identifier mydbinstance
```

Following is sample output for a secret:

```json
"MasterUserSecret": {
  "SecretArn": "arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!db-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx",
  "SecretStatus": "active",
  "KmsKeyId": "arn:aws:kms:eu-west-1:123456789012:key/0987dcba-09fe-87dc-65ba-ab0987654321"
}
```

When you have the secret ARN, you can view details about the secret using the `get-secret-value` Secrets Manager CLI command.

This example shows the details for the secret in the previous sample output.

**Example**

For Linux, macOS, or Unix:

```bash
aws secretsmanager get-secret-value \
  --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!db-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

For Windows:

```bash
aws secretsmanager get-secret-value ^ \
  --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!db-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

**RDS API**

You can view the ARN, status, and KMS key for a secret managed by RDS in Secrets Manager by using the `DescribeDBInstances` operation and setting the `DBInstanceIdentifier` parameter to a DB instance identifier. Details about the secret are included in the output.

When you have the secret ARN, you can view details about the secret using the `GetSecretValue` Secrets Manager operation.
Viewing the details about a secret for a Multi-AZ DB cluster

You can retrieve your secrets using the console (https://console.aws.amazon.com/secretsmanager/) or the AWS CLI (get-secret-value Secrets Manager command).

You can find the Amazon Resource Name (ARN) of a secret managed by RDS in Secrets Manager with the RDS console, the AWS CLI, or the RDS API.

Console

To view the details about a secret managed by RDS in Secrets Manager

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the name of the Multi-AZ DB cluster to show its details.
4. Choose the Configuration tab.

In Master Credentials ARN, you can view the secret ARN.
You can follow the **Manage in Secrets Manager** link to view and manage the secret in the Secrets Manager console.

**AWS CLI**

You can use the RDS AWS CLI [describe-db-clusters](https://docs.aws.amazon.com/cli/latest/reference/rds/describe-db-clusters.html) command to find the following information about a secret managed by RDS in Secrets Manager:

- **SecretArn** – The ARN of the secret
- **SecretStatus** – The status of the secret

The possible status values include the following:

- **creating** – The secret is being created.
- **active** – The secret is available for normal use and rotation.
- **rotating** – The secret is being rotated.
Viewing the details about a secret for a Multi-AZ DB cluster

- **impaired** – The secret can be used to access database credentials, but it can't be rotated. A secret might have this status if, for example, permissions are changed so that RDS can no longer access the secret or the KMS key for the secret.

  When a secret has this status, you can correct the condition that caused the status. If you correct the condition that caused status, the status remains impaired until the next rotation. Alternatively, you can modify the DB cluster to turn off automatic management of database credentials, and then modify the DB cluster again to turn on automatic management of database credentials. To modify the DB cluster, use the `--manage-master-user-password` option in the `modify-db-cluster` command.

- **KmsKeyId** – The ARN of the KMS key that is used to encrypt the secret

Specify the `--db-cluster-identifier` option to show output for a specific DB cluster. This example shows the output for a secret that is used by a DB cluster.

**Example**

```
aws rds describe-db-clusters --db-cluster-identifier mydbcluster
```

The following sample shows the output for a secret:

```
"MasterUserSecret": {
  "SecretArn": "arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx",
  "SecretStatus": "active",
  "KmsKeyId": "arn:aws:kms:eu-west-1:123456789012:key/0987dcba-09fe-87dc-65ba-ab0987654321"
}
```

When you have the secret ARN, you can view details about the secret using the `get-secret-value` Secrets Manager CLI command.

This example shows the details for the secret in the previous sample output.

**Example**

For Linux, macOS, or Unix:

```
aws secretsmanager get-secret-value \  
  --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

For Windows:

```
aws secretsmanager get-secret-value ^  
  --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

**RDS API**

You can view the ARN, status, and KMS key for a secret managed by RDS in Secrets Manager using the `DescribeDBClusters` RDS operation and setting the `DBClusterIdentifier` parameter to a DB cluster identifier. Details about the secret are included in the output.

When you have the secret ARN, you can view details about the secret using the `GetSecretValue` Secrets Manager operation.
Region and version availability

Feature availability and support varies across specific versions of each database engine and across AWS Regions. For more information about version and Region availability with Secrets Manager integration with Amazon RDS, see Secrets Manager integration (p. 161).

Data protection in Amazon RDS

The AWS shared responsibility model applies to data protection in Amazon Relational Database Service. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. This content includes the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see the AWS Shared Responsibility Model and GDPR blog post on the AWS Security Blog.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual users with AWS IAM Identity Center (successor to AWS Single Sign-On) or AWS Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with AWS CloudTrail.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a Name field. This includes when you work with Amazon RDS or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Topics
- Protecting data using encryption (p. 2602)
- Internetwork traffic privacy (p. 2622)

Protecting data using encryption

You can enable encryption for database resources. You can also encrypt connections to DB instances.

Topics
- Encrypting Amazon RDS resources (p. 2603)
- AWS KMS key management (p. 2606)
• Using SSL/TLS to encrypt a connection to a DB instance (p. 2608)
• Rotating your SSL/TLS certificate (p. 2613)

Encrypting Amazon RDS resources

Amazon RDS can encrypt your Amazon RDS DB instances. Data that is encrypted at rest includes the underlying storage for DB instances, its automated backups, read replicas, and snapshots.

Amazon RDS encrypted DB instances use the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your Amazon RDS DB instances. After your data is encrypted, Amazon RDS handles authentication of access and decryption of your data transparently with a minimal impact on performance. You don't need to modify your database client applications to use encryption.

Note
For encrypted and unencrypted DB instances, data that is in transit between the source and the read replicas is encrypted, even when replicating across AWS Regions.

Topics
• Overview of encrypting Amazon RDS resources (p. 2603)
• Encrypting a DB instance (p. 2604)
• Determining whether encryption is turned on for a DB instance (p. 2604)
• Availability of Amazon RDS encryption (p. 2605)
• Limitations of Amazon RDS encrypted DB instances (p. 2606)

Overview of encrypting Amazon RDS resources

Amazon RDS encrypted DB instances provide an additional layer of data protection by securing your data from unauthorized access to the underlying storage. You can use Amazon RDS encryption to increase data protection of your applications deployed in the cloud, and to fulfill compliance requirements for encryption at rest.

For an Amazon RDS encrypted DB instance, all logs, backups, and snapshots are encrypted. Amazon RDS uses an AWS KMS key to encrypt these resources. For more information about KMS keys, see AWS KMS keys in the AWS Key Management Service Developer Guide and AWS KMS key management (p. 2606). If you copy an encrypted snapshot, you can use a different KMS key to encrypt the target snapshot than the one that was used to encrypt the source snapshot.

A read replica of an Amazon RDS encrypted instance must be encrypted using the same KMS key as the primary DB instance when both are in the same AWS Region. If the primary DB instance and read replica are in different AWS Regions, you encrypt the read replica using the KMS key for that AWS Region.

You can use an AWS managed key, or you can create customer managed keys. To manage the customer managed keys used for encrypting and decrypting your Amazon RDS resources, you use the AWS Key Management Service (AWS KMS). AWS KMS combines secure, highly available hardware and software to provide a key management system scaled for the cloud. Using AWS KMS, you can create customer managed keys and define the policies that control how these customer managed keys can be used. AWS KMS supports CloudTrail, so you can audit KMS key usage to verify that customer managed keys are being used appropriately. You can use your customer managed keys with Amazon Aurora and supported AWS services such as Amazon S3, Amazon EBS, and Amazon Redshift. For a list of services that are integrated with AWS KMS, see AWS Service Integration.

Amazon RDS also supports encrypting an Oracle or SQL Server DB instance with Transparent Data Encryption (TDE). TDE can be used with RDS encryption at rest, although using TDE and RDS encryption at rest simultaneously might slightly affect the performance of your database. You must manage
different keys for each encryption method. For more information on TDE, see Oracle Transparent Data Encryption (p. 2113) or Support for Transparent Data Encryption in SQL Server (p. 1544).

**Encrypting a DB instance**

To encrypt a new DB instance, choose **Enable encryption** on the Amazon RDS console. For information on creating a DB instance, see Creating an Amazon RDS DB instance (p. 300).

If you use the `create-db-instance` AWS CLI command to create an encrypted DB instance, set the `--storage-encrypted` parameter. If you use the `CreateDBInstance` API operation, set the `StorageEncrypted` parameter to true.

When you create an encrypted DB instance, you can choose a customer managed key or the AWS managed key for Amazon RDS to encrypt your DB instance. If you don't specify the key identifier for a customer managed key, Amazon RDS uses the AWS managed key for your new DB instance. Amazon RDS creates an AWS managed key for Amazon RDS for your AWS account. Your AWS account has a different AWS managed key for Amazon RDS for each AWS Region.

For more information about KMS keys, see AWS KMS keys in the AWS Key Management Service Developer Guide.

Once you have created an encrypted DB instance, you can't change the KMS key used by that DB instance. Therefore, be sure to determine your KMS key requirements before you create your encrypted DB instance.

If you use the AWS CLI `create-db-instance` command to create an encrypted DB instance with a customer managed key, set the `--kms-key-id` parameter to any key identifier for the KMS key. If you use the Amazon RDS API `CreateDBInstance` operation, set the `KmsKeyId` parameter to any key identifier for the KMS key. To use a customer managed key in a different AWS account, specify the key ARN or alias ARN.

**Important**

Amazon RDS can lose access to the KMS key for a DB instance. For example, RDS loses access when the KMS key isn't enabled, or when RDS access to a KMS key is revoked. In these cases, the encrypted DB instance goes into inaccessible-encryption-credentials-recoverable state. The DB instance remains in this state for seven days. When you start the DB instance during that time, it checks if the KMS key is active and recovers the DB instance if it is. Restart the DB instance using the AWS CLI command `start-db-instance` or AWS Management Console. If the DB instance isn't recovered, then it goes into the terminal inaccessible-encryption-credentials state. In this case, you can only restore the DB instance from a backup. We strongly recommend that you always turn on backups for encrypted DB instances to guard against the loss of encrypted data in your databases.

**Determining whether encryption is turned on for a DB instance**

You can use the AWS Management Console, AWS CLI, or RDS API to determine whether encryption at rest is turned on for a DB instance.

**Console**

**To determine whether encryption at rest is turned on for a DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that you want to check to view its details.
4. Choose the **Configuration** tab, and check the **Encryption** value under **Storage**.

   It shows either **Enabled** or **Not enabled**.

2604
To determine whether encryption at rest is turned on for a DB instance by using the AWS CLI, call the `describe-db-instances` command with the following option:

- `--db-instance-identifier` – The name of the DB instance.

The following example uses a query to return either TRUE or FALSE regarding encryption at rest for the `mydb` DB instance.

**Example**

```bash
aws rds describe-db-instances --db-instance-identifier mydb --query "[*].{StorageEncrypted:StorageEncrypted}" --output text
```

**RDS API**

To determine whether encryption at rest is turned on for a DB instance by using the Amazon RDS API, call the `DescribeDBInstances` operation with the following parameter:

- `DBInstanceIdentifier` – The name of the DB instance.

**Availability of Amazon RDS encryption**

Amazon RDS encryption is currently available for all database engines and storage types, except for SQL Server Express Edition.

Amazon RDS encryption is available for most DB instance classes. The following table lists DB instance classes that don't support Amazon RDS encryption:

<table>
<thead>
<tr>
<th>Instance type</th>
<th>Instance class</th>
</tr>
</thead>
<tbody>
<tr>
<td>General purpose (M1)</td>
<td>db.m1.small</td>
</tr>
</tbody>
</table>
Limitations of Amazon RDS encrypted DB instances

The following limitations exist for Amazon RDS encrypted DB instances:

- You can only encrypt an Amazon RDS DB instance when you create it, not after the DB instance is created.

  However, because you can encrypt a copy of an unencrypted snapshot, you can effectively add encryption to an unencrypted DB instance. That is, you can create a snapshot of your DB instance, and then create an encrypted copy of that snapshot. You can then restore a DB instance from the encrypted snapshot, and thus you have an encrypted copy of your original DB instance. For more information, see Copying a DB snapshot (p. 619).

- You can't turn off encryption on an encrypted DB instance.

- You can't create an encrypted snapshot of an unencrypted DB instance.

- A snapshot of an encrypted DB instance must be encrypted using the same KMS key as the DB instance.

- You can't have an encrypted read replica of an unencrypted DB instance or an unencrypted read replica of an encrypted DB instance.

- Encrypted read replicas must be encrypted with the same KMS key as the source DB instance when both are in the same AWS Region.

- You can't restore an unencrypted backup or snapshot to an encrypted DB instance.

- To copy an encrypted snapshot from one AWS Region to another, you must specify the KMS key in the destination AWS Region. This is because KMS keys are specific to the AWS Region that they are created in.

  The source snapshot remains encrypted throughout the copy process. Amazon RDS uses envelope encryption to protect data during the copy process. For more information about envelope encryption, see Envelope encryption in the AWS Key Management Service Developer Guide.

- You can't unencrypt an encrypted DB instance. However, you can export data from an encrypted DB instance and import the data into an unencrypted DB instance.

AWS KMS key management

Amazon RDS automatically integrates with AWS Key Management Service (AWS KMS) for key management. Amazon RDS uses envelope encryption. For more information about envelope encryption, see Envelope encryption in the AWS Key Management Service Developer Guide.

You can use two types of AWS KMS keys to encrypt your DB instances.
If you want full control over a KMS key, you must create a customer managed key. For more information about customer managed keys, see Customer managed keys in the AWS Key Management Service Developer Guide.

You can't share a snapshot that has been encrypted using the AWS managed key of the AWS account that shared the snapshot.

AWS managed keys are KMS keys in your account that are created, managed, and used on your behalf by an AWS service that is integrated with AWS KMS. By default, the RDS AWS managed key (aws/rds) is used for encryption. You can’t manage, rotate, or delete the RDS AWS managed key. For more information about AWS managed keys, see AWS managed keys in the AWS Key Management Service Developer Guide.

To manage KMS keys used for Amazon RDS encrypted DB instances, use the AWS Key Management Service (AWS KMS) in the AWS KMS console, the AWS CLI, or the AWS KMS API. To view audit logs of every action taken with an AWS managed or customer managed key, use AWS CloudTrail. For more information about key rotation, see Rotating AWS KMS keys.

Important
If you turn off or revoke permissions to a KMS key used by an RDS database, RDS puts your database into a terminal state when access to the KMS key is required. This change could be immediate, or deferred, depending on the use case that required access to the KMS key. In this state, the DB instance is no longer available, and the current state of the database can't be recovered. To restore the DB instance, you must re-enable access to the KMS key for RDS, and then restore the DB instance from the latest available backup.

Authorizing use of a customer managed key

When RDS uses a customer managed key in cryptographic operations, it acts on behalf of the user who is creating or changing the RDS resource.

To create an RDS resource using a customer managed key, a user must have permissions to call the following operations on the customer managed key:

- kms:CreateGrant
- kms:DescribeKey

You can specify these required permissions in a key policy, or in an IAM policy if the key policy allows it.

You can make the IAM policy stricter in various ways. For example, if you want to allow the customer managed key to be used only for requests that originate in RDS, you can use the kms:ViaService condition key with the rds.<region>.amazonaws.com value. Also, you can use the keys or values in the Amazon RDS encryption context (p. 2607) as a condition for using the customer managed key for encryption.

For more information, see Allowing users in other accounts to use a KMS key in the AWS Key Management Service Developer Guide and Key policies in AWS KMS.

Amazon RDS encryption context

When RDS uses your KMS key, or when Amazon EBS uses the KMS key on behalf of RDS, the service specifies an encryption context. The encryption context is additional authenticated data (AAD) that AWS KMS uses to ensure data integrity. When an encryption context is specified for an encryption operation, the service must specify the same encryption context for the decryption operation. Otherwise, decryption fails. The encryption context is also written to your AWS CloudTrail logs to help you understand why a given KMS key was used. Your CloudTrail logs might contain many entries describing the use of a KMS key, but the encryption context in each log entry can help you determine the reason for that particular use.
At minimum, Amazon RDS always uses the DB instance ID for the encryption context, as in the following JSON-formatted example:

```
{ "aws:rds:db-id": "db-CQYSMDPBRZ7BPMH7Y3RTDG5QY" }
```

This encryption context can help you identify the DB instance for which your KMS key was used.

When your KMS key is used for a specific DB instance and a specific Amazon EBS volume, both the DB instance ID and the Amazon EBS volume ID are used for the encryption context, as in the following JSON-formatted example:

```
{
  "aws:rds:db-id": "db-BRG7VYS3SVIFQW7234EJQOM5RQ",
  "aws:ebs:id": "vol-ad8c6542"
}
```

### Using SSL/TLS to encrypt a connection to a DB instance

You can use Secure Socket Layer (SSL) or Transport Layer Security (TLS) from your application to encrypt a connection to a DB instance running MariaDB, Microsoft SQL Server, MySQL, Oracle, or PostgreSQL. SSL/TLS connections provide a layer of security by encrypting data that moves between your client and DB instance. Optionally, your SSL/TLS connection can perform server identity verification by validating the server certificate installed on your DB instance. To require server identity verification, follow this general process:

1. Choose the **certificate authority (CA)** that signs the **DB server certificate**, for your database. For more information about certificate authorities, see [Certificate authorities](p. 2608).
2. Download a certificate bundle to use when you are connecting to the database. To download a certificate bundle, see [Certificate bundles for all AWS Regions](p. 2612) and [Certificate bundles for specific AWS Regions](p. 2612).
   
   **Note**
   
   All certificates are only available for download using SSL/TLS connections.
3. Connect to the database using your DB engine's process for implementing SSL/TLS connections. Each DB engine has its own process for implementing SSL/TLS. To learn how to implement SSL/TLS for your database, follow the link that corresponds to your DB engine:
   
   - [Using SSL/TLS with a MariaDB DB instance](p. 1291)
   - [Using SSL with a Microsoft SQL Server DB instance](p. 1472)
   - [Using SSL/TLS with a MySQL DB instance](p. 1655)
   - [Using SSL with an RDS for Oracle DB instance](p. 1832)
   - [Using SSL with a PostgreSQL DB instance](p. 2191)

### Certificate authorities

The **certificate authority (CA)** is the certificate that identifies the root CA at the top of the certificate chain. The CA signs the **DB server certificate**, which is installed on each DB instance. The DB server certificate identifies the DB instance as a trusted server.
Amazon RDS provides the following CAs to sign the DB server certificate for a DB instance.

<table>
<thead>
<tr>
<th>Certificate authority (CA)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rds-ca-2019</td>
<td>Uses a certificate authority with RSA 2048 private key algorithm and SHA256 signing algorithm. This CA expires in 2024 and doesn't support automatic server certificate rotation. If you are using this CA and want to keep the same standard, we recommend that you switch to the rds-ca-rsa2048-g1 CA.</td>
</tr>
</tbody>
</table>
| rds-ca-rsa2048-g1         | Uses a certificate authority with RSA 2048 private key algorithm and SHA256 signing algorithm in most AWS Regions.  
In the AWS GovCloud (US) Regions, this CA uses a certificate authority with RSA 2048 private key algorithm and SHA384 signing algorithm.  
This CA remains valid for longer than the rds-ca-2019 CA. This CA supports automatic server certificate rotation. |
| rds-ca-rsa4096-g1         | Uses a certificate authority with RSA 4096 private key algorithm and SHA384 signing algorithm. This CA supports automatic server certificate rotation. |
| rds-ca-ecc384-g1          | Uses a certificate authority with ECC 384 private key algorithm and SHA384 signing algorithm. This CA supports automatic server certificate rotation. |

**Note**
If you are using the AWS CLI, you can see the validities of the certificate authorities listed above by using `describe-certificates`. 
These CA certificates are included in the regional and global certificate bundle. When you use the rds-ca-rsa2048-g1, rds-ca-rsa4096-g1, or rds-ca-ecc384-g1 CA with a database, RDS manages the DB server certificate on the database. RDS rotates the DB server certificate automatically before it expires.

### Setting the CA for your database

You can set the CA for a database when you perform the following tasks:

- Create a DB instance – You can set the CA when you create a DB instance. For instructions, see [Creating an Amazon RDS DB instance](p. 300).
- Modify a DB instance – You can set the CA for a DB instance by modifying it. For instructions, see [Modifying an Amazon RDS DB instance](p. 401).

**Note**

You can override the default CA for your AWS account by using the `modify-certificates` command.

The available CAs depend on the DB engine and DB engine version. When you use the AWS Management Console, you can choose the CA using the **Certificate authority** setting, as shown in the following image.

![Certificate authority - optional](image)

The console only shows the CAs that are available for the DB engine and DB engine version. If you are using the AWS CLI, you can set the CA for a DB instance using the `create-db-instance` or `modify-db-instance` command.

If you are using the AWS CLI, you can see the available CAs for your account by using the `describe-certificates` command. This command also shows the expiration date for each CA in **ValidTill** in the output. You can find the CAs that are available for a specific DB engine and DB engine version using the `describe-db-engine-versions` command.

The following example shows the CAs available for the default RDS for PostgreSQL DB engine version.

```bash
aws rds describe-db-engine-versions --default-only --engine postgres
```

Your output is similar to the following. The available CAs are listed in `SupportedCACertificateIdentifiers`. The output also shows whether the DB engine version supports rotating the certificate without restart in `SupportsCertificateRotationWithoutRestart`.

```json
{
    "DBEngineVersions": [
    {
        "Engine": "postgres",
        "MajorEngineVersion": "13",
        "EngineVersion": "13.4",
        "DBParameterGroupFamily": "postgres13",
        "DBEngineDescription": "PostgreSQL",
        "DBEngineVersionDescription": "PostgreSQL 13.4-R1",
        "ValidUpgradeTarget": [],
        "SupportsLogExportsToCloudwatchLogs": false,
        "SupportsReadReplica": true,
    }
    ]
}
```
DB server certificate validities

The validity of DB server certificate depends on the DB engine and DB engine version. If the DB engine version supports rotating the certificate without restart, the validity of the DB server certificate is 1 year. Otherwise the validity is 3 years.

For more information about DB server certificate rotation, see [Automatic server certificate rotation](p. 2620).

Viewing the CA for your database

You can view the details about the CA for a DB instance by viewing the Connectivity & security tab in the console, as in the following image.

If you are using the AWS CLI, you can view the details about the CA for a DB instance by using the `describe-db-instances` command.

To check the contents of your CA certificate bundle, use the following command:

```
keytool -printcert -v -file global-bundle.pem
```
Certificate bundles for all AWS Regions

To get a certificate bundle that contains both the intermediate and root certificates for all AWS Regions, download it from https://truststore.pki.rds.amazonaws.com/global/global-bundle.pem.

If your application is on Microsoft Windows and requires a PKCS7 file, you can download the PKCS7 certificate bundle. This bundle contains both the intermediate and root certificates at https://truststore.pki.rds.amazonaws.com/global/global-bundle.p7b.

Note
Amazon RDS Proxy uses certificates from the AWS Certificate Manager (ACM). If you are using RDS Proxy, you don't need to download Amazon RDS certificates or update applications that use RDS Proxy connections. For more information about using TLS/SSL with RDS Proxy, see Using TLS/SSL with RDS Proxy (p. 1221).

Certificate bundles for specific AWS Regions

To get a certificate bundle that contains both the intermediate and root certificates for an AWS Region, download it from the link for the AWS Region in the following table.

<table>
<thead>
<tr>
<th>AWS Region</th>
<th>Certificate bundle (PEM)</th>
<th>Certificate bundle (PKCS7)</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1-bundle.pem</td>
<td>us-east-1-bundle.p7b</td>

**AWS GovCloud (US) certificates**

If your application is on Microsoft Windows and requires a PKCS7 file, you can download the PKCS7 certificate bundle. This bundle contains both the intermediate and root certificates at https://truststore.pki.us-gov-west-1.rds.amazonaws.com/global/global-bundle.p7b.

To get a certificate bundle that contains both the intermediate and root certificates for an AWS GovCloud (US) Region, download from the link for the AWS GovCloud (US) Region in the following table.

<table>
<thead>
<tr>
<th>AWS GovCloud (US) Region</th>
<th>Certificate bundle (PEM)</th>
<th>Certificate bundle (PKCS7)</th>
</tr>
</thead>
</table>

**Rotating your SSL/TLS certificate**

Amazon RDS Certificate Authority certificates rds-ca-2019 are set to expire in August, 2024. If you use or plan to use Secure Sockets Layer (SSL) or Transport Layer Security (TLS) with certificate verification to connect to your RDS DB instances, you should consider using one of the new CA certificates rds-ca-rsa2048-g1, rds-ca-rsa4096-g1 or rds-ca-ecc384-g1. If you currently do not use SSL/TLS with certificate verification, you might still have an expired CA certificate and must update them to a new CA certificate if you plan to use SSL/TLS with certificate verification to connect to your RDS databases.

Follow these instructions to complete your updates. Before you update your DB instances to use the new CA certificate, make sure that you update your clients or applications connecting to your RDS databases.

Amazon RDS provides new CA certificates as an AWS security best practice. For information about the new certificates and the supported AWS Regions, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2608).

**Note**

Amazon RDS Proxy uses certificates from the AWS Certificate Manager (ACM). If you are using RDS Proxy, when you rotate your SSL/TLS certificate, you don't need to update applications that use RDS Proxy connections. For more information about using TLS/SSL with RDS Proxy, see Using TLS/SSL with RDS Proxy (p. 1221).
Note
If you are using a Go version 1.15 application with a DB instance that was created or updated to the rds-ca-2019 certificate prior to July 28, 2020, you must update the certificate again. Update the certificate to rds-ca-rsa2048-g1, rds-ca-rsa4096-g1, or rds-ca-ecc384-g1 depending on your engine. Run the modify-db-instance command shown in the AWS CLI section using the new CA certificate identifier. You can find the CAs that are available for a specific DB engine and DB engine version using the describe-db-engine-versions command. If you created your DB instance or updated its certificate after July 28, 2020, no action is required. For more information, see Go GitHub issue #39568.

Topics
• Updating your CA certificate by modifying your DB instance (p. 2614)
• Updating your CA certificate by applying DB instance maintenance (p. 2617)
• Automatic server certificate rotation (p. 2620)
• Sample script for importing certificates into your trust store (p. 2620)

Updating your CA certificate by modifying your DB instance

The following example updates your CA certificate from rds-ca-2019 to rds-ca-rsa2048-g1. You can choose a different certificate. For more information, see Certificate authorities (p. 2608).

To update your CA certificate by modifying your DB instance

1. Download the new SSL/TLS certificate as described in Using SSL/TLS to encrypt a connection to a DB instance (p. 2608).
2. Update your applications to use the new SSL/TLS certificate.

   The methods for updating applications for new SSL/TLS certificates depend on your specific applications. Work with your application developers to update the SSL/TLS certificates for your applications.

   For information about checking for SSL/TLS connections and updating applications for each DB engine, see the following topics:

   • Updating applications to connect to MariaDB instances using new SSL/TLS certificates (p. 1293)
   • Updating applications to connect to Microsoft SQL Server DB instances using new SSL/TLS certificates (p. 1427)
   • Updating applications to connect to MySQL DB instances using new SSL/TLS certificates (p. 1658)
   • Updating applications to connect to Oracle DB instances using new SSL/TLS certificates (p. 1832)
   • Updating applications to connect to PostgreSQL DB instances using new SSL/TLS certificates (p. 2194)

   For a sample script that updates a trust store for a Linux operating system, see Sample script for importing certificates into your trust store (p. 2620).

   Note
   The certificate bundle contains certificates for both the old and new CA, so you can upgrade your application safely and maintain connectivity during the transition period. If you are using the AWS Database Migration Service to migrate a database to a DB instance, we recommend using the certificate bundle to ensure connectivity during the migration.

3. Modify the DB instance to change the CA from rds-ca-2019 to rds-ca-rsa2048-g1. To check if your database requires a restart to update the CA certificates, use the describe-db-engine-versions command and check the SupportsCertificateRotationWithoutRestart flag.
Important
If you are experiencing connectivity issues after certificate expiry, use the apply immediately option by specifying Apply immediately in the console or by specifying the --apply-immediately option using the AWS CLI. By default, this operation is scheduled to run during your next maintenance window.
To set an override for your instance CA that's different from the default RDS CA, use the modify-certificates CLI command.

You can use the AWS Management Console or the AWS CLI to change the CA certificate from rds-ca-2019 to rds-ca-rsa2048-g1 for a DB instance.

Console
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance that you want to modify.
3. Choose Modify.

The Modify DB Instance page appears.
4. In the Connectivity section, choose rds-ca-rsa2048-g1.
5. Choose **Continue** and check the summary of modifications.
6. To apply the changes immediately, choose **Apply immediately**.
7. On the confirmation page, review your changes. If they are correct, choose **Modify DB Instance** to save your changes.

**Important**
When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

**AWS CLI**

To use the AWS CLI to change the CA from **rds-ca-2019** to **rds-ca-rsa2048-g1** for a DB instance, call the **modify-db-instance** command. Specify the DB instance identifier and the **--ca-certificate-identifier** option.

**Important**
When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

**Example**

The following code modifies **mydbinstance** by setting the CA certificate to **rds-ca-rsa2048-g1**.

**Important**
Use **--apply-immediately** to apply the update immediately. By default, this operation is scheduled to run during your next maintenance window.

For Linux, macOS, or Unix:

```sh/aws rds modify-db-instance --db-instance-identifier mydbinstance --ca-certificate-identifier rds-ca-rsa2048-g1
```

For Windows:

```sh
aws rds modify-db-instance ^
--db-instance-identifier mydbinstance ^
--ca-certificate-identifier rds-ca-rsa2048-g1
```
Note
If your instance requires reboot, you can use the `modify-db-instance` CLI command and specify the `--no-certificate-rotation-restart` option.

Updating your CA certificate by applying DB instance maintenance

Complete the following steps to update your CA certificate by applying DB instance maintenance.

To update your CA certificate by applying DB instance maintenance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.

   In the navigation pane, there is a Certificate update option that shows the total number of affected DB instance.
Choose **Certificate update** in the navigation pane.

The **Databases requiring certificate update** page appears.
Note
This page only shows the DB instances for the current AWS Region. If you have DB instances in more than one AWS Region, check this page in each AWS Region to see all DB instances with old SSL/TLS certificates.

3. Choose the DB instance you want to update.

You can schedule the certificate rotation for your next maintenance window by choosing Schedule. Apply the rotation immediately by choosing Apply now.

Important
If you experience connectivity issues after certificate expiry, use the Apply now option.

4. a. If you choose Schedule, you are prompted to confirm the CA certificate rotation. This prompt also states the scheduled window for your update.

b. If you choose Apply now, you are prompted to confirm the CA certificate rotation.
Important
Before scheduling the CA certificate rotation on your database, update any client applications that use SSL/TLS and the server certificate to connect. These updates are specific to your DB engine. After you have updated these client applications, you can confirm the CA certificate rotation.

To continue, choose the check box, and then choose Confirm.

5. Repeat steps 3 and 4 for each DB instance that you want to update.

Automatic server certificate rotation

If your CA supports automatic server certificate rotation, RDS automatically handles the rotation of the DB server certificate. RDS uses the same root CA for this automatic rotation, so you don't need to download a new CA bundle. See Certificate authorities (p. 2608).

The rotation and validity of your DB server certificate depend on your DB engine:

- If your DB engine supports rotation without restart, RDS automatically rotates the DB server certificate without requiring any action from you. RDS attempts to rotate your DB server certificate in your preferred maintenance window at the DB server certificate half life. The new DB server certificate is valid for 12 months.
- If your DB engine doesn't support rotation without restart, RDS notifies you about a maintenance event at least 6 months before the DB server certificate expires. The new DB server certificate is valid for 36 months.

Use the describe-db-engine-versions command and inspect the SupportsCertificateRotationWithoutRestart flag to identify whether the DB engine version supports rotating the certificate without restart. For more information, see Setting the CA for your database (p. 2610).

Sample script for importing certificates into your trust store

The following are sample shell scripts that import the certificate bundle into a trust store.
Each sample shell script uses keytool, which is part of the Java Development Kit (JDK). For information about installing the JDK, see [JDK Installation Guide](#).

**Topics**

- [Sample script for importing certificates on Linux (p. 2621)](#)
- [Sample script for importing certificates on macOS (p. 2621)](#)

**Sample script for importing certificates on Linux**

The following is a sample shell script that imports the certificate bundle into a trust store on a Linux operating system.

```bash
mydir=tmp/certs
if [ ! -e "${mydir}" ]
then
  mkdir -p "${mydir}"
fi

truststore=${mydir}/rds-truststore.jks
storepassword=changeit
awk 'split_after == 1 {n++;split_after=0} /-----END CERTIFICATE-----/ {split_after=1}{print > "rds-ca-" n ".pem"}' < ${mydir}/global-bundle.pem
for CERT in rds-ca-*; do
  alias=$(openssl x509 -noout -text -in $CERT | perl -ne 'next unless /Subject:/; s/.*(CN=|CN = )//; print')
  echo "Importing $alias"
  keytool -import -file ${CERT} -alias "$alias" -storepass ${storepassword} -keystore ${truststore} -noprompt
  rm $CERT
done
rm ${mydir}/global-bundle.pem

echo "Trust store content is: "
keytool -list -v -keystore "$truststore" -storepass ${storepassword} | grep Alias | cut -d " " -f3- | while read alias
do
  expiry=`keytool -list -v -keystore "$truststore" -storepass ${storepassword} -alias "$alias" | grep Valid | perl -ne 'if(/until: (.*?)\n/) { print "$1\n"; }'`
  echo " Certificate $alias expires in '$expiry'"
done
```

**Sample script for importing certificates on macOS**

The following is a sample shell script that imports the certificate bundle into a trust store on macOS.

```bash
mydir=tmp/certs
if [ ! -e "$mydir" ]
then
  mkdir -p "$mydir"
fi

truststore=${mydir}/rds-truststore.jks
```
Internetwork traffic privacy

Connections are protected both between Amazon RDS and on-premises applications and between Amazon RDS and other AWS resources within the same AWS Region.

Traffic between service and on-premises clients and applications

You have two connectivity options between your private network and AWS:

- An AWS Site-to-Site VPN connection. For more information, see What is AWS Site-to-Site VPN?
- An AWS Direct Connect connection. For more information, see What is AWS Direct Connect?

You get access to Amazon RDS through the network by using AWS-published API operations. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.
Identity and access management for Amazon RDS

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be authenticated (signed in) and authorized (have permissions) to use Amazon RDS resources. IAM is an AWS service that you can use with no additional charge.

Topics
- Audience (p. 2623)
- Authenticating with identities (p. 2623)
- Managing access using policies (p. 2626)
- How Amazon RDS works with IAM (p. 2627)
- Identity-based policy examples for Amazon RDS (p. 2633)
- AWS managed policies for Amazon RDS (p. 2645)
- Amazon RDS updates to AWS managed policies (p. 2649)
- Preventing cross-service confused deputy problems (p. 2657)
- IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 2659)
- Troubleshooting Amazon RDS identity and access (p. 2687)

Audience

How you use AWS Identity and Access Management (IAM) differs, depending on the work you do in Amazon RDS.

Service user – If you use the Amazon RDS service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more Amazon RDS features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in Amazon RDS, see Troubleshooting Amazon RDS identity and access (p. 2687).

Service administrator – If you're in charge of Amazon RDS resources at your company, you probably have full access to Amazon RDS. It's your job to determine which Amazon RDS features and resources your employees should access. You must then submit requests to your administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with Amazon RDS, see How Amazon RDS works with IAM (p. 2627).

Administrator – If you're an administrator, you might want to learn details about how you can write policies to manage access to Amazon RDS. To view example Amazon RDS identity-based policies that you can use in IAM, see Identity-based policy examples for Amazon RDS (p. 2633).

Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. You must be authenticated (signed in to AWS) as the AWS account root user, as an IAM user, or by assuming an IAM role.

You can sign in to AWS as a federated identity by using credentials provided through an identity source. AWS IAM Identity Center (successor to AWS Single Sign-On) (IAM Identity Center) users, your company's single sign-on authentication, and your Google or Facebook credentials are examples of federated identities. When you sign in as a federated identity, your administrator previously set up identity federation using IAM roles. When you access AWS by using federation, you are indirectly assuming a role.
Depending on the type of user you are, you can sign in to the AWS Management Console or the AWS access portal. For more information about signing in to AWS, see How to sign in to your AWS account in the AWS Sign-In User Guide.

If you access AWS programmatically, AWS provides a software development kit (SDK) and a command line interface (CLI) to cryptographically sign your requests by using your credentials. If you don't use AWS tools, you must sign requests yourself. For more information about using the recommended method to sign requests yourself, see Signing AWS API requests in the IAM User Guide.

Regardless of the authentication method that you use, you might be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see Multi-factor authentication in the AWS IAM Identity Center (successor to AWS Single Sign-On) User Guide and Using multi-factor authentication (MFA) in AWS in the IAM User Guide.

AWS account root user

When you create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account root user and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you don't use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see Tasks that require root user credentials in the IAM User Guide.

Federated identity

As a best practice, require human users, including users that require administrator access, to use federation with an identity provider to access AWS services by using temporary credentials.

A federated identity is a user from your enterprise user directory, a web identity provider, the AWS Directory Service, the Identity Center directory, or any user that accesses AWS services by using credentials provided through an identity source. When federated identities access AWS accounts, they assume roles, and the roles provide temporary credentials.

For centralized access management, we recommend that you use AWS IAM Identity Center (successor to AWS Single Sign-On). You can create users and groups in IAM Identity Center, or you can connect and synchronize to a set of users and groups in your own identity source for use across all your AWS accounts and applications. For information about IAM Identity Center, see What is IAM Identity Center? in the AWS IAM Identity Center (successor to AWS Single Sign-On) User Guide.

IAM users and groups

An IAM user is an identity within your AWS account that has specific permissions for a single person or application. Where possible, we recommend relying on temporary credentials instead of creating IAM users who have long-term credentials such as passwords and access keys. However, if you have specific use cases that require long-term credentials with IAM users, we recommend that you rotate access keys. For more information, see Rotate access keys regularly for use cases that require long-term credentials in the IAM User Guide.

An IAM group is an identity that specifies a collection of IAM users. You can't sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named IAMAdmins and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but
roles provide temporary credentials. To learn more, see When to create an IAM user (instead of a role) in the IAM User Guide.

You can authenticate to your DB instance using IAM database authentication.

IAM database authentication works with the following DB engines:

- RDS for MariaDB
- RDS for MySQL
- RDS for PostgreSQL

For more information about authenticating to your DB instance using IAM, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 2659).

IAM roles

An IAM role is an identity within your AWS account that has specific permissions. It is similar to a user, but is not associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by switching roles. You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see Using IAM roles in the IAM User Guide.

IAM roles with temporary credentials are useful in the following situations:

- **Temporary user permissions** – A user can assume an IAM role to temporarily take on different permissions for a specific task.
- **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see Creating a role for a third-party Identity Provider in the IAM User Guide. If you use IAM Identity Center, you configure a permission set. To control what your identities can access after they authenticate, IAM Identity Center correlates the permission set to a role in IAM. For information about permissions sets, see Permission sets in the AWS IAM Identity Center (successor to AWS Single Sign-On) User Guide.
- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.
- **Cross-service access** – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.
- **Principal permissions** – When you use an IAM user or role to perform actions in AWS, you are considered a principal. Policies grant permissions to a principal. When you use some services, you might perform an action that then triggers another action in a different service. In this case, you must have permissions to perform both actions. To see whether an action requires additional dependent actions in a policy, see Actions, Resources, and Condition Keys for Amazon RDS in the Service Authorization Reference.
- **Service role** – A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.
- **Service-linked role** – A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in
you AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

- **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see [Using an IAM role to grant permissions to applications running on Amazon EC2 instances](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles毗to-grant-permissions.html) in the *IAM User Guide*.

To learn whether to use IAM roles, see [When to create an IAM role (instead of a user)](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles毗to-grant-permissions.html) in the *IAM User Guide*.

### Managing access using policies

You control access in AWS by creating policies and attaching them to IAM identities or AWS resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. AWS evaluates these policies when an entity (root user, user, or IAM role) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see [Overview of JSON policies](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_policies毗to-permissions.html) in the *IAM User Guide*.

An administrator can use policies to specify who has access to AWS resources, and what actions they can perform on those resources. Every IAM entity (permission set or role) starts with no permissions. In other words, by default, users can do nothing, not even change their own password. To give a user permission to do something, an administrator must attach a permissions policy to a user. Or the administrator can add the user to a group that has the intended permissions. When an administrator gives permissions to a group, all users in that group are granted those permissions.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the `iam:GetRole` action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

### Identity-based policies

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as a permission set or role. These policies control what actions that identity can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see [Creating IAM policies](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_policies毗to-permissions.html) in the *IAM User Guide*.

Identity-based policies can be further categorized as **inline policies** or **managed policies**. Inline policies are embedded directly into a single permission set or role. Managed policies are standalone policies that you can attach to multiple permission sets and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see [Choosing between managed policies and inline policies](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_policies毗to-permissions.html) in the *IAM User Guide*.

For information about AWS managed policies that are specific to Amazon RDS, see [AWS managed policies for Amazon RDS](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_policies毗to-permissions.html) (p. 2645).

### Other policy types

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (permission set or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of
entity's identity-based policies and its permissions boundaries. Resource-based policies that specify
the permission set or role in the Principal field are not limited by the permissions boundary. An
explicit deny in any of these policies overrides the allow. For more information about permissions
boundaries, see Permissions boundaries for IAM entities in the IAM User Guide.

- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for
  an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service
  for grouping and centrally managing multiple AWS accounts that your business owns. If you enable all
  features in an organization, then you can apply service control policies (SCPs) to any or all of your
  accounts. The SCP limits permissions for entities in member accounts, including each AWS account
  root user. For more information about Organizations and SCPs, see How SCPs work in the AWS
  Organizations User Guide.

- **Session policies** – Session policies are advanced policies that you pass as a parameter when you
  programmatically create a temporary session for a role or federated user. The resulting session's
  permissions are the intersection of the permission sets or role's identity-based policies and the session
  policies. Permissions can also come from a resource-based policy. An explicit deny in any of these
  policies overrides the allow. For more information, see Session policies in the IAM User Guide.

### Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to
understand. To learn how AWS determines whether to allow a request when multiple policy types are
involved, see Policy evaluation logic in the IAM User Guide.

### How Amazon RDS works with IAM

Before you use IAM to manage access to Amazon RDS, you should understand what IAM features are
available to use with Amazon RDS.

#### IAM features you can use with Amazon RDS

<table>

To get a high-level view of how Amazon RDS and other AWS services work with IAM, see AWS services
that work with IAM in the IAM User Guide.
Amazon RDS identity-based policies

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Creating IAM policies in the IAM User Guide.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. You can't specify the principal in an identity-based policy because it applies to the user or role to which it is attached. To learn about all of the elements that you can use in a JSON policy, see IAM JSON policy elements reference in the IAM User Guide.

Identity-based policy examples for Amazon RDS

To view examples of Amazon RDS identity-based policies, see Identity-based policy examples for Amazon RDS (p. 2633).

Resource-based policies within Amazon RDS

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM role trust policies and Amazon S3 bucket policies. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. Adding a cross-account principal to a resource-based policy is only half of establishing the trust relationship. When the principal and the resource are in different AWS accounts, an IAM administrator in the trusted account must also grant the principal entity (user or role) permission to access the resource. They grant permission by attaching an identity-based policy to the

2628
entity. However, if a resource-based policy grants access to a principal in the same account, no additional identity-based policy is required. For more information, see How IAM roles differ from resource-based policies in the IAM User Guide.

**Policy actions for Amazon RDS**

| Supports policy actions | Yes |

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Action element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated AWS API operation. There are some exceptions, such as permission-only actions that don't have a matching API operation. There are also some operations that require multiple actions in a policy. These additional actions are called dependent actions.

Include actions in a policy to grant permissions to perform the associated operation.

Policy actions in Amazon RDS use the following prefix before the action: rds:. For example, to grant someone permission to describe DB instances with the Amazon RDS DescribeDBInstances API operation, you include the rds:DescribeDBInstances action in their policy. Policy statements must include either an Action or NotAction element. Amazon RDS defines its own set of actions that describe tasks that you can perform with this service.

To specify multiple actions in a single statement, separate them with commas as follows.

```
"Action": [
    "rds:action1",
    "rds:action2"
]
```

You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word Describe, include the following action.

```
"Action": "rds:Describe*"
```

To see a list of Amazon RDS actions, see Actions Defined by Amazon RDS in the Service Authorization Reference.

**Policy resources for Amazon RDS**

| Supports policy resources | Yes |

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Resource JSON policy element specifies the object or objects to which the action applies. Statements must include either a Resource or a NotResource element. As a best practice, specify a resource using its Amazon Resource Name (ARN). You can do this for actions that support a specific resource type, known as resource-level permissions.
For actions that don't support resource-level permissions, such as listing operations, use a wildcard (*) to indicate that the statement applies to all resources.

"Resource": "*"

The DB instance resource has the following Amazon Resource Name (ARN).

```markdown
arn:${Partition}:rds:${Region}:${Account}:${ResourceType}/${Resource}
```

For more information about the format of ARNs, see Amazon Resource Names (ARNs) and AWS service namespaces.

For example, to specify the dbtest DB instance in your statement, use the following ARN.

To specify all DB instances that belong to a specific account, use the wildcard (*).

"Resource": "arn:aws:rds:us-east-1:123456789012:db:*"

Some RDS API operations, such as those for creating resources, can't be performed on a specific resource. In those cases, use the wildcard (*).

"Resource": "*"

Many Amazon RDS API operations involve multiple resources. For example, CreateDBInstance creates a DB instance. You can specify that an user must use a specific security group and parameter group when creating a DB instance. To specify multiple resources in a single statement, separate the ARNs with commas.

"Resource": [
  "resource1",
  "resource2"
]

To see a list of Amazon RDS resource types and their ARNs, see Resources Defined by Amazon RDS in the Service Authorization Reference. To learn with which actions you can specify the ARN of each resource, see Actions Defined by Amazon RDS.

**Policy condition keys for Amazon RDS**

| Supports service-specific policy condition keys | Yes |

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Condition element (or Condition block) lets you specify conditions in which a statement is in effect. The Condition element is optional. You can create conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request.

If you specify multiple Condition elements in a statement, or multiple keys in a single Condition element, AWS evaluates them using a logical AND operation. If you specify multiple values for a single condition key, AWS evaluates the condition using a logical OR operation. All of the conditions must be met before the statement's permissions are granted.
You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see IAM policy elements: variables and tags in the IAM User Guide.

AWS supports global condition keys and service-specific condition keys. To see all AWS global condition keys, see AWS global condition context keys in the IAM User Guide.

Amazon RDS defines its own set of condition keys and also supports using some global condition keys. To see all AWS global condition keys, see AWS global condition context keys in the IAM User Guide.

All RDS API operations support the aws:RequestedRegion condition key.

To see a list of Amazon RDS condition keys, see Condition Keys for Amazon RDS in the Service Authorization Reference. To learn with which actions and resources you can use a condition key, see Actions Defined by Amazon RDS.

Access control lists (ACLs) in Amazon RDS

| Supports access control lists (ACLs) | No |

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Attribute-based access control (ABAC) in policies with Amazon RDS tags

| Supports attribute-based access control (ABAC) | Yes |

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes. In AWS, these attributes are called tags. You can attach tags to IAM entities (users or roles) and to many AWS resources. Tagging entities and resources is the first step of ABAC. Then you design ABAC policies to allow operations when the principal's tag matches the tag on the resource that they are trying to access.

ABAC is helpful in environments that are growing rapidly and helps with situations where policy management becomes cumbersome.

To control access based on tags, you provide tag information in the condition element of a policy using the aws:ResourceTag/key-name, aws:RequestTag/key-name, or aws:TagKeys condition keys.

If a service supports all three condition keys for every resource type, then the value is Yes for the service. If a service supports all three condition keys for only some resource types, then the value is Partial.

For more information about ABAC, see What is ABAC? in the IAM User Guide. To view a tutorial with steps for setting up ABAC, see Use attribute-based access control (ABAC) in the IAM User Guide.

For more information about tagging Amazon RDS resources, see Specifying conditions: Using custom tags (p. 2640). To view an example identity-based policy for limiting access to a resource based on the tags on that resource, see Grant permission for actions on a resource with a specific tag with two different values (p. 2637).
Using temporary credentials with Amazon RDS

| Supports temporary credentials | Yes |

Some AWS services don't work when you sign in using temporary credentials. For additional information, including which AWS services work with temporary credentials, see AWS services that work with IAM in the IAM User Guide.

You are using temporary credentials if you sign in to the AWS Management Console using any method except a user name and password. For example, when you access AWS using your company's single sign-on (SSO) link, that process automatically creates temporary credentials. You also automatically create temporary credentials when you sign in to the console as a user and then switch roles. For more information about switching roles, see Switching to a role (console) in the IAM User Guide.

You can manually create temporary credentials using the AWS CLI or AWS API. You can then use those temporary credentials to access AWS. AWS recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see Temporary security credentials in IAM.

Cross-service principal permissions for Amazon RDS

| Supports principal permissions | Yes |

When you use an IAM user or role to perform actions in AWS, you are considered a principal. Policies grant permissions to a principal. When you use some services, you might perform an action that then triggers another action in a different service. In this case, you must have permissions to perform both actions. To see whether an action requires additional dependent actions in a policy, see Actions, Resources, and Condition Keys for Amazon RDS in the Service Authorization Reference.

Service roles for Amazon RDS

| Supports service roles | Yes |

A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

**Warning**
Changing the permissions for a service role might break Amazon RDS functionality. Edit service roles only when Amazon RDS provides guidance to do so.

Service-linked roles for Amazon RDS

| Supports service-linked roles | Yes |

A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.
Identity-based policy examples for Amazon RDS

By default, permission sets and roles don't have permission to create or modify Amazon RDS resources. They also can't perform tasks using the AWS Management Console, AWS CLI, or AWS API. An administrator must create IAM policies that grant permission sets and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the permission sets or roles that require those permissions.

To learn how to create an IAM identity-based policy using these example JSON policy documents, see Creating policies on the JSON tab in the IAM User Guide.

Topics

- Policy best practices (p. 2633)
- Using the Amazon RDS console (p. 2634)
- Allow users to view their own permissions (p. 2634)
- Allow a user to create DB instances in an AWS account (p. 2635)
- Permissions required to use the console (p. 2636)
- Allow a user to perform any describe action on any RDS resource (p. 2636)
- Allow a user to create a DB instance that uses the specified DB parameter group and subnet group (p. 2637)
- Grant permission for actions on a resource with a specific tag with two different values (p. 2637)
- Prevent a user from deleting a DB instance (p. 2638)
- Deny all access to a resource (p. 2639)
- Example policies: Using condition keys (p. 2639)
- Specifying conditions: Using custom tags (p. 2640)

Policy best practices

Identity-based policies determine whether someone can create, access, or delete Amazon RDS resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- Get started with AWS managed policies and move toward least-privilege permissions – To get started granting permissions to your users and workloads, use the AWS managed policies that grant permissions for many common use cases. They are available in your AWS account. We recommend that you reduce permissions further by defining AWS customer managed policies that are specific to your use cases. For more information, see AWS managed policies or AWS managed policies for job functions in the IAM User Guide.

- Apply least-privilege permissions – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as least-privilege permissions. For more information about using IAM to apply permissions, see Policies and permissions in IAM in the IAM User Guide.

- Use conditions in IAM policies to further restrict access – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific AWS service, such as AWS CloudFormation. For more information, see IAM JSON policy elements: Condition in the IAM User Guide.
• Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions
  – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM
    policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy
    checks and actionable recommendations to help you author secure and functional policies. For more
    information, see IAM Access Analyzer policy validation in the IAM User Guide.

• Require multi-factor authentication (MFA) – if you have a scenario that requires IAM users or a root
  user in your AWS account, turn on MFA for additional security. To require MFA when API operations are
  called, add MFA conditions to your policies. For more information, see Configuring MFA-protected API
  access in the IAM User Guide.

For more information about best practices in IAM, see Security best practices in IAM in the IAM User
Guide.

Using the Amazon RDS console

To access the Amazon RDS console, you must have a minimum set of permissions. These permissions
must allow you to list and view details about the Amazon RDS resources in your AWS account. If you
create an identity-based policy that is more restrictive than the minimum required permissions, the
console won't function as intended for entities (users or roles) with that policy.

You don't need to allow minimum console permissions for users that are making calls only to the AWS
CLI or the AWS API. Instead, allow access to only the actions that match the API operation that you're
trying to perform.

To ensure that those entities can still use the Amazon RDS console, also attach the following AWS
managed policy to the entities.

AmazonRDSReadOnlyAccess

For more information, see Adding permissions to a user in the IAM User Guide.

Allow users to view their own permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed
policies that are attached to their user identity. This policy includes permissions to complete this action
on the console or programmatically using the AWS CLI or AWS API.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ViewOwnUserInfo",
            "Effect": "Allow",
            "Action": [
                "iam:GetUserPolicy",
                "iam:ListGroupsForUser",
                "iam:ListAttachedUserPolicies",
                "iam:ListUserPolicies",
                "iam:GetUser"
            ],
            "Resource": ["arn:aws:iam::*:user/${aws:username}"]
        },
        {
            "Sid": "NavigateInConsole",
            "Effect": "Allow",
            "Action": [
                "iam:GetGroupPolicy",
                "iam:GetPolicyVersion",
                "iam:GetPolicyVersion"
            ],
            "Resource": ["arn:aws:iam::*:group/${aws:username}"]
        }
    ]
}
```
Allow a user to create DB instances in an AWS account

The following is an example policy that allows the user with the ID 123456789012 to create DB instances for your AWS account. The policy requires that the name of the new DB instance begin with `test`. The new DB instance must also use the MySQL database engine and the `db.t2.micro` DB instance class. In addition, the new DB instance must use an option group and a DB parameter group that starts with `default`, and it must use the default subnet group.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowCreateDBInstanceOnly",
      "Effect": "Allow",
      "Action": ["rds:CreateDBInstance"],
      "Resource": [
        "arn:aws:rds:*:123456789012:db:test*",
        "arn:aws:rds:*:123456789012:og:default*",
        "arn:aws:rds:*:123456789012:pg:default*",
        "arn:aws:rds:*:123456789012:subgrp:default"
      ],
      "Condition": {
        "StringEquals": {
          "rds:DatabaseEngine": "mysql",
          "rds:DatabaseClass": "db.t2.micro"
        }
      }
    }
  ]
}
```

The policy includes a single statement that specifies the following permissions for the user:

- The policy allows the user to create a DB instance using the `CreateDBInstance` API operation (this also applies to the `create-db-instance` AWS CLI command and the AWS Management Console).
- The `Resource` element specifies that the user can perform actions on or with resources. You specify resources using an Amazon Resources Name (ARN). This ARN includes the name of the service that the resource belongs to (`rds`), the AWS Region (`*` indicates any region in this example), the AWS account number (123456789012 is the account number in this example), and the type of resource. For more information about creating ARNs, see [Working with Amazon Resource Names (ARNs) in Amazon RDS](p. 471).

The `Resource` element in the example specifies the following policy constraints on resources for the user:

- The DB instance identifier for the new DB instance must begin with `test` (for example, `testCustomerData1`, `test-region2-data`).
• The option group for the new DB instance must begin with default.
• The DB parameter group for the new DB instance must begin with default.
• The subnet group for the new DB instance must be the default subnet group.
• The Condition element specifies that the DB engine must be MySQL and the DB instance class must be `db.t2.micro`. The Condition element specifies the conditions when a policy should take effect. You can add additional permissions or restrictions by using the Condition element. For more information about specifying conditions, see `Policy condition keys for Amazon RDS` (p. 2630). This example specifies the `rds:DatabaseEngine` and `rds:DatabaseClass` conditions. For information about the valid condition values for `rds:DatabaseEngine`, see the list under the Engine parameter in `CreateDBInstance`. For information about the valid condition values for `rds:DatabaseClass`, see `Supported DB engines for DB instance classes (p. 14)`.

The policy doesn't specify the Principal element because in an identity-based policy you don't specify the principal who gets the permission. When you attach policy to a user, the user is the implicit principal. When you attach a permission policy to an IAM role, the principal identified in the role's trust policy gets the permissions.

To see a list of Amazon RDS actions, see `Actions Defined by Amazon RDS` in the Service Authorization Reference.

### Permissions required to use the console

For a user to work with the console, that user must have a minimum set of permissions. These permissions allow the user to describe the Amazon RDS resources for their AWS account and to provide other related information, including Amazon EC2 security and network information.

If you create an IAM policy that is more restrictive than the minimum required permissions, the console doesn't function as intended for users with that IAM policy. To ensure that those users can still use the console, also attach the `AmazonRDSReadOnlyAccess` managed policy to the user, as described in `Managing access using policies (p. 2626)`.

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the Amazon RDS API.

The following policy grants full access to all Amazon RDS resources for the root AWS account:

```json
AmazonRDSFullAccess
```

### Allow a user to perform any describe action on any RDS resource

The following permissions policy grants permissions to a user to run all of the actions that begin with `Describe`. These actions show information about an RDS resource, such as a DB instance. The wildcard character (*) in the Resource element indicates that the actions are allowed for all Amazon RDS resources owned by the account.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowRDSDescribe",
            "Effect": "Allow",
            "Action": "rds:*",
            "Resource": "*"
        }
    ]
}
```
Allow a user to create a DB instance that uses the specified DB parameter group and subnet group

The following permissions policy grants permissions to allow a user to only create a DB instance that must use the `mydbpg` DB parameter group and the `mydbsubnetgroup` DB subnet group.

```
{"Version": "2012-10-17",
 "Statement": [
  {
    "Sid": "VisualEditor0",
    "Effect": "Allow",
    "Action": "rds:CreateDBInstance",
    "Resource": [
      "arn:aws:rds:*:*:pg:mydbpg",
      "arn:aws:rds:*:*:subgrp:mydbsubnetgroup"
    ]
  }
]
}
```

Grant permission for actions on a resource with a specific tag with two different values

You can use conditions in your identity-based policy to control access to Amazon RDS resources based on tags. The following policy allows permission to perform the `CreateDBSnapshot` API operation on DB instances with either the `stage` tag set to `development` or `test`.

```
{"Version": "2012-10-17",
 "Statement": [
  {
    "Sid": "AllowAnySnapshotName",
    "Effect": "Allow",
    "Action": ["rds:CreateDBSnapshot"],
    "Resource": "arn:aws:rds:*:123456789012:snapshot:*"
  },
  {
    "Sid": "AllowDevTestToCreateSnapshot",
    "Effect": "Allow",
    "Action": ["rds:CreateDBSnapshot"],
    "Resource": "arn:aws:rds:*:123456789012:db:*",
    "Condition": {
      "StringEquals": {
        "rds:db-tag/stage": ["development", "test"]
      }
    }
  }
]
}
```
The following policy allows permission to perform the ModifyDBInstance API operation on DB instances with either the stage tag set to development or test.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowChangingParameterOptionSecurityGroups",
      "Effect": "Allow",
      "Action": ["rds:ModifyDBInstance"],
      "Resource": [
        "arn:aws:rds:*:123456789012:pg:*",
        "arn:aws:rds:*:123456789012:secgrp:*",
        "arn:aws:rds:*:123456789012:og:*"
      ]
    },
    {
      "Sid": "AllowDevTestToModifyInstance",
      "Effect": "Allow",
      "Action": ["rds:ModifyDBInstance"],
      "Resource": "arn:aws:rds:*:123456789012:db:*",
      "Condition": {
        "StringEquals": {
          "rds:db-tag/stage": ["development", "test"]
        }
      }
    }
  ]
}
```

Prevent a user from deleting a DB instance

The following permissions policy grants permissions to prevent a user from deleting a specific DB instance. For example, you might want to deny the ability to delete your production DB instances to any user that is not an administrator.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyDelete1",
      "Effect": "Deny",
      "Action": "rds:DeleteDBInstance",
    }
  ]
}
```
Deny all access to a resource

You can explicitly deny access to a resource. Deny policies take precedence over allow policies. The following policy explicitly denies a user the ability to manage a resource:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": "rds:*",
        }
    ]
}
```

Example policies: Using condition keys

Following are examples of how you can use condition keys in Amazon RDS IAM permissions policies.

Example 1: Grant permission to create a DB instance that uses a specific DB engine and isn't MultiAZ

The following policy uses an RDS condition key and allows a user to create only DB instances that use the MySQL database engine and don't use MultiAZ. The `Condition` element indicates the requirement that the database engine is MySQL.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowMySQLCreate",
            "Effect": "Allow",
            "Action": "rds:CreateDBInstance",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "rds:DatabaseEngine": "mysql"
                },
                "Bool": {
                    "rds:MultiAz": false
                }
            }
        }
    ]
}
```

Example 2: Explicitly deny permission to create DB instances for certain DB instance classes and create DB instances that use Provisioned IOPS

The following policy explicitly denies permission to create DB instances that use the DB instance classes `r3.8xlarge` and `m4.10xlarge`, which are the largest and most expensive DB instance classes. This policy also prevents users from creating DB instances that use Provisioned IOPS, which incurs an additional cost.

Explicitly denying permission supersedes any other permissions granted. This ensures that identities to not accidentally get permission that you never want to grant.

```
{
```

2639
Example 3: Limit the set of tag keys and values that can be used to tag a resource

The following policy uses an RDS condition key and allows the addition of a tag with the key stage to be added to a resource with the values test, qa, and production.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds:AddTagsToResource",
        "rds:RemoveTagsFromResource"
      ],
      "Resource": "*",
      "Condition": {
        "streq": {
          "rds:req-tag/stage": [
            "test",
            "qa",
            "production"
          ]
        }
      }
    }
  ]
}
```

Specifying conditions: Using custom tags

Amazon RDS supports specifying conditions in an IAM policy using custom tags.
For example, suppose that you add a tag named environment to your DB instances with values such as beta, staging, production, and so on. If you do, you can create a policy that restricts certain users to DB instances based on the environment tag value.

**Note**
Custom tag identifiers are case-sensitive.

The following table lists the RDS tag identifiers that you can use in a Condition element.

<table>
<thead>
<tr>
<th>RDS tag identifier</th>
<th>Applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>db-tag</td>
<td>DB instances, including read replicas</td>
</tr>
<tr>
<td>snapshot-tag</td>
<td>DB snapshots</td>
</tr>
<tr>
<td>ri-tag</td>
<td>Reserved DB instances</td>
</tr>
<tr>
<td>og-tag</td>
<td>DB option groups</td>
</tr>
<tr>
<td>pg-tag</td>
<td>DB parameter groups</td>
</tr>
<tr>
<td>subgrp-tag</td>
<td>DB subnet groups</td>
</tr>
<tr>
<td>es-tag</td>
<td>Event subscriptions</td>
</tr>
<tr>
<td>cluster-tag</td>
<td>DB clusters</td>
</tr>
<tr>
<td>cluster-pg-tag</td>
<td>DB cluster parameter groups</td>
</tr>
<tr>
<td>cluster-snapshot-tag</td>
<td>DB cluster snapshots</td>
</tr>
</tbody>
</table>

The syntax for a custom tag condition is as follows:

```
"Condition":{
    "StringEquals":{
        "rds:rds-tag-identifier/tag-name": ["value"]
    }
}
```

For example, the following Condition element applies to DB instances with a tag named environment and a tag value of production.

```
"Condition":{
    "StringEquals":{
        "rds:db-tag/environment": ["production"]
    }
}
```

For information about creating tags, see [Tagging Amazon RDS resources](#).

**Important**
If you manage access to your RDS resources using tagging, we recommend that you secure access to the tags for your RDS resources. You can manage access to tags by creating policies for the AddTagsToResource and RemoveTagsFromResource actions. For example, the following policy denies users the ability to add or remove tags for all resources. You can then create policies to allow specific users to add or remove tags.

```json
{
    "Version":"2012-10-17",
    "Statement":[
        {
            "Sid":"DenyTagUpdates",
            "Effect":"Deny",
            "Action":[
                "rds:AddTagsToResource",
                "rds:RemoveTagsFromResource"
            ],
            "Resource":"*"
        }
    ]
}
```
To see a list of Amazon RDS actions, see Actions Defined by Amazon RDS in the Service Authorization Reference.

Example policies: Using custom tags

Following are examples of how you can use custom tags in Amazon RDS IAM permissions policies. For more information about adding tags to an Amazon RDS resource, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 471).

Note
All examples use the us-west-2 region and contain fictitious account IDs.

Example 1: Grant permission for actions on a resource with a specific tag with two different values

The following policy allows permission to perform the CreateDBSnapshot API operation on DB instances with either the stage tag set to development or test.

```json
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowAnySnapshotName",
         "Effect":"Allow",
         "Action":
            ["rds:CreateDBSnapshot"],
         "Resource":"arn:aws:rds:*:123456789012:snapshot:*"
      },
      {
         "Sid":"AllowDevTestToCreateSnapshot",
         "Effect":"Allow",
         "Action":
            ["rds:CreateDBSnapshot"],
         "Resource":"arn:aws:rds:*:123456789012:db:*",
         "Condition":{
            "StringEquals":{
               "rds:db-tag/stage":[
                  "development",
                  "test"
               ]
         }
      }
   ]
}
```

The following policy allows permission to perform the ModifyDBInstance API operation on DB instances with either the stage tag set to development or test.

```json
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowChangingParameterOptionSecurityGroups",
         "Effect":"Allow",
         "Action":
            ["rds:ModifyDBInstance"
   ]
}
```
Identity-based policy examples

Example 2: Explicitly deny permission to create a DB instance that uses specified DB parameter groups

The following policy explicitly denies permission to create a DB instance that uses DB parameter groups with specific tag values. You might apply this policy if you require that a specific customer-created DB parameter group always be used when creating DB instances. Policies that use Deny are most often used to restrict access that was granted by a broader policy.

Explicitly denying permission supersedes any other permissions granted. This ensures that identities to not accidentally get permission that you never want to grant.

```
{
  "Version":"2012-10-17",
  "Statement":[
    {
      "Sid":"DenyProductionCreate",
      "Effect":"Deny",
      "Action":"rds:CreateDBInstance",
      "Resource":"arn:aws:rds:*:123456789012:pg:*",
      "Condition":{
        "StringEquals":{
          "rds:pg-tag/usage":"prod"
        }
      }
    }
  ]
}
```

Example 3: Grant permission for actions on a DB instance with an instance name that is prefixed with a user name

The following policy allows permission to call any API (except to AddTagsToResource or RemoveTagsFromResource) on a DB instance that has a DB instance name that is prefixed with the user's name and that has a tag called stage equal to devo or that has no tag called stage.

```
{
  "Version":"2012-10-17",
  "Statement":[
    {
      "Sid":"AllowDevTestToModifyInstance",
      "Effect":"Allow",
      "Action":[
        "rds:ModifyDBInstance"
      ],
      "Resource":"arn:aws:rds:*:123456789012:db:*",
      "Condition":{
        "StringEquals":{
          "rds:db-tag/stage":[
            "development",
            "test"
          ]
        }
      }
    }
  ]
}
```
The **Resource** line in the policy identifies a resource by its Amazon Resource Name (ARN). For more information about using ARNs with Amazon RDS resources, see [Working with Amazon Resource Names (ARNs) in Amazon RDS](p. 471).

```json
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowFullDevAccessNoTags",
         "Effect":"Allow",
         "NotAction":[
            "rds:AddTagsToResource",
            "rds:RemoveTagsFromResource"
         ],
         "Resource":"arn:aws:rds:*:123456789012:db:${aws:username}*",
         "Condition":{
            "StringEqualsIfExists":{
               "rds:db-tag/stage":"devo"
            }
         }
      }
   ]
}
```
AWS managed policies for Amazon RDS

To add permissions to permission sets and roles, it's easier to use AWS managed policies than to write policies yourself. It takes time and expertise to create IAM customer managed policies that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see AWS managed policies in the IAM User Guide.

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (permission sets and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services don't remove permissions from an AWS managed policy, so policy updates don't break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the ReadOnlyAccess AWS managed policy provides read-only access to all AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see AWS managed policies for job functions in the IAM User Guide.

Topics
- AWS managed policy: AmazonRDSReadOnlyAccess (p. 2645)
- AWS managed policy: AmazonRDSFullAccess (p. 2646)
- AWS managed policy: AmazonRDSDataFullAccess (p. 2646)
- AWS managed policy: AmazonRDSEnhancedMonitoringRole (p. 2646)
- AWS managed policy: AmazonRDSPerformanceInsightsReadOnly (p. 2647)
- AWS managed policy: AmazonRDSPerformanceInsightsFullAccess (p. 2647)
- AWS managed policy: AmazonRDSDirectoryServiceAccess (p. 2647)
- AWS managed policy: AmazonRDSServiceRolePolicy (p. 2648)
- AWS managed policy: AmazonRDSCustomServiceRolePolicy (p. 2648)

AWS managed policy: AmazonRDSReadOnlyAccess

This policy allows read-only access to Amazon RDS through the AWS Management Console.

Permissions details

This policy includes the following permissions:
- rds – Allows principals to describe Amazon RDS resources and list the tags for Amazon RDS resources.
- cloudwatch – Allows principals to get Amazon CloudWatch metric statistics.
- ec2 – Allows principals to describe Availability Zones and networking resources.
- logs – Allows principals to describe CloudWatch Logs log streams of log groups, and get CloudWatch Logs log events.
- devops-guru – Allows principals to describe resources that have Amazon DevOps Guru coverage, which is specified either by CloudFormation stack names or resource tags.

For more information about this policy, including the JSON policy document, see AmazonRDSReadOnlyAccess in the AWS Managed Policy Reference Guide.
AWS managed policy: AmazonRDSFullAccess

This policy provides full access to Amazon RDS through the AWS Management Console.

Permissions details

This policy includes the following permissions:

- `rds` – Allows principals full access to Amazon RDS.
- `application-autoscaling` – Allows principals describe and manage Application Auto Scaling scaling targets and policies.
- `cloudwatch` – Allows principals get CloudWatch metric statics and manage CloudWatch alarms.
- `ec2` – Allows principals to describe Availability Zones and networking resources.
- `logs` – Allows principals to describe CloudWatch Logs log streams of log groups, and get CloudWatch Logs log events.
- `outposts` – Allows principals to get AWS Outposts instance types.
- `pi` – Allows principals to get Performance Insights metrics.
- `sns` – Allows principals to Amazon Simple Notification Service (Amazon SNS) subscriptions and topics, and to publish Amazon SNS messages.
- `devops-guru` – Allows principals to describe resources that have Amazon DevOps Guru coverage, which is specified either by CloudFormation stack names or resource tags.

For more information about this policy, including the JSON policy document, see AmazonRDSFullAccess in the AWS Managed Policy Reference Guide.

AWS managed policy: AmazonRDSDataFullAccess

This policy allows full access to use the Data API and the query editor on Aurora Serverless clusters in a specific AWS account. This policy allows the AWS account to get the value of a secret from AWS Secrets Manager.

You can attach the AmazonRDSDataFullAccess policy to your IAM identities.

Permissions details

This policy includes the following permissions:

- `dbqms` – Allows principals to access, create, delete, describe, and update queries. The Database Query Metadata Service (`dbqms`) is an internal-only service. It provides your recent and saved queries for the query editor on the AWS Management Console for multiple AWS services, including Amazon RDS.
- `rds-data` – Allows principals to run SQL statements on Aurora Serverless databases.
- `secretsmanager` – Allows principals to get the value of a secret from AWS Secrets Manager.

For more information about this policy, including the JSON policy document, see AmazonRDSDataFullAccess in the AWS Managed Policy Reference Guide.

AWS managed policy: AmazonRDSEnhancedMonitoringRole

This policy provides access to Amazon CloudWatch Logs for Amazon RDS Enhanced Monitoring.

Permissions details

This policy includes the following permissions:
• Logs – Allows principals to create CloudWatch Logs log groups and retention policies, and to create and describe CloudWatch Logs log streams of log groups. It also allows principals to put and get CloudWatch Logs log events.

For more information about this policy, including the JSON policy document, see AmazonRDSEnhancedMonitoringRole in the AWS Managed Policy Reference Guide.

AWS managed policy: AmazonRDSPerformanceInsightsReadOnly

This policy provides read-only access to Amazon RDS Performance Insights for Amazon RDS DB instances and Amazon Aurora DB clusters.

Permissions details

This policy includes the following permissions:

• rds – Allows principals to describe Amazon RDS DB instances and Amazon Aurora DB clusters.
• pi – Allows principals make calls to the Amazon RDS Performance Insights API and access Performance Insights metrics.

For more information about this policy, including the JSON policy document, see AmazonRDSPerformanceInsightsReadOnly in the AWS Managed Policy Reference Guide.

AWS managed policy: AmazonRDSPerformanceInsightsFullAccess

This policy provides full access to Amazon RDS Performance Insights for Amazon RDS DB instances and Amazon Aurora DB clusters.

Permissions details

This policy includes the following permissions:

• rds – Allows principals to describe Amazon RDS DB instances and Amazon Aurora DB clusters.
• pi – Allows principals make calls to the Amazon RDS Performance Insights API, and create, view, and delete performance analysis reports.
• cloudwatch – Allows principals to list all the Amazon CloudWatch metrics, and get metric data and statistics.

For more information about this policy, including the JSON policy document, see AmazonRDSPerformanceInsightsFullAccess in the AWS Managed Policy Reference Guide.

AWS managed policy: AmazonRDSDirectoryServiceAccess

This policy allows Amazon RDS to make calls to the AWS Directory Service.

Permissions details

This policy includes the following permission:

• ds – Allows principals to describe AWS Directory Service directories and control authorization to AWS Directory Service directories.
For more information about this policy, including the JSON policy document, see AmazonRDSDirectoryServiceAccess in the AWS Managed Policy Reference Guide.

AWS managed policy: AmazonRDSServiceRolePolicy

You can’t attach the AmazonRDSServiceRolePolicy policy to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to perform actions on your behalf. For more information, see Service-linked role permissions for Amazon RDS (p. 2701).

AWS managed policy: AmazonRDSCustomServiceRolePolicy

You can’t attach the AmazonRDSCustomServiceRolePolicy policy to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to perform actions on your behalf. For more information, see Service-linked role permissions for Amazon RDS Custom (p. 2703).
Amazon RDS updates to AWS managed policies

View details about updates to AWS managed policies for Amazon RDS since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the Amazon RDS Document history page.

Preventing cross-service confused deputy problems

The confused deputy problem is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem.

Cross-service impersonation can occur when one service (the calling service) calls another service (the called service). The calling service can be manipulated to use its permissions to act on another customer's resources in a way that it shouldn't have permission to access. To prevent this, AWS provides tools that can help you protect your data for all services with service principals that have been given access to resources in your account. For more information, see The confused deputy problem in the IAM User Guide.

To limit the permissions that Amazon RDS gives another service for a specific resource, we recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource policies.

In some cases, the `aws:SourceArn` value doesn't contain the account ID, for example when you use the Amazon Resource Name (ARN) for an Amazon S3 bucket. In these cases, make sure to use both global condition context keys to limit permissions. In some cases, you use both global condition context keys and the `aws:SourceArn` value contains the account ID. In these cases, make sure that the `aws:SourceAccount` value and the account in the `aws:SourceArn` use the same account ID when they're used in the same policy statement. If you want only one resource to be associated with the cross-service access, use `aws:SourceArn`. If you want to allow any resource in the specified AWS account to be associated with the cross-service use, use `aws:SourceAccount`.

Make sure that the value of `aws:SourceArn` is an ARN for an Amazon RDS resource type. For more information, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 471).

The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition context key with the full ARN of the resource. In some cases, you might not know the full ARN of the resource or you might be specifying multiple resources. In these cases, use the `aws:SourceArn` global context condition key with wildcards (*) for the unknown portions of the ARN. An example is `arn:aws:rds:*:123456789012:*`.

The following example shows how you can use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in Amazon RDS to prevent the confused deputy problem.

```json
{
    "Version": "2012-10-17",
    "Statement": {
        "Sid": "ConfusedDeputyPreventionExamplePolicy",
        "Effect": "Allow",
        "Principal": {
            "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
            "ArnLike": {
                "aws:SourceArn": "arn:aws:rds:us-east-1:123456789012:db:mydbinstance"
            },
            "StringEquals": {
                "aws:SourceAccount": "123456789012"
            }
        }
    }
}
```

For more examples of policies that use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys, see the following sections:
• Granting permissions to publish notifications to an Amazon SNS topic (p. 859)
• Manually creating an IAM role for native backup and restore (p. 1438)
• Setting up Windows Authentication for SQL Server DB instances (p. 1418)
• Prerequisites for integrating RDS for SQL Server with S3 (p. 1481)
• Manually creating an IAM role for SQL Server Audit (p. 1556)
• Configuring IAM permissions for RDS for Oracle integration with Amazon S3 (p. 2008)
• Setting up access to an Amazon S3 bucket (p. 2247) (PostgreSQL import)
• Setting up access to an Amazon S3 bucket (p. 2267) (PostgreSQL export)
IAM database authentication for MariaDB, MySQL, and PostgreSQL

You can authenticate to your DB instance using AWS Identity and Access Management (IAM) database authentication. IAM database authentication works with MariaDB, MySQL, and PostgreSQL. With this authentication method, you don't need to use a password when you connect to a DB instance. Instead, you use an authentication token.

An authentication token is a unique string of characters that Amazon RDS generates on request. Authentication tokens are generated using AWS Signature Version 4. Each token has a lifetime of 15 minutes. You don't need to store user credentials in the database, because authentication is managed externally using IAM. You can also still use standard database authentication. The token is only used for authentication and doesn't affect the session after it is established.

IAM database authentication provides the following benefits:

- Network traffic to and from the database is encrypted using Secure Socket Layer (SSL) or Transport Layer Security (TLS). For more information about using SSL/TLS with Amazon RDS, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2608).
- You can use IAM to centrally manage access to your database resources, instead of managing access individually on each DB instance.
- For applications running on Amazon EC2, you can use profile credentials specific to your EC2 instance to access your database instead of a password, for greater security.

In general, consider using IAM database authentication when your applications create fewer than 200 connections per second, and you don't want to manage usernames and passwords directly in your application code.

The AWS JDBC Driver for MySQL supports IAM database authentication. For more information, see AWS IAM Database Authentication in the AWS JDBC Driver for MySQL GitHub repository.

- Creating and using an IAM policy for IAM database access (p. 2663)
- Creating a database account using IAM authentication (p. 2666)
- Connecting to your DB instance using IAM authentication (p. 2667)

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability with Amazon RDS and IAM database authentication, see IAM database authentication (p. 138).

CLI and SDK support

IAM database authentication is available for the AWS CLI and for the following language-specific AWS SDKs:
Limitations for IAM database authentication

When using IAM database authentication, the following limitations apply:

- The maximum number of connections per second for your DB instance might be limited depending on its DB instance class and your workload.
- Currently, IAM database authentication doesn't support all global condition context keys.

- For PostgreSQL, if the IAM role (rds_i_am) is added to a user (including the RDS master user), IAM authentication takes precedence over password authentication, so the user must log in as an IAM user.
- For PostgreSQL, Amazon RDS does not support enabling both IAM and Kerberos authentication methods at the same time.
- For PostgreSQL, you cannot use IAM authentication to establish a replication connection.

Recommendations for IAM database authentication

We recommend the following when using IAM database authentication:

- Use IAM database authentication when your application requires fewer than 200 new IAM database authentication connections per second.

The database engines that work with Amazon RDS don't impose any limits on authentication attempts per second. However, when you use IAM database authentication, your application must generate an authentication token. Your application then uses that token to connect to the DB instance. If you exceed the limit of maximum new connections per second, then the extra overhead of IAM database authentication can cause connection throttling.

Consider using connection pooling in your applications to mitigate constant connection creation. This can reduce the overhead from IAM DB authentication and allow your applications to reuse existing connections. Alternatively, consider using RDS Proxy for these use cases. RDS Proxy has additional costs. See [RDS Proxy pricing](https://aws.amazon.com/rds/pricing/).

- The size of an IAM database authentication token depends on many things including the number of IAM tags, IAM service policies, ARN lengths, as well as other IAM and database properties. The minimum size of this token is generally about 1 KB but can be larger. Since this token is used as the password in the connection string to the database using IAM authentication, you should ensure that your database driver (e.g., ODBC) and/or any tools do not limit or otherwise truncate this token due to its size. A truncated token will cause the authentication validation done by the database and IAM to fail.

- If you are using temporary credentials when creating an IAM database authentication token, the temporary credentials must still be valid when using the IAM database authentication token to make a connection request.
Unsupported AWS global condition context keys

IAM database authentication does not support the following subset of AWS global condition context keys.

- `aws:Referer`
- `aws:SourceIp`
- `aws:SourceVpc`
- `aws:SourceVpce`
- `aws:UserAgent`
- `aws:VpcSourceIp`

For more information, see [AWS global condition context keys](#) in the *IAM User Guide*.

Enabling and disabling IAM database authentication

By default, IAM database authentication is disabled on DB instances. You can enable or disable IAM database authentication using the AWS Management Console, AWS CLI, or the API.

You can enable IAM database authentication when you perform one of the following actions:

- To create a new DB instance with IAM database authentication enabled, see [Creating an Amazon RDS DB instance](#).
- To modify a DB instance to enable IAM database authentication, see [Modifying an Amazon RDS DB instance](#).
- To restore a DB instance from a snapshot with IAM database authentication enabled, see [Restoring from a DB snapshot](#).
- To restore a DB instance to a point in time with IAM database authentication enabled, see [Restoring a DB instance to a specified time](#).

IAM authentication for PostgreSQL DB instances requires that the SSL value be 1. You can't enable IAM authentication for a PostgreSQL DB instance if the SSL value is 0. You can't change the SSL value to 0 if IAM authentication is enabled for a PostgreSQL DB instance.

Console

Each creation or modification workflow has a Database authentication section, where you can enable or disable IAM database authentication. In that section, choose Password and IAM database authentication to enable IAM database authentication.

To enable or disable IAM database authentication for an existing DB instance

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Databases.
3. Choose the DB instance that you want to modify.
   
   **Note**
   Make sure that the DB instance is compatible with IAM authentication. Check the compatibility requirements in [Region and version availability](#).
4. Choose Modify.
5. In the Database authentication section, choose Password and IAM database authentication to enable IAM database authentication. Choose Password authentication or Password and Kerberos authentication to disable IAM authentication.
6. Choose Continue.
7. To apply the changes immediately, choose **Immediately** in the **Scheduling of modifications** section.
8. Choose **Modify DB instance**.

**AWS CLI**

To create a new DB instance with IAM authentication by using the AWS CLI, use the `create-db-instance` command. Specify the `--enable-iam-database-authentication` option, as shown in the following example.

```bash
aws rds create-db-instance \
   --db-instance-identifier mydbinstance \
   --db-instance-class db.m3.medium \
   --engine MySQL \
   --allocated-storage 20 \
   --master-username masterawsuser \
   --manage-master-user-password \
   --enable-iam-database-authentication
```

To update an existing DB instance to have or not have IAM authentication, use the AWS CLI command `modify-db-instance`. Specify either the `--enable-iam-database-authentication` or `--no-enable-iam-database-authentication` option, as appropriate.

**Note**
Make sure that the DB instance is compatible with IAM authentication. Check the compatibility requirements in [Region and version availability](p. 2659).

By default, Amazon RDS performs the modification during the next maintenance window. If you want to override this and enable IAM DB authentication as soon as possible, use the `--apply-immediately` parameter.

The following example shows how to immediately enable IAM authentication for an existing DB instance.

```bash
aws rds modify-db-instance \
   --db-instance-identifier mydbinstance \
   --apply-immediately \
   --enable-iam-database-authentication
```

If you are restoring a DB instance, use one of the following AWS CLI commands:

- `restore-db-instance-to-point-in-time`
- `restore-db-instance-from-db-snapshot`

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the `--enable-iam-database-authentication` or `--no-enable-iam-database-authentication` option, as appropriate.

**RDS API**

To create a new DB instance with IAM authentication by using the API, use the API operation `CreateDBInstance`. Set the `EnableIAMDatabaseAuthentication` parameter to `true`.

To update an existing DB instance to have IAM authentication, use the API operation `ModifyDBInstance`. Set the `EnableIAMDatabaseAuthentication` parameter to `true` to enable IAM authentication, or `false` to disable it.

**Note**
Make sure that the DB instance is compatible with IAM authentication. Check the compatibility requirements in [Region and version availability](p. 2659).
If you are restoring a DB instance, use one of the following API operations:

- `RestoreDBInstanceFromDBSnapshot`
- `RestoreDBInstanceToPointInTime`

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the `EnableIAMDatabaseAuthentication` parameter to `true` to enable IAM authentication, or `false` to disable it.

Creating and using an IAM policy for IAM database access

To allow a user or role to connect to your DB instance, you must create an IAM policy. After that, you attach the policy to a permissions set or role.

**Note**
To learn more about IAM policies, see [Identity and access management for Amazon RDS](p. 2623).

The following example policy allows a user to connect to a DB instance using IAM database authentication.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["rds-db:connect"],
    }
  ]
}
```

**Important**

A user with administrator permissions can access DB instances without explicit permissions in an IAM policy. If you want to restrict administrator access to DB instances, you can create an IAM role with the appropriate, lesser privileged permissions and assign it to the administrator.

**Note**

Don't confuse the `rds-db:` prefix with other RDS API operation prefixes that begin with `rds:`. You use the `rds-db:` prefix and the `rds-db:connect` action only for IAM database authentication. They aren't valid in any other context.

The example policy includes a single statement with the following elements:

- **Effect** – Specify `Allow` to grant access to the DB instance. If you don't explicitly allow access, then access is denied by default.
- **Action** – Specify `rds-db:connect` to allow connections to the DB instance.
- **Resource** – Specify an Amazon Resource Name (ARN) that describes one database account in one DB instance. The ARN format is as follows.

   `arn:aws:rds-db:region:account-id:dbuser:DbiResourceId/db-user-name`
In this format, replace the following:

- **region** is the AWS Region for the DB instance. In the example policy, the AWS Region is us-east-2.
- **account-id** is the AWS account number for the DB instance. In the example policy, the account number is 1234567890. The user must be in the same account as the account for the DB instance.

To perform cross-account access, create an IAM role with the policy shown above in the account for the DB instance and allow your other account to assume the role.

- **DbiResourceId** is the identifier for the DB instance. This identifier is unique to an AWS Region and never changes. In the example policy, the identifier is db-ABCDEFGHIJKL01234.

To find a DB instance resource ID in the AWS Management Console for Amazon RDS, choose the DB instance to see its details. Then choose the Configuration tab. The Resource ID is shown in the Configuration section.

Alternatively, you can use the AWS CLI command to list the identifiers and resource IDs for all of your DB instance in the current AWS Region, as shown following.

```
aws rds describe-db-instances --query "DBInstances[0].[DBInstanceIdentifier,DbiResourceId]"
```

If you are using Amazon Aurora, specify a DbClusterResourceId instead of a DbiResourceId. For more information, see [Creating and using an IAM policy for IAM database access](amazonauroraguide) in the *Amazon Aurora User Guide*.

**Note**

If you are connecting to a database through RDS Proxy, specify the proxy resource ID, such as prx-ABCDEFHJIKL01234. For information about using IAM database authentication with RDS Proxy, see [Connecting to a proxy using IAM authentication](amazonauroraguide) (p. 1235).

- **db-user-name** is the name of the database account to associate with IAM authentication. In the example policy, the database account is db_user.

You can construct other ARNs to support various access patterns. The following policy allows access to two different database accounts in a DB instance.

```json
{
"Version": "2012-10-17",
"Statement": [
{
"Effect": "Allow",
"Action": ["rds-db:connect"],
"Resource": [
]
}
}
```

The following policy uses the "*" character to match all DB instances and database accounts for a particular AWS account and AWS Region.
The following policy matches all of the DB instances for a particular AWS account and AWS Region. However, the policy only grants access to DB instances that have a `jane_doe` database account.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": ["rds-db:connect"],
      }
   ]
}
```

The user or role has access to only those databases that the database user does. For example, suppose that your DB instance has a database named `dev`, and another database named `test`. If the database user `jane_doe` has access only to `dev`, any users or roles that access that DB instance with the `jane_doe` user also have access only to `dev`. This access restriction is also true for other database objects, such as tables, views, and so on.

An administrator must create IAM policies that grant entities permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the permission sets or roles that require those permissions. For examples of policies, see Identity-based policy examples for Amazon RDS (p. 2633).

**Attaching an IAM policy to a permission set or role**

After you create an IAM policy to allow database authentication, you need to attach the policy to a permission set or role. For a tutorial on this topic, see Create and attach your first customer managed policy in the IAM User Guide.

As you work through the tutorial, you can use one of the policy examples shown in this section as a starting point and tailor it to your needs. At the end of the tutorial, you have a permission set with an attached policy that can make use of the `rds-db:connect` action.

**Note**

You can map multiple permission sets or roles to the same database user account. For example, suppose that your IAM policy specified the following resource ARN.
If you attach the policy to Jane, Bob, and Diego, then each of those users can connect to the specified DB instance using the jane_doe database account.

Creating a database account using IAM authentication

With IAM database authentication, you don't need to assign database passwords to the user accounts you create. If you remove a user that is mapped to a database account, you should also remove the database account with the DROP USER statement.

Note
The user name used for IAM authentication must match the case of the user name in the database.

Topics
• Using IAM authentication with MariaDB and MySQL (p. 2666)
• Using IAM authentication with PostgreSQL (p. 2667)

Using IAM authentication with MariaDB and MySQL

With MariaDB and MySQL, authentication is handled by AWSAuthenticationPlugin—an AWS-provided plugin that works seamlessly with IAM to authenticate your users. Connect to the DB instance as the master user or a different user who can create users and grant privileges. After connecting, issue the CREATE USER statement, as shown in the following example.

```sql
CREATE USER jane_doe IDENTIFIED WITH AWSAuthenticationPlugin AS 'RDS';
```

The IDENTIFIED WITH clause allows MariaDB and MySQL to use the AWSAuthenticationPlugin to authenticate the database account (jane_doe). The AS 'RDS' clause refers to the authentication method. Make sure the specified database user name is the same as a resource in the IAM policy for IAM database access. For more information, see Creating and using an IAM policy for IAM database access (p. 2663).

Note
If you see the following message, it means that the AWS-provided plugin is not available for the current DB instance.

```
ERROR 1524 (HY000): Plugin 'AWSAuthenticationPlugin' is not loaded
```
To troubleshoot this error, verify that you are using a supported configuration and that you have enabled IAM database authentication on your DB instance. For more information, see Region and version availability (p. 2659) and Enabling and disabling IAM database authentication (p. 2661).

After you create an account using AWSAuthenticationPlugin, you manage it in the same way as other database accounts. For example, you can modify account privileges with GRANT and REVOKE statements, or modify various account attributes with the ALTER USER statement.

Database network traffic is encrypted using SSL/TLS when using IAM. To allow SSL connections, modify the user account with the following command.

```sql
ALTER USER 'jane_doe'@'%' REQUIRE SSL;
```
Using IAM authentication with PostgreSQL

To use IAM authentication with PostgreSQL, connect to the DB instance as the master user or a different user who can create users and grant privileges. After connecting, create database users and then grant them the rds_iam role as shown in the following example.

```
CREATE USER db_userx;
GRANT rds_iam TO db_userx;
```

Make sure the specified database user name is the same as a resource in the IAM policy for IAM database access. For more information, see Creating and using an IAM policy for IAM database access (p. 2663).

Connecting to your DB instance using IAM authentication

With IAM database authentication, you use an authentication token when you connect to your DB instance. An authentication token is a string of characters that you use instead of a password. After you generate an authentication token, it's valid for 15 minutes before it expires. If you try to connect using an expired token, the connection request is denied.

Every authentication token must be accompanied by a valid signature, using AWS signature version 4. (For more information, see Signature Version 4 signing process in the AWS General Reference.) The AWS CLI and an AWS SDK, such as the AWS SDK for Java or AWS SDK for Python (Boto3), can automatically sign each token you create.

You can use an authentication token when you connect to Amazon RDS from another AWS service, such as AWS Lambda. By using a token, you can avoid placing a password in your code. Alternatively, you can use an AWS SDK to programmatically create and programmatically sign an authentication token.

After you have a signed IAM authentication token, you can connect to an Amazon RDS DB instance. Following, you can find out how to do this using either a command line tool or an AWS SDK, such as the AWS SDK for Java or AWS SDK for Python (Boto3).

For more information, see the following blog posts:

- [Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL](p. 2668)
- [Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL](p. 2670)

Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- [Enabling and disabling IAM database authentication](p. 2661)
- [Creating and using an IAM policy for IAM database access](p. 2663)
- [Creating a database account using IAM authentication](p. 2666)

Topics

- [Connecting to your DB instance using IAM authentication from the command line: AWS CLI and mysql client](p. 2668)
- [Connecting to your DB instance using IAM authentication from the command line: AWS CLI and psql client](p. 2670)
- [Connecting to your DB instance using IAM authentication and the AWS SDK for .NET](p. 2671)
- [Connecting to your DB instance using IAM authentication and the AWS SDK for Go](p. 2674)
Connecting to your DB instance using IAM authentication and the AWS SDK for Java (p. 2678)
Connecting to your DB instance using IAM authentication and the AWS SDK for Python (Boto3) (p. 2685)

Connecting to your DB instance using IAM authentication from the command line: AWS CLI and mysql client

You can connect from the command line to an Amazon RDS DB instance with the AWS CLI and mysql command line tool as described following.

Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

• Enabling and disabling IAM database authentication (p. 2661)
• Creating and using an IAM policy for IAM database access (p. 2663)
• Creating a database account using IAM authentication (p. 2666)

Note

For information about connecting to your database using SQL Workbench/J with IAM authentication, see the blog post Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL.

Topics

• Generating an IAM authentication token (p. 2668)
• Connecting to a DB instance (p. 2669)

Generating an IAM authentication token

The following example shows how to get a signed authentication token using the AWS CLI.

```
aws rds generate-db-auth-token \
    --hostname rdsmysql.123456789012.us-west-2.rds.amazonaws.com \
    --port 3306 \
    --region us-west-2 \
    --username jane_doe
```

In the example, the parameters are as follows:

• --hostname – The host name of the DB instance that you want to access
• --port – The port number used for connecting to your DB instance
• --region – The AWS Region where the DB instance is running
• --username – The database account that you want to access

The first several characters of the token look like the following.

```
rdsmysql.123456789012.us-west-2.rds.amazonaws.com:3306/?Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```

Note

You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.
Connecting to a DB instance

The general format for connecting is shown following.

```bash
mysql --host=hostName --port=portNumber --ssl-ca=full_path_to_ssl_certificate --enable-cleartext-plugin --user=userName --password=authToken
```

The parameters are as follows:

- **--host** – The host name of the DB instance that you want to access
- **--port** – The port number used for connecting to your DB instance
- **--ssl-ca** – The full path to the SSL certificate file that contains the public key

For more information about SSL/TLS support for MariaDB, see Using SSL/TLS with a MariaDB DB instance (p. 1291).

For more information about SSL/TLS support for MySQL, see Using SSL/TLS with a MySQL DB instance (p. 1655).

To download an SSL certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2608).

- **--enable-cleartext-plugin** – A value that specifies that AWSAuthenticationPlugin must be used for this connection

  If you are using a MariaDB client, the **--enable-cleartext-plugin** option isn't required.

- **--user** – The database account that you want to access
- **--password** – A signed IAM authentication token

The authentication token consists of several hundred characters. It can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows one way to perform this workaround. In the example, `/sample_dir/` is the full path to the SSL certificate file that contains the public key.

```bash
RDSHOST="mysqlbd.123456789012.us-east-1.rds.amazonaws.com"
TOKEN="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 3306 --region us-west-2 --username jane_doe )"
mysql --host=$RDSHOST --port=3306 --ssl-ca=/sample_dir/global-bundle.pem --enable-cleartext-plugin --user=jane_doe --password=$TOKEN
```

When you connect using AWSAuthenticationPlugin, the connection is secured using SSL. To verify this, type the following at the `mysql>` command prompt.

```
show status like 'Ssl%';
```

The following lines in the output show more details.

```
+-----------------+-------------+
| Variable_name   | Value       |
+-----------------+-------------+
| ...             | ...         |
| Ssl_cipher      | AES256-SHA  |
| ...             | ...         |
```

2669
<table>
<thead>
<tr>
<th>Ssl_version</th>
<th>TLSv1.1</th>
</tr>
</thead>
<tbody>
<tr>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>
|+-----------------------------+

If you want to connect to a DB instance through a proxy, see Connecting to a proxy using IAM authentication (p. 1235).

Connecting to your DB instance using IAM authentication from the command line: AWS CLI and psql client

You can connect from the command line to an Amazon RDS for PostgreSQL DB instance with the AWS CLI and psql command line tool as described following.

Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication (p. 2661)
- Creating and using an IAM policy for IAM database access (p. 2663)
- Creating a database account using IAM authentication (p. 2666)

**Note**

For information about connecting to your database using pgAdmin with IAM authentication, see the blog post Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL.

Topics

- Generating an IAM authentication token (p. 2670)
- Connecting to an Amazon RDS PostgreSQL instance (p. 2671)

Generating an IAM authentication token

The authentication token consists of several hundred characters so it can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows how to use the AWS CLI to get a signed authentication token using the `generate-db-auth-token` command, and store it in a `PGPASSWORD` environment variable.

```bash
export RDSHOST="rdspostgres.123456789012.us-west-2.rds.amazonaws.com"
export PGPASSWORD="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --region us-west-2 --username jane_doe )"
```

In the example, the parameters to the `generate-db-auth-token` command are as follows:

- `--hostname` – The host name of the DB instance that you want to access
- `--port` – The port number used for connecting to your DB instance
- `--region` – The AWS Region where the DB instance is running
- `--username` – The database account that you want to access

The first several characters of the generated token look like the following.

```
rdspostgres.123456789012.us-west-2.rds.amazonaws.com:5432/?
Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```

2670
Note
You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

Connecting to an Amazon RDS PostgreSQL instance

The general format for using psql to connect is shown following.

```sql
psql "host=hostName port=portNumber sslmode=verify-full
sslrootcert=full_path_to_ssl_certificate dbname=DBName user=userName password=authToken"
```

The parameters are as follows:

- **host** – The host name of the DB instance that you want to access
- **port** – The port number used for connecting to your DB instance
- **sslmode** – The SSL mode to use
  
  When you use `sslmode=verify-full`, the SSL connection verifies the DB instance endpoint against the endpoint in the SSL certificate.
- **sslrootcert** – The full path to the SSL certificate file that contains the public key
  
  For more information, see Using SSL with a PostgreSQL DB instance (p. 2191).
  
  To download an SSL certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2608).
- **dbname** – The database that you want to access
- **user** – The database account that you want to access
- **password** – A signed IAM authentication token

Note
You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

The following example shows using psql to connect. In the example, psql uses the environment variable RDSHOST for the host and the environment variable PGPASSWORD for the generated token. Also, `/sample_dir/` is the full path to the SSL certificate file that contains the public key.

```bash
export RDSHOST="rdspostgres.123456789012.us-west-2.rds.amazonaws.com"
export PGPASSWORD="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --region us-west-2 --username jane_doe )"

psql "host=$RDSHOST port=5432 sslmode=verify-full sslrootcert=/sample_dir/global-bundle.pem dbname=DBName user=jane_doe password=$PGPASSWORD"
```

If you want to connect to a DB instance through a proxy, see Connecting to a proxy using IAM authentication (p. 1235).

Connecting to your DB instance using IAM authentication and the AWS SDK for .NET

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for .NET as described following.

Prerequisites
The following are prerequisites for connecting to your DB instance using IAM authentication:
Enabling and disabling IAM database authentication (p. 2661)
Creating and using an IAM policy for IAM database access (p. 2663)
Creating a database account using IAM authentication (p. 2666)

Examples

The following code examples show how to generate an authentication token, and then use it to connect to a DB instance.

To run this code example, you need the AWS SDK for .NET, found on the AWS site. The AWSSDK .CORE and the AWSSDK .RDS packages are required. To connect to a DB instance, use the .NET database connector for the DB engine, such as MySqlConnector for MariaDB or MySQL, or Npgsql for PostgreSQL.

This code connects to a MariaDB or MySQL DB instance. Modify the values of the following variables as needed:

- **server** – The endpoint of the DB instance that you want to access
- **user** – The database account that you want to access
- **database** – The database that you want to access
- **port** – The port number used for connecting to your DB instance
- **SslMode** – The SSL mode to use

When you use SslMode=Required, the SSL connection verifies the DB instance endpoint against the endpoint in the SSL certificate.

- **SslCa** – The full path to the SSL certificate for Amazon RDS

To download a certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2608).

Note

You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

```csharp
using System;
using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;
using Amazon;

namespace ubuntu
{
    class Program
    {
        static void Main(string[] args)
        {
            var pwd = Amazon.RDS.Util.RDSAuthTokenGenerator.GenerateAuthToken(RegionEndpoint.USEast1, "mysqldb.123456789012.us-east-1.rds.amazonaws.com", 3306, "jane_doe");
            // for debug only Console.Write("{0}\n", pwd); //this verifies the token is generated

            MySqlConnection conn = new MySqlConnection($"server=mysqldb.123456789012.us-east-1.rds.amazonaws.com;user=jane_doe;database=mydB;port=3306;password={pwd};SslMode=Required;SslCa=full_path_to_ssl_certificate");
            conn.Open();

            // Define a query
            MySqlCommand sampleCommand = new MySqlCommand("SHOW DATABASES;", conn);

            // Execute a query
        }
    }
}
```
This code connects to a PostgreSQL DB instance.

Modify the values of the following variables as needed:

- **Server** – The endpoint of the DB instance that you want to access
- **User ID** – The database account that you want to access
- **Database** – The database that you want to access
- **Port** – The port number used for connecting to your DB instance
- **SSL Mode** – The SSL mode to use

When you use **SSL Mode=Required**, the SSL connection verifies the DB instance endpoint against the endpoint in the SSL certificate.

- **Root Certificate** – The full path to the SSL certificate for Amazon RDS

To download a certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2608).

---

```csharp
using System;
using Npgsql;
using Amazon.RDS.Util;

namespace ConsoleApp1
{
    class Program
    {
        static void Main(string[] args)
        {
            var pwd = RDSAuthTokenGenerator.GenerateAuthToken("postgresmydb.123456789012.us-east-1.rds.amazonaws.com", 5432, "jane_doe");
            // for debug only Console.Write("\n", pwd); //this verifies the token is generated
            NpgsqlConnection conn = new NpgsqlConnection("Server=postgresmydb.123456789012.us-east-1.rds.amazonaws.com;User Id=jane_doe;Password={pwd};Database=mydb;SSL Mode=Require;Root Certificate=full_path_to_ssl_certificate");
            conn.Open();

            // Define a query
            NpgsqlCommand cmd = new NpgsqlCommand("select count(*) FROM pg_user", conn);

            // Execute a query
            NpgsqlDataReader dr = cmd.ExecuteReader();
        }
    }
}
```
// Read all rows and output the first column in each row
while (dr.Read())
  Console.Write("{0}\n", dr[0]);
  // Close connection
  conn.Close();
}

If you want to connect to a DB instance through a proxy, see Connecting to a proxy using IAM authentication (p. 1235).

Connecting to your DB instance using IAM authentication and the AWS SDK for Go

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for Go as described following.

Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication (p. 2661)
- Creating and using an IAM policy for IAM database access (p. 2663)
- Creating a database account using IAM authentication (p. 2666)

Examples

To run these code examples, you need the AWS SDK for Go, found on the AWS site.

Modify the values of the following variables as needed:

- dbName – The database that you want to access
- dbUser – The database account that you want to access
- dbHost – The endpoint of the DB instance that you want to access
  
  **Note**
  You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.
- dbPort – The port number used for connecting to your DB instance
- region – The AWS Region where the DB instance is running

In addition, make sure the imported libraries in the sample code exist on your system.

**Important**

The examples in this section use the following code to provide credentials that access a database from a local environment:

```go
creds := credentials.NewEnvCredentials()
```

If you are accessing a database from an AWS service, such as Amazon EC2 or Amazon ECS, you can replace the code with the following code:

```go
sess := session.Must(session.NewSession())
creds := sess.Config.Credentials
```

If you make this change, make sure you add the following import:

```
"github.com/aws/aws-sdk-go/aws/session"
```

**Topics**
• Connecting using IAM authentication and the AWS SDK for Go V2 (p. 2675)
• Connecting using IAM authentication and the AWS SDK for Go V1. (p. 2676)

Connecting using IAM authentication and the AWS SDK for Go V2

You can connect to a DB instance using IAM authentication and the AWS SDK for Go V2.

The following code examples show how to generate an authentication token, and then use it to connect to a DB instance.

This code connects to a MariaDB or MySQL DB instance.

```go
package main
import (
    "context"
    "database/sql"
    "fmt"
    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/feature/rds/auth"
    _ "github.com/go-sql-driver/mysql"
)
func main() {
    var dbName string = "DatabaseName"
    var dbUser string = "DatabaseUser"
    var dbHost string = "mysql-db.123456789012.us-east-1.rds.amazonaws.com"
    var dbPort int = 3306
    var dbEndpoint string = fmt.Sprintf("%s:%d", dbHost, dbPort)
    var region string = "us-east-1"
    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        panic("configuration error: " + err.Error())
    }
    authenticationToken, err := auth.BuildAuthToken(
        context.TODO(), dbEndpoint, region, dbUser, cfg.Credentials)
    if err != nil {
        panic("failed to create authentication token: " + err.Error())
    }
    dsn := fmt.Sprintf("%s:%s@tcp(%s)/%s?tls=true&allowCleartextPasswords=true", 
        dbUser, authenticationToken, dbEndpoint, dbName,
    )
    db, err := sql.Open("mysql", dsn)
    if err != nil {
        panic(err)
    }
    err = db.Ping()
    if err != nil {
        panic(err)
    }
}
```

This code connects to a PostgreSQL DB instance.

```go
package main
import (
    "context"
    "database/sql"
    "fmt"
    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/feature/rds/auth"
    "github.com/lib/pq"
)
func main() {
    var dbName string = "DatabaseName"
    var dbUser string = "DatabaseUser"
    var dbHost string = "mysql-db.123456789012.us-east-1.rds.amazonaws.com"
    var dbPort int = 5432
    var dbEndpoint string = fmt.Sprintf("%s:%d", dbHost, dbPort)
    var region string = "us-east-1"
    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        panic("configuration error: " + err.Error())
    }
    authenticationToken, err := auth.BuildAuthToken(
        context.TODO(), dbEndpoint, region, dbUser, cfg.Credentials)
    if err != nil {
        panic("failed to create authentication token: " + err.Error())
    }
    dsn := fmt.Sprintf("%s:%s@tcp(%s)/%s?tls=true&allowCleartextPasswords=true", 
        dbUser, authenticationToken, dbEndpoint, dbName,
    )
    db, err := sql.Open("postgres", dsn)
    if err != nil {
        panic(err)
    }
    err = db.Ping()
    if err != nil {
        panic(err)
    }
    defer db.Close()
    err = db.Query("SELECT version();", &version)
    if err != nil {
        panic(err)
    }
}
```

This code connects to a PostgreSQL DB instance.
import (  "context"  "database/sql"  "fmt"  
- "github.com/lib/pq"
)

func main() {  
var dbName string = "DatabaseName"  
var dbUser string = "DatabaseUser"  
var dbHost string = "postgresmydb.123456789012.us-east-1.rds.amazonaws.com"  
var dbPort int = 5432  
var dbEndpoint string = fmt.Sprintf("%s:%d", dbHost, dbPort)  
var region string = "us-east-1"  

cfg, err := config.LoadDefaultConfig(context.TODO())  
if err != nil {  
panic("configuration error: " + err.Error())  
}  

authenticationToken, err := auth.BuildAuthToken(context.TODO(), dbEndpoint, region, dbUser, cfg.Credentials)  
if err != nil {  
panic("failed to create authentication token: " + err.Error())  
}  

dsn := fmt.Sprintf("host=%s port=%d user=%s password=%s dbname=%s",  
    dbHost, dbPort, dbUser, authenticationToken, dbName,  
)  

db, err := sql.Open("postgres", dsn)  
if err != nil {  
    panic(err)  
}  

err = db.Ping()  
if err != nil {  
    panic(err)  
}
}

If you want to connect to a DB instance through a proxy, see Connecting to a proxy using IAM authentication on p. 1235.

Connecting using IAM authentication and the AWS SDK for Go V1.

You can connect to a DB instance using IAM authentication and the AWS SDK for Go V1.

The following code examples show how to generate an authentication token, and then use it to connect to a DB instance.

This code connects to a MariaDB or MySQL DB instance.
func main() {

dbName := "app"
dbUser := "jane_doe"
dbHost := "mysql.db.123456789012.us-east-1.rds.amazonaws.com"
dbPort := 3306
dbEndpoint := fmt.Sprintf("%s:%d", dbHost, dbPort)
region := "us-east-1"
creds := credentials.NewEnvCredentials()
authToken, err := rdsutils.BuildAuthToken(dbEndpoint, region, dbUser, creds)
if err != nil {
    panic(err)
}

dsn := fmt.Sprintf("%s:%s@tcp(%s)/%s?tls=true&allowCleartextPasswords=true", 
dbUser, authToken, dbEndpoint, dbName, 
)

db, err := sql.Open("mysql", dsn)
if err != nil {
    panic(err)
}

er = db.Ping()
if err != nil {
    panic(err)
}
}

This code connects to a PostgreSQL DB instance.

package main
import ( 
    "database/sql"
    "fmt"
    "github.com/aws/aws-sdk-go/aws/credentials"
    "github.com/aws/aws-sdk-go/service/rds/rdsutils"
    _ "github.com/lib/pq"
)
func main() {

dbName := "app"
dbUser := "jane_doe"
dbHost := "postgresmydb.123456789012.us-east-1.rds.amazonaws.com"
dbPort := 5432
dbEndpoint := fmt.Sprintf("%s:%d", dbHost, dbPort)
region := "us-east-1"
creds := credentials.NewEnvCredentials()
authToken, err := rdsutils.BuildAuthToken(dbEndpoint, region, dbUser, creds)
if err != nil {
    panic(err)
}

dsn := fmt.Sprintf("host=%s port=%d user=%s password=%s dbname=%s", 
dbHost, dbPort, dbUser, authToken, dbName, 
)
IAM database authentication

```go
db, err := sql.Open("postgres", dsn)
if err != nil {
    panic(err)
}
err = db.Ping()
if err != nil {
    panic(err)
}
```

If you want to connect to a DB instance through a proxy, see [Connecting to a proxy using IAM authentication](p. 1235).

**Connecting to your DB instance using IAM authentication and the AWS SDK for Java**

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for Java as described following.

**Prerequisites**

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication (p. 2661)
- Creating and using an IAM policy for IAM database access (p. 2663)
- Creating a database account using IAM authentication (p. 2666)
- Set up the AWS SDK for Java

**Topics**

- Generating an IAM authentication token (p. 2678)
- Manually constructing an IAM authentication token (p. 2679)
- Connecting to a DB instance (p. 2682)

**Generating an IAM authentication token**

If you are writing programs using the AWS SDK for Java, you can get a signed authentication token using the `RdsIamAuthTokenGenerator` class. Using this class requires that you provide AWS credentials. To do this, you create an instance of the `DefaultAWSCredentialsProviderChain` class. `DefaultAWSCredentialsProviderChain` uses the first AWS access key and secret key that it finds in the default credential provider chain. For more information about AWS access keys, see [Managing access keys for users](p. 2679).

**Note**

You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

After you create an instance of `RdsIamAuthTokenGenerator`, you can call the `getAuthToken` method to obtain a signed token. Provide the AWS Region, host name, port number, and user name. The following code example illustrates how to do this.

```go
package com.amazonaws.codesamples;
import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.services.rds.auth.GetIamAuthTokenRequest;
```
Manually constructing an IAM authentication token

In Java, the easiest way to generate an authentication token is to use `RdsIamAuthTokenGenerator`. This class creates an authentication token for you, and then signs it using AWS signature version 4. For more information, see [Signature version 4 signing process](#) in the [AWS General Reference](#).

However, you can also construct and sign an authentication token manually, as shown in the following code example.

```java
import java.security.MessageDigest;
import java.util.SortedMap;
import java.util.TreeMap;
import static com.amazonaws.auth.internal.SignerConstants.AWS4_TERMINATOR;
import static com.amazonaws.util.StringUtils.UTF8;

public class CreateRDSAuthComponentManually {

    public static void main(String[] args) {
        String region = "us-west-2";
        String hostname = "rdsmysql.123456789012.us-west-2.rds.amazonaws.com";
        String port = "3306";
        String username = "jane_doe";
        System.out.println(generateAuthToken(region, hostname, port, username));
    }

    static String generateAuthToken(String region, String hostName, String port, String
        username) {
        RdsIamAuthTokenGenerator generator = RdsIamAuthTokenGenerator.builder()
            .credentials(new DefaultAWSCredentialsProviderChain())
            .region(region)
            .build();

        String authToken = generator.getAuthToken(
            GetIamAuthTokenRequest.builder()
                .hostname(hostName)
                .port(Integer.parseInt(port))
                .userName(username)
                .build());

        return authToken;
    }
}
```

Connecting to a DB instance

The following code example shows how to generate an authentication token, and then use it to connect to an instance running MariaDB or MySQL.

To run this code example, you need the AWS SDK for Java, found on the AWS site. In addition, you need the following:

- MySQL Connector/J. This code example was tested with mysql-connector-java-5.1.33-bin.jar.
- An intermediate certificate for Amazon RDS that is specific to an AWS Region. (For more information, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2608).) At runtime, the class loader looks for the certificate in the same directory as this Java code example, so that the class loader can find it.
- Modify the values of the following variables as needed:
  - RDS_INSTANCE_HOSTNAME – The host name of the DB instance that you want to access.
  - RDS_INSTANCE_PORT – The port number used for connecting to your PostgreSQL DB instance.
  - REGION_NAME – The AWS Region where the DB instance is running.
  - DB_USER – The database account that you want to access.
  - SSL_CERTIFICATE – An SSL certificate for Amazon RDS that is specific to an AWS Region.

To download a certificate for your AWS Region, see Using SSL/TLS to encrypt a connection to a DB instance (p. 2608). Place the SSL certificate in the same directory as this Java program file, so that the class loader can find the certificate at runtime.

This code example obtains AWS credentials from the default credential provider chain.

Note
Specify a password for DEFAULT_KEY_STORE_PASSWORD other than the prompt shown here as a security best practice.
import com.amazonaws.services.rds.auth.RdsIamAuthTokenGenerator;
import com.amazonaws.services.rds.auth.GetIamAuthTokenRequest;
import com.amazonaws.auth.BasicAWSCredentials;
import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.auth.AWSStaticCredentialsProvider;
import java.io.File;
import java.io.FileOutputStream;
import java.io.InputStream;
import java.security.KeyStore;
import java.security.cert.CertificateFactory;
import java.security.cert.X509Certificate;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.ResultSet;
import java.sql.Statement;
import java.util.Properties;
import java.net.URL;

public class IAMDatabaseAuthenticationTester {
    // AWS Credentials of the IAM user with policy enabling IAM Database Authenticated access to the db by the db user.
    private static final DefaultAWSCredentialsProviderChain creds = new DefaultAWSCredentialsProviderChain();
    private static final String AWS_ACCESS_KEY = creds.getCredentials().getAWSAccessKeyId();
    private static final String AWS_SECRET_KEY = creds.getCredentials().getAWSSecretKey();

    // Configuration parameters for the generation of the IAM Database Authentication token
    private static final String RDS_INSTANCE_HOSTNAME = "rdsmysql.123456789012.us-west-2.rds.amazonaws.com";
    private static final int RDS_INSTANCE_PORT = 3306;
    private static final String REGION_NAME = "us-west-2";
    private static final String DB_USER = "jane_doe";
    private static final String JDBC_URL = "jdbc:mysql://" + RDS_INSTANCE_HOSTNAME + ":" + RDS_INSTANCE_PORT;
    private static final String SSL_CERTIFICATE = "rds-ca-2019-us-west-2.pem";
    private static final String KEY_STORE_TYPE = "JKS";
    private static final String KEY_STORE_PROVIDER = "SUN";
    private static final String KEY_STORE_FILE_PREFIX = "sys-connect-via-ssl-test-cacerts";
    private static final String KEY_STORE_FILE_SUFFIX = ".jks";
    private static final String DEFAULT_KEY_STORE_PASSWORD = "changeit";

    public static void main(String[] args) throws Exception {
        // get the connection
        Connection connection = getDBConnectionUsingIam();

        // verify the connection is successful
        Statement stmt = connection.createStatement();
        ResultSet rs = stmt.executeQuery("SELECT 'Success!' FROM DUAL;" Malone);  
        while (rs.next())
        {
            String id = rs.getString(1);
            System.out.println(id); // Should print "Success!"
            break;
        }

        // close the connection
        stmt.close();
        connection.close();
        clearSslProperties();
    }
}
This method returns a connection to the db instance authenticated using IAM Database Authentication
@throws Exception
private static Connection getDBConnectionUsingIam() throws Exception {
    setSslProperties();
    return DriverManager.getConnection(JDBC_URL, setMySqlConnectionProperties());
}

This method sets the mysql connection properties which includes the IAM Database Authentication token
as the password. It also specifies that SSL verification is required.
@throws Exception
private static Properties setMySqlConnectionProperties() {
    Properties mysqlConnectionProperties = new Properties();
    mysqlConnectionProperties.setProperty("verifyServerCertificate","true");
    mysqlConnectionProperties.setProperty("useSSL", "true");
    mysqlConnectionProperties.setProperty("user", DB_USER);
    mysqlConnectionProperties.setProperty("password", generateAuthToken());
    return mysqlConnectionProperties;
}

This method generates the IAM Auth Token.
An example IAM Auth Token would look like follows:
btusi123.cmz7kenwo2ye.rds.cn-north-1.amazonaws.com.cn:3306/?
Action=connect&DBUser=iamtestuser&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Date=20171003T010726Z&X-Amz-SignedHeaders=host&X-Amz-Expires=899&X-Amz-Credential=AKIAPFXHGVDI5RNFO4AQ%2F20171003%2Fcnc-north-1%2Frds-db%2Faws4_request&X-Amz-Signature=f9f45ef96c1f770cdad11a5353e35f4a4c3730bc0fdee820cfdf1322e15483b
@throws Exception
private static String generateAuthToken() {
    BasicAWSCredentials awsCredentials = new BasicAWSCredentials(AWS_ACCESS_KEY,
    AWS_SECRET_KEY);
    RdsIamAuthTokenGenerator generator = RdsIamAuthTokenGenerator.builder()
    .credentials(new
    AWSStaticCredentialsProvider(awsCredentials)).region(REGION_NAME).build();
    return generator.getAuthToken(GetIamAuthTokenRequest.builder()
    .hostname(RDS_INSTANCE_HOSTNAME).port(RDS_INSTANCE_PORT).userName(DB_USER).build());
}

This method sets the SSL properties which specify the key store file, its type and password:
@throws Exception
private static void setSslProperties() throws Exception {
    System.setProperty("javax.net.ssl.trustStore", createKeyStoreFile());
    System.setProperty("javax.net.ssl.trustStoreType", KEY_STORE_TYPE);
    System.setProperty("javax.net.ssl.trustStorePassword", DEFAULT_KEY_STORE_PASSWORD);
}

This method returns the path of the Key Store File needed for the SSL verification during the IAM Database Authentication to
the db instance.
@return
If you want to connect to a DB instance through a proxy, see Connecting to a proxy using IAM authentication (p. 1235).

Connecting to your DB instance using IAM authentication and the AWS SDK for Python (Boto3)

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for Python (Boto3) as described following.

Prerequisites
The following are prerequisites for connecting to your DB instance using IAM authentication:

- [Enabling and disabling IAM database authentication](p. 2661)
- [Creating and using an IAM policy for IAM database access](p. 2663)
- [Creating a database account using IAM authentication](p. 2666)

In addition, make sure the imported libraries in the sample code exist on your system.

**Examples**

The code examples use profiles for shared credentials. For information about the specifying credentials, see [Credentials](#) in the AWS SDK for Python (Boto3) documentation.

The following code examples show how to generate an authentication token, and then use it to connect to a DB instance.

To run this code example, you need the [AWS SDK for Python (Boto3)](https://aws.amazon.com/getting-started/docs), found on the AWS site.

Modify the values of the following variables as needed:

- **ENDPOINT** – The endpoint of the DB instance that you want to access
- **PORT** – The port number used for connecting to your DB instance
- **USER** – The database account that you want to access
- **REGION** – The AWS Region where the DB instance is running
- **DBNAME** – The database that you want to access
- **SSLCERTIFICATE** – The full path to the SSL certificate for Amazon RDS

For `ssl_ca`, specify an SSL certificate. To download an SSL certificate, see [Using SSL/TLS to encrypt a connection to a DB instance](p. 2608).

**Note**

You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

This code connects to a MariaDB or MySQL DB instance.

Before running this code, install the PyMySQL driver by following the instructions in the [Python Package Index](https://pypi.org/project/PyMySQL/).

```python
import pymysql
import sys
import boto3
import os

ENDPOINT="mysqlb.123456789012.us-east-1.rds.amazonaws.com"
PORT="3306"
USER="jane_doe"
REGION="us-east-1"
DBNAME="mydb"
o.s.environ["LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN"] = '1'

#gets the credentials from .aws/credentials
session = boto3.Session(profile_name='default')
client = session.client('rds')

token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USER, Region=REGION)
```
try:
    conn = pymysql.connect(host=ENDPOINT, user=USER, passwd=token, port=PORT,
                          database=DBNAME, ssl_ca='SSLCERTIFICATE')
    cur = conn.cursor()
    cur.execute('"""SELECT now()"""
    query_results = cur.fetchall()
    print(query_results)
except Exception as e:
    print("Database connection failed due to {}".format(e))

This code connects to a PostgreSQL DB instance.

Before running this code, install psycopg2 by following the instructions in Psycopg documentation.

import psycopg2
import sys
import boto3
import os
ENDPOINT="postgresmydb.123456789012.us-east-1.rds.amazonaws.com"
PORT="5432"
USER="jane_doe"
REGION="us-east-1"
DBNAME="mydb"

#gets the credentials from .aws/credentials
session = boto3.Session(profile_name='RDSCreds')
client = session.client('rds')
token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, 
                                     DBUsername=USER, 
                                     Region=REGION)

try:
    conn = psycopg2.connect(host=ENDPOINT, port=PORT, database=DBNAME, user=USER,
                             password=token, sslrootcert="SSLCERTIFICATE")
    cur = conn.cursor()
    cur.execute('"""SELECT now()"""
    query_results = cur.fetchall()
    print(query_results)
except Exception as e:
    print("Database connection failed due to {}".format(e))

If you want to connect to a DB instance through a proxy, see Connecting to a proxy using IAM authentication (p. 1235).

Troubleshooting Amazon RDS identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with Amazon RDS and IAM.

Topics

- I'm not authorized to perform an action in Amazon RDS (p. 2688)
- I'm not authorized to perform iam:PassRole (p. 2688)
- I want to allow people outside of my AWS account to access my Amazon RDS resources (p. 2688)
I'm not authorized to perform an action in Amazon RDS

If the AWS Management Console tells you that you're not authorized to perform an action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your sign-in credentials.

The following example error occurs when the mateojackson user tries to use the console to view details about a widget but does not have rds:GetWidget permissions.

User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform: rds:GetWidget on resource: my-example-widget

In this case, Mateo asks his administrator to update his policies to allow him to access the my-example-widget resource using the rds:GetWidget action.

I'm not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the iam:PassRole action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your sign-in credentials. Ask that person to update your policies to allow you to pass a role to Amazon RDS.

Some AWS services allow you to pass an existing role to that service, instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when a user named marymajor tries to use the console to perform an action in Amazon RDS. However, the action requires the service to have permissions granted by a service role. Mary does not have permissions to pass the role to the service.

User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform: iam:PassRole

In this case, Mary asks her administrator to update her policies to allow her to perform the iam:PassRole action.

I want to allow people outside of my AWS account to access my Amazon RDS resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

• To learn whether Amazon RDS supports these features, see How Amazon RDS works with IAM (p. 2627).
• To learn how to provide access to your resources across AWS accounts that you own, see Providing access to an IAM user in another AWS account that you own in the IAM User Guide.
• To learn how to provide access to your resources to third-party AWS accounts, see Providing access to AWS accounts owned by third parties in the IAM User Guide.
• To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the IAM User Guide.
• To learn the difference between using roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.
Logging and monitoring in Amazon RDS

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon RDS and your AWS solutions. You should collect monitoring data from all of the parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. AWS provides several tools for monitoring your Amazon RDS resources and responding to potential incidents:

**Amazon CloudWatch Alarms**

Using Amazon CloudWatch alarms, you watch a single metric over a time period that you specify. If the metric exceeds a given threshold, a notification is sent to an Amazon SNS topic or AWS Auto Scaling policy. CloudWatch alarms do not invoke actions because they are in a particular state. Rather the state must have changed and been maintained for a specified number of periods.

**AWS CloudTrail Logs**

CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon RDS. CloudTrail captures all API calls for Amazon RDS as events, including calls from the console and from code calls to Amazon RDS API operations. Using the information collected by CloudTrail, you can determine the request that was made to Amazon RDS, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see [Monitoring Amazon RDS API calls in AWS CloudTrail](p. 940).

**Enhanced Monitoring**

Amazon RDS provides metrics in real time for the operating system (OS) that your DB instance runs on. You can view the metrics for your DB instance using the console, or consume the Enhanced Monitoring JSON output from Amazon CloudWatch Logs in a monitoring system of your choice. For more information, see [Monitoring OS metrics with Enhanced Monitoring](p. 797).

**Amazon RDS Performance Insights**

Performance Insights expands on existing Amazon RDS monitoring features to illustrate your database's performance and help you analyze any issues that affect it. With the Performance Insights dashboard, you can visualize the database load and filter the load by waits, SQL statements, hosts, or users. For more information, see [Monitoring DB load with Performance Insights on Amazon RDS](p. 720).

**Database Logs**

You can view, download, and watch database logs using the AWS Management Console, AWS CLI, or RDS API. For more information, see [Monitoring Amazon RDS log files](p. 895).

**Amazon RDS Recommendations**

Amazon RDS provides automated recommendations for database resources. These recommendations provide best practice guidance by analyzing DB instance configuration, usage, and performance data. For more information, see [Viewing Amazon RDS recommendations](p. 688).

**Amazon RDS Event Notification**

Amazon RDS uses the Amazon Simple Notification Service (Amazon SNS) to provide notification when an Amazon RDS event occurs. These notifications can be in any notification form supported by Amazon SNS for an AWS Region, such as an email, a text message, or a call to an HTTP endpoint. For more information, see [Working with Amazon RDS event notification](p. 855).

**AWS Trusted Advisor**

Trusted Advisor draws upon best practices learned from serving hundreds of thousands of AWS customers. Trusted Advisor inspects your AWS environment and then makes recommendations when opportunities exist to save money, improve system availability and performance, or help close security gaps. All AWS customers have access to five Trusted Advisor checks. Customers with a Business or Enterprise support plan can view all Trusted Advisor checks.
Trusted Advisor has the following Amazon RDS-related checks:

- Amazon RDS Idle DB Instances
- Amazon RDS Security Group Access Risk
- Amazon RDS Backups
- Amazon RDS Multi-AZ

For more information on these checks, see Trusted Advisor best practices (checks).

For more information about monitoring Amazon RDS, see Monitoring metrics in an Amazon RDS instance (p. 678).
Compliance validation for Amazon RDS

Third-party auditors assess the security and compliance of Amazon RDS as part of multiple AWS compliance programs. These include SOC, PCI, FedRAMP, HIPAA, and others.

For a list of AWS services in scope of specific compliance programs, see AWS services in scope by compliance program. For general information, see AWS compliance programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading reports in AWS Artifact.

Your compliance responsibility when using Amazon RDS is determined by the sensitivity of your data, your organization's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- Security and compliance quick start guides – These deployment guides discuss architectural considerations and provide steps for deploying security- and compliance-focused baseline environments on AWS.
- Architecting for HIPAA Security and Compliance on Amazon Web Services – This whitepaper describes how companies can use AWS to create HIPAA-compliant applications.
- AWS compliance resources – This collection of workbooks and guides that might apply to your industry and location.
- AWS Config – This AWS service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- AWS Security Hub – This AWS service provides a comprehensive view of your security state within AWS. Security Hub uses security controls to evaluate your AWS resources and to check your compliance against security industry standards and best practices. For a list of supported services and controls, see Security Hub controls reference.
- AWS Security Hub – This AWS service provides a comprehensive view of your security state within AWS. Security Hub uses security controls to evaluate your AWS resources and to check your compliance against security industry standards and best practices. For a list of supported services and controls, see Security Hub controls reference.
Resilience in Amazon RDS

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see AWS global infrastructure.

In addition to the AWS global infrastructure, Amazon RDS offers features to help support your data resiliency and backup needs.

Backup and restore

Amazon RDS creates and saves automated backups of your DB instance. Amazon RDS creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases.

Amazon RDS creates automated backups of your DB instance during the backup window of your DB instance. Amazon RDS saves the automated backups of your DB instance according to the backup retention period that you specify. If necessary, you can recover your database to any point in time during the backup retention period. You can also back up your DB instance manually, by manually creating a DB snapshot.

You can create a DB instance by restoring from this DB snapshot as a disaster recovery solution if the source DB instance fails.

For more information, see Backing up and restoring (p. 590).

Replication

Amazon RDS uses the MariaDB, MySQL, Oracle, and PostgreSQL DB engines' built-in replication functionality to create a special type of DB instance called a read replica from a source DB instance. Updates made to the source DB instance are asynchronously copied to the read replica. You can reduce the load on your source DB instance by routing read queries from your applications to the read replica. Using read replicas, you can elastically scale out beyond the capacity constraints of a single DB instance for read-heavy database workloads. You can promote a read replica to a standalone instance as a disaster recovery solution if the source DB instance fails. For some DB engines, Amazon RDS also supports other replication options.

For more information, see Working with DB instance read replicas (p. 438).

Failover

Amazon RDS provides high availability and failover support for DB instances using Multi-AZ deployments. Amazon RDS uses several different technologies to provide failover support. Multi-AZ deployments for Oracle, PostgreSQL, MySQL, and MariaDB DB instances use Amazon's failover technology. SQL Server DB instances use SQL Server Database Mirroring (DBM).

For more information, see Configuring and managing a Multi-AZ deployment (p. 492).
Infrastructure security in Amazon RDS

As a managed service, Amazon Relational Database Service is protected by AWS global network security. For information about AWS security services and how AWS protects infrastructure, see AWS Cloud Security. To design your AWS environment using the best practices for infrastructure security, see Infrastructure Protection in Security Pillar AWS Well-Architected Framework.

You use AWS published API calls to access Amazon RDS through the network. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

In addition, Amazon RDS offers features to help support infrastructure security.

Security groups

Security groups control the access that traffic has in and out of a DB instance. By default, network access is turned off to a DB instance. You can specify rules in a security group that allow access from an IP address range, port, or security group. After ingress rules are configured, the same rules apply to all DB instances that are associated with that security group.

For more information, see Controlling access with security groups (p. 2697).

Public accessibility

When you launch a DB instance inside a virtual private cloud (VPC) based on the Amazon VPC service, you can turn on or off public accessibility for that DB instance. To designate whether the DB instance that you create has a DNS name that resolves to a public IP address, you use the Public accessibility parameter. By using this parameter, you can designate whether there is public access to the DB instance. You can modify a DB instance to turn on or off public accessibility by modifying the Public accessibility parameter.

For more information, see Hiding a DB instance in a VPC from the internet (p. 2712).

Note

If your DB instance is in a VPC but isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy (p. 2622).
Amazon RDS API and interface VPC endpoints (AWS PrivateLink)

You can establish a private connection between your VPC and Amazon RDS API endpoints by creating an interface VPC endpoint. Interface endpoints are powered by AWS PrivateLink.

AWS PrivateLink enables you to privately access Amazon RDS API operations without an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. DB instances in your VPC don't need public IP addresses to communicate with Amazon RDS API endpoints to launch, modify, or terminate DB instances. Your DB instances also don't need public IP addresses to use any of the available RDS API operations. Traffic between your VPC and Amazon RDS doesn't leave the Amazon network.

Each interface endpoint is represented by one or more elastic network interfaces in your subnets. For more information on elastic network interfaces, see Elastic network interfaces in the Amazon EC2 User Guide.

For more information about VPC endpoints, see Interface VPC endpoints (AWS PrivateLink) in the Amazon VPC User Guide. For more information about RDS API operations, see Amazon RDS API Reference.

You don't need an interface VPC endpoint to connect to a DB instance. For more information, see Scenarios for accessing a DB instance in a VPC (p. 2718).

Considerations for VPC endpoints

Before you set up an interface VPC endpoint for Amazon RDS API endpoints, ensure that you review Interface endpoint properties and limitations in the Amazon VPC User Guide.

All RDS API operations relevant to managing Amazon RDS resources are available from your VPC using AWS PrivateLink.

VPC endpoint policies are supported for RDS API endpoints. By default, full access to RDS API operations is allowed through the endpoint. For more information, see Controlling access to services with VPC endpoints in the Amazon VPC User Guide.

Availability

Amazon RDS API currently supports VPC endpoints in the following AWS Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
• Europe (Frankfurt)
• Europe (Ireland)
• Europe (London)
• Europe (Paris)
• Europe (Stockholm)
• Europe (Milan)
• Israel (Tel Aviv)
• Middle East (Bahrain)
• South America (São Paulo)
• China (Beijing)
• China (Ningxia)
• AWS GovCloud (US-East)
• AWS GovCloud (US-West)

Creating an interface VPC endpoint for Amazon RDS API

You can create a VPC endpoint for the Amazon RDS API using either the Amazon VPC console or the AWS Command Line Interface (AWS CLI). For more information, see Creating an interface endpoint in the Amazon VPC User Guide.

Create a VPC endpoint for Amazon RDS API using the service name com.amazonaws.region.rds.

Excluding AWS Regions in China, if you enable private DNS for the endpoint, you can make API requests to Amazon RDS with the VPC endpoint using its default DNS name for the AWS Region, for example rds.us-east-1.amazonaws.com. For the China (Beijing) and China (Ningxia) AWS Regions, you can make API requests with the VPC endpoint using rds-api.cn-north-1.amazonaws.com.cn and rds-api.cn-northwest-1.amazonaws.com.cn, respectively.

For more information, see Accessing a service through an interface endpoint in the Amazon VPC User Guide.

Creating a VPC endpoint policy for Amazon RDS API

You can attach an endpoint policy to your VPC endpoint that controls access to Amazon RDS API. The policy specifies the following information:

• The principal that can perform actions.
• The actions that can be performed.
• The resources on which actions can be performed.

For more information, see Controlling access to services with VPC endpoints in the Amazon VPC User Guide.

Example: VPC endpoint policy for Amazon RDS API actions

The following is an example of an endpoint policy for Amazon RDS API. When attached to an endpoint, this policy grants access to the listed Amazon RDS API actions for all principals on all resources.

```json
{
    "Statement": [
        {
```
Security best practices for Amazon RDS

Use AWS Identity and Access Management (IAM) accounts to control access to Amazon RDS API operations, especially operations that create, modify, or delete Amazon RDS resources. Such resources include DB instances, security groups, and parameter groups. Also use IAM to control actions that perform common administrative actions such as backing up and restoring DB instances.

- Create an individual user for each person who manages Amazon RDS resources, including yourself.
- Don’t use AWS root credentials to manage Amazon RDS resources.
- Grant each user the minimum set of permissions required to perform his or her duties.
- Use IAM groups to effectively manage permissions for multiple users.
- Rotate your IAM credentials regularly.
- Configure AWS Secrets Manager to automatically rotate the secrets for Amazon RDS. For more information, see Rotating your AWS Secrets Manager secrets in the AWS Secrets Manager User Guide. You can also retrieve the credential from AWS Secrets Manager programmatically. For more information, see Retrieving the secret value in the AWS Secrets Manager User Guide.

For more information about Amazon RDS security, see Security in Amazon RDS (p. 2582). For more information about IAM, see AWS Identity and Access Management. For information on IAM best practices, see IAM best practices.
AWS Security Hub uses security controls to evaluate resource configurations and security standards to help you comply with various compliance frameworks. For more information about using Security Hub to evaluate RDS resources, see Amazon Relational Database Service controls in the AWS Security Hub User Guide.

You can monitor your usage of RDS as it relates to security best practices by using Security Hub. For more information, see What is AWS Security Hub?

Use the AWS Management Console, the AWS CLI, or the RDS API to change the password for your master user. If you use another tool, such as a SQL client, to change the master user password, it might result in privileges being revoked for the user unintentionally.

## Controlling access with security groups

VPC security groups control the access that traffic has in and out of a DB instance. By default, network access is turned off for a DB instance. You can specify rules in a security group that allow access from an IP address range, port, or security group. After ingress rules are configured, the same rules apply to all DB instances that are associated with that security group. You can specify up to 20 rules in a security group.

### Overview of VPC security groups

Each VPC security group rule makes it possible for a specific source to access a DB instance in a VPC that is associated with that VPC security group. The source can be a range of addresses (for example, 203.0.113.0/24), or another VPC security group. By specifying a VPC security group as the source, you allow incoming traffic from all instances (typically application servers) that use the source VPC security group. VPC security groups can have rules that govern both inbound and outbound traffic. However, the outbound traffic rules typically don't apply to DB instances. Outbound traffic rules apply only if the DB instance acts as a client. For example, outbound traffic rules apply to an Oracle DB instance with outbound database links. You must use the Amazon EC2 API or the Security Group option on the VPC console to create VPC security groups.

When you create rules for your VPC security group that allow access to the instances in your VPC, you must specify a port for each range of addresses that the rule allows access for. For example, if you want to turn on Secure Shell (SSH) access for instances in the VPC, create a rule allowing access to TCP port 22 for the specified range of addresses.

You can configure multiple VPC security groups that allow access to different ports for different instances in your VPC. For example, you can create a VPC security group that allows access to TCP port 80 for web servers in your VPC. You can then create another VPC security group that allows access to TCP port 3306 for RDS for MySQL DB instances in your VPC.

For more information on VPC security groups, see Security groups in the Amazon Virtual Private Cloud User Guide.

**Note**

If your DB instance is in a VPC but isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy (p. 2622).

### Security group scenario

A common use of a DB instance in a VPC is to share data with an application server running in an Amazon EC2 instance in the same VPC, which is accessed by a client application outside the VPC. For this scenario, you use the RDS and VPC pages on the AWS Management Console or the RDS and EC2 API operations to create the necessary instances and security groups:
1. Create a VPC security group (for example, sg-0123ec2example) and define inbound rules that use the IP addresses of the client application as the source. This security group allows your client application to connect to EC2 instances in a VPC that uses this security group.

2. Create an EC2 instance for the application and add the EC2 instance to the VPC security group (sg-0123ec2example) that you created in the previous step.

3. Create a second VPC security group (for example, sg-6789rdsexample) and create a new rule by specifying the VPC security group that you created in step 1 (sg-0123ec2example) as the source.

4. Create a new DB instance and add the DB instance to the VPC security group (sg-6789rdsexample) that you created in the previous step. When you create the DB instance, use the same port number as the one specified for the VPC security group (sg-6789rdsexample) rule that you created in step 3.

The following diagram shows this scenario.
Creating a VPC security group

You can create a VPC security group for a DB instance by using the VPC console. For information about creating a security group, see Provide access to your DB instance in your VPC by creating a security group (p. 177) and Security groups in the Amazon Virtual Private Cloud User Guide.

Associating a security group with a DB instance

You can associate a security group with a DB instance by using Modify on the RDS console, the ModifyDBInstance Amazon RDS API, or the modify-db-instance AWS CLI command.

For information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 401). For security group considerations when you restore a DB instance from a DB snapshot, see Security group considerations (p. 615).

Note
The RDS console displays different security group rule names for your database if the Port value is configured to a non-default value.

Master user account privileges

When you create a new DB instance, the default master user that you use gets certain privileges for that DB instance. You can't change the master user name after the DB instance is created.

Important
We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

Note
If you accidentally delete the permissions for the master user, you can restore them by modifying the DB instance and setting a new master user password. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 401).

The following table shows the privileges and database roles the master user gets for each of the database engines.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>System privilege</th>
<th>Database role</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL and MariaDB</td>
<td>SELECT, INSERT, UPDATE, DELETE, CREATE, DROP, RELOAD, PROCESS, REFERENCES, INDEX, ALTER, SHOW DATABASES, CREATE TEMPORARY TABLES, LOCK TABLES, EXECUTE, REPLICATION CLIENT, CREATE VIEW, SHOW VIEW, CREATE ROUTINE, ALTER ROUTINE, CREATE USER, EVENT, TRIGGER ON <em>.</em> WITH GRANT OPTION, REPLICATION SLAVE</td>
<td></td>

</table>
Using service-linked roles for Amazon RDS

Amazon RDS uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Amazon RDS. Service-linked roles are predefined by Amazon RDS and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes using Amazon RDS easier because you don't have to manually add the necessary permissions. Amazon RDS defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon RDS can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete the roles only after first deleting their related resources. This protects your Amazon RDS resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS services that work with IAM and look for the services that have Yes in the Service-Linked Role column. Choose a Yes with a link to view the service-linked role documentation for that service.

Service-linked role permissions for Amazon RDS

Amazon RDS uses the service-linked role named AWSServiceRoleForRDS to allow Amazon RDS to call AWS services on behalf of your DB instances.

The AWSServiceRoleForRDS service-linked role trusts the following services to assume the role:

- rds.amazonaws.com

This service-linked role has a permissions policy attached to it called AmazonRDSServiceRolePolicy that grants it permissions to operate in your account. The role permissions policy allows Amazon RDS to complete the following actions on the specified resources:

For more information about this policy, including the JSON policy document, see AmazonRDSServiceRolePolicy in the AWS Managed Policy Reference Guide.

Note

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message:

Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.

Make sure you have the following permissions enabled:

```json
{
    "Action": "iam:CreateServiceLinkedRole",
    "Effect": "Allow",
    "Resource": "arn:aws:iam::*:role/aws-service-role/rds.amazonaws.com/AWSServiceRoleForRDS",
    "Condition": {
        "StringLike": {
            "iam:AWSServiceName": "rds.amazonaws.com"
        }
    }
}
```

For more information, see Service-linked role permissions in the IAM User Guide.
Creating a service-linked role for Amazon RDS

You don't need to manually create a service-linked role. When you create a DB instance, Amazon RDS creates the service-linked role for you.

Important

If you were using the Amazon RDS service before December 1, 2017, when it began supporting service-linked roles, then Amazon RDS created the AWSServiceRoleForRDS role in your account. To learn more, see A new role appeared in my AWS account.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a DB instance, Amazon RDS creates the service-linked role for you again.

Editing a service-linked role for Amazon RDS

Amazon RDS does not allow you to edit the AWSServiceRoleForRDS service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the IAM User Guide.

Deleting a service-linked role for Amazon RDS

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must delete all of your DB instances before you can delete the service-linked role.

Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first confirm that the role has no active sessions and remove any resources used by the role.

To check whether the service-linked role has an active session in the IAM console

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane of the IAM console, choose Roles. Then choose the name (not the check box) of the AWSServiceRoleForRDS role.
3. On the Summary page for the chosen role, choose the Access Advisor tab.
4. On the Access Advisor tab, review recent activity for the service-linked role.

Note

If you are unsure whether Amazon RDS is using the AWSServiceRoleForRDS role, you can try to delete the role. If the service is using the role, then the deletion fails and you can view the AWS Regions where the role is being used. If the role is being used, then you must wait for the session to end before you can delete the role. You cannot revoke the session for a service-linked role.

If you want to remove the AWSServiceRoleForRDS role, you must first delete all of your DB instances.

Deleting all of your instances

Use one of these procedures to delete each of your instances.

To delete an instance (console)

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the instance that you want to delete.
4. For **Actions**, choose **Delete**.
5. If you are prompted for **Create final Snapshot?**, choose **Yes** or **No**.
6. If you chose **Yes** in the previous step, for **Final snapshot name** enter the name of your final snapshot.
7. Choose **Delete**.

**To delete an instance (CLI)**

See `delete-db-instance` in the *AWS CLI Command Reference*.

**To delete an instance (API)**

See `DeleteDBInstance` in the *Amazon RDS API Reference*.

You can use the IAM console, the IAM CLI, or the IAM API to delete the AWSServiceRoleForRDS service-linked role. For more information, see [Deleting a service-linked role](https://docs.aws.amazon.com/IAM/latest/UserGuide/idelman.html) in the *IAM User Guide*.

## Service-linked role permissions for Amazon RDS Custom

Amazon RDS Custom uses the service-linked role named `AWSServiceRoleForRDSCustom` to allow RDS Custom to call AWS services on behalf of your DB instances and DB clusters.

The `AWSServiceRoleForRDSCustom` service-linked role trusts the following services to assume the role:

- `custom.rds.amazonaws.com`

This service-linked role has a permissions policy attached to it called `AmazonRDSCustomServiceRolePolicy` that grants it permissions to operate in your account. The role permissions policy allows RDS Custom to complete the following actions on the specified resources:

For more information about this policy, including the JSON policy document, see `AmazonRDSCustomServiceRolePolicy` in the *AWS Managed Policy Reference Guide*.

Creating, editing, or deleting the service-linked role for RDS Custom works the same as for Amazon RDS. For more information, see [Service-linked role permissions for Amazon RDS](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/Chap_SecurityConfig.html) (p. 2701).

**Note**

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message:

**Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.**

Make sure you have the following permissions enabled:

```json
{
    "Action": "iam:CreateServiceLinkedRole",
    "Effect": "Allow",
    "Resource": "arn:aws:iam::*:role/aws-service-role/custom.rds.amazonaws.com/AmazonRDSCustomServiceRolePolicy",
    "Condition": {
        "StringLike": {
            "iam:AWSServiceName": "custom.rds.amazonaws.com"
        }
    }
}
```
For more information, see Service-linked role permissions in the IAM User Guide.
Amazon VPC VPCs and Amazon RDS

Amazon Virtual Private Cloud (Amazon VPC) makes it possible for you to launch AWS resources, such as Amazon RDS DB instances, into a virtual private cloud (VPC).

When you use a VPC, you have control over your virtual networking environment. You can choose your own IP address range, create subnets, and configure routing and access control lists. There is no additional cost to run your DB instance in a VPC.

Accounts have a default VPC. All new DB instances are created in the default VPC unless you specify otherwise.

Topics
- Working with a DB instance in a VPC (p. 2705)
- Updating the VPC for a DB instance (p. 2717)
- Scenarios for accessing a DB instance in a VPC (p. 2718)
- Tutorial: Create a VPC for use with a DB instance (IPv4 only) (p. 2723)
- Tutorial: Create a VPC for use with a DB instance (dual-stack mode) (p. 2728)
- Moving a DB instance not in a VPC into a VPC (p. 2735)

Following, you can find a discussion about VPC functionality relevant to Amazon RDS DB instances. For more information about Amazon VPC, see Amazon VPC Getting Started Guide and Amazon VPC User Guide.

Working with a DB instance in a VPC

Your DB instance is in a virtual private cloud (VPC). A VPC is a virtual network that is logically isolated from other virtual networks in the AWS Cloud. Amazon VPC makes it possible for you to launch AWS resources, such as an Amazon RDS DB instance or Amazon EC2 instance, into a VPC. The VPC can either be a default VPC that comes with your account or one that you create. All VPCs are associated with your AWS account.

Your default VPC has three subnets that you can use to isolate resources inside the VPC. The default VPC also has an internet gateway that can be used to provide access to resources inside the VPC from outside the VPC.

For a list of scenarios involving Amazon RDS DB instances in a VPC and outside of a VPC, see Scenarios for accessing a DB instance in a VPC (p. 2718).

Topics
- Working with a DB instance in a VPC (p. 2706)
- Working with DB subnet groups (p. 2706)
- Shared subnets (p. 2707)
- Amazon RDS IP addressing (p. 2707)
- Hiding a DB instance in a VPC from the internet (p. 2712)
- Creating a DB instance in a VPC (p. 2713)

In the following tutorials, you can learn to create a VPC that you can use for a common Amazon RDS scenario:
- Tutorial: Create a VPC for use with a DB instance (IPv4 only) (p. 2723)
- Tutorial: Create a VPC for use with a DB instance (dual-stack mode) (p. 2728)
Working with a DB instance in a VPC

Here are some tips on working with a DB instance in a VPC:

- Your VPC must have at least two subnets. These subnets must be in two different Availability Zones in the AWS Region where you want to deploy your DB instance. A subnet is a segment of a VPC's IP address range that you can specify and that you can use to group DB instances based on your security and operational needs.

For Multi-AZ deployments, defining a subnet for two or more Availability Zones in an AWS Region allows Amazon RDS to create a new standby in another Availability Zone as needed. Make sure to do this even for Single-AZ deployments, just in case you want to convert them to Multi-AZ deployments at some point.

**Note**

The DB subnet group for a Local Zone can have only one subnet.

- If you want your DB instance in the VPC to be publicly accessible, make sure to turn on the VPC attributes DNS hostnames and DNS resolution.

- Your VPC must have a DB subnet group that you create. You create a DB subnet group by specifying the subnets you created. Amazon RDS chooses a subnet and an IP address within that subnet group to associate with your DB instance. The DB instance uses the Availability Zone that contains the subnet.

- Your VPC must have a VPC security group that allows access to the DB instance.

For more information, see Scenarios for accessing a DB instance in a VPC (p. 2718).

- The CIDR blocks in each of your subnets must be large enough to accommodate spare IP addresses for Amazon RDS to use during maintenance activities, including failover and compute scaling. For example, a range such as 10.0.0.0/24 and 10.0.1.0/24 is typically large enough.

- A DB instance can have an instance tenancy attribute of either default or dedicated. All default VPCs have the instance tenancy attribute set to default, and a default VPC can support any DB instance class.

If you choose to have your DB instance in a dedicated VPC where the instance tenancy attribute is set to dedicated, the DB instance class of your DB instance must be one of the approved Amazon EC2 dedicated instance types. For example, the r5.large EC2 dedicated instance corresponds to the db.r5.large DB instance class. For information about instance tenancy in a VPC, see Dedicated instances in the Amazon Elastic Compute Cloud User Guide.

For more information about the instance types that can be in a dedicated instance, see Amazon EC2 dedicated instances on the EC2 pricing page.

**Note**

When you set the instance tenancy attribute to dedicated for a DB instance, it doesn't guarantee that the DB instance will run on a dedicated host.

- When an option group is assigned to a DB instance, it's associated with the DB instance's VPC. This linkage means that you can't use the option group assigned to a DB instance if you attempt to restore the DB instance into a different VPC.

- If you restore a DB instance into a different VPC, make sure to either assign the default option group to the DB instance, assign an option group that is linked to that VPC, or create a new option group and assign it to the DB instance. With persistent or permanent options, such as Oracle TDE, you must create a new option group that includes the persistent or permanent option when restoring a DB instance into a different VPC.

Working with DB subnet groups

Subnets are segments of a VPC's IP address range that you designate to group your resources based on security and operational needs. A DB subnet group is a collection of subnets (typically private) that you create in a VPC and that you then designate for your DB instances. By using a DB subnet group, you can
specify a particular VPC when creating DB instances using the AWS CLI or RDS API. If you use the console, you can choose the VPC and subnet groups you want to use.

Each DB subnet group should have subnets in at least two Availability Zones in a given AWS Region. When creating a DB instance in a VPC, you choose a DB subnet group for it. From the DB subnet group, Amazon RDS chooses a subnet and an IP address within that subnet to associate with the DB instance. The DB uses the Availability Zone that contains the subnet.

If the primary DB instance of a Multi-AZ deployment fails, Amazon RDS can promote the corresponding standby and later create a new standby using an IP address of the subnet in one of the other Availability Zones.

The subnets in a DB subnet group are either public or private. The subnets are public or private, depending on the configuration that you set for their network access control lists (network ACLs) and routing tables. For a DB instance to be publicly accessible, all of the subnets in its DB subnet group must be public. If a subnet that's associated with a publicly accessible DB instance changes from public to private, it can affect DB instance availability.

To create a DB subnet group that supports dual-stack mode, make sure that each subnet that you add to the DB subnet group has an Internet Protocol version 6 (IPv6) CIDR block associated with it. For more information, see Amazon RDS IP addressing (p. 2707) and Migrating to IPv6 in the Amazon VPC User Guide.

Note
The DB subnet group for a Local Zone can have only one subnet.

When Amazon RDS creates a DB instance in a VPC, it assigns a network interface to your DB instance by using an IP address from your DB subnet group. However, we strongly recommend that you use the Domain Name System (DNS) name to connect to your DB instance. We recommend this because the underlying IP address changes during failover.

Note
For each DB instance that you run in a VPC, make sure to reserve at least one address in each subnet in the DB subnet group for use by Amazon RDS for recovery actions.

Shared subnets
You can create a DB instance in a shared VPC.

Some considerations to keep in mind while using shared VPCs:

- You can move a DB instance from a shared VPC subnet to a non-shared VPC subnet and vice-versa.
- Participants in a shared VPC must create a security group in the VPC to allow them to create a DB instance.
- Owners and participants in a shared VPC can access the database by using SQL queries. However, only the creator of a resource can make any API calls on the resource.

Amazon RDS IP addressing
IP addresses enable resources in your VPC to communicate with each other, and with resources over the internet. Amazon RDS support both the Internet Protocol version 4 (IPv4) and IPv6 addressing protocols. By default, Amazon RDS and Amazon VPC use the IPv4 addressing protocol. You can’t turn off this behavior. When you create a VPC, make sure to specify an IPv4 CIDR block (a range of private IPv4 addresses). You can optionally assign an IPv6 CIDR block to your VPC and subnets, and assign IPv6 addresses from that block to DB instances in your subnet.

Support for the IPv6 protocol expands the number of supported IP addresses. By using the IPv6 protocol, you ensure that you have sufficient available addresses for the future growth of the internet. New and
existing RDS resources can use IPv4 and IPv6 addresses within your Amazon VPC. Configuring, securing, and translating network traffic between the two protocols used in different parts of an application can cause operational overhead. You can standardize on the IPv6 protocol for Amazon RDS resources to simplify your network configuration.

**Topics**
- IPv4 addresses (p. 2708)
- IPv6 addresses (p. 2708)
- Dual-stack mode (p. 2708)

**IPv4 addresses**

When you create a VPC, you must specify a range of IPv4 addresses for the VPC in the form of a CIDR block, such as 10.0.0.0/16. A **DB subnet group** defines the range of IP addresses in this CIDR block that a DB instance can use. These IP addresses can be private or public.

A private IPv4 address is an IP address that's not reachable over the internet. You can use private IPv4 addresses for communication between your DB instance and other resources, such as Amazon EC2 instances, in the same VPC. Each DB instance has a private IP address for communication in the VPC.

A public IP address is an IPv4 address that's reachable from the internet. You can use public addresses for communication between your DB instance and resources on the internet, such as a SQL client. You control whether your DB instance receives a public IP address.

For a tutorial that shows you how to create a VPC with only private IPv4 addresses that you can use for a common Amazon RDS scenario, see Tutorial: Create a VPC for use with a DB instance (IPv4 only) (p. 2723).

**IPv6 addresses**

You can optionally associate an IPv6 CIDR block with your VPC and subnets, and assign IPv6 addresses from that block to the resources in your VPC. Each IPv6 addresses is globally unique.

The IPv6 CIDR block for your VPC is automatically assigned from Amazon's pool of IPv6 addresses. You can't choose the range yourself.

When connecting to an IPv6 address, make sure that the following conditions are met:

- The client is configured so that client to database traffic over IPv6 is allowed.
- RDS security groups used by the DB instance are configured correctly so that client to database traffic over IPv6 is allowed.
- The client operating system stack allows traffic on the IPv6 address, and operating system drivers and libraries are configured to choose the correct default DB instance endpoint (either IPv4 or IPv6).

For more information about IPv6, see IP Addressing in the Amazon VPC User Guide.

**Dual-stack mode**

When a DB instance can communicate over both the IPv4 and IPv6 addressing protocols, it's running in dual-stack mode. So, resources can communicate with the DB instance over IPv4, IPv6, or both. RDS disables Internet Gateway access for IPv6 endpoints of private dual-stack mode DB instances. RDS does this to ensure that your IPv6 endpoints are private and can only be accessed from within your VPC.

**Topics**
- Dual-stack mode and DB subnet groups (p. 2709)
- Working with dual-stack mode DB instances (p. 2709)
• Modifying IPv4-only DB instances to use dual-stack mode (p. 2710)
• Region and version availability (p. 2712)
• Limitations for dual-stack network DB instances (p. 2712)

For a tutorial that shows you how to create a VPC with both IPv4 and IPv6 addresses that you can use for a common Amazon RDS scenario, see Tutorial: Create a VPC for use with a DB instance (dual-stack mode) (p. 2728).

Dual-stack mode and DB subnet groups

To use dual-stack mode, make sure that each subnet in the DB subnet group that you associate with the DB instance has an IPv6 CIDR block associated with it. You can create a new DB subnet group or modify an existing DB subnet group to meet this requirement. After a DB instance is in dual-stack mode, clients can connect to it normally. Make sure that client security firewalls and RDS DB instance security groups are accurately configured to allow traffic over IPv6. To connect, clients use the DB instance's endpoint. Client applications can specify which protocol is preferred when connecting to a database. In dual-stack mode, the DB instance detects the client's preferred network protocol, either IPv4 or IPv6, and uses that protocol for the connection.

If a DB subnet group stops supporting dual-stack mode because of subnet deletion or CIDR disassociation, there's a risk of an incompatible network state for DB instances that are associated with the DB subnet group. Also, you can't use the DB subnet group when you create new dual-stack mode DB instance.

To determine whether a DB subnet group supports dual-stack mode by using the AWS Management Console, view the Network type on the details page of the DB subnet group. To determine whether a DB subnet group supports dual-stack mode by using the AWS CLI, call the describe-db-subnet-groups command and view SupportedNetworkTypes in the output.

Read replicas are treated as independent DB instances and can have a network type that's different from the primary DB instance. If you change the network type of a read replica's primary DB instance, the read replica isn't affected. When you are restoring a DB instance, you can restore it to any network type that's supported.

Working with dual-stack mode DB instances

When you create or modify a DB instance, you can specify dual-stack mode to allow your resources to communicate with your DB instance over IPv4, IPv6, or both.

When you use the AWS Management Console to create or modify a DB instance, you can specify dual-stack mode in the Network type section. The following image shows the Network type section in the console.

<table>
<thead>
<tr>
<th>Network type</th>
<th>Info</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPv4</td>
<td>Your resources can communicate only over the IPv4 addressing protocol.</td>
</tr>
<tr>
<td>Dual-stack mode</td>
<td>Your resources can communicate over IPv4, IPv6, or both.</td>
</tr>
</tbody>
</table>

When you use the AWS CLI to create or modify a DB instance, set the --network-type option to DUAL to use dual-stack mode. When you use the RDS API to create or modify a DB instance, set the NetworkType parameter to DUAL to use dual-stack mode. When you are modifying the network type of a DB instance, downtime is possible. If dual-stack mode isn't supported by the specified DB engine version or DB subnet group, the NetworkTypeNotSupported error is returned.
For more information about creating a DB instance, see Creating an Amazon RDS DB instance (p. 300). For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 401).

To determine whether a DB instance is in dual-stack mode by using the console, view the Network type on the Connectivity & security tab for the DB instance.

Modifying IPv4-only DB instances to use dual-stack mode

You can modify an IPv4-only DB instance to use dual-stack mode. To do so, change the network type of the DB instance. The modification might result in downtime.

It is recommended that you change the network type of your Amazon RDS instances during a maintenance window. Setting the network type of new instances to dual stack by default is currently unsupported. Set network type manually by using the modify-db-instance command.

Before modifying a DB instance to use dual-stack mode, make sure that its DB subnet group supports dual-stack mode. If the DB subnet group associated with the DB instance doesn't support dual-stack mode, specify a different DB subnet group that supports it when you modify the DB instance. Modifying the DB subnet group of a DB instance can cause downtime.

If you modify the DB subnet group of a DB instance before you change the DB instance to use dual-stack mode, make sure that the DB subnet group is valid for the DB instance before and after the change.

For example:

For RDS for PostgreSQL, RDS for MySQL, RDS for Oracle, and RDS for MariaDB Single-AZ instances, we recommend that you call the modify-db-instance command with just the --network-type parameter with value DUAL to change the network to dual stack. Adding other parameters along with the --network-type parameter in the same API call could result in downtime. If you wish to modify multiple parameters, please ensure that the network type modification API action is successfully completed before sending another modify-db-instance request with other parameters.

Network type modifications for RDS for PostgreSQL, RDS for MySQL, RDS for Oracle, and RDS for MariaDB Multi-AZ instances cause a brief downtime and trigger a failover if you only use the --network-type parameter or if you combine parameters in a modify-db-instance command.

Network type modifications on RDS for SQL Server Single-AZ or Multi-AZ instances cause downtime if you only use the --network-type parameter or if you combine parameters in a modify-db-instance command. Network type modifications cause failover in an SQL Server Multi-AZ instance.

```
aws rds modify-db-instance --db-instance-identifier my-instance --network-type "DUAL"
```

If you can't connect to the DB instance after the change, make sure that the client and database security firewalls and route tables are accurately configured to allow cross traffic to the database on the selected network (either IPv4 or IPv6). You might also need to modify operating system parameter, libraries, or drivers to connect using an IPv6 address.

The following limitations apply to modifying a DB instance to use dual-stack mode:

- Dual-stack mode DB instances can't be publicly accessible.
- DB instances can't have an IPv6-only endpoint.
- There can't be a pending change from a Single-AZ deployment to a Multi-AZ deployment, or from a Multi-AZ deployment to a Single-AZ deployment.

**To modify an IPv4-only DB instance to use dual-stack mode**

1. Modify a DB subnet group to support dual-stack mode, or create a DB subnet group that supports dual-stack mode:
a. Associate an IPv6 CIDR block with your VPC.

For instructions, see Associate an IPv6 CIDR block with your VPC in the Amazon VPC User Guide.

b. Attach the IPv6 CIDR block to all of the subnets in your the DB subnet group.

For instructions, see Associate an IPv6 CIDR block with your subnet in the Amazon VPC User Guide.

c. Confirm that the DB subnet group supports dual-stack mode.

If you are using the AWS Management Console, select the DB subnet group, and make sure that the Supported network types value is Dual, IPv4.

If you are using the AWS CLI, call the describe-db-subnet-groups command, and make sure that the SupportedNetworkType value for the DB instance is Dual, IPv4.

2. Modify the security group associated with the DB instance to allow IPv6 connections to the database, or create a new security group that allows IPv6 connections.

For instructions, see Security group rules in the Amazon VPC User Guide.

3. Modify the DB instance to support dual-stack mode. To do so, set the Network type to Dual-stack mode.

If you are using the console, make sure that the following settings are correct:

- **Network type** – Dual-stack mode
  
<table>
<thead>
<tr>
<th>Network type</th>
<th>Info</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPv4</td>
<td>Your resources can communicate only over the IPv4 addressing protocol.</td>
</tr>
<tr>
<td>Dual-stack mode</td>
<td>Your resources can communicate over IPv4, IPv6, or both.</td>
</tr>
</tbody>
</table>

- **DB subnet group** – The DB subnet group that you configured in a previous step
- **Security group** – The security that you configured in a previous step

If you are using the AWS CLI, make sure that the following settings are correct:

- --network-type – dual
- --db-subnet-group-name – The DB subnet group that you configured in a previous step
- --vpc-security-group-ids – The VPC security group that you configured in a previous step

4. Confirm that the DB instance supports dual-stack mode.

If you are using the console, choose the Connectivity & security tab for the DB instance. On that tab, make sure that the Network type value is Dual-stack mode.

If you are using the AWS CLI, call the describe-db-instances command, and make sure that the NetworkType value for the DB instance is dual.

Run the dig command on the DB instance endpoint to identify the IPv6 address associated with it.

```
dig db-instance-endpoint AAAA
```

Use the DB instance endpoint, not the IPv6 address, to connect to the DB instance.
Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability with dual stack mode, see [Dual-stack mode](p. 125).

Limitations for dual-stack network DB instances

The following limitations apply to dual-stack network DB instances:

- DB instances can't use the IPv6 protocol exclusively. They can use IPv4 exclusively, or they can use the IPv4 and IPv6 protocol (dual-stack mode).
- Amazon RDS doesn't support native IPv6 subnets.
- DB instances that use dual-stack mode must be private. They can't be publicly accessible.
- Dual-stack mode doesn't support the db.m3 and db.r3 DB instance classes.
- For RDS for SQL Server, dual-stack mode DB instances that use Always On AGs availability group listener endpoints only present IPv4 addresses.
- You can't use RDS Proxy with dual-stack mode DB instances.
- You can't use dual-stack mode with RDS on AWS Outposts DB instances.
- You can't use dual-stack mode with DB instances in a Local Zone.

Hiding a DB instance in a VPC from the internet

One common Amazon RDS scenario is to have a VPC in which you have an EC2 instance with a public-facing web application and a DB instance with a database that isn't publicly accessible. For example, you can create a VPC that has a public subnet and a private subnet. Amazon EC2 instances that function as web servers can be deployed in the public subnet. The DB instances are deployed in the private subnet. In such a deployment, only the web servers have access to the DB instances. For an illustration of this scenario, see [A DB instance in a VPC accessed by an EC2 instance in the same VPC](p. 2718).

When you launch a DB instance inside a VPC, the DB instance has a private IP address for traffic inside the VPC. This private IP address isn't publicly accessible. You can use the Public access option to designate whether the DB instance also has a public IP address in addition to the private IP address. If the DB instance is designated as publicly accessible, its DNS endpoint resolves to the private IP address from within the VPC. It resolves to the public IP address from outside of the VPC. Access to the DB instance is ultimately controlled by the security group it uses. That public access is not permitted if the security group assigned to the DB instance doesn't include inbound rules that permit it. In addition, for a DB instance to be publicly accessible, the subnets in its DB subnet group must have an internet gateway. For more information, see [Can't connect to Amazon RDS DB instance](p. 2744).

You can modify a DB instance to turn on or off public accessibility by modifying the Public access option. The following illustration shows the Public access option in the Additional connectivity configuration section. To set the option, open the Additional connectivity configuration section in the Connectivity section.
Creating a DB instance in a VPC

The following procedures help you create a DB instance in a VPC. To use the default VPC, you can begin with step 2, and use the VPC and DB subnet group have already been created for you. If you want to create an additional VPC, you can create a new VPC.

Note
If you want your DB instance in the VPC to be publicly accessible, you must update the DNS information for the VPC by enabling the VPC attributes DNS hostnames and DNS resolution. For information about updating the DNS information for a VPC instance, see Updating DNS support for your VPC.

For information about modifying a DB instance to set the Public access option, see Modifying an Amazon RDS DB instance (p. 401).
Follow these steps to create a DB instance in a VPC:

- **Step 1: Create a VPC (p. 2714)**
- **Step 2: Create a DB subnet group (p. 2714)**
- **Step 3: Create a VPC security group (p. 2717)**
- **Step 4: Create a DB instance in the VPC (p. 2717)**

**Step 1: Create a VPC**

Create a VPC with subnets in at least two Availability Zones. You use these subnets when you create a DB subnet group. If you have a default VPC, a subnet is automatically created for you in each Availability Zone in the AWS Region.

For more information, see Create a VPC with private and public subnets (p. 2724), or see Create a VPC in the Amazon VPC User Guide.

**Step 2: Create a DB subnet group**

A DB subnet group is a collection of subnets (typically private) that you create for a VPC and that you then designate for your DB instances. A DB subnet group allows you to specify a particular VPC when you create DB instances using the AWS CLI or RDS API. If you use the console, you can just choose the VPC and subnets you want to use. Each DB subnet group must have at least one subnet in at least two Availability Zones in the AWS Region. As a best practice, each DB subnet group should have at least one subnet for every Availability Zone in the AWS Region.

For Multi-AZ deployments, defining a subnet for all Availability Zones in an AWS Region enables Amazon RDS to create a new standby replica in another Availability Zone if necessary. You can follow this best practice even for Single-AZ deployments, because you might convert them to Multi-AZ deployments in the future.

For a DB instance to be publicly accessible, the subnets in the DB subnet group must have an internet gateway. For more information about internet gateways for subnets, see Connect to the internet using an internet gateway in the Amazon VPC User Guide.

**Note**
The DB subnet group for a Local Zone can have only one subnet.

When you create a DB instance in a VPC, you can choose a DB subnet group. Amazon RDS chooses a subnet and an IP address within that subnet to associate with your DB instance. If no DB subnet groups exist, Amazon RDS creates a default subnet group when you create a DB instance. Amazon RDS creates and associates an Elastic Network Interface to your DB instance with that IP address. The DB instance uses the Availability Zone that contains the subnet.

For Multi-AZ deployments, defining a subnet for two or more Availability Zones in an AWS Region allows Amazon RDS to create a new standby in another Availability Zone should the need arise. You need to do this even for Single-AZ deployments, just in case you want to convert them to Multi-AZ deployments at some point.

In this step, you create a DB subnet group and add the subnets that you created for your VPC.

**To create a DB subnet group**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Subnet groups**.
3. Choose **Create DB Subnet Group**.
4. For **Name**, type the name of your DB subnet group.
5. For **Description**, type a description for your DB subnet group.
6. For **VPC**, choose the default VPC or the VPC that you created.
7. In the **Add subnets** section, choose the Availability Zones that include the subnets from **Availability Zones**, and then choose the subnets from **Subnets**.
Create DB Subnet Group

To create a new subnet group, give it a name and a description, and choose an existing VPC. You will then be able to add subnets related to that VPC.

Subnet group details

Name
You won’t be able to modify the name after your subnet group has been created.

mydbsubnetgroup
Must contain from 1 to 255 characters. Alphanumeric characters, spaces, hyphens, underscores, and periods are allowed.

Description
My DB Subnet Group

VPC
Choose a VPC identifier that corresponds to the subnets you want to use for your DB subnet group. You won’t be able to choose a different VPC identifier after your subnet group has been created.

tutorial-vpc (vpc-06bfe38858eaf014)

Add subnets

Availability Zones
Choose the Availability Zones that include the subnets you want to add.

Choose an availability zone

us-east-1a ✗ us-east-1c ✗

Subnets
Choose the subnets that you want to add. The list includes the subnets in the selected Availability Zones.

Select subnets

subnet-079bd4b8953aee1dd (10.0.0.0/24) ✗
subnet-057e85b72c46fdd9a (10.0.1.0/24) ✗

Subnets selected (2)

<table>
<thead>
<tr>
<th>Availability zone</th>
<th>Subnet ID</th>
<th>CIDR block</th>
</tr>
</thead>
<tbody>
<tr>
<td>us-east-1a</td>
<td>subnet-079bd4b8953aee1dd</td>
<td>10.0.0.0/24</td>
</tr>
<tr>
<td>us-east-1c</td>
<td>subnet-057e85b72c46fdd9a</td>
<td>10.0.1.0/24</td>
</tr>
</tbody>
</table>
If you have enabled a Local Zone, you can choose an Availability Zone group on the Create DB subnet group page. In this case, choose the Availability Zone group, Availability Zones, and Subnets.

8. Choose Create.

Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see details, including all of the subnets associated with the group, in the details pane at the bottom of the window.

**Step 3: Create a VPC security group**

Before you create your DB instance, you can create a VPC security group to associate with your DB instance. If you don't create a VPC security group, you can use the default security group when you create a DB instance. For instructions on how to create a security group for your DB instance, see Create a VPC security group for a private DB instance (p. 2725), or see Control traffic to resources using security groups in the Amazon VPC User Guide.

**Step 4: Create a DB instance in the VPC**

In this step, you create a DB instance and use the VPC name, the DB subnet group, and the VPC security group you created in the previous steps.

**Note**

If you want your DB instance in the VPC to be publicly accessible, you must enable the VPC attributes DNS hostnames and DNS resolution. For more information, see DNS attributes for your VPC in the Amazon VPC User Guide.

For details on how to create a DB instance, see Creating an Amazon RDS DB instance (p. 300).

When prompted in the Connectivity section, enter the VPC name, the DB subnet group, and the VPC security group.

**Updating the VPC for a DB instance**

You can use the AWS Management Console to move your DB instance to a different VPC.

For information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 401). In the Connectivity section of the modify page, shown following, enter the new DB subnet group for DB subnet group. The new subnet group must be a subnet group in a new VPC.

```
Connectivity

<table>
<thead>
<tr>
<th>Subnet group</th>
</tr>
</thead>
<tbody>
<tr>
<td>default-vpc-665e7a1f</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Security group</th>
</tr>
</thead>
<tbody>
<tr>
<td>List of DB security groups to associate with this DB instance.</td>
</tr>
</tbody>
</table>
```

You can't change the VPC for a DB instance if the following conditions apply:
Scenarios for accessing a DB instance in a VPC

Amazon RDS supports the following scenarios for accessing a DB instance in a VPC:

- An EC2 instance in the same VPC (p. 2718)
- An EC2 instance in a different VPC (p. 2720)
- A client application through the internet (p. 2721)
- A private network (p. 2722)

A DB instance in a VPC accessed by an EC2 instance in the same VPC

A common use of a DB instance in a VPC is to share data with an application server that is running in an EC2 instance in the same VPC.

The following diagram shows this scenario.
The simplest way to manage access between EC2 instances and DB instances in the same VPC is to do the following:

- Create a VPC security group for your DB instances to be in. This security group can be used to restrict access to the DB instances. For example, you can create a custom rule for this security group. This might allow TCP access using the port that you assigned to the DB instance when you created it and an IP address you use to access the DB instance for development or other purposes.
- Create a VPC security group for your EC2 instances (web servers and clients) to be in. This security group can, if needed, allow access to the EC2 instance from the internet by using the VPC's routing table. For example, you can set rules on this security group to allow TCP access to the EC2 instance over port 22.
- Create custom rules in the security group for your DB instances that allow connections from the security group you created for your EC2 instances. These rules might allow any member of the security group to access the DB instances.

There is an additional public and private subnet in a separate Availability Zone. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easy to switch to a Multi-AZ DB instance deployment in the future.

For a tutorial that shows you how to create a VPC with both public and private subnets for this scenario, see Tutorial: Create a VPC for use with a DB instance (IPv4 only) (p. 2723).

Tip
You can set up network connectivity between an Amazon EC2 instance and a DB instance automatically when you create the DB instance. For more information, see .
To create a rule in a VPC security group that allows connections from another security group, do the following:

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc.
2. In the navigation pane, choose Security groups.
3. Choose or create a security group for which you want to allow access to members of another security group. In the preceding scenario, this is the security group that you use for your DB instances. Choose the Inbound rules tab, and then choose Edit inbound rules.
5. For Type, choose the entry that corresponds to the port you used when you created your DB instance, such as MYSQL/Aurora.
6. In the Source box, start typing the ID of the security group, which lists the matching security groups. Choose the security group with members that you want to have access to the resources protected by this security group. In the scenario preceding, this is the security group that you use for your EC2 instance.
7. If required, repeat the steps for the TCP protocol by creating a rule with All TCP as the Type and your security group in the Source box. If you intend to use the UDP protocol, create a rule with All UDP as the Type and your security group in Source.
8. Choose Save rules.

The following screen shows an inbound rule with a security group for its source.

For more information about connecting to the DB instance from your EC2 instance, see Connecting to an Amazon RDS DB instance (p. 325).

A DB instance in a VPC accessed by an EC2 instance in a different VPC

When your DB instances is in a different VPC from the EC2 instance you are using to access it, you can use VPC peering to access the DB instance.

The following diagram shows this scenario.
A VPC peering connection is a networking connection between two VPCs that enables you to route traffic between them using private IP addresses. Resources in either VPC can communicate with each other as if they are within the same network. You can create a VPC peering connection between your own VPCs, with a VPC in another AWS account, or with a VPC in a different AWS Region. To learn more about VPC peering, see VPC peering in the Amazon Virtual Private Cloud User Guide.

A DB instance in a VPC accessed by a client application through the internet

To access a DB instances in a VPC from a client application through the internet, you configure a VPC with a single public subnet, and an internet gateway to enable communication over the internet. The following diagram shows this scenario.

We recommend the following configuration:

- A VPC of size /16 (for example CIDR: 10.0.0.0/16). This size provides 65,536 private IP addresses.
- A subnet of size /24 (for example CIDR: 10.0.0.0/24). This size provides 256 private IP addresses.
- An Amazon RDS DB instance that is associated with the VPC and the subnet. Amazon RDS assigns an IP address within the subnet to your DB instance.
- An internet gateway which connects the VPC to the internet and to other AWS products.
• A security group associated with the DB instance. The security group's inbound rules allow your client application to access to your DB instance.

For information about creating a DB instances in a VPC, see Creating a DB instance in a VPC (p. 2713).

A DB instance in a VPC accessed by a private network

If your DB instance isn't publicly accessible, you have the following options for accessing it from a private network:

• An AWS Site-to-Site VPN connection. For more information, see What is AWS Site-to-Site VPN?
• An AWS Direct Connect connection. For more information, see What is AWS Direct Connect?
• An AWS Client VPN connection. For more information, see What is AWS Client VPN?

The following diagram shows a scenario with an AWS Site-to-Site VPN connection.

For more information, see Internetwork traffic privacy (p. 2622).
Tutorial: Create a VPC for use with a DB instance (IPv4 only)

A common scenario includes a DB instance in a virtual private cloud (VPC) based on the Amazon VPC service. This VPC shares data with a web server that is running in the same VPC. In this tutorial, you create the VPC for this scenario.

The following diagram shows this scenario. For information about other scenarios, see Scenarios for accessing a DB instance in a VPC (p. 2718).

Your DB instance needs to be available only to your web server, and not to the public internet. Thus, you create a VPC with both public and private subnets. The web server is hosted in the public subnet, so that it can reach the public internet. The DB instance is hosted in a private subnet. The web server can connect to the DB instance because it is hosted within the same VPC. But the DB instance isn't available to the public internet, providing greater security.

This tutorial configures an additional public and private subnet in a separate Availability Zone. These subnets aren't used by the tutorial. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easier to switch to a Multi-AZ DB instance deployment in the future.

This tutorial describes configuring a VPC for Amazon RDS DB instances. For a tutorial that shows you how to create a web server for this VPC scenario, see Tutorial: Create a web server and an Amazon RDS DB instance (p. 249). For more information about Amazon VPC, see Amazon VPC Getting Started Guide and Amazon VPC User Guide.
**Tip**
You can set up network connectivity between an Amazon EC2 instance and a DB instance automatically when you create the DB instance. The network configuration is similar to the one described in this tutorial. For more information, see Configure automatic network connectivity with an EC2 instance (p. 300).

**Create a VPC with private and public subnets**

Use the following procedure to create a VPC with both public and private subnets.

**To create a VPC and subnets**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the top-right corner of the AWS Management Console, choose the Region to create your VPC in. This example uses the US West (Oregon) Region.
3. In the upper-left corner, choose VPC dashboard. To begin creating a VPC, choose Create VPC.
4. For Resources to create under VPC settings, choose VPC and more.
5. For the VPC settings, set these values:
   - Name tag auto-generation – tutorial
   - IPv4 CIDR block – 10.0.0.0/16
   - IPv6 CIDR block – No IPv6 CIDR block
   - Tenancy – Default
   - Number of Availability Zones (AZs) – 2
   - Customize AZs – Keep the default values.
   - Number of public subnet – 2
   - Number of private subnets – 2
   - Customize subnets CIDR blocks – Keep the default values.
   - NAT gateways ($) – None
   - VPC endpoints – None
   - DNS options – Keep the default values.

   **Note**
   Amazon RDS requires at least two subnets in two different Availability Zones to support Multi-AZ DB instance deployments. This tutorial creates a Single-AZ deployment, but the requirement makes it easier to convert to a Multi-AZ DB instance deployment in the future.

6. Choose Create VPC.

**Create a VPC security group for a public web server**

Next, you create a security group for public access. To connect to public EC2 instances in your VPC, you add inbound rules to your VPC security group. These allow traffic to connect from the internet.

**To create a VPC security group**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose VPC Dashboard, choose Security Groups, and then choose Create security group.
3. On the Create security group page, set these values:
   - Security group name: tutorial-securitygroup
4. **Add inbound rules to the security group.**

   a. Determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH). To determine your public IP address, in a different browser window or tab, you can use the service at [https://checkip.amazonaws.com](https://checkip.amazonaws.com). An example of an IP address is 203.0.113.25/32.

   In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, find the range of IP addresses used by client computers.

   **Warning**
   If you use 0.0.0.0/0 for SSH access, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances using SSH.

   b. In the **Inbound rules** section, choose **Add rule**.

   c. Set the following values for your new inbound rule to allow SSH access to your Amazon EC2 instance. If you do this, you can connect to your Amazon EC2 instance to install the web server and other utilities. You also connect to your EC2 instance to upload content for your web server.

      • **Type:** SSH  
      • **Source:** The IP address or range from Step a, for example: 203.0.113.25/32.

   d. Choose **Add rule**.

   e. Set the following values for your new inbound rule to allow HTTP access to your web server:

      • **Type:** HTTP  
      • **Source:** 0.0.0.0/0

5. **Choose Create security group** to create the security group.

   Note the security group ID because you need it later in this tutorial.

### Create a VPC security group for a private DB instance

To keep your DB instance private, create a second security group for private access. To connect to private DB instances in your VPC, you add inbound rules to your VPC security group that allow traffic from your web server only.

#### To create a VPC security group

1. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:

    • **Security group name:** tutorial-db-securitygroup  
    • **Description:** Tutorial DB Instance Security Group  
    • **VPC:** Choose the VPC that you created earlier, for example: vpc-identifier (tutorial-vpc)

4. Add inbound rules to the security group.

   a. In the **Inbound rules** section, choose **Add rule**.

   b. Set the following values for your new inbound rule to allow MySQL traffic on port 3306 from your Amazon EC2 instance. If you do this, you can connect from your web server to your DB instance.
instance. By doing so, you can store and retrieve data from your web application to your database.

- **Type:** MySQL/Aurora
- **Source:** The identifier of the tutorial-securitygroup security group that you created previously in this tutorial, for example: sg-9edd5cfb.

5. Choose Create security group to create the security group.

### Create a DB subnet group

A **DB subnet group** is a collection of subnets that you create in a VPC and that you then designate for your DB instances. A DB subnet group makes it possible for you to specify a particular VPC when creating DB instances.

**To create a DB subnet group**

1. Identify the private subnets for your database in the VPC.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose VPC Dashboard, and then choose Subnets.
   c. Note the subnet IDs of the subnets named tutorial-subnet-private1-us-west-2a and tutorial-subnet-private2-us-west-2b.

   You need the subnet IDs when you create your DB subnet group.

2. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.

   Make sure that you connect to the Amazon RDS console, not to the Amazon VPC console.

3. In the navigation pane, choose Subnet groups.

4. Choose Create DB subnet group.

5. On the Create DB subnet group page, set these values in Subnet group details:
   - **Name:** tutorial-db-subnet-group
   - **Description:** Tutorial DB Subnet Group
   - **VPC:** tutorial-vpc (vpc-identifier)

6. In the Add subnets section, choose the Availability Zones and Subnets.

   For this tutorial, choose us-west-2a and us-west-2b for the Availability Zones. For Subnets, choose the private subnets you identified in the previous step.

7. Choose Create.

   Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see details in the details pane at the bottom of the window. These details include all of the subnets associated with the group.

**Note**

If you created this VPC to complete Tutorial: Create a web server and an Amazon RDS DB instance (p. 249), create the DB instance by following the instructions in Create an Amazon RDS DB instance (p. 255).

### Deleting the VPC

After you create the VPC and other resources for this tutorial, you can delete them if they are no longer needed.
Note
If you added resources in the VPC that you created for this tutorial, you might need to delete these before you can delete the VPC. For example, these resources might include Amazon EC2 instances or Amazon RDS DB instances. For more information, see Delete your VPC in the Amazon VPC User Guide.

To delete a VPC and related resources

1. Delete the DB subnet group.
   a. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   b. In the navigation pane, choose Subnet groups.
   c. Select the DB subnet group you want to delete, such as tutorial-db-subnet-group.
   d. Choose Delete, and then choose Delete in the confirmation window.

2. Note the VPC ID.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose VPC Dashboard, and then choose VPCs.
   c. In the list, identify the VPC that you created, such as tutorial-vpc.
   d. Note the VPC ID of the VPC that you created. You need the VPC ID in later steps.

3. Delete the security groups.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose VPC Dashboard, and then choose Security Groups.
   c. Select the security group for the Amazon RDS DB instance, such as tutorial-db-securitygroup.
   d. For Actions, choose Delete security groups, and then choose Delete on the confirmation page.
   e. On the Security Groups page, select the security group for the Amazon EC2 instance, such as tutorial-securitygroup.
   f. For Actions, choose Delete security groups, and then choose Delete on the confirmation page.

4. Delete the VPC.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose VPC Dashboard, and then choose VPCs.
   c. Select the VPC you want to delete, such as tutorial-vpc.
   d. For Actions, choose Delete VPC.

   The confirmation page shows other resources that are associated with the VPC that will also be deleted, including the subnets associated with it.
   e. On the confirmation page, enter delete, and then choose Delete.
Tutorial: Create a VPC for use with a DB instance (dual-stack mode)

A common scenario includes a DB instance in a virtual private cloud (VPC) based on the Amazon VPC service. This VPC shares data with a public Amazon EC2 instance that is running in the same VPC.

For more information about IP addressing, see Amazon RDS IP addressing (p. 2707).

Dual-stack network instances are supported in most regions. For more information see Region and version availability (p. 2712). To see the limitations of dual-stack mode, see Limitations for dual-stack network DB instances (p. 2712).

In this tutorial, you create the VPC for this scenario that works with a database running in dual-stack mode.

The following diagram shows this scenario.

For information about other scenarios, see Scenarios for accessing a DB instance in a VPC (p. 2718).

Your DB instance needs to be available only to your Amazon EC2 instance, and not to the public internet. Thus, you create a VPC with both public and private subnets. The Amazon EC2 instance is hosted in the public subnet, so that it can reach the public internet. The DB instance is hosted in a private subnet. The Amazon EC2 instance can connect to the DB instance because it's hosted within the same VPC. However, the DB instance is not available to the public internet, providing greater security.
This tutorial configures an additional public and private subnet in a separate Availability Zone. These subnets aren’t used by the tutorial. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easy to switch to a Multi-AZ DB instance deployment in the future.

To create a DB instance that uses dual-stack mode, specify Dual-stack mode for the Network type setting. You can also modify a DB instance with the same setting. For more information, see Creating an Amazon RDS DB instance (p. 300) and Modifying an Amazon RDS DB instance (p. 401).

This tutorial describes configuring a VPC for Amazon RDS DB instances. For more information about Amazon VPC, see Amazon VPC Getting Started Guide and Amazon VPC User Guide.

Create a VPC with private and public subnets

Use the following procedure to create a VPC with both public and private subnets.

To create a VPC and subnets

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the upper-right corner of the AWS Management Console, choose the Region to create your VPC in. This example uses the US East (Ohio) Region.
3. In the upper-left corner, choose VPC dashboard. To begin creating a VPC, choose Create VPC.
4. For Resources to create under VPC settings, choose VPC and more.
5. For the remaining VPC settings, set these values:
   - Name tag auto-generation – tutorial-dual-stack
   - IPv4 CIDR block – 10.0.0.0/16
   - IPv6 CIDR block – Amazon-provided IPv6 CIDR block
   - Tenancy – Default
   - Number of Availability Zones (AZs) – 2
   - Customize AZs – Keep the default values.
   - Number of public subnet – 2
   - Number of private subnets – 2
   - Customize subnets CIDR blocks – Keep the default values.
   - NAT gateways ($) – None
   - Egress only internet gateway – No
   - VPC endpoints – None
   - DNS options – Keep the default values.

   Note
   Amazon RDS requires at least two subnets in two different Availability Zones to support Multi-AZ DB instance deployments. This tutorial creates a Single-AZ deployment, but the requirement makes it easy to convert to a Multi-AZ DB instance deployment in the future.

6. Choose Create VPC.

Create a VPC security group for a public Amazon EC2 instance

Next, you create a security group for public access. To connect to public EC2 instances in your VPC, add inbound rules to your VPC security group that allow traffic to connect from the internet.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose VPC Dashboard, choose Security Groups, and then choose Create security group.

3. On the Create security group page, set these values:
   - Security group name: tutorial-dual-stack-security-group
   - Description: Tutorial Dual-Stack Security Group
   - VPC: Choose the VPC that you created earlier, for example: vpc-identifier (tutorial-dual-stack-vpc)

4. Add inbound rules to the security group.
   a. Determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH).

      To determine your public IP address, in a different browser window or tab use the service at https://checkip.amazonaws.com. An example of an Internet Protocol version 4 (IPv4) address is 203.0.113.25/32. An example of an Internet Protocol version 6 (IPv6) address is 2001:DB8::/32.

      In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, find the range of IP addresses used by client computers.

      Warning
      If you use 0.0.0.0/0 for IPv4 or ::0 for IPv6, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances.

   b. In the Inbound rules section, choose Add rule.

   c. Set the following values for your new inbound rule to allow Secure Shell (SSH) access to your Amazon EC2 instance. If you do this, you can connect to your EC2 instance to install SQL clients and other applications. Specify an IP address so you can access your EC2 instance:
      - Type: SSH
      - Source: The IP address or range from step a. An example of an IPv4 IP address is 203.0.113.25/32. An example of an IPv6 IP address is 2001:DB8::/32.

5. Choose Create security group to create the security group.

   Note the security group ID because you need it later in this tutorial.

Create a VPC security group for a private DB instance

To keep your DB instance private, create a second security group for private access. To connect to private DB instances in your VPC, add inbound rules to your VPC security group. These allow traffic from your Amazon EC2 instance only.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

2. Choose VPC Dashboard, choose Security Groups, and then choose Create security group.

3. On the Create security group page, set these values:
   - Security group name: tutorial-dual-stack-db-securitygroup
   - Description: Tutorial Dual-Stack DB Instance Security Group
   - VPC: Choose the VPC that you created earlier, for example: vpc-identifier (tutorial-dual-stack-vpc)

4. Add inbound rules to the security group:
a. In the **Inbound rules** section, choose **Add rule**.

b. Set the following values for your new inbound rule to allow MySQL traffic on port 3306 from your Amazon EC2 instance. If you do, you can connect from your EC2 instance to your DB instance. Doing this means that you can store and retrieve data from your EC2 instance to your database.

- **Type:** MySQL/Aurora
- **Source:** The identifier of the tutorial-dual-stack-securitygroup security group that you created previously in this tutorial, for example sg-9edd5cfb.

5. To create the security group, choose **Create security group**.

### Create a DB subnet group

A **DB subnet group** is a collection of subnets that you create in a VPC and that you then designate for your DB instances. By using a DB subnet group, you can specify a particular VPC when creating DB instances. To create a DB subnet group that is DUAL compatible, all subnets must be DUAL compatible. To be DUAL compatible, a subnet must have an IPv6 CIDR associated with it.

#### To create a DB subnet group

1. Identify the private subnets for your database in the VPC.
   a. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
   b. Choose **VPC Dashboard**, and then choose **Subnets**.
   c. Note the subnet IDs of the subnets named tutorial-dual-stack-subnet-private1-us-west-2a and tutorial-dual-stack-subnet-private2-us-west-2b.

      You will need the subnet IDs when you create your DB subnet group.

2. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).

   Make sure that you connect to the Amazon RDS console, not to the Amazon VPC console.

3. In the navigation pane, choose **Subnet groups**.

4. Choose **Create DB subnet group**.

5. On the **Create DB subnet group** page, set these values in **Subnet group details**:
   - **Name:** tutorial-dual-stack-db-subnet-group
   - **Description:** Tutorial Dual-Stack DB Subnet Group
   - **VPC:** tutorial-dual-stack-vpc (vpc-identifier)

6. In the **Add subnets** section, choose values for the **Availability Zones** and **Subnets** options.

   For this tutorial, choose us-east-2a and us-east-2b for the **Availability Zones**. For **Subnets**, choose the private subnets you identified in the previous step.

7. Choose **Create**.

Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see its details. These include the supported addressing protocols and all of the subnets associated with the group and the network type supported by the DB subnet group.

### Create an Amazon EC2 instance in dual-stack mode

To create an Amazon EC2 instance, follow the instructions in **Launch an instance using the new launch instance wizard** in the *Amazon EC2 User Guide for Linux Instances*. 

2731
Create a DB instance in dual-stack mode

In this step, you create a DB instance that runs in dual-stack mode.

To create a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the console, choose the AWS Region where you want to create the DB instance. This example uses the US East (Ohio) Region.
3. In the navigation pane, choose Databases.
4. Choose Create database.
5. On the Create database page, make sure that the Standard create option is chosen, and then choose the MySQL DB engine type.
6. In the Connectivity section, set these values:

   - **Network type** – Choose Dual-stack mode.

   - **Virtual private cloud (VPC)** – Choose an existing VPC with both public and private subnets, such as tutorial-dual-stack-vpc (vpc-identifier) created in Create a VPC with private and public subnets (p. 2729).

   The VPC must have subnets in different Availability Zones.

   - **DB subnet group** – Choose a DB subnet group for the VPC, such as tutorial-dual-stack-db-subnet-group created in Create a DB subnet group (p. 2731).

   - **Public access** – Choose No.

   - **VPC security group (firewall)** – Select Choose existing.

   - **Existing VPC Security groups** – Choose an existing VPC security group that is configured for private access, such as tutorial-dual-stack-db-securitygroup created in Create a VPC security group for a private DB instance (p. 2730).
Remove other security groups, such as the default security group, by choosing the X associated with each.

- **Availability Zone** – Choose `us-west-2a`.

  To avoid cross-AZ traffic, make sure the DB instance and the EC2 instance are in the same Availability Zone.

7. For the remaining sections, specify your DB instance settings. For information about each setting, see [Settings for DB instances](#).

### Connect to your Amazon EC2 instance and DB instance

After you create your Amazon EC2 instance and DB instance in dual-stack mode, you can connect to each one using the IPv6 protocol. To connect to an Amazon EC2 instance using the IPv6 protocol, follow the instructions in [Connect to your Linux instance](#) in the *Amazon EC2 User Guide for Linux Instances*.

To connect to your DB instance, follow the instructions in [Connecting to an Amazon RDS DB instance](#).

### Deleting the VPC

After you create the VPC and other resources for this tutorial, you can delete them if they are no longer needed.

If you added resources in the VPC that you created for this tutorial, you might need to delete these before you can delete the VPC. Examples of resources are Amazon EC2 instances or DB instances. For more information, see [Delete your VPC](#) in the *Amazon VPC User Guide*.

#### To delete a VPC and related resources

1. Delete the DB subnet group:
   a. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
   b. In the navigation pane, choose **Subnet groups**.
   c. Select the DB subnet group to delete, such as `tutorial-db-subnet-group`.
   d. Choose **Delete**, and then choose **Delete** in the confirmation window.

2. Note the VPC ID:
   a. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
   b. Choose **VPC Dashboard**, and then choose **VPCs**.
   c. In the list, identify the VPC you created, such as `tutorial-dual-stack-vpc`.
   d. Note the **VPC ID** value of the VPC that you created. You need this VPC ID in subsequent steps.

3. Delete the security groups:
   a. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
   b. Choose **VPC Dashboard**, and then choose **Security Groups**.
   c. Select the security group for the Amazon RDS DB instance, such as `tutorial-dual-stack-db-securitygroup`.
   d. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.
   e. On the **Security Groups** page, select the security group for the Amazon EC2 instance, such as `tutorial-dual-stack-securitygroup`.
   f. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.

4. Delete the NAT gateway:
a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

b. Choose VPC Dashboard, and then choose NAT Gateways.

c. Select the NAT gateway of the VPC that you created. Use the VPC ID to identify the correct NAT gateway.

d. For Actions, choose Delete NAT gateway.

e. On the confirmation page, enter delete, and then choose Delete.

5. Delete the VPC:

a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

b. Choose VPC Dashboard, and then choose VPCs.

c. Select the VPC that you want to delete, such as tutorial-dual-stack-vpc.

d. For Actions, choose Delete VPC.

The confirmation page shows other resources that are associated with the VPC that will also be deleted, including the subnets associated with it.

e. On the confirmation page, enter delete, and then choose Delete.

6. Release the Elastic IP addresses:

a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

b. Choose EC2 Dashboard, and then choose Elastic IPs.

c. Select the Elastic IP address that you want to release.

d. For Actions, choose Release Elastic IP addresses.

e. On the confirmation page, choose Release.
Moving a DB instance not in a VPC into a VPC

Some legacy DB instances on the EC2-Classic platform are not in a VPC. If your DB instance is not in a VPC, you can use the AWS Management Console to easily move your DB instance into a VPC. Before you can move a DB instance not in a VPC, into a VPC, you must create the VPC.

EC2-Classic was retired on August 15, 2022. If you haven’t migrated from EC2-Classic to a VPC, we recommend that you migrate as soon as possible. For more information, see Migrate from EC2-Classic to a VPC in the Amazon EC2 User Guide and the blog EC2-Classic Networking is Retiring – Here’s How to Prepare.

Important
If you are a new Amazon RDS customer, if you have never created a DB instance before, or if you are creating a DB instance in an AWS Region you have not used before, in almost all cases you are on the EC2-VPC platform and have a default VPC. For information about working with DB instances in a VPC, see Working with a DB instance in a VPC (p. 2705).

Follow these steps to create a VPC for your DB instance.

- **Step 1: Create a VPC** (p. 2714)
- **Step 2: Create a DB subnet group** (p. 2714)
- **Step 3: Create a VPC security group** (p. 2717)

After you create the VPC, follow these steps to move your DB instance into the VPC.

- **Updating the VPC for a DB instance** (p. 2717)

We highly recommend that you create a backup of your DB instance immediately before the migration. Doing so ensures that you can restore the data if the migration fails. For more information, see Backing up and restoring (p. 590).

The following are some limitations to moving your DB instance into the VPC.

- **Previous generation DB instance classes** – Previous generation DB instance classes might not be supported on the VPC platform. When moving a DB instance to a VPC, choose a db.m3 or db.r3 DB instance class. After you move the DB instance to a VPC, you can scale the DB instance to use a later DB instance class. For a full list of VPC supported instance classes, see Amazon RDS instance types.
- **Multi-AZ** – Moving a Multi-AZ DB instance not in a VPC into a VPC is not currently supported. To move your DB instance to a VPC, first modify the DB instance so that it is a single-AZ deployment. Change the Multi-AZ deployment setting to No. After you move the DB instance to a VPC, modify it again to make it a Multi-AZ deployment. For more information, see Modifying an Amazon RDS DB instance (p. 401).
- **Read replicas** – Moving a DB instance with read replicas not in a VPC into a VPC is not currently supported. To move your DB instance to a VPC, first delete all of its read replicas. After you move the DB instance to a VPC, recreate the read replicas. For more information, see Working with DB instance read replicas (p. 438).
- **Option groups** – If you move your DB instance to a VPC, and the DB instance is using a custom option group, change the option group that is associated with your DB instance. Option groups are platform-specific, and moving to a VPC is a change in platform. To use a custom option group in this case, assign the default VPC option group to the DB instance, assign an option group that is used by other DB instances in the VPC you are moving to, or create a new option group and assign it to the DB instance. For more information, see Working with option groups (p. 331).
Alternatives for moving a DB instance not in a VPC into a VPC with minimal downtime

Using the following alternatives, you can move a DB instance not in a VPC into a VPC with minimal downtime. These alternatives cause minimum disruption to the source DB instance and allow it to serve user traffic during the migration. However, the time required to migrate to a VPC will vary based on the database size and the live workload characteristics.

- **AWS Database Migration Service (AWS DMS)** – AWS DMS enables the live migration of data while keeping the source DB instance fully operational, but it replicates only a limited set of DDL statements. AWS DMS doesn’t propagate items such as indexes, users, privileges, stored procedures, and other database changes not directly related to table data. In addition, AWS DMS doesn’t automatically use RDS snapshots for the initial DB instance creation, which can increase migration time. For more information, see [AWS Database Migration Service](https://aws.amazon.com/dms/).

- **DB snapshot restore or point-in-time recovery** – You can move a DB instance to a VPC by restoring a snapshot of the DB instance or by restoring a DB instance to a point in time. For more information, see [Restoring from a DB snapshot](https://docs.aws.amazon.com/documentdb/latest/dbinstance/working-with-snapshots.html) and [Restoring a DB instance to a specified time](https://docs.aws.amazon.com/documentdb/latest/dbinstance/).
Quotas and constraints for Amazon RDS

Following, you can find a description of the resource quotas and naming constraints for Amazon RDS.

Topics

- Quotas in Amazon RDS (p. 2737)
- Naming constraints in Amazon RDS (p. 2740)
- Maximum number of database connections (p. 2741)
- File size limits in Amazon RDS (p. 2743)

Quotas in Amazon RDS

Each AWS account has quotas, for each AWS Region, on the number of Amazon RDS resources that can be created. After a quota for a resource has been reached, additional calls to create that resource fail with an exception.

The following table lists the resources and their quotas per AWS Region.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Adjust</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Authorizations per DB security group</td>
<td>Each supported Region: 20</td>
<td>No</td>
<td>Number of security group authorizations per DB security group</td>
</tr>
<tr>
<td>Custom engine versions</td>
<td>Each supported Region: 40</td>
<td>Yes</td>
<td>The maximum number of custom engine versions allowed in this account in the current Region</td>
</tr>
<tr>
<td>DB cluster parameter groups</td>
<td>Each supported Region: 50</td>
<td>No</td>
<td>The maximum number of DB cluster parameter groups</td>
</tr>
<tr>
<td>DB clusters</td>
<td>Each supported Region: 40</td>
<td>Yes</td>
<td>The maximum number of Aurora clusters allowed in this account in the current Region</td>
</tr>
<tr>
<td>DB instances</td>
<td>Each supported Region: 40</td>
<td>Yes</td>
<td>The maximum number of DB instances allowed in this account in the current Region</td>
</tr>
<tr>
<td>DB subnet groups</td>
<td>Each supported Region: 50</td>
<td>Yes</td>
<td>The maximum number of DB subnet groups</td>
</tr>
<tr>
<td>Data API HTTP request body size</td>
<td>Each supported Region: 4 Megabytes</td>
<td>No</td>
<td>The maximum size allowed for the HTTP request body.</td>
</tr>
<tr>
<td>Name</td>
<td>Default</td>
<td>Adjust</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------------------------</td>
<td>--------------------------------------</td>
<td>--------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Data API maximum concurrent cluster-secret pairs</td>
<td>Each supported Region: 30</td>
<td>No</td>
<td>The maximum number of unique pairs of Aurora Serverless DB clusters and secrets in concurrent Data API requests for the current account and AWS Region.</td>
</tr>
<tr>
<td>Data API maximum concurrent requests</td>
<td>Each supported Region: 500</td>
<td>No</td>
<td>The maximum number of Data API requests to an Aurora Serverless DB cluster that use the same secret and can be processed at the same time. Additional requests are queued and processed as in-process requests complete.</td>
</tr>
<tr>
<td>Data API maximum result set size</td>
<td>Each supported Region: 1 Megabytes</td>
<td>No</td>
<td>The maximum size of the database result set that can be returned by the Data API.</td>
</tr>
<tr>
<td>Data API maximum size of JSON response string</td>
<td>Each supported Region: 10 Megabytes</td>
<td>No</td>
<td>The maximum size of the simplified JSON response string returned by the RDS Data API.</td>
</tr>
<tr>
<td>Data API requests per second</td>
<td>Each supported Region: 1,000 per second</td>
<td>No</td>
<td>The maximum number of requests to the Data API per second allowed in this account in the current AWS Region.</td>
</tr>
<tr>
<td>Event subscriptions</td>
<td>Each supported Region: 20</td>
<td>Yes</td>
<td>The maximum number of event subscriptions</td>
</tr>
<tr>
<td>IAM roles per DB cluster</td>
<td>Each supported Region: 5</td>
<td>Yes</td>
<td>The maximum number of IAM roles associated with a DB cluster</td>
</tr>
<tr>
<td>IAM roles per DB instance</td>
<td>Each supported Region: 5</td>
<td>Yes</td>
<td>The maximum number of IAM roles associated with a DB instance</td>
</tr>
<tr>
<td>Manual DB cluster snapshots</td>
<td>Each supported Region: 100</td>
<td>Yes</td>
<td>The maximum number of manual DB cluster snapshots</td>
</tr>
<tr>
<td>Manual DB instance snapshots</td>
<td>Each supported Region: 100</td>
<td>Yes</td>
<td>The maximum number of manual DB instance snapshots</td>
</tr>
<tr>
<td>Option groups</td>
<td>Each supported Region: 20</td>
<td>Yes</td>
<td>The maximum number of option groups</td>
</tr>
</tbody>
</table>
## Quotas in Amazon RDS

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Adjust</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter groups</td>
<td>Each supported Region: 50</td>
<td>Yes</td>
<td>The maximum number of parameter groups</td>
</tr>
<tr>
<td>Proxies</td>
<td>Each supported Region: 20</td>
<td>Yes</td>
<td>The maximum number of proxies allowed in this account in the current AWS Region</td>
</tr>
<tr>
<td>Read replicas per primary</td>
<td>Each supported Region: 15</td>
<td>Yes</td>
<td>The maximum number of read replicas per primary DB instance. This quota cant be adjusted for Amazon Aurora.</td>
</tr>
<tr>
<td>Reserved DB instances</td>
<td>Each supported Region: 40</td>
<td>Yes</td>
<td>The maximum number of reserved DB instances allowed in this account in the current AWS Region</td>
</tr>
<tr>
<td>Rules per security group</td>
<td>Each supported Region: 20</td>
<td>No</td>
<td>The maximum number of rules per DB security group</td>
</tr>
<tr>
<td>Security groups</td>
<td>Each supported Region: 25</td>
<td>Yes</td>
<td>The maximum number of DB security groups</td>
</tr>
<tr>
<td>Security groups (VPC)</td>
<td>Each supported Region: 5</td>
<td>No</td>
<td>The maximum number of DB security groups per Amazon VPC</td>
</tr>
<tr>
<td>Subnets per DB subnet group</td>
<td>Each supported Region: 20</td>
<td>No</td>
<td>The maximum number of subnets per DB subnet group</td>
</tr>
<tr>
<td>Tags per resource</td>
<td>Each supported Region: 50</td>
<td>No</td>
<td>The maximum number of tags per Amazon RDS resource</td>
</tr>
<tr>
<td>Total storage for all DB instances</td>
<td>Each supported Region: 100,000 Gigabytes</td>
<td>Yes</td>
<td>The maximum total storage (in GB) on EBS volumes for all Amazon RDS DB instances added together. This quota does not apply to Amazon Aurora, which has a maximum cluster volume of 128 TiB for each DB cluster.</td>
</tr>
</tbody>
</table>

**Note**

By default, you can have up to a total of 40 DB instances. RDS DB instances, Aurora DB instances, Amazon Neptune instances, and Amazon DocumentDB instances apply to this quota. The following limitations apply to the Amazon RDS DB instances:

- 10 for each SQL Server edition (Enterprise, Standard, Web, and Express) under the "license-included" model
- 10 for Oracle under the "license-included" model
If your application requires more DB instances, you can request additional DB instances by opening the Service Quotas console. In the navigation pane, choose AWS services, Choose Amazon Relational Database Service (Amazon RDS), choose a quota, and follow the directions to request a quota increase. For more information, see Requesting a quota increase in the Service Quotas User Guide.

For RDS for Oracle and RDS for SQL Server, the read replica limit is 5 per source database for each Region.

Backups managed by AWS Backup are considered manual DB snapshots, but don't count toward the manual snapshot quota. For information about AWS Backup, see the AWS Backup Developer Guide.

If you use any RDS API operations and exceed the default quota for the number of calls per second, the Amazon RDS API issues an error like the following one.

ClientError: An error occurred (ThrottlingException) when calling the API_name operation: Rate exceeded.

Here, reduce the number of calls per second. The quota is meant to cover most use cases. If higher limits are needed, request a quota increase by contacting AWS Support. Open the AWS Support Center page, sign in if necessary, and choose Create case. Choose Service limit increase. Complete and submit the form.

Note
This quota can't be changed in the Amazon RDS Service Quotas console.

Naming constraints in Amazon RDS

The following table describes naming constraints in Amazon RDS.

<table>
<thead>
<tr>
<th>Resource or item</th>
<th>Constraints</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB instance identifier</td>
<td>Identifiers have these naming constraints:</td>
</tr>
<tr>
<td></td>
<td>• Must contain 1–63 alphanumeric characters or hyphens.</td>
</tr>
<tr>
<td></td>
<td>• First character must be a letter.</td>
</tr>
<tr>
<td></td>
<td>• Can't end with a hyphen or contain two consecutive hyphens.</td>
</tr>
<tr>
<td></td>
<td>• Must be unique for all DB instances per AWS account, per AWS Region.</td>
</tr>
<tr>
<td>Database name</td>
<td>Database name constraints differ for each database engine. For more information, see the available settings when creating each DB instance.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> This approach doesn't apply to SQL Server. For SQL Server, you create your databases after you create your DB instance.</td>
</tr>
<tr>
<td>Master user name</td>
<td>Master user name constraints differ for each database engine. For more information, see the available settings when creating each DB instance.</td>
</tr>
</tbody>
</table>
Maximum number of database connections

The maximum number of simultaneous database connections varies by the DB engine type and the memory allocation for the DB instance class. The maximum number of connections is generally set in the parameter group associated with the DB instance. The exception is Microsoft SQL Server, where it is set in the server properties for the DB instance in SQL Server Management Studio (SSMS).

Database connections consume memory. Setting one of these parameters too high can cause a low memory condition that might cause a DB instance to be placed in the `incompatible-parameters` status. For more information, see Diagnosing and resolving incompatible parameters status for a memory limit (p. 2752).

If your applications frequently open and close connections, or keep a large number of long-lived connections open, we recommend that you use Amazon RDS Proxy. RDS Proxy is a fully managed, highly available database proxy that uses connection pooling to share database connections securely and efficiently. To learn more about RDS Proxy, see Using Amazon RDS Proxy (p. 1215).

**Note**
For Oracle, you set the maximum number of user processes and user and system sessions.

### Maximum database connections

<table>
<thead>
<tr>
<th>DB engine</th>
<th>Parameter</th>
<th>Allowed values</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
</table>
| MariaDB and MySQL    | max_connections | 1–100000   | Default for all MariaDB and MySQL versions except for MariaDB version 10.5 and 10.6:  
{DBInstanceClassMemory/12582880}  | Number of simultaneous client connections allowed |

---

Resource or item | Constraints
--- | ---
Master password | The password for the database master user can include any printable ASCII character except `/`, ` `, `", @, or a space. For Oracle, & is an additional character limitation. The password has the following number of printable ASCII characters depending on the DB engine:
- MariaDB and MySQL: 8–41
- Oracle: 8–30
- SQL Server and PostgreSQL: 8–128

DB parameter group name | These names have these constraints:
- Must contain 1–255 alphanumeric characters.
- First character must be a letter.
- Hyphens are allowed, but the name cannot end with a hyphen or contain two consecutive hyphens.

DB subnet group name | These names have these constraints:
- Must contain 1–255 characters.
- Alphanumeric characters, spaces, hyphens, underscores, and periods are allowed.
## Maximum number of database connections

<table>
<thead>
<tr>
<th>DB engine</th>
<th>Parameter</th>
<th>Allowed values</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td>Default for MariaDB version 10.5 and 10.6: LEAST({DBInstanceClassMemory/25165760},12000)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Note</td>
<td>In either case, if the default value calculation results in a value greater than 16,000, Amazon RDS sets the limit to 16,000 for MariaDB and MySQL DB instances.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Oracle</td>
<td>processes</td>
<td>80–20000</td>
<td>LEAST({DBInstanceClassMemory/9868951},20000)</td>
<td>User processes</td>
</tr>
<tr>
<td></td>
<td>sessions</td>
<td>100–65535</td>
<td>–</td>
<td>User and system sessions</td>
</tr>
<tr>
<td>PostgreSQL</td>
<td>max_connections</td>
<td>6–8388607</td>
<td>LEAST({DBInstanceClassMemory/15531392},5000)</td>
<td>Maximum number of concurrent connections</td>
</tr>
<tr>
<td>SQL Server</td>
<td>Maximum number of concurrent connections</td>
<td>0–32767</td>
<td>0 (unlimited)</td>
<td>Maximum number of concurrent connections</td>
</tr>
</tbody>
</table>

DBInstanceClassMemory is in bytes. For details about how this value is calculated, see [Specifying DB parameters](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/USER_MariaDB.html#USER_MariaDB.DBInstanceClassMemory) (p. 369). Because of memory reserved for the operating system and RDS management processes, this memory size is smaller than the value in gibibytes (GiB) shown in [Hardware specifications for DB instance classes](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/CHAP_AWSResources.html#AWSResources.DBInstances) (p. 87).

For example, some DB instance classes have 8 GiB of memory, which is 8,589,934,592 bytes. For a MySQL DB instance running on a DB instance class with 8 GiB of memory, such as db.m7g.large, the equation that uses the total memory would be 8589934592/12582880=683. However, the variable DBInstanceClassMemory automatically subtracts the amounts reserved to the operating system and the RDS processes that manage the DB instance. The remainder of the subtraction is then divided by 12,582,880. This calculation results in approximately 630 for the value of max_connections instead of 683. This value depends on the DB instance class and DB engine.

When a MariaDB or MySQL DB instance is running on a small DB instance class, such as db.t3.micro or db.t3.small, the total memory available is low. For these DB instance classes, RDS reserves a significant portion of the available memory, which affects the value max_connections. For example, the default maximum number of connections for a MySQL DB instance running on a db.t3.micro DB instance class is approximately 60. You can determine the max_connections value for your DB MariaDB or MySQL DB instance by connecting to it and running the following SQL command:

```
SHOW GLOBAL VARIABLES LIKE 'max_connections';
```
File size limits in Amazon RDS

File size limits apply to certain Amazon RDS DB instances. For more information, see the following engine-specific limits:

- MariaDB file size limits in Amazon RDS (p. 1368)
- MySQL file size limits in Amazon RDS (p. 1770)
- Oracle file size limits in Amazon RDS (p. 1820)
Troubleshooting for Amazon RDS

Use the following sections to help troubleshoot problems you have with DB instances in Amazon RDS and Amazon Aurora.

Topics
- Can’t connect to Amazon RDS DB instance (p. 2744)
- Amazon RDS security issues (p. 2746)
- Troubleshooting incompatible-network state (p. 2747)
- Resetting the DB instance owner password (p. 2748)
- Amazon RDS DB instance outage or reboot (p. 2748)
- Amazon RDS DB parameter changes not taking effect (p. 2749)
- Amazon RDS DB instance running out of storage (p. 2749)
- Amazon RDS insufficient DB instance capacity (p. 2750)
- Freeable memory issues in Amazon RDS (p. 2751)
- MySQL and MariaDB issues (p. 2751)
- Can’t set backup retention period to 0 (p. 2758)

For information about debugging problems using the Amazon RDS API, see Troubleshooting applications on Amazon RDS (p. 2759).

Can’t connect to Amazon RDS DB instance

When you can’t connect to a DB instance, the following are common causes:

- **Inbound rules** – The access rules enforced by your local firewall and the IP addresses authorized to access your DB instance might not match. The problem is most likely the inbound rules in your security group.

By default, DB instances don’t allow access. Access is granted through a security group associated with the VPC that allows traffic into and out of the DB instance. If necessary, add inbound and outbound rules for your particular situation to the security group. You can specify an IP address, a range of IP addresses, or another VPC security group.

**Note**
When adding a new inbound rule, you can choose My IP for Source to allow access to the DB instance from the IP address detected in your browser.

For more information about setting up security groups, see Provide access to your DB instance in your VPC by creating a security group (p. 177).

**Note**
Client connections from IP addresses within the range 169.254.0.0/16 aren’t permitted. This is the Automatic Private IP Addressing Range (APIPA), which is used for local-link addressing.

- **Public accessibility** – To connect to your DB instance from outside of the VPC, such as by using a client application, the instance must have a public IP address assigned to it.

To make the instance publicly accessible, modify it and choose Yes under Public accessibility. For more information, see Hiding a DB instance in a VPC from the internet (p. 2712).

- **Port** – The port that you specified when you created the DB instance can’t be used to send or receive communications due to your local firewall restrictions. To determine if your network allows the
Testing the DB instance connection

specified port to be used for inbound and outbound communication, check with your network administrator.

- **Availability** – For a newly created DB instance, the DB instance has a status of `creating` until the DB instance is ready to use. When the state changes to `available`, you can connect to the DB instance. Depending on the size of your DB instance, it can take up to 20 minutes before an instance is available.

- **Internet gateway** – For a DB instance to be publicly accessible, the subnets in its DB subnet group must have an internet gateway.

**To configure an internet gateway for a subnet**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**, and then choose the name of the DB instance.
3. In the **Connectivity & security** tab, write down the values of the VPC ID under **VPC** and the subnet ID under **Subnets**.
4. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
5. In the navigation pane, choose **Internet Gateways**. Verify that there is an internet gateway attached to your VPC. Otherwise, choose **Create Internet Gateway** to create an internet gateway. Select the internet gateway, and then choose **Attach to VPC** and follow the directions to attach it to your VPC.
6. In the navigation pane, choose **Subnets**, and then select your subnet.
7. On the **Route Table** tab, verify that there is a route with `0.0.0.0/0` as the destination and the internet gateway for your VPC as the target.

    If you're connecting to your instance using its IPv6 address, verify that there is a route for all IPv6 traffic (`::/0`) that points to the internet gateway. Otherwise, do the following:

    a. Choose the ID of the route table (rtb-xxxxxxxxx) to navigate to the route table.
    b. On the **Routes** tab, choose **Edit routes**. Choose **Add route**, use `0.0.0.0/0` as the destination and the internet gateway as the target.
    c. For IPv6, choose **Add route**, use `::/0` as the destination and the internet gateway as the target.
    d. Choose **Save routes**.

    Also, if you are trying to connect to IPv6 endpoint, make sure that client IPv6 address range is authorized to connect to the DB instance.

For more information, see [Working with a DB instance in a VPC (p. 2705)](https://console.aws.amazon.com/rds/).

For engine-specific connection issues, see the following topics:

- **Troubleshooting connections to your SQL Server DB instance (p. 1401)**
- **Troubleshooting connections to your Oracle DB instance (p. 1827)**
- **Troubleshooting connections to your RDS for PostgreSQL instance (p. 2189)**
- **Maximum MySQL and MariaDB connections (p. 2751)**

**Testing a connection to a DB instance**

You can test your connection to a DB instance using common Linux or Microsoft Windows tools.
From a Linux or Unix terminal, you can test the connection by entering the following. Replace `DB-instance-endpoint` with the endpoint and `port` with the port of your DB instance.

```
nc -zv DB-instance-endpoint port
```

For example, the following shows a sample command and the return value.

```
nc -zv postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 8299
Connection to postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 8299 port [tcp/v4r-data] succeeded!
```

Windows users can use Telnet to test the connection to a DB instance. Telnet actions aren't supported other than for testing the connection. If a connection is successful, the action returns no message. If a connection isn't successful, you receive an error message such as the following.

```
C:\>telnet sg-postgresql1.c6c8mntfake0.us-west-2.rds.amazonaws.com 819
Connecting To sg-postgresql1.c6c8mntfake0.us-west-2.rds.amazonaws.com...Could not open connection to the host, on port 819: Connect failed
```

If Telnet actions return success, your security group is properly configured.

**Note**

Amazon RDS doesn't accept internet control message protocol (ICMP) traffic, including ping.

**Troubleshooting connection authentication**

In some cases, you can connect to your DB instance but you get authentication errors. In these cases, you might want to reset the master user password for the DB instance. You can do this by modifying the RDS instance.

For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](p. 401).

**Amazon RDS security issues**

To avoid security issues, never use your master AWS user name and password for a user account. Best practice is to use your master AWS account to create users and assign those to DB user accounts. You can also use your master account to create other user accounts, if necessary.

For information about creating users, see [Creating an IAM user in your AWS account](p. 401). For information about creating users in AWS IAM Identity Center (successor to AWS Single Sign-On), see [Manage identities in IAM Identity Center](p. 401).

**Error message "failed to retrieve account attributes, certain console functions may be impaired."**

You can get this error for several reasons. It might be because your account is missing permissions, or your account hasn't been properly set up. If your account is new, you might not have waited for the account to be ready. If this is an existing account, you might lack permissions in your access policies to perform certain actions such as creating a DB instance. To fix the issue, your administrator needs to provide the necessary roles to your account. For more information, see [the IAM documentation](p. 401).
Troubleshooting incompatible-network state

The incompatible-network state means that the database might still be accessible at the database level but you can’t modify or reboot it.

Causes

The incompatible-network state of your DB instance could be a result of one of the following actions:

- Modifying the DB instance class.
- Modifying the DB instance to use Multi-AZ DB cluster deployment.
- Replacing a host due to a maintainence event.
- Launching a replacement DB instance.
- Restoring from a snapshot backup.
- Starting a DB instance that was stopped.

Resolution

Use start-db-instance command

To fix a database that is in an incompatible-network state, follow these instructions:

1. Open the https://console.aws.amazon.com/rds/ and choose Databases from the navigation pane.
2. Choose the DB instance that is in the incompatible-network state and note the DB instance identifier, VPC ID, and subnet IDs from the Connectivity & Security tab.
3. Use the AWS CLI to run the start-db-instance command. Specify the --db-instance-identifier value.

Note
Running this command when your database is in incompatible mode might cause some downtime.
The start-db-instance command does not resolve this issue for RDS for SQL Server DB instances.

Your database status changes to Available if the command executes successfully.

If your database restarts, the DB instance might execute the last operation run on the instance before it was moved to incompatible-network state. This might move the instance back to the incompatible-network state.

If the start-db-instance command is unsuccessful or the instance moves back to incompatible-network state, open the Databases page in the RDS console and select the database. Navigate to the Logs & events section. The Recent events section displays further resolution steps to follow. The messages are classified as follows:

- INTERNAL RESOURCE CHECK: There might be issues with your internal resources.
- DNS CHECK: Check DNS resolution and hostnames for the VPC in the VPC console.
- ENI CHECK: The elastic network interface (ENI) for your database might not exist.
- GATEWAY CHECK: The internet gateway for your publicly available database is not attached to the VPC.
- IP CHECK: There are no free IP addresses in your subnets.
Perform point-in-time recovery

It is best practice to have a backup (snapshot or logical), in case your database enters incompatible-network state. See Working with backups (p. 591). If you turned on automated backups, then temporarily stop any writes to the database and perform a point-in-time recovery.

**Note**
After an instance enters the incompatible-network state, the DB instance might not be accessible to perform a logical backup.

If you didn't turn on automated backups, create a new DB instance. Then migrate the data using AWS Database Migration Service (AWS DMS), or by using a backup and restore tool.

If this does not resolve the issue, contact AWS Support for further assistance.

Resetting the DB instance owner password

If you get locked out of your DB instance, you can log in as the master user. Then you can reset the credentials for other administrative users or roles. If you can't log in as the master user, the AWS account owner can reset the master user password. For details of which administrative accounts or roles you might need to reset, see Master user account privileges (p. 2699).

You can change the DB instance password by using the Amazon RDS console, the AWS CLI command modify-db-instance, or by using the ModifyDBInstance API operation. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 401).

Amazon RDS DB instance outage or reboot

A DB instance outage can occur when a DB instance is rebooted. It can also occur when the DB instance is put into a state that prevents access to it, and when the database is restarted. A reboot can occur when you manually reboot your DB instance. A reboot can also occur when you change a DB instance setting that requires a reboot before it can take effect.

A DB instance reboot occurs when you change a setting that requires a reboot, or when you manually cause a reboot. A reboot can occur immediately if you change a setting and request that the change take effect immediately. Or it can occur during the DB instance’s maintenance window.

A DB instance reboot occurs immediately when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0. You then set **Apply Immediately** to **true**.
- You change the DB instance class, and **Apply Immediately** is set to **true**.
- You change the storage type from **Magnetic (Standard)** to **General Purpose (SSD)** or ** Provisioned IOPS (SSD)**, or from **Provisioned IOPS (SSD)** or **General Purpose (SSD)** to **Magnetic (Standard)**.

A DB instance reboot occurs during the maintenance window when one of the following occurs:
You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0, and **Apply Immediately** is set to false.

- You change the DB instance class, and **Apply Immediately** is set to false.

When you change a static parameter in a DB parameter group, the change doesn't take effect until the DB instance associated with the parameter group is rebooted. The change requires a manual reboot. The DB instance isn't automatically rebooted during the maintenance window.

To see a table that shows DB instance actions and the effect that setting the **Apply Immediately** value has, see Modifying an Amazon RDS DB instance (p. 401).

## Amazon RDS DB parameter changes not taking effect

In some cases, you might change a parameter in a DB parameter group but don't see the changes take effect. If so, you likely need to reboot the DB instance associated with the DB parameter group. When you change a dynamic parameter, the change takes effect immediately. When you change a static parameter, the change doesn't take effect until you reboot the DB instance associated with the parameter group.

You can reboot a DB instance using the RDS console. Or you can explicitly call the `RebootDBInstance` API operation. You can reboot without failover if the DB instance is in a Multi-AZ deployment. The requirement to reboot the associated DB instance after a static parameter change helps mitigate the risk of a parameter misconfiguration affecting an API call. An example of this is calling `ModifyDBInstance` to change the DB instance class. For more information, see Modifying parameters in a DB parameter group (p. 352).

## Amazon RDS DB instance running out of storage

If your DB instance runs out of storage space, it might no longer be available. We highly recommend that you constantly monitor the `FreeStorageSpace` metric published in CloudWatch to make sure that your DB instance has enough free storage space.

If your database instance runs out of storage, its status changes to `storage-full`. For example, a call to the `DescribeDBInstances` API operation for a DB instance that has used up its storage outputs the following.

```bash
aws rds describe-db-instances --db-instance-identifier mydbinstance
```

```
DBINSTANCE mydbinstance 2009-12-22T23:06:11.915Z db.m5.large mysql8.0 50 sa storage-full mydbinstance.clla4j4jgyph.us-east-1.rds.amazonaws.com 3306 us-east-1b 3 SECGROUP default active PARAMGRP default.mysql8.0 in-sync
```

To recover from this scenario, add more storage space to your instance using the `ModifyDBInstance` API operation or the following AWS CLI command.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance --db-instance-identifier mydbinstance --allocated-storage 60
```

To recover from this scenario, add more storage space to your instance using the `ModifyDBInstance` API operation or the following AWS CLI command.

For Linux, macOS, or Unix:
Insufficient DB instance capacity

---apply-immediately

For Windows:

```bash
aws rds modify-db-instance
  --db-instance-identifier mydbinstance
  --allocated-storage 60
  --apply-immediately
```

Now, when you describe your DB instance, you see that your DB instance has modifying status, which indicates the storage is being scaled.

```bash
aws rds describe-db-instances --db-instance-identifier mydbinstance
```

After storage scaling is complete, your DB instance status changes to available.

```bash
aws rds describe-db-instances --db-instance-identifier mydbinstance
```

You can receive notifications when your storage space is exhausted using the DescribeEvents operation. For example, in this scenario, if you make a DescribeEvents call after these operations you see the following output.

```bash
aws rds describe-events --source-type db-instance --source-identifier mydbinstance
```

Amazon RDS insufficient DB instance capacity

The InsufficientDBInstanceCapacity error can be returned when you try to create, start, or modify a DB instance. It can also be returned when you try to restore a DB instance from a DB snapshot. When this error is returned, a common cause is that the specific DB instance class isn't available in the requested Availability Zone. You can try one of the following to solve the problem:
Freeable memory issues in Amazon RDS

Freeable memory is the total random access memory (RAM) on a DB instance that can be made available to the database engine. It's the sum of the free operating-system (OS) memory and the available buffer and page cache memory. The database engine uses most of the memory on the host, but OS processes also use some RAM. Memory currently allocated to the database engine or used by OS processes isn't included in freeable memory. When the database engine is running out of memory, the DB instance can use the temporary space that is normally used for buffering and caching. As previously mentioned, this temporary space is included in freeable memory.

You use the FreeableMemory metric in Amazon CloudWatch to monitor the freeable memory. For more information, see Overview of monitoring metrics in Amazon RDS.

If your DB instance consistently runs low on freeable memory or uses swap space, consider scaling up to a larger DB instance class. For more information, see DB instance classes.

You can also change the memory settings. For example, on RDS for MySQL, you might adjust the size of the innodb_buffer_pool_size parameter. This parameter is set by default to 75 percent of physical memory. For more MySQL troubleshooting tips, see How can I troubleshoot low freeable memory in an Amazon RDS for MySQL database?

MySQL and MariaDB issues

You can diagnose and correct issues with MySQL and MariaDB DB instances.

Topics
- Maximum MySQL and MariaDB connections (p. 2751)
- Diagnosing and resolving incompatible parameters status for a memory limit (p. 2752)
- Diagnosing and resolving lag between read replicas (p. 2753)
- Diagnosing and resolving a MySQL or MariaDB read replication failure (p. 2754)
- Creating triggers with binary logging enabled requires SUPER privilege (p. 2755)
- Diagnosing and resolving point-in-time restore failures (p. 2757)
- Replication stopped error (p. 2757)
- Read replica create fails or replication breaks with fatal error 1236 (p. 2758)

Maximum MySQL and MariaDB connections

The maximum number of connections allowed to an RDS for MySQL or RDS for MariaDB DB instance is based on the amount of memory available for its DB instance class. A DB instance class with more memory available results in a larger number of connections available. For more information on DB instance classes, see DB instance classes.
The connection limit for a DB instance is set by default to the maximum for the DB instance class. You can limit the number of concurrent connections to any value up to the maximum number of connections allowed. Use the max_connections parameter in the parameter group for the DB instance. For more information, see Maximum number of database connections (p. 2741) and Working with parameter groups (p. 347).

You can retrieve the maximum number of connections allowed for a MySQL or MariaDB DB instance by running the following query.

```
SELECT @@max_connections;
```

You can retrieve the number of active connections to a MySQL or MariaDB DB instance by running the following query.

```
SHOW STATUS WHERE `variable_name` = 'Threads_connected';
```

### Diagnosing and resolving incompatible parameters status for a memory limit

A MariaDB or MySQL DB instance can be placed in incompatible-parameters status for a memory limit when the following conditions are met:

- The DB instance is restarted at least three times in one hour or at least five times in one day when the DB instance status is Available.
- An attempt to restart the DB instance fails because a maintenance action or monitoring process couldn't restart the DB instance.
- The potential memory usage of the DB instance exceeds 1.2 times the memory allocated to its DB instance class.

When a DB instance is restarted for the third time in one hour or for the fifth time in one day, it performs a check for memory usage. The check makes a calculation of the potential memory usage of the DB instance. The value returned by the calculation is the sum of the following values:

- **Value 1** – The sum of the following parameters:
  - `innodb_additional_mem_pool_size`
  - `innodb_buffer_pool_size`
  - `innodb_log_buffer_size`
  - `key_buffer_size`
  - `query_cache_size` (MySQL version 5.7 only)
  - `tmp_table_size`

- **Value 2** – The `max_connections` parameter multiplied by the sum of the following parameters:
  - `binlog_cache_size`
  - `join_buffer_size`
  - `read_buffer_size`
  - `read_rnd_buffer_size`
  - `sort_buffer_size`
  - `thread_stack`

- **Value 3** – If the `performance_schema` parameter is enabled, then multiply the `max_connections` parameter by 257700.
If the `performance_schema` parameter is disabled, then this value is zero.

So, the value returned by the calculation is the following:

\[ \text{Value 1 + Value 2 + Value 3} \]

When this value exceeds 1.2 times the memory allocated to the DB instance class used by the DB instance, the DB instance is placed in `incompatible-parameters` status. For information about the memory allocated to DB instance classes, see [Hardware specifications for DB instance classes](https://docs.aws.amazon.com/rds/latest/guides/hardware.html) (p. 87).

The calculation multiplies the value of the `max_connections` parameter by the sum of several parameters. If the `max_connections` parameter is set to a large value, it might cause the check to return an inordinately high value for the potential memory usage of the DB instance. In this case, consider lowering the value of the `max_connections` parameter.

To resolve the problem, complete the following steps:

1. Adjust the memory parameters in the DB parameter group associated with the DB instance. Do so such that the potential memory usage is lower than 1.2 times the memory allocated to its DB instance class.

   For information about setting parameters, see [Modifying parameters in a DB parameter group](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/USER_AMEParameterGroups.html) (p. 352).

2. Restart the DB instance.

   For information about setting parameters, see [Starting an Amazon RDS DB instance that was previously stopped](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/CHAP_Monitoring.html#CHAP_Monitoring.StopStart) (p. 384).

### Diagnosing and resolving lag between read replicas

After you create a MySQL or MariaDB read replica and the replica is available, Amazon RDS first replicates the changes made to the source DB instance from the time the read replica create operation started. During this phase, the replication lag time for the read replica is greater than 0. You can monitor this lag time in Amazon CloudWatch by viewing the Amazon RDS `ReplicaLag` metric.

The `ReplicaLag` metric reports the value of the `Seconds_Behind_Master` field of the MariaDB or MySQL `SHOW REPLICA STATUS` command. For more information, see [SHOW REPLICA STATUS Statement](https://dev.mysql.com/doc/refman/8.0/en/show-replication-status.html) in the MySQL documentation.

When the `ReplicaLag` metric reaches 0, the replica has caught up to the source DB instance. If the `ReplicaLag` metric returns `-1`, replication might not be active. To troubleshoot a replication error, see [Diagnosing and resolving a MySQL or MariaDB read replication failure](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/CHAP_ReplFail.html) (p. 2754). A `ReplicaLag` value of `-1` can also mean that the `Seconds_Behind_Master` value can't be determined or is `NULL`.

**Note**

Previous versions of MariaDB and MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MariaDB version before 10.5 or a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

The `ReplicaLag` metric returns `-1` during a network outage or when a patch is applied during the maintenance window. In this case, wait for network connectivity to be restored or for the maintenance window to end before you check the `ReplicaLag` metric again.

The MySQL and MariaDB read replication technology is asynchronous. Thus, you can expect occasional increases for the `BinLogDiskUsage` metric on the source DB instance and for the `ReplicaLag` metric on the read replica. For example, consider a situation where a high volume of write operations to the
source DB instance occur in parallel. At the same time, write operations to the read replica are serialized using a single I/O thread. Such a situation can lead to a lag between the source instance and read replica.

For more information about read replicas and MySQL, see [Replication implementation details](https://dev.mysql.com/doc/refman/8.0/en/replication-implementation-details.html) in the MySQL documentation. For more information about read replicas and MariaDB, see [Replication overview](https://mariadb.com/kb/en/mariadb/replication-overview/) in the MariaDB documentation.

You can reduce the lag between updates to a source DB instance and the subsequent updates to the read replica by doing the following:

- Set the DB instance class of the read replica to have a storage size comparable to that of the source DB instance.
- Make sure that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the `max_allowed_packet` parameter in the next section.
- Disable the query cache. For tables that are modified often, using the query cache can increase replica lag because the cache is locked and refreshed often. If this is the case, you might see less replica lag if you disable the query cache. You can disable the query cache by setting the `query_cache_type` parameter to 0 in the DB parameter group for the DB instance. For more information on the query cache, see [Query cache configuration](https).
- Warm the buffer pool on the read replica for InnoDB for MySQL or MariaDB. For example, suppose that you have a small set of tables that are being updated often and you're using the InnoDB or XtraDB table schema. In this case, dump those tables on the read replica. Doing this causes the database engine to scan through the rows of those tables from the disk and then cache them in the buffer pool. This approach can reduce replica lag. The following shows an example.

For Linux, macOS, or Unix:

```bash
PROMPT> mysqldump \
    -h <endpoint> \
    --port=<port> \
    -u=<username> \
    -p <password> \
    database_name table1 table2 > /dev/null
```

For Windows:

```bash
PROMPT> mysqldump ^
    -h <endpoint> ^
    --port=<port> ^
    -u=<username> ^
    -p <password> ^
    database_name table1 table2 > /dev/null
```

### Diagnosing and resolving a MySQL or MariaDB read replication failure

Amazon RDS monitors the replication status of your read replicas. RDS updates the `Replication State` field of the read replica instance to `Error` if replication stops for any reason. You can review the details of the associated error thrown by the MySQL or MariaDB engines by viewing the `Replication Error` field. Events that indicate the status of the read replica are also generated, including `RDS-EVENT-0045` (p. 887), `RDS-EVENT-0046` (p. 888), and `RDS-EVENT-0047` (p. 883). For more information about events and subscribing to events, see [Working with Amazon RDS event notification](https://docs.aws.amazon.com/rds/latest/userguide/WorkingWithEvents.html). If a MySQL error message is returned, check the error in the [MySQL error message documentation](https://dev.mysql.com/doc/refman/8.0/en/error-messages.html). If a MariaDB error message is returned, check the error in the [MariaDB error message documentation](https://mariadb.com/kb/en/mariadb/error-messages/).
Common situations that can cause replication errors include the following:

- The value for the `max_allowed_packet` parameter for a read replica is less than the `max_allowed_packet` parameter for the source DB instance.

  The `max_allowed_packet` parameter is a custom parameter that you can set in a DB parameter group. The `max_allowed_packet` parameter is used to specify the maximum size of data manipulation language (DML) that can be run on the database. In some cases, the `max_allowed_packet` value for the source DB instance might be larger than the `max_allowed_packet` value for the read replica. If so, the replication process can throw an error and stop replication. The most common error is `packet bigger than 'max_allowed_packet' bytes`. You can fix the error by having the source and read replica use DB parameter groups with the same `max_allowed_packet` parameter values.

- Writing to tables on a read replica. If you're creating indexes on a read replica, you need to have the `read_only` parameter set to 0 to create the indexes. If you're writing to tables on the read replica, it can break replication.

- Using a nontransactional storage engine such as MyISAM. Read replicas require a transactional storage engine. Replication is only supported for the following storage engines: InnoDB for MySQL or MariaDB.

  You can convert a MyISAM table to InnoDB with the following command:

  ```sql
  alter table <schema>.<table_name> engine=innodb;
  ```

- Using unsafe nondeterministic queries such as `SYSDATE()`. For more information, see Determination of safe and unsafe statements in binary logging in the MySQL documentation.

The following steps can help resolve your replication error:

- If you encounter a logical error and you can safely skip the error, follow the steps described in Skipping the current replication error (p. 1760). Your MySQL or MariaDB DB instance must be running a version that includes the `mysql_rds_skip_repl_error` procedure. For more information, see `mysql.rds_skip_repl_error` (p. 1795).

- If you encounter a binary log (binlog) position issue, you can change the replica replay position with the `mysql_rds_next_master_log` command. Your MySQL or MariaDB DB instance must be running a version that supports the `mysql_rds_next_master_log` command to change the replica replay position. For version information, see `mysql.rds_next_master_log` (p. 1783).

- You might encounter a temporary performance issue due to high DML load. If so, you can set the `innodb_flush_log_at_trx_commit` parameter to 2 in the DB parameter group on the read replica. Doing this can help the read replica catch up, though it temporarily reduces atomicity, consistency, isolation, and durability (ACID).

- You can delete the read replica and create an instance using the same DB instance identifier. If you do this, the endpoint remains the same as that of your old read replica.

If a replication error is fixed, the Replication State changes to replicating. For more information, see Troubleshooting a MySQL read replica problem (p. 1734).

**Creating triggers with binary logging enabled requires SUPER privilege**

When trying to create triggers in an RDS for MySQL or RDS for MariaDB DB instance, you might receive the following error.

"You do not have the SUPER privilege and binary logging is enabled"
To use triggers when binary logging is enabled requires the SUPER privilege, which is restricted for RDS for MySQL and RDS for MariaDB DB instances. You can create triggers when binary logging is enabled without the SUPER privilege by setting the `log_bin_trust_function_creators` parameter to true. To set the `log_bin_trust_function_creators` to true, create a new DB parameter group or modify an existing DB parameter group.

You can create a new DB parameter group so you can create triggers in your RDS for MySQL or RDS for MariaDB DB instance with binary logging enabled. To do so, use the following CLI commands. To modify an existing parameter group, start with step 2.

**To create a new parameter group to allow triggers with binary logging enabled using the CLI**

1. Create a new parameter group.

   For Linux, macOS, or Unix:
   ```
   aws rds create-db-parameter-group \
   --db-parameter-group-name allow-triggers \
   --db-parameter-group-family mysql8.0 \
   --description "parameter group allowing triggers"
   ```

   For Windows:
   ```
   aws rds create-db-parameter-group ^
   --db-parameter-group-name allow-triggers ^
   --db-parameter-group-family mysql8.0 ^
   --description "parameter group allowing triggers"
   ```

2. Modify the DB parameter group to allow triggers.

   For Linux, macOS, or Unix:
   ```
   aws rds modify-db-parameter-group \
   --db-parameter-group-name allow-triggers \
   --parameters "ParameterName=log_bin_trust_function_creators, ParameterValue=true, ApplyMethod=pending-reboot"
   ```

   For Windows:
   ```
   aws rds modify-db-parameter-group ^
   --db-parameter-group-name allow-triggers ^
   --parameters "ParameterName=log_bin_trust_function_creators, ParameterValue=true, ApplyMethod=pending-reboot"
   ```

3. Modify your DB instance to use the new DB parameter group.

   For Linux, macOS, or Unix:
   ```
   aws rds modify-db-instance \
   --db-instance-identifier mydbinstance \
   --db-parameter-group-name allow-triggers \
   --apply-immediately
   ```

   For Windows:
   ```
   aws rds modify-db-instance ^
   --db-instance-identifier mydbinstance ^
   --db-parameter-group-name allow-triggers ^
   ```
4. For the changes to take effect, manually reboot the DB instance.

```
aws rds reboot-db-instance --db-instance-identifier mydbinstance
```

## Diagnosing and resolving point-in-time restore failures

### Restoring a DB Instance That Includes Temporary Tables

When attempting a point-in-time restore (PITR) of your MySQL or MariaDB DB instance, you might encounter the following error.

```
Database instance could not be restored because there has been incompatible database activity for restore functionality. Common examples of incompatible activity include using temporary tables, in-memory tables, or using MyISAM tables. In this case, use of Temporary table was detected.
```

PITR relies on both backup snapshots and binary logs (binlogs) from MySQL or MariaDB to restore your DB instance to a particular time. Temporary table information can be unreliable in binlogs and can cause a PITR failure. If you use temporary tables in your MySQL or MariaDB DB instance, you can lower the possibility of a PITR failure. To do so, perform more frequent backups. A PITR failure is most probable in the time between a temporary table's creation and the next backup snapshot.

### Restoring a DB Instance That Includes In-Memory Tables

You might encounter a problem when restoring a database that has in-memory tables. In-memory tables are purged during a restart. As a result, your in-memory tables might be empty after a reboot. We recommend that when you use in-memory tables, you architect your solution to handle empty tables in the event of a restart. If you're using in-memory tables with replicated DB instances, you might need to recreate the read replicas after a restart. This might be necessary if a read replica reboots and can't restore data from an empty in-memory table.

For more information about backups and PITR, see [Working with backups](p. 591) and [Restoring a DB instance to a specified time](p. 660).

### Replication stopped error

When you call the `mysql.rds_skip_repl_error` command, you might receive an error message stating that replication is down or disabled.

This error message appears because replication is stopped and can't be restarted.

If you need to skip a large number of errors, the replication lag can increase beyond the default retention period for binary log files. In this case, you might encounter a fatal error due to binary log files being purged before they have been replayed on the replica. This purge causes replication to stop, and you can no longer call the `mysql.rds_skip_repl_error` command to skip replication errors.

You can mitigate this issue by increasing the number of hours that binary log files are retained on your replication source. After you have increased the binlog retention time, you can restart replication and call the `mysql.rds_skip_repl_error` command as needed.

To set the binlog retention time, use the `mysql.rds_set_configuration` procedure. Specify a configuration parameter of ‘binlog retention hours’ along with the number of hours to retain binlog files.
Read replica create fails or replication breaks with fatal error 1236

After changing default parameter values for a MySQL or MariaDB DB instance, you might encounter one of the following problems:

- You can't create a read replica for the DB instance.
- Replication fails with fatal error 1236.

Some default parameter values for MySQL and MariaDB DB instances help to make sure that the database is ACID compliant and read replicas are crash-safe. They do this by making sure that each commit is fully synchronized by writing the transaction to the binary log before it's committed. Changing these parameters from their default values to improve performance can cause replication to fail when a transaction hasn't been written to the binary log.

To resolve this issue, set the following parameter values:

- `sync_binlog = 1`
- `innodb_support_xa = 1`
- `innodb_flush_log_at_trx_commit = 1`

Can't set backup retention period to 0

There are several reasons why you might need to set the backup retention period to 0. For example, you can disable automatic backups immediately by setting the retention period to 0.

In some cases, you might set the value to 0 and receive a message saying that the retention period must be between 1 and 35. In these cases, check to make sure that you haven't set up a read replica for the instance. Read replicas require backups for managing read replica logs, and therefore you can't set a retention period of 0.
Amazon RDS API reference

In addition to the AWS Management Console and the AWS Command Line Interface (AWS CLI), Amazon RDS also provides an API. You can use the API to automate tasks for managing your DB instances and other objects in Amazon RDS.

- For an alphabetical list of API operations, see Actions.
- For an alphabetical list of data types, see Data types.
- For a list of common query parameters, see Common parameters.
- For descriptions of the error codes, see Common errors.

For more information about the AWS CLI, see AWS Command Line Interface reference for Amazon RDS.

Topics
- Using the Query API (p. 2759)
- Troubleshooting applications on Amazon RDS (p. 2759)

Using the Query API

The following sections briefly discuss the parameters and request authentication used with the Query API.

For general information about how the Query API works, see Query requests in the Amazon EC2 API Reference.

Query parameters

HTTP Query-based requests are HTTP requests that use the HTTP verb GET or POST and a Query parameter named Action.

Each Query request must include some common parameters to handle authentication and selection of an action.

Some operations take lists of parameters. These lists are specified using the param.n notation. Values of n are integers starting from 1.

For information about Amazon RDS Regions and endpoints, go to Amazon Relational Database Service (RDS) in the Regions and Endpoints section of the Amazon Web Services General Reference.

Query request authentication

You can only send Query requests over HTTPS, and you must include a signature in every Query request. You must use either AWS signature version 4 or signature version 2. For more information, see Signature Version 4 signing process and Signature version 2 signing process.

Troubleshooting applications on Amazon RDS

Amazon RDS provides specific and descriptive errors to help you troubleshoot problems while interacting with the Amazon RDS API.
Retrieving errors

Typically, you want your application to check whether a request generated an error before you spend any time processing results. The easiest way to find out if an error occurred is to look for an Error node in the response from the Amazon RDS API.

XPath syntax provides a simple way to search for the presence of an Error node. It also provides a relatively easy way to retrieve the error code and message. The following code snippet uses Perl and the XML::XPath module to determine if an error occurred during a request. If an error occurred, the code prints the first error code and message in the response.

```
use XML::XPath;
  my $xp = XML::XPath->new(xml =>$response);
  if ( $xp->find("//Error") )
    {print "There was an error processing your request:\n", " Error code: ",
      $xp->findvalue("//Error[1]/Code"), "\n", " ",
      $xp->findvalue("//Error[1]/Message"), "\n\n"; }
```

Troubleshooting tips

We recommend the following processes to diagnose and resolve problems with the Amazon RDS API:

- Verify that Amazon RDS is operating normally in the AWS Region that you’re targeting by checking http://status.aws.amazon.com.
- Check the structure of your request.

    Each Amazon RDS operation has a reference page in the Amazon RDS API Reference. Double-check that you are using parameters correctly. For ideas about what might be wrong, look at the sample requests or user scenarios to see if those examples do similar operations.
- Check AWS re:Post.

    Amazon RDS has a development community where you can search for solutions to problems others have experienced along the way. To view the topics, go to AWS re:Post.
## Document history

**Current API version:** 2014-10-31

The following table describes important changes in each release of the *Amazon RDS User Guide* after May 2018. For notification about updates to this documentation, you can subscribe to an RSS feed.

*Note*  
You can filter new Amazon RDS features on the What’s New with Database? page. For Products, choose Amazon RDS. Then search using keywords such as RDS Proxy or Oracle 2023.

</tr>
<tr>
<td>Amazon RDS supports the db.m7g and db.r7g instance classes</td>
<td>You can now use the db.m7g and db.r7g instance classes for RDS for MySQL, RDS for MariaDB, and RDS for PostgreSQL DB instances. For more information, see Supported DB engines for DB instance classes.</td>
<td>April 12, 2023</td>
</tr>
</tbody>
</table>
Update to Amazon RDS Custom service-linked role permissions (p. 2761)
The AmazonRDSCustomServiceRolePolicy now grants additional permissions to allow RDS Custom for SQL Server to use Amazon SQS and create snapshots. For more information, see Updates to AWS managed policies.

Migrate to an RDS for MySQL Multi-AZ DB cluster using a read replica (p. 2761)
You can now use a read replica to migrate an RDS for MySQL Single-AZ deployment or Multi-AZ DB instance deployment to an RDS for MySQL Multi-AZ DB cluster deployment with reduced downtime. For more information, see Migrating to a Multi-AZ DB cluster using a read replica.

Create a DB instance read replica from a Multi-AZ DB cluster (p. 2761)
You can now create a DB instance read replica from a Multi-AZ DB cluster in order to scale beyond the compute capacity of the source cluster. For more information, see Creating a DB instance read replica from a Multi-AZ DB cluster.

Amazon RDS Custom for SQL Server supports Multi-AZ (p. 2761)
You can create a Multi-AZ deployment with RDS Custom for SQL Server. For more information, see Managing a Multi-AZ deployment for RDS Custom for SQL Server.

Update to AWS managed policy permissions (p. 2761)
The AmazonRDSFullAccess and AmazonRDSReadOnlyAccess policies now grants additional permissions to allow the display of Amazon DevOps Guru findings in the RDS console. For more information, see Amazon RDS updates to AWS managed policies.

Amazon RDS supports Oracle APEX version 22.2.v1 (p. 2761)
You can use APEX 22.2.v1 with all supported versions of Oracle Database. For more information, see Oracle Application Express.
<p>| Amazon DevOps Guru available for RDS for PostgreSQL (p. 2761) | RDS for PostgreSQL alerts you to recent anomalies detected by Amazon DevOps Guru. The database details page of the console alerts you to current and anomalies that occurred in the past 24 hours. DevOps Guru publishes proactive insights with recommendations to help address issues in your RDS for PostgreSQL databases before they are predicted to happen. For more information, see How DevOps Guru for RDS works. | March 30, 2023 |
| RDS Custom supports the Amazon EBS gp3 storage volume (p. 2761) | RDS Custom for Oracle and RDS Custom for SQL Server both support the io1, gp2, and gp3 SSD-based EBS volumes. For more information, see General requirements for RDS Custom for Oracle and General requirements for RDS Custom for SQL Server. | March 29, 2023 |
| Update to AWS managed policy permissions (p. 2761) | The AmazonRDSFullAccess and AmazonRDSReadOnlyAccess policies now grants additional permissions to Amazon CloudWatch. For more information, see Amazon RDS updates to AWS managed policies. | March 16, 2023 |
| RDS Proxy is available in the China Regions (p. 2761) | RDS Proxy is now available in the China (Beijing) and China (Ningxia) regions. For more information about RDS Proxy, see Using Amazon RDS Proxy. | March 15, 2023 |
| RDS Proxy is available in the Asia Pacific (Jakarta) Region (p. 2761) | RDS Proxy is now available in the Asia Pacific (Jakarta) Region. For more information about RDS Proxy, see Using Amazon RDS Proxy. | March 8, 2023 |
| Amazon RDS Optimized Writes improves the performance of write transactions for RDS for MariaDB (p. 2761) | You can improve the performance of write transactions for RDS for MariaDB DB instances with Amazon RDS Optimized Writes. For more information, see Improving write performance with Amazon RDS Optimized Writes for MariaDB. | March 7, 2023 |
| <strong>Amazon RDS for PostgreSQL versions 15.2</strong> (p. 2761) | New features in Amazon RDS for PostgreSQL 15.2 include the SQL standard &quot;MERGE&quot; command for conditional SQL queries, performance improvements for both in-memory and disk-based sorting, and support for two-phase commit and row/column filtering for logical replication. | February 27, 2023 |
| <strong>RDS Custom for Oracle is available in the Canada (Central) Region and South America (São Paulo) Regions</strong> (p. 2761) | For a table that shows all supported AWS Regions, see RDS Custom for Oracle. | February 22, 2023 |
| <strong>Amazon RDS supports cross-Region automated backups for RDS for MariaDB and RDS for MySQL</strong> (p. 2761) | You can now replicate DB snapshots and transaction logs between AWS Regions for RDS for MariaDB and RDS for MySQL DB instances. For more information, see Replicating automated backups to another AWS Region. | February 22, 2023 |
| <strong>Amazon RDS for Oracle supports advance notice of automatic minor version upgrades</strong> (p. 2761) | RDS notifies you in advance of the date when a new minor version of the RDS for Oracle engine will become available. RDS begins scheduling automatic minor version upgrades of your RDS for Oracle DB instances on the availability date. For more information, see Before an automatic minor version upgrade is scheduled. | February 21, 2023 |
| <strong>Amazon RDS for SQL Server supports Database Activity Streams</strong> (p. 2761) | You can now monitor a SQL Server DB instance using Database Activity Streams. A SQL Server database instance has the server audit which is managed by Amazon RDS. You can define the policies to record server events in the server audit specification. You can create a database audit specification and define the policies to record database events. The stream of activity is collected and transmitted to Amazon Kinesis. From Kinesis, you can monitor the activity stream for further analysis. For more information, see Monitoring Amazon RDS with Database Activity Streams. | February 15, 2023 |</p>

</tr>
<tr>
<td><strong>Amazon RDS for Oracle supports local instance storage for temporary data (p. 2761)</strong></td>
<td>You can now launch Amazon RDS for Oracle on Amazon EC2 db.r5d and db.m5d instance types with the temporary tablespace and Database Smart Flash Cache (the flash cache) configured to use an instance store. By storing temporary data locally, you can achieve lower read and write latencies when compared to standard storage based on Amazon EBS. For more information, see Storing temporary Oracle data in the instance store.</td>
<td>September 14, 2022</td>
</tr>
</tbody>
</table>
Performance Insights shows the top 25 SQL queries (p. 2761)  
In the Performance Insights dashboard, the Top SQL tab shows the 25 SQL queries that are contributing the most to DB load. For more information, see Overview of the Top SQL tab.  
September 13, 2022

RDS supports MySQL 8.0.30 (p. 2761)  
You can now create Amazon RDS DB instances running MySQL version 8.0.30. For more information, see MySQL on Amazon RDS versions.  
September 9, 2022

Amazon RDS is available in the Middle East (UAE) Region (p. 2761)  
Amazon RDS is now available in the Middle East (UAE) Region. For more information, see Regions and Availability Zones.  
August 30, 2022

Amazon RDS for SQL Server supports SSRS Email subscriptions (p. 2761)  
You can now use the SQL Server Reporting Services (SSRS) Email extension to send reports to users and subscribe to reports on the report server. For more information, see Support for SQL Server Reporting Services in RDS for SQL Server.  
August 26, 2022

RDS for Oracle supports read replica backups (p. 2761)  
You can turn on automatic backups and create manual snapshots of RDS for Oracle replicas. For more information, see Working with RDS for Oracle replica backups.  
August 23, 2022

RDS for Oracle supports Oracle Data Guard switchover (p. 2761)  
A switchover is a role reversal between a primary database and a mounted or open Oracle replica. During a switchover, the original primary database transitions to a standby role, while the original standby database transitions to the primary role. For more information, see Performing an Oracle Data Guard switchover.

RDS Proxy supports RDS for MariaDB (p. 2761)

You can now create an RDS Proxy for an RDS DB instance that runs MariaDB version 10.2, 10.3, 10.4, or 10.5. The MariaDB support is included under the MySQL engine family. For more information about RDS Proxy, see Using Amazon RDS Proxy.

RDS for MariaDB supports the db.r5b DB instance classes (p. 2761)

You can now create RDS for MariaDB DB instances that use the db.r5b DB instance classes. For more information, see Supported DB engines for DB instance classes.

RDS for Oracle supports modifying database activity streams (p. 2761)

If you use RDS for Oracle, you can change the audit policy state of a database activity stream to either locked (default) or unlocked. Instead of stopping an activity stream, you can unlock its policy state, customize your audit policy, and then relock the policy state. For more information, see Modifying a database activity stream.

Performance Insights supports the Asia Pacific (Jakarta) Region (p. 2761)

Formerly, you couldn't use Performance Insights in the Asia Pacific (Jakarta) Region. This restriction has been removed. For more information, see AWS Region support for Performance Insights.

Microsoft SQL Server 2012 has reached its end of support on Amazon RDS (p. 2761)

Microsoft SQL Server 2012 has reached its end of support, coinciding with the Microsoft plan to end extended support for this version on July 12, 2022. Any existing Microsoft SQL Server 2012 instances are to be automatically upgraded to the latest minor version of Microsoft SQL Server 2014 starting on June 1, 2022. For more information, see Microsoft SQL Server 2012 support on Amazon RDS.

RDS supports MariaDB 10.6.8, 10.5.16, 10.4.25, 10.3.35, and 10.2.44 (p. 2761)

You can now create Amazon RDS DB instances running MariaDB versions 10.6.8, 10.5.16, 10.4.25, 10.3.35, and 10.2.44. For more information, see Supported MariaDB versions on Amazon RDS.

<td>February 3, 2022</td>
</tr>
</tbody>
</table>
Performance Insights supports plan capture for Oracle queries (p. 2761)

The Performance Insights console supports a new plan dimension for top SQL. When you slice by plan, you can see which plans your top Oracle queries are using. If a query uses multiple plans, you can compare the plans side by side in the console and determine which plan is most efficient. You can also drill down to see which steps in a plan have the highest cost. For more information, see Analyzing Oracle execution plans using the Performance Insights dashboard.

Performance Insights supports new APIs (p. 2761)

Performance Insights supports the following APIs: GetResourceMetadata, ListAvailableResourceDimensions, and ListAvailableResourceMetrics. For more information, see Retrieving metrics with the Performance Insights API in this manual and the Amazon RDS Performance Insights API Reference.

RDS Proxy supports events (p. 2761)

RDS Proxy now generates events that you can subscribe to and view in CloudWatch Events or configure to send to Amazon EventBridge. For more information, see Working with RDS Proxy events.

Amazon RDS for SQL Server supports SSAS Multidimensional mode (p. 2761)

RDS for SQL Server supports running SQL Server Analysis Services (SSAS) in Tabular or Multidimensional mode. For more information, see Support for SQL Server Analysis Services in RDS for SQL Server.

RDS Proxy available in additional AWS Regions (p. 2761)

RDS Proxy is now available in the following Regions: Africa (Cape Town), Asia Pacific (Hong Kong), Asia Pacific (Osaka), Europe (Milan), Europe (Paris), Europe (Stockholm), Middle East (Bahrain), and South America (São Paulo). For more information about RDS Proxy, see Using Amazon RDS Proxy.

</tbody>
</table>
Amazon RDS plans to deprecate Oracle Database 18c (p. 2761)

Oracle Database 18c (18.0.0.0) is on a deprecation path. Oracle Corporation will no longer provide patches for Oracle Database 18c after the end-of-support date. On July 1, 2021, Amazon RDS plans to begin automatically upgrading Oracle Database 18c instances to Oracle Database 19c. Before the automatic upgrades begin, we highly recommend that you manually upgrade your existing Oracle Database 18c instances to Oracle Database 19c. For more information, see Preparing for the automatic upgrade of Oracle Database 18c.

March 11, 2021

Amazon RDS has ended support for Oracle Database 11g (p. 2761)

You can only create DB instances for Oracle Database 12c Release 1 (12.1.0.2) and later. If you have Oracle Database 11g snapshots, upgrade them to a later release. For more information, see Upgrading an Oracle DB snapshot.

March 11, 2021

Amazon RDS supports continuous backups of DB instances in AWS Backup (p. 2761)

You can now create automated backups in AWS Backup and restore DB instances from these backups to a specified time. For more information, see Using AWS Backup to manage automated backups.

March 10, 2021

Amazon RDS supports Oracle Management Agent (OMA) version 13.4 (p. 2761)

You can use Oracle Management Agent (OMA) version 13.4 with Oracle Enterprise Manager (OEM) Cloud Control 13c Release 4 Update 9. Amazon RDS for Oracle installs OMA, which then communicates with your Oracle Management Service (OMS) to provide monitoring information. If you run OMS 13.4, you can manage databases by installing OMA 13.4. For more information, see Oracle Management Agent for Enterprise Manager Cloud Control.

<td>June 10, 2019</td>
</tr>
</tbody>
</table>
| **Amazon RDS adds support**  
| **native restores of SQL Server databases up to 16 TB (p. 2761)** | You can now do native restores of up to 16 TB from SQL Server to Amazon RDS. For more information, see [Amazon RDS for SQL Server: Limitations and recommendations](#). | June 4, 2019 |
| **Amazon RDS adds support**  
<p>| <strong>for Microsoft SQL Server audit (p. 2761)</strong> | Using Amazon RDS for Microsoft SQL Server, you can audit server and database level events using SQL Server Audit, and view the results on your DB instance or send the audit log files directly to Amazon S3. For more information, see <a href="#">SQL Server Audit</a>. | May 23, 2019 |
| <strong>Improvements to Amazon RDS recommendations (p. 2761)</strong> | Amazon RDS has improved its automated recommendations for database resources. For example, Amazon RDS now provides recommendations for database parameters. For more information, see <a href="#">Using Amazon RDS recommendations</a>. | May 22, 2019 |
| <strong>Support for more databases per DB instance for Amazon RDS for SQL Server (p. 2761)</strong> | You can create up to 30 databases on each of your DB instances running Microsoft SQL Server. For more information, see <a href="#">Limits for Microsoft SQL Server DB instances</a>. | May 21, 2019 |
| <strong>Support for 64 TiB and 80k IOPS of storage for Amazon RDS for MariaDB, MySQL and PostgreSQL (p. 2761)</strong> | You can now create Amazon RDS DB instances for MariaDB, MySQL and PostgreSQL with up to 64 TiB of storage and up to 80,000 provisioned IOPS. For more information, see <a href="#">DB instance storage</a>. | May 20, 2019 |
| <strong>Amazon RDS for MySQL supports upgrade prechecks (p. 2761)</strong> | When you upgrade a DB instance from MySQL 5.7 to MySQL 8.0, Amazon RDS performs prechecks for incompatibilities. For more information, see <a href="#">Prechecks for upgrades from MySQL 5.7 to 8.0</a>. | May 17, 2019 |
| <strong>Support for the MySQL password validation plugin (p. 2761)</strong> | You can now use the MySQL validate_password plugin for improved security of Amazon RDS for MySQL DB instances. For more information, see <a href="#">Using the Password Validation Plugin</a>. | May 16, 2019 |</p>

<td>July 10, 2018</td>
</tr>
<tr>
<td>Amazon RDS for Oracle supports publishing logs to Amazon CloudWatch Logs (p. 2761)</td>
<td>Amazon RDS for Oracle now supports publishing alert, audit, trace, and listener log data to a log group in CloudWatch Logs. For more information, see <a href="#">Publishing Oracle logs to Amazon CloudWatch Logs</a>.</td>
<td>July 9, 2018</td>
</tr>
</tbody>
</table>
You can now create Amazon RDS DB instances running MariaDB versions 10.2.15, 10.1.34, and 10.0.35. For more information, see MariaDB on Amazon RDS versions.

Aurora PostgreSQL 1.2 is now available and is compatible with PostgreSQL 9.6.8. For more information, see Version 1.2.

RDS read replicas in Amazon RDS PostgreSQL now support multiple Availability Zones. For more information, see Working with PostgreSQL read replicas.

Performance Insights is generally available for Aurora PostgreSQL, with support for extended retention of performance data. For more information, see Using Amazon RDS performance insights.

Aurora PostgreSQL is now available in the western United States (Northern California) region. For more information, see Availability for Amazon Aurora PostgreSQL.

Amazon RDS for Oracle supports configuring the number of CPU cores and the number of threads for each core for the processor of a DB instance class. For more information, see Configuring the processor of the DB instance class.

Earlier updates

<tr>
<td>Aurora MySQL supports encrypted migration and replication from external MySQL</td>
<td>Aurora MySQL now supports encrypted migration and replication from an external MySQL database. For more information, see Migrating data from an external MySQL database to an Amazon Aurora MySQL DB cluster and Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster.</td>
<td>April 25, 2018</td>
</tr>
<tr>
<td>Aurora PostgreSQL-Compatible Edition support for the Copy-on-Write protocol.</td>
<td>You can now clone databases in an Aurora PostgreSQL database cluster. For more information see, Cloning databases in an Aurora DB cluster.</td>
<td>April 10, 2018</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------</td>
</tr>
<tr>
<td>MariaDB 10.2.12, 10.1.31, and 10.0.34</td>
<td>You can now create Amazon RDS DB instances running MariaDB versions 10.2.12, 10.1.31, and 10.0.34. For more information, see MariaDB on Amazon RDS versions (p. 1281).</td>
<td>March 21, 2018</td>
</tr>
<tr>
<td>Aurora PostgreSQL Support for new regions</td>
<td>Aurora PostgreSQL is now available in the EU (London) and Asia Pacific (Singapore) regions. For more information, see Availability for Amazon Aurora PostgreSQL.</td>
<td>March 13, 2018</td>
</tr>
<tr>
<td>MySQL 5.7.21, 5.6.39, and 5.5.59</td>
<td>You can now create Amazon RDS DB instances running MySQL versions 5.7.21, 5.6.39, and 5.5.59. For more information, see MySQL on Amazon RDS versions (p. 1645).</td>
<td>March 9, 2018</td>
</tr>
<tr>
<td>Amazon RDS for Oracle now supports Oracle REST Data Services</td>
<td>Amazon RDS for Oracle supports Oracle REST Data Services as part of the APEX option. For more information, see Oracle Application Express (APEX) (p. 2025).</td>
<td>March 9, 2018</td>
</tr>
<tr>
<td>Amazon Aurora MySQL-Compatable Edition available in new AWS Region</td>
<td>Aurora MySQL is now available in the Asia Pacific (Singapore) region. For the complete list of AWS Regions for Aurora MySQL, see Availability for Amazon Aurora MySQL.</td>
<td>March 6, 2018</td>
</tr>
<tr>
<td>Amazon RDS DB instances running Microsoft SQL Server support change data capture (CDC)</td>
<td>DB instances running Amazon RDS for Microsoft SQL Server now support change data capture (CDC). For more information, see Change data capture support for Microsoft SQL Server DB instances (p. 1383).</td>
<td>February 6, 2018</td>
</tr>
<tr>
<td>Aurora MySQL supports a new major version</td>
<td>You can now create Aurora MySQL DB clusters running MySQL version 5.7. For more information, see Amazon Aurora MySQL database engine updates 2018-02-06.</td>
<td>February 6, 2018</td>
</tr>
<tr>
<td>Publish MySQL and MariaDB logs to Amazon CloudWatch Logs</td>
<td>You can now publish MySQL and MariaDB log data to CloudWatch Logs. For more information, see Publishing MySQL logs to Amazon CloudWatch Logs (p. 918) and Publishing MariaDB logs to Amazon CloudWatch Logs (p. 904).</td>
<td>January 17, 2018</td>
</tr>
<tr>
<td>Multi-AZ support for read replicas</td>
<td>You can now create a read replica as a Multi-AZ DB instance. Amazon RDS creates a standby of your replica in another Availability Zone for failover support for the replica. Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance. For more information, see Working with DB instance read replicas (p. 438).</td>
<td>January 11, 2018</td>
</tr>
<tr>
<td>Amazon RDS for MariaDB supports a new major version</td>
<td>You can now create Amazon RDS DB instances running MariaDB version 10.2. For more information, see MariaDB 10.2 support on Amazon RDS.</td>
<td>January 3, 2018</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>

<td>December 22, 2017</td>
</tr>
<tr>
<td>Aurora PostgreSQL supports new instance types</td>
<td>Aurora PostgreSQL now supports new instance types. For the complete list of instance types, see <a href="#">Choosing the DB instance class</a>.</td>
<td>December 20, 2017</td>
</tr>
<tr>
<td>Amazon Aurora MySQL-Compatible Edition available in new AWS Region</td>
<td>Aurora MySQL is now available in the EU (Paris) region. For the complete list of AWS Regions for Aurora MySQL, see <a href="#">Availability for Amazon Aurora MySQL</a>.</td>
<td>December 18, 2017</td>
</tr>
<tr>
<td>Aurora MySQL supports hash joins</td>
<td>This feature can improve query performance when you need to join a large amount of data by using an equijoin. For more information, see <a href="#">Working with hash joins in Aurora MySQL</a>.</td>
<td>December 11, 2017</td>
</tr>
<tr>
<td>Aurora MySQL supports native functions to invoke AWS Lambda functions</td>
<td>You can call the native functions <code>lambda_sync</code> and <code>lambda_async</code> when you use Aurora MySQL. For more information, see <a href="#">Invoking a Lambda function from an Amazon Aurora MySQL DB cluster</a>.</td>
<td>December 11, 2017</td>
</tr>
<tr>
<td>Added Aurora PostgreSQL HIPAA eligibility</td>
<td>Aurora PostgreSQL now supports building HIPAA compliant applications. For more information, see <a href="#">Working with Amazon Aurora PostgreSQL</a>.</td>
<td>December 6, 2017</td>
</tr>
<tr>
<td>Additional AWS Regions available for Amazon Aurora with PostgreSQL compatibility</td>
<td>Amazon Aurora with PostgreSQL compatibility is now available in four new AWS Regions. For more information, see <a href="#">Availability for Amazon Aurora PostgreSQL</a>.</td>
<td>November 22, 2017</td>
</tr>
<tr>
<td>Modify storage for Amazon RDS DB instances running Microsoft SQL Server</td>
<td>You can now modify the storage of your Amazon RDS DB instances running SQL Server. For more information, see <a href="#">Modifying an Amazon RDS DB instance</a> (p. 401).</td>
<td>November 21, 2017</td>
</tr>
<tr>
<td>Amazon RDS supports 16 TiB storage for Linux-based engines</td>
<td>You can now create MySQL, MariaDB, PostgreSQL, and Oracle RDS DB instances with up to 16 TiB of storage. For more information, see <a href="#">Amazon RDS DB instance storage</a> (p. 101).</td>
<td>November 21, 2017</td>
</tr>
<tr>
<td>Amazon RDS supports fast scale up of storage</td>
<td>You can now add storage to MySQL, MariaDB, PostgreSQL, and Oracle RDS DB instances in a few minutes. For more information, see <a href="#">Amazon RDS DB instance storage</a> (p. 101).</td>
<td>November 21, 2017</td>
</tr>
<tr>
<td>Amazon RDS supports MariaDB versions 10.1.26 and 10.0.32</td>
<td>You can now create Amazon RDS DB instances running MariaDB versions 10.1.26 and 10.0.32. For more information, see <a href="#">MariaDB on Amazon RDS versions</a> (p. 1281).</td>
<td>November 20, 2017</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>--------------</td>

<tr>
<td>Amazon RDS for Microsoft SQL Server now supports new DB instance classes</td>
<td>You can now create Amazon RDS DB instances running SQL Server that use the db.r4 and db.m4.16xlarge DB instance classes. For more information, see [DB instance class support for Microsoft SQL Server](p. 1374).</td>
<td>November 20, 2017</td>
</tr>
<tr>
<td>Amazon RDS for MySQL and MariaDB now supports new DB instance classes</td>
<td>You can now create Amazon RDS DB instances running MySQL and MariaDB that use the db.r4, db.m4.16xlarge, db.t2.xlarge, and db.t2.2xlarge DB instance classes. For more information, see [DB instance classes](p. 11).</td>
<td>November 20, 2017</td>
</tr>
<tr>
<td>SQL Server 2017</td>
<td>You can now create Amazon RDS DB instances running Microsoft SQL Server 2017. You can also create DB instances running SQL Server 2016 SP1 CU5. For more information, see [Amazon RDS for Microsoft SQL Server](p. 1370).</td>
<td>November 17, 2017</td>
</tr>
<tr>
<td>Restore MySQL backups from Amazon S3</td>
<td>You can now create a backup of your on-premises database, store it on Amazon S3, and then restore the backup file onto a new Amazon RDS DB instance running MySQL. For more information, see [Restoring a backup into a MySQL DB instance](p. 1696).</td>
<td>November 17, 2017</td>
</tr>
<tr>
<td>Auto Scaling with Aurora Replicas</td>
<td>Amazon Aurora MySQL now supports Aurora Auto Scaling. Aurora Auto Scaling dynamically adjusts the number of Aurora Replicas based on increases or decreases in connectivity or workload. For more information, see [Using Amazon Aurora Auto Scaling with Aurora replicas](p. 2055).</td>
<td>November 17, 2017</td>
</tr>
<tr>
<td>Oracle default edition support</td>
<td>Amazon RDS for Oracle DB instances now supports setting the default edition for the DB instance. For more information, see [Setting the default edition for a DB instance](p. 1895).</td>
<td>November 3, 2017</td>
</tr>
<tr>
<td>Oracle DB instance file validation</td>
<td>Amazon RDS for Oracle DB instances now supports validating DB instance files with the Oracle Recovery Manager (RMAN) logical validation utility. For more information, see [Validating DB instance files](p. 1916).</td>
<td>November 3, 2017</td>
</tr>
<tr>
<td>Management Agent for OEM 13c</td>
<td>Amazon RDS for Oracle DB instances now support the Management Agent for Oracle Enterprise Manager (OEM) Cloud Control 13c. For more information, see [Oracle Management Agent for Enterprise Manager Cloud Control](p. 2055).</td>
<td>November 1, 2017</td>
</tr>
<tr>
<td>Storage reconfiguration for Microsoft SQL Server snapshots</td>
<td>You can now reconfigure the storage when you restore a snapshot to an Amazon RDS DB instance running Microsoft SQL Server. For more information, see [Restoring from a DB snapshot](p. 615).</td>
<td>October 26, 2017</td>
</tr>
<tr>
<td>Asynchronous key prefetch for Aurora MySQL-Compatible Edition</td>
<td>Asynchronous key prefetch (AKP) improves the performance of noncached index joins, by prefetching keys in memory ahead of when they are needed. For more information, see [Working with asynchronous key prefetch in Amazon Aurora](p. 2055).</td>
<td>October 26, 2017</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>--------------</td>
</tr>
<tr>
<td>MySQL 5.7.19, 5.6.37, and 5.5.57</td>
<td>You can now create Amazon RDS DB instances running MySQL versions 5.7.19, 5.6.37, and 5.5.57. For more information, see <a href="#">MySQL on Amazon RDS versions</a> (p. 1643).</td>
<td>October 25, 2017</td>
</tr>
<tr>
<td>General availability of Amazon Aurora with PostgreSQL compatibility</td>
<td>Amazon Aurora with PostgreSQL compatibility makes it simple and cost-effective to set up, operate, and scale your new and existing PostgreSQL deployments, thus freeing you to focus on your business and applications. For more information, see <a href="#">Working with Amazon Aurora PostgreSQL</a>.</td>
<td>October 24, 2017</td>
</tr>
<tr>
<td>Amazon RDS for Oracle DB instances support new DB instance classes</td>
<td>Amazon RDS for Oracle DB instances now support memory optimized next generation (db.r4) instance classes. Amazon RDS for Oracle DB instances also now support the following new current generation instance classes: db.m4.16xlarge, db.t2.xlarge, and db.t2.2xlarge. For more information, see <a href="#">DB instance classes</a> (p. 11) and <a href="#">RDS for Oracle instance classes</a> (p. 1812).</td>
<td>October 23, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Your new and existing Reserved Instances can now cover multiple sizes in the same DB instance class. Size-flexible reserved instances are available for DB instances with the same AWS Region, database engine, and instance family, and across AZ configuration. Size-flexible reserved instances are available for the following database engines: Amazon Aurora, MariaDB, MySQL, Oracle (Bring Your Own License), PostgreSQL. For more information, see <a href="#">Size-flexible reserved DB instances</a> (p. 166).</td>
<td>October 11, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use the Oracle SQLT option to tune a SQL statement for optimal performance. For more information, see <a href="#">Oracle SQLT</a> (p. 2094).</td>
<td>September 22, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>If you have existing manual DB snapshots of your Amazon RDS for Oracle DB instances, you can now upgrade them to a later version of the Oracle database engine. For more information, see <a href="#">Upgrading an Oracle DB snapshot</a> (p. 2128).</td>
<td>September 20, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use Oracle Spatial to store, retrieve, update, and query spatial data in your Amazon RDS DB instances running Oracle. For more information, see <a href="#">Oracle Spatial</a> (p. 2091).</td>
<td>September 15, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use Oracle Locator to support internet and wireless service-based applications and partner-based GIS solutions with your Amazon RDS DB instances running Oracle. For more information, see <a href="#">Oracle Locator</a> (p. 2068).</td>
<td>September 15, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use Oracle Multimedia to store, manage, and retrieve images, audio, video, and other heterogeneous media data in your Amazon RDS DB instances running Oracle. For more information, see <a href="#">Oracle Multimedia</a> (p. 2071).</td>
<td>September 15, 2017</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now export audit logs from your Amazon Aurora MySQL DB clusters to Amazon CloudWatch Logs. For more information, see <a href="#">Publishing Aurora MySQL logs to Amazon CloudWatch Logs</a>.</td>
<td>September 14, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports multiple versions of Oracle Application Express (APEX) for your DB instances running Oracle. For more information, see <a href="#">Oracle Application Express (APEX)</a> (p. 2025).</td>
<td>September 13, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use Amazon Aurora to migrate an unencrypted or encrypted DB snapshot or MySQL DB instance to an encrypted Aurora MySQL DB cluster. For more information, see <a href="#">Migrating an RDS for MySQL snapshot to Aurora</a> and <a href="#">Migrating data from a MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica</a>.</td>
<td>September 5, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can use Amazon RDS for Microsoft SQL Server databases to build HIPAA-compliant applications. For more information, see <a href="#">Compliance program support for Microsoft SQL Server DB instances</a> (p. 1377).</td>
<td>August 31, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use Amazon RDS for MariaDB databases to build HIPAA-compliant applications. For more information, see <a href="#">Amazon RDS for MariaDB</a> (p. 1271).</td>
<td>August 31, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now create Amazon RDS DB instances running Microsoft SQL Server with allocated storage up to 16 TiB, and Provisioned IOPS to storage ranges of 1:1–50:1. For more information, see <a href="#">Amazon RDS DB instance storage</a> (p. 101).</td>
<td>August 22, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use Multi-AZ deployments for DB instances running Microsoft SQL Server in the EU (Frankfurt) region. For more information, see <a href="#">Multi-AZ deployments for Amazon RDS for Microsoft SQL Server</a> (p. 1466).</td>
<td>August 3, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now create Amazon RDS DB instances running MariaDB versions 10.1.23 and 10.0.31. For more information, see <a href="#">MariaDB on Amazon RDS versions</a> (p. 1281).</td>
<td>July 17, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports Microsoft SQL Server Enterprise Edition with the License Included model in all AWS Regions. For more information, see <a href="#">Licensing Microsoft SQL Server on Amazon RDS</a> (p. 1395).</td>
<td>July 13, 2017</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS for Oracle now supports Linux kernel huge pages for increased database scalability. The use of huge pages results in smaller page tables and less CPU time spent on memory management, increasing the performance of large database instances. You can use huge pages with your Amazon RDS DB instances running all editions of Oracle versions 12.1.0.2 and 11.2.0.4. For more information, see [Turning on Huge Pages for an RDS for Oracle instance](p. 1958).</td>
<td>July 7, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support encryption at rest (EAR) for db.t2.small and db.t2.medium DB instance classes for all non-Aurora DB engines. For more information, see [Availability of Amazon RDS encryption](p. 2605).</td>
<td>June 27, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Amazon Aurora in the Europe (Frankfurt) region. For more information, see [Availability for Amazon Aurora MySQL](p. 2605).</td>
<td>June 16, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now specify an option group when you copy a DB snapshot across AWS regions. For more information, see [Option group considerations](p. 624).</td>
<td>June 12, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now copy DB snapshots created from specialized DB instances across AWS regions. You can copy snapshots from DB instances that use Oracle TDE, Microsoft SQL Server TDE, and Microsoft SQL Server Multi-AZ with Mirroring. For more information, see [Copying a DB snapshot](p. 625).</td>
<td>June 12, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon Aurora now allows you to run an ALTER TABLE <code>tbl_name</code> ADD COLUMN <code>col_name</code> <code>column_definition</code> operation nearly instantaneously. The operation completes without requiring the table to be copied and without materially impacting other DML statements. For more information, see [Altering tables in Amazon Aurora using fast DDL](p. 625).</td>
<td>June 12, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports Microsoft SQL Server 2016 SP1 CU2. For more information, see [Amazon RDS for Microsoft SQL Server](p. 1370).</td>
<td>June 7, 2017</td>
</tr>
<tr>
<td>Preview</td>
<td>Public preview of Amazon Aurora with PostgreSQL Compatibility. For more information, see [Working with Amazon Aurora PostgreSQL](p. 625).</td>
<td>April 19, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>We have added a new monitoring command, SHOW VOLUME STATUS, to display the number of nodes and disks in a volume. For more information, see [Displaying volume status for an Aurora DB cluster](p. 625).</td>
<td>April 5, 2017</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use your own custom logic in your custom password verification functions for Oracle on Amazon RDS. For more information, see Creating custom functions to verify passwords (p. T878).</td>
<td>March 21, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now access your online and archived redo log files on your Oracle DB instances on Amazon RDS. For more information, see Accessing online and archived redo logs (p. 1910).</td>
<td>March 21, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now copy both encrypted and unencrypted DB cluster snapshots between accounts in the same region. For more information, see Copying a DB cluster snapshot across accounts.</td>
<td>March 7, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now share encrypted DB cluster snapshots between accounts in the same region. For more information, see Sharing a DB cluster snapshot.</td>
<td>March 7, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now replicate encrypted Amazon Aurora MySQL DB clusters to create cross-region Aurora Replicas. For more information, see Replicating Aurora MySQL DB clusters across AWS Regions.</td>
<td>March 7, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now require that all connections to your DB instance running Microsoft SQL Server use Secure Sockets Layer (SSL). For more information, see Using SSL with a Microsoft SQL Server DB instance (p. 1472).</td>
<td>February 27, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now set your local time zone to one of 15 additional time zones. For more information, see Supported time zones (p. 1387).</td>
<td>February 27, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use the Amazon RDS procedure msdb.dbo.rds_shrink_tempdbfile to shrink the tempdb database on your DB instances running Microsoft SQL Server. For more information, see Shrinking the tempdb database (p. 1619).</td>
<td>February 17, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now compress your backup file when you export your Enterprise and Standard Edition Microsoft SQL Server database from an Amazon RDS DB instance to Amazon S3. For more information, see Compressing backup files (p. 1451).</td>
<td>February 17, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports custom DNS servers to resolve DNS names used in outbound network access on your DB instances running Oracle. For more information, see Setting up a custom DNS server (p. 1881).</td>
<td>January 26, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports creating an encrypted read replica in another region. For more information, see Creating a read replica in a different AWS Region (p. 452) and CreateDBInstanceReadReplica.</td>
<td>January 23, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports upgrading a MySQL DB snapshot from MySQL 5.1 to MySQL 5.5.</td>
<td>January 20, 2017</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports copying an encrypted DB snapshot to another region for the MariaDB, MySQL, Oracle, PostgreSQL, and Microsoft SQL Server database engines. For more information, see Copying a DB snapshot (p. 625) and CopyDBSnapshot.</td>
<td>December 20, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon Aurora MySQL now supports spatial indexing. Spatial indexing improves query performance on large datasets for queries that use spatial data. For more information, see Amazon Aurora MySQL and spatial data.</td>
<td>December 14, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports outbound network access on your DB instances running Oracle. You can use utl_http, utl_tcp, and utl_smtp to connect from your DB instance to the network. For more information, see Configuring UTL_HTTP access using certificates and an Oracle wallet (p. 1846).</td>
<td>December 5, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS has retired support for MySQL version 5.1. However, you can restore existing MySQL 5.1 snapshots to a MySQL 5.5 instance. For more information, see Supported storage engines for RDS for MySQL (p. 1640).</td>
<td>November 15, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports Microsoft SQL Server 2016 RTM CU2. For more information, see Amazon RDS for Microsoft SQL Server (p. 1370).</td>
<td>November 4, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports major version upgrades for DB instances running Oracle. You can now upgrade your Oracle DB instances from 11g to 12c. For more information, see Upgrading the RDS for Oracle DB engine (p. 2119).</td>
<td>November 2, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now create DB instances running Microsoft SQL Server 2014 Enterprise Edition. Amazon RDS now supports SQL Server 2014 SP2 for all editions and all regions. For more information, see Amazon RDS for Microsoft SQL Server (p. 1370).</td>
<td>October 25, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon Aurora MySQL now integrates with other AWS services: You can load text or XML data into a table from an Amazon S3 bucket, or invoke an AWS Lambda function from database code. For more information, see Integrating Aurora MySQL with other AWS services.</td>
<td>October 18, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now access the tempdb database on your Amazon RDS DB instances running Microsoft SQL Server. You can access the tempdb database by using Transact-SQL through Microsoft SQL Server Management Studio (SSMS), or any other standard SQL client application. For more information, see Accessing the tempdb database on Microsoft SQL Server DB instances on Amazon RDS (p. 1619).</td>
<td>September 29, 2016</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------</td>

<tr>
<td>New feature</td>
<td>You can now use the UTL_MAIL package with your Amazon RDS DB instances running Oracle. For more information, see Oracle UTL_MAIL (p. 2115).</td>
<td>September 20, 2016</td>
</tr>
<tr>
<td>New features</td>
<td>You can now set the time zone of your new Microsoft SQL Server DB instances to a local time zone, to match the time zone of your applications. For more information, see Local time zone for Microsoft SQL Server DB instances (p. 1387).</td>
<td>September 19, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use the Oracle Label Security option to control access to individual table rows in your Amazon RDS DB instances running Oracle Database 12c. With Oracle Label Security, you can enforce regulatory compliance with a policy-based administration model, and ensure that an access to sensitive data is restricted to only users with the appropriate clearance level. For more information, see Oracle Label Security (p. 2065).</td>
<td>September 8, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now connect to an Amazon Aurora DB cluster using the reader endpoint, which load-balances connections across the Aurora Replicas that are available in the DB cluster. As clients request new connections to the reader endpoint, Aurora distributes the connection requests among the Aurora Replicas in the DB cluster. This functionality can help balance your read workload across multiple Aurora Replicas in your DB cluster. For more information, see Amazon Aurora endpoints.</td>
<td>September 8, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now support the Oracle Enterprise Manager Cloud Control on your Amazon RDS DB instances running Oracle. You can enable the Management Agent on your DB instances, and share data with your Oracle Management Service (OMS). For more information, see Oracle Management Agent for Enterprise Manager Cloud Control (p. 2055).</td>
<td>September 1, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>This release adds support to get an ARN for a resource. For more information, see Getting an existing ARN (p. 475).</td>
<td>August 23, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now assign up to 50 tags for each Amazon RDS resource, for managing your resources and tracking costs. For more information, see Tagging Amazon RDS resources (p. 461).</td>
<td>August 19, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports the License Included model for Oracle Standard Edition Two. For more information, see Creating an Amazon RDS DB instance (p. 300).</td>
<td>August 5, 2016</td>
</tr>
<tr>
<td></td>
<td>You can now change the license model of your Amazon RDS DB instances running Microsoft SQL Server and Oracle. For more information, see Licensing Microsoft SQL Server on Amazon RDS (p. 1395) and RDS for Oracle licensing options (p. 1809).</td>
<td></td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>----------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports native backup and restore for Microsoft SQL Server databases using full backup files (.bak files). You can now easily migrate SQL Server databases to Amazon RDS, and import and export databases in a single, easily-portable file, using Amazon S3 for storage, and AWS KMS for encryption. For more information, see [Importing and exporting SQL Server databases using native backup and restore](p. 1435).</td>
<td>July 27, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now copy the source files from a MySQL database to an Amazon Simple Storage Service (Amazon S3) bucket, and then restore an Amazon Aurora DB cluster from those files. This option can be considerably faster than migrating data using mysqldump. For more information, see [Migrating data from an external MySQL database to an Aurora MySQL DB cluster](p. 315).</td>
<td>July 20, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now restore an unencrypted Amazon Aurora DB cluster snapshot to create an encrypted Amazon Aurora DB cluster by including an AWS Key Management Service (AWS KMS) encryption key during the restore operation. For more information, see [Encrypting Amazon RDS resources](p. 2152).</td>
<td>June 30, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can use the Oracle Repository Creation Utility (RCU) to create a repository on Amazon RDS for Oracle. For more information, see [Using the Oracle Repository Creation Utility on RDS for Oracle](p. 2152).</td>
<td>June 17, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Adds support for PostgreSQL cross-region read replicas. For more information, see [Creating a read replica in a different AWS Region](p. 452).</td>
<td>June 16, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use the AWS Management Console to easily add Multi-AZ with Mirroring to a Microsoft SQL Server DB instance. For more information, see [Adding Multi-AZ to a Microsoft SQL Server DB instance](p. 1467).</td>
<td>June 9, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use Multi-AZ Deployments Using SQL Server Mirroring in the following additional regions: Asia Pacific (Sydney), Asia Pacific (Tokyo), and South America (São Paulo). For more information, see [Multi-AZ deployments for Amazon RDS for Microsoft SQL Server](p. 1466).</td>
<td>June 9, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support MariaDB version 10.1. For more information, see [Amazon RDS for MariaDB](p. 1271).</td>
<td>June 1, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Amazon Aurora cross-region DB clusters that are read replicas. For more information, see [Replicating Aurora MySQL DB clusters across AWS Regions](p. 401).</td>
<td>June 1, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Enhanced Monitoring is now available for Oracle DB instances. For more information, see [Monitoring OS metrics with Enhanced Monitoring](p. 797) and [Modifying an Amazon RDS DB instance](p. 401).</td>
<td>May 27, 2016</td>
</tr>
</tbody>
</table>
## Earlier updates

<table>
<thead>
<tr>
<th>Change</th>
<th>Description</th>
<th>Date changed</th>
</tr>
</thead>
<tbody>
<tr>
<td>New feature</td>
<td>Updated to support manual snapshot sharing for Amazon Aurora DB cluster snapshots. For more information, see <a href="#">Sharing a DB cluster snapshot</a>.</td>
<td>May 18, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use the MariaDB Audit Plugin to log database activity on MariaDB and MySQL database instances. For more information, see <a href="#">Options for MariaDB database engine (p. 1350)</a> and <a href="#">Options for MySQL DB instances (p. 1748)</a>.</td>
<td>April 27, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>In-place, major version upgrades are now available for upgrading from MySQL version 5.6 to version 5.7. For more information, see <a href="#">Upgrading the MySQL DB engine (p. 1680)</a>.</td>
<td>April 26, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Enhanced Monitoring is now available for Microsoft SQL Server DB instances. For more information, see <a href="#">Monitoring OS metrics with Enhanced Monitoring (p. 797)</a>.</td>
<td>April 22, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to provide an Amazon Aurora Clusters view in the Amazon RDS console. For more information, see <a href="#">Viewing an Aurora DB cluster</a>.</td>
<td>April 1, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support SQL Server Multi-AZ with mirroring in the Asia Pacific (Seoul) region. For more information, see <a href="#">Multi-AZ deployments for Amazon RDS for Microsoft SQL Server (p. 1466)</a>.</td>
<td>March 31, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Amazon Aurora Multi-AZ with mirroring in the Asia Pacific (Seoul) region. For more information, see <a href="#">Availability for Amazon Aurora MySQL</a>.</td>
<td>March 31, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>PostgreSQL DB instances have the ability to require connections to use SSL. For more information, see <a href="#">Using SSL with a PostgreSQL DB instance (p. 2191)</a>.</td>
<td>March 25, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Enhanced Monitoring is now available for PostgreSQL DB instances. For more information, see <a href="#">Monitoring OS metrics with Enhanced Monitoring (p. 797)</a>.</td>
<td>March 25, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Microsoft SQL Server DB instances can now use Windows Authentication for user authentication. For more information, see <a href="#">Working with AWS Managed Active Directory with RDS for SQL Server (p. 1417)</a>.</td>
<td>March 23, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Enhanced Monitoring is now available in the Asia Pacific (Seoul) region. For more information, see <a href="#">Monitoring OS metrics with Enhanced Monitoring (p. 797)</a>.</td>
<td>March 16, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now customize the order in which Aurora Replicas are promoted to primary instance during a failover. For more information, see <a href="#">Fault tolerance for an Aurora DB cluster</a>.</td>
<td>March 14, 2016</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------------</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support encryption when migrating to an Aurora DB cluster. For more information, see <a href="#">Migrating data to an Aurora DB cluster</a>.</td>
<td>March 2, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support local time zone for Aurora DB clusters. For more information, see <a href="#">Local time zone for Aurora DB clusters</a>.</td>
<td>March 1, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to add support for MySQL version 5.7 for current generation Amazon RDS DB instance classes.</td>
<td>February 22, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support <code>db.r3</code> and <code>db.t2</code> DB instance classes in the AWS GovCloud (US-West) region.</td>
<td>February 11, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support encrypting copies of DB snapshots and sharing encrypted DB snapshots. For more information, see [Copying a DB snapshot](p. 619) and [Sharing a DB snapshot](p. 633).</td>
<td>February 11, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Amazon Aurora in the Asia Pacific (Sydney) region. For more information, see <a href="#">Availability for Amazon Aurora MySQL</a>.</td>
<td>February 11, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support SSL for Oracle DB instances. For more information, see [Using SSL with an RDS for Oracle DB instance](p. 1832).</td>
<td>February 9, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support local time zone for MySQL and MariaDB DB instances. For more information, see [Local time zone for MySQL DB instances](p. 1765) and [Local time zone for MariaDB DB instances](p. 1365).</td>
<td>December 21, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Enhanced Monitoring of OS metrics for MySQL and MariaDB instances and Aurora DB clusters. For more information, see [Viewing metrics in the Amazon RDS console](p. 696).</td>
<td>December 18, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support <code>db.t2</code>, <code>db.r3</code>, and <code>db.m4</code> DB instance classes for MySQL version 5.5. For more information, see [DB instance classes](p. 11).</td>
<td>December 4, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support modifying the database port for an existing DB instance.</td>
<td>December 3, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support major version upgrades of the database engine for PostgreSQL instances. For more information, see [Upgrading the PostgreSQL DB engine for Amazon RDS](p. 2214).</td>
<td>November 19, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support modifying the public accessibility of an existing DB instance. Updated to support <code>db.m4</code> standard DB instance classes.</td>
<td>November 11, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support manual DB snapshot sharing. For more information, see [Sharing a DB snapshot](p. 633).</td>
<td>October 28, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Microsoft SQL Server 2014 for the Web, Express, and Standard editions.</td>
<td>October 26, 2015</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support the MySQL-based MariaDB database engine. For more information, see Amazon RDS for MariaDB (p. 1271).</td>
<td>October 7, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Amazon Aurora in the Asia Pacific (Tokyo) region. For more information, see Availability for Amazon Aurora MySQL.</td>
<td>October 7, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support db.t2 burst-capable DB instance classes for all DB engines and the addition of the db.t2.large DB instance class. For more information, see DB instance classes (p. 11).</td>
<td>September 25, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Oracle DB instances on R3 and T2 DB instance classes. For more information, see DB instance classes (p. 11).</td>
<td>August 5, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Microsoft SQL Server Enterprise Edition is now available with the License Included service model. For more information, see Licensing Microsoft SQL Server on Amazon RDS (p. 1395).</td>
<td>July 29, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon Aurora has officially released. The Amazon Aurora DB engine supports multiple DB instances in a DB cluster. For detailed information, see What is Amazon Aurora?.</td>
<td>July 27, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support copying tags to DB snapshots.</td>
<td>July 20, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support increases in storage size for all DB engines and an increase in Provisioned IOPS for SQL Server.</td>
<td>June 18, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated options for reserved DB instances.</td>
<td>June 15, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support using Amazon CloudHSM with Oracle DB instances using TDE.</td>
<td>January 8, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to include the new Amazon DB engine: Aurora. The Amazon Aurora DB engine supports multiple DB instances in a DB cluster. Amazon Aurora is currently in preview release and is subject to change. For detailed information, see What is Amazon Aurora?.</td>
<td>November 12, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support PostgreSQL read replicas.</td>
<td>November 10, 2014</td>
</tr>
<tr>
<td>New API and features</td>
<td>Updated to support the GP2 storage type and new API version 2014-09-01. Updated to support the ability to copy an existing option or parameter group to create a new option or parameter group.</td>
<td>October 7, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support InnoDB Cache Warming for DB instances running MySQL version 5.6.19 and later.</td>
<td>September 3, 2014</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support SSL certificate verification when connecting to MySQL version 5.6, SQL Server, and PostgreSQL database engines.</td>
<td>August 5, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support the db.t2 burstable DB instance classes.</td>
<td>August 4, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support the db.r3 memory optimized DB instance classes for use with the MySQL (version 5.6), SQL Server, and PostgreSQL database engines.</td>
<td>May 28, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support SQL Server Multi-AZ deployments using SQL Server Mirroring.</td>
<td>May 19, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support upgrades from MySQL version 5.5 to version 5.6.</td>
<td>April 23, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Oracle GoldenGate.</td>
<td>April 3, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support the M3 DB instance classes.</td>
<td>February 20, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support the Oracle Timezone option.</td>
<td>January 13, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support replication between MySQL DB instances in different regions.</td>
<td>November 26, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support the PostgreSQL DB engine.</td>
<td>November 14, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support SQL Server transparent data encryption (TDE).</td>
<td>November 7, 2013</td>
</tr>
<tr>
<td>New API and new feature</td>
<td>Updated to support cross region DB snapshot copies; new API version, 2013-09-09.</td>
<td>October 31, 2013</td>
</tr>
<tr>
<td>New features</td>
<td>Updated to support Oracle Statspack.</td>
<td>September 26, 2013</td>
</tr>
<tr>
<td>New features</td>
<td>Updated to support using replication to import or export data between instances of MySQL running in Amazon RDS and instances of MySQL running on-premises or on Amazon EC2.</td>
<td>September 5, 2013</td>
</tr>
<tr>
<td>New features</td>
<td>Updated to support the db.cr1.8xlarge DB instance class for MySQL 5.6.</td>
<td>September 4, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support replication of read replicas.</td>
<td>August 28, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support parallel read replica creation.</td>
<td>July 22, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support fine-grained permissions and tagging for all Amazon RDS resources.</td>
<td>July 8, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support MySQL 5.6 for new instances, including support for the MySQL 5.6 memcached interface and binary log access.</td>
<td>July 1, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support major version upgrades from MySQL 5.1 to MySQL 5.5.</td>
<td>June 20, 2013</td>
</tr>
